This ingenious chemiſt obſerved, that if oxy-muriatic acid and ammonia be mixed, an efferveſcence takes place; azot is diſengaged, a quantity of water formed, and the oxy-muriatic acid is converted into common muriatic acid. Now the ſubſtances mixed were ammonia and oxy-muriatic acid, which is compoſed of oxygen and muriatic acid; the products were, muriatic acid, azot, and water, which is compoſed of oxygen and hydrogen. The oxygen of the water was furniſhed by the acid; the other products muſt have been furniſhed by the ammonia, which has diſappeared. Ammonia, therefore, muſt be compoſed of azot and hydrogen. Mr Berthollet proved, that ammonia was compoſed of theſe ingredients by a number of other experiments. For inſtance, if the oxide of copper be heated in contact with ammoniacal gas, it is reſtored to the metallic ſtate; the ammonia diſappears, a quantity of water is formed, and azotic gas is diſengaged. It follows from Mr Berthollet's experiments, that ammonia is compoſed of 121 parts of azot and 29 of hydrogen*. According to Dr Auſtin, it is compoſed of 121 parts of azot, and 32 of hydrogen†.

* *Mem. Par.* 1785.
† *Phil. Tranſ.* 1788.

385 Formation of ammonia.

After the compoſition of ammonia had been thus aſcertained, it became a queſtion of ſome conſequence, Whether it could be formed artificially? Dr Auſtin accordingly mixed hydrogen and azotic gas together in the proper proportions, and endeavoured to make them combine by the application of heat, by electricity, and by cold; but he found, that while theſe two ſubſtances were in a gaſeous ſtate, they could not be combined by any method which he could deviſe. It could not be doubted, however, that the combination often takes place when theſe bodies are preſented to each other in a different form. Dr Prieſtley‡ and Mr Kirwan‖ had actually produced it, even before its compoſition was known. Accordingly he found, that when tin is moiſtened with nitric acid, and after being allowed to digeſt for a minute or two, a little potaſs or lime is added, ammonia is immediately exhaled§. In that caſe, the nitric acid and the water which it contains are decompoſed; the oxygen of each unites with the tin, and reduces it to the ſtate of an oxide; and at the ſame time the hydrogen of the water combines with the azot of the acid, and forms ammonia, which is driven off by the ſtronger affinity of the potaſs or lime. Dr Auſtin ſucceeded alſo in forming ammonia by ſeveral other methods. He introduced into a glaſs tube filled with mercury a little azotic gas, and then put into the gas ſome iron filings moiſtened with water. The iron decompoſes the water and combines with its oxygen; and the hydrogen meeting with azot at the moment of its admiſſion, combines with it, and forms ammonia. This experiment ſhews, that the gaſeous ſtate of the azot does not prevent its combination with hydrogen.

§ *Dr Auſtin.*

386 Sulphuret of ammonia.

Ammonia may be combined with ſulphur by mixing together two parts of muriat of ammonia (ammonia combined with muriatic acid), two parts of lime, and one part of ſulphur, and diſtilling; a yellow liquor is obtained, which contains ſulphuret of ammonia. It is capable of cryſtallizing.

The phoſphuret of ammonia is unknown.

Ammonia is capable of combining with ſeveral of the metallic oxides, particularly copper.

It combines with fixed oils, and forms *ſoap.*

The order of its affinities is preciſely the ſame with that of the fixed alkalies.

Chap.

(q) We have adopted this word, which is Dr Black's, becauſe we think it preferable to *ammoniac* or *ammoniaca*, the words propoſed and uſed by the French chemiſts.

Chap. V. *Of Acids.*

Substances possessed of the following properties are denominated *acids*.

387 Properties of acids.

1. When applied to the tongue they excite that sensation which is called *sour* or *acid*.

2. They change the blue colours of vegetables to a red. The vegetable blues employed for this purpose are generally tincture of litmus and syrup of violets or of radishes, which have obtained the name of *reagents* or *tests*. If these colours have been previously converted to a *green* by alkalies, the acids restore them again.

3. They unite with water in almost any proportion.

4. They combine with all the alkalies, and most of the metallic oxides and earths, and form with them those compounds which are called *neutral salts*.

It must be remarked, however, that every acid does not possess all these properties; but all of them possess a sufficient number of them to distinguish them from other substances. And this is the only purpose which artificial definition is meant to answer.

388 Theories about the acid principle.

Paracelsus believed that there was only one acid principle in nature, which communicated taste and solubility to the bodies in which it was combined. Becher embraced the same opinion; and added to it, that this acid principle was a compound of earth and water, which he considered as two elements. Stahl adopted the theory of Becher, and endeavoured to prove, that his acid principle was sulphuric acid; of which, according to him, all the other acids were mere compounds. But his proofs were only conjectures or vague experiments, from which nothing could be deduced. Nevertheless, his opinion, like every other which he advanced in chemistry, continued to have supporters for a long time, and was even countenanced by Macquer. At last its defects began to be perceived; Bergman and Scheele declared openly against it; and their discoveries, together with those of the French chemists, notwithstanding the ill-natured attempts of Monnet to support it, demonstrated the falsehood of both parts of the theory, by shewing that sulphuric acid did not exist in the other acids, and that it was not composed of water and earth, but of sulphur and oxygen.

The opinion, however, that acidity is owing to some principle common to all the salts, was not abandoned. Wallerius, Meyer, and Sage, had advanced different theories in succession about the nature of this principle; but as they were founded rather on conjecture and analogy than direct proof, they obtained but few advocates.

389 Lavoisier's theory.

At last Mr Lavoisier, by a number of ingenious and accurate experiments, proved, that several combustible substances when united with oxygen form acids; that a great number of acids contain oxygen; and that when this principle is separated from them, they lose their acid properties. He concluded, therefore, that the acidifying principle is oxygen, and that acids are nothing else but combustible substances combined with oxygen, and differing from one another according to the nature of the combustible base. This conclusion has been confirmed by every subsequent observation. All the acids hitherto analysed contain oxygen, *one* perhaps excepted, *the Prussic acid*, which possesses properties so different from the rest, that it might, without great impropriety, be placed in a distinct class. It is probable, therefore, that those acids which it has not yet been possible to decompose consist of oxygen combined with a combustible base: but till this analysis has actually been accomplished, the theory of Mr Lavoisier cannot be considered as completely demonstrated (R).

390 List of the acids.

The acids at present known amount to about 39, most of which have been examined within these 30 years. Their names are as follows:

1. Sulphuric acid,	21. Benzoic,
2. Sulphurous,	22. Succinic,
3. Nitric,	23. Camphoric,
4. Nitrous,	24. Suberic,
5. Muriatic,	25. Laccic,
6. Oxy-muriatic,	26. Pyromucous,
7. Phosphoric,	27. Pyrolignous,
8. Phosphorous,	28. Pyrotartarous,
9. Boracic,	29. Prussic,
10. Fluoric,	30. Formic,
11. Carbonic,	31. Sebacic,
12. Acetic,	32. Bombic,
13 Acetous,	33. Zoonic,
14. Oxalic,	34. Arsenic,
15. Tartarous,	35. Tungstic,
16. Citric,	36. Molybdic,
17. Malic,	37. Chromic,
18. Lactic,	38. Platinic,
19. Saccholactic,	39. Stannic,
20. Gallic,	

These acids shall form the subject of the following sections.

Sect. I. *Of Sulphuric Acid.*

Sulphur combines with two different quantities of oxygen: with the smaller quantity it forms *sulphurous acid*; with the larger *sulphuric acid*. The last of these is the subject of the present section.

391 Discovery of sulphuric acid.

The ancients were acquainted with some of the compounds into which sulphuric acid enters; *alum*, for instance, and *green vitriol*: but they appear to have been ignorant of the acid itself. It is first mentioned in the works of Basil Valentine, which were published about the end of the 15th century.

It was for a long time obtained by distilling *green vitriol*, a salt composed of sulphuric acid and green oxide of iron; hence it was called *oil of vitriol*, and afterwards *vitriolic acid*. Another method of obtaining it was by burning sulphur under a glass bell; hence it was called also *oleum sulphuris per campanam*. The French chemists in 1787, when they formed a new chemical nomenclature, gave it the name of *sulphuric acid*.

392 Method of procuring it.

At present it is generally procured by burning a mixture of sulphur and nitre in chambers lined with lead. The theory of this process requires no explanation. The nitre supplies a quantity of oxygen to the sulphur,

(R) This theory has been carried so far by some chemists, that they have considered it as a conclusive proof that oxygen did not enter into the composition of a body, if they could shew that the body was not an acid. Thus, according to them, *water* cannot contain oxygen, because water is not an *acid*.—But surely no theory, however ingenious and satisfactory, can for a moment be put in competition with experiment. The ways of Nature are not as our ways, nor her thoughts as our thoughts.

Sulphuric Acid.

ſulphur, and the air of the atmoſphere furniſhes the reſt. The acid thus obtained is not quite pure, containing a little potaſs, ſome lead, and perhaps alſo nitric and ſulphurous acids. Theſe acids may be driven off by applying for ſome time a gentle heat, and afterwards the ſulphuric acid itſelf may be diſtilled over pure.

393 Its component parts.

It appears from an experiment of Mr Berthollet, that ſulphuric acid contains 63,2 parts of ſulphur, and 36,8 of oxygen. He aſcertained, in the firſt place *, that nitre is totally decompoſed by being heated with $\frac{1}{4}$th of ſulphur. He then mixed together 288 grains of nitre and 72 of ſulphur; and after expoſing them to a ſufficient heat, he found 12 grains of ſulphur ſublimed, and 228 grains of ſulphat of potaſs †. But the ſum of the ingredients was 360 grains; conſequently 120 grains have been diſſipated. All this loſs muſt have been ſuffered by the acid of the nitre, for the heat was too ſmall to ſeparate any of the alkali. According to Mr Kirwan, 288 grains of nitre contain 132,96 of alkali, and 155,04 of acid. 155,04 — 120 = 35,04 = quantity of oxygen furniſhed by the nitre to convert 60 grains of ſulphur into acid.

* Mem. Par. 1781, 232.

† Mem. Par. 1782, 603.

394 Its properties.

Sulphuric acid is a liquid, ſomewhat of an oily conſiſtence, tranſparent and colourleſs as water, without any ſmell, and of a very ſtrong acid taſte. When applied to animal or vegetable ſubſtances, it very ſoon deſtroys their texture.

It always contains a quantity of water; part of which, however, may be driven off by the application of a moderate heat. This is called *concentrating the acid.* When as much concentrated as poſſible, its ſpecific gravity is 2,000.

It changes all vegetable blues to a red, except indigo.

According to Erxleben, it boils at 546°; according to Bergman, at 572°.

395 Its cryſtals.

When expoſed to a ſufficient degree of cold, it cryſtallizes or freezes; and after this has once taken place, it freezes again by the application of a much inferior cold. Moreveau froze it at — 4°; it aſſumed the appearance of frozen ſnow. After the proceſs began it went on in a cold not nearly ſo intenſe. The acid melted ſlowly at 27,5°; but it froze again at the ſame temperature, and took five days to melt in the temperature of 43° ‡. Chaptal, who manufactured this acid, once obſerved a large glaſs veſſel full of it cryſtallized at the temperature of 48°. Theſe cryſtals were in groups, and conſiſted of flat hexahedral priſms, terminated by a ſix ſided pyramid. They felt hotter than the ſurrounding bodies, and melted on being handled §. Chaptal has obſerved, that ſulphuric acid, in order to cryſtallize, muſt not be too concentrated. This obſervation has been extended a good deal further by Mr Keir. He found, that ſulphuric acid, of the ſpecific gravity of 1,780, froze at 45°; but if it was either much more or much leſs concentrated, it required a much greater cold for congelation *.

‡ Encyc. Method. Chim. i. 376.

§ Journ. de Phyſ. xxxi. 473.

396 Its affinity for water.

Sulphuric acid has a very ſtrong attraction for water. Neumann found, that when expoſed to the atmoſphere it attracted 6,25 times its own weight. Mr Gould found, that 180 grains of acid, when expoſed to the atmoſphere, attracted 68 grains of water the firſt day, 58 the ſecond, 39 the third, 23 the fourth, 18 the fifth, and at laſt only 5, 4, 3, 4, 3, &c. The 28th day, the augmentation was only half a grain †. The affinity therefore between ſulphuric acid and water, as is the caſe in general with other ſubſtances, becomes weaker the nearer they approach to ſaturation. He does not ſpecify the ſpecific gravity of his acid; but as it only attracted 3,166 times its own weight, it could not have been very concentrated.

* Phil. Tranſ. lxxvii. Part ii.

† Phil. Tranſ. 1684.

When ſulphuric acid is mixed with water, a great quantity of caloric is evolved. A mixture of equal parts of theſe liquids cauſes a heat almoſt equal to that of boiling water. Lavoiſier and De la Place found, that when 2,625 lbs. troy of ſulphuric acid, of the ſpecific gravity 1,87058, was mixed with 1,969lbs. troy of water, as much caloric was evolved as melted 4,1226 pounds troy of ice, or as much caloric as the acid and water would have given out had they been heated without mixture to 155,9° ‡. This caloric is owing chiefly, if not ſolely, to the increaſe of denſity in the water; for when equal quantities of ſulphuric acid and water are mixed together, the ſpecific gravity is much greater than the mean; and it has been formerly ſhewn, that whenever bodies become denſer they give out caloric.

‡ Mem. Par. 1780.

397 Strength of ſulphuric acid of various denſities.

Since there is ſuch a ſtrong affinity between ſulphuric acid and water, and ſince the denſity of the mixture is different from the mean denſity of the ingredients, it becomes a problem of the greateſt importance to determine how much of the ſtrongeſt ſulphuric acid that can be prepared exiſts in any given quantity of ſulphuric acid of inferior ſpecific gravity, and which conſequently conſiſts of a determined quantity of this ſtrong acid diluted with water.

This problem has been ſolved by Mr Kirwan §. He took ſulphuric acid of the ſpecific gravity 2,000, which is the ſtrongeſt that can be procured, for his ſtandard, and the point was to determine how much of this ſtandard acid exiſted in a given quantity of acid of inferior denſity.

§ Iriſh Tranſ. iv.

He concluded, from a number of experiments with ſulphuric acid, of the ſpecific gravities 1,8846, 1,8689, 1,8042, 1,7500 (for he could not procure an acid of the ſpecific gravity 2,000 at the temperature of 60°, in which his experiments were performed), that when equal parts of ſtandard acid and water are mixed, the denſity is increaſed by $\frac{1}{11}$th part of the whole mixture. Then, by applying a formula given by Mr Poujet (s), he calculated, that the increaſe of denſity, on mixing different

(s) Mr Poujet undertook the examination of the ſpecific gravity of alcohol mixed with different quantities of water. He took for his ſtandard alcohol whoſe ſpecific gravity was 0,8199, at the temperature of 65,75°. He then formed ten mixtures; the firſt containing nine meaſures of alcohol and one of water, the ſecond eight meaſures of alcohol and two of water, and ſo on, till the laſt contained only one meaſure of alcohol and nine of water. He took care that each of theſe meaſures ſhould contain equal bulks, which he aſcertained by weight, obſerving that a meaſure of water was to a meaſure of alcohol as 1 to 0,8199. Thus 10000 grains of water and 8199 of alcohol formed a mixture containing equal bulks of each. From the ſpecific gravity of each of theſe mixtures he diſcovered how much they had diminiſhed in bulk in conſequence of mixture, by the following method.

Calling

Sulphuric Acid.

different quantities of ſtandard acid and water, was as in the following table :

Number of parts of water.	Number of parts of ſtandard acid.	Augmentation of denſity.
5	95	0,0252
10	90	0,0479
15	85	0,0679
20	80	0,0856
25	75	0,0699
30	70	0,1119
35	65	0,1213
40	60	0,1279
45	55	0,1319
50	50	0,1333

The firſt 50 numbers of the following table were formed by adding theſe augmentations to the ſpecific gravity of the above mixture found by calculation, and taking the arithmetical mean for the intermediate quantities. The remaining numbers were formed from actual obſervation. He found by the firſt part of the table, that 100 parts of acid, of the ſpecific gravity 1,8472, contained 88,5 parts ſtandard, conſequently 400 grains of this acid contain 354 grains ſtandard. He took ſix portions of this acid, each containing 400 grains, and added to them as much water as made them contain reſpectively 48, 46, 44, 42, 40, 38 grains ſtandard. The quantity of water to be added in order to produce this effect, he found by the following method. Suppoſe $x =$ the quantity of water to be added to 400 parts of acid, that the mixture may contain 48 *per cent.* of ſtandard acid. Then $400 + x : 354 :: 100 : 48$, and conſequently $x = 337,5$. After finding the ſpecific gravity of theſe, the half of each was taken out, and as much water added; and thus the ſpecific gravities, correſponding to 24, 23, 22, 21, 20, 19, were found. Then ſix more portions, of 400 grains each, were taken, of the ſpecific gravity 1,8393, and the proper quantity of water added to make them contain 36, 34, 32, 30, 28, 26 *per cent.* of ſtandard. Their ſpecific gravities were found, the half of them taken out, and as much water added; and thus the ſpecific gravity of 18, 17, 16, 15, 14, and 13 found. Care was taken, after every addition of water, to allow the ingredient ſufficient time to unite.

The laſt 11 numbers were only found by analogy; obſerving the ſeries of decrement of the four laſt numbers before them.

Table

Calling A the real ſpecific gravity of any of the mixtures; B its ſpecific gravity found by calculation, ſuppoſing no diminution of bulk; n the number of meaſures compoſing the whole maſs; $n - x$ the number to which it is reduced in conſequence of mutual penetration—it is evident, ſince the increaſe of denſity does not diminiſh the weight of the whole maſs, that $n\,\mathrm{B} = \overline{n - x} \times \mathrm{A}$. Therefore $x = \frac{\mathrm{A} - \mathrm{B}}{\mathrm{A}} \times n$, or (making $n = 1$) $= \frac{\mathrm{A} - \mathrm{B}}{\mathrm{A}}$. $\frac{\mathrm{A} - \mathrm{B}}{\mathrm{A}}$ is therefore the diminution of volume produced by the mixture.

The following table contains the reſult of Mr Poujet's experiments, calculated according to that formula; the whole volume or n being $= 1$.

Meaſures of		Diminution of the whole volume = 1 by experiment.	By calculation.
Water.	Alcohol.		
1	9	0,0109	0,0103
2	8	0,0187	0,0184
3	7	0,0242	0,0242
4	6	0,0268	0,0276
5	5	0,0288	
6	4	0,0266	0,0276
7	3	0,0207	0,0242
8	2	0,0123	0,0184
9	1	0,0044	0,0103

It is evident, from this table, that the diminution of the bulk of the mixture follows a regular progreſſion. It is greateſt when the meaſures of water and alcohol are equal, and diminiſhes as it approaches both ends of the ſeries. Mr Poujet accounts for this by conceiving the alcohol to be diſſolved in the water, which retains a part of it in its pores, or abſorbs it. The quantity abſorbed ought to be in the ratio of that of the ſolvent and of the body diſſolved, and each meaſure of water will retain a quantity of alcohol proportional to the number of meaſures of alcohol in the mixture. Thus in a mixture formed of nine meaſures of alcohol and one of water, the water will contain a quantity of alcohol = 9; in one of eight meaſures of alcohol and two of water, the water will contain a quantity of alcohol = 8. Therefore the diminution of bulk in each mixture is in a ratio compounded of the meaſures of alcohol and water which form it; in the above table, as 1×9, 2×8, 3×7, 4×6, &c. And in general, taking the diminution of bulk when the meaſures of both liquids are equal for a conſtant quantity, and calling it c, calling the number of meaſures n, the number of meaſures of alcohol x, the increaſe of denſity

Sulphuric Acid.

Sulphuric Acid.

But we have no reason to suppose that sulphuric acid, at the density 2,000, is free from all mixture of water; so far from that, we know for certain that it contains a considerable proportion; for when it is combined with other bodies, barytes, for instance, or potass, there is a considerable quantity of water which remains behind, and does not enter into the combination. Now, is it possible to determine what would be the density of sulphuric acid, supposing it to be deprived of all water, or at least of all water except what is necessary for its existence as an acid? or to determine, how much real acid exists in a given quantity of standard acid?

398 Quantity of real acid in strong sulphuric acid.

Homberg first attempted to answer this question. It was afterwards undertaken by Bergman, and Wenzel, and Wiegleb. They do not inform us of the quantity of water contained in a given weight of acid, but they put it in our power to find it, by informing us how much real acid is necessary to saturate a given quantity of potass. Their respective experiments give the following numbers:

	Homb.	Berg.	Wenzel.	Wiegleb.
100 parts of potass require	38,3	78,5	82,63	101,92.

Homberg used carbonat of potass, and did not take into consideration the carbonic acid driven off by the sulphuric. When this is taken in, his number should be 54 instead of 38,3.

Now to discover the quantity of real acid in any sulphuric acid mixture, we have only to find out how much potass it would require for saturation. The differences between the above results are so great, that there was reason to suspect their accuracy. Mr Kirwan therefore attempted to ascertain the density of pure sulphuric acid by another method, and he rated it at 4,226. As this method has been already described in the article CHEMISTRY, *Encycl.* we cannot enter upon it here. At any rate, it would be unnecessary, as many of the principles upon which Mr Kirwan went were erroneous, as Mr Morveau* and Mr Keir † have sufficiently shewn; and Mr Kirwan, with his usual candour, has accordingly abandoned it, and adopted another method which is not liable to the same exceptions. He dissolved 1523,5 grains

* *Encyc. Method.* art. *Affinité.*

† *Keir's Dictionary*, art. *Acid.*

density or diminution of bulk z; we shall have $c : z :: \frac{n}{2} \times \frac{n}{2} : \overline{n - x}, \times x$ and $z = \frac{4c}{n^2} \times \overline{nx - x^2}$, or (making $n = 1$) $= 4cx^2$.

The diminution of bulk, calculated according to this formula, make the last column of the above table. They correspond very well with experiment, while the measures of alcohol are more than those of water, but not when the reverse is the case. This Mr Poujet thinks is owing to the attraction which exists between the particles of water, and which, when the water is considerable compared with the alcohol, resists the union of the water with the alcohol.

By the formula $z = \frac{4cnx - 4cx^2}{n^2}$, the quantity of alcohol of the standard may be determined in any mixture where the alcohol exceeds the water.

Let the number of measures, or the whole mass - - -	$= 1$
The measures of alcohol - - - - - - - -	$= x$
The diminution of bulk at equal measures - - - -	$= c$
The diminution of bulk of a mixture containing x measures of alcohol -	$= 4cx - 4cx^2$
The specific gravity of water - - - - - -	$= a$
The specific gravity of the alcohol - - - - -	$= b$
The specific gravity of the unknown mixture - - - -	$= y$

Sulphuric Acid.

grains of pure carbonat of potafs, dried in a red heat, in diftilled water. The whole weighed 4570 grains. He took 360 grains of this mixture, which contained 120 grains of carbonat of potafs, and faturated it with pure fulphuric acid of the fpecific gravity 1,565, which, according to the above table, contained 61 *per cent.* of ftandard acid. The acid required for faturating the folution of potafs amounted to 130 grains, and contained therefore 79 of ftandard. The carbonic acid difengaged was 34 grains, and confequently the quantity of alkali was 120 — 34 = 86 grains. The folution being turbid, was diluted with 3238 grains of water. Its fpecific gravity was then 1,013 at the temperature of 60°. The weight of the whole was 3694 grains. Forty-five grains of fulphat of potafs (potafs combined with fulphuric acid), diffolved in 1017 grains of diftilled water, have the fame fpecific gravity at the fame temperature; from whence it follows, that the proportion of falt in each was equal. But in the laft folution the quantity of falt was $\frac{1}{23,6}$ of the whole; therefore the quantity of falt in the firft was $\frac{3694}{23,6} = 159,52$ grs. Now of this weight 86 grains were alkali; the remainder, therefore, which amounts to 70,52 grains, muft be acid. But the quantity of ftandard acid employed was 79 grains; of this there were $8\frac{1}{2}$ grains which did not enter into the combination, and which muft have been pure water: 79 parts of ftandard acid, therefore, contain at leaft 8,5 parts of water, and confequently 100 parts of ftandard acid contain 10,75 parts of water. It only remains now to confider how much water fulphat of potafs contains. Mr Kirwan thinks it contains none, becaufe it lofes no weight in any degree of heat below ignition, and even when expofed to a red heat for half an hour it hardly lofes a grain. This is certainly fufficient to prove, at leaft, that it contains very little water; and confequently we may conclude, with Mr Kirwan, that 100 parts of fulphuric acid, of the fpecific gravity 2,000, are compofed pretty nearly of 89,25 of pure acid and 10,75 of water. This method ufed by Mr Kirwan is nearly the fame with that propofed by Mr Keir *.

* *Keir's Dictionary,* art. *Acid.*

It feems even poffible to obtain fulphuric acid free from all the water that may not be neceffary to its acid ftate. When it is procured by diftillation from green vitriol, if the receiver be changed after the procefs has gone on for fome time, a quantity of acid is obtained in a folid form, or cryftallized. This, as Morveau has fhewn, is fulphuric acid deprived of the water with which it is ufually combined. When this *glacial* acid, as it has been called, is expofed to the air, it rifes in white fumes, and is foon diffipated. This fingular effect is produced by its violent attraction for the water which exifts in atmofpheric air. When thrown into water, it feizes it with violence; a great deal of caloric is evolved, fufficient, if the quantity of water be not too great, to elevate the whole in vapours *.

* *Encyc. Method. Chim.* i. 590.

399 Action of this acid on other bodies.

Sulphuric acid is capable of decompofing alcohol and oils; and when affifted by heat, it decompofes alfo fome of the metallic oxides which contain the greateft quantity of oxygen; as red oxide of lead, black oxide of manganefe. It decompofes likewife all the fulphurets and phofphurets which have an alkaline or earthy bafis.

It oxidates iron, zinc, and manganefe, in the cold. By the affiftance of heat it oxidates filver, mercury, copper, antimony, bifmuth, arfenic, tin, and tellurium. At a boiling heat it oxidates lead, cobalt, nickel, molybdenum. It does not act upon gold, platinum, tungften, nor titanium.

It unites readily with all the alkalies, the alkaline earths, alumina, and jargonia, and with moft of the metallic oxides, and forms falts denominated *fulphats*. Thus the combination of fulphuric acid and foda is called *fulphat of foda*; the compound of fulphuric acid and lime, *fulphat of lime*, and fo on. It does not act upon filica nor adamanta.

400 Its affinities.

Oil,
Water.

Sect. II. *Of Sulphurous Acid.*

401 Component parts of ſulphurous acid.

Sulphurous acid is compoſed of ſulphur and oxygen combined: the proportions have not been aſcertained; but the fact itſelf, and that the quantity of oxygen is leſs than what enters into ſulphuric acid, has been proved beyond the poſſibility of doubt. Neither can it be doubted, though the fact has not been attended to, that in this acid the ſulphur and oxygen mutually ſaturate each other; and that ſulphuric acid is not compoſed of ſulphur and oxygen, but of ſulphurous acid and oxygen. Phoſphorus is capable of decompoſing ſulphuric acid by the aſſiſtance of heat, of ſeizing a quantity of its oxygen, and converting it into ſulphurous acid; but upon ſulphurous acid it has no effect whatever *. The affinity of phoſphorus therefore for oxygen is leſs than that of ſulphur; yet it is capable of taking oxygen from ſulphuric acid. Is it not evident from this, that ſulphuric acid is compoſed of ſulphurous acid and oxygen? and that ſulphur has a ſtronger affinity for oxygen than ſulphurous acid has? For if both the acids were compoſed directly of ſulphur and oxygen, it would follow from experiment, that the affinity of phoſphorus for oxygen was both ſtronger and weaker than that of ſulphur; which would be abſurd.

* *Fourcroy* and *Vauquelin.*

402 Its diſcovery.

Sulphurous acid has been known ſince the time of Stahl. Scheele firſt diſcovered the method of obtaining it in quantities; and Dr Prieſtley firſt procured it in a ſtate of purity; for Scheele's acid was diſſolved in water.

403 Method of procuring it.

Stahl's method of procuring ſulphurous acid was to burn ſulphur at a low temperature, and expoſe to its flames cloth dipped in a ſolution of potaſs. By this method he obtained a combination of potaſs and ſulphurous acid; for at a low temperature ſulphur forms by combuſtion only ſulphurous acid. On this ſalt Scheele poured a quantity of tartarous acid, and then applied a gentle heat. The ſulphurous acid is in this manner diſplaced, becauſe its affinity for potaſs is not ſo ſtrong as that of tartarous acid; and it comes over into the receiver diſſolved in water. It is now commonly procured by mixing with ſulphuric acid oil, greaſe, metals, or any other ſubſtance that has a ſtronger affinity for oxygen than ſulphurous acid, and applying a heat ſufficient to diſtil over the ſulphurous acid as it forms. Mr Berthollet has found, that ſugar is the beſt ſubſtance to employ for this purpoſe.

Dr Prieſtley poured a little oil on ſulphuric acid, applied heat, and received the product in a glaſs jar filled with mercury. It was ſulphurous acid free from all ſuperfluous water, and in a gaſeous form.

404 Its properties,

In this ſtate it is colourleſs and inviſible like common air. It is incapable of maintaining combuſtion; nor can animals breathe it without death. It has a ſtrong and ſuffocating odour. It is this odour which burning ſulphur exhales. Its ſpecific gravity, according to Bergman, is 0,00246 *; according to Lavoiſier, 0,00251 †. Clouet and Mongé found, that by the application of extreme cold it is converted into a liquid.

Dr Prieſtley diſcovered, that when a ſtrong heat is applied to this acid in cloſe veſſels, a quantity of ſulphur is precipitated, and the acid is converted into ſulphuric ‡. Berthollet obtained the ſame reſult: but Fourcroy and Vauquelin could not ſucceed §.

Water abſorbs this acid with avidity. According to Dr Prieſtley, 1000 grains of water, at the temperature 54,5°, abſorb 39,6 grains of this acid. The ſpecific gravity of water ſaturated with ſulphurous acid is 1,040 ‖. Water in the ſtate of ice abſorbs it very rapidly, and is inſtantly melted. Water ſaturated with this acid can be frozen without parting with any of it. When water, which has been ſaturated with this acid at the freezing temperature, is expoſed to the heat of 65,25°, it is filled with a vaſt number of bubbles, which continually increaſe and riſe to the ſurface. Theſe bubbles are a part of the acid ſeparating from it. It freezes a few degrees below 32 ¶.

Sulphuric acid abſorbs it at zero; but allows great part of it to eſcape at 32 *.

It reddens tincture of turnſol; but deſtroys the colour of ſyrup of violets.

It is decompoſed by hydrogen and carbon, and ſulphurated hydrogen gas, when aſſiſted by heat †.

Oxygen gas gradually converts it into ſulphuric acid; but this change does not take place unleſs water be preſent.

It does not ſeem capable of oxidating any of the metals except iron, zinc, and manganeſe.

When in the ſtate of gas it is abſorbed by oils and ether.

When glaſs tubes, filled with ſulphurous acid in the ſtate of gas, are expoſed to a ſtrong heat, a quantity of ſulphur precipitates, and the reſt of the acid is converted into the ſulphuric.

It combines with the alkalies, alkaline earths, and alumina, and many of the metallic oxides, and forms neutral ſalts, known by the name of *ſulphites*. 405 Its combinations,

Its affinities, as far as they have been inveſtigated, are as follows ‡: 406 And affinities.

Sect. III. *Of Nitric Acid.*

There are three different ſubſtances compoſed of azot and oxygen, *nitric acid*, *nitrous acid*, and *nitrous gas*. The firſt contains moſt oxygen; the laſt contains leaſt.

Nitric acid ſeems to have been firſt obtained in a ſeparate ſtate by Raymond Lully, who was born at Majorca in 1235. He procured it by diſtilling a mixture of nitre and clay. Baſil Valentine, who lived in the 15th century, deſcribes the proceſs minutely, and calls the acid *water of nitre*. It was afterwards denominated 407 Diſcovery of nitric acid.

Nitric Acid.

ted *aqua fortis* and *spirit of nitre*. The name *nitric acid* was first given it in 1787 by the French chemists.

408 Method of procuring it.

Nitric acid is generally obtained in large manufactories by distilling a mixture of nitre (T) and clay; but the acid procured by this process is weak and impure. Chemists generally prepare it by distilling three parts of nitre and one of sulphuric acid in a glass retort. This method was first used by Glauber. When obtained in this manner it contains some nitrous acid, which may be expelled by the application of a very gentle heat *.

* *Scheele.*

Nitric acid is one of the most important instruments of analysis which the chemist possesses; nor is it of inferior consequence when considered in a political or commercial view, as it forms one of the most essential ingredients of gunpowder. Its nature and composition accordingly have long occupied the attention of philosophers. We shall endeavour to trace the various steps by which its component parts were discovered.

409 Discovery of its component parts.

As nitre is often produced upon the surface of the earth, and never except in places which have a communication with atmospheric air, it was natural to suppose that air, or some part of the air, entered into the composition of nitric acid. Mayow having observed, that nitre and atmospherical air were both possessed of the property of giving a red colour to the blood, and that air was deprived of this property by combustion and respiration concluded, that nitre *contained that part of the air which supported combustion, and was necessary for respiration.*

Dr Hales, by applying heat to nitric acid, and what he called *Walton mineral*, obtained a quantity of air possessed of singular properties. When atmospherical air was let into the jar which contained it, a reddish turbid fume appeared, a quantity of air was absorbed, and the remainder became transparent again *. Dr Priestley discovered that this air could only be obtained from nitric (U) acid; and therefore called it *nitrous air*. He found that when this gas was mixed with oxygen gas, nitrous acid was reproduced. Here, then, we find, that oxygen is a part of the nitric acid, and consequently that Mayow's affirmation is verified.

* *Veget. Statics,* ii. 284.

Dr Priestley, however, explained this fact in a different manner. According to him, nitrous gas is composed of nitrous acid and phlogiston. When oxygen is added, it separates this phlogiston, and the acid of course is precipitated. This hypothesis was adopted by Macquer and Fontana; and these three philosophers endeavoured to support it with their usual ingenuity. But there was one difficulty which they were unable to surmount. When the two gases are mixed in proper proportions, almost the whole assumes the form of nitric acid; and the small residuum ($\frac{1}{14}$th part), in all probability, or rather certainly, depends on some accidental impurity in the oxygen gas. What then becomes of the oxygen and phlogiston? Dr Priestley supposed that they formed carbonic acid gas: but Mr Cavendish proved, that when proper precautions are taken, no such acid appears †.

† *Phil. Trans.* 1784.

Dr Priestley had procured his nitrous gas by dissolving metals in nitric acid; during the solution of which a great deal of nitrous gas escapes. He supposed that nitrous gas contained phlogiston, because the metal was oxidated (and consequently, according to the then received theory, must have lost phlogiston) during its formation. Mr Lavoisier proved that this supposition was ill-founded by the following celebrated experiment *: To 945 grains of nitric acid (specific gravity 1,316) he added 1104 grains of mercury. During the solution 273,234 cubic inches of nitrous gas were produced. He then distilled the salt (oxide of mercury) which had been formed to dryness. As soon as it became red hot it emitted oxygen gas, and continued to do so till almost the whole of the mercury was revived: The quantity of oxygen emitted was 287,742 cubic inches. All that had happened, therefore, during the solution of the mercury, was the separation of the acid into two parts; nitrous gas, which flew off, and oxygen, which united with the metal (X).

* *Mem. Par.* 1776, p. 673.

Mr Lavoisier concluded, therefore, that the whole of the nitrous gas was derived from the nitric acid; that nitric acid is composed of oxygen and nitrous gas; and that the proportions are nearly 64 parts by weight of nitrous gas, and 36 of oxygen gas.

But there was one difficulty which Mr Lavoisier acknowledged he could not remove. The quantity of oxygen obtained by decomposing nitric acid was often much greater than what was necessary to saturate the nitrous gas. Mr De Morveau attempted to account for this; but without success †. Nitrous gas itself was evidently a compound; but the difficulty was to discover the ingredients. Mr Lavoisier concluded, from an experiment made by decomposing nitre by means of charcoal, that it contained azot: and several of Dr Priestley's experiments led to the same result. But what was the other ingredient?

† *Encyc. Method. Chim. Acide Nitrique.*

Mr Cavendish had observed, while he was making experiments on the composition of water, that some nitric acid was formed during the combustion of oxygen and hydrogen gas, and that its quantity was increased by adding a little azot to the two gases before the explosion. Hence he concluded that the formation of the acid was owing to the accidental presence of azotic gas. To verify this conjecture, he passed an electrical shock through a quantity of common air enclosed in a glass tube: the air was diminished, and some nitric acid formed. He repeated the experiment, by mixing together oxygen and azotic gas; and found that when they bore a certain proportion to each other, they were totally convertible into nitric acid. In one experiment, the proportion of azot to oxygen (in bulk) was as 416 to 914; in another, as 1920 to 4860 ‡.

‡ *Phil. Trans.* 1783.

These experiments were immediately repeated by Messrs Van Marum and Van Trooftwyk, and with nearly the same result.

The most convenient method of performing them is the following: Take a glass tube, the diameter of which

(T) Nitre is composed of nitric acid and potass.

(U) Or nitrous acid: for at the period of Dr Priestley's discovery (1772) they were not accurately distinguished.

(X) We have already mentioned, in a preceding note, that this experiment was first made by Mr Bayen. See Part I. chap. iii. of this Article.

Nitric Acid.

which is about the sixth part of an inch, through the cork that shuts one end of which let a small metallic conductor pass with a ball at each end. Fill this tube with mercury, and plunge its open end into a bason of mercury: then put into it a mixture of 0,13 of azotic and 0,87 of oxygen gas, till it occupies three inches of the tube; and introduce a solution of potass till it fill half an inch more. Then, by means of the conductor, make electrical explosions (from a very powerful machine) to pass through the tube till the air is as much diminished as possible. Part of the potass will be found converted into nitre. Mr Cavendish actually saturated the potass with this acid. Mr Van Marum did not, though a good deal more gas had disappeared than in the experiments of Mr Cavendish. This difference evidently depends on the quantity of potass contained in a given weight of the solution. The solution which Mr Van Marum used was no doubt stronger than that which Mr Cavendish employed.

Dr Priestley had observed, several years before these experiments were made, that atmospherical air was diminished by the electric spark, and that during the diminution the infusion of turnsol became red; but he concluded merely that he had precipitated the acid of the air. Landriani, who thought, on the contrary, that carbonic acid gas was formed, enounced the alteration of lime-water by it as a proof of his opinion. It was to refute this notion that Mr Cavendish undertook his experiments. He has since that time repeated them with the same success *.

* *Phil. Trans.* 1788.

It cannot be doubted, then, that nitric acid is composed of azot and oxygen; for the objections of Dr Priestley have been considered while we were treating of water. Consequently nitrous gas must also be composed of the same ingredients. According to Lavoisier, nitric acid is composed of four parts, by weight, of oxygen and one part of azot.

410 Its properties.

Nitric acid is liquid, colourless, and transparent; but the affinity between its component parts is so weak, that the action of light is sufficient to drive off a part of its oxygen in the form of gas; and thus, by converting it partly into nitrous acid, to make it assume a yellow colour. Its taste is exceedingly acid and peculiar. It is very corrosive, and tinges the skin of a yellow colour, which does not disappear till the epidermis comes off.

It has a strong affinity for water, and has never yet been obtained except mixed with that liquid. When concentrated, it attracts moisture from the atmosphere, but not so powerfully as sulphuric acid. It also produces heat when mixed with water, owing evidently to the concentration of the water.

411 Its strength at different specific gravities.

The specific gravity of the strongest nitric acid that can be procured is, according to Rouelle, 1,583; but at the temperature of 60°, Mr Kirwan could not procure it stronger than 1,5543.

Taking this acid for the standard, Mr Kirwan has calculated how much of it exists in nitric acid of inferior density. His determination may be seen in the following Table, which was formed precisely in the same manner as that formerly given of the strength of sulphuric acid.

100 parts, at the specific gravity	Contain of standard acid	100 parts, at the specific gravity	Contain of standard acid	100 parts, at the specific gravity	Contain of standard acid
1,5543	100	1,4018	70	1,2586	44
1,5295	95	1,3975	69	1,2525	43
1,5183	94	1,3925	68	1,2464	42
1,5070	93	1,3875	67	1,2419	41
1,4957	92	1,3825	66	1,2374	40
1,4844	91	1,3775	65	1,2291	39
1,4731	90	1,3721	64	1,2209	38
1,4719	89	1,3671	63	1,2180	37
1,4707	88	1,3621	62	1,2152	36
1,4695	87	1,3571	61	1,2033	35
1,4683	86	1,3521	60	1,2015	34
1,4671	85	1,3468	59	1,1963	33
1,4640	84	1,3417	58	1,1911	32
1,4611	83	1,3366	57	1,1845	31
1,4582	82	1,3315	56	1,1779	30
1,4553	81	1,3264	55	1,1704	29
1,4524	80	1,3212	54	1,1639	28
1,4471	79	1,3160	53	1,1581	27
1,4422	78	1,3108	52	1,1524	26
1,4373	77	1,3056	51	1,1421	25
1,4324	76	1,3004	50	1,1319	24
1,4275	75	1,2911	49	1,1284	23
1,4222	74	1,2812	48	1,1241	22
1,4171	73	1,2795	47	1,1165	21
1,4120	72	1,2779	46	1,1111	20
1,4069	71	1,2687	45	1,1040	19

Now, how much water does nitric acid contain, the density of which is 1,5543?

412 Quantity of real acid contained in concentrated nitric acid.

Mr Kirwan dried a quantity of crystallized carbonat of soda in a red heat, and dissolved it in water, in such a proportion, that 367 grains of the solution contained 50,05 of alkali. He saturated 367 grains of this solution with 147 grains of nitric acid, the specific gravity of which was 1,2754, and which, therefore, by the preceding table, contained 45,7 *per cent.* of acid standard. The carbonic acid driven off amounted to 14 grains. On adding 939 grains of water, the specific gravity of the solution, at the temperature of 58,5°, was 1,0401. By comparing this with a solution of nitrat of soda, of the same density, precisely in the manner described formerly under sulphuric acid, he found, that the salt contained in it amounted to $\frac{1}{16,901}$ of the whole. There was an excess of acid of about two grains. The weight of the whole was 1439 grains: The quantity of salt, consequently, was $\frac{1439}{16,901} = 85,142$ grains. The quantity of alkali was $50,05 - 14 = 36,05$. The quantity of standard acid employed was 66,7. The whole of which amounted to 102,75 grains; but as only 85,142 grains entered into the composition of the salt, the remaining 17,668 must have been pure water mixed with the nitric acid. But if 66,7 of standard acid contain 17,608 of water, 100 parts of the same acid must contain 26,38 *.

* *Irish Trans.* iv.

One hundred parts of standard nitric acid, therefore, is composed of 73,62 parts of pure nitric acid and 26,38 of water. But as Mr Kirwan has not proved that nitrat of soda contains no water, perhaps the proportion of

Nitric Acid.

of water may be greater. He has rendered it probable, however, that nitrat of soda contains very little water.

413 Its action on other bodies,

Nitric acid is decomposed by a great variety of substances. When poured upon oils, it sets them on fire. This is occasioned by a decomposition both of the acid and oil. The oxygen of the acid combines with the carbon and with the hydrogen of the oils, and at the same time lets go a quantity of caloric. Hence we see that the oxygen which enters into the composition of the nitric acid still contains a great deal of caloric; a fact which is confirmed by a great number of other phenomena. The combustion of oils by this acid was first taken notice of by Borrichius and Slare; but it is probable that Homberg communicated it to Slare. In order to set fire to the fixed oils, it must be mixed with some sulphuric acid; the reason of which seems to be, that these oils contain *water*, which must be previously removed. The sulphuric acid combines with this water, and allows the nitric acid, or rather the oil and nitric acid together, to act. The drying oils do not require any sulphuric acid: they have been boiled, and consequently deprived of all moisture. It sets fire also to charcoal, provided it be perfectly dry. This fact was first observed by Proust, and afterwards confirmed by the Dijon academicians. It sets fire also to zinc, bismuth, and tin, if it be poured on them in fusion, and to filings of iron, if they be perfectly dry *. In all these cases the acid is decomposed. Sulphurated hydrogen gas also takes fire, and burns with a strong flame by means of this acid †.

* *Proust, Dijon Academicians*, and *Cornette*.

† *Tromsdorff*.

It is capable of oxidating all the metals except gold, platinum (x), and titanium. It appears, from the experiments of Scheffer, Bergman, Sage, and Tillet, that nitric acid is capable of dissolving (and consequently of oxidating) a very minute quantity even of gold.

414 Its combinations,

Nitric acid combines with alkalies, alkaline earths, alumina, and jargonia, and with the oxides of metals, and forms compounds which are called *nitrats*. It does not act upon silica nor adamanta.

415 And affinities.

The order of its affinities is as follows:

- Barytes,
- Potass,
- Soda,
- Strontites ‡,
- Lime,
- Magnesia,
- Ammonia,
- Alumina,
- Jargonia §?
- Metallic oxides, in the same order as for sulphuric acid.
- Water.

‡ *Dr Hope*.

§ *Vauquelin, Ann. de Chim.* xxii. 208.

Sect. IV. *Of Nitrous Acid.*

Nitrous Acid.

416 Component parts of nitrous acid.

If oxygen gas be mixed with nitrous gas, a quantity of red fumes appear, which are readily absorbed by water. These red fumes are *nitrous acid*.

If a glass vessel containing nitric acid be inverted into another vessel containing the same acid, and exposed to the light, the inverted glass will become partly full of oxygen gas, and at the same time part of the nitric acid is converted into nitrous acid *. It follows, from this experiment, that nitrous acid contains less oxygen than nitric acid. Lavoisier has calculated, that it contains somewhat less than three parts of oxygen to one of azot.

* *Scheele, Crell's Annals* 1786.

417 Its properties.

Nitrous acid is of a brown or red colour, exceedingly volatile, and emitting a very suffocating and scarcely tolerable odour. When to this acid, concentrated, a fourth part by weight of water is added, the colour is changed from red to a fine green; and when equal parts of water are added, it becomes blue †. Dr Priestley observed, that water impregnated with this acid in the state of vapour became first blue, then green, and lastly yellow. A green nitrous acid became orange-coloured while hot, and retained a yellow tinge when cold. A blue acid became yellow on being heated in a tube hermetically sealed. An orange-coloured acid, by long keeping, became green, and afterwards of a deep blue; and when exposed to air, resumed its original colour. These colours seem to depend upon the concentration of the acid.

† *Bergman*.

Dr Priestley found that water absorbed great quantities of this acid in the state of vapour; and that when saturated, its bulk was increased one-third.

In the state of vapour, it is absorbed rapidly by oils. Whale oil, by absorbing it, became green, thick, and heavier It gradually decomposed the acid, retained the oxygen, and emitted the azot in the state of gas ‡.

‡ *Priestley*, iii. 111.

It is absorbed by sulphuric acid, but seemingly without producing any change; for when water is poured into the mixture, the heat produced expels it in the usual form of red fumes §. The only singular circumstance attending this impregnation is, that it disposes the sulphuric acid to crystallize ‖. This fact, first observed by Dr Priestley in 1777 (y), was afterwards confirmed by Mr Cornette.

§ *Ibid.* p. 144.

‖ *Ibid.* p. 156.

Nitrous acid appears capable of combining with most of the bodies with which nitric acid unites. The salts which it forms are called *nitrites*.

Its affinities have never been accurately examined. Bergman supposes them the same with those of nitric acid.

Of

(x) Nitre, however, acts upon platinum, as Mr Tennant has proved. *Phil. Transf.* 1797. Morveau had made the same observation in the *Elemens de Chimie de l'Academie de Dijon*.

(y) Bernhardt, however, relates, in 1765, that once, when he was distilling a mixture of ten pounds of nitre with an equal quantity of calcined vitriol, which he had put into a retort, to which was fitted an adapter between the retort and the receiver, which contained a quantity of water—he observed a considerable quantity of a white crystalline salt formed in the adapter, while the liquid acid passed as usual into the receiver. This salt was very volatile, smoked strongly when it was exposed to the air, and exhaled a red vapour; it burnt, to a black coal, wood, feathers, or linen, as sulphuric acid does; and where a piece of it fell, it evaporated in form of a blood red vapour, till the whole of it disappeared. Half an ounce of these crystals dissolved in water with spurting and hissing, like that of a red-hot iron dipped in water, and formed a green nitrous acid. Some of this salt being put into a bottle, which was not well stopped, entirely vanished. These crystals were evidently the same with Dr Priestley's. See *Keir's Dictionary*.

Nitrous Gas.

Of Nitrous Gas.

418 Discovery of nitrous gas. Nitrous gas was first obtained by Dr Hales, but its properties were discovered by Dr Priestley. It may be procured by dissolving metals in nitric or nitrous acid, and catching the product by means of a pneumatic apparatus.

As nitrous acid is formed by combining nitrous gas and oxygen, it is evident that nitrous gas contains less oxygen than nitrous acid. According to Lavoisier, it is composed of two parts of oxygen and one of azot.

419 Its properties. Nitrous gas is elastic, and invisible like common air. It extinguishes light, and instantly kills all those animals that are obliged to breathe it. Its specific gravity, according to Mr Kirwan, is 0,001458 *.

Dr Priestley found that water was capable of absorbing about one-tenth of nitrous gas, and that by the absorption it acquired an astringent taste †. Water parts with all the nitrous gas it has imbibed on being frozen ‡.

Neither phosphorus nor sulphur seem capable of decomposing nitrous gas.

Mr Linck, professor at Rostoc, found, that three parts of nitrous gas and two of hydrogen gas, obtained by sulphuric acid and iron, are scarcely, or not at all, diminished when exposed to day-light over water. Common air is not more dminished by this admixture kept a long time: but the mixture itself of these two gases is diminished by the addition of new portions of nitrous gas. Mr Linck concludes, from this observation, that part of the oxygen of the nitrous gas combined with the hydrogen and formed water, and that the remaining oxygen and azot formed a mixture similar to the air of the atmosphere. Mr Vauquelin had previously made the same observation. The affinity of hydrogen, therefore, for oxygen is greater than that of azot §.

Oils imbibe nitrous gas with avidity, and decompose it.

Nitric acid absorbs a vast quantity of it, and is by that means converted into nitrous acid.—Sulphuric acid also absorbs it.

The most important property of nitrous gas is that of combining instantly with oxygen gas, and forming nitrous acid, which is instantly absorbed by water. This property induced Dr Priestley to use nitrous gas as a test of the purity of common air. He mixed together equal bulks of these substances, and judged of the purity of the air by the diminution of bulk. The apparatus used for this purpose, which consists of a graduated tube, has been called a *eudiometer*. This eudiometer has been greatly improved by Fontana, but it is still liable to uncertainty in its application. Perhaps the best eudiometer is sulphuret of potass, which, as Morveau has discovered, absorbs, on the application of heat, the whole oxygen in a given bulk of air almost instantaneously.

420 The eudiometer.

Dr Priestley found that nitrous gas was decomposed by passing electric explosions through it.

Let us now consider in what manner oxygen and azot are combined in the three substances which have been just described.

421 Manner in which azot and oxygen are combined. It can hardly be conceived that azot is capable of combining with three different proportions of oxygen, and of being saturated with each: it is surely much more probable, that in nitrous gas the oxygen and azot saturate each other directly and completely; that nitrous acid is composed of nitrous gas and oxygen, and nitric acid of nitrous acid and oxygen. And this supposition is confirmed by considering that the strength of affinity by which the oxygen is retained in each of these substances is very different. Some substances, as light, are capable of decomposing nitric acid, by seizing some of its oxygen, and of converting it into nitrous acid; but they have no effect whatever upon nitrous acid or nitrous gas. Others, as bismuth, copper, phosphorus, and sulphur, are capable of decomposing both nitric and nitrous acids, but are incapable of altering nitrous gas: And others, again, as carbon, zinc, and iron, are capable of decomposing all the three. Every body which is capable of decomposing nitrous acid is capable also of decomposing nitric acid; and every body that decomposes nitrous gas is capable also of decomposing the other two. But the reverse of this is not true. The affinity of oxygen, then, for azot, nitrous gas, and nitrous acid, is different: oxygen has a stronger affinity for azot than it has for nitrous gas, and a stronger affinity for nitrous gas than for nitrous acid. But if all these bodies were direct combinations of azot and oxygen, how could this difference of affinity take place? Is it reasonable to suppose that a substance has a stronger affinity for one proportion of any other body than for another proportion? or that, if such a difference existed, the strongest affinity should not always prevail? Mix together nitric acid and nitrous gas in proper proportions, and the whole mixture is converted into nitrous acid: but mix nitrous and nitric acids together, and no change whatever is produced. In the first case, is it not evident that the affinity of nitrous gas for oxygen is greater than that of nitrous acid; that therefore it decomposes the nitric acid, deprives it of oxygen, and leaves it in the state of nitrous acid? But, in the second case, no change can take place, because nitric acid is composed of nitrous acid and oxygen; and it would be absurd to suppose, that *nitrous acid* has a stronger affinity for oxygen than *nitrous acid* has. But were azot and oxygen capable of uniting in various proportions, why should not a mixture of nitric and nitrous acids, or of nitrous gas and nitrous acid, form new substances? And why are the only substances which appear in decompositions nitrous acid and nitrous gas? Surely these reasons are sufficient to shew us, that these bodies are combined in the following manner:

Azot and Oxygen	form nitrous gas;
Nitrous gas and oxygen	form nitrous acid;
Nitrous acid and oxygen	form nitric acid.

Perhaps there may be even more links in the chain than we are aware of. The dephlogisticated nitrous air of Dr Priestley, which Dieman and Van Troostwyck have lately proved to be composed of 37 parts of oxygen and 63 of azot, and of which little more is known than that it supports flame, is noxious to animals, absorbed by water, and only obtained by means of substances capable of decomposing nitrous gas—perhaps this *air* is composed directly of oxygen and azot, nitrous gas of this air and oxygen, and so on. There may be even links still farther back than that.

Muriatic Acid.

Sect. V. *Of Muriatic Acid.*

Muriatic acid appears to have been known to Basil Valentine; but Glauber was the first who extracted it from 422 Discovery of muriatic acid.

* *On Phlogiston*, p. 28.

† *Priestley*, i. 365.

‡ *Ibid.* p. 407.

§ *Nicholson's Jour.* ii. 72.

Muriatic Acid.

from common salt by means of sulphuric acid. Common salt is composed of muriatic acid and soda, for which last substance sulphuric acid has a stronger affinity. This acid was first called *spirit of salt*, afterwards *marine acid*, and now, pretty generally, *muriatic acid* *.

* From *muria.*

It is sometimes prepared by mixing one part of common salt with seven or eight parts of clay, and distilling the mixture. The clay, in this instance, is supposed to act chiefly by means of the sulphuric acid which it always contains (z): But this subject still requires farther elucidation. By these processes, muriatic acid is obtained dissolved in water. Dr Priestley discovered, that by applying heat to this solution, and receiving the product in vessels filled with mercury, a gas was procured; which gas is muriatic acid in a state of purity.

423
Its properties.

Muriatic acid gas is invisible and elastic, like common air. It destroys life and extinguishes flame. A candle, just before it goes out in it, burns with a beautiful green, or rather light blue flame; and the same flame appears when it is first lighted again †.

† *Priestley*, ii. 293.

The specific gravity of muriatic acid in the state of gas is, according to Mr Kirwan ‡, 0,002315, which is nearly double that of common air.

‡ *Irish Transf.* iv.

Water absorbs this gas with avidity. Ten grains of water are capable of absorbing ten grains of the gas. The solution thus obtained occupies the space of 13,3 grains of water nearly. Hence its specific gravity is 1,500, and the density of the pure muriatic acid in it is 3,03 § (A).

§ *Kirwan, Irish Transf.* vol. iv.

As muriatic acid can only be used conveniently when dissolved in water, it is of much consequence to know how much pure acid is contained in a given quantity of liquid muriatic acid of any particular density.

424
Quantity of it contained in acids of various densities.

Now the specific gravity of the purest muriatic acid that can easily be procured and preserved, is 1,196; it would be needless, therefore, to examine the purity of any muriatic acid of superior density. Mr Kirwan calculated that muriatic acid, of the density 1,196, contains $\frac{49}{100}$ parts of acid of the density 1,500, which he took for the standard; then, by means of experiments, he formed the following Table:

100 parts, at the specific gravity	Contain of standard acid	100 parts, at the specific gravity	Contain of standard acid	100 parts, at the specific gravity	Contain of standard acid
1,196	49	1,147	37	1,1036	26
1,191	48	1,1414	36	1,0984	25
1,187	47	1,1396	35	1,0942	24
1,183	46	1,1358	34	1,0910	23
1,179	45	1,1320	33	1,0868	22
1,175	44	1,1282	32	1,0826	21
1,171	43	1,1244	31	1,0784	20
1,167	42	1,1206	30	1,0742	19
1,163	41	1,1168	29	1,0630	16
1,159	40	1,1120	28	1,0345	10
1,155	39	1,1078	27	1,0169	5
1,151	38				

Muriatic acid (for this solution of the acid in water is always called by that name) is generally of a pale yellow colour, owing, as Dr Priestley supposed, to some earthy matter dissolved in it; but much more probably to its having absorbed a quantity of oxygen, for which it has a strong affinity. Indeed, that this is the cause appears evidently from Dr Priestley's own observations; for it was destroyed only by those bodies which had a stronger affinity for oxygen. It is very volatile, as might be expected, constantly emitting white fumes of a peculiar and unpleasant odour.

Oxy-muriatic Acid.

425
Its action on other bodies.

Muriatic acid is capable, by the assistance of heat, of oxidating the following metals: Iron, tin, lead, zinc, bismuth, cobalt, nickel, manganese, antimony, arsenic. Several of these, as iron, for instance, it oxidates even without the assistance of heat.

At a boiling heat, it oxidates silver and copper. It has no action on gold, platinum, mercury, tungsten, molybdenum, tellurium, titanium. Its action on uranium has not been tried.

In the state of gas, it appears to decompose alcohol and oils by its affinity for water *.

* *Priestley*, ii. 281.

It is capable of dissolving a little sulphat and fluat † of lime, and arseniat of mercury.

† See sect. ix.

It combines with the alkalies, alkaline earths, alumina, and jargonia, and with most of the metallic oxides, and forms neutral salts, known by the name of *muriats*.

426
Destroys putrid miasmata.

Morveau first shewed, that this acid, in the state of gas, neutralized putrid miasmata, and by that means destroyed their bad effects. In 1773, the cathedral of Dijon was so infected by putrid exhalations, that it was deserted, after several unsuccessful attempts to purify it. Application was made to Mr Morveau to see whether he knew any method of destroying these exhalations. He poured two pounds of sulphuric acid on six pounds of common salt, contained in a glass capsule, which had been placed on a few live coals in the middle of the church. He withdrew precipitately, and shut all the doors. The muriatic acid gas soon filled the whole cathedral, and could even be perceived at the door. After 12 hours, the doors were thrown open, and a current of air made to pass through to remove the gas. This destroyed completely every putrid odour †.

† *Jour. de Phys.* i. 436.

427
Its affinities.

The affinities of muriatic acid are as follow:

Barytes,
Potass,
Soda,
Strontites §,
Lime,
Magnesia,
Ammonia,
Alumina,
Jargonia ‖,
Metallic oxides as in sulphuric acid,
Water.

§ *Dr Hope.*

‖ *Vauquelin, Ann. de Chim.* xxii. 208.

Sect. VI. *Of Oxy-muriatic Acid.*

428
Discovery and preparation of oxy-muriatic acid.

Put into a glass retort one part of the black oxide of manganese and three parts of muriatic acid; place it in a sand-bath in such a manner that the liquor which rises up into the neck of the retort may fall back again into

(z) Morveau has shewn, that even alumina contains sulphuric acid, provided a precipitation, on adding muriat of barytes, be a sufficient test.

(A) For let D = the density of a mixture; *m* the weight of the denser ingredient; *d* its density; *l* the weight of an

Oxy-muriatic Acid.

into the veſſel; and apply a ſmall receiver, with a little water in it, luted to the retort merely by a fillet of brown paper. In about a quarter of an hour the receiver will appear filled with a yellow-coloured gas; it is then to be removed, and others applied ſucceſſively till the operation be finiſhed.

This gas is oxy-muriatic acid, firſt diſcovered by Scheele, while he was making experiments on manganeſe, and called by him *dephlogiſticated muriatic acid*, becauſe he thought it muriatic acid deprived of phlogiſton. The French chemiſts called it *oxygenated muriatic acid*, which Dr Pearſon contracted into *oxy-muriatic acid;* and this laſt name we have adopted, becauſe it is ſhorter and equally diſtinct.

429 Its compoſition.

The true theory of the formation and compoſition of this acid, which was firſt given by Berthollet, will appear from the following facts: The *black* oxide of manganeſe is, during the proceſs, converted into *white* oxide, and muſt therefore have given out a quantity of oxygen. When oxy-muriatic acid diſſolved in water is preſented to the light in a veſſel half empty, oxygen gas is diſengaged and floats above, and the acid is converted into common muriatic acid: Conſequently oxy-muriatic acid is compoſed of muriatic acid and oxygen. Black oxide of manganeſe is compoſed of white oxide and oxygen; muriatic acid has a ſtronger affinity for oxygen than the white oxide; during the diſtillation the black oxide is decompoſed, the oxygen combines with muriatic acid, and the product is oxy-muriatic acid gas.

430 Its properties.

Oxy-muriatic acid gas is of a yellow colour. It ſupports flame, but cannot be breathed without proving noxious. The death of the ingenious and induſtrious Pelletier, to whom we have ſo often referred, was occaſioned by his attempting to reſpire it. A conſumption was the conſequence of this attempt, which, in a ſhort time, proved fatal.

It does not unite readily with water. Scheele found, that after ſtanding 12 hours over water, $\frac{4}{7}$ths of the gas were abſorbed: the remainder was common air, which no doubt had been contained in the veſſel before the operation. Berthollet ſurrounded ſeveral bottles containing it with ice: as ſoon as the water in theſe bottles was ſaturated, the gas became concrete, and ſunk to the bottom of the veſſels; but the ſmalleſt heat made it riſe in bubbles, and endeavour to eſcape in the form of gas*. Weſtrum obſerved that it became ſolid when expoſed in large veſſels to the temperature of 40°; and that then it exhibited a kind of cryſtallization †. The ſpecific gravity of water ſaturated with this gas, at the temperature of 43°, is 1,003 *. Water impregnated with it has not an acid, but an auſtere taſte †, unlike that of other acids.

* Journ. de Phyſ. 1785.
† Journ. de Phyſique, xxxvii. 382.

* Berthollet, Journ. de Phyſ. 1785.
† Scheele.

It renders vegetable colours *white*, and not red, as other acids do; and the colour thus deſtroyed can neither be reſtored by acids nor alkalies. It has the ſame effects on yellow wax. If the quantity of vegetable colours to which it is applied be ſufficiently great, it is found reduced to the ſtate of common muriatic acid. Hence it is evident, that it deſtroys theſe colours by communicating oxygen. This property has rendered oxy-muriatic acid a very important article in bleaching.

Nitrous gas, hydrogen, ſulphur, ſulphurous acid, and phoſphorus, decompoſe this acid, by depriving it of its oxygen, and leaving the muriatic acid in a ſeparate ſtate. Phoſphorus, however, does not produce this effect ſo readily, except when aſſiſted by heat *.

* Morveau, Encyc. Method. Chimie, i. 251.

When muriatic acid is mixed with nitric acid, the compound has preciſely the ſmell and the qualities of oxy-muriatic. It can ſcarcely be doubted, therefore, that as far as it acts as an acid, different from the muriatic and the nitric, it is nothing elſe but oxy-muriatic acid.

431 Nitro-muriatic acid.

This mixture of the two acids was formerly called *aqua regia;* but at preſent it is called by the French chemiſts *nitro-muriatic acid.* It is firſt mentioned by Iſaac the Hollander, and ſeems to have been known before the muriatic acid itſelf. It was prepared by pouring nitric acid on common ſalt. The nitric acid decompoſes the ſalt, and part of it unites with the muriatic acid thus ſet at liberty.

432 Its action on other bodies.

Oxy-muriatic acid oxidates all the metals (except, perhaps, titanium) without the aſſiſtance of heat.

It decompoſes red ſulphuret of mercury, or cinnabar, which neither ſulphuric nor nitric acid is able to accompliſh §.

§ Bergman.

All the ſubſtances placed before muriatic acid in the table of the affinities of oxygen, are capable of decompoſing this acid. Many of them, when plunged into it while in the ſtate of gas, actually take fire. Weſtrum obſerved, for inſtance, that when pieces of wood were plunged into this gas, they took fire; that arſenic burned with a blue and green flame; biſmuth, with a lively bluiſh flame; nickel, with a white flame, bordering on yellow; cobalt, with a white flame, approaching to blue; zinc, with a lively white flame; tin, with a feeble bluiſh flame; lead, with a ſparkling white flame; copper and iron, with a red flame: that powdered charcoal took fire in it at the temperature of 90°, and that ammonia produced with it a loud detonation ‖.

‖ Journ. de Phyſique, xxxvii. 385.

With

an equal bulk of water; and m', d', and l', the ſame elements of the rarer: Then $D = \frac{m+m'}{l+l'}$. In the above caſe, $m+m' = 20$, and $l+l' = 13,3$. Then $D = \frac{20}{13,3} = 1,5$. Now to find the ſpecific gravity of the condenſed muriatic acid gas, we have from the above equation $l = \frac{m+m'-l'D}{D} = \frac{5}{1,5} = 3,3$; and $d = \frac{m}{l} = \frac{10}{3,3} = 3,03$. *See Iriſh Tranſactions*, vol. iv.

This calculation, however, is formed upon the ſuppoſition that the water ſuffers no condenſation at all—a ſuppoſition certainly contradicted by every analogy, and which, as Mr Keir has ſhewn, the experiments mentioned in Mr Kirwan's firſt paper are inſufficient to prove.

Oxy-muriatic Acid.

With alkalies, earths, and metallic oxides, it is capable of combining and forming neutral salts, which have been called *oxy-mariats*.

433 Its affinities. The affinities of this acid, according to Lavoisier, are as follows:

Alumina,
Jargonia * ?
Ammonia,
Oxide of antimony,
——— silver,
——— arsenic,
Barytes,
Strontites ?
Oxide of bismuth,
Lime,
Oxide of cobalt,
——— copper,
——— tin,

Magnesia (B),
Oxide of manganese,
——— mercury,
——— molybdenum,
——— nickel,
——— gold,
——— platinum,
——— lead,
Potass,
Soda,
Oxide of tungsten,
——— zinc (C).

* *Vauquelin, Ann. de Chim.* xxii. 208.

434 Of the component parts of muriatic acid. The component parts of muriatic acid are still imperfectly known. Dr Girtanner pretended, about the year 1790, that he had decomposed it; and that it consisted of hydrogen combined with a greater proportion of oxygen than enters into the composition of water. He passed electrical explosions through muriatic acid, and obtained a quantity of oxygen and hydrogen gas. But a repetition of these experiments shewed, that the gases were owing, not to the decomposition of the acid, but to that of the water with which the acid was combined.

The experiments of Mr Lambe (D) have lately opened a new and unexpected path, which seems to lead directly to the discovery of the component parts of this acid. He found, that when iron was acted upon by sulphurated hydrogen gas, a substance was produced which possessed all the properties of oxy-muriat of iron (oxy-muriatic acid combined with iron). The sulphurated hydrogen gas which he used was obtained from sulphuret of iron, formed by fusing equal parts of iron and flowers of sulphur; and it was extricated by diluted sulphuric acid. In a solution of this gas in distilled water, he digested iron filings, previously purified by repeated washings with distilled water. The bottle was filled with the solution, and corked. The iron was presently acted upon; numerous bubbles arose, which drove the cork out of the bottle; they were strongly inflammable, and probably, therefore, pure hydrogen gas. The liquor gradually lost its odour of sulphurated hydrogen gas, and after some days smelled very much like stagnant rain-water. As the bubbles ceased to be produced, it recovered its transparency. On evaporating a small quantity of this solution in a watch-glass to dryness, a bitter deliquescent salt was left behind. On this salt a little sulphuric acid was dropped, and paper moistened with ammonia was held over the glass; white vapours were immediately formed over the glass; and consequently some volatile acid was separated by the sulphuric acid. Mr Lambe evaporated about eight ounce measures of the same liquor, and, as before, dropped a little sulphuric acid on the residuum; a strong effervescence was excited, very pungent acid fumes arose, which, from their smell, were readily known to be muriatic. The same truth was established beyond a doubt, by holding a bit of paper moistened with water, which made the vapours visible in the form of a grey smoke; a distinguishing characteristic, as Bergman has observed, of the muriatic acid.—When manganese and mercury were dissolved in sulphurated hydrogen gas, the salts formed gave the same unequivocal marks of the presence of muriatic acid *.

* *Lambe, ibid.*

Shall we conclude from these facts, that the basis of muriatic acid is sulphurated hydrogen; that muriatic acid is sulphurated hydrogen combined with oxygen; that this combination takes place during the solution of the iron; and that the escape of hydrogen is owing to the decomposition of the water?

Phosphoric Acid.

Sect. VII. *Phosphoric Acid.*

Phosphorus is capable of forming combinations with two different quantities of oxygen; with the larger it forms phosphoric; and with the smaller phosphorous acid. 435 Discovery of phosphorus.

Phosphoric acid was unknown till after the discovery of phosphorus. Boyle is perhaps the first person who mentions it: he discovered it by allowing phosphorus to burn slowly in common air. But Margraf was the first person who examined its properties, and discovered it to be a peculiar acid.

It may be procured by exposing phosphorus to a moderate heat: the phosphorus takes fire, combines with oxygen, and is converted into an acid.

It may also be prepared by exposing phosphorus during some weeks to the ordinary temperature of the atmosphere, even in winter; when the phosphorus undergoes a slow combustion, and is gradually changed into a liquid acid. For this purpose, it is usual to put small pieces of phosphorus on the inclined side of a glass funnel, through which the liquor which is formed drops into the bottle placed to receive it. From one ounce of phosphorus about three ounces of acid liquor may be thus prepared, called *phosphoric acid by deliquescence*. 436 Method of preparing it

Scheele has contrived another mode of obtaining the phosphoric

(B) According to Trommsdorf, oxy-muriatic acid is incapable of combining with magnesia. *Ann. de Chim.* xxii. 218.

(C) This is the order of the affinities of nitro-muriatic acid. Many facts (some of which shall appear afterwards) concur to prove that the affinities of the oxy-muriatic acid are the same, and indeed that they are the same acids.

(D) Analysis of the waters of two mineral springs at Leminton Priors. *Manchester Memoirs*, vol. V. part 1st.

Phosphoric Acid.

phosphoric acid from phosphorus without combustion, by the mere action of the nitric acid on phosphorus *. Mr Lavoisier has repeated and described this process †. He put two pounds of nitric acid, the specific gravity of which was 1,29895, into a retort, the contents of which were equal to six or seven French pints, and to which a balloon was fitted. Having placed this retort in a sand-bath, and brought the heat of the acid contained in it to $133\frac{1}{4}$ deg. he added successively small quantities of phosphorus, about 10 or 12 grains at a time, until he had dissolved $2\frac{1}{4}$ oz. At first the effervescence was great, but at last he was obliged to apply heat to effect the solution. The operation lasted 17 or 18 hours. A good deal of nitrous acid had passed into the receiver. He then poured the contents of the retort into a smaller retort, and evaporated by means of a stronger heat, until the phosphoric acid began to distil in white vapours. The remaining acid was so thick that he could not pour it out of the retort, and therefore could not ascertain its quantity; but he supposes it might be 8 or 9 ounces, in which he thinks there were about $2\frac{1}{2}$ ounces of phosphorus; the remaining $\frac{1}{4}$ ounce being supposed to have evaporated. The quantity of oxygen imbibed he reckons at $3\frac{1}{2}$ ounces, and the quantity of water at about 2 ounces.

* On Fire, § lxxvii.
† Mem. Acad. 1780.

Lavoisier computes that phosphoric acid contains 100 parts of phosphorus and 154 of oxygen.

437 Its properties.

The colour of this acid is white; it has no smell, has an acid taste; but is not corrosive (E).

It is exceedingly fixed. When exposed to the fire in a matrass with a long neck, it loses at first the greater part of its water; then an odour of garlic is felt, owing to some phosphorus, from which it is exceedingly difficult to clear it entirely; there is likewise a small quantity of the acid volatilized along with the water. The liquor then becomes thick and milky: small luminous decrepitations take place from time to time, and they continue for some time after the vessel is taken from the fire. If the matter be then put into a crucible, and placed among burning coals, it first boils violently, and gives out a vapour which tinges flame green, and is at last converted to a white transparent glass, insoluble in water.

The specific gravity of this acid in a state of dryness is 2,687 ‡, that of phosphoric acid by deliquescence 1,417 §. It is capable of crystallizing; its crystals are quadrangular prisms terminated by quadrangular pyramids.

‡ Bergman.
§ Morveau.

Phosphoric acid obtained by deliquescence, when mixed with an equal quantity of distilled water, acquired so little *heat* as to raise the thermometer only one degree, as Mr Sage observed.

Mr Lavoisier raised Reaumur's thermometer from 8° to 14° or 15° by mixing phosphoric acid boiled to the consistence of a syrup, with an equal quantity of water; and from 8° to 32° or 33° when the acid was as thick as turpentine ||.

|| Keir's Dictionary.

438 Its action on other bodies.

Phosphoric acid is capable of oxidating iron, tin, lead, zinc, antimony, bismuth, manganese. When fused with several of these metals, as tin, lead, iron, and zinc, it is converted into phosphorus; a proof that they have a stronger affinity for oxygen.

Boracic Acid.

It does not act upon gold, platinum, silver, copper, mercury, arsenic, cobalt, nickel. It appears, however, to have some action on gold in the *dry way*, as it is called; for when fused with gold-leaf it assumes a purple colour; a proof that the gold has been oxidated.

It is capable of combining with alkalies, alkaline earths, alumina, and metallic oxides; and of forming salts known by the name of *phosphats*.

Phosphoric acid, by the assistance of heat, is capable of decomposing glass.

439 Its affinities.

Its affinities are as follows:

Lime,
Barytes,
Strontites*,
Magnesia,
Potass,
Soda,
Ammonia,
Alumina,
Jargonia †,
Metallic oxides as in sulphuric acid,
Water.

* Hope, Trans. Edin. iv.
† Vauquelin, Ann. de Chim. xxii. 208.

440 Phosphorous acid.

The Phosphorous Acid is formed when phosphorus is exposed to a slow spontaneous combustion at the temperature of the atmosphere; but it gradually absorbs more oxygen, and is converted into phosphoric acid.

Concerning phosphorous acid nothing of any consequence is at present known, except that it contains less oxygen than phosphoric acid.

Sect. VIII. *Boracic Acid.*

441 Borax.

The word *borax* first occurs in the works of Geber, an Arabian chemist of the 10th century. It is a name given to a species of white salt much used by various artists. Its use in soldering metals appears to have been known to Agricola.

Borax is found mixed with other substances in Thibet. It seems to exist in some lands adjacent to lakes, from which it is extracted by water, and deposited in those lakes; whence in summer, when the water is shallow, it is extracted and carried off in large lumps. Sometimes the water in these lakes is admitted into reservoirs, at the bottom of which, when the water is exhaled by the summer's heat, this salt is found.—Hence it is carried to the East Indies, where it is in some measure purified and crystallized: in this state it comes to Europe, and is called *tincal*. In other parts of Thibet, it seems, by accounts received from China, they dig it out of the ground at the depth of about two yards, where they find it in small crystalline masses, called by the Chinese *mi poun*, *houi poun*, and *pin poun*; and the earth or ore is called *pounxa* ‡.

‡ Kirwan's Mineralogy, ii. 37.

442 Discovery of boracic acid.

Though borax has been in common use for nearly three centuries, it was only in 1702 that Homberg, by distilling a mixture of borax and green vitriol, discovered the *boracic acid*. He called it *narcotic* or *sedative salt*, from a notion of his, that it possessed the properties indicated by these names. In his opinion, it was merely a product of the vitriol which he had used; but Lemery the Younger soon after discovered, that it could likewise be obtained from borax by means of the nitric and muriatic acids. Geoffroi afterwards discovered, that

(E) We have observed, however, that when very much concentrated it destroyed the texture of vegetable substances, paper for instance, very completely.

Boracic Acid.

that borax contained soda: and at last Baron proved, by a number of experiments, that borax was composed of boracic acid and soda; that it might be reproduced by combining these two substances—and that therefore the boracic acid was not formed during the decomposition of borax, as former chemists had imagined, but was a peculiar substance which pre-existed in that salt.

443 Attempts to prove that it does not exist in borax;

This conclusion has been called in question by Mr Cadet *, who affirmed that it was composed of *soda, the vitrifiable earth of copper, another unknown metal, and muriatic acid.* But this assertion has never been confirmed by a single proof; Mr Cadet has only proved that boracic acid sometimes contains copper; and Beaumé's experiments are sufficient to convince us that this metal is merely accidentally present, and that it is probably derived from the vessels employed in crystallizing borax: That boracic acid generally contains a little of the acid employed to separate it from the soda, with which it is combined in borax: And that crude borax contains a quantity of earth imperfectly saturated with boracic acid:—All which may be very true; but they are altogether insufficient to prove that boracic acid is not a peculiar substance, since it displays properties different from every other body.

* *Journ. de Phys.* 1782.

444 And to prove that it is phosphoric acid.

Messrs Exschaquet and Struve have endeavoured, on the other hand, to prove that the phosphoric and boracic acids are the same. But their experiments merely shew that these acids resemble one another in several particulars; and though they add considerably to our knowledge of the properties of the phosphoric acid, they are quite inadequate to establish the principle which these chemists had in view; since it is not sufficient to prove the identity of the two acids, to shew us a resemblance in a few particulars, while they differ in many others. Boracic acid must therefore be considered as a distinct substance, the component parts of which are entirely unknown.

445 Method of procuring it.

The easiest method of procuring boracic acid is the following one: Dissolve borax in hot water, and filter the solution; then add sulphuric acid, by little and little, till the liquor be rather more than saturated. Lay it aside to cool, and a great number of small, shining, laminated crystals will form. These are the boracic acid. They are to be washed with cold water, and drained upon brown paper.

446 Its properties.

This acid has a sourish taste at first, then makes a bitterish cooling impression, and at last leaves an agreeable sweetness. Its crystals have some resemblance to spermaceti, and it has the same kind of feel.

It changes vegetable blues to red; it has no smell; but when sulphuric acid is poured on it, a transient odour of musk is produced *. The air produces no change on it.

* *Reuss De Sale Sedat.* 1778.

According to Reuss, it is soluble in 20 parts of cold water, eight parts of warm water, and 2,5 of boiling water. According to Wenzel, 960 grains of boiling water dissolve 434 of this acid. According to Morveau, one pound of boiling water dissolves only 183 grains.

It is exceedingly fixed when not combined with water. When exposed to a violent fire it is converted into a white transparent glass; which, however, is soluble in water, and produces the acid again by evaporation.

Boracic acid is also soluble in alcohol; and alcohol containing it burns with a green flame.

Its specific gravity is 1,479 ‡.

‡ *Kirwan's Miner.* ii. 4.

Fluoric Acid.

Paper dipped into a solution of boracic acid burns with a green flame.

Though mixed with fine powder of charcoal, it is nevertheless capable of vitrification; and with soot it melts into a black bitumen-like mass, which is, however, soluble in water, and cannot be easily calcined to ashes, but sublimes in part *.

* *Keir's Dictionary.*

With the assistance of a distilling heat it dissolves in oils, especially in mineral oils; and with these it yields fluid and solid products, which give a green colour to spirit of wine.

When boracic acid is rubbed with phosphorus, it does not prevent its inflammation; but an earthy yellow matter is left behind †.

† *Ibid.*

It is hardly capable of oxidating or dissolving any of the metals except iron and zinc, and perhaps copper. 447 Its action on other bodies.

Boracic acid combines with alkalies, alkaline earths, and alumina, and most of the metallic oxides, and forms compounds, which are called *borats*.

Its affinities are as follows: 448 Its affinities.

Lime,
Barytes,

§ *Vauquelin, Ann. de Chim.* xxii. 208.

Sect. IX. *Fluoric Acid.*

449 Discovery of fluoric acid.

The mineral called *fluor* or *fusible spar*, was not properly distinguished from other spars till Margraf published a dissertation on it in the Berlin Transactions for 1768. He first proved that it contained no sulphuric acid, as had been formerly supposed; he then attempted to decompose it, by mixing together equal quantities of this mineral and sulphuric acid, and distilling them. By this method he obtained a *white sublimate*, which he supposed to be the fluor itself volatilized by the acid. He observed, with astonishment, that the glass retort was corroded, and even pierced with holes. Nothing more was known concerning fluor till Scheele published his experiments three years after; by which he proved that it was composed chiefly of lime and a particular acid, which has been called *fluoric acid.*

450 Method of obtaining it.

To obtain it, put eight ounces of finely powdered fluor into a retort, and pour on it an equal quantity of sulphuric acid, and lute to the retort, as exactly as possible, a receiver containing eight ounces of water. Vapours immediately appear and darken the inside of the vessel: These are the acid in the state of gas. The distillation is to be conducted with a very moderate heat, not only to allow the gas to condense, but also to prevent the fluor itself from subliming. After the process, Fluoric Acid.

cess, a crust of white earth is found in the receiver, which has all the properties of silica.

Scheele supposed that the silica produced was formed of fluoric acid and water, and Bergman adopted the same opinion. But Wiegleb and Buccholz shewed, that the quantity of silica was exactly equal to what the retort lost in weight; and Meyer completed the proof that it was derived from the glass, by the following experiment: He put into each of three equal cylindrical tin vessels a mixture of three oz. of sulphuric acid and one oz. of fluor, which had been pulverized in a mortar of metal. Into the first he put one oz. of pounded glass; into the second, the same quantity of quartz in powder; and into the third, nothing. Above each of the vessels he hung a sponge moistened with water; and having covered them, he exposed them to a moderate heat. The sponge in the first cylinder was covered with the crust in half an hour; the sponge in the second in two hours; but no crust was formed in the third, though it was exposed several days. In consequence of this decisive experiment, Bergman gave up his opinion, and wrote an account of Meyer's experiment to Morveau, who was employed in translating his works, to enable him to correct the mistake in his notes.

451 Attempts to disprove its existence.

Soon after the discovery of this acid, difficulties and doubts concerning its existence as a peculiar acid were started by some French chemists, disguised under the name of Boulanger, and afterwards by Mr Achard and Mr Monnet. To remove these objections, Mr Scheele instituted and published a new set of experiments; which not only completely established the peculiar nature of the fluoric acid, but once more displayed the unrivalled abilities of the illustrious discoverer. These important particulars we pass over thus slightly, because they have been partly treated of already in the article CHEMISTRY, *Encycl.* One experiment, however, we cannot omit, because it is sufficient of itself to destroy almost all the objections of his antagonists, which consisted in attempting to prove, that the fluoric acid was merely a modification of the acid employed to extract it. We shall give it in Mr Sheele's own words.

452 Refuted by Scheele,

"I melted together (says he) in a crucible two ounces of finely pulverized fluor spar with four ounces of potass. As soon as they were melted, I poured out the mass, rubbed it, when it was become cold, to a powder, and extracted the alkali from it again by lixiviation with water. I evaporated the lixivium to dryness; and threw away the remaining undissolved powder (which was only one of the component parts of the fluor, and which dissolved readily, and with effervescence, in acids) from its solution, in which it may be precipitated by sulphuric acid in the form of selenite (sulphat of lime). Upon a little of the dried alkali, put into a small retort, I poured some sulphuric acid, fitted to it a receiver containing some water; and even before the retort was become hot, I observed this water to be covered over with a pellicle of siliceous earth: a certain proof that the alkali had extracted the acid from the fluor during its exposure to the fire with it. Should Mr Achard, agreeably to the opinion which he has adopted, conclude from this experiment, that the alkali separated the volatile earth from the fluor (F); still he must certainly allow this earth of his to be of an acid nature, since the alkali is capable of disengaging it from the calcareous earth.—The remaining portion of the dried alkali I dissolved again in water, and saturated the superfluous alkali with pure nitric acid. After expelling from this saturated solution, by means of heat, the carbonic acid gas, which in such cases is always retained in the liquor, I dropped some of it into lime-water; whereupon I obtained a white precipitate, which was a regenerated fluor. I now dissolved some oxide of lead in vinegar, and continued to add to the ley, which had been saturated with nitric acid, as much of this solution as was requisite, till all precipitation ceased. Thus I transferred the fluor acid from the alkali to the oxide of lead. After washing the precipitate in cold water, and drying it, I dropped upon a small quantity of it a few drops of sulphuric acid; a frothing up immediately ensued, accompanied with an extrication of fluor acid vapours. But perhaps, in this case, the volatile earth of fluor unites with the sulphuric acid, and converts this fixed, or almost fixed acid into acid gas. I can easily make allowance to Dr Priestley for being inclined to draw such a conclusion, since this celebrated philosopher does not pretend to be a chemist (G). Being desirous of seeing whether heat alone was capable of expelling this acid from the oxide of lead, I put a little of this fluorated oxide into a small retort, the receiver to which contained some water. The oxide was melted; but I could not perceive any acid. The bottom of the retort was moreover quite corroded and dissolved, so that the whole ran into the fire. Thus the oxide of lead retains this acid in the fire, and will not part with it, unless the oxide is combined with some other substance. I therefore rubbed the remainder of my fluorated oxide of lead with an equal quantity of charcoal powder, and distilled the mixture in an open fire in a small glass retort, to which was adapted a receiver containing some water. As soon as the reduction of the oxide of lead took place, the neck of the retort became incrusted with a white sublimate, and a siliceous pellicle appeared upon the water. The sublimate had a sour taste, because the siliceous earth of which it consists is penetrated with fluoric acid; and the acid water in the receiver let fall, on the addition of volatile alkali, a siliceous earth *."

* *Crell's Journal*, i. 222. Eng. Transl.

Sorry are we to add, that since the death of this admirable man, to use the words of Mr Kirwan †, a man as eminent in the chemical as Newton in the mathematical branch of natural philosophy, Mr Monnet ‡ has thought proper to renew his attacks in a style of haughtiness and acrimony that inspires infinite disgust. The falacy of his reasoning is sufficiently exposed by Mr Leonhardi, in the 6th volume of his late learned edition of Macquer's Dictionary.

† *Mineralogy*, i. 126.

‡ *Journ. de Phys.* xxx. 253.

453 And Leonhardi.

454 Its properties.

Fluoric acid may be obtained in the form of gas, by applying a moderate heat to sulphuric acid and fluor spar, and receiving the product over mercury.

This gas is the acid in a state of purity. It is invisible and elastic like air; it does not maintain combustion,

(F) Mr Achard affirmed that fluor was composed of a peculiar volatile earth.

(G) Dr Priestley at first advanced this hypothesis, but he afterwards gave it up.

Carbonic Acid.

tion, nor can animals breathe it without death. It has a pungent smell, not unlike that of muriatic acid.

It is heavier than common air. It corrodes the skin almost instantly. It combines rapidly with water; and if it has been obtained by means of glass vessels, it deposites at the same time a quantity of silica.

Water impregnated with this gas does not freeze at a higher temperature than 23° *.

* Priestley, ii 362.

455 Its action on other bodies.

In the state of gas this acid does not act upon nitrous gas nor sulphur. Alcohol and ether absorb it, but it does not alter their qualities †.

† Ibid.

It is capable of oxidating iron, zinc, copper, and arsenic.

It does not act upon gold, platinum, silver, mercury, lead? tin, antimony, cobalt.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms compounds denominated *fluats*.

It is capable, as we have seen, of dissolving silica, which is insoluble in every other acid; accordingly it corrodes glass. This property has induced several ingenious men to attempt, by means of it, to engrave, or rather etch, upon glass.

456 Its affinities.

The affinities of fluoric acid are as follows:

Lime,
Barytes,
Strontites ‡,
Magnesia,
Potass,
Soda,
Ammonia,
Oxide of zinc,
——— manganese §,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,
——— nickel,
——— arsenic,
——— bismuth,
——— mercury,
——— silver,
——— gold,
——— platinum,
Alumina,
Jargonia ‖ ?
Water,
Silica,
Alcohol.

‡ Dr Hope.

§ Lavoisier.

‖ Vauquelin, Ann. de Chim. xxii. 208.

Sect. X. *Of Carbonic Acid.*

Carbonic acid is composed of carbon and oxygen. According to Lavoisier's experiments, the proportions are 28 parts of carbon and 72 of oxygen. Mr Proust informs us that there is also a *carbonous acid* (H); but with this acid we are not at present acquainted, and cannot therefore describe it.

457 Discovery of carbonic acid.

Paracelsus and Van Helmont were acquainted with the fact, that air is extricated from solid bodies during certain processes, and the latter gave to air thus produced the name of *gas*. Boyle called these kinds of air *artificial airs*, aud suspected that they might be different from the air of the atmosphere. Hales ascertained the quantity of air that could be extricated from a great variety of bodies, and shewed that it formed an essential part of their composition. Dr Black proved, that the substances then called *lime*, *magnesia*, and *alkalies*, are compounds, consisting of a *peculiar species of air*, and pure lime, magnesia, and alkali. To this species of air he gave the name of *fixed air*, because it existed in these bodies in a fixed state. This air or gas was afterwards investigated by Dr Priestley, and a great number of its properties ascertained. From these properties Mr Keir * first concluded that it was an acid; and this opinion was soon confirmed by the experiments of Bergman, Fontana, &c. Dr Priestley at first suspected that this acid entered as an element into the composition of atmospherical air; and Bergman adopting the same opinion, gave it the name of *aerial acid*. Mr Bewdly called it *mephitic acid*, because it could not be respired without occasioning death; and this name was also adopted by Morveau. Mr Keir called it *calcareous acid*; and at last Mr Lavoisier, after discovering its composition, gave it the name of *carbonic acid gas*.

* Keir's Macquer, art. Air.

458 Theories about its composition.

The opinions of chemists concerning the *composition* of carbonic acid have undergone as many revolutions as its name. Dr Priestley and Bergman seem at first to have considered it as an element; and several celebrated chemists maintained that it was the acidifying principle. Afterwards it was discovered that it was a compound, and that oxygen gas was one of its component parts. Upon this discovery the prevalent opinion of chemists was, that it consisted of oxygen and phlogiston; and when hydrogen and phlogiston came (according to Mr Kirwan's theory) to signify the same thing, it was of course maintained that carbonic acid was composed of oxygen and hydrogen: and though Mr Lavoisier demonstrated that it was formed by the combination of carbon and oxygen, this did not prevent the old theory from being maintained; because carbon was itself considered as a compound, into which a very great quantity of hydrogen entered. But after Mr Lavoisier had demonstrated that the weight of the carbonic acid produced was precisely equal to the carbon and oxygen employed; after Mr Cavendish had discovered that oxygen and hydrogen when combined did not form carbonic acid, but water—it was no longer possible to hesitate that this acid was composed of carbon and oxygen. Accordingly all farther dispute about it seems now at an end. At any rate, as we have already examined the objections that have been made to this conclusion, it would be improper to enter upon them here.

459 Its analysis.

If any thing was still wanting to put this conclusion beyond the reach of doubt, it was to *decompound* carbonic acid, and thus to exhibit its component parts by analysis as well as synthesis. This has been actually done by the ingenious Mr Tennant. Into a tube of glass he introduced a bit of phosphorus and some

(H) When there are two acids having the same base, but containing different quantities of oxygen, they are distinguished by their termination. The name of that which contains most oxygen ends in *ic*, the other in *ous*. Thus sulphuric and sulphurous acids, nitric and nitrous, phosphoric and phosphorous, carbonic and carbonous.

Carbonic Acid.

some carbonat of lime. He then sealed the tube hermetically, and applied heat. Phosphat of lime was formed, and a quantity of carbon deposited. Now phosphat of lime is composed of phosphoric acid and lime; and phosphoric acid is composed of phosphorus and oxygen. The substances introduced into the tube were phosphorus, lime, and carbonic acid; and the substances found in it were phosphorus, lime, oxygen, and carbon. The carbonic acid, therefore, must have been decomposed, and it must have consisted of oxygen and carbon. This experiment was repeated by Dr Pearson, who ascertained that the weight of the oxygen and carbon were together equal to that of the carbonic acid which had been introduced; and in order to shew that it was the carbonic acid which had been decomposed, he introduced pure lime and phosphorus; and instead of obtaining phosphat of lime and carbon, he got nothing but phosphuret of lime. These experiments were also confirmed by Messrs Fourcroy, Vauquelin, Sylvestre, and Broigniart (I) *.

* *Ann. de Chim.* xiii. 312.

Carbonic acid may be obtained by pouring sulphuric acid upon chalk, and receiving the product in a pneumatic apparatus.

460 Its properties,

It is invisible and elastic like common air. It extinguishes a candle, and is unfit for respiration. It has no smell.

Its specific gravity is 0,0018 †; but this varies according to its dryness or moisture.

† *Bergman*, i. 9.

It reddens the tincture of turnsole, but no other vegetable colour ‡.

‡ *Ibid.*

Atmospheric air contains about $\frac{1}{100}$ part of this gas (K).

Water absorbs it by agitation, or by allowing it to remain long in contact with it. At the temperature of 41° water absorbs its own bulk of this gas. The specific gravity of water saturated with it is 1,0015. This water, at the temperature of 35°, has little taste; but if it be left a few hours in the temperature of 88°, it assumes an agreeable acidity, and a sparkling appearance §.

§ *Ibid.*

Ice absorbs no carbonic acid; and if water containing it be frozen, the whole separates in the act of freezing ||.

|| *Priestley*, i. 120.

This gas also separates from water at the boiling temperature ¶.

¶ *Ibid.*

Alcohol and oil of turpentine absorb double their weight of this gas; olive oil its own bulk. Ether mixes with it in the state of gas *.

* *Bergman, ibid.*

Phosphorus suffers no change in this gas except it contains a mixture of oxygen gas †. It has an affinity for common air. Bergman left a bottle of it uncorked, and found that in a few days it contained nothing but common air. Common air, indeed, has so strong an affinity for this gas, that it attracts it from water, as Mr Welter has observed ‡.

† *Brugnatelli, Nicholson's Journal*, i. 446.

‡ *Ann. de Chim.* iii. 91.

It is absorbed by red hot charcoal, as Morozzo and La Metherie have shewn.

461 Compounds,

It is capable of combining with alkalies, alkaline earths, and alumina, and several metallic oxides, and of forming compounds known by the name of *carbonats*. It has no affinity for jargonia, according to Klaproth *; but, according to Vauquelin, it has †.

* *Journ. de Phys.* xxxvi. 186.

† *Ann. de Chim.* xxii. 204.

462 And affinities.

Its affinities, as arranged by Bergman, are as follows:

Barytes,
Lime,
Strontites ‡,
Potass,
Soda,
Magnesia,
Alumina,
Metallic oxides as in *sulphuric acid*,
Oxygen gas §,
Water,
Alcohol.

‡ *Dr Hope.*

§ *Mr Welter.*

Acetous Acid.

Sect. XI. *Of Acetous Acid.*

Acetous acid or vinegar was known many ages before the discovery of any other acid, those only excepted which exist ready formed in vegetables. It is mentioned by Moses, and indeed seems to have been in common use among the Israelites and other eastern nations at a very early period.

The methods of procuring, purifying, and concentrating this acid, have been already given in the articles Chemistry, Fermentation, and Vinegar, *Encycl.* and cannot therefore be repeated in this place.

It has been ascertained beyond a doubt, that this acid is composed of carbon, hydrogen, and oxygen; but neither the manner in which these substances are combined, nor their proportions, have been accurately ascertained.

463 Lowitz's method of obtaining pure acetous acid.

Acetous acid, as commonly prepared, is very fluid, has a pleasant smell, and an acid taste. It reddens vegetable colours. In this state it is mixed with a great proportion of water; but Mr Lowitz of Petersburg has discovered that it may be obtained in a solid crystallized form. Of this curious and instructive process we shall transcribe his own account ||.

|| *Crell's Journal*, i. 242. Eng. Transl.

"I have long been accustomed (says he) to prepare concentrated vinegar by congelation in the following manner: I freeze a whole barrel of vinegar as much as possible, then distil the remaining unfrozen vinegar in a water-bath; by which means I at first especially collect the spirituous ethereal part; the vinegar, which next comes over, I freeze again as much as possible, and afterwards purify it, by distilling it again with three or four pounds of charcoal powder. Thus I never fail to get a very pure, sweet-smelling, highly concentrated vinegar; the agreeable odour of which, however, may be still

(I) Count Mussin-Puschin having boiled a solution of carbonat of potass on purified phosphorus, obtained carbon. This he considered as an instance of the decomposition of carbonic acid, and as a confirmation of the experiments related in the text. See *Ann. de Chim.* xxv. 105.

(K) At least near the surface of the earth. Lamanon, Mongez, and the other unfortunate philosophers who accompanied La Perouse in his last voyage, have rendered it not improbable that at great heights the quantity of this gas is much smaller. They could detect none in the atmosphere at the summit of the Peak of Teneriffe. See *Lamanon's Memoir at the end of La Perouse's Voyage.*

Acetous Acid.

ſtill improved by the addition of a proper quantity of the ethereal liquor collected at the beginning of the firſt diſtillation, but which muſt be previouſly dephlegmated by two or three rectifications.

"After the diſtillation in the water-bath was over, that no vinegar might be loſt, I uſed to move the retort, with the charcoal powder which remained in it, to a ſand-bath; and thus I obtained, by means of a ſtrong fire, a few ounces more of a remarkably concentrated vinegar, which was of a yellow colour.

"Having collected about ten ounces of this concentrated vinegar, I expoſed it laſt winter in the month of December to a cold equal to —22°; in which ſituation it ſhot into cryſtals from every part. I let what remained fluid drop away from the cryſtals into a baſon placed underneath, firſt in the cold air, and afterwards at the window within doors. There remained in the bottle ſnow-white finely foliated cryſtals, cloſely accumulated one upon the other, and which I at firſt took to be nothing but ice: on placing them upon the warm ſtove, they diſſolved into a fluid which was perfectly as limpid as water, had an uncommonly ſtrong, highly pungent, and almoſt ſuffocating acetous ſmell, and in the temperature of —37° immediately congealed into a ſolid white cryſtallized maſs, reſembling camphor.

"After I had obſerved that vinegar in this ſtate is of ſuch an extraordinary ſtrength and purity as to be in its higheſt degree of perfection, I took all poſſible pains to find out a method of obtaining all the acetous acid in the ſtate of glacial vinegar.

"To avoid circumlocution, I ſhall denote the ſtrength of each ſort of vinegar, which it was neceſſary for me to know in my experiments, by degrees, which I aſcertain in the following manner: *viz.* to one drachm of vinegar I add, drop by drop, a clear ſolution of equal parts of carbonat of potaſs and water, till all at once a cloudineſs or precipitation appears. Although, on the appearance of this ſign, the acid is already ſuperſaturated with the alkali, yet it ſeems to me to be a more accurate teſt for aſcertaining its ſtrength than the ceſſation of effervescence; for as the point of ſaturation approaches, the effervescence becomes ſo imperceptible, that it is almoſt impoſſible to determine with preciſion when it is really at an end. Now, every five drops of the alkaline ſolution, which I find it neceſſary to add to the vinegar till the precipitation takes place, I reckon as one degree. Thus, for example, if a determinate quantity of vinegar requires 25 drops for that effect, I denote its ſtrength by five degrees. This is about the ſtrength of good diſtilled vinegar.

"I call that vinegar which, in conſequence of its concentration, is capable of cryſtallizing in a great degree of cold, *cryſtallizable vinegar;* the cryſtals of vinegar, ſeparated after the cryſtallization is completed from the remaining fluid portion, I call *glacial vinegar;* and, laſtly, to the fluid reſiduum I give the name of *mother-ley of vinegar.*

"From a great number of experiments, I have found that vinegar muſt have at leaſt 24 degrees of concentration before it can be brought to cryſtallize by expoſure to the moſt intenſe cold. Vinegar muſt be of the ſtrength of 42 degrees at leaſt, in order to become glacial vinegar; *viz.* in this ſtate of concentration it has the property of cryſtallizing in a degree of cold not exceeding that in which water begins to freeze.

"I have found that charcoal, on being diſtilled with vinegar in a water-bath, poſſeſſes the ſingular and hitherto unknown property of imbibing a certain quantity of the acetous acid in a very concentrated ſtate, and of retaining it ſo ſtrongly, that the acid cannot be ſeparated from it again but by the application of a conſiderably greater degree of heat than that of boiling water. Upon this circumſtance is founded the new method which I have diſcovered of concentrating vinegar, ſo as to obtain all its acid in the pureſt ſtate, *viz.* that of a glacial vinegar.

"Let a barrel of vinegar be concentrated by freezing in the manner above deſcribed, and let the concentrated vinegar thus obtained, free from all inflammable or ſpirituous parts, be put into two retorts: Add to each of them five pounds of good charcoal reduced to a fine powder, and ſubject them to diſtillation in a water-bath. When no more drops of vinegar come over, put the diſtilled liquor into two freſh retorts; and after adding five pounds of charcoal powder to each, proceed as before to the diſtillation in a water-bath. In the mean while, the two firſt retorts are to be placed in a ſand-bath, that, by means of a briſk fire, the cryſtallizable vinegar, which is retained in the apparently dry charcoal powder, may be expelled from it. The heat muſt be ſtrong enough to make the drops follow one another every two ſeconds; and when, in this degree of heat, 20 ſeconds intervene between each drop, the vinegar which has been collected muſt be removed; for what follows is hardly any thing elſe but mere water. In this manner about ſix ounces and a half of cryſtallizable vinegar, which is generally of the ſtrength of between 36 and 40 degrees, may be collected from each retort. As ſoon as the diſtillation by the water-bath in the two retorts is over, the diſtilled liquor is to be poured back again into the firſt retorts upon the charcoal powder, which remains in them, and which has been already uſed; and from each of theſe retorts the remaining cryſtallizable vinegar (which generally amounts to as much as the firſt quantity) is to be abſtracted by diſtillation in a ſand-bath. Theſe operations may be alternately repeated till all the acid of the vinegar which had been concentrated by freezing is converted into cryſtallizable vinegar; or until the diſtilled liquor, conſtantly becoming weaker and weaker at every repetition of the diſtillation, comes over at length in the ſtate of mere water, which, with the above mentioned quantity of charcoal powder, generally happens at the fourth or fifth diſtillation. Now, in order to obtain the greateſt part of the pure acid contained in the cryſtallizable vinegar in the form of glacial vinegar, it muſt be ſet to cryſtallize in a great degree of cold; and the mother-ley muſt be afterwards thoroughly drained from the glacial vinegar, by letting it drop from the cryſtals, firſt in the cold, and then in the room before the window. The mother-ley may be rendered further cryſtallizable by diſtilling it with a little charcoal powder; the weaker part, which comes over firſt, being put aſide. But if a perſon wiſhes to keep the cryſtallizable vinegar for other purpoſes, and without ſeparating any glacial vinegar from it, he muſt diſtil the whole of it again with charcoal powder in a ſand-bath.

"I have found by accurate experiments, that, by means of this curious proceſs, ten pounds of vinegar, concentrated by freezing to the 90th degree, may be made

Acetous Acid.

made to yield 38 ounces of cryſtallizable vinegar, from which 20 ounces of glacial vinegar may be obtained.

"What conſtitutes the excellence of this method is, that the concentration and purification are effected by one and the ſame medium, viz. the charcoal powder; in conſequence of which, both intentions are fulfilled at the ſame time.

"Laſt year, after much reflection, I was ſo happy as to find out another very effectual method of ſeparating the acetous acid from the other ſubſtances combined with it, ſo as to obtain it at once in the ſtate of a glacial vinegar of the greateſt poſſible ſtrength. The ſeparating medium which I thought of is ſulphat of potaſs ſuperſaturated with ſulphuric acid; a ſalt in which, conformably to my purpoſe, the ſulphuric acid exiſts in a perfectly dry and dephlegmated ſtate.

"By means of this ſalt a highly concentrated glacial vinegar may be obtained in the following manner:

"Let three parts of acetated ſoda, prepared with vinegar diſtilled over charcoal, and evaporated to perfect dryneſs, be melted in a ſtrong heat; then pour it out, and rub it to a very fine powder. Mix this powder very accurately with eight parts of ſuperſaturated ſulphat of potaſs that has been previouſly well dried, and in like manner reduced to a fine powder; put the whole into a retort, and diſtil with a gentle heat, in ſuch manner that, along with the drops, ſome vapours alſo may be perceived to come out of the neck of the retort; but by no means ſo that the receiver ſhall be filled with theſe vapours. Notwithſtanding the moderate heat, the vinegar comes over very faſt, and the quantity of glacial vinegar, of the ſtrength of 54 degrees, which is thus obtained, amounts to nearly two parts."

464 Action of acetous acid on other bodies.

Acetous acid is capable of oxidating iron, zinc, lead, nickel, tin, copper.

It does not act upon gold, ſilver, platinum, mercury, biſmuth, cobalt, antimony, arſenic.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms compounds known by the name of *acetites*.

465 Its affinities.

Its affinities are as follows:

Acetic Acid.

SECT. XII. *Of Acetic Acid.*

If acetite of copper be diſtilled, an acid comes over, of a more pungent ſmell than acetous acid, capable of cryſtallizing, and having a ſtronger affinity for other bodies than acetous acid. It is called *acetic acid*, and is ſuppoſed to contain a larger proportion of oxygen than acetous acid. This additional doſe it is ſuppoſed to receive from the oxide of copper, which during the proceſs is reduced to the metallic ſtate. It can hardly be doubted that the glacial vinegar of Lowitz, deſcribed in the preceding ſection, is really acetic acid, though it would perhaps be difficult to explain its formation. Its affinities are the ſame with thoſe of the acetous acid.

SECT. XIII. *Of Oxalic Acid.*

Sugar, a well-known ſubſtance extracted from the ſugar-cane, appears to have been uſed in the Eaſt at a very early period; but it made its way weſtward very ſlowly. As a medicine, it is mentioned by Dioſcorides; but it was not in common uſe in Europe till after the 14th century.

466 Compoſition of ſugar.

It has been proved that ſugar is compoſed of oxygen, carbon, and hydrogen. Lavoiſier concluded, from a long ſeries of delicate experiments, that it conſiſts of 8 parts of hydrogen, 64 of oxygen, and 28 of carbon.

467 Diſcovery of oxalic acid.

From ſugar, by a particular proceſs, an acid has been obtained called *oxalic acid*, becauſe it exiſts ready formed, as Scheele has proved, in the *oxalis acetoſella*, or wood ſorrel. At firſt, however, it was called the *acid of ſugar*, or the *ſaccharine acid*.

As the earlieſt and beſt account of the oxalic acid was publiſhed by Bergman, he was for a long time reckoned the diſcoverer of it; but Mr Ehrhart, one of Scheele's intimate friends, informs us, that the world is indebted for its knowledge of this acid to that illuſtrious chemiſt *, and Hermſtadt and Weſtrum aſſign the diſcovery to the ſame author †. The aſſertions of theſe gentlemen, who had the beſt opportunity of obtaining accurate information, are certainly ſufficient to eſtabliſh the fact, that Scheele was the real diſcoverer of oxalic acid.

* *Elwart's Magazine for Apothecaries*, 1785, Part i. p. 54.
† *Keir's Dictionary.*

468 Method of procuring it.

Bergman gives us the following proceſs for obtaining this acid. "Put one ounce of white ſugar powdered into a tubulated retort, with three ounces of ſtrong nitric acid, the ſpecific gravity of which is to that of water as 1,567. When the ſolution is over, during which many fumes of the nitrous acid eſcape, let a receiver be fitted, and the liquor made to boil, by which abundance of nitrous gas is expelled. When the liquor in the retort acquires a reddiſh brown colour, add three ounces more of nitric acid, and continue the boiling till the fumes ceaſe, and the colour of the liquor vaniſhes. Then let the contents of the retort be emptied into a wide veſſel; and upon cooling, a cryſtallization will take place of ſlender, quadrilateral priſms, which are often affixed to each other at an angle of 45°. Theſe cryſtals, collected and dried on blotting paper, will be found to weigh $1\frac{1}{4}$ dr. 19 gr. By boiling the remaining lixivium with two ounces of nitric acid in the retort, till the red fumes almoſt diſappear, and by repeating the cryſtallization as before, $\frac{1}{2}$ dr. 13 gr. of ſolid acid will be obtained. If the proceſs be repeated

once

Oxalic Acid.

once more upon the residuum, which has now a glutinous consistence, with the successive additions of small quantities of nitric acid, amounting in all to two ounces, a saline brown deliquescent mass will be formed, weighing half a dram, of which about a half will be lost by a farther purification. The crystals obtained thus at different times may be purified by solution and crystallization, and by digesting the last lixivium with some nitric acid, and evaporation with the heat of the sun."

By the same process Bergman obtained it from gum arabic, alcohol, and honey: Scheele, Hermstadt, Westrum, Hoffman, &c. from a great variety of other vegetable productions; and Berthollet from a great number of animal substances.

It is of great consequence not to use too much nitric acid, otherwise the quantity of oxalic acid will be diminished; and if a very great quantity of nitric acid be used, no oxalic acid will be obtained at all *. On the contrary, if too small a quantity of nitric acid be used, the acid obtained will not be the oxalic, but the tartarous †. We think we have observed, that a considerably larger proportion of oxalic acid may be obtained by pouring nitric acid on sugar, and allowing these substances to act upon each other while cold. When the process is conducted in that manner, hardly any thing separates but nitrous gas.

* Bergman.

† Hermstadt.

469 Its properties.

Oxalic acid is capable of crystallization, or rather it is generally obtained in that state. Its crystals are quadrilateral prisms, the ends of which often terminate in ridges ‡.

‡ Bergman, i. 255.

They are soluble in their own weight of boiling water: water at the temperature of 65,7° dissolves half its weight of them. The specific gravity of the solution is 1,0593 ||. One hundred parts of boiling alcohol dissolve 56 parts of these crystals; but at a mean temperature only 40 parts §. They are not easily soluble in ether. Fixed and volatile oils dissolve them, and they may be again obtained by gentle evaporation. Too violent a heat would sublime the acid itself.

|| Ibid.

§ Ibid.

Oxalic acid has a very acrid taste when it is concentrated, but a very agreeable acid taste when sufficiently diluted with water ¶.

¶ Ibid.

It changes all vegetable blues except indigo to a red. One grain of crystallized acid, dissolved in 1920 grains of water, reddens the blue paper with which sugar loaves are wrapt: one grain of it, dissolved in 3600 grains of water, reddens paper stained with turnsole *. According to Morveau, one part of the crystallized acid is sufficient to communicate a sensible acidity to 2633 parts of water †.

* Ibid.

† Encyc. Method. art. Acide Saccharin.

Its fixity is such, that none of it is sublimed when water containing it in solution is raised to the boiling temperature.

When this crystallized acid is exposed to heat in an open vessel, there arises a smoke from it, which affects disagreeably the nose and lungs. The residuum is a powder of a much whiter colour than the acid had been. By this process it loses $\frac{3}{10}$ths of its weight; but soon recovers them again on exposure to the air. When distilled, it first loses its water of crystallization, then liquifies and becomes brown; a little phlegm passes over, a white saline crust sublimes, some part of which passes into the receiver; but the greatest part of the acid is destroyed, leaving in the retort a mass $\frac{1}{50}$th of the whole, which has an empyreumatic smell, blackens sulphuric acid, renders nitric acid yellow, and dissolves in muriatic acid without alteration. That part of the acid which sublimes is unaltered. When this acid is distilled a second time, it gives out a white smoke, which, condensing in the receiver, produces a colourless uncrystallizable acid, and a dark coloured matter remains behind*. During all this distillation a vast quantity of elastic vapour makes its escape. From 279 grains of oxalic acid, Bergman obtained 109 cubic inches of gas, half of which was carbonic acid and half hydrogen. Fontana from an ounce of it obtained 430 cubic inches of gas, one-third of which was carbonic acid, the rest hydrogen. From these facts, it is evident that oxalic acid is composed of oxygen, hydrogen, and carbon; but the proportions are still unknown.

Tartarous Acid.

* Bergman.

When nitric acid is frequently distilled off oxalic acid, acetous acid is produced †. The sulphuric acid, when concentrated, seems to produce the same effect. Muriatic and acetous acids dissolve oxalic acid, but without altering it ‡.

† Westrum.

‡ Bergman.

470 Its action on other bodies.

Oxalic acid is capable of oxidating lead, copper, iron, tin, bismuth, nickel, cobalt, zinc, manganese.

It does not act upon gold, silver, platinum, mercury, arsenic?

Oxalic acid combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms salts known by the name of *oxalats*.

471 Its affinities.

Its affinities, according to Bergman, are as follows:

Lime,
Barytes,
Strontites §,
Magnesia,
Potass,
Soda,
Ammonia,
Alumina,
Jargonia || ?
Metallic oxides as in *sulphuric acid*,
Water,
Alcohol.

§ Dr Hope, Trans. Edin. iv.

|| Vauquelin, Ann. de Chim. xxii. 208.

Sect. XIV. *Of Tartarous Acid.*

472 Discovery of tartarous acid.

Tartar, or *cream of tartar* as it is commonly called when pure, has occupied the attention of chemists for several centuries. Duhamel and Grosse, and after them Margraf and Rouelle the Younger, proved that it was composed of an acid united to potass: but Scheele was the first who obtained this acid in a separate state. He communicated his process for obtaining it to Retzius, who published it in the Stockholm Transactions for 1770. It consisted in boiling tartar with lime, and in decomposing the tartrite of lime thus formed by means of sulphuric acid.

473 Its properties.

This acid, by a gentle evaporation, yields crystals so irregular in their figure, that every chemist who has treated of this subject has given a different description of them. According to Bergman, they generally consist of divaricating lamellæ *; according to Van Packen, they assume oftenest the form of long pointed prisms †; Spielman and Corvinus ‡ obtained them in groups, some of them lance-shaped, others needle-formed, others pyramidal. Morveau obtained them needle-form §. They do not experience any change in the air; heat

* Bergman, iii. 308.

† De Sale Essent. acidi Tartari.

‡ Analecta de Tartaro.

§ Encyc. Method. Chim. i. 323.

Citric Acid.

heat decomposes them. In the open fire they burn without leaving any other residuum than a coal, which generally contains a little lime *. In close vessels, the product is carbonic acid and hydrogen gas †. If the proper quantity of nitric acid be distilled off the crystals, they are converted into oxalic acid, and the nitric acid, as usual, passes into the nitrous acid ‡. Hence it is evident that tartarous acid also, like the four former, is composed of oxygen, hydrogen, and carbon; but the proportions are equally unascertained.

* Bergman, ibid and ii. 465
† Spielman and Corvinus, ibid.
‡ Hermstadt and Westrum.

This acid, when in crystals, dissolves readily in water. Bergman obtained a solution, the specific gravity of which was 1,230 §. Morveau observed, however, that crystals formed spontaneously in a solution, the specific gravity of which was 1,084.

§ Bergman, i. 250.

474 Its action on other bodies.

It has a very sharp acid taste, and reddens vegetable blues.

Tartarous acid does not oxidate gold, silver, platinum, lead, bismuth, nor tin, and hardly antimony and nickel.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms salts known by the name of *tartrites*.

475 Its affinities.

The order of its affinities is the same as that given for oxalic acid; except that, according to Lavoisier, the oxide of silver comes before that of mercury.

Sect. XV. *Of Citric Acid.*

476 Method of obtaining citric acid.

Chemists have always considered the juice of oranges and lemons as a peculiar acid. This juice contains a quantity of mucilage and water, which render the acid impure, and subject to spontaneous decomposition. Mr Georgius took the following method to separate the mucilage. He filled a bottle entirely with lemon-juice, corked it, and placed it in a cellar: in four years the liquid was become as limpid as water, a quantity of mucilage had fallen to the bottom in the form of flakes, and a thick crust had formed under the cork. He exposed this acid to a cold of 23°, which froze a great part of the water, and left behind a strong and pretty pure acid ‖. It was Scheele, however, that first pointed out a method of obtaining this acid perfectly pure. He saturated lemon-juice with lime, edulcorated the precipitate, which consisted of citric acid and lime, separated the lime from it by diluted sulphuric acid, cleared it from the sulphat of lime by repeated filtrations and evaporation; then evaporated it to the consistence of a syrup, and set it by in a cool place: a quantity of crystals formed, which were pure citric acid ¶. It exists ready formed also in the juices of the following berries: *Vaccinium occicoccos, vaccinium vitis idæa, prunus padus, solanum dulcamara, rosa canina* *, *cherries* †.

‖ Stockholm Transf. 1774.
¶ Scheele's Essays.
* Scheele, Crell's Annals, 1788.
† Westrum.

Scheele advises the use of an excess of sulphuric acid, in order to ensure the separation of all the lime; but according to Dizé, this excess is necessary for another purpose ‡. A quantity of mucilage still adheres to the citric acid in its combination with lime, and sulphuric acid is necessary to decompose this mucilage, which, as Fourcroy and Vauquelin have proved, it is capable of doing. His proof of the presence of mucilage is, that when the solution of citric acid in water, which he had obtained, was sufficiently concentrated by evaporation, it assumed a brown colour, and even became black towards the end of the evaporation. The crystals also were black. By repeated solutions and evaporations, this black matter was separated, and found to be carbon. Hence he concluded that mucilage had been present; for mucilage is composed of carbon, hydrogen, and oxygen; sulphuric acid causes the hydrogen and oxygen to combine and form water, and the carbon remains behind. It is not certain, however, as Mr Nicholson remarks very justly *, that the sulphuric acid may not act upon the citric acid itself, and that the carbon may not proceed from the decomposition of it; at least the experiments of Mr Dizé are insufficient to prove the contrary. In that case the smaller the excess of sulphuric acid used the better.

‡ Nicholson's Journal, ii. 43.
* Nicholson, ibid.

477 Its properties.

The crystals of citric acid are rhomboidal prisms, the sides of which are inclined to each other in angles of about 120 and 60 degrees, terminated at each end by four trapezoidal faces, which include the solid angles †. They are not altered by exposure to the air.

† Dizé, ibid.

An ounce of distilled water, at the temperature of the atmosphere, dissolves one ounce and two drams of crystallized citric acid; and during the solution the temperature is lowered 29,75°. Boiling water dissolves twice its weight of this acid ‡.

‡ Id. ibid.

Citric acid has a very acid taste; it turns vegetable blues to a red.

478 Its action on other bodies.

It is capable of oxidating iron, zinc, tin. It does not act upon gold, silver, platinum, mercury, bismuth, antimony, arsenic.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms salts known by the name of *citrats*.

Fire decomposes this acid, converting it into an acidulous phlegm, carbonic acid gas, and carbonated hydrogen gas. Its solution in water is also gradually decomposed, if access of air be permitted. It is evident, therefore, that this acid is also composed of oxygen, hydrogen, and carbon.

Scheele said that he could not convert it into oxalic acid by means of nitric acid, as he had done several other acids; but Westrum affirms, that this conversion may be effected; and thinks that Scheele had probably failed from having used too large a quantity of nitric acid, by which he had proceeded beyond the conversion into oxalic acid, and had changed the citric acid into vinegar; and in support of his opinion, he quotes his own experiments: from which it appeared that, by treating sixty grains of citron acid with different quantities of nitric acid, his products were very different. Thus with 200 grains of nitric acid he got 30 grains of oxalic acid; with 300 grains of nitric acid he obtained only 15 grains of the oxalic acid; and with 600 grains of nitric acid no vestige appeared of the oxalic acid. On distilling the products of these experiments, especially of the last, he obtained vinegar mixed with nitric acid.

479 Its affinities.

The affinities of this acid are as follows §:

Lime (L),
Barytes,
Strontites ‖,
Magnesia,
Potass,
Soda,

SECT. XVI. *Of Malic Acid.*

480 Diſcovery of malic acid. SCHEELE diſcovered a peculiar acid in the juices of ſeveral fruits, which, becauſe it is found moſt abundantly in apples, has been called *malic acid.*

481 Method of obtaining it. He obtained it by the following proceſs: Saturate the juice of apples with potaſs, and add to the ſolution acetite of lead till no more precipitation enſues. Waſh the precipitate carefully with a ſufficient quantity of water; then pour upon it diluted ſulphuric acid till the mixture has a perfectly acid taſte, without any of that ſweetneſs which is perceptible as long as any lead remains diſſolved in it; then ſeparate the ſulphat of lead, which has precipitated, by filtration, and there remains behind pure malic acid ‖.

‖ *Swediſh Tranſ.* and *Crell's Annals for* 1785.

This acid is contained in the berries of the *barberis vulgaris*, the *ſambucus nigra*, the *prunus ſpinoſa*, the *ſorbus aucuparia*, and the *prunus domeſtica* ¶.

¶ *Ibid.*

If nitric acid be diſtilled with an equal quantity of ſugar, till the mixture aſſumes a brown colour (which is a ſign that all the nitric acid has been abſtracted from it), this ſubſtance will be found of an acid taſte; and after all the oxalic acid which may have been formed is ſeparated by lime-water, there remains another acid, which may be obtained by the following proceſs: Saturate it with lime, and filter the ſolution; then pour upon it a quantity of alcohol, and a coagulation takes place. This coagulum is the acid combined with lime. Separate it by filtration, and edulcorate it with freſh alcohol; then diſſolve it in diſtilled water, and pour in acetite of lead till no more precipitation enſues. The precipitate is the acid combined with lead, from which it may be ſeparated by diluted ſulphuric acid. It poſſeſſes all the properties of malic acid *. This acid, therefore, may be obtained from ſugar; and it may be converted into oxalic acid, by diſtilling off it the proper quantity of nitric acid †.

* *Ibid.*

† *Hermſtadt, Phyſ. Chem.*

482 Its properties. This acid bears a ſtrong reſemblance to the citric, but differs from it in the following particulars:

1. The citric acid ſhoots into fine cryſtals, but this acid does not cryſtallize.

2. The ſalt formed from the citric acid with lime is almoſt inſoluble in boiling water; whereas the ſalt made with malic acid and the ſame baſis is readily ſoluble by boiling water.

3. Malic acid precipitates mercury, lead, and ſilver, from the nitrous acid, and alſo the ſolution of gold when diluted with water; whereas citric acid does not alter any of theſe ſolutions.

3. Malic acid ſeems to have a leſs affinity than citric acid for lime; for when a ſolution of lime in the former acid is boiled one minute with a ſalt formed from volatile alkali and citric acid, a decompoſition takes place, and the latter acid combines with the lime and is precipitated.

The malic acid combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms ſalts known by the name of *malats.* 483 Its combinations.

Its affinities have not yet been aſcertained.

SECT. XVII. *Of Lactic Acid.*

IF milk be kept for ſome time it becomes ſour. The acid which then appears in it was firſt examined by Scheele, and found by him to have peculiar properties. It is called *lactic* acid. In the whey of milk this acid is mixed with a little curd, ſome phoſphat of lime, ſugar of milk, and mucilage. All theſe muſt be ſeparated before the acid can be examined. Scheele accompliſhed this by the following proceſs:

Evaporate a quantity of ſour whey to an eighth part, 484 Method of obtaining lactic acid. and then filtrate it: this ſeparates the cheeſy part. Saturate the liquid with lime-water, and the phoſphat of lime precipitates. Filtrate again, and dilute the liquid with three times its own bulk of water; then let fall into it oxalic acid, drop by drop, to precipitate the lime which it has diſſolved from the lime-water: then add a very ſmall quantity of lime-water, to ſee whether too much oxalic acid has been added. If there has, oxalat of lime immediately precipitates. Evaporate the ſolution to the conſiſtence of honey, pour in a ſufficient quantity of alcohol, and filtrate again; the acid paſſes through diſſolved in the alcohol, but the ſugar of milk and every other ſubſtance remains behind. Add to the ſolution a ſmall quantity of water, and diſtil with a ſmall heat, the alcohol paſſes over, and leaves behind the lactic acid diſſolved in water *.

* *Scheele, Stockholm Tranſ.* 1780.

This acid is incapable of cryſtallizing: when evaporated to dryneſs, it deliqueſces again in the air †.

† *Ibid.*

When diſtilled, water comes over firſt, then a weak 485 Its properties. acid reſembling the tartarous, then an empyreumatic oil mixed with more of the ſame acid, and laſtly carbonic acid and hydrogen gas—there remains behind a ſmall quantity of coal ‡.

‡ *Ibid.*

The combinations which this acid forms with alkalies, earths, and metallic oxides, are called *lactats.* 486 Combinations,

Its affinities, according to Bergman, are as follows: 487 And affinities.

Barytes,
Potaſs,
Soda,
Ammonia,
Lime,
Magneſia,
Alumina,
Jargonia § ? § *Vauquelin, Ann. de Chim.* xxii. 208.

Water,
Alcohol.

SECT. XVIII. *Of Saccholactic Acid.*

488 Sugar of milk. IF a quantity of freſh whey of milk be filtrated, and then evaporated by a gentle fire till it is of the conſiſtence of honey, and afterwards allowed to cool, a ſolid maſs

Saccholactic Acid.

mass is obtained. If this be dissolved in water, clarified with the white of eggs, filtrated, and evaporated to the consistence of a syrup, it deposites on cooling a number of brilliant, white, cubic crystals, which have a sweet taste, and for that reason have been called *sugar of milk*. Fabricius Bartholet, an Italian, was the first European who mentioned this sugar. He described it in his *Encyclopædia Hermetico dogmatica*, published at Boulognia in 1619; but it seems to have been known in India long before that period.

489 Method of obtaining saccholactic acid.

After Mr Scheele had obtained oxalic acid from sugar, he wished to examine whether the sugar of milk would furnish the same product. Upon four ounces of pure sugar of milk, finely powdered, he poured 12 ounces of diluted nitric acid, and put the mixture in a large glass retort, which he placed in a sand-bath. A violent effervescence ensuing, he was obliged to remove the retort from the sand-bath till the commotion ceased. He then continued the distillation till the mixture became yellow. As no crystals appeared in the liquor remaining in the retort, after standing two days he repeated the distillation as before, with the addition of eight ounces of nitric acid, and continued the operation till the yellow colour, which had disappeared on addition of the nitrous acid, returned. The liquor in the retort contained a white powder, and when cold was observed to be thick. Eight ounces of water were added to dilute this liquor, which was then filtrated, by which the white powder was separated; which being edulcorated and dried, weighed $7\frac{1}{2}$ dr. The filtrated solution was evaporated to the consistence of a syrup, and again subjected to distillation, with four ounces of nitric acid as before; after which, the liquor, when cold, was observed to contain many small, oblong, four crystals, together with some white powder. This powder being separated, the liquor was again distilled with more nitric acid as before; by which means the liquor was rendered capable of yielding crystals again; and by one distillation more, with more nitrous acid, the whole of the liquor was converted into crystals. These crystals, added together, weighed five drams; and were found, upon trial, to have the properties of the oxalic acid.

Mr Scheele next examined the properties of the white powder, and found it to be an acid of a peculiar nature; he therefore called it the *acid of sugar of milk*. It is now called the *saccholactic acid*.

490 Its properties.

According to Scheele, it is soluble in 60 parts of its weight of boiling water; but Messrs Hermstadt * and Morveau † found, that boiling water only dissolved $\frac{1}{80}$th part: it deposited about $\frac{1}{4}$th part on cooling in the form of crystals ‡.

The solution has an acid taste, and reddens the infusion of turnsole §. Its specific gravity, at the temperature of 53,7°, is 1,0015 ‖.

* *Phys. Chem.*
† *Encyc. Method.* i. 290.
‡ *Scheele.*
§ *Id.*
‖ *Morveau, ibid.*

When distilled, it melts very readily, becomes black, and frothes; a brown salt sublimes into the neck of the retort, which has the odour of a mixture of amber and benzoin, having an acid taste, easily soluble in alcohol, with greater difficulty in water, and burning in the fire with a flame. There passes into the receiver a brown liquid, having some of this salt dissolved in it: There remains behind a coal *, which Hermstadt found to contain a small quantity of lime. Concentrated sulphuric acid distilled on this salt becomes black, frothes, and decomposes it †.

* *Scheele, ibid.*
† *Id. ibid.*

491 Hermstadt attempts to disprove its existence.

Mr Hermstadt of Berlin had made similar experiments on sugar of milk at the same time with Scheele, and with similar results; but he concluded that the white powder which he obtained was nothing else than oxalat of lime with excess of acid, as indeed Scheele himself did at first. After he became acquainted with Scheele's conclusions, he published a paper in defence of his own opinion; but his proofs are very far from establishing it, or even rendering its truth probable. He acknowledges himself, that he has not been able to decompose this supposed salt: he allows that it possesses properties distinct from the oxalic acid; but he ascribes this difference to the lime which it contains; yet all the lime which he could discover in 240 grains of this salt was only 20 grains; and if the alkali which he employed was a carbonat (as it probably was), these 20 must be reduced to 11. Now Morveau has shewn, that oxalic acid, containing the same quantity of lime, exhibits very different properties. Besides, this acid, whatever it is when united with lime, is separated by the oxalic, and must therefore be different from it, as it would be absurd to suppose that an acid could displace itself ‡. The saccholactic acid must therefore be considered as a distinct acid, as it possesses peculiar properties.

‡ *Morveau, Encyc. Method.* i. p. 291.

492 Its compounds and affinities.

Its compounds with alkalies, earths, and metallic oxides, are denominated *saccholats*.

Its affinities, according to Bergman, are as follows:

Lime,
Barytes,
Magnesia,
Potass,
Soda,
Ammonia,
Alumina,
Jargonia §?
Metallic oxides as in *sulphuric acid*,
Water,
Alcohol.

§ *Vauquelin, Ann. de Chim.* xxii. 208.

Sect. XIX. *Of Gallic Acid.*

493 Nut-galls.

There is an excrescence, known by the name of *nutgall*, which grows on some species of oaks. This substance contains a peculiar acid, called from that circumstance *gallic acid*, the properties of which were first examined with attention by the commissioners of the academy of Dijon; and the result of their experiments was published in 1777, in the third volume of their Elements of Chemistry. In these experiments, however, they employed the infusion of galls, in which the acid is combined with the tanning principle (M). It was reserved for Scheele to obtain it in a state of purity.

He

(M) A substance lately discovered by French chemists, which exists also in oak-bark, and every other body which may be substituted for that bark in the operation of tanning. It resembles the resins in many properties; but its distinguishing property is that of forming with glue a compound insoluble in water. When a little of the decoction of glue is dropped into an infusion of nut-galls, a white curdy precipitate is instantly seen: This is the tanning principle combined with glue. The name *tanning principle* has been applied to it, because *tanning* consists in combining this principle with *skins*, by which they are converted into leather.

Gallic Acid.

494 Diſcovery of gallic acid.

He obſerved, in an infuſion of galls made with cold water, a ſediment, which proved on examination to have a cryſtalline form and an acid taſte. By letting an infuſion of galls remain a long time expoſed to the air, and removing now and then the mouldy ſkin which formed on its ſurface, a large quantity of this ſediment was obtained; which being edulcorated with cold water, rediſſolved in hot water, filtrated, and evaporated very ſlowly, yielded an acid ſalt in cryſtals as fine as ſand*.

* *Stockholm Tranſ.* 1786.

There is a ſhorter method of obtaining this acid in a ſtill purer ſtate than Scheele obtained it.

495 Method of obtaining it.

Pour ſulphuric ether on a quantity of powdered galls, and allow it to remain a few hours; by which time it becomes coloured. Put this tincture into a retort, and diſtil off the ether with a ſmall heat. The reſiduum poſſeſſes the colour and brittleneſs of a reſin, and has all the characters of Rouelle's reſiduous-extract; it does not attract moiſture from the atmoſphere. Diſſolve it in its own weight of water, and add ſulphuric acid, drop by drop, till the liquor has become of a manifeſtly acid taſte. It cauſes a white precipitate, which becomes coloured, and is immediately rediſſolved. At the end of ſome hours a reſinous matter will have precipitated. Decant off the fluid, dilute it with half its weight of water, filtrate and evaporate it to $\frac{3}{4}$ths in a moderate heat; add pure barytes till the liquor is no longer capable of decompoſing muriat of barytes; then filtrate it again; and on evaporation in a moderate heat ſmall white priſmatic cryſtals of gallic acid are formed on the ſides of the veſſel †.

† *Mr J. J. Dizé Jour. de Phyſ.* Dec. 1791.

It appears from the experiments of Deyeux, that the ſubſtance extracted from nut-galls by ether does not differ much from the extract by water ‡. Probably, then, the only reaſon for employing ether is the ſmall heat neceſſary for evaporating it.

‡ *Ann. de Chim.* xvii. 8.

There is ſtill another method of obtaining this acid. Diſtil nut-galls in a ſtrong heat, a white ſubſtance ſublimes, which cryſtallizes in the form of needles: This is gallic acid. If the cryſtals are impure, they may be purified by a ſecond ſublimation: but the heat muſt not be too violent, otherwiſe the cryſtals will melt into a brown maſs §. This proceſs was diſcovered by Scheele.

§ *Ibid.*

496 Prouſt's method.

But the moſt elegant method of obtaining gallic acid is that of Mr Prouſt. When a ſolution of muriat of tin is poured into an infuſion of nut-galls, a copious yellow precipitate is inſtantly formed, conſiſting of the tanning principle, combined with the oxide of tin. After diluting the liquid with a ſufficient quantity of water to ſeparate any portion of this precipitate which the acids might hold in ſolution, the precipitate is to be ſeparated by filtration. The liquid contains gallic acid, muriatic acid, and muriat of tin. To ſeparate the tin, a quantity of ſulphurated hydrogen gas is to be mixed with the liquid. Sulphuret of oxide of tin is precipitated under the form of a brown powder. The liquid is then to be expoſed for ſome days to the light, covered with paper, till the ſuperfluous ſulphurated hydrogen gas exhales. After this, it is to be evaporated to the proper degree of concentration, and put by to cool. Cryſtals of gallic acid are depoſited. Theſe are to be ſeparated by filtration, and waſhed with a little cold water. The evaporation of the reſt of the liquid is to be repeated till all the gallic acid is obtained from it ‖.

‖ *Ibid.* xxv. 225.

The gallic acid thus obtained has a very acid taſte, and reddens vegetable colours. It is ſoluble in $1\frac{1}{2}$ parts of boiling water, and in 12 parts of water at the temperature of the atmoſphere. Alcohol diſſolves one-fourth of its weight of this acid at the temperature of the atmoſphere. When boiling hot it diſſolves a quantity equal to its own weight. 497 Its properties.

When placed upon burning coals, gallic acid takes fire, and at the ſame time diffuſes a very ſtrong odour, which has ſomething aromatic in it. When ſtrongly heated, it melts, boils, becomes black, is diſſipated, and leaves a quantity of charcoal behind it. When diſtilled, a quantity of oxygen gas is diſengaged, an acid liquor is found in the receiver, with ſome gallic acid not decompoſed, and there remains in the retort a quantity of carbon. If what has paſſed into the receiver be again diſtilled, more oxygen gas is obtained, ſome gallic acid ſtill ſublimes, and a quantity of carbon remains in the retort. By repeated diſtillations the whole of the acid may be decompoſed. This decompoſition may be more eaſily accompliſhed by diſtilling repeatedly a ſolution of gallic acid in water. The products are oxygen gas, charcoal, and an acid liquor.

498 Its compoſition.

From theſe experiments, Mr Deyeux, who performed them, has concluded, that gallic acid is compoſed of oxygen, and a much larger proportion of carbon than enters into the compoſition of carbonic acid. But this concluſion is not warranted by the analyſis; for Mr Deyeux did not find that the quantity of oxygen gas and carbon obtained was equal to that of the gallic acid decompoſed: and in the acid liquor which came over, there evidently exiſted a quantity of water, which doubtleſs was formed during the diſtillation. Scheele, by treating gallic acid with nitric acid in the uſual manner, converted it into oxalic acid. Now it is certain that oxalic acid contains hydrogen as well as carbon. It cannot be doubted, then, that gallic acid is compoſed of oxygen, hydrogen, and carbon, in proportions not yet aſcertained. But Mr Deyeux has proved, that the quantity of carbon is very great, compared with that of the hydrogen.

Gallic acid combines with alkalies, earths, and metallic oxides, and forms compounds known by the name of *gallats*.

Its affinities have not yet been determined; but oxide of iron ſeems to have a ſtronger affinity for it than for any other ſubſtance; for gallic acid is capable of taking it from every other acid. In conſequence of this property, the infuſion of galls is employed to detect the preſence of iron in any liquid. As ſoon as it is poured in, if iron be preſent, a black or purple colour is produced.

SECT. XX. *Of Benzoic acid.*

499 Benzoin.

BENZOIN or *benjamin* (as it is ſometimes called) is a kind of reſin brought from the Eaſt Indies; obtained, according to Dr Dryander, from the ſtyrax benzoe, a tree which grows in the iſland of Sumatra. This ſubſtance conſiſts partly of a peculiar acid, deſcribed as long ago as 1608 by Blaiſe de Vigenere, in his Treatiſe on Fire and Salt, under the name of *flowers of benzoin*, becauſe it was obtained by ſublimation. This acid, which is now called *the benzoic acid*, may be ſublimed from benzoin by heat; or it may be obtained by

Scheele's

Succinic Acid.

Scheele's process, which has been described in the article Chemistry, *Encycl.*

500 Properties of benzoic acid.

Benzoic acid has little or none of the peculiar odour which distinguishes benzoin. Its taste is not acid, but sweetish, and very pungent *. It hardly affects the infusion of violets; but it reddens that of turnsole, especially if that infusion be hot †. Heat volatilizes this acid, and makes it give out a strong odour, which excites coughing. When exposed to the heat of the blow-pipe in a silver spoon, it melts, becomes as fluid as water, and evaporates without taking fire. It only burns when in contact with flame, and then it leaves no residuum behind. When thrown upon burning coals, it rises in a white smoke. When allowed to cool after being melted, it hardens, and a radiated crust forms on its surface ‡.

It suffers no other alteration in the air than losing the little of the odour of benzoin which remained to it §.

Cold water dissolves no sensible quantity of it; but it is soluble enough in hot water: 480 grains of boiling water dissolve 20 grains of it; 19 of these are deposited, when the water cools, in long, slender, flat, feather-like crystals ||.

Concentrated sulphuric acid dissolves it without heat or any other change except becoming somewhat brown: when water is poured into the solution, the benzoic acid separates and coagulates on the surface without any alteration ¶. Nitric acid presents precisely the same phenomena, and also the sulphurous and nitrous acids. Neither the muriatic, the oxy-muriatic, nor the phosphoric acids dissolve it. The acetous, formic, and sebacic acids, when hot, dissolve it precisely as water does; but it crystallizes again when these acids cool *.

Alcohol dissolves it copiously, and lets it fall on the addition of water †.

501 Its combinations and affinities.

Little is known respecting its base.

It combines with alkalies, earths, and metallic oxides, and forms salts known by the name of *benzoats*.

Its affinities, from the experiments of Trommsdorf, appear to be as follows:

White oxide of arsenic,
Potass,
Soda,
Ammonia,
Barytes,
Lime,
Magnesia,
Alumina,
Jargonia ‡?
Water,
Alcohol.

Sect. XXI. *Of Succinic Acid.*

502 Amber.

Amber is a well-known brown, transparent, inflammable body, pretty hard, and susceptible of polish, found at some depth in the earth, and on the sea-coast of several countries. It was in high estimation among the ancients both as an ornament and a medicine.—When this substance is distilled, a volatile salt is obtained, which is mentioned by Agricola under the name of *salt of amber*; but its nature was long unknown. Boyle was the first who discovered that it was an acid §. From *succinum*, the Latin name of amber, this acid has received the appellation of *succinic acid*.

§ *Boyle abridged by Shaw*, iii. 369.

Camphoric Acid.

503 Method of obtaining succinic acid.

It is obtained by the following process: Fill a retort half way with powdered amber, and cover the powder with a quantity of dry sand; lute on a receiver, and distil in a sand-bath without employing too much heat. There passes over first an insipid phlegm; then a weak acid, which, according to Scheele, is the acetous *; then the succinic acid attaches itself to the neck of the retort; and if the distillation be continued, there comes over at last a thick brown oil, which has an acid taste.

* *Bergman's Notes on Scheffer.*

The succinic acid is at first mixed with a quantity of oil. Perhaps the best method of purifying it is that recommended by Pott, to dissolve it in hot water, and to put upon the filter a little cotton, previously moistened with oil of amber; this substance retains most of the oil, and allows the solution to pass clear. The acid is then to be crystallized by a gentle evaporation. And this process is to be repeated till the acid be quite pure. The crystals are white, shining, and 504 Its properties, of a foliated triangular prismatic form: they have an acid taste, but are not corrosive: they redden tincture of turnsole, but have little effect on that of violets.

They sublime when exposed to a considerable heat, but not at the heat of a water-bath. In a sand-bath they melt, and then sublime and condense in the upper part of the vessel; but the coal which remains shews that they are partly decomposed †.

One part of this acid dissolves in 96 parts of water at the temperature of 50°, according to Spielman ‡, in 24 parts at the temperature of 52°, and in 2 parts of water at the temperature of 212°, according to Stockar de Neuforn §; but the greatest part crystallizes as the water cools. According to Roux, however, it still retains more of the acid than cold water is capable of dissolving ||.

240 grains of boiling alcohol dissolve 177 of this acid; but crystals again shoot as the solution cools ¶.

505 Combinations and affinities.

The combinations of this acid are called *succinats*.

Its component parts are still unknown.

Its affinities, according to Morveau, are as follows:

Barytes,
Lime,
Potass,
Soda,
Ammonia,
Magnesia,
Alumina,
Jargonia *?
Metallic oxides as in *sulphuric acid*,
Water,
Alcohol.

¶ *Wenzel.*
* *Vauquelin, Ann de Chim.* xxii. 208.

Sect. XXII. *Of Camphoric Acid.*

506 Camphor.

Camphor is a well-known white crystalline substance, of a strong taste and smell, obtained from a species of laurel in the East Indies; and Mr Proust has shewn that several volatile oils contain a considerable quantity of it †. It is so volatile, that it cannot be melted in open vessels, and so inflammable that it burns even on the surface of water.

When camphor is set on fire in contact with oxygen gas, it burns with a very brilliant flame; much caloric is disengaged, water is formed, the inner surface of the vessel is covered with a black matter, which is undoubtedly carbon, and a quantity of carbonic acid gas is also produced ‡. Hence it follows, that it is composed of hydrogen and carbon, at least principally.

† *Ann. de Chim.* iv. 179.
‡ *LaGrange, ibid.* xxiii. 153.

If

Camphoric Acid.

If one part of camphor and ſix parts of pulveriſed clay be mixed together, by means of alcohol, in a mortar, the mixture made up into balls, and when dry put into a retort, and diſtilled by a moderate heat—a quantity of oil comes over, and there remains in the retort a black ſubſtance, which conſiſts of the clay intimately mixed with a quantity of carbon. If the fire be not cautiouſly managed, a quantity of camphor alſo ſublimes. By this proceſs camphor is decompounded, and ſeparated into oil and carbon.

122,248 parts of camphor
produced 45,856 parts of oil
and 30,571 of carbon.

Total 76,427
Loſs 45,821

Carbonated hydrogen gas and carbonic acid were alſo formed *.

* *Ann. de Chim.* xxiii. 153.

507 Oil of camphor.

The oil obtained has the following properties:

It has a ſharp cauſtic taſte, and leaves upon the tongue a ſenſe of coldneſs. It has an aromatic odour, approaching to that of thyme or roſemary. Its colour is a golden yellow.

When expoſed to the air, it partly evaporates, and there remains a thick brown matter with a ſharp bitteriſh taſte, which at laſt alſo evaporates.

With alkalies, it forms a ſoap, which poſſeſſes all the characters of ſoaps made with volatile oils.

Alcohol diſſolves it entirely; and when water is added to the ſolution it becomes milky, but no precipitate is produced †.

† *Ibid.* 159.

Theſe properties ſhew that this is a volatile oil, and conſequently it is probable that camphor is compoſed of volatile oil and carbon.

508 Camphoric acid.

Mr Koſegarten, by diſtilling nitric acid off camphor eight times ſucceſſively, obtained an acid in cryſtals ‡, to which the name of *camphoric acid* has been given.

‡ *Koſegarten, de Camphora*, &c. 1785.

His experiments have been repeated by Mr Bouillon La Grange. He mixed together 122,284 parts of camphor with 489,136 parts of nitric acid of the ſpecific gravity 1,33, and diſtilled them. Much nitrous and carbonic acid gas were diſengaged, and part of the camphor was ſublimed; but part was converted into an acid. He returned the ſublimed camphor into the retort, poured on it the ſame quantity of nitric acid as at firſt, and diſtilled again. This proceſs he repeated till the whole camphor was acidified §. The quantity of camphoric acid obtained amounted to 53,498. The quantity of nitric acid was 2114,538.

§ *Ann. de Chim. ibid.*

509 Its properties.

Camphoric acid thus obtained is in ſnow-white cryſtals, of the form of parallelopipedons ‖.

‖ *Koſegarten.*

Theſe cryſtals effloreſce in the air ¶.

¶ *La Grange.*

Camphoric acid has a ſlightly acid bitter taſte, and ſmell like that of ſaffron.

It reddens vegetable colours.

It is ſoluble in 200 parts of cold water, according to Koſegarten; in 96 parts of water at the temperature of 60°, according to La Grange. Boiling water diſſolves $\frac{1}{12}$th of its weight *.

* *Koſegarten.*

According to Koſegarten, it is inſoluble in alcohol; according to La Grange, alcohol diſſolves it, and when the ſolution is left in contact with the air of the atmoſphere, the acid cryſtallizes. It is not precipitated from its ſolution in alcohol by the addition of water †.

† *Bouillon La Grange, Ann. de Chim.* xxvii. 40

When this acid is placed on ignited coals, it emits a denſe aromatic fume, and is entirely diſſipated. By a gentler heat, it melts, and is ſublimed. If it be put into a heated porcelain tube, and oxygen gas be paſſed through it, the acid does not undergo any change, but is ſublimed.

By mere diſtillation, it firſt melts and then ſublimes; by which proceſs its properties are in ſome reſpect changed. It no longer reddens the tincture of turnſole, but acquires a briſk aromatic ſmell; its taſte becomes leſs penetrating, and it is no longer ſoluble either in water or the ſulphuric and muriatic acids. Heated nitric acid turns it yellow and diſſolves it. Alcohol likewiſe diſſolves it; and if this ſolution be left in contact with the air of the atmoſphere, it cryſtallizes.

Camphoric acid does not produce any change in ſulphur; alcohol and the mineral acids totally diſſolve it; and ſo likewiſe do the volatile and the fat oils.

Camphoric acid does not precipitate lime from lime-water. It produces no change on the ſolution of indigo in ſulphuric acid.

It forms combinations with the alkalies, earths, and metallic oxides, which are called *camphorats*. 510 Its combinations and affinities.

Its affinities, as far as aſcertained by La Grange, are as follows *:

* *Ann. de Chim.* xxvii. 21.

Lime,
Potaſs,
Soda,
Barytes,
Ammonia,
Alumina,
Magneſia.

Sect. XXIII. *Of Suberic Acid.*

Cork, a ſubſtance too well known to require any 511 Diſcovery of ſuberic acid.
deſcription, is the bark of a tree which bears the ſame name. By means of nitric acid, Brugnatelli converted it into an acid †, which has been called the *ſuberic acid*, from *Suber*, the Latin name of the cork-tree. Several chemiſts affirmed that this acid was the oxalic, becauſe it poſſeſſed ſeveral properties in common with it. Theſe aſſertions induced Bouillon la Grange to undertake a ſet of experiments on ſuberic acid. Theſe experiments, which have been publiſhed in the 23d volume of the *Annales de Chimie*, completely eſtabliſh the peculiar nature of ſuberic acid, by ſhewing that it poſſeſſes properties different from thoſe of every other acid.

† *Crell's Annals*, 1787.

To prepare it, a quantity of ſound cork grated down 512 Method of preparing it.
ſmall is to be put into a retort, ſix times its weight of nitric acid of the ſpecific gravity 1,261 poured upon it, and the mixture diſtilled by means of a gentle heat. Red vapours are immediately diſcharged; the cork ſwells up and becomes yellow, and as the diſtillation advances, it ſinks to the bottom, and its ſurface remains frothy. If that froth does not form properly, it is a proof that ſome part of the cork has eſcaped the action of the acid. In that caſe, after the diſtillation is pretty far advanced, the acid which has paſſed into the receiver is to be poured back into the retort, and the diſtillation continued till no more red vapours can be perceived; and then the retort is to be immediately taken out of the ſand-bath, otherwiſe its contents would become black and adhere to it. While the matter contained in the retort is hot, it is to be poured into a glaſs veſſel, placed upon a ſand-bath over a gentle fire, and conſtantly ſtirred with a glaſs rod. By this means it becomes gradually

Suberic Acid.

gradually thick. As ſoon as white vapours, exciting a tickling in the throat, begin to diſengage themſelves, the veſſel is removed from the bath, and the maſs continually ſtirred till it is almoſt cold.

By this means an orange-coloured maſs is obtained of the conſiſtence of honey, of a ſtrong and ſharp odour while hot, but having a peculiar aromatic ſmell when cold.

On this maſs twice its weight of boiling water is to be poured, and heat applied till it becomes liquid; and then that part of it which is inſoluble in water is to be ſeparated by filtration (N). The filtered liquor becomes muddy; on cooling it depoſites a powdery ſediment, and a thin pellicle forms on its ſurface. The ſediment is to be ſeparated by filtration, and the liquor reduced to a dry maſs by evaporating in a gentle heat. This maſs is *ſuberic acid*. It is ſtill a little coloured, owing to ſome accidental mixture, from which it may be purified either by ſaturating it with potaſs and precipitating it by means of an acid, or by boiling it along with charcoal powder.

513 Its properties.

Suberic acid thus obtained is not cryſtallizable, but when precipitated from potaſs by an acid, it aſſumes the form of a powder; when obtained by evaporation it forms thin irregular pellicles.

Its taſte is acid and ſlightly bitter; and when diſſolved in a ſmall quantity of boiling water it acts upon the throat, and excites coughing.

It reddens vegetable blues; and when dropped into a ſolution of indigo in ſulphuric acid (*liquid blue*, as it is called in this country), it changes the colour of the ſolution, and renders it green.

Water at the temperature of 60° or even 70° diſſolves only $\frac{1}{57,6}$ part of its weight of ſuberic acid, and if the acid be very pure, only $\frac{1}{144}$th part: boiling water, on the contrary, diſſolves half its weight of it.

When expoſed to the air, it attracts moiſture, eſpecially if it be impure.

When expoſed to the light of day, it becomes at laſt brown; and this effect is produced much ſooner by the direct rays of the ſun.

When heated in a matraſs, the acid ſublimes, and the inſide of the glaſs is ſurrounded with zones of different colours. If the ſublimation be ſtopped at the proper time, the acid is obtained on the ſides of the veſſel in ſmall points formed of concentric circles. When expoſed to the heat of the blow-pipe on a ſpoon of platinum, it firſt melts, then becomes pulverulent, and at laſt ſublimes entirely with a ſmell reſembling that of ſebacic acid (O).

It is not altered by oxygen gas:—the other acids do not diſſolve it completely. Alcohol developes an aromatic odour, and an ether may be obtained by means of this acid.

It converts the blue colour of nitrat of copper to a green; the ſulphat of copper alſo to a geen; green ſulphat of iron to a deep yellow; and ſulphat of zinc to a golden yellow (P).

514 Its action on other bodies.

It has no action either on platinum, gold, or nickel; but it oxidates ſilver, mercury, copper, lead, tin, iron, biſmuth, arſenic, cobalt, zinc, antimony, manganeſe, and molybdenum.

With alkalies, earths, and metallic oxides, it forms compounds known by the name of *ſuberats*.

515 Its affinities.

Its affinities are as follows (Q):

Barytes,

(N) When this ſubſtance is put into a matraſs, water poured on it, and heat applied, it melts; and when the veſſel is taken from the fire and allowed to cool, one part of it, which is of the conſiſtence of wax, ſwims on the ſurface of the water, and another part precipitates to the bottom of the veſſel, and aſſumes the appearance of a whitiſh magma. When this magma is ſeparated by filtration, and waſhed and dried, a white taſteleſs powder is obtained, mixed with ligneous threads, ſoluble in acids and alkalies.

(O) An acid which ſhall be afterwards deſcribed.

(P) Owing perhaps to the preſence of a little iron in the ſulphat.

(Q) The place which the ſuberic acid occupies in the affinities of the alkalies, earths, and metallic oxides, as far as this ſubject has been inveſtigated by Bouillon La Grange, will appear by the following Tables:

* Ann. de Chim. xxiii. 42.

Mr Bouillon La Grange, to whom we are indebted for all the facts relative to this acid, fuppofes that it is compofed of oxygen, hydrogen, and carbon: but Mr Jamefon, in confequence of the refult of a feries of experiments which he made on charcoal, has been led to fufpect that it confifts entirely of carbon and oxygen. He found, that by the action of nitric acid upon charcoal, a brown, bitter, deliquefcent mafs was formed, foluble in water, alcohol, and alkalies, and which emitted, particularly when heated, a very fragrant odour. This matter was more or lefs foluble in water according to the time that it had been expofed to the action of the acid. When the nitric acid ufed was concentrated, and confiderable in quantity, part of the charcoal was converted into an acid, which poffeffed the characters of the fuberic †.

516 Its compofition.

† *Jamefon's Mineralogy of Shetland and Arran*, p. 167.

These facts are curious, and may extend our knowledge of the nature of vegetable acids, but they are infufficient to prove the abfence of hydrogen in fuberic acid, becaufe charcoal cannot eafily be procured perfectly free from hydrogen, and becaufe feveral of the properties of fuberic acid indicate the prefence of hydrogen in it, its becoming brown, for inftance, when expofed to the light. Mr Jamefon has obferved, that the acid which exifts ready formed in peat poffeffes the properties of fuberic acid.

Sect. XXIV. *Of Laccic Acid.*

517 Difcovery of white lac.

About the year 1786, Dr Anderfon of Madras mentioned, in a letter to the governor and council of that place, that nefts of infects, refembling fmall cowry fhells, had been brought to him from the woods by the natives, who eat them with avidity. Thefe fuppofed nefts he foon afterwards difcovered to be the coverings of the females of an undefcribed fpecies of coccus, which he fhortly found means to propagate with great facility on feveral of the trees and fhrubs growing in his neighbourhood (R).

On examining this fubftance, which he called *white lac*, he obferved in it a very confiderable refemblance to bees wax; he noticed alfo, that the animal which fecretes it provides itfelf by fome means or other with a fmall quantity of honey, refembling that produced by our bees; and in one of his letters he complains, that the children whom he employed to gather it were tempted by its fweetnefs to eat fo much of it as materially to reduce the produce of his crop. Small quantities of this matter were fent into Europe in 1789, both in its natural ftate and melted into cakes; and in 1793 Dr Pearfon, at the requeft of Sir Jofeph Banks, undertook a chemical examination of its qualities, and his experiments were publifhed in the Philofophical Tranfactions for 1794.

518 Its analyfis.

A piece of white lac, from 3 to 15 grains in weight, is probably produced by each infect. Thefe pieces are of a grey colour, opaque, rough, and roundifh. When white lac was purified by being ftrained through muflin, it was of a brown colour, brittle, hard, and had a bitterifh tafte. It melted in alcohol, and in water of the temperature of 145°. In many of its properties it refembles bees wax, though it differs in others; and Dr Pearfon fuppofes that both fubftances are compofed of the fame ingredients, but in different proportions.

Two thoufand grains of white lac were expofed in fuch a degree of heat as was juft fufficient to melt them. As they grew foft and fluid, there oozed out 550 grains of a reddifh watery liquid, which fmelled like newly baken bread (s). To this liquid Dr Pearfon has given the name of *laccic acid* *.

* *Pearfon's Tranf. of the Chemical Nomenclature.*

519 Properties of laccic acid.

It poffeffes the following properties:

It turns paper ftained with turnfole to a red colour.

After being filtered, it has a flightly faltifh tafte with bitternefs, but is not at all four.

When heated, it fmells precifely like newly baken hot bread.

On ftanding, it grows fomewhat turbid, and depofites a fmall quantity of fediment.

Its fpecific gravity at the temperature of 60° is 1,025.

A little of it having been evaporated till it grew very turbid, afforded on ftanding fmall needle-fhaped cryftals in mucilaginous matter.

Two hundred and fifty grains of it were poured into a very fmall retort and diftilled. As the liquor grew warm, mucilage-like clouds appeared; but as the heat increafed they difappeared again. At the temperature of 200°, the liquor diftilled over very faft: A fmall quantity of extractive matter remained behind. The diftilled liquor while hot fmelled like newly baken bread, and was perfectly tranfparent and yellowifh. A fhred of paper ftained with turnfole, which had been put into the receiver, was not reddened; nor did another which had been immerfed in a folution of fulphat of iron, and alfo placed in the receiver, turn to a blue colour upon being moiftened with the folution of potafs (T).

Cobalt and Zinc the fame with arfenic.

(R) The Chinefe collect a kind of wax, which they call *pe-la*, from a coccus, depofited for the purpofe of breeding on feveral fhrubs, and manage it exactly as the Mexicans manage the cochineal infect. It was the knowledge of this that induced Dr Anderfon to attempt to propagate his infect.

(s) The fame liquid appears on preffing the crude lac between the fingers; and we are told, that when newly gathered it is replete with juice.

(T) A proof that the acid was not the pruffic.

Laccic Acid.

About one hundred grains of this diſtilled liquid being evaporated till it grew turbid, after being ſet by for a night, afforded acicular cryſtals, which under a lens appeared in a group not unlike the umbel of parſley. The whole of them did not amount to the quarter of a grain. They taſted only bitteriſh.

Another 100 grains being evaporated to dryneſs in a very low temperature, a blackiſh matter was left behind, which did not entirely diſappear on heating the ſpoon containing it very hot in the naked fire; but on heating oxalic acid to a much leſs degree, it evaporated and left not a trace behind.

Carbonat of lime diſſolved in this diſtilled liquid with effervеſcence. The ſolution taſted bitteriſh, did not turn paper ſtained with turnſole red, and on adding to it carbonat of potaſs a copious precipitation enſued. A little of this ſolution of lime and of alkali being evaporated to dryneſs, and the reſiduum made red hot, nothing remained but carbonat of lime and carbonat of potaſs.

This liquid did not render nitrat of lime turbid, but it produced turbidneſs in nitrat and muriat of barytes.

To five hundred grains of the reddiſh-coloured liquor obtained by melting white lac, carbonat of ſoda was added till the effervеſcence ceaſed, and the mixture was neutraliſed; for which purpoſe three grains of the carbonat were neceſſary. During this combination a quantity of mucilaginous matter, with a little carbonat of lime, was precipitated. The ſaturated ſolution being filtrated and evaporated to the due degree, afforded on ſtanding deliqueſcent cryſtals, which on expoſure to fire left only a reſiduum of carbonat of ſoda.

Lime-water being added to this reddiſh-coloured liquor produced a light purple turbid appearance; and on ſtanding there were clouds juſt perceptible.

Sulphuret of lime occaſioned a white precipitation, but no ſulphurated hydrogen gas was perceptible by the ſmell.

Tincture of galls produced a green precipitation.

Sulphat of iron produced a purpliſh colour, but no precipitation; nor was any precipitate formed by the addition firſt of a little vinegar, and then of a little potaſs, to the mixture.

Acetite of lead occaſioned a reddiſh precipitation, which rediſſolved on adding a little nitric acid.

Nitrat of mercury produced a whitiſh turbid liquor.

Oxalic acid produced immediately the precipitation of white acicular cryſtals, owing probably to the preſence of a little lime in the liquid.

Tartrite of potaſs produced a precipitation not unlike what takes place on adding tartarous acid to tartrite of potaſs (u); but it did not diſſolve again on adding potaſs.

Such were the properties of this acid diſcovered by Dr Pearſon. Its deſtructibility by fire, and its affording carbon, diſtinguiſh it from all the acids deſcribed in this article before the acetous; and its peculiar ſmell when heated, its precipitating tartrite of potaſs without forming tartar, its bitteriſh taſte, and its being converted into vapour at the temperature of 200°, diſtinguiſh it from all the acids hitherto examined *.

* Phil. Tranſ. 1794, p. 383.

Pyromucous Acid.

Sect. XXV. *Of Pyromucous Acid.*

520 Method of obtaining pyromucous acid.

Pyromucous (v) acid is procured by diſtilling ſugar or any of the ſweet juices. As they foam very much, the retort ſhould be large, and ſeven-eighths of it empty. A prodigious quantity of carbonic acid and carbonated hydrogen gas is diſengaged: A very thin light coal remains behind in the retort. Morveau found the glaſs of the retort attacked. The quantity of ſugar diſtilled was 2304 grains; the coal weighed 982 grains. There were 428 grains of a brown liquor in the receiver, conſiſting moſtly of an acid phlegm. This rediſtilled gave 313 grains of a liquor almoſt limpid, the ſpecific gravity of which was 1,0115 at the temperature of 77°. It reddened blue paper. This acid may be concentrated by freezing, or by combining it with ſome baſe, potaſs, for inſtance, and decompoſing the compound by a ſtronger acid, as, for example, the ſulphuric.

521 Its properties,

It has a very ſharp taſte. When expoſed to heat in open veſſels, it evaporates, leaving a brown ſpot. Diſtilled in cloſe veſſels, it leaves charcoal behind it.

It does not diſſolve gold as Schrickel and Lemery and ſeveral other chemiſts affirmed.

It does not attack ſilver nor mercury, nor even their oxides †. It corrodes lead, and forms ſtyptic and long cryſtals. Copper forms with it a green ſolution: With iron it forms green cryſtals; with antimony and zinc greeniſh ſolutions.

† Schrickel.

522 Combinations, and affinities.

The compounds which it forms are called *pyromucites*.

Its affinities, according to Morveau, are as follows:

Potaſs,
Soda,
Barytes,
Lime,
Magneſia,
Ammonia,
Alumina,
Jargonia ‡.
Metallic oxides as in *ſulph. acid*,
Water,
Alcohol.

‡ Vauquelin, Ann. de Chim. xxii. 208.

Sect. XXVI. *Of Pyro-lignous Acid.*

523 Method of obtaining pyro-lignous acid.

It is well known that the ſmoke of burning wood is exceedingly offenſive to the eyes: And chemiſts have long ago obſerved, that an acid might be obtained by diſtilling wood.

It is to Mr Goettling, however, and to the Dijon academicians, who repeated his experiment, that we are indebted for what knowledge we poſſeſs of the peculiar properties of this acid, which, becauſe it is obtained from wood by means of fire, has been called *the pyrolignous acid* (w). It appears to be the ſame from whatever kind of wood it is obtained.

Mr Goettling filled an iron retort with pieces of birch tree bark, and obtained by diſtillation a thick, brown, very empyreumatic acid liquor. This liquor he allowed

---

(u) On this addition, tartar, or acidulated tartrite of potaſs, is formed, which precipitates, becauſe it is very little ſoluble in water. The addition of potaſs diſſolves it again.

(v) Morveau called this acid *ſyrupous* acid.

(w) Goettling called it *ligneous acid.*

Pyro-ligneous Acid.

allowed to remain at reſt for three months, and then ſeparated from it a quantity of oil which had riſen to the top. By diſtilling this liquor again, and then ſaturating it with potaſs, and evaporating to dryneſs, he obtained a brown ſaline maſs; which, by being rediſſolved in water, and evaporated, yielded greyiſh white cryſtals: Theſe cryſtals were compoſed of pyro-lignous acid and potaſs. He poured upon them, by little and little, a quantity of ſulphuric acid; and by applying a gentle heat, the pyro-lignous acid came over in conſiderable purity *.

* Crell's Journal, 1779.

The Dijon academicians obtained this acid from beech wood: by diſtilling 55 ounces, they procured 17 ounces of acid; which, when rectified by a ſecond diſtillation, was of the ſpecific gravity 1,02083.

524 Its properties, combinations, and affinities.

It reddens vegetable colours: when expoſed to a ſtrong heat, it takes fire and is deſtroyed. It unites very well with alcohol.

Its compounds are called *pyro-lignites.*

Its affinities, as fixed by Mr Eloy Bourſier de Clervaux and Mr de Morveau, are as follows:

Lime,
Barytes,
Potaſs,
Soda,
Magneſia,
Ammonia,
Oxide of zinc,
——— manganeſe,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,

——— arſenic,
——— biſmuth,
——— mercury,
——— antimony,
——— ſilver,
——— gold,
——— platinum,
Alumina,
Jargonia † ?

† Vauquelin, Ann. de Chim. xxii. 208.

Sect. XXVII. *Of Pyro-tartarous Acid.*

An acid may alſo be obtained by diſtilling tartar; it is called *pyro-tartarous acid.*

525 Properties of pyro-tartarous acid.

It has an empyreumatic taſte and odour; reddens the tincture of turnſole; but has no effect on that of violets.

Little is known concerning this acid, except that many of its properties are the ſame with thoſe of the pyro-lignous; and Morveau conjectures that, if properly purified, it would probably be diſcovered to be the ſame with it.

The compounds which it forms are called *pyro-tartrites.*

Its affinities are unknown. Morveau ſuppoſes that they are the ſame with thoſe of the pyro-lignous acid.

526 Vegetable acids,

The 18 preceding acids are all (except the lactic and ſaccholactic) denominated *vegetable acids,* becauſe they are obtained from vegetable ſubſtances. We have placed the lactic and ſaccholactic acids in the ſame claſs; becauſe they bear a ſtrong reſemblance to vegetable acids, and becauſe they are evidently compoſed of the ſame ingredients with them.

527 Deſtroyed by fire.

Vegetable acids are diſtinguiſhed from all the acids deſcribed in the beginning of this chapter, by their deſtructibility by fire.

528 Convertible into each other.

There is no circumſtance in chemiſtry which has attracted greater attention than the poſſibility of converting the various vegetable acids into each other by means of different proceſſes. To explain what paſſes during theſe proceſſes, it would be neceſſary to know exactly the component parts of every vegetable acid, the manner in which theſe acids are combined, and the affinities which exiſt between each of their ingredients. This, however, is very far from being the caſe at preſent. Though a vaſt number of experiments have been made on purpoſe to throw light on this very point, the difficulties which were to be encountered have been ſo great, that no accurate reſults have yet been obtained.

529 Inquiry into the proportions of their ingredients.

It follows from theſe experiments, that all the vegetable acids are compoſed, chiefly at leaſt, of oxygen, hydrogen, and carbon; but that the proportions differ in every individual acid. We ſay chiefly, becauſe it has been ſuſpected from ſome phenomena, that one or two of theſe acids contain beſides a little azot. Let us take a view of what is at preſent known of the compoſition of theſe acids in their order.

1. As to carbonic acid, its compoſition has been aſcertained with tolerable accuracy; it conſiſts of about 28 parts of carbon and 72 of oxygen.

2. By diſtilling 7680 grains of acetite of potaſs, Dr Higgens obtained the following products *:

* Higgens on Acetous Acid, p. 26.

Potaſs,	- - - -	3862,994 grains.
Carbonic acid gas,	- -	1473,564
Carbonated hydrogen gas,	-	1047,6018
Reſiduum, conſiſting of carbon,	-	78,0000
Oil,	- - - - - -	180,0000
Water,	- - - -	340,0000
Deficiency (x),	- - -	726,9402

This deficiency Dr Higgens found to be owing to a quantity of water and oil which is carried off by the elaſtic fluids, and afterwards depoſited by them. He calculated it, in the preſent caſe, at 700 grains of water and 26,9402 grains of oil. Now, ſince acetite of potaſs is compoſed of acetous acid and potaſs, and ſince the whole of the potaſs remained unaltered, it follows that the acetous acid was converted into carbonic acid gas, carbonated hydrogen gas, carbon, oil, and water; all of which are compoſed of oxygen, hydrogen, and carbon.

Now 1473,564 gr. of carbonic acid gas are compoſed of 1060,966 gr. of oxygen, and 415,598 gr. of carbon.

1047,6018 grains of carbonated hydrogen gas, from a compariſon of the experiments of Dr Higgens and Lavoiſier, may be ſuppoſed to conſiſt of about 714,6008 grains of carbon, and 333,0010 of hydrogen.

200,9402 grains of oil contain 163,4828 grains of carbon and 43,4574 grains of hydrogen.

1040 grains of water contain 884 grains of oxygen and 156 grains of hydrogen.

Therefore

(x) For 29,1 grains of oxygen gas had alſo diſappeared from the air of the veſſels.

Therefore 3817,006 grains of acetous acid are compoſed of 1944,966 — 29,1 = 1915,866 grains of oxygen, 532,4584 grains of hydrogen, and 1368,6816 grains of carbon. Conſequently 100 parts of acetous acid are compoſed of

50,19 oxygen,
13,94 hydrogen,
35,87 carbon.

100,00

Theſe numbers can only be conſidered as approximations to the truth; for the object of Dr Higgens was not to aſcertain the proportions of the ingredients which compoſe acetous acid; and therefore his experiments were not conducted with that rigid accuracy which would have been neceſſary for that purpoſe.

It is extremely probable, that during the acetous fermentation, or the converſion of alcohol into acetous acid, a quantity of water is formed *; and it is certain that oxygen is abſorbed. It follows from this that acetous acid contains more carbon and leſs hydrogen than alcohol. Now we have reaſon, from Lavoiſier's experiments, to believe that alcohol is formed of

* *Hermſtadt, Crell's Annals*, 1786.

51,72 oxygen,
18,40 hydrogen,
29,88 carbon.

Lavoiſier ſuppoſes that this acid contains alſo azot.

3. Acetic acid is ſuppoſed to conſiſt of the ſame baſe with acetous acid, combined with a larger proportion of oxygen; we would rather ſay, that it is acetous acid combined with oxygen.

4. When oxalic acid is diſtilled with ſix times its weight of ſulphuric acid, the products are acetous acid, ſulphurous acid, carbonic acid gas, and ſulphuric acid remains in the retort †. Hence it follows, that oxalic acid contains more carbon than acetous acid; but that it is compoſed of the ſame ingredients. It has been ſuppoſed that oxalic acid is compoſed of ſugar and oxygen. Now ſugar, according to Lavoiſier, is compoſed of

† *Crell, Jour. de Phyſ.* 1785.

Hydrogen, - - - - -	8
Oxygen, - - - - -	64
Carbon, - - - - -	28

Theſe proportions are rather unfavourable to that notion; at leaſt if any dependence can be put in the compoſition of acetous acid as deduced from the experiments of Dr Higgens.

5. Hermſtadt diſſolved four ounces of tartarous acid in 16 ounces of water, and kept the ſolution in a veſſel covered with paper in a warm place. In three months the taſte of the ſolution was changed, and the air in the upper part of the veſſel was found to be carbonic acid. In ſix months the ſolution was converted into acetous acid. It follows, from this experiment, that tartarous acid contains more carbon than acetous acid, and that their ingredients are the ſame. If any doubts ſhould remain, the following experiment is ſufficient to remove them. Weſtrum mixed ſtrong ſulphuric acid with tartarous acid, and added mangane ſe; acetous acid was produced, and a great quantity of carbonic acid gas was diſengaged. When nitric acid is diſtilled off tartarous acid, it is converted into oxalic acid, as Scheele firſt proved. Hence it has been ſuppoſed by ſome, that oxalic acid differs from tartarous merely in containing more oxygen: but this is very far indeed from being proved. According to Haſſenfratz, tartarous acid contains a conſiderable quantity of azot.

6. When citrat of lime is allowed to remain in a bottle ſlightly corked along with a little alcohol, the citric acid is gradually converted into acetous acid *. Weſtrum converted it into oxalic acid by means of nitric acid.

* *Stahl.*

7. Malic acid was converted into oxalic by means of nitric acid by Scheele. It has been ſuppoſed to contain more oxygen than oxalic acid. Some of it is always formed during the common proceſs of converting ſugar into oxalic acid. Were we to judge from an experiment, which, however, was not performed with ſufficient accuracy, we would conclude that the baſe of malic acid is gum; for by diſtilling two parts of weak nitric acid off one part of gum in a very ſmall heat, we obtained a quantity of acid more in weight than the gum, which exhibited ſeveral of the diſtinguiſhing properties of malic acid. It was exceedingly light, white, and ſpongy, and attracted water very quickly from the atmoſphere, and could not afterwards be brought by evaporation to its former ſtate.

8. Scheele converted lactic acid into acetous by mere expoſure to the atmoſphere, and found that a quantity of carbonic acid was diſengaged. Hence this acid is merely the acetous with a ſmaller proportion of carbon.

9. The gallic acid, we have ſeen, contains more carbon than any of the others.

10. Nothing is known concerning the compoſition of the benzoic and ſuccinic acids. Hermſtadt ſays he converted benzoic acid to oxalic by means of nitric acid: but Morveau did not obſerve that any change was produced.

11. The baſe of camphoric is probably camphor.

Though theſe eighteen are the only acids which have hitherto been examined with attention, it cannot be doubted that the number of vegetable acids, either exiſting naturally, or at leaſt capable of being formed by art, is conſiderably greater. Morveau has lately aſcertained, that the red colours of flowers are owing to acids: This had already been conjectured by Linnæus.

Sect. XXVIII. *Of Pruſſic Acid.*

About the beginning of the preſent century, Dieſbach, a chemiſt of Berlin, wiſhing to precipitate a ſolution of cochineal mixed with a little alum and ſulphat of iron, borrowed from Dippel ſome potaſs, from which that chemiſt had *diſtilled* ſeveral times his *animal oil*. On pouring in the potaſs, Dieſbach was ſurpriſed to ſee, inſtead of the red precipitate which he had expected, a beautiful blue powder falling to the bottom of the veſſel. By reflecting on the materials which he had employed, he eaſily diſcovered the method of procuring the blue powder at pleaſure †. This powder was called *Pruſſian blue*, from the place where it was diſcovered. It was announced in the Berlin Memoirs for 1710; but the proceſs was concealed, becauſe it had become a lucrative article of commerce. A method of preparing it, however, was publiſhed by Woodward in the Philoſophical Tranſactions for 1724, which he ſaid he had got from one of his friends in Germany. This method was as follows: Detonate together 4 ounces of nitre and as much tartar, in order to procure an extemporaneous alkali; then add 4 ounces of dried bullock's blood, mix the

530 Diſcovery of Pruſſian blue.

† *Stahl's 300 Experiments.*

531 Method of preparing it.

Prussic Acid.

the ingredients well together, and put them into a crucible covered with a lid, in which there is a small hole; calcine with a moderate fire till the blood emits no more smoke or flame capable of blackening any white body exposed to it: increase the fire towards the end, so that the whole matter contained in the crucible shall be moderately but sensibly red. In this state throw it into two pints of water, and boil it for half an hour. Decant off this water, and continue to pour on more till it come off insipid. Add all these liquids together, and boil them down to two pints. Dissolve two ounces of sulphat of iron and eight ounces of alum in two pints of boiling water; mix this with the former liquor while both are hot. An effervescence takes place, and a powder is precipitated of a green colour mixed with blue. Separate this precipitate by filtration, and pour muriatic acid upon it till it becomes of a beautiful blue; then wash it with water and dry it.

Different explanations were given of the nature of this precipitate by different chemists. All of them acknowledged that it contained iron, but to account for the colour was the difficult point. Brown, and Geoffroy, and Neumann, discovered in succession, that a great many other animal substances besides blood communicated to alkalies the property of forming Prussian blue. Macquer undertook an examination of this substance, and published the result of his experiments in the Memoirs of the French Academy for 1752.

532 Its composition discovered by Macquer.

He observed that, when alkali is added to a solution of iron in any acid, the iron is precipitated of a yellow colour, and soluble in acids; but if iron be precipitated from an acid by an alkali prepared as above described, by calcination with blood (which has been called a *Prussian alkali)*, it is of a green colour. Acids dissolve only a part of this precipitate, and leave behind an insoluble powder which is of an intense blue colour. The green precipitate therefore is composed of two different substances, one of which is Prussian blue; the other, as he ascertained by experiment, is the brown or yellow oxide of iron: and the green colour is owing to the mixture of the blue and yellow substances. When heat is applied to the insoluble precipitate, its blue colour is destroyed, and it becomes exactly similar to common oxide of iron. It is composed therefore of iron and some other substance, which heat has the property of driving off. If this insoluble precipitate be boiled with a very pure alkali, it loses its blue colour also, and at the same time the alkali acquires the property of precipitating of a blue colour solutions of iron in acids, or it has become precisely the same with the Prussian alkali. Prussian blue, therefore, is composed of iron and something which a pure alkali can separate from it, something which has a greater affinity for alkali than for iron. By boiling a quantity of alkali with Prussian blue, it may be completely saturated with this something, which we shall call *colouring matter*, and then it has lost all its alkaline properties. No acid can separate this colouring matter from iron after it is once united with it. When iron dissolved in an acid is mixed with an alkali saturated with the colouring matter, a double decomposition takes place, the acid unites with the alkali, and the colouring matter with the iron, and forms Prussian blue. The reason that, in the common method of preparing Prussian blue, a quantity of yellow oxide is precipitated, is, that there is not a sufficient quantity of colouring matter (for the alkali is never saturated with it) to saturate all the iron displaced by the alkali; a part of it therefore is mixed with Prussian blue. Muriatic acid dissolves this oxide, carries it off, and leaves the blue in a state of purity. Such were the conclusions which Macquer drew from his experiments; experiments which not only discovered the composition of Prussian blue, but threw a ray of light on the nature of affinities, which has contributed much towards the advancement of that important branch of chemistry.

The nature of the colouring matter, however, was still unknown. Macquer himself supposed that it was pure phlogiston; but the opinion was untenable. He had shewn that it possessed the property of forming neutral salts, and therefore Bergman and Morveau suspected that it was an acid.

Scheele undertook the task of examining its nature, and published the result of his experiments in the Stockholm Transactions for 1782.

He observed that the Prussian alkali, after being exposed for some time to the air, lost the property of forming Prussian blue; the colouring matter must therefore have left it.

He put a small quantity of it into a large glass globe, corked it up, and kept it some time; but no change was produced either in the air or the Prussian alkali. Something must therefore displace the colouring matter when the alkali is exposed to the open air, which is not present in a glass vessel. Was it carbonic acid gas? To ascertain this, he put a quantity of Prussian alkali into a glass globe filled with that gas, and in 24 hours the alkali was incapable of producing Prussian blue. It is therefore carbonic acid gas which displaces the colouring matter. He repeated this experiment with this difference, that he hung in the globe a bit of paper which had been previously dipped into a solution of sulphat of iron, and on which he had let fall two drops of an alkaline lixivium, in order to precipitate the iron. This paper was taken out in two hours, and became covered with a fine blue on adding a little muriatic acid. Carbonic acid, then, has the property of separating the colouring matter from alkali without decomposing it. 533 Decomposed by Scheele.

He found also that other acids produced the same effect. The colouring matter then may be obtained perhaps in a separate state. He accordingly made a number of attempts to procure it, and at last discovered the following process: He boiled together for some minutes two ounces of Prussian blue in powder, one ounce of the red oxide of mercury, and six ounces of water; then passed the whole through a filter, and washed the residuum with two ounces of boiling water. The oxide of mercury has a greater affinity for the colouring matter than the oxide of iron; it therefore unites with it, and forms with it a salt soluble in water. The iron remains behind upon the filter, and the liquid is a solution of the colouring matter combined with mercury. He poured this solution upon half an ounce of pure iron-filings, and added at the same time three grains of sulphuric acid. The iron separates the oxygen from the mercury, in order to combine with the sulphuric acid; the mercury is precipitated in its metallic state, and leaves behind it a quantity of sulphat of iron and of colouring matter dissolved in water, but not combined, as the colouring matter is unable to separate the iron from the acid *. 534 The colouring matter separated.

He then distilled in a gentle heat; the colouring matter

* *Berthollet, Ann. de Chimie*, i. 30.

Pruffic Acid.

ter came over by the time that one-fourth of the liquor had paffed into the receiver. It was mixed, however, with a fmall quantity of fulphuric acid; from which he feparated it by diftilling a fecond time over a quantity of carbonat of lime. The fulphuric acid combines with the lime and remains behind, which the colouring matter cannot do, becaufe carbonic acid has a ftronger affinity for lime than it has. Thus he obtained the colouring matter in a ftate of purity.

535 Its component parts. It remained now to difcover its component parts. He formed a very pure Pruffian blue, which he diftilled, and increafed the fire till the veffel became red. The fmall quantity of water which he had put into the receiver contained a portion of the blue colouring matter and of ammonia; and the air of the receiver confifted of azot, carbonic acid gas, and the colouring matter. He concluded from this experiment, that the colouring matter was compofed of ammonia and carbon. He mixed together equal quantities of pounded charcoal and potafs, put the mixture into a crucible, and kept it red hot for a quarter of an hour: he then added a quantity of fal ammoniac in fmall pieces, which he pufhed to the bottom of the melted mixture, kept it in the fire for two minutes till it had ceafed to give out vapours of ammonia, and then threw it into a quantity of water. The folution poffeffed all the properties of the Pruffian alkali. Thus Mr Scheele fucceeded in forming the colouring matter; and it was confidered as proved that it was compofed of ammonia and carbon.

But after the publication of Scheele's experiments, it was difcovered that ammonia itfelf is compofed of azot and hydrogen. It became therefore a queftion, Whether ammonia entered into the compofition of this fubftance, or merely its ingredients? Whether it was compofed of ammonia and carbon, or of azot, hydrogen, and carbon combined in a different manner? This point has been decided by the following experiments: Mr Clouet made a quantity of ammoniacal gas pafs through a red hot porcelain tube filled with charcoal, and by this procefs formed a quantity of the colouring matter *. Here the temperature was fo high that the ammonia muft have been decompofed: and the colouring matter cannot be formed by combining ammonia and charcoal except at a temperature equally high. There is reafon therefore to fuppofe that the ammonia is decompofed. When oxy-muriatic acid is mixed with the colouring matter, it communicates to it a quantity of oxygen, and caufes it in confequence to affume very different properties. When a fixed alkali or lime is added to it in this ftate, it is immediately decompofed, and converted into ammonia and carbonic acid gas. The colouring matter in this ftate contains all the ingredients neceffary to form thefe two fubftances, namely, azot, hydrogen, carbon, oxygen: but in order to induce the ingredients to form thefe two compounds, the affiftance of an alkali or lime to combine with the carbonic acid is neceffary; juft as fulphur combines more eafily with oxygen when united with an alkali or with iron than when feparate †.

* *Ann. de Chim.* xi.

† *Bertholle*t, *ibid.* i.

The colouring matter, then, which we fhall henceforth call the *Pruffic acid*, is compofed of azot, hydrogen, and carbon; but the proportions of thefe ingredients have not yet been determined. It is confidered as an acid, though the prefence of oxygen has not been proved, becaufe it has the property of forming neutral falts with the fame bafes as other acids.

The Pruffic acid is exceedingly volatile, and evidently capable of exifting in a gafeous ftate. It has a peculiar odour, not difagreeable, and which has been compared to the flowers of the peach. It has a fweetifh and fomewhat hot tafte, and excites cough*. 536 Properties of Pruffic acid.

It has no affinity for alumina nor for alcohol †.

* *Scheele.*

† *Morveau.*

This fubftance differs exceedingly in its action from all other acids.

It is capable of combining, like them, with earths, alkalies, and metallic oxides, and of forming compounds which have been denominated *Pruffiats*. But it enters much more readily into triple compounds with alkalies or earths, and metallic oxides, than into combinations with earths or alkalies feparately; and though its affinity appears to be greater for alkalies and earths than for metallic oxides, yet when in a free or gafeous ftate it does not enter into combinations with earths or alkalies without difficulty, and it is feparated from them much more eafily than from metallic oxides. Mere expofure to the light of the fun, or to a heat of 110°, is fufficient for that purpofe. 537 Its action on other bodies.

Its affinities are fuppofed to be as follows: 538 Its affinities.

Potafs,
Soda,
Ammonia,
Lime,
Barytes,

Sect. XXIX. *Of Formic Acid.*

In the 15th century feveral botanifts obferved, with aftonifhment, that the flower of fuccory, when thrown into an ant hill, became as red as blood: But it was Mr S. Fifher who firft difcovered that ants poffeffed a peculiar acid, which he obtained by diftilling thefe animals. His experiments were publifhed in the Philofophical Tranfactions for 1670. Though Hoffman afterwards repeated 539 Difcovery of formic acid.

(Y) We fufpect that this is not the real order of the affinities of this acid; the metallic oxides ought probably to be placed before the alkalies and earths, and the metallic Pruffiats ought to occupy the place which is at prefent filled by the metallic oxides. The reafons for this conjecture will appear afterwards. See Part III. chap. ii. fect. 23. of this article.

Formic Acid.

repeated his proceſs, little was known concerning the nature of this acid till Margraf undertook its examination, and publiſhed his experiments in the Berlin Memoirs for 1749.

The ſpecies of ants from which the formic acid is obtained is the *formica rufa*, which reſide moſt commonly in woods, or at leaſt in elevated and dry places. They have been found to contain the greateſt quantity of acid in the months of June and July. If at that ſeaſon one of theſe animals be preſſed upon paper tinged with turnſole, it changes the colour of it to a moſt lively red: they even ſometimes ſtain it merely by crawling over it.

540 Methods of obtaining it.

There are two methods of obtaining the formic acid, diſtillation and lixiviation.

When the firſt method is to be employed, the ants are to be waſhed clean, dried with a gentle heat, put into a retort, and diſtilled with a moderate heat, gradually increaſed till all the acid has come over. It is mixed with an empyreumatic oil, from which it is ſeparated by paſſing it through a ſtrainer previouſly moiſtened with water. By this proceſs Meſſrs Ardviſſon and Oehrn obtained from a pound of ants $7\frac{1}{2}$ ounces of acid, the ſpecific gravity of which, at the temperature of 60°, was 1,0075 *. Morveau obtained from 49 ounces of ants 23 ounces of pretty ſtrong acid †. Margraf added a quantity of water; but it is evident that this ſerves merely to weaken the acid.

When the other method is preferred, the ants are to be waſhed in cold water, put upon a clean linen cloth, and boiling water poured on them repeatedly till it can extract no more acid. The linen is then to be ſqueezed, and the ſeveral liquors mixed and filtrated. This method was firſt uſed by Ardviſſon and Oehrn: they obtained from a pound of ants an acid liquor which had more ſpecific gravity than common vinegar. It is to be purified from the oil which adheres to it by repeated diſtillations. After four diſtillations the empyreumatic oil ſtill manifeſts its preſence by its ſmell, but this ſmell vaniſhes if the acid be expoſed for ſome time to the air; a quantity of eſſential oil, however, ſtill remains, which cannot be ſeparated. The ſpecific gravity of the acid thus rectified is 1,0011 ‡.

Hermſtadt employed a third method. He expreſſed the juice of dry ants, and by this means obtained from 2 lbs. of theſe animals 21 oz. 2 dr. of juice, which on diſtillation yielded a clear pure acid, equal in ſtrength to very concentrated vinegar §.

541 Its properties.

This acid ſeems to be capable of aſſuming a gaſeous form; at leaſt Hermſtadt obſerved, that when he put ſome of it into a bottle with a glaſs ſtopper, the ſtopper was frequently raiſed by an elaſtic fluid making its eſcape, and that after ſome days it had loſt its ſmell ‖. When this acid is boiled with nitric acid, a gas is extricated, which renders lime-water turbid, and has a very pungent odour ¶.

This acid has a ſtrong but not unpleaſant ſmell, a cauſtic taſte, and when much diluted a pleaſant acidity. When moſt concentrated, its ſpecific gravity is 1,0453 *.

One part of this acid, mixed with 75 parts of water, gives a faint red to ſyrup of violets; mixed with 430 parts of water, it reddens paper coloured with turnſole; mixed with 1300 parts of water, it produces no effect on the infuſion of turnſole †. It mixes readily with alcohol.

Sebacic Acid.

It unites readily with the other acids. When boiled with ſulphuric acid, it becomes black. White acrid vapours riſe when the mixture becomes hot; and when it boils, a gas riſes which unites with difficulty to water and lime-water; the formic acid is again obtained, but its quantity is diminiſhed *.

Nitric acid decompoſes it altogether, and is itſelf converted into nitrous acid. Muriatic acid does not alter it. Oxy-muriatic acts like nitric acid †.

Its compounds are called *formiats*. 542 Its compounds and affinities.

Its affinities are the ſame with thoſe given above for the Pruſſic acid.

* Ibid.

† Ibid.

Sect. XXX. *Of Sebacic Acid.*

Chemists had long ſuſpected that an acid could be obtained from tallow, on account of the acrid nature of the fumes which it emitted at a high temperature; but it was M. Grutzmacher who firſt demonſtrated this acid in a diſſertation *De Oſſium Medulla*, publiſhed in 1748 ‡. Mr Rhodes mentioned it in 1753, and Segner publiſhed a diſſertation on it in 1754, and Crell examined its properties very fully in two diſſertations publiſhed in the Phil. Tranſ. for 1780 and 1782. It was called at firſt *acid of fat*, and afterwards *ſebacic acid*. 543 Diſcovery of ſebacic acid.

‡ Leonhardi.

It may be procured by heating together a mixture of ſuet and lime. Sebat of lime is formed, which may be purified by ſolution in water. It is then to be put into a retort, and ſulphuric acid poured on it. Sebacic acid paſſes over on the application of heat.

Sebacic acid has an acid, ſharp, bitteriſh taſte, and a very pungent ſmell. It reddens tincture of litmus. 544 Its properties,

Heat cauſes it to aſſume a yellow colour.

It oxidates ſilver, mercury, copper, iron, lead, tin, zinc, antimony, mangan eſe.

It does not act upon biſmuth, cobalt, nickel. When mixed with nitric acid it diſſolves gold.

Its compounds are called *ſebats*. 545 Compounds and affinities.

Its affinities, according to Morveau, are as follows:

Barytes,
Potaſs,
Soda,
Lime,
Magneſia,
Ammonia,
Alumina,
Jargonia §,
Oxide of zinc,
——— mangan eſe,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,
——— nickel,
——— arſenic,
——— biſmuth,
——— mercury,
——— antimony,
——— ſilver.

§ Vauquelin, Ann. de Chim. xxii. 208.

Sect. XXXI. *Of Bombyc Acid.*

Mr Boissier de Sauvages obſerved, that the juice of the ſilkworm, in the diſeaſe called in France *muſcadine*, was acid; and Chauſſier remarked, that the ſilkworm, after being converted into a butterfly, gives out a 546 Diſcovery of bombyc acid.

Zoonic Acid.

a liquor which turns vegetable blues to a red. He found, that during the time that the animal was forming its cocon, the acid was depofited in a refervoir near the anus. By means of a pair of fciffars he collected fome which reddened blue paper, united with alkalies with effervefcence, and even attacked the fciffars. He afterwards collected it by infufing the chryfalids in alcohol, which diffolved the acid, but left the impurities untouched.

This acid has never been examined with attention; fo that almoft all its properties are unknown.

Sect. XXXII. *Of Zoonic Acid.*

547 Method of obtaining zoonic acid.

Mr Berthollet has obtained a peculiar acid by diftilling vegetable and animal fubftances, to which he has given the name of the *zoonic acid* *. He procured it by diftilling the gluten of wheat, the yeft of beer, bones, and woollen rags; and concludes, therefore, that it may be produced by the diftillation of all animal fubftances.

* *Ann. de Chim.* xxvi. 86.

To obtain this acid pure, he mixed lime with the diftilled liquid, after having feparated the oil, which it always contains (for the product of the diftillation of animal fubftances is chiefly oil and carbonat of ammonia.) He boiled this mixture till the carbonat of ammonia was exhaled: he then filtered it, added a little more lime, and boiled it again till the fmell of the ammonia had gone off entirely. The liquor, which now contained only zoonat of lime, he filtered again, and then added a little water impregnated with carbonic acid, in order to precipitate any lime which might happen to be diffolved in the liquid without being combined with the zoonic acid.

After concentrating the zoonat of lime, he mixed it with phofphoric acid, and diftilled it in a retort. At a heat nearly equal to that of boiling water, the zoonic acid paffes over in a ftate of purity.

548 Its properties.

The zoonic acid has an odour like that of meat when frying, and it is actually formed during that procefs. It has an auftere tafte.

It gives a red colour to paper tinged with turnfole.

With alkalies and earths it produces falts, which do not appear capable of cryftallizing.

It forms a white precipitate in the folutions of acetite of lead and nitrat of mercury.

Part of the zoonic acid feems to be deftroyed by the action of heat during the diftillation of the zoonat of lime with phofphoric acid: for the liquor, which is in ebullition, becomes brown, and grows black at the end of the operation; hence Mr Berthollet concludes that the zoonic acid contains carbon. The zoonat of filver, when kept, becomes gradually brown; hence he concludes that the acid contains hydrogen. Thefe conclufions he draws from a very ingenious theory of his, which has been already defcribed in the article Bleaching in this *Supplement* †.

† *Berthollet, Ann. de Chim.* xxvi.

549 Animal acids.

The five preceding acids have obtained the name of *animal acids*, becaufe they are all obtained from the animal kingdom. It can fcarcely be doubted that a more accurate examination of animal fubftances will add confiderably to the number of thefe acids.

Sect. XXXIII. *Of Arfenic Acid.*

Arsenic acid, which was firft difcovered by Scheele, may be produced by fimply mixing the white oxide of arfenic with oxy-muriatic acid, and applying a heat fufficient to fublime the muriatic acid. The theory of this operation is evident: the white oxide has a greater affinity for oxygen than muriatic acid has; of courfe it combines with it, and is thus converted into arfenic acid, and the muriatic acid is eafily fublimed by applying heat.

Arfenic Acid.

550 Method of obtaining arfenic acid.

Landriani has informed us, that this acid may be alfo formed by fubliming feveral times fucceffively the white oxide of arfenic, and taking care every time to renew the air. This procefs is equally fimple; the oxide combines at a high temperature with the oxygen of the atmofphere.

551 Its properties.

This acid is exceedingly fixed. When expofed to the air it attracts humidity, and at laft becomes liquid. At the temperature of 60° it diffolves in two-thirds of its weight of water. Its folution may be evaporated to drynefs, and even converted into a glafs, which attracts moifture from the air, and acts powerfully on the crucible.

It is poifonous as well as the white oxide of arfenic *.

* *Scheele.*

When expofed to a red heat, it is partly decompofed and converted into white oxide of arfenic †.

† *Id.*

It does not act upon gold, platinum, filver, mercury.

It oxidates copper, iron, lead, tin, zinc, bifmuth, antimony, cobalt, nickel, manganefe, and arfenic, and in a very ftrong heat, mercury and filver.

According to Berthollet's experiments, arfenic acid is compofed of eight parts of white oxide of arfenic and one part of oxygen.

552 Its compounds and affinities.

Its compounds are called *arfeniats*.

Its affinities are as follows:

Lime,
Barytes,
Magnefia,
Potafs,
Soda,
Ammonia,
Oxide of zinc,
——— manganefe,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,
——— nickel,
——— bifmuth,
——— mercury,
——— antimony,
——— filver,
——— gold,
——— platinum,
Alumina,
Jargonia ‡?
Water.

‡ *Vauquelin, Ann. de Chim.* xxii. 208.

Sect. XXXIV. *Of Tungstic Acid.*

553 Properties of tungftic acid.

Tungstic acid, or oxide of tungften, was firft difcovered by Scheele; but the acid which he examined was not pure, being compofed, as Mr Luyart has fhewn, of nitric acid, ammonia, and tungftic acid. The real acid is infoluble in water, taftelefs, and incapable of turning vegetable blues red till it has been firft rendered

 foluble

Molybdic Acid.

soluble by being partly combined with ammonia. It is of a beautiful yellow colour, which becomes blue when exposed to the light, or heated violently in close vessels. It does not recover its yellow colour except by calcination in the open air, and then increases in weight. When put into muriatic acid along with tin, zinc, or iron, the liquor becomes blue *. Treated with acetous acid, it becomes blue. When reduced to a glass with phosphat of soda, the blue colour appears and disappears according as the blue or yellow part of the flame is directed to it, as happens to manganese. Probably this blue substance is an oxide of tungsten with a smaller quantity of oxygen.

* Renman.

554 Its compounds and affinities.

Its compounds are called *tungstats*.

Its affinities are as follows †:

Lime,
Barytes,
Magnesia,
Potass,
Soda,
Ammonia,
Alumina,
Jargonia ‡ ?

† Luyarts.

‡ Vauquelin, Ann. de Chim. xxii. 208.

Sect. XXXV. *Of Molybdic Acid.*

555 Properties of molybdic acid.

Concrete molybdic acid, first discovered by Scheele, is white, and has an acid but metallic taste. Its specific gravity is 3,75 §. It is not altered in the air. When heated in a crucible till it is beginning to melt, it experiences no alteration. It remains fixed even in a great fire as long as the crucible is covered; but the moment it is uncovered the acid rises unaltered in a white smoke. It dissolves in 570 parts of water. The solution reddens turnsole; nitric acid does not affect it, but sulphuric and muriatic acids dissolve it by the assistance of heat.

§ Bergman.

It may be prepared by treating the ore of molybdenum with nitric acid, and washing the acid when formed in water.

When combined with potass, it forms a colourless salt.

Mixed with filings of tin and muriatic acid, it immediately becomes blue, and precipitates flakes of the same colour, which disappear after some time, if an excess of muriatic acid has been added, and the liquor assumes a brownish colour.

With the solution of nitrat of lead it forms a white precipitate, soluble in nitric acid.

When mixed with a little alcohol and nitric acid, it does not change its colour.

With a solution of nitrat of mercury, or of nitrat of silver, it gives a white flaky precipitate.

With the nitrat of copper it forms a greenish precipitate.

With solutions of sulphat of zinc, muriat of bismuth, muriat of antimony, nitrat of nickel, muriats of gold and platinum, it produces white precipitates when these solutions do not contain an excess of acid.

When melted with borax, it gives it a bluish colour.

Paper dipt in this acid becomes in the sun of a beautiful blue colour ‖.

Sulphur is capable of partly decomposing it by heat.

Its compounds are called *molybdats*.

Its affinities are unknown.

‖ Vauquelin, Philosophical Magazine, i. 282.

Sect. XXXVI. *Of Chromic Acid.*

Chromic Acid.

556 Analysis of the red lead of Siberia,

In the year 1770, Mr Pallas discovered in the gold mine of Beresof, near Ekaterimbourg in Siberia, a mineral of a red colour, with a shade of yellow, crystallized in small acute angled quadrangular prisms, sometimes smooth, sometimes longitudinally streaked, and often hollow. Mr Macquart, professor of medicine at Paris, who in 1783 had been sent to the north by the French government in order to collect mineralogical information, brought with him a quantity of this mineral, which has been distinguished by the name of *red lead ore of Siberia*, and in 1789 analysed four ounces of it along with Mr Vauquelin. They found it to contain,

Lead - -	$36\frac{1}{9}$
Oxygen - -	$37\frac{5}{9}$
Iron - -	$24\frac{8}{9}$
Alumina - -	2
	$100\frac{5}{9}$

and a little silver *.

Mr Bindheim of Moscow analysed it soon after, and found it to contain,

* Ann de Chim. i. 301.

Lead - -	60
Molybdic acid	11,66
Nickel -	5,66
Oxide of iron -	1
Air and water	5
Silica - -	4,5
	87,82

and a little copper and cobalt †.

Vauquelin examined it again in 1797, and found that all the former analyses were inaccurate.

† Berl. Beob iv. 2911.

A hundred parts of this mineral, reduced to a fine powder, were mixed with 300 parts of the saturated carbonat of potass, and about 4000 parts of water; and this mixture was exposed for an hour to a boiling heat. He observed, 1st, that when these matters began to act upon each other there was produced a strong effervescence, which continued a long time; 2d, that the orange colour of the lead became a brick red; 3d, that at a certain period the whole matter seemed to dissolve; 4th, that in proportion as the effervescence advanced the matter reappeared under the form of a granulated powder of a dirty yellow colour; 5th, that the liquor assumed a beautiful golden yellow colour. When the effervescence had entirely subsided, and appeared to have no longer any action on the substances, the liquor was filtered, and the metallic dust collected on the paper. After being washed and dried, it weighed no more than 78 parts: the potass, therefore, had taken from it 22 parts.

He poured upon the 78 parts just mentioned some of the nitric acid, diluted in 12 parts of water, which produced a brisk effervescence. The greater part of the matter was dissolved: the liquor assumed no colour, and there remained only a small quantity of powder of an orange-yellow colour. The liquor of the residuum was separated by the help of a syphon, the matter washed several times, and the washings united with the first liquor. This residuum, dried, weighed no more than 14 parts: from which it follows, that the nitric acid had dissolved 64.

He again mixed these 14 parts with 42 parts of the carbonat of potass and the necessary quantity of water, and

Chromic Acid.

and then treated them as before, and the phenomena were the fame. The liquor, after being filtered, was united to the former; and the refiduum, wafhed and dried, weighed no more than two parts, which were ftill red lead, and therefore thrown away.

The two nitric folutions, united and evaporated, produced 92 parts of nitrat of lead, cryftallized in octahedra, perfectly white and tranfparent. Thefe 92 parts of nitrat of lead, diffolved in water, were precipitated by a folution of the fulphat of foda. This produced 81 parts of the fulphat of lead, which were equivalent to 56,68 of metallic lead.

557 And difcovery of chromic acid.

The alkaline liquors were found to contain a falt compofed of potafs combined with a peculiar acid, which Mr Vauquelin afterwards called *chromic acid*.

Thefe liquors, fubjected to evaporation until a faline pellicle was formed on their furface, produced, on cooling, yellow cryftals; among which there was a carbonat of potafs, not decompofed. Thefe cryftals, diffolved in water, and the folution united with the mother-water, the whole was mixed with weak nitric acid until the carbonat of potafs was faturated. The liquor then had a very dark orange-red colour. Being united with a folution of the muriat of tin, newly made, it firft affumed a brown colour, which afterwards became greenifh. Mixed with a folution of the nitrat of lead, it immediately produced the red lead. Laftly, evaporated fpontaneoufly, it produced ruby-red cryftals, mixed with cryftals of the nitrat of potafs. Ninety-eight parts of this mineral, decompofed as above-mentioned, having produced 81 parts of the fulphat of lead, 100 parts would have given 82,65, which are equivalent to 57,1 of metallic lead. "But admitting, as experiment proves (fays Mr Vauquelin), that 100 parts of lead abforb, in combining with acids, 12 parts of oxygen, the 57,1 of metallic lead ought to contain in the red lead 6,86 of this principle, and we ought to have for the mineralizing acid 36,4.

558 Its properties.

Chromic acid cryftallizes in the form of elongated prifms of a ruby colour.

When mixed with filings of tin and the muriatic acid, it becomes at firft yellowifh brown, and afterwards affumes a beautiful green colour.

When mixed with a little alcohol and nitric acid, it immediately affumes a bluifh green colour, which preferves the fame fhade even after deficcation. Ether alone gives it the fame colour.

With a folution of nitrat of mercury, it gives a precipitate of a dark cinnabar colour.

With a folution of nitrat of filver, it gives a precipitate, which, the moment it is formed, appears of a beautiful carmine colour, but becomes purple by expofure to the light. This combination, expofed to the heat of the blow-pipe, melts before the charcoal is inflamed. It affumes a blackifh and metallic appearance. If it be then pulverifed, the powder is ftill purple; but after the blue flame of the lamp is brought in contact with this matter, it affumes a green colour, and the filver appears in globules diffeminated throughout its fubftance.

With nitrat of copper, it gives a chefnut red precipitate.

With the folutions of fulphat of zinc, muriat of bifmuth, muriat of antimony, nitrat of nickel, and muriat of platinum, it produces yellowifh precipitates when thefe folutions do not contain excefs of acid. With muriat of gold, it produces a greenifh precipitate.

When melted with borax or glafs, it communicates to them a beautiful emerald green colour.

Paper impregnated with chromic acid affumes in the light a greenifh colour.

When mixed with muriatic acid, the mixture was capable of diffolving gold like aqua regia; when this mixture of the two acids is diftilled, oxy-muriatic acid is difengaged, and the liquor affumes a very beautiful green colour.

Sulphuric acid, while cold, produces no effect upon it; but when warmed, it makes it affume a bluifh green colour, probably by favouring the difengagement of oxygen.

When this acid is heated along with charcoal, it is reduced to the metal called *chromum*. It is therefore compofed of this metal and oxygen. From Vauquelin's experiments, it appears to contain one part of chromum and two parts of oxygen.

Such are the properties of this acid, as far as they have hitherto been difcovered. Vauquelin is the only chemift who has examined it; and from his memoir the above account has been taken *.

* *Ann. de Chim.* xxv. 114. and *Philofophical Magazine*, i. 279. and 361.

The four laft defcribed acids are called *metallic acids*, becaufe they are compofed of metals and oxygen.

559 Metallic acids.

It is believed that moft of the metals, we would rather fay of the metallic oxides, are capable of being converted into acids by being combined with oxygen. It is certain that this is the cafe with platinum; and Hermftadt, by diftilling nitric acid off tin, converted it into a white mafs, foluble in three parts of water, which has been called *ftannic acid* †. Several more of the metallic oxides act the part of acids: But no complete fet of experiments on this important fubject has yet appeared.

† *Ann. de Chim.* iv. 162.

Chap. VI. *Of* Affinity.

560 Importance of affinity.

The meaning of the word *affinity* has been already explained; and it muft appear evident, from the ufe which has been made of it in this article, that the confideration of the nature of affinity is the moft important part of chemiftry. While its laws are unknown, chemiftry is not a fcience, but a wildernefs of facts without beauty or regularity: every thing is equally perplexing and incomprehenfible. The chemift, inftead of being able to trace the operations of Nature, is loft in an endlefs maze of uncertainty, without a guide to conduct him, or a ray of light to illuminate his fteps. It is the knowledge of affinity which difpels the darknefs, removes the confufion, fhews us the order which fubfifts in all the phenomena of nature, points out their dependence on one another, and enables us to direct them as we think proper, to make them fubfervient to the improvement of the arts, and thus to render them the minifters of our comforts and enjoyments.

561 It unites bodies, particle to particle.

1. When two bodies are united together by affinity, how fmall a portion foever of the compound we examine, we fhall always find it to contain both of the ingredients. From this it is evident, that affinity combines bodies, particle with particle.

By *particles* we do not mean what philofophers have called *atoms*, or the fmalleft parts into which it is poffible to divide matter; but the fmalleft parts which make

Affinity.

make an integrant of any ſubſtance. Water, for inſtance, conſiſts of oxygen and hydrogen; but when we ſpeak of a particle of water, we do not mean the oxygen or the hydrogen ſeparately, but the ſmalleſt poſſible quantity of theſe combined in ſuch a manner as to form water. It is the *integrant particles* of bodies which are united by affinity. Thus ſulphuric acid is compoſed of ſulphur and oxygen combined together; and ammonia, of hydrogen and azot combined in the ſame manner. Now when ſulphuric acid and ammonia combine, it is not their elements, ſulphur, oxygen, azot, and hydrogen, which unite together, particle with particle, but the particles of the acid and the alkali as integrants. This is evident; becauſe if theſe ſubſtances be ſeparated from each other by means of a ſtronger affinity, they are found preciſely in the ſame ſtate as before they entered into combination.—When the ſubſtances which combine are *ſimple*, the ultimate and integrant particles are the ſame. But we are not certain that any of the bodies with which we are acquainted is ſimple, in the ſtrict and proper ſenſe of the word.

562 Opinions of the older chemiſts about affinity.

2. What is this *affinity* which unites bodies together? The older chemiſts thought that all ſolvents, or ſubſtances capable of diſſolving others, were compoſed of particles which had the form of wedges or hooks; that ſolution conſiſted in the inſinuation of theſe wedges or hooks between the particles of the bodies to be diſſolved; and that chemical combination was merely the linking of the different particles together by means of holes in one ſet of particles, into which the hooks or the wedges of the other ſet were thruſt. Such explanations, abſurd as they may appear, were faſhionable among chemical philoſophers till the days of Sir Iſaac Newton, who firſt aſcribed the chemical union of bodies to an *attraction* between the particles themſelves. This explanation, after a violent ſtruggle on the part of the chemiſts, has been at laſt unanimouſly adopted.

563 It is an attraction between the particles of bodies.

Affinity, then, is an *attraction* between the particles of different bodies, by which they are *drawn* towards one another, and kept united. This we take for granted, and conſider as a *fact*, without pretending to explain *how* they come to be poſſeſſed of this power, or *how* they exert it; both of which are evidently beyond the reach of the human underſtanding.

But though we cannot diſcover the manner in which affinity acts, we can ſee, at leaſt, that it follows certain laws, and that they are invariable; for ſimilar phenomena always occur when the circumſtances are the ſame.

564 Whether the ſame with gravitation.

Now what are the laws which affinity follows? There is a ſpecies of attraction which matter poſſeſſes, called *gravitation*, the laws of which were inveſtigated by Sir Iſaac Newton. Is affinity the *ſame* with gravitation, or does it follow different laws?

Upon a ſlight view of theſe two attractions, their phenomena appear very different. Gravitation acts at very great diſtances; affinity not until the bodies are mixed together: Gravitation acts on the whole maſs; affinity only on the particles: Bodies gravitate to one another directly as their maſſes, and inverſely as the ſquares of their diſtances. But how can affinity follow theſe laws, when it does not act till the bodies are apparently in contact? or ſuppoſing that it does act, how can they account for the phenomena of affinity? If barytes be preſented to a compound of ſulphuric acid and potaſs, the acid immediately leaves the alkali and combines with the earth: But had gravitation been the only power acting, ought not the barytes to have united with the ſulphat of potaſs without producing any decompoſition?

Theſe ſtriking differences have convinced many philoſophers, as they ſeem to have done Newton himſelf, that gravitation and affinity are different ſpecies of attraction. Let us not, however, embrace this concluſion vaguely, or without affixing a preciſe meaning to our words.

565 No poſitive proof that it is different.

Gravitation and chemical affinity are ſaid to be different ſpecies of attraction. But what is attraction? It is merely a general *fact*, or that tendency which is *obſerved* among all the portions of matter towards each other, but which exhibits very different appearances under different circumſtances. The tendency of matter towards matter at *ſenſible* diſtances is called *gravitation*, and its laws have been completely inveſtigated; but neither that tendency, nor theſe laws, have been, or can be, ſhewn to be *eſſential* to the exiſtence of matter. Chemical affinity is the tendency of particles towards each other at *inſenſible* diſtances, or when theſe particles are mixed together; and this tendency appears to be regulated by laws different from thoſe of gravitation. Like gravitation, it is merely an *obſerved fact*; and however different theſe facts may appear to be, they are probably both brought about by the ſame forces. It is indeed true, that gravitation is directly as the maſſes of matter, and inverſely as the ſquares of the diſtances of theſe maſſes; while the attraction, which is called *chemical affinity*, ſeems to obſerve very different rules. But we have ſhewn elſewhere (ſee OPTICS, n° 62—68, *Encycl.*; and BOSCOVICH in this *Suppl.*), that the ſame forces repel at one diſtance and attract at another; and that they may produce all the various phenomena of chemical affinity.

The difficulties to be accounted for in chemical affinities are their intenſity, their different degrees of ſtrength, and their being elective, or, which is the ſame thing, the capacity which one body has of diſplacing another.

How come affinities, it may be aſked, to differ in intenſity? Perhaps we might with propriety refer this queriſt to the ſtudy of Boſcovich's curve; but as our modern chemiſts are not generally verſant in ſuch ſtudies, we beg leave to obſerve, in this place, that we have no proof whatever of abſolute contact between bodies. On the contrary, it is highly probable, we had almoſt ſaid demonſtrable, that particles are in every inſtance at ſome diſtance from one another. For, on the ſuppoſition that two bodies were in actual contact, their attraction for each other would not only be as great as poſſible, but as great as the attraction of any other body for either of them *could poſſibly* be: Conſequently, it neceſſarily follows, that, ſince bodies chemically combined *can* be ſeparated, they are not in actual contact (A); but if they are not in contact, their diſtance from one another

(A) Perhaps the following demonſtration, which we borrow from the ingenious Mr Broughman, will render this more evident. In fig. 7. let the body A have for P an attraction which at the diſtance of AP is proportional

Plate XVII.

Affinity. another *may* vary in different cafes, and the force of affinity will vary with the diftance. Here then is a reafon why the affinity of different bodies varies in ftrength. Sulphuric acid, for inftance, has a ftronger affinity for barytes than for lime; becaufe when the combinations are formed, the diftance between the acid and barytes is not fo great as that between the acid and lime.

But why do the diftances differ? If affinity be the fame with gravitation, it muft tend to bring the particles nearer one another: And what then prevents the lime from approaching as near the acid as the barytes does? We reply, *the figure of its particles*. This anfwer was firft given to the queftion by Buffon, and it is fully adequate to folve the difficulty. The particles of bodies, indeed, are a great deal too minute for us to difcover their figure by actual infpection; but the phenomena of cryftallization fhew us that this difference actually exifts.

The cryftals of every body affume a peculiar figure. Now as thefe cryftals are all formed in the fame manner, and by the fame law, it is impoffible to conceive any other reafon for their variety but the difference in the form of the particles which compofe them.

But why does one body difplace another? When a particle of barytes is brought within a certain diftance of a particle of fulphuric acid and lime combined together, affinity acts and draws them nearer to one another; and the barytes, from its figure, approaches nearer the acid than the lime could, and forms with it a compound, the figure of which is fuch, relatively to that of the lime, that they cannot approach within a fmall enough diftance of each other to counteract the attraction of the earth. Accordingly no compound is formed; for all that is meant by two particles having formed a compound, is, that their attraction for each other is greater than the attraction of the furrounding bodies for either.

566 Confequently it ought to be confidered as the *fame*.

Having thus feen that none of the phenomena of *affinity* are inconfiftent with their refulting from the forces which bring about the phenomena of gravitation, we have a right to conclude, that it is at leaft highly probable, that all the motions of the corporeal world are produced by the fame power which, though not effential to matter, was impreffed upon every atom of it by the Great Creator when he formed this univerfe; and that as the effects of this power are modified according to the fituation of the bodies on which it acts, they are known by the different names of *gravity*, *adhefion*, *cohefion*, and *affinity*.

Gravity is the attraction between bodies fo diftant, that the maffes alone influence the refult, and that the power may be confidered as placed in the centre of the attracting bodies.

Adhesion fuppofes a diftance too fmall for our fenfes. It has been demonftrated to be proportional to the number of touching points, which depends upon the figure of the particles that form the bodies.

Cohesion takes place only between particles of the fame nature. Thefe, inftead of touching only in one fuperficies, as in adhefion, touch in every point where their figure will allow contact: confequently the force of cohefion alfo muft depend upon the figure of the particles.

Affinity unites bodies of a different nature, not merely by one fuperficies, as *adhefion* does, but particle to particle, like *cohefion*; and the moft perfect contact is formed that the figure of the particles will admit. Therefore, in this cafe alfo, the intenfity depends upon the figure of the particles.

567 Saturation explained.

3. If we make the attempt, we fhall find that water will not diffolve any quantity of common falt that we pleafe. Water which refufes to take up any more is faid to be *faturated* with falt. Neither can we combine *any* quantity of potafs with a given portion of fulphuric acid: we may add as much of it as we pleafe, indeed; but if we evaporate the liquid, in order to obtain the falt in cryftals, we fhall find that only *part* of the potafs has united with the acid, and that the reft has cryftallized feparately. From thefe examples, it muft appear evident, that bodies combine with one another by affinity only in certain proportions; or, which is the fame thing, that a determinate number of particles of each of the ingredients goes to the formation of an integrant particle of the compound, and that into this integrant *no additional particles* of either ingredient *can* be admitted. Let us fuppofe, for inftance, that the particles of fulphuric acid are tetrahedrons, and that the particles of potafs are of fuch a form, that one of them can attach itfelf to each of the fides of the acid particle: In that cafe an integrant particle of fulphat of potafs would be compofed of five particles, one of acid and four of alkali; for it is evident, that juft four particles of potafs would combine with every particle of acid, and that the acid would then be faturated, or, which is the fame thing, would be incapable of receiving any more alkaline particles into combination with it. Let us fuppofe now, that there is juft as much potafs as faturates the acid; if more acid be poured in, it cannot enter into combination with the potafs, becaufe all the potafs is already combined with acid.

Thus it appears evident, from the nature of affinity, that the ingredients in every combination muft mutually *faturate* each other, and that no more of either can be

---

tional to PM; then let P move towards A, fo as to come to the fituation P′, and let the attraction here be P′M′; as it is continual during the motion of P to P′, MM′ is a curve line. Now in the cafe of the attraction of bodies for one another, PM is lefs than P′M′; and confequently MM′ does not ever return into itfelf, and therefore it muft go *ad infinitum*, having its arc between AB and AC, to which it approaches as afymptotes, the abfciffa always reprefenting the diftance, and the ordinate the attraction at that diftance. Let P′ now continue its motion to P″, and M′ will move M″; and if P″ meets A, or the bodies come into perfect contact, P″M′ will be infinite; fo that the attraction being changed into cohefion will be infinite, and the bodies infeparable, contrary to univerfal experience; fo that P can never come nearer to A than a given diftance. *Nicholfon's Journal*, I. 555.

Affinity.

be admitted into the compound than what is necessary to produce this saturation. It follows equally, that there can be *no union* without saturation, except there be a deficiency in some one of the ingredients: For supposing that there is a sufficient number of particles of potass, and that every particle of sulphuric acid requires four of them, as before, for saturation, the very same cause that produces the union of one, two, or three particles of potass with a particle of acid, must produce the union of all the four.

Even when there is a deficiency of one of the ingredients, saturation must equally take place; for those particles of acid that happen to be nearest the alkali must still be saturated; because the affinity of all the acid particles for alkali was originally equal, and the difference of the distance must give the superiority to those that are nearest; and those particles of acid that are once saturated with potass cannot be deprived of it by any of the other particles, otherwise the affinity of some particles of sulphuric acid for potass would be greater than that of others; which is absurd.

It will no doubt be objected to all this, that there are innumerable instances of additional portions of some one of the ingredients being received into a compound after saturation, and that some substances seem to be equally well saturated with different doses of another. Oxygen, for instance, combines with azot in three different proportions, and forms nitrous gas, nitrous acid, and nitric acid. The metals, too, form, in the same manner, different oxides; and a great many instances of the same kind occur among the neutral salts.

But it ought to be remembered, that the conclusions against which these objections are urged, are consequences deduced, we think fairly, from a proposition which we consider as demonstrated, that *affinity is a species of attraction* (B). These phenomena cannot therefore be admitted as valid objections, except it can be shewn that they are really *incompatible* with these conclusions. Now that this is not the case, has been shewn, in the most satisfactory manner, by Morveau*. These apparent exceptions are owing to an affinity which exists between the compound as an integrant and one of its ingredients, and are not instances of various degrees of saturation, but of the formation of new compounds. According to this very ingenious idea, which, we believe, first originated with Bergman, and was first seen in its full extent by Morveau, we have formerly explained in what manner the various metallic oxides are formed: the first oxide is a compound of the metal and oxygen; the second, of the first oxide and oxygen; the third, of the second oxide and oxygen; and so on. In the same manner we have explained the various combinations of azot and oxygen: and the explanation may easily be extended to every other case. These apparent objections, then, are not incompatible with the above conclusions, but perfectly consistent with them; and consequently they cannot be admitted as of any force.

* Encyc. Method. i. 560.

There is one phenomenon, indeed, which proves, independent of these conclusions, that these combinations are actually formed in the manner we have supposed, and which therefore merits particular attention. The phenomena is, that the affinity between the two simple substances is *almost always greater* than that between the compound and any of its ingredients. The affinity, for instance, between azot and oxygen is greater than that between nitrous gas and oxygen; and the affinity between nitrous gas and oxygen greater than that between nitrous acid and oxygen: For if nitrous gas be mixed with nitric acid, the whole is converted into nitrous acid; but no change whatever is produced when nitric and nitrous acids, or nitrous gas and nitrous acid, are mixed: and every substance which is capable of decomposing nitrous gas is capable also of decomposing nitrous and nitric acids; but many substances are capable of decomposing nitrous and nitric acids which have no effect upon nitrous gas. In the same manner, the affinity between sulphur and oxygen is greater than that between sulphurous acid and oxygen: for when sulphur is mixed with sulphuric acid, the whole is converted into sulphurous acid; but no change takes place when sulphur and sulphurous acid, or sulphurous and sulphuric acids are mixed together. A great many instances of the same kind might easily be produced, if these were not sufficient to establish the point. This curious fact affords a very strong proof that the bases, as well as the quantity of oxygen, is different in almost all the vegetable acids. Did the tartarous, oxalic, and acetous acids, for instance, consist of the same base with various doses of oxygen; were the tartarous composed of the base and oxygen; the oxalic, of tartarous acid and oxygen; the acetous, of oxalic acid and oxygen: in that case, a mixture of acetous and tartarous acids ought to form oxalic acid: but that this does not happen, any one may convince himself by actual experiment.

We do not mean to affirm that this fact, though it is certainly very often true, holds in all cases; in some, perhaps, the reverse may be true, though we do not recollect at present any instance of that kind.

568 Of the strength of affinity.

4. Since the affinity of almost every two bodies for each other differs *in strength* from that between every other two, it becomes an important problem *to determine the strength of every affinity in numbers*. The solution of this problem would give a clearness and precision to chemistry equal to that of any other branch of natural philosophy whatever, and enable it to advance with a degree of rapidity hitherto thought unattainable. No wonder, then, that this problem has occupied the attention of some of the most eminent philosophers who have dedicated their time to chemistry.

569 Attempts to ascertain it.

If the observations formerly made, in order to shew that

(B) Were any farther proof of this proposition required, we would observe, that *cohesion* acts as an antagonist to affinity, and may be often rendered so strong as to prevent affinity from acting with efficacy. Thus alumina and jargonia, when sufficiently heated, become insoluble in acids, without undergoing any other alteration than that of an increase of cohesion by their particles being brought nearer each other; for destroy this cohesion, and they become as soluble as ever. Now it follows from this, that if cohesion be *attraction*, so must *affinity*. The experiments of Morveau, to be afterwards mentioned, demonstrate, that *adhesion* and *affinity* are produced by the same cause: Consequently, if adhesion be attraction, so must affinity.

Affinity.

that the difference in the strength of affinities depends upon the different forms of the particles which have an affinity for each other, be conclusive, it is evident that the certain method of learning the strength of affinities would be to discover the forms of the parricles of all bodies. But no method has hitherto been discovered by which it is possible of becoming acquainted with the figure of the particles of bodies. The experiments indeed of the Abbé Hauy (afterwards to be described) point out a method by which the primary figure of crystals may be investigated with a good deal of plausibility; but this leaves the knowledge of the figure of the particles which compose these crystals still uncertain.

As nobody, therefore, has attempted to take this road, in order to calculate the strength of affinities, let us at present consider the different methods which have been proposed for that purpose, that we may see whether any of them will answer the end intended.

570 By Wenzel,

Wenzel supposed that the time taken by one body to dissolve another is a measure of the affinity which subsists between them. But the hypothesis of that ingenious philosopher will not bear the test of examination; for the *time* of solution evidently depends upon circumstances unconnected with affinity. The cohesion of the body to be dissolved, and the nature of the compound formed, must occasion very great differences in the time of solution of different bodies, even on the supposition that their affinities were all the same.

571 Fourcroy,

Fourcroy proposed to measure the affinity of bodies by the difficulty of separating them after they are combined: but we have no method for measuring this difficulty. Lavoisier and De la Place, indeed, proposed *caloric* for this purpose; but there are many compounds which caloric cannot separate; and it never produces a separation except by means of its affinity for one or other of the ingredients of the compound. Before caloric, therefore, could be employed as a measure, it would be necessary to know exactly the strength of its own affinity for every other substance; which is just a case of the problem to be resolved.

572 Macquer,

Macquer supposed that the affinity of bodies for one another was in the compound ratio of the facility of their union and the difficulty of their separation: But as we are in possession of no method of ascertaining either of these, it is evident that this theory, even allowing it to be just (which it certainly is not), could be of no use for assisting us to calculate the force of affinities.

573 Morveau,

Another method has been proposed by the distinguished philosophical chemist Mr de Morveau (c).

In 1713 Dr Brook Taylor made some experiments on the adhesion of surfaces; and concluded from them, that the force of adhesion might be determined by the weight necessary to produce a separation. But in 1772, Messrs La Grange and Cigna, observing that the surfaces of water and oil adhere together, and taking it for granted that these two liquids *repel* each other, concluded, in consequence, that their adhesion was not owing to *attraction*; and hence inferred, that *adhesion*, in general, is always owing to the pressure of the atmosphere. This conclusion induced Morveau to examine the subject: he found that adhesion was *not affected* by the pressure of the atmosphere; for it required the same weight to separate a disk of glass (30 lines in diameter) from the surface of mercury in the open air, and under an exhausted receiver. He observed that the same disk adhered to water with a force of 258 grains, and to the solution of potass, though denser, only with a force of 210. This result not only proved that adhesion was owing to attraction, but made him conceive the possibility of applying this method to the calculation of affinities: For the force of adhesion being necessarily proportional to the points of contact, and this being the case also with affinity, it is evident that the adhesion and the affinity between the same substances are proportional, and that therefore the knowledge of the one would furnish us with the ratio of the other.

Affinity.

Struck with this idea, he constructed cylinders of different metals, perfectly round, an inch in diameter and the same in thickness, and having a small ring in their upper surface, by which they might be hung exactly in equilibrium. He suspended these cylinders, one after another, to the beam of a balance; and after counterpoising them exactly, applied them to a quantity of mercury placed about two lines below them, making them slide along its surface, to prevent any air from lodging between them and the mercury. He then marked exactly the weight necessary to overcome their adhesion, taking care to change the mercury after every experiment. The table of the results is as follows:

Gold adheres to mercury with a force of	446 gr.
Silver, - - - - - - -	429
Tin, - - - - - - -	418
Lead, - - - - - - -	397
Bismuth, - - - - - -	372
Platinum, - - - - - -	282 *
Zinc, - - - - - - -	204
Copper, - - - - - -	142
Antimony, - - - - - -	126
Iron, - - - - - - -	115
Cobalt, - - - - - - -	8

* *Morveau, Ann de Chim.* xxv. 10.

The differences of these results cannot be owing to the pressure of the air, which was the same in all; nor do they correspond to the densities of the metals; nor can they be owing to accidental differences in the polish of the cylinders, for a plate of rough iron adheres more strongly to mercury than one of the same diameter exquisitely polished;—but they follow precisely the order of affinity, and therefore may be considered as the measure of the strength of the affinity between these different metals and mercury. They furnish us also with a convincing proof that *affinity* is *attraction*, and the same species of attraction with *adhesion*; and that therefore, if the one be reducible to *gravitation*, so must the other.

Mr Achard, convinced of the importance of Mr Morveau's observations, made a great many experiments on *adhesion*, and published the result of them in 1780. He proved

(c) Now Mr Guyton: we have used the old name all along in the text to avoid ambiguity.

Affinity.

proved that the force of adhesion was not affected by alterations in the height of the barometer, but that its force became weaker as the heat of the fluid increased (D); and that the temperature remaining the same, the force of adhesion increased in the same ratio with the surfaces of the adhering bodies. He made about 600 experiments on the adhesion of different solids and fluids, proved that the force of adhesion did not depend on the densities of the adhering bodies, nor on the different cohesive force of the fluids; and, after a laborious calculation, concluded that it depended on the figure of the particles of the adhering fluid and solid.

These experiments and calculations of Mr Achard are certainly of importance; and we would have given them here, had not the objects of them been substances which can furnish but few data for calculating the force of affinities.

This method of measuring the force of affinities seems to be an accurate one, and if it could be applied to every case of affinity, would, in all probability, enable us to solve the problem which we are now considering: But, unfortunately, its application is very limited, being confined to those cases alone in which one of the bodies can be presented in a fluid, and the other in a solid state. Nor can it be applied indiscriminately to all those cases; for whenever the cohesion of any liquid is much inferior to the force of its adhesion to any solid, the separation takes place in the particles of the liquid itself, and consequently we do not obtain the measure of its adhesion to the solid, but of its own cohesion, and that, too, imperfectly. Thus, for instance, Mr Achard found that sealing-wax adhered to water with a force of 92 grains, and to alcohol only with a force of $53\frac{3}{4}$ths; yet we know that sealing-wax has a greater affinity for alcohol than for water; because alcohol dissolves it, which water is incapable of doing. The difference in the result in this instance was evidently owing to the smaller cohesion of alcohol. Mr Morveau's method must therefore be confined to those cases in which the cohesion of the liquid is stronger than its adhesion to the solid, which may be known by the surface of the solid not being moistened; and to those in which the cohesion is not much inferior to the adhesion; for then, it is evident, that the force of cohesion will be increased as the force of adhesion. Let us suppose, for instance, that two solids, A and B, are made to adhere to the surface of a liquid, and that A can only form an adhesion with 50 particles of the liquid, whilst B adheres to 100; it is evident that a much smaller force will destroy the cohesion of the 50 particles to which A adheres with the rest of the liquid, than what will be required to destroy the cohesion of the 100 particles united to B with the same liquid *.

* Morveau, Encyc. Method. Chim. art. Adhesion.

The method of Mr Morveau, then, may be applied with accuracy in both cases; and *when* they occur can only be determined by experiment. It cannot, however, be applied indiscriminately even then; for unless the solid and the fluid be presented in such a state that no gas is extricated when the adhesion takes place, an accurate judgment cannot be formed of the force of adhesion. When marble (carbonat of lime), for instance, is applied to the surface of sulphuric acid, there is an extrication of gas, which very soon destroys the adhesion, and prevents an accurate result. Were it possible to employ quicklime instead of marble, this would be prevented; or if this cannot be accomplished, why might not lime be employed, united with some acid that would not assume a gaseous form, and at the same time has a weaker affinity than sulphuric acid for lime? Why might not the phosphat of lime, for instance, be used, which may be reduced to a state of hardness sufficiently great for the purpose? The extrication of gas, during the application of metals to the surfaces of acids, might be prevented by oxidating their surfaces. It is true, indeed, this could not be done with all the metals, on account of the nature of the oxide, but it might with several; copper, for instance, and silver. It cannot be doubted, that by these methods, and other contrivances that might be fallen upon, a sufficient number of results might be obtained to render this method of the greatest importance. It is rather surprising, therefore, that it has never been prosecuted.

574 And Kirwan.

Mr Kirwan has proposed another method of solving the problem. While he was engaged in his experiments on the strength of acids, he observed that the quantity of real acid necessary to saturate a given quantity of each of the bases, was inversely as the affinity between the respective bases and the acid; and that the quantity of each of the bases necessary to saturate a given quantity of acid was directly as the affinity between the base and the acid. Thus 100 grains of each of the acids require more alkali for saturation than lime, and more lime than magnesia, as may be seen in the following table:

100 grains of	Potass.	Soda.	Lime.	Amm.	Mag.	Alum.
Sulphuric acid	215	165	110	90	80	75
Nitric acid	215	165	96	87	75	65
Muriatic acid,	215	158	89	79	71	55

He concluded, therefore, that the affinity between acids and their bases may be estimated by the quantity of bases necessary for saturation. Thus the affinity between potass and sulphuric acid is 215, and that between nitric acid and lime 96 *.

* Phil. Trans. 1783.

We have mentioned formerly, that the principle on which Mr Kirwan calculated the strength of the acids was founded on a mistake. It must follow of course, therefore, that the numbers which result from it must also be wrong. This Mr Kirwan has acknowledged, and seems to have given up all thoughts of ascertaining the strength of affinities by this method. But before it be abandoned altogether we wish the following observations were considered.

575 Attempt to remedy the defects of his method;

Bergman long ago established as a principle, under the name of a chemical paradox, that *the stronger any salt was, the less of any other it required for saturation.* Thus, according to him,

100

(D) Strictly speaking, this is owing not so much to a decrease of the force of adhesion, as of that of the cohesion of the fluid itself.

Affinity.

100 parts of potaſs require 78,5 Sulphuric acid,
64 Nitric,
51,5 Muriatic,
42 Carbonic,
100 parts of ſoda - - 177 Sulphuric,
135,5 Nitric,
125 Muriatic,
80 Carbonic.

This propoſition, which has been admirably illuſtrated by Morveau *, evidently reſolves itſelf into the two following:

1. A *baſe* requires *the more* of an acid for ſaturation *the ſtronger* its affinity for that acid is.

2. An *acid* requires *the more* of any baſe for ſaturation *the greater affinity* it has for that baſe.

* Encyc. Method. Chim. i. 597.

In order to judge of the truth of the firſt of theſe propoſitions, let us examine the following table, drawn up from the experiments of Bergman, Wenzel, and Kirwan.

	Bergman.			Wenzel.			Kirwan.		
100 parts of	Sulphuric.	Nitric.	Muriatic.	Sulphuric.	Nitric.	Muriatic.	Sulphuric.	Nitric.	Muriatic.
Barytes	15,4		30,8						
Potaſs	78,6	64	51,5	82,4	107,7	54	81,8	87,1	78,2
Soda	175	135,5	125	125,8	166,6	83	129,4	136,1	114,2
Lime	143,7	134,4	70,45	147,74	195,6	103,6	141	180	86
Magneſia	173,67	159,25	82,92	181,8	257,15	122,27	170,5	255	104,275
Ammonia				142,42	201,22	96,25	187,5	233	116
Alumina	211,11		220,2	77,7	68,7	38,6			

It is evident at firſt ſight, that Bergman's experiments correſpond exactly with the propoſition. To ſaturate, according to him, 100 parts of potaſs, requires 78,6 of ſulphuric acid, 64 of nitric, and 51,5 of muriatic acid. There is only one deviation from the propoſition in the whole table, and this regards barytes, which, according to him, is ſaturated with 15,4 of ſulphuric and 30,8 of muriatic acid. But Mr Morveau has ſhewn, by ſeveral accurate experiments, that barytes requires much more ſulphuric acid for ſaturation than Bergman ſuppoſed *. And Klaproth has ſhewn, that 100 parts of barytes require 49,2 of ſtrong ſulphuric acid for ſaturation †. And Dr Withering's calculation ‡ agrees almoſt exactly with this; nor does that of Fourcroy differ much from it §. Inſtead of 15,4 of ſulphuric acid, therefore, which, according to Bergman, are neceſſary to ſaturate 100 of barytes, it ſhould be 42,8.

* Encyc. Method. Chim. i. 591.
† Chim. Ann. ii. 1785.
‡ Phil. Tranſ. 1784.
§ Ann. de Chim. iv. 65.

The firſt and laſt columns of Wenzel and Kirwan's experiments agree equally well with the propoſition, but the ſecond deviates from it completely. Wenzel probably might have been miſled by the manner of performing his experiments; but the ſame objection does not ſeem to lie againſt thoſe of Kirwan.

It can ſcarcely be doubted, however, to whatever cauſe the error is to be imputed, that the numbers in the ſecond column of Mr Kirwan's table are too large. The following experiment of Morveau is ſufficient to ſhew this.

According to Mr Kirwan's experiments, the proportions of acid and alkali in the four following ſalts are as under:

Sulphat of potaſs { Acid 100, Potaſs 108,7 }

Sulphat of lime { Acid 100, Lime 80,6 }

Nitrat of potaſs { Acid 100, Potaſs 83,33 }

Nitrat of lime { Acid 100, Lime 34,4. }

Now when ſulphat of potaſs and nitrat of lime are mixed together, a double decompoſition takes place, and ſulphat of lime and nitrat of potaſs are formed. Let theſe two ſalts be mixed together; let the quantity of ſulphat of potaſs be ſuch, that the acid contained in it amounts to 100; and let a more than ſufficient quantity of nitrat of lime be added, to ſaturate the ſulphuric acid with lime. It is evident that for that purpoſe 80,6 of lime muſt be preſent; and the quantity of nitric acid combined with theſe 80,6 muſt be 234,4. This quantity would require for ſaturation 195,32 of potaſs, but there are only 108,7 in the mixture; conſequently there ought to exiſt in the mixture, after the mutual decompoſition of the ſalts, 64,87 of nitric acid in a ſtate of liberty. Such would be the reſult, provided Mr Kirwan's numbers were accurate; but the fact is, that no ſuch exceſs of acid exiſts in the mixture †; and conſequently the quantity of nitric acid contained in nitrat of lime is ſtated too high by Mr Kirwan. Although therefore Mr Kirwan's tables do not coincide with the propoſition which we are conſidering, this is not to be conſidered as a proof of its falſehood; as there is reaſon, from the experiment above deſcribed, to ſuſpect ſome error in the data from which Mr Kirwan calculated the ſtrength of the acids.

† Ann. de Chim. xxv. 295.

The truth of the ſecond propoſition may be judged of by the following Tables:

According to Bergman.

100 parts of	Baryt.	Potass.	Soda.	Lime.	Magn.	Amm.	Alum.
Sulp. acid	646	127,5	56,5	69,5	578	42	473
Nitric acid		148,4	74,4	74,4	62,8		
Mur. acid	324,7	194	78	141,9	120,5		40

According to Wenzel.

100 parts of	Byryt.	Potass.	Soda.	Lime.	Magn.	Amm.	Alum.
Sulp. acid		120,8	79,16	67,2	55	70,2	128
Nitric acid		92,7	60	51,1	38,8	49,7	147,8
Mur. acid		183,8	119,2	96,5	81,7	103,9	259

According to Kirwan.

100 parts of	Baryt.	Potass.	Soda.	Lime.	Magn.	Amm.	Alum.
Sulp. acid		122,2	77,2	70,4	57,3	53,3	
Nitric acid		112	73,8	55,5	39,2	44,8	
Mur. acid		168,6	133	112,7	89,9	78,5	

It appears that all the table of Bergman agrees with the propofition except the numbers which correfpond to fulphat of foda, fulphat of alumina, nitrat of lime, and muriat of foda, which the late experiments of Mr Kirwan have fufficiently fhewn to be inaccurate.

Wenzel's table correfponds exactly, except the columns under ammonia and alumina, which Morveau has proved to be inaccurate.

Kirwan's table correfponds exactly, except with regard to the quantity of ammonia neceffary to faturate muriatic acid, which does not appear to have been accurately determined by experiment.

Let us therefore take the truth of thefe two propofitions for granted, and let us confider every deviation from them as an error; and let us fee whether they will enable us to difcover the abfolute affinity of fulphuric, nitric, and muriatic acids, for their refpective bafes.

Table I. *Quantity of Bafe neceffary to Saturate* 100 *Parts of the three Acids.*

100 parts	Baryt.	Potass.	Soda.	Lime.	Magn.	Amm.
Sulph. acid	233,3	123,3	78,7	68,3	56,8	49,3
Nitric acid	258,4	148,4	95,6	74,4	62,8	54,8
Muriat. acid	324,7	188,8	126,1	116,7	97,3	78,5

Table II. *Quantity of Acid neceffary to Saturate* 100 *Parts of the fix Bafes.*

100 parts	Sulph. acid.	Nitric acid.	Mur. acid.
Barytes	42,8	38,7	30,8
Potafs	81	64	52,9
Soda	126,7	101,4	79
Lime	145,7	134,4	87,5
Magnefia	176,2	159,25	105,4
Ammonia	202,6	182,4	127,25

The firft of thefe tables reprefents the affinity between the fame acid and its various bafes; and the fecond that of the bafes for the different acids. If it were required to know the ratios of the affinity which different bafes have for any particular acid, the firft table, fuppofing it accurate, would give it exactly. In like manner, if it were required to know the ratios of the affinity of the acids for the various bafes, we would find them in the fecond table.

576 And to conftruct tables of affinity.

But if we wifhed to know what was the affinity between one acid and bafe, compared with that between another acid and a different bafe; or if we wanted to have not the relative but the abfolute affinity between two bodies—it is plain that we could not find it in either of the tables; for the abfolute affinity muft confift of two things, the affinity which the acid has for the bafe, and the affinity which the bafe has for the acid. Now the firft table gives us the one of thefe, and the fecond the other; fo that in order to reprefent affinity in abfolute numbers, the two tables muft be multiplied into one another. This was the miftake into which Mr Kirwan fell. His method confifted merely in conftructing a table like our firft, which (fuppofing the numbers accurate) gave only the affinity between the bafes and the fame acid, but left out the affinity between the different acids and the fame bafe; confequently the different columns could not be compared with each other.

It is evident, however, that if the tables were multiplied together in their prefent ftate, they could not poffibly give an accurate table of affinities. For that purpofe, it is neceffary to put the fame number in the firft column of each table, and then to fubftitute other numbers in the remaining columns, having the fame ratio to one another with the numbers in the original columns. This is done in the following Tables:

Table I. *Ratios of the Affinity of fix Bafes for three Acids.*

	Barytes.	Potass.	Soda.	Lime.	Magn.	Amm.
Sulph. acid	100,00	52,85	33,73	29,27	24,34	21,12
Nitric acid	100,00	57,43	36,98	28,77	24,28	19,59
Mur. acid	100,00	58,11	38,81	35,70	29,94	24,15

Table

Affinity.

Table II. *Ratios of the Affinity of three Acids for six Bases.*

	Sulph. acid.	Nitric acid.	Mur. acid.
Barytes	100,00	90,42	74,54
Potafs	100,00	79,01	65,30
Soda	100,00	80,03	62,35
Lime	100,00	92,24	60,05
Magnefia	100,00	90,34	59,68
Ammonia	100,00	90,02	62,77

Table III. *Affinity between three Acids and six Bases in Absolute Numbers.*

	Sulph. acid.	Nitric acid.	Mur. acid.
Barytes	10000	9042	7454
Potafs	5285	4537	3794
Soda	3373	2969	2419
Lime	2927	2653	2143
Magnefia	2434	2193	1786
Ammonia	2112	1763	1515

On the fuppofition that the two propofitions mentioned above were ftrictly true, and that the numbers which we fixed upon were precifely the quantities of acid and bafe neceffary to faturate each other reciprocally, this laft table would reprefent accurately in numbers the ftrength of the affinities of the three acids for each of the fix bafes refpectively.

We muft acknowledge, however, that the truth of thefe propofitions has not hitherto by any means been fufficiently proved; but a great number of facts concur to render them exceedingly probable, and highly worthy of the attention of chemical philofophers. And we hope that the method propofed by Morveau, and which had been previoufly practifed by Richter, of verifying theoretical calculations of the compofition of the falts, by mixing together two falts which mutually decompofe each other, and afcertaining whether the refult correfponds with calculation, will be followed out, and that it will be the means of enfuring more accuracy than it has hitherto been poffible to obtain.

No one will fufpect that any thing which has here been faid is meant as a reflection on the ingenious chemifts who have attempted to folve this moft difficult of all chemical problems, the proportion of the ingredients which enter into the compofition of the falts. Mr Kirwan, in particular, is entitled to the greateft praife for the perfevering induftry with which he has profecuted the fubject, for the candour which he has difplayed, and for the new rout which he has opened to the chemical philofopher. Though this problem has not hitherto been folved, and though the difficulties which furround it are almoft infurmountable, we may hope much from the general fenfe which is at prefent entertained of its importance, and from the zeal and abilities of thofe philofophers who have particularly turned their attention to it.

577 Morveau's table of affinity.

In the mean time, the following Table of the ftrength of affinities by Morveau, though the numbers be arbitrary, will be found of very great ufe *.

	Sulph. acid	Nitric acid.	Muriat. acid.	Acetous acid.	Carbonic acid.
Barytes	66	62	36	28	14
Potafs	62	58	32	26	9
Soda	58	50	31	25	8
Lime	54	44	24	19	12
Ammonia	46	38	21	20	4
Magnefia	50	40	22	17	6
Alumina	40	36	18	15	2 (D)

5. Although every chemical combination is produced by the fame general law, yet as their phenomena vary fomewhat according to circumftances, affinities have, for the fake of greater perfpicuity, been divided into claffes. Thefe claffes may be reduced to *three*—*fimple*, *compound*, and *difpofing* affinities. 578 Three claffes of affinity,

The *firft clafs* comprehends all thofe cafes in which only *two bodies combine* together; as, for inftance, fulphuric acid and potafs, oxygen and carbon. The affinities which belong to this clafs are known by the name of *fimple* or *fingle affinities*. Although one of the fubftances to be combined happens to be already united with another body, the combination is ftill reckoned a cafe of fingle affinity. Thus fuppofe the fulphuric acid previoufly combined with magnefia, and forming with it the falt called *fulphat of magnefia*, as foon as potafs is prefented, the acid leaves the earth (which is precipitated), and unites with the alkali. Even when three bodies combine, it often happens that the union is produced merely by fingle affinity. Thus, when fome potafs is dropped into tartarous acid, part of the acid unites with the alkali, and forms tartrite of potafs; after this the remainder of the acid combines with the tartrite juft formed, and compofes a new falt known by the name of *acidulous tartrite of potafs*, or *tartar*. This is evidently nothing elfe than two inftances of fimple affinity immediately following each other. 579 Viz. fimple affinity,

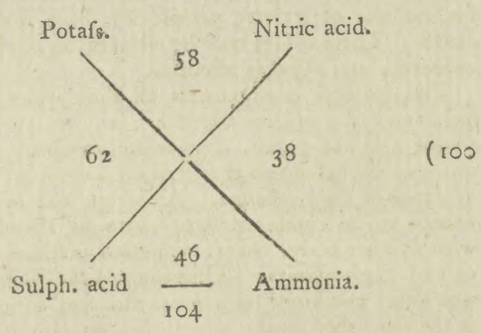
When more than three bodies are mixed, decompofitions and new combinations often take place, which could 580 Compound affinity,

* *Encyc. Method. Chim.* i. 773.

(D) This table, however, does not correfpond quite accurately to all the phenomena. For inftance, according to it, fulphat of barytes is not decompofed by carbonat of foda, although the contrary takes place in fact.

Affinity.

could not have been produced had the bodies been presented in a different ſtate. If, for inſtance, into a ſolution of ſulphat of potaſs there be poured nitric acid, no decompoſition is produced, becauſe the ſulphuric acid has a ſtronger affinity for potaſs than nitric acid has. For the very ſame reaſon, ammonia may be poured into the ſolution without producing any change. But if nitrat of ammonia be poured in, a decompoſition inſtantly takes place, and two new bodies, *ſulphat of ammonia* and *nitrat of potaſs*, are formed. Such caſes of decompoſition form the *ſecond claſs of affinities.* They were called by Bergman caſes of *double elective attraction ;* a name which is exceedingly proper when there are only four bodies concerned. But as there are often more than four, it is neceſſary, as Mr Morveau has obſerved, to employ ſome more comprehenſive term. We ſhall therefore call the affinities belonging to this claſs *compound affinities* (E) ; and comprehend under the term all caſes where more than three bodies are preſent, and produce combinations which would not have been formed without their united action. In theſe caſes the affinity of all the various bodies for each other acts, and the reſulting combination is produced by the action of thoſe affinities which are ſtrongeſt. The manner in which theſe combinations and decompoſitions take place, was firſt clearly explained by Dr Black. Let the affinity between potaſs and ſulphuric acid be = 62; that between nitric acid and ammonia = 38 ; that between the ſame acid and potaſs = 58 ; and that between the ſulphuric acid and ammonia = 46. Now, let us ſuppoſe that all theſe forces are placed ſo as to draw the ends of two cylinders croſſing one another, and fixed in the middle in this manner,



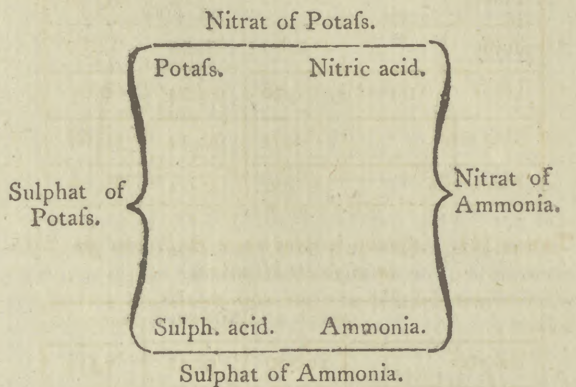
It is evident, that as 58 and 46 = 104, are greater than 62 + 38 = 100, they would overcome the other forces and ſhut the cylinders. Juſt ſo the affinity between potaſs and nitric acid, together with that between ſulphuric acid and ammonia, overcomes the affinity between potaſs and ſulphuric acid, and that between nitric acid and ammonia, and produces new combinations.

In all caſes of compound affinity, there are two kinds of affinities to be conſidered ; 1*ſt*, Thoſe affinities which tend to preſerve the old compound, theſe Mr Kirwan has called *quieſcent* affinities ; and thoſe which tend to deſtroy them, which he has called *divellent* affinities.

Thus, in the inſtance above given, the affinity between potaſs and ſulphuric acid, and that between nitric acid and ammonia, are quieſcent affinities, which endeavour to preſerve the old compound ; and if they are ſtrongeſt, it is evident that no new compound can take place. On the contrary, the affinity between potaſs and nitric acid, and that between ſulphuric acid and ammonia, are divellent affinities ; and as they are in this caſe ſtrongeſt, they actually deſtroy the former combinations and form new ones.

Affinity.

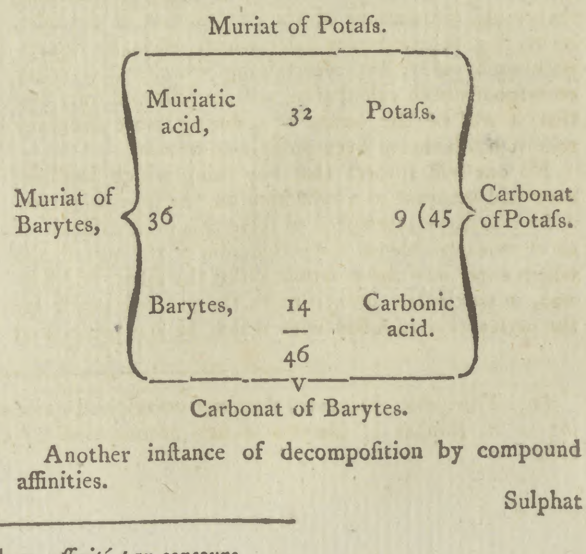
Bergman, who publiſhed a great many caſes of compound affinities, employed to explain them a method ſomewhat different from this. He would have repreſented the above caſe in the following manner :



At the four corners of an imaginary ſquare are placed the four ſubſtances, ſo that one acid ſhall be diagonally oppoſite to another. On the right and left ſide of the ſquare are placed the old compounds, each on the ſide of its own ingredients, and above and below are placed the new compounds.

Mr Elliot improved this method of Bergman, by adding numbers expreſſive of the affinity of the various ſubſtances. It is in caſes of compound affinity that the ratios of affinities, if we were poſſeſſed of them, would be peculiarly uſeful. For it is evident, that if we knew the ſtrength of affinities in abſolute numbers, we would be able to determine before hand all the caſes of compound affinity.

If we knew, for inſtance, that the affinity between the muriatic acid and barytes were = 36; that between the ſame acid and potaſs = 32 ; the affinity between potaſs and carbonic acid = 9 ; and that between the ſame acid and barytes = 14 ;—we would be certain, previous even to experiment, that when muriat of barytes and carbonat of potaſs are mixed, a double decompoſition would take place ; which we know from experiment to be actually the caſe.



Another inſtance of decompoſition by compound affinities.

Sulphat

(E) Morveau called them *affinité par concours.*

		Sulphat of Lime.		
	Sulph. acid,	54	Lime.	
Sulphat of Ammonia,	46		44 (90	Nitrat of Lime.
	Ammonia,	38 — 92	Nitric acid.	
		Nitrat of Ammonia.		

Suppoſing Morveau's numbers exact, it follows alſo, even prior to experiment, that no decompoſition takes place when ſulphat of lime and muriat of potaſs are mixed;

	Sulphuric acid,	62	Potaſs.	
Sulphat of Lime,	54		32 (86	Muriat of Potaſs.
	Lime,	20 — 82	Muriatic acid.	

for the quieſcent affinities are 86, and the divellent only 82.

Nor when acetite of lime and muriat of ſoda are mixed;

	Acetous acid,	25	Soda.	
Acetite of Lime,	19		28 (47	Muriat of Soda.
	Lime,	20 — 45	Muriatic acid.	

becauſe the quieſcent affinities are 47, and the divellent only 45. Theſe caſes where no decompoſition takes place have been called by Morveau caſes of *inverſe* compound affinity.

Morveau has propoſed the following improvements in repreſenting theſe caſes of compound affinities*.

When decompoſition does not take place, nothing is to be written above and below the ſquare, as in the two laſt examples. When a new compound remains diſſolved, a ſtraight line is to be placed between it and the ſquare, as in the following ſcheme.

		Sulphat of Magneſia.		
	Sulphuric acid,	50	Magneſia.	
Sulphat of ſoda,	58		40 (98	Nitrat of magneſia.
	Soda,	50 — 100	Nitric acid.	
		Nitrat of Soda.		

When a new compound is precipitated, a line bent downwards in the middle is to be placed between it and the ſquare, as in the following ſcheme:

		Sulphat of Potaſs.		
	Sulph. acid,	62	Potaſs.	
Sulphat of Barytes,	65		9 (74	Carbonat of Potaſs.
	Barytes,	14 — 76	Carbonic acid.	
		Carbonat of Barytes.		

When a new compound is ſublimed, the line between it and the ſquare is to be pointed upwards in the middle, thus ⌐——^——¬.

When a new compound is partly diſſolved and partly precipitated, the line placed between it and the ſquare is to aſſume the following ſhape :——⌐——⌐.

When it is partly diſſolved and partly ſublimed, the following is the line to be uſed : ——⌐——¬.

581 And diſpoſing affinity.

The third claſs of affinities has been called by Mr Morveau *diſpoſing affinities*, becauſe they *diſpoſe* ſubſtances to combine that would not otherwiſe have done it. Suppoſe, for inſtance, that ſulphur is preſented to oxygen gas, it does not manifeſt any affinity for it; but combine it previouſly with potaſs, and it unites with oxygen with avidity. Its previous union with potaſs, in this caſe, *diſpoſed* it to unite with oxygen. The cauſe of this curious affinity is not yet well underſtood. If we conſider what it was that prevented the ſulphur and oxygen from combining, we ſhall find that it can only be its own attraction of coheſion, and the affinity between the oxygen and caloric which are combined. Whatever then diminiſhes this attraction of coheſion, or of *aggregation* as it has been called, muſt facilitate the union of

* *Encyc. Method. Chim.* i. 556.

Affinity.

of the sulphur with oxygen. This is done in some measure by the potass. Besides, if affinity depends upon the figure of particles, it is evident that there must be an affinity between the new compound and oxygen; but the moment the oxygen approaches within a certain distance of the sulphur, it unites with it, as its affinity is much greater for that substance than for the compound.

The following is another instance of this curious affinity: Sugar, as Lavoisier has proved, is composed of oxygen, hydrogen, and carbon: Now if concentrated sulphuric acid be poured upon sugar, the oxygen and hydrogen combine, and form water, which unites with the acid, and the carbon is precipitated. In this case, the presence of the acid *disposed* the oxygen and hydrogen to combine. In what manner this new combination is produced, it would not be easy to explain: not by weakening the attraction of cohesion; for we do not see how the acid could produce that effect. The only explanation that can be given, is to suppose that the sulphuric acid, when it approaches within a certain distance of the oxygen and hydrogen, attracts them; and that this attraction, together with the affinity between the oxygen and hydrogen, is greater than that which produces the combination between the ingredients of the sugar themselves: the consequence of which must be decomposition.

582 Why bodies require different temperatures to unite,

6. We come now to one of the most difficult questions in chemistry—Why do bodies require different temperatures in order to unite? and why does the presence of caloric in many cases favour or rather produce union, while it prevents or destroys it in others?

These questions were proposed at the end of the second Chapter of this article; and we reserved them for this place, not because we hoped to be able to answer them in a satisfactory manner, but because no intelligible answer could be given till the nature of affinity had been previously considered. Some substances, phosphorus for instance, combine with oxygen at the common temperature of the atmosphere; others, as carbon, require a higher temperature; and others, as hydrogen and azotic gas, do not combine except at a very high temperature. To what are these differences owing?

In answer to this question, we observe, that the attraction of *cohesion* evidently opposes that of *affinity*. Those bodies which we present to combine together are generally aggregates, or, which is the same thing, consist of many similar particles united by cohesion: for we have no method of separating bodies into their integrant particles, except *affinity*. Now we can conceive the attraction of cohesion between the particles of a body to be so great as to prevent them altogether from obeying the impulse of affinity. That this actually happens in some cases cannot be doubted: for if pure alumina be formed into a paste, and heated sufficiently, it becomes so hard that no acid can act upon it; yet its nature is not in the least changed: by proper trituration, it may be again rendered soluble; and when precipitated from this new solution, it has recovered all its original properties. The effect of the fire, then, was merely to increase the cohesion, by separating all the water, and allowing the particles to approach nearer each other.

It is evident, that whatever diminishes the cohesion which exists between the particles of any body, must tend to facilitate their chemical union with the particles of other bodies. This is the reason that bodies combine more easily when held in solution by water, or when they have been previously reduced to a fine powder. Now caloric possesses the property of diminishing cohesion. And one reason why some bodies require a high temperature to cause them to combine is, that at a low temperature the attraction of *cohesion* is in them superior to that of affinity; accordingly, it becomes necessary to weaken that attraction by caloric till it becomes inferior to that of affinity. The quantity of caloric necessary for this purpose must vary according to the strength of the cohesion and of the affinity; it must be inversely as the affinity, and directly as the cohesion. Wherefore, if we knew precisely the force of the cohesion between the particles of any body, and of the affinity between the particles of that body and of any other, we could easily reduce the temperature necessary to calculation.

That caloric or temperature acts in this manner cannot be doubted, if we consider that other methods of diminishing the attraction of cohesion may be substituted for it with success. A large lump of charcoal, for instance, will not unite with oxygen at so low a temperature as the same charcoal will do when reduced to a very fine powder; and charcoal will combine with oxygen at a still lower temperature, if it be reduced to its integrant particles, by precipitating it from alcohol, as Dr Priestley did by passing the alcohol through red hot copper. And to shew that there is nothing in the nature of oxygen and carbon which renders a high temperature necessary for their union, if they be presented to each other in different circumstances, they combine at the common temperature of the atmosphere; for if nitric acid, at the temperature of 60°, be poured upon charcoal powder, well dried in a close crucible, the charcoal takes fire, owing to its combining with the oxygen of the acid *: And in some other situations carbon is so completely divided, that it is capable of combining with the oxygen of the atmosphere, or, which is the same thing, of catching fire at the common temperature. This seems to be the case with it in those pyrophori that are formed by distilling to dryness several of the neutral salts which contain acetous acid †. These observations are sufficient to shew that caloric is in many cases necessary in order to diminish the attraction of *cohesion*.

* *Proust* and *Morveau*, *Encyc. Method. Chim.* i. 474.

† *Morveau*, *ibid.*

But there is a difficulty still remaining, How comes it that certain bodies will combine with oxygen without the assistance of any foreign heat, provided the combination be once begun, though a quantity of caloric is necessary to begin the combination? and that other bodies require to be surrounded by a great quantity of caloric during the whole time of their combining with oxygen? Alcohol, for instance, if once kindled, burns till it is quite consumed; and this is the case with oils also, provided they be furnished with a wick.

We must observe, in the first place, that we would err very much, were we to suppose that a high temperature is not as necessary to these substances during the whole of their combustion as at the commencement of it; for Mr Mongé found, on making the trial, that a candle would not burn after the temperature of the air around it was reduced below a certain point.

All substances which continue to burn after being once kindled are *volatile*, and they burn the easier in proportion

proportion to that volatility. The application of a certain quantity of caloric to alcohol volatilizes part of it; that is to say, diminishes the attraction of its cohesion so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol; which combines with oxygen in its turn; more heat is given out; and thus the process goes on. Oils and tallow exhibit the very same phenomena; only as they are less volatile, it is necessary to assist the process by means of the capillary attraction of the wick, which confines the action of the caloric evolved to a small quantity of oil, and thus enables it to produce the proper effect. In short, then, every substance which is capable of continuing to burn, after being once kindled, is volatile, or capable of being converted into vapour by the degree of heat at first applied. The reason that a live coal will not burn when suspended insulated in the air, is not, as Dr Hutton supposed*, because its *light* is dissipated; but because the coal cannot be converted into vapour by the degree of heat which it contains, and because the cohesion of its particles is too great to allow it to combine with oxygen without some such change. There are some coals, however, which contain such a quantity of bitumen that they will burn even in the situation supposed by Dr Hutton, and continue to burn, provided they be furnished with any thing to act as a wick. It is needless to add, that bitumen, like oil, is easily converted into vapour.

* On *Light* and *Heat*.

But this explanation, instead of removing our difficulties, has only served to increase them: For if caloric only acts by diminishing the attraction of cohesion, and converting these substances into vapour, why do not all elastic fluids combine at once without any additional caloric? why do not oxygen and hydrogen, when mixed together in the state of gas, unite at once and form water? and why do not oxygen and azot, which are constantly in contact in the atmosphere, unite also and form nitrous gas? Surely it cannot be the attraction of cohesion that prevents this union. And if it be ascribed to their being already combined with caloric, how comes it that an additional dose of one of the ingredients of a compound decomposes it? Surely, as Mr Mongé has observed, this is contrary to all the other operations in chemistry.

That the particles of fluids are not destitute of an attraction for each other, is evident from numberless facts. The particles of water draw one another after them in cases of capillary attraction; which is probably owing to the attraction of cohesion. It is owing to the attraction of cohesion, too, that small quantities of water form themselves into spheres: Nor is this attraction so weak as not to be perceptible. If a small plate of glass be laid upon a globule of mercury, the globule, notwithstanding the pressure, continues to preserve its round figure. If the plate be gradually charged with weights one after another, the mercury becomes thinner and thinner, and extends itself in the form of a plate; but as soon as the weights are removed, it recovers its globular figure again, and pushes up the glass before it. Here we see the attraction of cohesion, not only superior to gravitation, but actually overcoming an external force*. And if the workman, after charging his plate of glass with weights, when he is forming mirrors, happen to remove these weights, the mercury which had been forced from under the glass, and was going to separate, is drawn back to its place, and the glass again pushed up. Nor is the attraction of cohesion confined to solids and liquids; it cannot be doubted, that it exists also in gases; at least it is evident, that there subsists an attraction between gases of a different kind: for although oxygen and azotic gas are of different gravities, and ought therefore to occupy different parts of the atmosphere, we find them always mixed together; and this can only be ascribed to an attraction. And were we to allow, with Humbolt and several other chemists, that these two gases are chemically combined in atmospherical air, an opinion contradicted by a late experiment in France (F); still the existence of carbonic acid gas in every part of the atmosphere can only be ascribed (if the inaccuracy of the expression may be tolerated) to a kind of cohesion. And whoever has been accustomed to pneumatic experiments, must have observed that small portions of *air*, as well as water, form themselves into spheres, and that the attraction of cohesion is so strong in gases, that large globules of them often adhere by a single point to the bottom of vessels filled with heavy fluids: whereas, had there been no attraction of cohesion, every part of the globule ought to have ascended to the surface of the fluid, except the particles immediately in contact with the vessel. Allowing, then, that there is an attraction of cohesion between the particles of gases, let us see whether that will not assist us in removing the difficulty.

* *Morveau, Affinité*, p. 543.

583 Explained.

It seems evident, in the first place, that the affinity between the bases of the gases under consideration and oxygen is greater than their affinity for that dose of caloric which produces their elastic form; for when they are combined with oxygen, the same dose will not separate them again. Let us take hydrogen for an instance: The affinity of hydrogen is greater for oxygen than for the caloric which gives it its gaseous form; but the oxygen is also combined with caloric, and there exists an attraction of cohesion between the particles of the hydrogen gas; the same attraction subsists between those of oxygen gas. Now the sum of all these affinities, namely, the affinity between hydrogen and caloric, the affinity between oxygen and caloric, the cohesion of the particles of the hydrogen, and the cohesion of the particles of oxygen—is greater than the affinity between the hydrogen and oxygen; and therefore no decomposition can take place. Let the affinity between

Oxygen and caloric be - - -	50
Hydrogen and caloric - - - -	50
Cohesion of oxygen - - - -	4
Cohesion of hydrogen - - - -	2
Sum of quiescent affinities, - -	106
The affinity of oxygen and hydrogen, -	105

The quiescent affinities being greater than the divellent affinities, no decomposition can take place.

Let

(F) Air brought by means of a balloon from a great height in the atmosphere was found to contain less oxygen gas than the same quantity of air near the ground.

Let now a quantity of caloric be added to the oxygen and hydrogen gas, it has the property of expanding them, and of courſe of diminiſhing their coheſion; while its affinity for them is ſo ſmall that it may be neglected. Let us ſuppoſe that it diminiſhes the coheſion of the oxygen 1, and of the hydrogen alſo 1, their coheſion will now be 3 and 1; and the quieſcent affinities being only 104, while the divellent are 105, the decompoſition would of courſe take place, and a quantity of caloric would thus be ſet at liberty to produce the ſame effects upon the neighbouring particles.

Thus, then, caloric acts only by diminiſhing coheſion: And the reaſon that it is required ſo much in gaſeous ſubſtances, and in thoſe combinations into which oxygen enters, is the ſtrong affinity of oxygen and the other baſes of the gaſes for caloric; for, owing to the repulſion which exiſts between the particles of that ſubtile ſubſtance, an effect is produced by adding large doſes of it, contrary to what happens in other caſes. The more of it is accumulated, the ſtronger is the repulſion between its particles; and therefore the more powerful is its tendency to fly off: and as this tendency is oppoſed by its affinity for the body and the coheſion of its particles, it muſt diminiſh both theſe attractions.

Though we have thus attempted to explain what has been always conſidered as one of the moſt difficult problems in chemiſtry, we are far from ſuppoſing that we have removed every difficulty. Much ſtill remains to be done before the action of light and caloric can be fully underſtood; and there may be other agents, of whoſe exiſtence we have not yet even conceived the idea.

One difficulty ſtill remains to be examined. Heat not only produces the combination of ſome bodies, but alſo occaſions the decompoſition of others. How does it act in theſe caſes?

584 How heat decompoſes bodies.

That many of theſe decompoſitions are produced by chemical affinity, will be evident from the following examples.

When ſulphur and arſenic acid are expoſed to heat, ſulphuret of arſenic is formed * evidently by a kind of compound affinity.

* *Pelletier.*

Oxygen Gas.

Caloric	12	Oxygen	
	60		Arſenic Acid.
Sulphur	50	Arſenic	

Sulphuret of Arſenic.

In the ſame manner, when nitrat of potaſs and boracic acid are expoſed to heat, the nitric acid is volatilized, and borat of potaſs is left behind.

Nitric Acid in Vapour.

Caloric	4	Nitric acid	
	58		Nitrat of Potaſs.
Boracic acid	55	Potaſs	

Borat of Potaſs.

By the ſame compound affinity boracic acid and heat decompoſes muriat of ſoda.

Muriatic Acid Gas.

Caloric	10	Muriatic acid	
	31		Muriat of Soda.
Boracic acid	24	Soda	

Borat of Soda.

In the ſame manner, it would be eaſy to explain how all the decompoſitions by the *dry way*, as it is called, are produced.

But how comes caloric to decompoſe water after having produced the union of oxygen and hydrogen? The union, we have ſeen, was probably brought about by the play of oppoſite affinities; but in the ſeparation, caloric ſeems to act by its peculiar power, or the repulſion which exiſts between its particles. When caloric combines with an integrant particle of water, this repulſion muſt ſeparate the component parts ſomewhat from one another; conſequently it muſt weaken their affinity; for every increaſe of diſtance produces that effect. Now let us ſuppoſe that the affinity between oxygen and hydrogen is 105, and that the affinity between caloric and each of theſe bodies is 50: as ſoon as the particles of oxygen and hydrogen are ſo far ſeparated from each other that their affinity is leſs than 100, they will unite with caloric in preference, becauſe the ſum of their affinities for caloric is equal to 100; conſequently, whenever that takes place water will be decompoſed. Hence we ſee the reaſon why more heat is always neceſſary to produce the decompoſition of bodies than what produced their union.

Caloric poſſeſſes another ſingular property, that of changing the compound affinities of bodies, even when it

Affinity.

it does not appear to enter as an ingredient. What we mean will appear evident from the following examples:

Muriat of ammonia, } decompoſe each other at the
Carbonat of magneſia, } ordinary temperature of the
atmoſphere, and form muriat of magneſia and carbonat of ammonia: but, on the contrary,

Muriat of magneſia, and } decompoſe each other at
Carbonat of ammonia, } a high temperature; for
inſtance, at 212°. The products are muriat of ammonia and carbonat of magneſia *.

Again, if muriat of ſoda and ſulphat of magneſia be mixed together at a low temperature, for inſtance at zero, they decompoſe each other, and muriat of magneſia and ſulphat of ſoda are formed; but no decompoſition takes place at a temperature above 32°.—Muriat of ſoda, and ſulphat of alumina, exhibit preciſely the ſame phenomena †.

Laſtly, ſulphat of magneſia and carbonat of ammonia decompoſe each other at the ordinary temperature; but at 212° the carbonic acid flies off, and the remaining ſubſtances form a triple ſalt ‡.

* *Weſtrum, Ann. de Chim.* ii. 118.

† *Scheele* and *Gren, Ann. de Chim.* xxiii.

‡ *Fourcroy, Ann. de Chim.* ii. 291.

The laſt of theſe phenomena appears owing to the affinity between carbonic acid and caloric, and the two firſt to the affinity between muriat of ammonia and caloric, for that ſalt is volatilized.

It would not be ſo eaſy to explain the mutual decompoſition of muriat of ſoda and ſulphat of magneſia at a low temperature. It is probably connected with the alterations in the diſtance of the ingredients of chemical compounds, which are produced by the preſence and abſence of caloric.

585 Of Count Rumford's opinion reſpecting affinity.

From the important part which caloric acts in chemical combinations, Count Rumford has been lately induced to ſuſpect that this ſubtile fluid is the *only agent* by which they are produced.

That caloric is a *neceſſary* agent in all chemical decompoſitions and new combinations, we very readily allow; becauſe we know no other cauſe except caloric to prevent the particles of bodies from actual contact; in which caſe decompoſition would be impoſſible: and if this be the ſenſe in which that ingenious philoſopher aſcribes chemical combinations to caloric, we very readily agree with him; but if he ſuppoſes that caloric is the *agent* by which the particles of bodies are brought near each other, and the *force* by which they adhere to one another, we cannot help thinking that he is miſtaken: For that bodies, chemically combined, are kept near each other by ſome force, cannot poſſibly be denied. Now, what is that force? We have ſaid, after Newton, an *attraction between the particles themſelves*; acknowledging, at the ſame time, that we are unable to explain what that is.

Count Rumford ſeems to ſuppoſe that there is no ſuch thing as attraction between the particles themſelves, but that caloric is the agent which keeps them together. If ſo, how does caloric perform this office? For our part, we do not pretend to underſtand it any more than the nature of attraction; nor do we ſee that it is poſſible to render it more intelligible. But there is another queſtion of ſtill greater importance, What are the proofs that caloric is the only agent in all caſes of chemical combinations? For our part, we can think of no proof that can render this opinion in the ſmalleſt degree plauſible.

Has this celebrated and candid philoſopher conſidered this ſubject with his uſual accuracy? If heat be a body, it cannot ſurely be the cauſe of affinity, unleſs it be poſſeſſed of properties which, ſo far from being proved, have not even been ſuſpected. On the contrary, if it be a property of matter, what property is it? If it be a peculiar motion, as Count Rumford ſuſpects, we would aſk if it be poſſible for any motion whatever, independent of attraction, to produce the permanent union of two bodies?

Part III. Of DOUBLY COMPOUND BODIES.

THE bodies which conſiſt of combinations of thoſe ſubſtances that have been denominated *compound*, and which, for that reaſon, we have ventured to call *doubly compound bodies*, may be reduced to three claſſes:

Soaps,
Neutral ſalts,
Hydroſulphurets.

Theſe ſhall form the ſubject of the three following Chapters; and we ſhall finiſh this part of the article with ſome obſervations on *cryſtallization*.

Chap. I. *Of* Soaps.

The compounds into which *oils* enter without decompoſition have been denominated *ſoaps*.

Oils are capable of combining with alkalies, earths, and metallic oxides; they are capable alſo of combining with ſeveral of the acids. There are therefore two claſſes of ſoaps; 1. Alkaline, earthy, and metallic ſoaps, which, for the ſake of brevity, we ſhall call *alkaline ſoaps*; and, 2. Acid ſoaps. Theſe two claſſes form the ſubject of the two following Sections.

Sect. I. *Of Alkaline Soaps.*

As there are a great number of oils, all or moſt of which are capable of combining with alkalies, earths, and oxides, it is natural to ſuppoſe that there are as many genera of alkaline ſoaps as there are oils. That there are differences in the nature of ſoaps correſponding to the oil which enters into their compoſition, is certain; but theſe differences are not of ſufficient importance to require very particular deſcription. We ſhall therefore deſcribe all the alkaline ſoaps together, and notice, as we go along, ſome of the moſt important differences reſulting from the oily ingredients.

1. Soap of ſoda, or common ſoap. The word *ſoap* (*ſapo*, σαπων) firſt occurs in the works of Pliny and Galen, and is evidently derived from the old German word *ſepe* (G). Pliny informs us, that ſoap was firſt diſcovered by the Gauls; that it was compoſed of tallow 586 Common hard ſoap.

 and

(G) *Beckmann's Hiſtory of Inventions*, III. 239.—A ſimilar word is ſtill uſed by the common people of Scotland.

Alkaline Soaps.

and aſhes; and that the German ſoap was reckoned the beſt *.

* *Pliny*, lib. xviii. c. 51.

587 Method of forming it.

Soap may be prepared by the following proceſs. A quantity of the ſoda of commerce, which is a carbonat of ſoda, and which is often called *barilla* from the name of a plant, by burning which it is procured in great quantities in Spain, is pounded and mixed in a wooden veſſel, with about a fifth part of its weight of lime, ſlacked and paſſed through a ſieve immediately before. Upon this mixture a quantity of water is poured, conſiderably more than what is ſufficient to cover it, and allowed to remain on it for ſeveral hours. The lime attracts the carbonic acid from the ſoda, and the water becomes ſtrongly impregnated with the pure alkali. This water is then drawn off by means of a ſtop-cock, and called the *firſt ley*. Its ſpecific gravity ſhould be about 1,200.

Another quantity of water is then to be poured upon the ſoda, which, after ſtanding two or three hours, is alſo to be drawn off by means of the ſtop-cock, and called the *ſecond ley*.

Another portion of water is poured on; and after ſtanding a ſufficient time, is drawn off like the other two, and called the *third ley*.

Another portion of water may ſtill be poured on, in order to be certain that the whole of the ſoda is diſſolved; and this weak ley may be put aſide, and employed afterwards in forming the firſt ley in ſubſequent operations.

A quantity of oil, equal to ſix times the weight of the ſoda uſed, is then to be put into the boiler, together with a portion of the *third* or *weakeſt ley*, and the mixture muſt be kept boiling, and agitated conſtantly by means of a wooden inſtrument. The whole of the third ley is to be added at intervals to the mixture; and after it is conſumed, the *ſecond ley* muſt be added in the ſame manner. The oil becomes milky, combines with the alkali, and after ſome hours it begins to acquire conſiſtence. A little of the *firſt ley* is then to be added, not forgetting to agitate the mixture conſtantly. Portions of the firſt ley are to be added at intervals; the ſoapy ſubſtance acquires gradually greater conſiſtency, and at laſt it begins to ſeparate from the watery part of the mixture. A quantity of common ſalt is then to be added, which renders the ſeparation much more complete. The boiling is to be continued ſtill for two hours, and then the fire muſt be withdrawn, and the liquor muſt be no longer agitated. After ſome hours repoſe the ſoap ſeparates completely from the watery part, and ſwims upon the ſurface of the liquor. The watery part is then to be drawn off; and as it contains a quantity of carbonat of ſoda, it ought to be reſerved for future uſe.

The fire is then to be kindled again; and, in order to facilitate the melting of the ſoap, a little water, or rather weak ley, is to be added to it. As ſoon as it boils, the remainder of the firſt ley is to be added to it at intervals. When the ſoap has been brought to the proper conſiſtence, which is judged of by taking out ſmall portions of it and allowing it to cool, it is to be withdrawn from the fire, and the watery part ſeparated from it as before. It is then to be heated again, and a little water mixed with it, that it may form a proper paſte. It is then to be poured into the veſſels proper for cooling it; in the bottom of which there ought to be a little chalk in powder, to prevent the ſoap from attaching itſelf to it. In a few days the ſoap will have acquired ſufficient conſiſtence to be taken out, and formed into proper cakes (H).

The uſe of the common ſalt in the above proceſs is to ſeparate the water from the ſoap; for common ſalt has a ſtronger affinity for water than ſoap has.

Olive oil has been found to anſwer beſt for making ſoap, and next to it perhaps tallow may be placed: but a great variety of other oils may be employed for that purpoſe, as appears from the experiments of the French chemiſts above quoted. They found, however, that lintſeed oil and whale oil were not proper for making *hard ſoaps*, though they might be employed with advantage in the manufacture of *ſoft ſoaps*. Whale oil has been long uſed by the Dutch for this laſt purpoſe.

Soap may alſo be made without the aſſiſtance of heat; but in that caſe a much longer time and a larger proportion of alkali is neceſſary.

588 Its ſophiſtication.

Manufacturers have contrived various methods of ſophiſticating ſoap, or of adding ingredients which increaſe its weight without increaſing its value. The moſt common ſubſtance uſed for that purpoſe is water; which may be added in conſiderable quantities, eſpecially to ſoap made with tallow (the ingredient uſed in this country), without diminiſhing its conſiſtency. This fraud may be eaſily detected, by allowing the ſoap to lie for ſome time expoſed to the air. The water will evaporate from it, and its quantity will be diſcovered by the diminiſhing of the weight of the ſoap. As ſoap ſophiſticated in this manner would loſe its water by being kept, manufacturers, in order to prevent that, keep their ſoap in ſaturated ſolutions of common ſalt; which do not diſſolve the ſoap, and at the ſame time, by preventing all evaporation, preſerve, or rather increaſe, the weight of the ſoap. Meſſrs Darcet, Lelievre, and Pelletier, took two pieces equal in weight of ſoap ſophiſticated in this manner, and placed the one in a dry place in the open air, and the other in a ſaturated ſolution of common ſalt. After a month, the firſt had loſt $\frac{56}{100}$ of its weight, the other had gained about $\frac{10}{100}$ parts *. Various other methods have been fallen upon to ſophiſticate ſoap; but as they are not, we hope, generally known, it would be doing an injury to the public to deſcribe them here.

* *Ann. de Chim.* xix. 336.

589 Proportion of its ingredients.

Different chemiſts have analyſed ſoap, in order to aſcertain the proportions of its ingredients; but the reſult of their experiments is various, becauſe they uſed ſoap containing various quantities of water. From the experiments of Darcet, Lelievre, and Pelletier, it appears that ſoap newly made and expoſed to ſale contains

9,75 Oil,
1,37 Alkali,
4,87 Water.

Soap is ſoluble both in water and in alcohol. Its properties as a detergent are too well known to require any deſcription.

It

(H) See the *Memoir of Darcet, Lelievre*, and *Pelletier*, in the *Ann. de Chim.* XIX. 253.

Alkaline Soaps.

It is decomposed by lime, and by compound affinity (1) by sulphat of lime, nitrat of lime, muriat of lime, and probably all the salts which contain lime.

590 Soft soap. 2. Soap of potass.—Potass may be substituted for soda in making soap, and in that case precisely the same process is to be followed. It is remarkable, that when potass is used, the soap does not assume a solid form; its consistence is never greater than that of hog's lard. This is what in this country is called *soft soap*. Its properties as a detergent do not differ materially from those of *hard soap*, but it is not nearly so convenient for use. The alkali employed by the ancient Gauls and Germans in the formation of soap was potass: hence we see the reason that it is described by the Romans as an unguent.

Some persons have affirmed that they knew a method of making hard soap with potass. Their method is this: After forming the soap in the manner above described, they add to it a large quantity of common salt, boil it for some time, and the soap becomes solid when cooled in the usual way. That this method may be practised with success has been ascertained by Messrs Darcet, Lelievre, and Pelletier; but then the hard soap thus formed does not contain potass, but soda: for when the common salt (muriat of soda) is added, the potass of the soap decomposes it, and combines with its muriatic acid, while at the same time the soda of the salt combines with the oil, and forms hard soap: and the muriat of potass formed by this double decomposition is dissolved in the water, and drawn off along with it*.

* *Ann. de Chim.* xix. 322.

Chaptal has lately proposed to substitute wool in place of oil in the making of soap. The ley is formed in the usual manner, and made boiling hot, and shreds of woollen cloth of any kind are gradually thrown into it; they are soon dissolved. New portions are to be added sparingly, and the mixture is to be constantly agitated. When no more cloth can be dissolved, the soap is made†. This soap is said to have been tried with success. It might doubtless be substituted for soap with advantage in several manufactures, provided it can be obtained at a cheaper rate than the soaps at present employed.

† *Ibid.* xxi. 27.

Fish, too, have been lately substituted for oil with equal success. The only disadvantage which soap made in this manner is liable to, is a disagreeable smell, from which it cannot easily be freed.

591 Soap of ammonia. 3. Soap of ammonia.—This soap was first particularly attended to by Mr Berthollet. It may be formed by pouring carbonat of ammonia on soap of lime. A double decomposition takes place, and the soap of ammonia swims upon the surface of the liquor in the form of an oil; or it may be formed with still greater ease by pouring a solution of muriat of ammonia into common soap dissolved in water. We have formed it often by mixing caustic ammonia and oil ‡.

‡ *Berthollet, Mem. Par.* 1780, or *Nicholson's Journal*, i. 170

It has a more pungent taste than common soap. Water dissolves a very small quantity of it; but it is easily dissolved in alcohol. When exposed to the air, it is gradually decomposed.

592 Soap of Lime. 4. Soap of lime.—This soap may be formed by pouring lime-water into a solution of common soap. It is insoluble both in water and alcohol. Carbonat of fixed alkali decomposes it by compound affinity *. It melts with difficulty, and requires a strong heat.

* *Thouvenel.*

5. Soap of magnesia.—This soap may be formed by mixing together solutions of common soap and sulphat of magnesia. 593 Soap of magnesia,

It is exceedingly white. It is unctuous, dries with difficulty, and preserves its whiteness after desiccation. It is insoluble in boiling water. Alcohol and fixed oil dissolve it in considerable quantity. Water renders its solution in alcohol milky. A moderate heat melts it; a transparent mass is formed, slightly yellow, and very brittle †.

† *Berthollet, ibid.*

6. Soap of alumina.—This soap may be formed by mixing together solutions of alum and of common soap. It is a flexible soft substance, which retains its suppleness and tenacity when dry. It is insoluble in alcohol, water, and oil. Heat easily melts it, and reduces it to a beautiful transparent yellowish mass ‡. 594 Of alumina,

‡ *Ibid.*

7. Soap of barytes resembles almost exactly the soap of lime §. 595 Of barytes,

§ *Ibid.*

8. Soap of mercury.—This soap may be formed by mixing together a solution of common soap and of corrosive muriat of mercury. The liquor becomes milky, and the soap of mercury is gradually precipitated. This soap is viscid, not easily dried, loses its white colour when exposed to the air, and acquires a slate colour, which gradually becomes deeper, especially if exposed to the sun or to heat. It dissolves very well in oil, but sparingly in alcohol. It readily becomes soft and fluid when heated ||. 596 Of mercury,

|| *Ibid.*

9. Soap of zinc.—This soap may be formed by mixing together a solution of sulphat of zinc and of soap. It is of a white colour, inclining to yellow. It dries speedily, and becomes friable ¶. 597 Of zinc,

¶ *Ibid.*

10. Soap of cobalt.—This soap, made by mixing nitrat of cobalt and common soap, is of a dull leaden colour, and dries with difficulty, though its parts are not connected. 598 Of cobalt,

Mr Berthollet observed, that towards the end of the precipitation there fell down some green coagula, much more consistent than soap of cobalt. These he supposed to be a soap of nickel, which is generally mixed with cobalt *. 599 Of nickel,

* *Ibid.*

11. Soap of tin.—It may be formed by mixing common soap with a solution of tin in nitro-muriatic acid. It is white. Heat does not fuse it like other metallic soaps, but decomposes it †. 600 Of tin,

† *Ibid.*

12. Soap of iron.—Formed by means of sulphat of iron. It is of a reddish brown colour, tenacious, and easily fusible. When spread upon wood, it sinks in and dries. It is easily soluble in oil, especially of turpentine. Berthollet proposes it as a varnish ‡. 601 Of iron,

‡ *Ibid.*

13. Soap of copper.—Formed by means of sulphat of copper. It is of a green colour, has the feel of a resin, and becomes dry and brittle. Hot alcohol renders its colour deeper, but scarcely dissolves it. Ether dissolves it, liquefies it, and renders its colour deeper and more beautiful. It is very soluble in oils, and gives them a pleasant green colour §. 602 Of copper,

§ *Ibid.*

14. Soap of lead.—It may be formed by means of acetite 603 Of lead,

---

(1) In this and the following chapter, *compound affinity* is not taken always in its strict and proper sense, but is applied to all those decompositions in which the affinities of more than three bodies act.

Alkaline Soaps.

acetite of lead. It is white, tenacious, and very adhesive when heated. When fused, it is transparent, and becomes somewhat yellow if the heat be increased*.

604 Of silver, 15. Soap of silver.—It may be formed by means of nitrat of silver. It is at first white, but becomes reddish by exposure to the air. When fused, its surface becomes covered with a very brilliant iris; beneath the surface it is black †.

605 Of gold, 16. Soap of gold.—It is at first white, and of the consistence of cream. It gradually assumes a dirty purple colour, and adheres to the skin so that it is difficult to efface the impression ‡.

606 And of manganese. 17. Soap of manganese.—It is at first white, but it assumes in the air a reddish colour, owing evidently to the absorption of oxygen. It speedily dries to a hard brittle substance, and by liquefaction assumes a brown blackish colour §.

We owe the following resinous soaps to Mr Mezaize.

607 Soap of turpentine and potass. 18. Soap of turpentine and potass.—576 grains of turpentine were dissolved in 9216 grains of alcohol, and then 576 grains of potass were added. The alcohol was distilled off at a boiling water heat. There remained in the retort 648 grains of a brownish soapy matter, which when spread on glass appeared transparent. There remained also nearly the same quantity of potass dissolved in water. This soap was put in a vessel for six weeks; during which time 72 grains of solution of potass separated from it. It had assumed the consistence of honey. Its colour was browner. It was completely soluble in water: the solution was milky. It dissolved also in alcohol. It had no disagreeable taste. Vinegar decomposed it.

608 Soap of benzoin, 19. Soap of benzoin and potass.—By treating 9216 grains of alcohol, 1728 grains of benzoin, and 576 grains of potass, as above, 1728 grains of a soap were obtained, browner than that of turpentine, of an odour a little aromatic. When left in a cellar for six weeks, it became solid. Its solution in water was yellowish. Vinegar decomposed it. This compound is the same with Starkey's soap.

609 Of balm of Peru, 20. Soap of balm of Peru and potass—1152 grains of balm, 2304 grains of potass, and 9216 grains of alcohol, produced a soap of a reddish colour, and pretty consistent.

610 Of guaiac, 21. Soap of guaiac and potass.—1728 grains of guaiac was dissolved in 18648 grains of alcohol, and the solution filtered, and to this 1728 grains of potass were added, and the soap obtained as above. It was solid, of a brown colour at first, which afterwards became green on the surface, but remained unaltered within. Its solution in water was greenish. It had no disagreable taste. It dissolved in alcohol, and formed a green tincture. Vinegar decomposed it.

611 And of scammony. 22. Soap of scammony and potass.—By the above process a soap was obtained with scammony pretty consistent, of a brown colour, soluble in water, and not decomposed by the water of pits from which selenites is obtained. It has no disagreable taste. Its solution in alcohol is of a deep amber colour ‖.

* Berthollet, ibid.

† Ibid.

‖ Jour. de Phys. xv. 441.

Sect. II. *Of Acid Soaps.*

612 Method of forming acid soaps. Sulphuric acid may be combined with oils in the following manner: Put two ounces of it into a glass mortar, and add, by little and little, three ounces of the oil nearly boiling hot, triturating it constantly. A substance is obtained of the consistence of turpentine. Dissolve it in about six ounces of boiling water, and the soap will unite into a mass as the water cools. If it still contain an excess of acid, dissolve it again in boiling water, and continue this process till the soap is perfectly neutralized.

Acid Soaps.

1. Soap of sulphuric acid and lintseed oil.—It dissolves entirely in water. The solution is opaque, of a bluish white colour, viscid, and frothes when agitated. Alcohol dissolves it. The solution is transparent and brown. Potass decomposes it, forming sulphat of potass. The oil swims on the top, of the consistence of wax. Ammonia decomposes it; and if too much be added it forms soap of ammonia. Magnesia, lime, nitric acid, and muriatic acid, also decompose it. Distilled, it yielded a few drops of water and an oil, which coagulated, and was of the consistence of wax. 613 Acid soap of lintseed oil,

2. Soap of sulphuric acid and oil of almonds.—Soluble in water; solution milky. Frothes. Soluble in alcohol; solution brown and transparent. Potass, lime, nitric acid, muriatic acid, sulphurous acid (the oil separated assumed the consistence of turpentine), tartar, acidulous oxalat of potass, sal ammoniac, muriat of lead and zinc decompose it. It is not decomposed by vinegar, boracic acid, acetite of ammonia, borax, copper, tin, nor lead. When distilled, there passed over a little water and an oil, which coagulated and smelt very rancid: there remained behind a coal. 614 Of almond oil.

3. Soap of sulphuric acid and olive oil.—It is brown, and of the consistence of wax. Solution in hot water white, opaque, viscid; frothes. Solution in alcohol transparent and brown. Potass, ammonia, magnesia, nitric acid, muriatic acid, vinegar, nitre, sal ammoniac, acetite of lead and white oxide of lead, decompose it. 615 Of olive oil,

4. Soap of sulphuric acid and butter of cocao.—It is hard, and marbled like Venice soap. Solution in water grey, opaque, viscid; frothes. Solution in alcohol yellow and transparent. Potass, ammonia, nitric, muriatic, and acetous acids, tartar, sal ammoniac, tartrite of potass, acetite of lead, and zinc in powder, decompose it. When distilled, there came over water, an oil that coagulated, and a few drops of a black oil, which also congealed: both were rancid. 616 Of butter of cocao,

5. Soap of sulphuric acid and wax.—It is white, and becomes very hard. Its solution in water is white, and opaque, and frothes: Its solution in alcohol is yellow and transparent. Potass, ammonia, nitric and muriatic acids, decompose it. 617 Of wax,

6. Soap of sulphuric acid and spermaceti.—It is brown. It dissolves in water: the solution is milky, viscid, and frothes on agitation. It dissolves in alcohol; the solution is transparent and yellow. It is decomposed by as much alkali as saturates the acid: if more be added, it unites with the oil, and forms a new soap. Lime and magnesia decompose it. The oil is also separated, and appears in the form of a coagulum on adding to the solution nitric acid, muriatic acid, tartar, nitre, nitrat of soda, common salt, and zinc in powder; but not on adding vinegar, tin, lead. 618 Of spermaceti,

7. Soap of sulphuric acid and oil of eggs.—Its solution in water is white, opaque, viscid; frothes: that in alcohol yellow and transparent. Alkalies decompose it; but if too much be added a new soap is formed. Nitric and muriatic acids separate the oil of the consistence of wax, 619 Of oil of eggs,

Neutral Salts.

wax, the first yellow, the last a deep brown. Nitre, sal ammoniac, acetite of lead, iron filings, zinc powder, decompose it; vinegar, borax, filings of lead do not.

To unite this acid with the essential oils, three ounces were put into a glass mortar, and four ounces of the oil were added drop by drop, and care taken to prevent its becoming hot: equal parts of water were then poured on, and the whole heated slowly nearly to the temperature of boiling water: on cooling, the soap united into a brown mass.

620 Of turpentine,

8. Soap of sulphuric acid and turpentine. It is brown, and of the consistence of soft wax. Its solution in water is grey, opaque, viscid; frothes: Its solution in alcohol is brown and transparent. Alkalies decompose it: with too much it forms at the boiling heat a new soap.

Nitric and muriatic acids separated the oil thickened, as did also white oxide of lead, muriat of lead, muriat of soda and iron filings; but acetous acid, boracic acid, tartrite of potass, and tin filings, produced no such effect.

621 And of amber oil.

9. Soap of sulphuric acid and amber oil.—Its solution in water and alcohol as in the last soap. Alkalies, magnesia, and lime, decomposed it. Nitric and muriatic acids separated the oil of the consistence of wax. Tartar, sal ammoniac, muriat of antimony, acetite of lead, iron filings, decomposed it; vinegar, acetite of ammonia, and lead did not.

Mr Achard, to whom we owe these soaps*, could not succeed in his attempts to form soaps with nitric and muriatic acids.

* Journ. de Phys. xvi. 409.

Chap. II. *Of* Neutral Salts.

622 Salt explained.

The word *salt* has been used in chemistry in a very extensive, and not very definite sense. Every body which is sapid, easily melted, soluble in water, and not combustible, has been called a *salt*.

Salts were considered by the older chemists as a class of bodies intermediate between earths and water. Many disputes arose about what bodies ought to be comprehended under this class, and what ought to be excluded from it. Acids and alkalies were allowed by all to be salts; but the difficulty was to determine concerning earths and metals. Several of the earths possess all the properties which have been ascribed to salts; and the metals are capable of entering into combinations which possess saline properties. It is needless for us to enter into this dispute at present, as we have taken the liberty, in imitation of some of the best modern chemists, to expunge the class of salts altogether, and to arrange those subordinate classes, which are usually referred to it, under distinct heads.

623 Neutral salt explained.

The word *neutral salt* was originally applied exclusively to combinations of acids and alkalies, which were considered as substances possessing neither the properties of acids nor alkalies, but properties intermediate between the two. But the word is now always taken in a more extensive sense, and signifies all compounds formed by the combination of acids with alkalies, earths, or metallic oxides. In these compounds, the earth, alkali, or oxide, is denominated the *base*. Each order of salts is denominated after the acid which enters into its composition; and every individual salt is distinguished by subjoining the name of its base. Thus all the salts into which sulphuric acid enters are called *sulphats*, and the salt formed by the combination of sulphuric acid and potass is called *sulphat of potass*.

It is evident, then, that there must be as many orders of neutral salts as there are acids; and as many salts in each order as there are alkalies, earths, and metallic oxides, supposing every acid capable of combining with every one of these substances. But besides these simple combinations of one acid and one base, there are others more complex, composed of two acids combined with one base, or two bases combined with one acid, or a neutral salt combined with an acid or a base. These combinations have been called *triple salts*; and they increase the number of neutral salts very considerably.

In the following sections we shall take a short view of the properties of the principal neutral salts at present known; for this wide and important region of chemistry is still very far from being completely explored.

Sulphats.

Sect. I. *Of Sulphats.*

Sulphuric acid is capable of combining with all the alkalies, with alkaline earths, alumina, jargonia, and the greater number of the metallic oxides. The principal neutral salts which it forms are as follows:

1. Sulphat of potass.—This salt may be formed by saturating diluted potass with sulphuric acid, and then evaporating the solution gently till crystals are formed. It seems to have been known at a very early period by chemists, and a great variety of names were given to it, according to the manner of forming it, or the fancy of the operator. Some of these names were, *specificum purgans*, *nitrum fixum*, *arcanum duplicatum*, *panacea holsatica*, *sal de duobus*, *sal polychrest glaseri*, &c.; but it was commonly known by the name of *vitriolated tartar* till the French chemists called it *sulphat of potass*, when they formed their new nomenclature in 1787 (K). 624 Sulphat of potass.

When the solution of sulphat of potass is sufficiently diluted, it affords by evaporation hexahedral pyramids, or short hexangular prisms, terminated by one or more hexangular pyramids. But these crystals vary much in their figure, according to the care with which they are prepared. 625 Its properties.

It has a very disagreeable bitter taste. Its specific gravity is 2,298*.

* Brisson.

It is soluble in the temperature of 60° in 16 times its weight of water; in a boiling heat, it is soluble in 5 times its weight †.

† Bergman.

According to Bergman, it is composed of 40 parts of acid, 52 parts of alkali, and 8 of water; but according to Kirwan, whose experiment has been already described, it is composed of 45 parts of acid and 55 of alkali.

It suffers no alteration in the air.

When placed upon burning coals, it breaks into pieces with a noise resembling a number of small explosions succeeding each other at short intervals (L), but suffers no other alteration. In a red heat it melts.

It has hitherto been applied to little use. It is a purgative,

(K) Bergman called it *alkali vegetabile vitriolatam*, and Morveau *vitriol of potass*.

(L) This is called *decrepitation*.

Sulphats.

purgative, but its disagreeable taste prevents it from being much employed for that purpose.

It often has an excess of acid, owing, as Mr Bergman and Morveau have very ingeniously explained, to an affinity which exists between this salt and sulphuric acid.

It is decomposed by compound affinity by the following salts:

Nitrat of soda (M),	Nitrat of silver,
——— lime,	——— lead,
——— barytes*,	Acetite of barytes,
——— strontites †,	Muriat of lime ‡,
——— ammonia,	——— lead §,
——— magnesia,	——— magnesia?
——— mercury,	——— soda ‖.

* Kirwan. † Id. ‡ Bergman. § Id. ‖ Fuchs, Ann. de Chim. vi. 29.

It is sometimes luminous in the dark, as Mr Giobert has observed ¶.

¶ Ann. de Chim. x. 40.

626 Sulphat of soda.

2. Sulphat of soda.—This salt was first discovered by Glauber a German chemist, and for that reason was long known by the name of *Glauber's salt*. He himself called it *sal mirabile*. It may be prepared by saturating soda with sulphuric acid, but is more usually obtained by decomposing common salt in order to procure muriatic acid.

Its crystals are transparent, and when formed by slow evaporation, are six-sided prisms terminated by dihedral summits.

Its taste at first has some resemblance to that of common salt, but soon becomes very disagreeably bitter.

It is soluble in 2,67 times its weight of water at the temperature of 60°, and in 0,8 of boiling water.

It is composed, according to Bergman, of 27 parts of acid, 15 of alkali, and 58 of water; but, according to the experiments of Kirwan, of 22 parts of acid, 17 of alkali, and 61 of water.

When exposed to the air, it loses great part of its water, and falls into a white powder (N).

When exposed to heat, it first undergoes the *watery fusion* (O), then its water is evaporated, it is reduced to a white powder, and at last in a red heat it melts. Mr Kirwan has observed, that part of the acid, as well as the water, is driven off by the application of a strong heat *.

* Irish Trans. iv.

This salt is used as a purgative.

It often combines with an excess of acid.

It is decomposed by compound affinity, by the following substances:

Nitrat of lime,	Acetite of barytes,
——— magnesia,	——— potass,
Muriat of potass,	——— lime,
——— soda,	Carbonat of barytes,
——— magnesia,	——— potass.
——— lime †,	

† Scheele.

627 Sulphat of ammonia.

3. Sulphat of ammonia.—This salt was discovered by Glauber, and called by him *secret sal ammoniac*. It was also called *vitriolated ammoniac*. It may be prepared by saturating ammonia with sulphuric acid.

Its crystals are generally small six-sided prisms, whose planes are unequal, terminated by six-sided pyramids.

It has a sharp bitter taste.

It is soluble in twice its own weight of water at the temperature of 60°, and in its own weight of boiling water.

According to Mr Kirwan, it is composed of 29,7 of alkali, 55,7 of sulphuric acid, and 14,16 of water *.

* Irish Trans. ibid.

When exposed to the air, it slowly attracts moisture.

When heated, it first decrepitates, then melts, and in close vessels sublimes, but with some loss of its alkali †.

† Kirwan's Mineral. ii. [illegible]

It has not hitherto been applied to any use.

It is apt to contain an excess of acid.

It is decomposed by compound affinity by the following salts:

Nitrat of lime,	Acetite of soda,
——— magnesia,	——— barytes,
——— mercury?	——— lime,
Muriat of potass,	——— magnesia,
——— soda,	Carbonat of potass,
——— barytes,	——— soda,
——— lime,	——— barytes,
——— magnesia,	——— lime,
——— mercury*,	——— magnesia,
Acetite of potass,	Phosphat of lime †.

* Bergman. † Delkeskamp Ann. de Chim. vi. 37.

628 Sulphat of barytes.

4. Sulphat of barytes.—This substance was first discovered by Scheele. It abounds in nature. It is generally in the form of a hard, very heavy, stone.

It is sometimes found crystallized; but the variety of forms is so great that they baffle all description.

It is soluble in 43,000 times its weight of water at the temperature of the atmosphere ‖.

‖ Kirwan's Min. i. 136.

Sulphuric acid dissolves it when concentrated and boiling, but it is precipitated by the addition of water.

When exposed to heat it melts, and, if the heat be very strong, gradually dissipates.

629 Bologna stone.

After being heated red hot, it has the property of being luminous in the dark. This was first observed in a variety of this substance known by the name of Bologna stone. Lemery informs us, that this property was first discovered by an Italian shoemaker named Vincenzo Casciarolo. This man found a Bologna stone at the foot of Mount Paterno, and its brightness and gravity made him suppose that it contained silver. Having exposed it to the fire, doubtless in order to extract from it the precious metal, he observed that it was luminous in the dark. Struck with the discovery, he repeated the experiment, and it constantly succeeded with him.

From an experiment of Mr Klaproth, it appears to be composed of 33 parts of acid and 77 of barytes.

It is decomposed by compound affinity by the following salts:

Nitrat of soda,	Nitrat of magnesia,
——— lime,	Carbonat of potass,
——— ammonia,	——— soda *.

‖ Afzwelius.

630 Sulphat of lime.

5. Sulphat of lime.—This substance was well known to the ancients under the name *gypsum*; but the composition of gypsum was not known till Margraf and Macquer analysed it, and proved that it was composed of sulphuric acid and lime. The artificial compound

(M) Most of these double decompositions in this and the following sections are inserted on the authority of Morveau. See his Table of *Affinity*, page 360 of this article.

(N) This is called *efflorescing*.

(O) When substances melt by means of the water they contain on the application of heat, they are said to undergo the watery fusion.

Sulphats. pound formed by the union of these two bodies was formerly called *selenite*.

It is found crystallized in various forms, sometimes transparent and sometimes opaque; and when pure it is of a white colour.

It has a slightly nauseous taste, scarcely perceptible except by drinking a glass of water impregnated with it *.

* Macquer.

It is soluble in 500 parts of water at the temperature of 60°, but much more soluble in boiling water.

It is composed, according to Bergman, of 46 parts of acid, 32 of earth, and 22 of water: according to the late experiments of Mr Kirwan, when so far dried as still to retain its glassy appearance, it contains 48 of acid, 34 of earth, and 18 of water; which differs very little from the determination of Bergman.

It is not affected by exposure to the air.

It is soluble in sulphuric acid.

When exposed to heat, it undergoes a kind of watery fusion, but afterwards it cannot be melted by the strongest heat. In a clay crucible indeed it fuses at 130° Wedgewood, owing evidently to the presence of the clay.

631 Plaster of Paris.

When heated red hot and cooled, it is called *plaster of Paris*; a substance so useful for casting moulds, &c. on account of its property of becoming solid almost immediately when reduced into a paste with water.

By compound affinity it is decomposed by the following substances:

Acetite of barytes,	Carbonat of potass,
——— potass,	——— soda,
Carbonat of barytes,	——— magnesia?
	——— alumina †.

† Bergman.

632 Sulphat of strontites.

6. Sulphat of strontites. This salt, first formed by Dr Hope, is a white powder destitute of taste. It is soluble in 3840 parts of boiling water. Sulphuric acid dissolves it readily when assisted by heat, but it is precipitated by the addition of water to the solution ‡.

‡ Dr Hope, Transf. Edin. iv. 10.

633 Sulphat of magnesia.

7. Sulphat of magnesia. This salt was first observed in the springs at Epsom in England by Grew in 1675; but Dr Black was the first who accurately ascertained its composition. It has been called *Epsom salt*, *sal catharticus amarus*, and *Seydler salt*.

It crystallizes in quadrangular prisms, whose plains are equal, surmounted by quadrangular pyramids.

It has an excessively bitter taste.

At the temperature of 60° it is soluble in its own weight of water, and in ¾ths of its weight of boiling water. The volume of water is increased ¼th by adding the salt §.

§ Bergman.

It is insoluble in alcohol.

It is composed, according to Bergman, of 19 parts of earth, 33 of acid, and 48 of water; according to Mr Kirwan, of 17 parts of earth, 29,46 of acid, and 53,54 of water.

When exposed to the air it effloresces, and is reduced to powder.

When exposed to heat it undergoes the watery fusion, and by increasing the temperature its water is evaporated, but it cannot be decomposed by means of heat.

It is sometimes employed as a cathartic, but its chief use is to furnish magnesia by its decomposition.

It is decomposed by compound affinity by the following salts.

Muriat of potass,	Acetite of lime,
——— soda (P),	Carbonat of barytes,
——— lime,	——— potass,
Acetite of barytes,	——— soda *,
——— potass,	——— ammonia (Q).

* Bergman.

634 Sulphat of ammonia and magnesia.

8. Sulphat of ammonia and magnesia. This triple salt was discovered by Mr Fourcroy. Into the solution of 100 parts of sulphat of magnesia in 500 parts of water, 12 parts of ammonia being poured, a very small quantity of magnesia was precipitated, and a considerable quantity more on the addition of another dose of ammonia; but farther additions had no effect. From the magnesia precipitated, it appeared that 38 parts of the sulphat had been decomposed. There remained, therefore, 62 parts in solution, mixed with a large quantity of ammonia. By evaporation, 92 parts of a white transparent rhomboidal salt were obtained, evidently composed of sulphuric acid, ammonia, and magnesia, in the proportions that would have formed 62 parts of sulphat of magnesia and 30 of sulphat of ammonia, and probably consisting of a combination of these two sulphats †.

† Ann. de Chim. iv. 211.

635 Sulphat of alumina.

9. Sulphat of alumina. This salt may be formed by dissolving alumina in sulphuric acid. It has an astringent taste, is very soluble in water, and crystallizes in thin plates which have very little consistence ‡. Little attention has hitherto been paid to this salt, which was never properly distinguished from *alum* till two memoirs, one by Vauquelin and another by Chaptal, on the nature of alum, made their appearance in the 22d volume of the *Annales de Chimie*. This salt generally contains an excess of acid, and is not neutralized without considerable difficulty §.

‡ Vauquelin, Ann. de Chim. xxii. 277. and Chaptal, ibid. 294.

§ Ibid. p. 277.

636 Alum.

10. Sulphat of alumina and potass, or alum. The στυπτηρια of the Greeks, and the *alumen* of the Romans, was a native substance, which appears to have been nearly related to *green vitriol* or *sulphat of iron*; and which consequently was very different from what we at present denominate *alum*. From the researches of Professor Beckmann, it appears that we owe the discovery of alum to the Asiatics; but at what period, or by what means, the discovery was made, is altogether unknown.

It continued to be imported from the East till the 15th century, when a number of alum works were established in Italy. In the 16th century it was manufactured in Germany and Spain; and during Queen Elizabeth's reign an alum work was established in England by Thomas Chalomer.

The alum of commerce is usually obtained from earths containing sulphur and clay, or sulphuric acid and clay.

637 Its composition,

The composition of alum has been but lately understood

(P) Only below the temperature of 32°. *Scheele, Gren, Ann. de Chim.* xxiii.
(Q) Only below the temperature of 212°. *Fourcroy, Ibid.* ii. 291.

Sulphats.

stood with accuracy. It has been long known, indeed, that one of its ingredients is sulphuric acid (R); and the experiments of Geoffroy, Hellot, Pot, Margraf, and Macquer, proved incontestibly that alumina is another ingredient. But sulphuric acid and alumina are incapable of forming alum: Manufacturers knew, that the addition of a quantity of potass, or of ammonia, or of some substance containing these alkalies, is almost always necessary; and it was proved, that in every case in which such additions are unnecessary, the earth from which the alum is obtained contained already a quantity of potass. Various conjectures were made about the part which potass acts in this case; but Chaptal and Vauquelin appear to have been the first chemists that ascertained, by decisive experiments, that alum was a triple salt, composed of sulphat of alumina and of potass united together (S).

638 And properties.

Alum crystallizes in large octahedrons, composed of two tetrahedral pyramids, applied to each other at their bases.

It has a sweetish and astringent taste, and always reddens the tincture of turnsole.

It is soluble at the temperature of 60°, in from 10 * to 15 † times its own weight of water, according to its purity; pure alum being most insoluble. Seventy-five parts of boiling-water dissolve 100 of alum ‡.

* Neumann and Chaptal.
† Kirwan and Chaptal.
‡ Bergman.

A hundred parts of alum contain, according to Kirwan, 17,62 parts of acid, 18 of earth (and alkali), and 64,38 of water §.

§ Kirwan's Min. ii. 14.

When exposed to the air it effloresces slightly.

When exposed to a gentle heat it undergoes the watery fusion. A strong heat causes it to swell and foam, and to lose about 44 *per cent.* of its weight, consisting chiefly of water of crystallization‖. What remains is called *calcined* or *burnt alum*, and is sometimes used as a corrosive.

‖ Ibid.

Alum is of great importance as a mordant in dyeing, and is used also in several other arts.

By compound affinity it is decomposed by the following salts.

Nitrat of soda,	Acetite of potass,
—— lime,	—— —— soda,
—— ammonia,	—— —— lime,
—— magnesia,	—— —— ammonia,
Muriat of barytes,	—— —— magnesia,
—— —— potass,	Carbonat of barytes,
—— —— soda,	—— —— potass,
—— —— lime,	—— —— soda,
—— —— ammonia,	—— —— lime,
—— —— magnesia,	—— —— ammonia,
Acetite of barytes,	—— —— magnesia.

639 Homberg's pyrophorus.

If three parts of alum and one of flour or sugar be melted together in an iron ladle, and the mixture dried till it becomes blackish and ceases to swell; if it be then pounded small, put into a glass phial, and placed in a sand-bath till a blue flame issues from the mouth of the phial, and after burning for a minute or two be allowed to cool (T), a substance is obtained known by the name of *Homberg's pyrophorus*, which has the property of catching fire whenever it is exposed to the open air, especially if the air be moist.

This substance was accidentally discovered by Homberg about the beginning of the 18th century, while he was engaged in his experiments on the human fæces. He had distilled a mixture of human fæces and alum till he could obtain nothing more from it by means of heat; and four or five days after, while he was taking the residuum out of the retort, he was surprised to see it take fire spontaneously. Soon after Lemery the Younger discovered that honey, sugar, flour, or almost any animal or vegetable matter, could be substituted for human fæces; and afterwards Mr Lejoy de Suvigny shewed that several other salts containing sulphuric acid might be substituted for alum *. Scheele proved, that alum deprived of potass was incapable of forming pyrophorus, and that sulphat of potass might be substituted for alum †. And Mr Proust has shewn, that a number of neutral salts, composed of vegetable acids and alkalies, or earths, when distilled by a strong fire in a retort, left a residuum which took fire spontaneously on exposure to the air.

* See Macquer's Dict.
† Scheele on Fire, and on Pyrophorus.

These facts have thrown a great deal of light on the nature of Homberg's pyrophorus, and enabled us in some measure to account for its spontaneous inflammation. It has been ascertained, that part of the sulphuric acid is decomposed during the formation of the pyrophorus, and of course a part of the alkaline base becomes uncombined with acid, and the carbon, which gives it its black colour, is evidently divided into very minute particles. It has been ascertained, that during the combustion of the pyrophorus a quantity of oxygen is absorbed, The inflammation seems to be owing to a *disposing affinity*. Part of the carbon and of the sulphur attract oxygen from the atmosphere, in order to combine with the potass, and the caloric disengaged produces a temperature sufficiently high to kindle the rest of the carbon.

Alum is capable of combining with alumina, and of forming what has been called *alum saturated with its earth*, which is an insoluble, tasteless, earthy-like substance.

It is capable also, as Chaptal informs us, of combining with several other bases, and of forming many triple salts, which have never yet been examined with attention ‡.

‡ Ann. de Chim. xxii. 293.

11. Sulphat

(R) Some chemists have thought proper to call the sulphuric acid, obtained by distilling alum, *spirit of alum*.

(S) This they did in the two memoirs above quoted, and which were first published in the 22d volume of the *Annales de Chimie*. An account of Vauquelin's memoir has been already given under the article ALUM in this *Supplement*. Chaptal's memoir is no less interesting. This celebrated chemist appears, from the facts stated in the 23d volume of the *Annales*, p. 222. to have made his discovery before Vauquelin: who, however, was ignorant of what Chaptal had done, as he informs us in the *Ann. de Chim.* xxv. 107. that his paper was read to the Institute a fortnight before that of Chaptal's came to Paris. He informs us, too, that Descroisilles had long before made the same discovery, and that he had published it in Berthollet's *Art de la Teinture*.

(T) Care must be taken not to keep it too long exposed to the heat.

640 Sulphat of jargonia.

11. Sulphat of jargonia (υ). In order to combine jargonia with acids, they should be poured upon it while it is yet moist, after being precipitated from some of its solvents; for after it is dry, acids do not act upon it without difficulty. By this method sulphat of jargonia is easily formed. It is white, and without sensible taste. Heat expels the acid from it, and the jargonia remains in a state of purity. At a high temperature charcoal converts it into a sulphuret, which is soluble in water, and which, by evaporation, furnishes crystals of hydrosulphuret (τ) of jargonia *.

Klaproth informs us, that with excess of acid sulphat of jargonia forms transparent stelliform crystals, soluble in water, and having an astringent taste †.

* *Vauquelin, Ann. de Chim.* xxii. 199.

† *Jour. de Phys.* xxxvi. 187.

12. Sulphat of iron. There are two sulphats of iron, which were first accurately distinguished by Mr Proust. The one contains the green oxide, the other the red oxide of iron. We shall, in imitation of Mr Proust, denominate them from their colours.

641 Green sulphat of iron.

The *green sulphat of iron*.—This salt, which is composed of sulphuric acid and green oxide of iron, is found native, and was known to the ancients. It is mentioned by Pliny under the names of *misy*, *sory*, *calchantum* ‡. It was formerly called *green vitriol*.

‡ *Lib.* xxxiv. c. 12.

It is generally prepared by exposing native sulphuret of iron, a very abundant mineral, to air and moisture.

Its crystals are of a light green colour, and in the form of rhomboidal parallelopipeds.

It has a sharp astringent taste.

It is soluble in six times its weight of water at the temperature of 60°, and in $\frac{3}{4}$ths of its weight of boiling water §.

§ *Bergman.*

It is insoluble in alcohol.

According to Bergman, it is composed of 39 parts of acid, 23 of oxide, and 38 of water; but according to Mr Kirwan, of 26 parts of acid, 28 (υ) of oxide, and 46 of water.

When exposed to the air, it effloresces; but if it be moistened, it is gradually converted into red sulphat of iron.

When heated, it first assumes a yellow colour, loses its water and its acid; if the heat be increased, nothing remains but a yellow powder.

The Prussic alkali precipitates from the solution of this salt a white powder, which gradually becomes blue by attracting oxygen *.

* *Proust.*

It is used in dyeing, and in making ink, &c.

It is decomposed by compound affinity by

Nitrat of silver,

Muriat of soda †.

† *Ballen and Tutben, Ann. de Chim.* xi. 320.

The *red sulphat of iron* may be formed by exposing a solution of green sulphat to the air, or by treating it with nitric acid. It was formerly called *mother water of vitriol*.

642 Red sulphat of iron.

Little is known of its properties, except that it is deliquescent, incrystallizable, and soluble in alcohol.

It was first accurately examined by Mr Proust.

The green sulphat of iron generally contains some of it, which may be separated by means of alcohol.

It is alone capable of forming Prussian blue with the Prussic acid, and of striking a black colour with the gallic acid ‡.

We have observed, that when it is diluted with water, and an excess of sulphuric acid is poured in, it is again slowly converted into green sulphat.

‡ See *Proust's paper, Nicholson's Journal*, i. 435.

643 Sulphat of zinc.

13. Sulphat of zinc.—This salt, according to the best accounts, was discovered at Rammelsberg in Germany, about the middle of the 16th century. Many ascribe

(υ) *Jargonia*, or, as the French chemists call it, *zirconia*, has been discovered in great abundance in France by Morveau, who found that the hyacinths of Expailly contained more than half their weight of it. From Vauquelin's analysis they appear to be composed of

32	parts of silica,
64	jargonia,
2	oxide of iron.

Jargonia has been examined with great care by these two philosophers, the experiments of Klaproth have been confirmed, and several new properties of it have been discovered. Perhaps a more detailed account than we have hitherto given of this new earth may not be unacceptable to our readers.

Jargonia is a white powder, its specific gravity is considerable, it has a feel resembling that of silica, it has no taste, and is insoluble in water. When separated from its solutions by pure alkalies, it retains, when exposed to the air to dry, a pretty considerable quantity of water, which renders it transparent, and gives it a resemblance to gum arabic both in its colour and fracture.

When exposed to the heat of the blow-pipe it does not melt; but Vauquelin melted it by exposing it surrounded with charcoal in a porcelain crucible to an intense heat for an hour and a half. Its specific gravity was then 4,35, its colour was grey, and its hardness such that it was capable of scratching glass. It melts with borax, and forms a transparent and colourless glass; but phosphat of soda and the fixed alkalies do not attack it.

It is insoluble in the fixed alkalies, has very little affinity for carbonic acid, and is precipitated from its solutions together with iron by the Prussic alkali.

Its affinities, as far as they have been ascertained by Vauquelin, are as follows:

Vegetable acids, order unknown,
Sulphuric acid,
Muriatic,
Nitric.

See upon this subject the Memoirs of Morveau and Vauquelin, *Ann. de Chim.* xxi. 72. and xxii. 179.

(τ) These curious salts form the subject of the next chapter.

(υ) Perhaps the quantity of oxide is somewhat over-rated here; for before it was examined by Mr Kirwan, it had assumed a red colour: it must therefore have been converted into the brown or red oxide by attracting oxygen from the atmosphere.

Sulphats.

ascribe the invention to Julius Duke of Brunſwick. Henkel and Neumann were the firſt chemiſts who proved that it contained zinc; and Brandt firſt aſcertained its compoſition completely *. It is generally formed for commercial purpoſes from ſulphuret of zinc or *blende*, as it is called. This ſalt is called alſo *white vitriol*.

* *Beckmann's Hiſt. of Inventions*, art. *Zinc*.

It is of a white colour, and its cryſtals are rhomboidal priſms, terminated by quadrangular pyramids: there is generally a ſlight defect in two of the oppoſite angles of the priſm, which produces a quadrangular ſection †. Its ſpecific gravity is 2,000.

† *Bergman*, ii. 327.

It has a ſharp ſtyptic taſte.

It is ſoluble in 2,28 parts of water at the temperature of 60°; but in a much ſmaller quantity of boiling water ‡.

‡ *Ibid.*

It is compoſed, according to Bergman, of 40 (v) parts of acid, 20 of oxide, and 40 of water: Kirwan ſuppoſes that it is compoſed of 12 parts of acid, 26,4 of zinc, 20 of oxide, 41,6 of water (w).

According to Bergman, this ſalt is not altered in the air; others affirm that it effloreſces. This, no doubt, depends upon the place where it is kept.

Heat decompoſes this ſalt.

644 Sulphat of manganeſe.

14. Sulphat of manganeſe.—This ſalt was firſt obtained by Scheele (x): It is compoſed of ſulphuric acid and white oxide of manganeſe.

Its cryſtals are oblique parallelopipeds; they are of a white colour, and very bitter §.

§ *Scheele*,

Theſe cryſtals are decompoſed by a ſtrong red heat, and the ſulphuric is converted into ſulphurous acid by the oxide attracting its oxygen, and being changed into black oxide ‖.

‖ *Id.*

645 Sulphat of nickel.

15. Sulphat of nickel.—This ſalt, which is compoſed of ſulphuric acid and oxide of nickel, was firſt deſcribed by Bergman. Its cryſtals are in the form of decahedrons, compoſed of two quadrangular truncated pyramids; they are of a green colour ¶.

¶ *Bergman*, ii. 268.

646 Sulphat of cobalt.

16. Sulphat of cobalt.—This ſalt was firſt mentioned by Mr Brandt. Its cryſtals are of a reddiſh colour; but if any nickel be preſent, they are green.

647 Sulphat of lead.

17. Sulphat of lead.—This ſalt has been long known: it is compoſed of ſulphuric acid and white oxide of lead. The cryſtals are white, ſmall, and moſt commonly needle-ſhaped: according to Sage, they are tetrahedral priſms.

It is ſoluble in 18 parts of water,

Heat decompoſes it.—It is very cauſtic.

18. Sulphat of tin.—Nothing is known concerning this ſalt, except that it cryſtallizes in fine needles interlaced with one another *.

* *Monnet.*

648 Sulphat of copper.

19. Sulphat of copper.—This ſalt appears to have been known to the ancients. It is generally obtained by evaporating thoſe waters which naturally contain it. It is called alſo *blue vitriol*.

Its cryſtals are of a deep blue colour; they are in the form of oblong rhomboids. Its ſpecific gravity is 2,230.

It has a very ſtrong ſtyptic taſte; and indeed is employed as a cauſtic.

It is ſoluble in four parts of water at the temperature of 60°; but in a much ſmaller quantity of boiling water *.

* *Bergman*.

It is compoſed, according to Bergman, of 46 parts of acid, 26 of oxide of copper, and 28 of water. Kirwan ſuppoſes it to contain 27,68 of acid, 35 of oxide, and 37,32 of water †.

† *Miner.* ii. 23.

When expoſed to the air, it effloreſces, and is covered with a yellowiſh grey powder.

It requires a very ſtrong heat to decompoſe it.

It has the property of communicating a green colour to flame.

It is uſed in the preparation of ſeveral paints, and for a variety of other purpoſes.

It is decompoſed by compound affinity by acetite of lead.

20. Sulphat of biſmuth.—Little is known of this ſalt, except that it is with difficulty cryſtallized, and is very deliqueſcent. 649 Sulphat of biſmuth,

21. Sulphat of antimony.—This ſalt does not cryſtallize. It is eaſily decompoſed by heat. 650 Antimony,

22. Sulphat of arſenic.—This ſalt is ſcarcely known. It does not appear to be cryſtallizable. It is decompoſed by water. 651 Arſenic,

23. White ſulphat of mercury.—This ſalt may be formed by boiling together two parts of mercury and three of concentrated ſulphuric acid, and ſtopping the proceſs whenever the mercury is converted into a white maſs. This maſs, in order to remove the exceſs of acid, is to be waſhed repeatedly with ſmall portions of water, till it ceaſes to redden turnſole. The ſulphat of mercury, thus obtained, is very white. Its cryſtals are either ſmall plates or priſms. Its taſte is not very cauſtic. It is ſoluble in 500 parts of water at the temperature of 55°, and in 287 parts of boiling water. It is compoſed of 83 parts of white oxide of mercury, 12 of ſulphuric acid, and 5 of water ‡. It is not altered by expoſure to the air. Heat decompoſes it. 652 White ſulphat of mercury.

‡ *Fourcroy, Ann. de Chim.* x. 299.

This ſulphat is capable of combining with a new portion of acid: It was in that ſtate before it was waſhed with water. This ſalt, which may be called *acidulous white ſulphat of mercury*, has a very cauſtic taſte, and is corroſive. It reddens vegetable blues. It is ſoluble in 157 parts of water at the temperature of 55°, and in 33 parts of boiling water §.

§ *Fourcroy, ibid.*

24. Yellow ſulphat of mercury.—This ſalt may be obtained by continuing to boil the preceding mixture of mercury and ſulphuric acid till the mercury aſſumes a yellow colour. It appears to be compoſed of yellow oxide of mercury and a ſmall portion of ſulphuric acid. It is ſoluble in 2000 parts of water at the temperature of 55°, and in 600 parts of boiling water. The ſolution is colourleſs. It was formerly called *turbith mineral* ‖. 653 Yellow ſulphat of mercury.

‖ *Fourcroy, ibid.*

25. Sulphat of ammonia and mercury.—This triple ſalt may be formed by pouring ammonia into a ſolution of ſulphat of mercury. If only a ſmall quantity of ammonia be uſed, a copious blackiſh precipitate takes place, part of which is converted into running mercury by expoſure to light; and conſequently is black oxide of mercury; the remaining part is the triple ſalt. If a large quantity of ammonia be uſed, only the black oxide is 654 Sulphat of ammonia and mercury.

(v) There is evidently ſome miſtake in this ſtatement; it does not correſpond with what he ſays elſewhere.

(w) *Mineralogy*, ii. 24. We do not underſtand this ſtatement.

(x) Weſtfield, indeed, obtained it; but he miſtook it for ſulphat of magneſia.

Sulphats. is precipitated; for the triple ſalt is rendered much more ſoluble by an exceſs of ammonia. As this exceſs evaporates, the ſalt cryſtallizes. The cryſtals are polygons, very brilliant and hard. It has a ſharp, auſtere, metallic taſte. It has no peculiar odour. It is ſcarcely ſoluble, except with exceſs of ammonia. It is compoſed, according to Fourcroy's analyſis, of 18 parts of ſulphuric acid, 33 of ammonia, and 39 of oxide of mercury. Heat decompoſes it. The products obtained by diſtilling it are, a little ammonia, azotic gas, a little pure mercury, ſome *ſulphite of ammonia*; and there remains yellow ſulphat of mercury *.

This triple ſalt may be formed alſo by pouring ammonia upon acidulous ſulphat of mercury, or on yellow ſulphat of mercury †.

655 Sulphat of ſilver. 26. Sulphat of ſilver.—This ſalt is formed by pouring ſulphuric acid on oxide of ſilver. Its cryſtals are ſmall needles. It melts when expoſed to a ſtrong heat, but does not ſublime.

It is decompoſed by muriat of lead ‡.

27. Sulphat of gold.—This ſalt is unknown.

28. Sulphat of platinum.—Unknown.

29. Sulphat of tungſten.—Probably no ſuch combination is poſſible.

30. Sulphat of molybdenum.—Probably impoſſible.

656 Sulphat of uranium, 31. Sulphat of uranium.—This ſalt was firſt formed by Mr Klaproth. He formed it by pouring ſulphuric acid on the oxide of uranium. Nothing farther is known of it, except that its cryſtals are ſmall, and of a yellow colour.

657 Titanium, 32. Sulphat of titanium.—This ſalt was firſt formed by Mr M'Gregor. It does not appear, from Klaproth's experiments, to be cryſtallizable.

658 Tellurium. 33. Sulphat of tellurium.—When one part of tellurium is mixed cold in a well-ſtopped veſſel with a hundred parts of concentrated ſulphuric acid, the latter gradually aſſumes a beautiful crimſon red colour: when a ſmall quantity of water is added, drop by drop, the colour diſappears, and the metal is precipitated in the form of black flakes. The ſolution is deſtroyed by heat, the colour diſappears, and the metal ſeparates in the ſtate of a white oxide. When ſulphuric acid is diluted with two or three parts of water, and a ſmall quantity of nitric acid is added, it diſſolves a conſiderable quantity of tellurium. The ſolution is tranſparent and colourleſs, and is not decompoſed by the addition of a larger quantity of water §.

* Fourcroy, ibid.

† Ibid.

‡ Bergman.

§ Klaproth, Philoſophical Mag. i. 80.

Sect. II. *Of Sulphites.*

Salts compoſed of ſulphurous acid united reſpectively with alkalies, earths, or oxides, are called *ſulphites*. Thoſe hitherto examined are the following:

659 Sulphite of potaſs. 1. Sulphite of potaſs.—This ſalt was firſt formed by Stahl; but was firſt accurately deſcribed by Berthollet, Fourcroy, and Vauquelin.

It may be formed by paſſing ſulphurous acid into a ſaturated ſolution of carbonat of potaſs till all effervеſcence ceaſes. The ſolution becomes hot, and cryſtallizes by cooling ‖.

Its cryſtals are white and tranſparent; their figure that of rhomboidal plates. Its cryſtallization often preſents ſmall needles diverging from a common centre ¶.

Its taſte is penetrating and ſulphurous. At the common temperature of the atmoſphere, it is ſoluble in its own weight of water, but much more ſoluble in boiling water.

‖ Fourcroy, and Vauquelin, Nicholſon's Journ. i. 317.

¶ Ibid.

Sulphites. When expoſed to the air, it effloreſces, becomes opaque and hard, and is gradually converted into *ſulphat of potaſs* by abſorbing oxygen.

When expoſed to a ſudden heat, it decrepitates, loſes its water: at a red heat ſome ſulphurous vapours are emitted; at laſt a portion of ſulphur ſeparates, and the reſiduum is ſulphat of potaſs, with a ſlight exceſs of alkali.

Nitric and oxy-muriatic acids convert it into ſulphat of potaſs by imparting oxygen.

It decompoſes the oxides of gold, ſilver, mercury, the red oxide of lead, the black oxide of mangaueſe, and the brown oxide of iron. When the green oxide of iron and the white oxide of iron are boiled with it in water, and an acid added, a precipitate takes place of theſe bodies united to ſome ſulphur, and the ſalt is converted into a ſulphat: at the ſame time ſulphurated hydrogen gas is emitted.

By compound affinity it is decompoſed by

All ſalts with baſe of ſoda, except the borat and carbonat;

All metallic ſalts except carbonats;

All neutral ſalts whoſe acid has a ſtronger affinity for potaſs than ſulphurous acid has *.

2. Sulphite of ſoda.—This ſalt was firſt accurately deſcribed by Fourcroy and Vauquelin. 660 Sulphite of ſoda.

It is white and perfectly tranſparent. Its cryſtals are four-ſided priſms, with two very broad ſides and two very narrow ones, terminated by dehedral pyramids.

Its taſte is cool and ſulphurous.

It is ſoluble in four times its weight of cold water, but it is more ſoluble in hot water.

It is compoſed of 18,8 parts of ſoda, 31,2 of acid, and 50 of water.

By expoſure to air, it effloreſces, and is ſlowly converted into a ſulphat.

When expoſed to heat, it undergoes the watery fuſion, and afterwards exhibits preciſely the ſame phenomena as the ſulphite of potaſs.

Metallic oxides and ſalts affect it preciſely as they do ſulphite of potaſs.

It is decompoſed by compound affinity by carbonat of potaſs, and the other ſalts which decompoſe ſulphite of potaſs †.

3. Sulphite of ammonia.—This ſalt was firſt deſcribed by Fourcroy and Vauquelin ‡. 661 Sulphite of ammonia.

It cryſtallizes in ſix-ſided priſms terminated by ſix-ſided pyramids.

Its taſte is cool and penetrating like that of the other ammoniacal ſalts, but it leaves a ſulphurous impreſſion in the mouth.

It is ſoluble in its own weight of cold water. Its ſolubility is increaſed by heat.

It is compoſed of 29,07 parts of ammonia, 60,06 of acid, and 10,87 of water.

When expoſed to the air, it attracts moiſture, and is ſoon converted into a ſulphat.

Heat volatilizes it without decompoſition.

Its habitudes with metallic oxides and ſalts are nearly the ſame with thoſe of the above deſcribed ſulphites, only it is capable of forming with ſeveral of them triple ſalts §.

4. Sulphite of barytes.—This ſalt was firſt deſcribed by Berthollet ‖. 662 Sulphite of barytes.

It is incryſtallizable; it has no perceptible taſte; and is perfectly inſoluble in water ¶.

* Ibid.

† Ibid.

‡ Fourcroy and Vauquelin, Nicholſon's Journ. i. 317.

§ Ibid.

‖ Ann. de Chim. ii 57.

¶ Fourcroy and Vauquelin.

It

Sulphites

It is compoſed of 59 parts of barytes, 39 parts of acid, and 2 of water.

It does not eaſily change into a ſulphat by expoſure to air; but heat produces this effect *.

* Ibid.

663 Sulphite of lime.

5. Sulphite of lime.—This ſalt was firſt deſcribed by Berthollet †.

† Ann. de Chim. ibid.

Its cryſtals are ſix-ſided priſms, terminated each by a very long pyramid ‡.

‡ Fourcroy and Vauquelin.

It has ſcarcely any taſte; however, when kept long in the mouth, it communicates to the tongue a taſte which is manifeſtly ſulphurous.

It is very ſparingly ſoluble in water, except with exceſs of acid.

It is compoſed of 47 parts of lime, 48 of ſulphurous acid, and 5 of water.

By contact of air it is converted into a ſulphat, but very ſlowly.

Heat converts it into a ſulphat by depriving it of a portion of ſulphur.

It is decompoſed by compound affinity by

Carbonates of alkalies,	Fluats of alkalies,
Phoſphats of alkalies,	Moſt metallic ſalts §.

§ Ibid.

664 Sulphite of magneſia.

6. Sulphite of magneſia.—This ſalt was firſt deſcribed by Fourcroy and Vauquelin.

Its cryſtals are white and tranſparent, and in the form of depreſſed tetrahedrons.

Its taſte is mild and earthy at firſt, and afterwards ſulphurous.

It is ſparingly ſoluble in water, except when there is an exceſs of acid.

It is compoſed of 16 parts of magneſia, 39 of acid, and 45 of water.

It becomes opaque when expoſed to the air; is very ſlowly converted into a ſulphat.

By expoſure to heat, it ſoftens, ſwells up, and becomes ductile like gum; a ſtrong heat decompoſes it altogether.

It is decompoſed by

Alkaline ſalts,

Earthy ſalts, except thoſe of alumina ‖.

‖ Fourcroy and Vauquelin.

665 Sulphite of alumina.

7. Sulphite of alumina.—Firſt formed by Berthollet.

It does not cryſtallize, but is converted into a ſoft ductile maſs. It is not ſoluble in water, but becomes abundantly ſo when there is an exceſs of acid.

It is compoſed of 44 parts of alumina, 32 of acid, and 24 of water.

Heat decompoſes it ¶.

¶ Fourcroy and Vauquelin.

666 Sulphite of iron.

8. Sulphite of iron.—It was firſt formed by Berthollet.

Its cryſtals are white, and have but very little of the ſtyptic taſte of iron ſalts *.

Berthollet alſo formed the ſulphites of zinc and tin, but he has not deſcribed them.

* Ann. de Chim. ii. 58.

Sect. III. *Of Nitrats.*

Those ſalts, in the compoſition of which the nitric acid forms one ingredient, are called *nitrats*.

667 Nitre.

1. Nitrat of potaſs, nitre, or ſaltpetre.—As this ſalt is produced naturally in conſiderable quantities, particularly in Egypt, it is highly probable that the ancients were acquainted with it; but ſcarcely any thing certain can be collected from their writings. If Pliny mentions it at all, he confounds it with ſoda, which was known by the names of *nitron* and *nitrum*. It is certain, however, that it has been known in the eaſt from time immemorial. Roger Bacon mentions this ſalt in the 13th century under the name of *nitre*.

Nitrats.

It cryſtallizes in ſlender oblong hexagonal priſms, often ſtriated, terminated by hexagonal pyramids obliquely truncated. Its ſpecific gravity is 1,920.

Its taſte is ſharp, bitteriſh, and cooling.

It is ſoluble in ſeven times its weight of water at the temperature of 60°, and in nearly its own weight of boiling water *.

* Bergman.

According to Bergman, it is compoſed of 31 parts of acid, 61 of potaſs, and 8 of water; but this proportion of acid is undoubtedly too ſmall. According to Mr Kirwan, it is compoſed of 41,2 of acid, 46,15 of alkali, and 12,65 of water †.

† Mineral. ii. 27.

It is not altered by expoſure to the air.

When expoſed to a ſtrong heat, it melts; and congeals by cooling into an opaque maſs, which has been called *mineral cryſtal*. If the heat be continued, the acid is gradually decompoſed and driven off. When the ſolution of nitre is expoſed to a boiling heat, part of the ſalt is evaporated along with the water, as Wallerius, Kirwan, and Lavoiſier, obſerved ſucceſſively. When nitre is expoſed to heat along with many combuſtible ſubſtances, its acid is decompoſed; the combuſtible ſeizes the oxygen, and at the ſame time a lively white flame appears, attended with a decrepitation: this is called the *detonation of nitre*.

Nitre mixed with charcoal and ſulphur in proper proportions forms *gunpowder*.

Nitre is decompoſed by compound affinities by

Acetite of barytes.

668 Reproduction of nitre.

No phenomenon has excited the attention of chemical philoſophers more than the continual reproduction of nitre in certain places after it had been extracted from them. Prodigious quantities of this ſalt are neceſſary for the purpoſes of war; and as Nature has not laid up great magazines of it as ſhe has of ſome other ſalts, this annual reproduction is the only ſource from which it can be procured. It became, therefore, of the utmoſt conſequence, if poſſible, to diſcover the means which Nature employed in forming it, in order to enable us to imitate her proceſſes by art, or at leaſt to accelerate and facilitate them at pleaſure. Numerous attempts accordingly have been made to explain and to imitate theſe proceſſes.

Stahl, ſetting out on the principle that there is only one acid in nature, ſuppoſed that nitric acid is merely ſulphuric acid combined with phlogiſton; and that this combination is produced by putrefaction: he affirmed accordingly, that nitre is compoſed by uniting together potaſs, ſulphuric acid, and phlogiſton. But this opinion, which was merely ſupported by very far-fetched analogies, could not ſtand the teſt of a rigorous examination.

Lemery the Younger accordingly advanced another; affirming, that all the nitre obtained exiſts previouſly in animals and vegetables, and that it is formed in theſe ſubſtances by the proceſſes of vegetation and animalization. But it was ſoon diſcovered that nitre exiſts, and is actually formed, in many places where no animal nor vegetable ſubſtance has been decompoſed; and conſequently this theory was as untenable as the former. So far indeed is it from being true that nitre is formed alone by theſe proceſſes, that the quantity of nitre in plants has been found to depend entirely on the ſoil in which they grow ‡.

‡ Bouillon.

At

Nitrats.

At last by the numerous experiments of several French philosophers, particularly by those of Thouvenel, it was discovered that nothing else is necessary for the production of nitre but a basis of lime, heat, and an open but not too free communication with dry atmospheric air. When these circumstances combine, the acid is first formed, and afterwards the alkali makes its appearance. How the air furnishes materials for this production is easily explained, now that the component parts of the nitric acid are known to be oxygen and azot. But how lime contributes to their union it is not so easy to see. It is a disposing affinity, which, like most others referred to that singular class, our present knowledge of the nature of affinity does not enable us to explain. The appearance of the potass is equally extraordinary. If any thing can give countenance to the hypothesis, that potass is composed of lime and azot, it is this singular fact.

669 Nitrat of soda.

2. Nitrat of soda. This salt was called formerly *cubic nitre.*

It forms rhomboidal crystals. Its specific gravity is 1,870.

It has a cool sharp taste, and is somewhat more bitter than nitre.

It is soluble in about three parts of water at the temperature of 60°, and is scarcely more soluble in boiling water.

It is composed, according to Bergman, of 43 parts of acid, 32 of soda, and 25 of water. From an experiment formerly described, Mr Kirwan concludes, that it contains 57,65 of acid, and 42,35 of alkali; but perhaps the proportion of acid may be somewhat over-rated, as no direct proof has been brought that the salt contains no water.

When exposed to the air it rather attracts moisture.

Its phenomena in the fire are the same with those of nitre, only it does not melt so easily.

It is decomposed by compound affinity by the following salts:

Sulphat of barytes,	Muriat of ammonia,
——— potass,	Acetite of barytes,
——— alumina,	——— potass,
Muriat of barytes,	Carbonat of barytes,
——— potass,	——— potass.
——— lime,	

670 Nitrat of ammonia.

3. Nitrat of ammonia. This salt crystallizes with difficulty into regular needles. It was formerly called *nitrum semivolatile*, and *nitrum flammans.*

It has a sharp, acrid, somewhat urinous taste.

It is soluble in about half its weight of boiling water.

It is composed of 58 parts of acid, about 26 of alkali, and 16 of water*.

* Kirwan.

When exposed to the air it deliquesces.

When exposed to heat, it first undergoes the watery fusion, afterwards detonates, and is completely decomposed. Berthollet has shewn, that this phenomenon is owing to the hydrogen of the alkali entering into combination with the oxygen of the acid, and forming water, while the acid flies off in a gaseous form.

By compound affinity it is decomposed by the following substances:

Sulphat of barytes,	Acetite of barytes,
——— potass,	——— potass,
——— alumina,	——— soda,
Acetite of lime	Muriat of lime,
——— magnesia,	——— magnesia,
——— alumina,	——— alumina,
Muriat of barytes,	Carbonat of barytes,
——— potass,	——— potass,
——— soda,	——— soda.

671 Nitrat of barytes.

4. Nitrat of barytes. This salt may be formed into hexagonal crystals, but it requires great address to produce them.

It attracts moisture from the atmosphere.

Heat decomposes it, and leaves pure barytes. The decomposition of this salt by heat is the most convenient method of procuring pure barytes yet known. It was first proposed by Mr Vauquelin.

By compound affinity it is decomposed by

Alkaline carbonats,
Oxalat of ammonia *.

* Bergman.

672 Nitrat of lime.

5. Nitrat of lime. This salt forms by crystallization six-sided prisms, terminated by dehedral pyramids, but more commonly small regular octahedral needles.

It has a sharp bitterish taste.

It is soluble in two parts of cold water, and in its own weight of boiling water.

Boiling alcohol dissolves its own weight of it †.

† Bergman.

According to Bergman, it is composed of 43 parts of acid, 32 of lime, and 25 of water. Kirwan has found, that 100 parts of lime require for saturation 180 parts of acid ‡.

‡ Miner. ii. 29.

Nitrat of lime deliquesces when exposed to the air.

Heat decomposes it like all other nitrats.

By compound affinity it is decomposed by

Sulphat of barytes,	Acetite of potass,
——— potass,	Carbonat of barytes,
——— soda,	——— potass,
——— ammonia,	——— soda,
——— alumina,	——— ammonia,
Muriat of barytes,	——— alumina,
——— potass,	——— magnesia,
Acetite of barytes,	Tungstat of ammonia §.

§ Scheele.

673 Nitrat of strontites.

6. Nitrat of strontites. This salt, first formed by Dr Hope, crystallizes readily, but the crystals are very irregular in their shape: sometimes they are hexagonal truncated pyramids; sometimes octahedrons, consisting of two four-sided pyramids united at their bases.

It is soluble in its own weight of water, at the temperature of 60°, and in little more than half its weight of boiling water. It has a strong pungent taste.

In a dry air it effloresces, but in a moist air it deliquesces.

It deflagrates on hot coals. Subjected to heat in a crucible, it decrepitates gently, and then melts. In a red heat it boils, and the acid is dissipated. If a combustible substance be at this time brought into contact with it, a deflagration with a very vivid red flame is produced ||.

|| Hope, *Transf. Edin.* iv. 12.

674 Nitrat of magnesia.

7. Nitrat of magnesia. The composition of this salt was first ascertained by Dr Black.

Its crystals are quadrangular prisms. It has a very bitter taste. It is very soluble in water. Alcohol dissolves $\frac{1}{9}$th of its own weight of it ¶.

¶ Bergman, ii. 381.

One hundred parts of magnesia require 255 of nitric acid for saturation *.

* Kirwan.

It deliquesces in the air, according to Bergman; but Dijonval affirms, that he has procured it in crystals which rather effloresce.

It

Nitrats.

It is decomposed by heat.

By compound affinity it is decomposed by

Sulphat of barytes,	Muriat of lime,
——— potass,	Acetite of barytes,
——— soda,	——— potass,
——— ammonia,	——— soda,
——— alumina,	——— lime,
Muriat of barytes,	Carbonat of barytes,
——— potass,	——— potass,
——— soda,	——— lime.

675 Nitrat of ammonia and magnesia.

8. Nitrat of ammonia and magnesia. This triple salt was discovered by Mr Fourcroy. Into a saturated solution of nitrat of magnesia, containing 73 grains of magnesia, he poured ammonia as long as any precipitate could be obtained. Twenty-one grains of magnesia were precipitated, 52 grains remained combined with the acid and the ammonia. He found that 52 grains of magnesia produced, when saturated with nitric acid, 288 grains of nitrat; and that the quantity of nitric acid necessary to saturate 21 grains of magnesia, when saturated with ammonia, produced 84 grains of nitrat of ammonia. He concludes, therefore, though the data are not quite satisfactory, that the triple salt is composed of 288 grains of nitrat of magnesia, and 84 of nitrat of ammonia *.

* *Ann. de Chim.* iv. 215.

676 Nitrat of alumina.

9. Nitrat of alumina. This seems to have been first attended to by Beaumé.

Its crystals are pyramidal. It has a very astringent taste. It is soluble in water, and deliquesces in the air.

677 Nitrat of jargonia.

10. Nitrat of jargonia. This salt may be easily formed by pouring nitric acid on newly precipitated jargonia.

It always contains an excess of acid. By evaporation a yellowish transparent matter is obtained, exceedingly tenacious and viscid, and which dries with difficulty. It has an astringent taste, and leaves on the tongue a viscid matter, owing to its being decomposed by the saliva. It is only very sparingly soluble in water; the greatest part remains under the form of gelatinous and transparent flakes. Like all the other salts into which jargonia enters, it is decomposed by heat. It is decomposed also by sulphuric acid, which occasions a white precipitate, soluble in excess of acid; by carbonat of ammonia, which produces a precipitate soluble by adding more carbonat; and by an infusion of nut-galls in alcohol, which produces a white precipitate, soluble in an excess of the infusion; unless the jargonia contains iron; in which case the precipitate is a greyish blue, and part of it remains insoluble, giving the liquor a blue colour. This liquor, mixed with carbonat of ammonia, produces a matter purple by transmitted light, but violet by reflected light. Gallic acid also precipitates nitrat of jargonia of a greyish blue, but the colour is not so fine. Most of the other vegetable acids decompose this salt, and form combinations insoluble in water †.

† *Vauquelin, Ann. de Chim.* xxii. 199.

678 Nitrat of iron.

11. Nitrat of iron. The green oxide of iron decomposes, but does not combine with nitric acid. The brown oxide forms with it a red or brown solution, which by evaporation may be reduced to a jelly, but will not crystallize.

679 Nitrat of zinc.

12. Nitrat of zinc. The oxide of zinc combines with nitric acid, and forms with it a salt which crystallizes in compressed and striated tetrahedral prisms, terminated by four-sided pyramids.

Its solution is exceedingly caustic. When placed on burning coals it melts and detonates as it dries. It can scarcely be dried without being in some measure decomposed.

It deliquesces in the air *.

* *Fourcroy.*

680 Nitrat of manganese.

13. Nitrat of manganese. This salt, composed of oxide of manganese and nitric acid, was first examined by Scheele. Its crystals are small and shining, of a very bitter taste, and soluble in water †.

† *Scheele on Manganese.*

681 Nitrat of cobalt.

14. Nitrat of cobalt. It is of a pale red colour, and crystallizes in needles. It deliquesces when exposed to the air. Heat decomposes it. When nickel is present, this salt assumes a green colour.

682 Of nickel.

15. Nitrat of nickel. Its crystals are of a green colour, and in the form of rhomboidal cubes. They are deliquescent, and are gradually decomposed when exposed to the air, the acid leaving them ‡.

‡ *Bergman,* ii. 268.

683 Of lead.

16. Nitrat of lead. Nitric acid combines with the white oxide of lead. The crystals of this salt are of a white colour; their form an irregular octagon, or rather truncated hexahedral pyramid. When exposed to heat it decrepitates, and melts with a yellowish flame. By compound affinity it is decomposed by

Muriat of potass,
——— soda,
——— ammonia,
Carbonat of soda §.

§ *Bergman.*

684 Of tin.

17. Nitrat of tin. Tin is converted into an acid by nitric acid: it is not probable, therefore, that any permanent nitrat of tin can be formed.

685 Of copper.

18. Nitrat of copper. This salt appears to have been first obtained by Macquer.

Its form, when properly crystallized, is an oblong parallelogram. It is of a fine blue colour. It is exceedingly caustic. It melts at 77° ‖.

‖ *Sage.*

It is deliquescent in a moist air, but in a dry place is covered with a green efflorescence. It is very soluble in water. Heat decomposes it.

686 Of bismuth.

19. Nitrat of bismuth. This salt crystallizes in various forms. Fourcroy obtained it in flattened rhomboids. It effloresces in the air. Water decomposes it. It detonates in the fire.

687 Of antimony.

20. Nitrat of antimony. Little is known concerning this salt, except that it is very deliquescent, and is decomposed by heat.

688 Of arsenic.

21. Nitrat of arsenic. With white oxide of arsenic nitric acid forms a salt which crystallizes. It is very deliquescent. It does not detonate.

689 Of mercury.

22. Nitrat of mercury. This salt may be formed by dissolving mercury in nitric acid. It crystallizes in the cold in regular flat 14-sided figures; but their form differs according to the manner in which the crystallization has been performed.

It is soluble in water.

This salt is exceedingly caustic. It detonates on coals. When heated in a crucible it melts, and is decomposed. The oxide attracts oxygen from the acid, which flies off in the form of nitrous gas, and red oxide of mercury remains behind.

It is slowly decomposed also in the air. It is decomposed by compound affinity by

Sulphat of copper, and a great many other sulphats,
Phosphat of soda,
Borax.

690 Of ammonia and of mercury.

23. Nitrat of ammonia and mercury. This triple salt may be formed by pouring ammonia into a solution of

Muriats.

of nitrat of mercury. If only enough of ammonia to saturate the acid be used, the triple salt precipitates in the form of a white powder; but with an excess of ammonia it remains dissolved, and forms by evaporation very bright polyhedral crystals.

It has a very sharp taste. It is soluble in 1200 parts of water at the temperature of 55°. Hot water separates a little ammonia, which renders it still more insoluble. It turns vegetable blues green. Muriatic acid dissolves it.

According to Fourcroy's analysis, it is composed of 68,20 parts of oxide of mercury, 16 of ammonia, and 15,80 of nitric acid and water.

When distilled it yields ammonia, azotic gas, oxygen gas, yellow oxide of mercury, and pure mercury *.

* Fourcroy, *Ann. de Chim.* xiv. 37.

691 Nitrat of silver,

24. Nitrat of silver. This salt may be formed by dissolving silver in nitric acid.

It forms flat transparent crystals composed of needles. It is exceedingly caustic. When melted it forms a grey mass called *lapis infernalis*, from its great corrosiveness.

It is very soluble in water. It is not altered by exposure to the air. Light decomposes it.

By compound affinity it is decomposed by

The sulphats,
The muriats.

692 Nitrat of uranium,

25. Nitrat of uranium. This salt was first formed by Klaproth. Its crystals are hexagonal plates of a greenish yellow colour. The largest were ¾ths of an inch in length and ¼th in breadth †.

† *Klaproth, Journ. de Phys.* xxxvii. 158

693 Titanium,

26. Nitrat of titanium. It is capable of crystallizing.

694 Tellurium.

27. Nitrat of tellurium. The solution of tellurium in nitric acid is transparent and colourless. When concentrated, it produces in time small white light crystals in the form of needles, which exhibit a dendritic aggregation ‡.

‡ *Klaproth, Phil. Mag.* i. 80.

Sect. IV. *Of Nitrites.*

The salts which the nitrous acid forms with alkalies, earths, and metallic oxides, are denominated *nitrites*. Very few of them have been examined; we shall not therefore attempt a description of them.

Sect. V. *Of Muriats.*

Salts into which the muriatic acid enters are called *muriats*.

695 Muriat of potass.

1. Muriat of potass. This salt was formerly called *febrifuge* or *digestive salt of Sylvius*, and *regenerated sea salt*.

Its crystals are cubes, but rather irregular.

It has a disagreeable bitter taste. Its specific gravity is 1,836 §.

§ *Kirwan.*

It is soluble in three times its weight of water at the temperature of 60°, and in double its weight of boiling water ‖.

‖ *Bergman.*

It is composed, according to Bergman, of 31 parts of acid, 61 of potass, and 8 of water. Kirwan has found it to contain 36 of acid, 46 of alkali, and 18 of water ¶.

¶ *Kirwan's Mineral.* ii. 30.

It suffers little alteration from exposure to the air.

When exposed to heat, it first decrepitates, then melts, and at last is volatilized, but without decomposition.

The following salts decompose it by compound affinity:

Sulphat of soda,	Nitrat of ammonia,
—— ammonia,	—— magnesia,
—— alumina,	—— alumina,
Nitrat of soda,	—— lead.
—— lime,	

696 Muriat of soda.

2. Muriat of soda, common or sea salt. This salt has been known, and in common use, from the earliest ages. It is sometimes called also *sal gem*.

Its crystals are cubes, but they often assume other forms. Its specific gravity is 2,120 *.

* *Kirwan.*

Its taste is universally known, and is what is strictly speaking denominated *salt*.

It is soluble in $2\frac{14}{17}$ times its weight of water at the temperature of 60°, and in $2\frac{13}{17}$ its weight of boiling water †.

† *Bergman.*

According to Bergman, it is composed of 52 parts of acid, 42 of alkali, and 6 of water. According to the late experiments of Mr Kirwan, of 40 parts of acid, 35 of alkali, and 25 of water.

It is not affected by exposure to the air. It ought to be observed, however, that the muriat of soda in common use contains, besides other impurities, a quantity of muriat of magnesia, which renders it deliquescent.

When heated it decrepitates. Heat volatilizes, but does not decompose it.

The following salts decompose it by compound affinity:

Sulphat of ammonia,	Nitrat of silver §,
—— alumina,	Acetite of barytes,
—— potass *,	Pyrolignite of barytes ‖,
—— iron †,	—— lead ‖,
Nitrat of ammonia,	Carbonat of potass (*a*),
—— magnesia,	Alum (*b*),
—— alumina,	Red oxide of lead (*c*).
—— lead ‡,	

* *Fuchs, Ann. de Chim.* vi. 29.
† *Bullen, ibid.* xi. 320.
‡ *Morveau.*
§ *Bergman.*
‖ *Morveau, Ann. de Chim.* xix. 109.
(*a*) *Bergman*
(*b*) *Crell, Ann. de Chim.* xxvi. 297.
(*c*) *Scheele.*

697 How decomposed by red oxide of lead.

That the red oxide of lead decomposes this salt is a well known fact, and it has been considered as contrary to the laws of affinity. Mr Hassenfratz endeavoured to account for it by supposing that the oxide is combined with carbonic acid, and that therefore it is a case of compound affinity. Mr Curaudau has proved that carbonic acid, instead of promoting, impedes the decomposition; and that, in fact, carbonat of lead is incapable of decomposing muriat of soda. He concludes, therefore, that the phenomenon cannot be accounted for by the commonly received laws of affinity * We cannot, however, think that the phenomenon is so unaccountable as Mr Curaudau supposes; for muriatic acid is capable of decomposing the red oxide of lead, of combining with part of its oxygen, and of being converted into oxy-muriatic acid. Now if oxy-muriatic and nitro-muriatic acids be merely the same substance in a different form, as there is the strongest reason for supposing, the white oxide of lead has a stronger affinity for it than soda has, and ought therefore to decompose it.

* *Ann. de Chim.* xiv. 15.

698 Muriat of ammonia.

3. Muriat of ammonia, or sal ammoniac. This salt was known to the ancients, and was called by them *sal ammoniac*, because it was found in great quantities near the temple of Jupiter Ammon in Africa †.

† *Pliny*, lib. xxxi. c. 7. See *Sal Ammoniac*, Encyc.

It assumes the form of plumose crystals. The individual crystals are long hexahedral pyramids. Its specific gravity is 1,420 ‡.

‡ *Kirwan.*

It has an acrid, poignant, urinous taste.

It dissolves in about three times its weight of water at the temperature of 60°, and in a much smaller quantity of boiling water.

It is composed, according to Kirwan, of 35 parts of acid, 30 of alkali, and 45 of water §.

§ *Kirwan's Mineral.* ii. 34.

In its common form (which is an opaque mass) it is not affected by the air, but its crystals are liable to deliquesce.

Heat

Muriats.

Heat volatilizes without decomposing it.

The following salts decompose it by compound affinity :

Sulphat of alumina,	Acetite of magnesia,
Nitrat of soda,	——— alumina,
——— lead,	——— lead,
Acetite of barytes,	Carbonat of barytes,
——— potass,	——— potass,
——— soda,	——— magnesia (Y)
——— lime,	

When this salt is sublimed with gold leaf, there is found in the neck of the retort an amethyst coloured matter, bordering on purple, soluble in water, and forming a purple solution. When filtered there remains behind a purple powder. This salt seems from this to be capable of oxidating gold *.

* Storr, Crell's New Discoveries, &c. Part ii. p. 41.

699 Muriat of barytes,

4. Muriat of barytes. This salt was first described by Bergman, but it has been most particularly attended to by Dr Crawford.

It affords oblong square crystals.

It has an unpleasant astringent taste.

It is not very soluble in water. It is soluble in alcohol.

It is not altered by exposure to the air, nor does heat in all probability decompose it.

Dr Crawford wrote a treatise on it in 1790, in which he recommended its use internally for scrofulous complaints. Care ought to be taken not to give it in too large quantities, as, like the other compounds of barytes, it is poisonous.

The following salts decompose it by compound affinity (z) :

Sulphat of soda	Nitrat of lime,
——— ammonia,	——— ammonia,
——— magnesia,	——— magnesia,
——— alumina,	——— alumina,
Nitrat of soda,	Phosphat of lime †.

† Dr Pearson.

700 Muriat of ammonia and barytes,

5. Muriat of ammonia and barytes. This triple salt was first discovered by Fourcroy. It may be formed by pouring a carbonat of ammonia into a solution of muriat of barytes. It is easily decomposed by heat, but none of the alkalies nor their carbonats are capable of altering it ‡.

‡ Ann. de Chim. iv. 8.

701 Muriat of lime,

6. Muriat of lime. This salt was formerly called *fixed ammoniac*, because it was commonly obtained by decomposing sal ammoniac by means of lime.

Its crystals are four-sided striated prisms, terminated by a very sharp pyramid ; but it is not easily crystallized.

Its taste is very bitter.

It is soluble in about 1½ parts of cold water, and in less than its own weight of boiling water. Alcohol dissolves its own weight of it.

According to Bergman, it is composed of 31 parts of acid, 44 of lime, and 25 of water. According to Kirwan, 100 parts of lime require for saturation 86 parts of muriatic acid.

It very speedily deliquesces when exposed to the air. By heat it melts into a very hard vitreform substance.

The following salts decompose it by compound affinity :

Sulphat of soda,	Carbonat of potass,
——— ammonia,	——— soda,
——— magnesia,	——— ammonia *,
——— alumina,	——— barytes,
Nitrat of soda,	——— magnesia,
——— ammonia,	——— alumina,
——— magnesia,	Acetite of barytes,
——— alumina,	——— potass,
	——— soda.

* Bergman.

702 Muriat of strontites,

7. Muriat of strontites. This salt was first formed by Dr Hope. Its crystals are very long, slender, hexagonal prisms. It has a peculiar, sharp, penetrating taste.

Three parts of these crystals are soluble in two parts of water at the temperature of 60°. Boiling water dissolves any quantity of them whatever.

They contain 42 *per cent.* of water of crystallization.

They suffer no change when exposed to the air except it be very moist ; in which case they deliquesce.

When heated, they first undergo the watery fusion, and are then reduced to a white powder. A very violent heat decomposes this salt.

Muriatic acid precipitates this salt from its solution in water. That acid, therefore, has a stronger affinity for water than the salt has †.

† Hope, Trans. Edin. iv. 12.

703 Muriat of magnesia,

8. Muriat of magnesia. This salt abounds in sea water.

It is not easily crystallized. Bergman's method was to evaporate it by a considerable heat to the proper degree of concentration, and then to expose it to a sudden cold. By this method he obtained it in small needles ‡.

‡ Bergman, ii 383.

It has a very bitter taste. It is soluble in its own weight of water §, and in five parts of alcohol ‖.

§ Fourcroy.

‖ Bergman, ii. 383.

A saturated solution of it quickly forms a jelly ; on which if hot water be poured spongy masses are formed not even soluble in muriatic acid ¶.

¶ Bergman, ibid.

It is composed, according to Bergman, of 34 parts of acid, 41 of earth, and 25 of water. According to Kirwan, 100 parts of magnesia require for saturation 104,275 of acid *.

* Irish Trans. iv.

It deliquesces very speedily when exposed to the air.

A strong heat decomposes it. When dried in a high temperature, it is very caustic †.

† Westrum, Ann. de Chim. ii. 135.

The following substances decompose it by compound affinity :

Sulphat of soda,	Acetite of potass,
——— ammonia,	——— soda,
——— alumina,	——— silver ‡.
Nitrat of ammonia,	

‡ Bergman.

Carbonat

(Y) Only at the common temperature. At a high temperature carbonat of ammonia decomposes muriat of magnesia. See *Westrum, Ann. de Chim.* ii. 118.

(z) Bergman affirmed, that this salt decomposed all the sulphats, and proposed it therefore as a certain means of discovering the presence of sulphuric acid, however combined in any solution ; for the sulphat of barytes is almost entirely insoluble in water. But Mr Pissis has observed, that it does not decompose sulphat of lime nor of potass. See *Ann. de Chim.* xv. 317.

Muriats.

Carbonat of barytes,	Carbonat of ſoda
——— potaſs,	——— ammonia (Y).

704 Muriat of ammonia and magneſia, 9. Muriat of ammonia and magneſia. This triple ſalt was firſt mentioned, we believe, by Bergman. It may be formed by pouring ammonia into a ſolution of muriat of magneſia. Part of the magneſia is precipitated, but great part of it remains diſſolved, and combined with the acid and the ammonia. This triple ſalt is compoſed, according to Fourcroy, of 73 parts of muriat of magneſia and 27 of muriat of ammonia *.

* *Ann. de Chim.* iv. 222.

705 Muriat of alumina, 10. Muriat of alumina.—This ſalt cryſtallizes with difficulty. It has an aſtringent taſte. Its ſolution is gelatinous, and cannot be filtrated without much dilution in water. It is deliqueſcent. When evaporated to dryneſs, it forms a gummy maſs: in a ſtrong heat it is decompoſed.

The following ſalts decompoſe it by compound affinity:

Nitrat of ammonia,	Acetite of magneſia,
Acetite of barytes,	Carbonat of barytes,
——— potaſs,	——— potaſs,
——— ſoda,	——— ſoda,
——— lime,	——— ammonia.

706 Muriat of jargonia, 11. Muriat of jargonia.—This ſalt is eaſily formed by pouring muriatic acid on newly precipitated jargonia. It is colourleſs; its taſte is very aſtringent: by evaporation it furniſhes ſmall tranſparent cryſtals in needles, which loſe their tranſparence in the air. Muriat of jargonia is very ſoluble in water and in alcohol; to the flame of which it does not communicate any particular colour. Heat decompoſes it; and it is decompoſed likewiſe by the ſaliva when taken into the mouth.

When muriat of jargonia contains a little ſilica, it forms cubic cryſtals without conſiſtence, and reſembling a jelly. Theſe cryſtals, when expoſed to the air, gradually loſe their tranſparency, and diminiſh in volume, and there are formed in the middle of the ſalt white ſilky needle-ſhaped cryſtals.

Muriat of jargonia is decompoſed by ſulphuric acid; part of the ſulphat precipitates, and part remains diſſolved in the muriatic acid. When this acid is driven off by heat, the remainder of the ſulphat is gradually depoſited: if the evaporation be ſtopped before the maſs be reduced to dryneſs, it forms a kind of jelly when cold. It is alſo decompoſed by the phoſphoric, citric, tartarous, oxalic, and ſaccholactic acids, which form with jargonia inſoluble compounds that precipitate in white flakes.

The gallic acid poured into muriat of jargonia produces a white precipitate; but a green, bordering on grey, if the jargonia contain iron; and this laſt precipitate becomes, when dry, of a bright black colour, and reſembles China ink. The liquid preſerves a greeniſh colour; new portions of gallic acid produce no farther precipitation; but carbonat of ammonia ſeparates in great abundance a flaky matter of a purpliſh colour, not unlike that of the leys of wine. From theſe experiments it follows, that gallic acid has a greater affinity for jargonia than muriatic acid has; and that the gallats of jargonia and iron are ſoluble in muriatic acid.

Carbonat of potaſs decompoſes muriat of jargonia, and part of the carbonic acid combines with the earth, and renders it eaſily ſoluble in acids though dried.

Carbonat of ammonia occaſions a precipitate, which is moſtly diſſolved by adding more carbonat.

Pruſſiat of mercury produces an abundant precipitate, which is ſoluble in muriatic acid; and which conſequently is not muriat of mercury.

A plate of zinc, introduced into a ſolution of muriat of jargonia, occaſions a ſlight efferveſcence; the liquor becomes milky, and in a few days becomes a white ſemitranſparent jelly.

Alumina decompoſes muriat of jargonia with the aſſiſtance of a ſlight heat: the alumina diſſolves, the liquor becomes milky, and aſſumes the form of a jelly. When the muriat contains iron, it remains in the ſolution, and the precipitated jargonia is quite pure. Here, then, is a method of freeing jargonia from iron *.

* *Vauquelin, Ann. de Chim.* xxii. 201.

12. Muriat of iron.—Muriatic acid forms with the green oxide of iron a ſalt which cryſtallizes in flat needles. When expoſed to the air, they deliqueſce, and the green oxide attracts oxygen, and is gradually converted into a brown oxide. Heat decompoſes this ſalt. 707 Muriat of iron,

13. Muriat of zinc.—This ſalt, procured by diſſolving zinc or its oxide in muriatic acid, does not cryſtallize. Its ſolution is colourleſs. When heated, it becomes of a blackiſh brown. By diſtillation, a part of the acid is ſeparated, and muriat of zinc remains behind of a milk-white colour, ſolid, and formed of ſmall radiated needles. It attracts moiſture in the air. 708 Muriat of zinc,

14. Muriat of mangaueſe.—Muriatic acid diſſolves the white oxide of manganeſe. Its ſolution affords by evaporation angular ſhining cryſtals †: They are deliqueſcent and ſoluble in alcohol ‡. 709 Muriat of manganeſe,

† *Scheele* on *Manganeſe.*
‡ *Kirwan's Mineral.* ii. 37.

14. Muriat of cobalt.—The ſolution of oxide of cobalt in muriatic acid is of a pale red, except it be contaminated with nickel or iron, when it is greeniſh. It cryſtallizes in ſmall needles, which are very deliqueſcent. Heat decompoſes it. 710 Cobalt,

16. Muriat of nickel.—This ſalt is deliqueſcent, and loſes its acid when expoſed to the air §. 711 Nickel,

§ *Bergman*, ii. 268.

17. Muriat of lead.—Muriatic acid combines with oxide of lead eaſily enough: but this ſalt is more readily procured by pouring muriatic acid into a ſolution of nitrat of lead; the muriat immediately precipitates in the form of a white powder. It is ſoluble in 30 times its weight of boiling water; and the ſolution yields by evaporation ſmall, ſlender, brilliant needles in bundles. 712 Lead,

It is ſomewhat deliqueſcent. When expoſed to heat, it melts into a brown maſs, formerly called *corneous lead.*

It is decompoſed by compound affinity by

Sulphat of ſilver ||,
Carbonat of ſoda.

|| *Bergman.*

18. Muriat of tin.—This ſalt may be formed by diſſolving tin in hot muriatic acid. By evaporation it affords needle-ſhaped cryſtals, which are deliqueſcent. 713 Tin,

This ſalt has a ſtrong affinity for oxygen. It decompoſes oxy-muriatic, nitric, ſulphurous, arſenic, molybdic, and tungſtic acids, the red oxide of mercury, black oxide of manganeſe, oxide of antimony, zinc, ſilver,

(Y) Only at a high temperature. See *Muriat of Ammonia.*

Muriats. ver, and gold; and by that means is converted into oxy-muriat of tin. It even abſorbs oxygen when expoſed to the air *. Theſe compoſitions are doubtleſs produced by *diſpoſing affinity*.

* Pelletier, Ann. de Chim. xii. 225.

714 Muriat of copper,

19. Muriat of copper.—This ſalt may be formed by diſſolving copper or its oxide in muriatic acid.

Its cryſtals are priſmatic. It is of a beautiful graſs green colour. It has a very aſtringent and cauſtic taſte. It deliqueſces when expoſed to the air. A moderate heat is ſufficient to melt it; and when cooled it congeals into a maſs. It requires a ſtrong heat to volatilize it. It is decompoſed by nitrat of ſilver †.

† Bergman.

715 Muriat of biſmuth,

20. Muriat of biſmuth.—This ſalt cryſtallizes with difficulty. By ſublimation it forms a ſoft fuſible ſubſtance, formerly called *butter of biſmuth*.

716 Antimony,

21. Muriat of antimony.—This ſalt is found native. It cryſtallizes in priſms. When heated it evaporates.

717 Arſenic,

22. Muriat of arſenic.—This ſalt cryſtallizes; it is very volatile, and not very ſoluble, in water ‡.

‡ Bergman, ii. 293.

718 Mercury,

23. Muriat of mercury.—This ſalt may be prepared by pouring diluted muriatic acid into a diluted ſolution of nitrat of mercury: the muriat of mercury is immediately precipitated in the form of a white powder. Common ſalt may be uſed inſtead of muriatic acid. This ſalt was formerly called *white mercurial precipitate* and *calomel*.

It cryſtallizes; but the form of the cryſtals, which are very ſmall, has not been determined.

It has little taſte. It is almoſt inſoluble in water. It is uſed as a medicine.

It is decompoſed by ſulphat of ammonia §.

§ Bergman.

719 Muriat of ammonia and mercury,

24. Muriat of ammonia and mercury.—This triple ſalt was firſt diſcovered by Fourcroy. It may be formed by pouring ammonia into a ſolution of corroſive muriat of mercury. It has the appearance of a white powder. Its taſte is at firſt earthy, afterwards metallic. It is nearly inſoluble in water. According to Fourcroy's analyſis, it is compoſed of 81 parts of oxide of mercury, 16 of muriatic acid, and 3 of ammonia.

Heat decompoſes it; producing ammonia, azotic gas, and muriat of mercury.

Sulphuric, nitric, and muriatic acids decompoſe it ‖.

‖ Fourcroy, Ann. de Chim. xiv. 47.

720 Muriat of ſilver,

25. Muriat of ſilver.—This ſalt may be formed by diſſolving oxide of ſilver in muriatic acid, or, which is better, by pouring muriatic acid into nitrat of ſilver; muriat of ſilver immediately precipitates. It is very little ſoluble in water; according to Monnet, one part of it requires 3072 parts of water.

When expoſed to a ſmall heat, it melts into a grey ſemitranſparent maſs, not unlike horn; hence it was formerly called *luna cornea*. A long continued heat decompoſes it. This ſalt is very cauſtic: it is employed as an eſcharotic under the name of *lunar cauſtic*.

721 Muriat of titanium.

26. Muriat of titanium has been formed by Mr Klaproth.

Sect. VI. *Of Oxy-muriats.*

Those ſalts, into which the oxy-muriatic acid enters as an ingredient, are called *oxy-muriats*. As we conſider the nitro-muriatic acid to be preciſely the ſame with the oxy-muriatic, its combinations of courſe muſt receive the ſame name.

Oxy-muriats.

722 Oxy-muriat of potaſs,

1. Oxy-muriat of potaſs.—This ſingular ſalt was diſcovered by Mr Berthollet in 1786. It may be formed by ſaturating a ſolution of potaſs with oxy-muriatic acid gas. By evaporating this ſolution in the dark, common muriat of potaſs is firſt obtained: When it is ſeparated, and the liquor allowed to cool, oxy-muriat of potaſs cryſtallizes.

Its cryſtals are rhomboids, of a ſilvery brilliancy.

It has an inſipid cooling taſte, reſembling that of nitre. It is ſoluble in 17 parts of water at the temperature of 60, and in $2\frac{1}{2}$ parts of boiling water *. It does not deliqueſce in the air; but light converts it into common muriat by ſeparating oxygen. When heated, it melts, and gives out oxygen gas; and this is the beſt method hitherto diſcovered of obtaining that gas in a ſtate of purity. According to Mr Hoyle, it contains about half its weight of concrete oxygen †.

* Hoyle, Nicholſon's Journal, ii. 292.

† Ibid.

When mixed with charcoal, iron, and many other combuſtibles, and heated, it detonates with aſtoniſhing violence. This property induced the French chemiſts to propoſe it as a ſubſtitute for nitre in the preparation of gunpowder. The attempt was made at Eſſons in 1788; but no ſooner had the workmen begun to triturate the mixture of charcoal, ſulphur, and oxy-muriat, than it exploded with violence, and proved fatal to Mr Letors and Mademoiſelle Chevraud. The force of this gunpowder when it is prepared is much greater than that of the common ſort of powder; but the danger of preparing it, and even of uſing it after it is prepared, is ſo great, that it can hardly ever be ſubſtituted with advantage for common gunpowder.

Fourcroy and Vauquelin aſcertained by experiment, that this ſalt exploded when triturated with ſulphur, charcoal, antimony, arſenic, cinnabar, ſugar, gums, oils, alcohol, ether, and ſulphuret of iron. When theſe ſubſtances were mixed, and ſtruck with a hammer, the exploſion took place. The theory of theſe exploſions was firſt pointed out by Mr Berthollet. The oxygen of the oxy-muriatic acid combines with the combuſtible, and at the ſame time lets go a quantity of caloric; and trituration or percuſſion acts merely by bringing the particles which combine within the ſphere of each others attraction.

723 Oxy-muriat of ſoda,

2. Oxy-muriat of ſoda. This ſalt was diſcovered at the ſame time by Mr Berthollet. Its properties are the ſame with the laſt, except that it is too deliqueſcent to be uſed.

3. Oxy-muriat of ammonia.—This combination is impoſſible. The oxy-muriatic acid and ammonia decompoſe each other.

724 Oxy-muriat of barytes, lime, magneſia,

4. Oxy-muriat of barytes. }
5. ——————— lime. } Theſe ſalts were diſcovered by Berthollet
6. ——————— magneſia. } alſo. They all poſſeſs

the property of detonating with combuſtibles, and of being reduced by that means to the ſtate of common muriats. Mr Tennant has lately propoſed the oxy-muriat of lime as a ſubſtitute for the other ſubſtances formerly uſed in the new mode of bleaching; particularly for bleaching printed cottons: And, as far as we can learn, it anſwers the purpoſe remarkably well (z).

725 Oxy-muriat of mercury,

7. Oxy-muriat of mercury.—This ſalt was formerly called *corroſive ſublimate*, and afterwards *corroſive muriat*

(z) We have been informed, that this ſalt had been uſed by bleachers in Scotland ſome years before Mr Tennant propoſed it.

Oxy-muriat. *of mercury*. Berthollet first pointed out the nature of its composition.

This salt was mentioned by Rhases in the 10th century; and it seems to have been known in the east at a much earlier period (A). The methods of preparing it used by the older chemists were numerous, complicated, and generally concealed as secrets. We shall not attempt, therefore, to give any account of them; and the methods used by later chemists have been described at considerable length in the article CHEMISTRY (*Encycl.* n° 815.)

It may be prepared by dissolving mercury in a sufficient quantity of oxy-muriatic acid, or by dissolving red oxide of mercury in common muriatic acid.

When carefully crystallized, this salt assumes the form of cubes or oblique parallelopipeds, or rather quadrangular prisms, with sides alternately narrower, and terminated by two inclined planes meeting together.

It has an exceedingly disagreeable metallic taste.

It is soluble in 19 times its weight of water at the temperature of 50°*. Boiling water, according to Macquer, dissolves half its weight of it. Alcohol, at the temperature of 70°, dissolves $\frac{3}{8}$ths of its weight of this salt †.

* Spielman.

† Macquer.

It does not attract moisture from the air.

It is soluble in sulphuric, nitric, and muriatic acids.

When triturated with $\frac{3}{4}$ths of its weight of mercury and a little water, and then sublimed, it forms a white insipid salt, called formerly *calomel* or *sweet mercury:* This, as Scheele has proved, is precisely the same with common muriat of mercury.

The theory of these two preparations is now pretty obvious. The experiments of Adet and Pelletier have shewn, that oxy-muriatic acid may be obtained from corrosive muriat of mercury ‡. We may conclude, therefore, with confidence, that the salt is an oxy-muriat. It cannot be prepared by means of common muriatic acid, except with red oxide of mercury, or some other substance from which it may absorb oxygen. When pure mercury is added to oxy-muriat, it seizes the oxygen from the oxy-muriat, and the whole is converted into common muriat.

‡ Ann. de Chim. i. 1. and xii. 225.

It is decomposed by

Tartar,

Most metals.

726 Oxy-muriat of tin,

8. Oxy-muriat of tin. When an amalgam of tin is triturated with its own weight of corrosive muriat of mercury, and the mixture is distilled in a glass retort by means of a very gentle heat, there passes over a thick white smoke, which condenses into a colourless liquor that emits copious fumes, and has been called, in consequence, *smoking liquor of Libavius*. This liquor was examined by Mr Adet. He found, that when about $\frac{1}{7}$d part of water was added to this liquor, it ceased to fume, and assumed a crystalline form; that then it might even be made red hot without subliming. It therefore owes its volatility to want of water, or rather to a strong attraction for water. He found that this substance was capable of dissolving, and therefore of oxidating more tin, without the emission of any hydrogen, and consequently without the decomposition of water; he concluded from this, that it was composed of oxy-muriatic acid and tin *. This has been completely proved by Mr Pelletier, who found that when oxide of tin was combined with oxy-muriatic acid, it formed a compound precisely the same with the smoking liquor of Libavius †.

* Ann. de Chim. i. 3.

† Ann. de Chim. xiii. 225.

This salt may be prepared, as Pelletier has proved, by dissolving tin in muriatic acid, and then saturating it with oxy-muriatic acid gas.

It is used in dyeing.

727 Oxy-muriat of iron.

9. Oxy-muriat of iron. This salt is deliquescent; colourless; of a pure bitter taste, without any of the sweet astringency of the common salts of iron ‡.

‡ Lambe, Manchester Mem. v. p. 1.

Few of the other oxy-muriats have been hitherto examined with attention: Many of the metals, indeed, have been dissolved in aqua-regia; but in most of these solutions the salt produced is a common muriat. The nitric acid supplies oxygen, and the muriatic acid dissolves the oxide.

SECT. VII. *Of Phosphats.*

Phosphats.

THOSE salts, into which phosphoric acid enters as an ingredient, are called *phosphats*. This class of salts was first discovered by Margraf.

728 Phosphat of potass,

1. Phosphat of potass. This salt crystallizes in short tetrahedral prisms, terminated by quadrangular pyramids.

It is very soluble in cold water, and still more so in hot water.

It decrepitates on ignited coals like common salt. When a very strong heat is applied, it melts into an opaque vitreous mass, still soluble in water.

The following salts decompose it by compound affinity:

Sulphat of lime,	Muriat of mercury,
Nitrat of mercury,	Acetite of lead.

729 Phosphat of soda,

2. Phosphat of soda.—Dr Pearson, who first formed this salt, gives the following process for preparing it:

Dissolve in a long-necked matrass 1400 grains of crystallized carbonat of soda in 2100 grains of water at the temperature of 150°. Add gradually 500 grains of phosphoric acid of the specific gravity 1,85. Boil the liquor for some minutes; and while it is boiling hot, filtrate it, and pour it into a shallow vessel. Let it remain in a cool place, and crystals will continue to form for several days. From the above quantities of materials he has obtained from 1450 to 1550 grains of crystals.

Its crystals are rhomboidal prisms, of which the acute angles are 60°, and the obtuse angles 120°, terminated by a three-sided pyramid.

Its taste is almost the same with that of common salt.

It is soluble in water. When exposed to the air it effloresces.

This salt has been introduced into medicine as a purgative, and on account of its pleasant taste has of late been much used. It is usually taken in broth, which it is employed to season instead of common salt.

Hellot remarked a particular salt in urine, different from those that had usually been observed, in 1737. Haupt described it in 1740 under the name of *sal mirabile*

(A) If we listen to Junker, the ancients applied the name *mercurium* to this salt; mercury they called *argentum vivum*.

Phosphats. *rabile perlatum*, or *wonderful perlated salt*. It was called *perlated* from the grey, opaque, pearl-like colour which it assumed when melted by the blow-pipe. Margraf described it in 1745, and found it would not yield phosphorus when treated with charcoal, as the other salts of urine did. Rouelle the Younger analysed it in 1776, and concluded from his experiments that it was a compound of phosphoric acid and soda; but Mr Proust, being unable to obtain phosphorus from it, concluded, that it did not contain phosphoric acid, but another acid analogous to the boracic. To this substance, which Mr Proust actually obtained, Bergman gave the name of *perlated acid*, and Morveau afterwards called it *ouretic acid*. But Mr Klaproth soon afterwards analysed it, and proved that it consisted of soda supersaturated with phosphoric acid. Scheele soon after made the same discovery. This acid of Mr Proust, then, is merely phosphat of soda combined with phosphoric acid, or *acidulous phosphat of soda*.

730 Phosphat of ammonia, 3. Phosphat of ammonia.—This salt forms oblong-pointed crystals, or, as Mr Lavoisier affirms, crystals resembling those of alum.

It is soluble in water. Heat evaporates it so easily, that it is difficult to obtain it in crystals except by adding an excess of alkali.

Microcosmic salt, or salt of urine, is merely a mixture of these two last described salts.

731 Of barytes, 4. Phosphat of barytes.—This salt is insoluble in water *.

* Morveau.

732 Of lime, 5. Phosphat of lime.—This salt is tasteless, and almost perfectly insoluble in water. It forms the basis of bones, and is therefore often called *earth of bones*. Wenzel observed it crystallize when held in solution by phosphoric acid.

It is decomposed by sulphat of ammonia †.

Carbonat of potass ‡,

——— soda §.

† Dellestamp Ann. de Chim. vi. 37.

‡ Bergman.

§ Id.

733 Of strontites, 6. Phosphat of strontites.—This salt was first formed by Dr Hope. It is a white powder soluble in 1920 parts of boiling water ‖.

‖ Dr Hope Trans. Edin. iv. 16.

734 Of magnesia, 7. Phosphat of magnesia.—This salt does not crystallize except with excess of acid, and then the crystals are very small. Somewhat longer crystals may be formed by dropping phosphoric acid into acetite of magnesia. It most commonly forms by evaporation a gummy mass. It is soluble in alcohol ¶.

It is insoluble in nitric acid. It melts by a strong heat into a porcelain-like substance *.

¶ Bergman, ii. 390.

* Wenzel.

735 Of alumina, 8. Phosphat of alumina.—This is a saline powder, insoluble in water. Dissolved in phosphoric acid, it yields a gritty powder, and a gummy solution, which by heat is converted into a transparent glass.

736 Of iron, 9. Phosphat of iron.—This salt is merely a dry adhesive mass, insoluble in water, but soluble in acids. With excess of acid, it forms crystals which do not deliquesce, and by heat are converted into a garnet-coloured glass †.

† Id.

737 Of zinc, 10. Phosphat of zinc.—It does not crystallize, but when evaporated becomes a gummy mass, which may be melted into a transparent glass ‡.

‡ Id.

738 Of manganese, 11. Phosphat of manganese.—The solution of the oxide of manganese in phosphoric acid is reddish, but becomes white on exposure to the air.

739 Of nickel, 12. Phosphat of nickel.—It is greenish, and does not crystallize §.

§ Bergman, ii. 268.

13. Phosphat of arsenic.—It crystallizes in small grains hardly soluble in water *. Borats. 740 Of arsenic,

* Bergman, ii. 290.

14. Phosphat of uranium.—First formed by Klaproth. It does not crystallize, but assumes the appearance of yellowish white flakes, difficultly soluble in water. 741 Of uranium,

15. Phosphat of antimony and lime.—Dr Pearson has discovered, that the well known medicine called *James's Powder* is a triple salt, composed of phosphoric acid, oxide of antimony, and lime. It is very insoluble in water. 742 James's powder.

The remaining phosphats are scarcely known.

Sect. VIII. *Of Borats.*

The compounds into which the boracic acid enters are called *borats*.

1. Borat of potass.—This salt, formed by combining boracic acid and potass, is very little known. Baron first formed it. Borat of potass crystallizes, is soluble in water, and may be melted into a vitreous mass, soluble in water. 743 Borat of potass,

2. Borat of soda or borax.—This salt is brought from the East Indies in an impure state under the name of *tinkal*. When purified in Europe, it takes the name of *borax*. 744 Of soda,

Its crystals are hexangular prisms, of which two sides are much broader than the remainder, terminated by triangular pyramids. It is of a white colour. Its specific gravity is 1,740.

Its taste is styptic and alkaline.

It is soluble in 18 times its weight of water of the temperature of 60°, and 6 times its weight of boiling water.

It is composed, according to Bergman, of 17 parts of soda, 39 of acid, and 44 of water.

When exposed to the air, it effloresces slowly and slightly.

When heated, it swells, loses about four-tenths of its weight, becomes ropy, and then assumes the form of a light, porous, and very friable mass, known by the name of *calcined borax*; it then melts into a transparent glass, still soluble in water.

By compound affinity it is decomposed by

Nitrat of mercury †.

† Bergman.

When two pieces of borax are struck together in the dark, a flash of light is emitted ‡.

‡ Accum, Nicholson's Journal, ii. 28.

Borax has the property of facilitating the fusion of a great number of bodies. This property renders it useful in glass-making, in assaying ores, and in soldering metals.

Borax turns syrup of violets green; it appears therefore to be supersaturated with alkali.

The real borat of soda, or the salt in which boracic acid and soda saturate each other, has not yet been examined with attention. According to Dr Withering, soda requires twice its weight of boracic acid to saturate it.

3. Borat of ammonia.—This salt has been examined only by Mr Fourcroy. 745 Of ammonia,

Its crystals are polyhedral pyramids.

It has a poignant urinous taste, and turns syrup of violets green. It dissolves readily enough in water. When exposed to the air, it gradually loses its crystalline form and becomes brown §.

§ Fourcroy's Chemistry, Part ii. ch. 4.

4. Borat

Borats. 4. Borat of barytes.—Unknown.

5. Borat of lime.—It is difficultly soluble in water, and did not crystallize with Beaumé.
746 Of lime,

747 Of strontites, 6. Borat of strontites.—This salt was first formed by Dr Hope.—It is a white powder, soluble in about 130 parts of boiling water. The solution turns the syrup of violets green *.

* Hope, Trans. Edin. iv. 17.

748 Of magnesia, 7. Borat of magnesia.—It assumes the appearance of small irregular crystals. It is soluble in acetous and formic acids. Alcohol decomposes it. It melts easily in the fire without being decomposed †.

† Bergman, ii. 386.

749 Of alumina, 8. Borat of alumina.—It does not crystallize, and is scarcely soluble in water.

750 Of iron, 9. Borat of iron.—Its crystals are of a yellow colour, but the salt has never been examined with attention.

751 Of zinc, 10. Borat of zinc.—This salt does not appear to be capable of crystallizing. By heat, it melts into a light green insoluble slag ‡.

‡ Reuss.

752 Cobalt, 11. Borat of cobalt.—When oxide of cobalt is melted with boracic acid, a bluish grey slag is produced. This, by lixiviation and evaporation, yields crystals of a reddish white colour and ramified form §.

§ Id.

753 Nickel, 12. Borat of nickel.—A saline substance difficultly soluble ‖.

‖ Bergman.

754 Lead, 13. Borat of lead.—When boracic acid and red oxide of lead are melted together, the product is a fine greenish yellow, transparent, hard, insoluble glass ¶.

¶ Reuss.

755 Tin, 14. Borat of tin.—When equal parts of boracic acid and tin filings are melted together, the product dissolved in water yields by evaporation transparent white polygonous crystals.

756 Copper, 15. Borat of copper.—When borax is poured into a solution of sulphat of copper, borat of copper is precipitated in the form of a pale light green jelly, which when dried is with great difficulty soluble in water. It easily melts into a dark red vitreous substance*. According to Palm, by long trituration of filings of copper and boracic acid in water, and then digesting the mixture, it dissolves, and crystals may be obtained from it.

* Bergman.

757 Bismuth, 16. Borat of bismuth.—A white powder, which melts into a white transparent permanent glass †.

† Wenzel.

758 Arsenic, 17. Borat of arsenic.—White oxide of arsenic and boracic acid form a salt soluble in water and crystallizable ‡.

‡ Reuss.

Sect. IX. *Of Fluats.*

Those salts into which fluoric acid enters are called *fluats*. They were first formed by Scheele.

759 Fluat of potass, 1. Fluat of potass. It forms a gelatinous mass almost without taste.

It dissolves readily in water. When exposed to the fire it melts without any ebulition §.

§ Scheele on Fluor.

760 Soda, 2. Fluat of soda. This salt resembles exactly the fluat of potass ‖.

‖ Ibid.

761 Ammonia, 3. Fluat of ammonia. It crystallizes in small prisms. It is deliquescent, and is partly decomposed by heat ¶.

¶ Wiegleb.

It is decomposed by

Nitrat of mercury,
——— — silver,
——— — lead.

762 Barytes, 4. Fluat of barytes. A powder which requires a large quantity of water to dissolve it *.

* Bergman.

763 Lime, 5. Fluat of lime. This salt abounds in nature. It is known by the name of fluor spar.

It crystallizes most commonly in the form of cubes.

Fluats. It is tasteless and nearly insoluble in water.

It is not altered by the air. Its specific gravity is about 3,1.

When exposed to a sudden heat it decrepitates. A very violent heat melts it into a white opaque mass.

When reduced to powder and heated it becomes phosphorescent; but it loses this quality altogether if it be heated red hot.

6. Fluat of strontites. This salt was formed by Dr Hope: but its properties have not been examined.

7. Fluat of magnesia.—It is not soluble in water except there be an excess of acid. In that case, by spontaneous evaporation, it forms hexagonal prisms, terminated by a low pyramid composed of three rhomboidal sides. 764 Magnesia,

These crystals are hardly soluble in water. Alcohol dissolves a small portion of them. Heat does not decompose them *.

* Bergman, ii. 384.

8. Fluat of alumina. A saline mass; which is sweetish, clammy, and gelatinous. 765 Alumina,

9. Fluat of silica. Little is known concerning this singular combination, except that it can exist in a gaseous form, and that it deposites silica in crystals after a certain time. 766 Silica,

10. Fluat of silica and potass or soda. This triple salt may be formed by pouring fixed alkali into a solution of fluat of silica. It contains an excess of acid. On evaporation it yields a kind of jelly, which when dry separates into gritty particles like sand. It is soluble in 96 parts of hot water. In the fire it readily melts into a white mass. If the heat be continued the acid separates, and there remains a transparent glass, which is soluble in water, and forms a *liquor silicum* †.

† Scheele, Crell's Journal, i. 207. Eng. Transl.

11. Fluat of iron. It is incrystallizable; but when evaporated leaves a hard mass.

12. Fluat of zinc. It resembles that of iron.

13. Fluat of manganese. It may be formed by pouring fluat of ammonia into a solution of oxide of zinc in any of the three mineral acids. It crystallizes. 767 Metallic fluats.

14. Fluat of cobalt. A yellow gelatinous mass.

15. Fluat of nickel. It affords green crystals.

16. Fluat of lead. A sweet tasted powder.

17. Fluat of tin. A nauseous tasted jelly.

18. Fluat of copper. Blue crystals; some of them oblong, others cubic.

19. Fluat of arsenic. Small crystals.

20. Fluat of mercury. A powder. Before the blowpipe it melts into a yellow glass, most of which evaporates by a continued heat ‡.

‡ Scheele on Fluor.

Sect. X. *Of Carbonats.*

The compounds into which the carbonic acid enters are called *carbonats*. They were first analysed by Dr Black.

1. Carbonat of potass. This salt is formed by saturating potass with carbonic acid, which is best done by exposing a solution of potass for a considerable time to carbonic acid gas. 768 Carbonat of potass.

It crystallizes, according to Bergman, in quadrangular prisms; the apexes of which are composed of two inverted triangles, converging like the roof of a house ‖. According to Pelletier they are tetrahedral rhomboidal prisms, with dihedral summits. The complete crystal has eight faces, two hexagons, two rectangles, and four rhombs ¶.

‖ Bergman.

¶ Ann. de Chim. xv. 29.

It

Carbonats.

It has an alkaline, but not a caustic taste.

It is soluble at the common temperature in about four times its weight in water *. Boiling water dissolves $\frac{5}{6}$ths of its weight †. Alcohol, even when hot, does not dissolve above $\frac{1}{1200}$ parts of it.

* *Bergman*, i. 13.
† *Pelletier.*

According to Bergman, it is composed of 48 parts of potass, 20 of acid, and 32 of water. According to Pelletier, of 43 parts of acid, 40 of potass, and 17 of water. Bergman under-rated the quantity of acid from not observing that the salt loses part of its acid when heated. Even solution in hot water produces a separation of some acid ‡.

‡ *Id.*

It is not altered by exposure to the air.

Heat deprives it of its water and part of its acid, but does not decompose it completely. The following salts decompose it by compound affinity:

Sulphat of lime,	Nitrat of barytes,
——— barytes,	——— soda,
——— soda,	——— ammonia,
——— ammonia,	——— magnesia,
——— magnesia,	——— alumina,
——— alumina,	Acetite of barytes,
Muriat of barytes,	——— lime,
——— lime,	——— ammonia,
——— ammonia,	——— magnesia,
——— magnesia,	——— alumina,
——— alumina,	Oxy-muriat of mercury,
——— soda §,	Phosphat of lime ‖.
Nitrat of lime,	

§ *Bergman.*
‖ *Id.*

When potass is saturated with carbonic acid it always lets fall a quantity of silica. Mr Pelletier has proposed this saturation as the best method of purifying potass from that earth.

769 Carbonat of soda,

2. Carbonat of soda. This salt may be formed in the same manner with carbonat of potass.

Its crystals are five-sided prisms, with one of the angles frequently truncated, surmounted by dihedral pyramids with rhomboidal faces.

Its taste is precisely the same with that of carbonat of potass.

It is soluble in double its weight of cold water.

It is composed, according to Bergman, of 16 parts of acid, 20 of alkali, and 64 of water.

It effloresces when exposed to the air. Heat is incapable of decomposing it completely ¶.

¶ *Bergman*, i. 18.

The following salts decompose it by compound affinity:

Sulphat of ammonia,	Acetite of barytes,
——— barytes,	——— ammonia,
——— lime,	——— lime,
——— magnesia ‡,	——— magnesia,
——— alumina,	——— alumina,
Muriat of barytes,	Nitrat of ammonia,
——— ammonia,	——— magnesia,
——— lime,	——— alumina,
——— magnesia,	——— lead *,
——— alumina,	Phosphat of lime †.

‡ *Bergman.*
* *Id.*
† *Id.*

770 Carbonat of ammonia,

3. Carbonat of ammonia. This salt forms octahedral crystals, having for the most part their two opposite apexes truncated ‡.

‡ *Bergman*, i. [illegible]

Its taste and smell, though much weaker, are the same with those of pure ammonia. Like all the alkaline carbonats it converts vegetable blues to green, precisely as pure alkalies do.

It is soluble in rather less than twice its weight of cold water. Hot water dissolves its own weight of it.

According to Bergman it is composed of 43 parts of alkali, 45 of acid, and 12 of water.

When exposed to the air it becomes somewhat moist.

The smallest heat is sufficient to evaporate it.

The following salts decompose it by compound affinity:

Sulphat of alumina,	Acetite of barytes,
Nitrat of lime,	——— lime,
Muriat of lime,	——— magnesia,
——— magnesia,	——— alumina.
——— alumina,	

771 Carbonat of barytes,

4. Carbonat of barytes. This salt has been found native.

Its crystals have been observed to assume four different forms; double six-sided and double four-sided pyramids, six-sided columns terminated by a pyramid with the same number of faces, and small radiated crystals $\frac{1}{2}$ an inch in length, and very thin, appearing to be hexagonal prisms, rounded towards the point.

Cold water dissolves $\frac{1}{4304}$ part, and boiling water $\frac{1}{2304}$ part of this salt. Water saturated with carbonic acid dissolves $\frac{1}{830}$th part*.

* *Fourcroy, Ann. de Chim.* iv. 64.

According to Dr Withering, who first discovered it native, it is composed of 80 parts of barytes and 20 of acid. Bergman informs us, that artificial carbonat is composed of 7 parts of acid, 28 of water, and 65 of earth †.

† *Bergman*, i. 21.

It is not altered by exposure to the air.

It is decomposed by the application of a very violent heat ‡.

‡ *Dr Hope.*

By compound affinity it is decomposed by the following salts:

Sulphat of soda,	Nitrat of alumina,
——— lime,	Muriat of lime,
——— ammonia,	——— ammonia,
——— magnesia,	——— magnesia,
——— alumina,	——— alumina,
Nitrat of soda,	Acetite of lime,
——— lime,	——— magnesia,
——— ammonia,	——— alumina.
——— magnesia,	

772 Carbonat of lime.

5. Carbonat of lime. This substance, under the names of marble, chalk, lime-stone, &c. exists in great abundance in nature, variously mixed with other bodies.

When pure, it is of a white colour, and has very little taste.

It is insoluble in pure water; but water saturated with carbonic acid dissolves $\frac{1}{1500}$ part of it; from this solution it gradually precipitates as the acid leaves it in the form of small rhomboidal crystals §.

§ *Bergman*, i. 21.

It is composed, according to Bergman, of 34 parts of acid, 11 of water, and 55 of lime.

It suffers little or no alteration by being exposed to the air.

When exposed to heat, it first loses its water, and afterwards its acid separates as the heat is increased: But to separate the acid completely, a very strong heat is required.

The following salts decompose it by compound affinity:

Sulphat of alumina,
——— copper.

773 Carbonat of strontites,

6. Carbonat of strontites. This salt, which was first examined by Dr Hope, is insipid, and soluble in 1536 parts

Carbonats.

parts of boiling water. It is compoſed of 30,2 parts of acid, 69,8 of ſtrontites. A violent heat decompoſes it *.

* Hope, Tranſ. Edin. iv. 5.

7. Carbonat of magneſia. This ſalt may be formed by ſaturating the common magneſia of the ſhops with carbonic acid gas.

774 Carbonat of magneſia.

It diſſolves in water ſaturated with carbonic acid; and forms by evaporation cryſtals, which are tranſparent hexagonal priſms, terminated by a hexagonal plane; theſe are partly in groups and partly ſolitary: their length is about ſix lines, their breadth two †. They were diſcovered by Mr Butini of Geneva.

† Butini ſur la Magneſie.

Water at the temperature of 50 diſſolves $\frac{1}{48}$ part of its weight of this ſalt ‡. When in the ſtate of powder, and of courſe deprived of its water of cryſtallization, it is much more inſoluble; and what is very remarkable, it is more ſoluble in cold than in hot water, impregnated with carbonic acid §.

‡ Fourcroy, Ann. de Chim. ii. 298.

§ Butini.

It is compoſed, according to Fourcroy, of 50 parts of acid, 25 of magneſia, and 25 of water.

When expoſed to the air, it effloreſces, and falls into powder ||.

|| Fourcroy, ibid.

When heated, it decrepitates, falls into powder, and is decompoſed ¶.

¶ Id. ibid.

The following ſalts decompoſe it by compound affinity:

Sulphat of lime,	Nitrat of lime,
——— ammonia,	Muriat of lime,
——— alumina,	Acetite of lime.

775 Carbonat of alumina.

8. Carbonat of alumina. Carbonic acid is capable of diſſolving alumina; for if alum be decompoſed by an alkaline carbonat, ſome alumina remains diſſolved in the liquor, and may be precipitated by a heat ſufficient to drive off the carbonic acid *. It cannot be doubted, then, that there may be produced a carbonat of alumina; but the ſalt has never been examined with accuracy.

* Bergman, i. 21.

776 Metallic carbonats.

9. Carbonat of iron. Water ſaturated with carbonic acid diſſolves $\frac{1}{10000}$ part of its weight of iron, which gradually precipitates by expoſure to the air †. Ruſt of iron is a kind of carbonat, at leaſt it always contains carbonic acid.

† Bergman, i. 33.

10. Carbonat of zinc. Zinc is copiouſly diſſolved by water ſaturated with carbonic acid ‡. As the metallic oxides, when ſaturated with carbonic acid, do not differ materially in their appearance from pure oxides, we ſhall not attempt to deſcribe any of the metallic carbonats. We ſhall, however, preſent our readers with the following Table, exhibiting a view of the weight which metallic oxides gain by being ſaturated with this acid.

‡ Ibid.

100 parts of	By Bergman. Precipitated by Carb. of Soda. Weight.	By Wenzel. Precipitated by Carb. of Potaſs. Weight.
Oxide of zinc,	100,930	100,774
iron,	100,250	100,863
manganeſe,	100,800	
cobalt,	100,600	
nickel,	100,350	
lead,	100,320	100,304
tin,	100,310	100,345
copper,	100,940	100,884
biſmuth,	100,300	100,224
antimony,	100,400	100,395
mercury,	100,100	100,062
ſilver,	100,290	100,288
gold,	100,060	100,326

Quantity of loſs by driving off the gas by ſolution according to Wenzel:

Acetites.

Zinc,	0,137
Iron,	0,009
Cobalt,	0,352
Lead,	0,157
Tin,	0,000
Copper,	0,174
Biſmuth,	0,056
Antimony,	0,000
Mercury,	0,038
Silver,	0,158
Gold,	0,144

Theſe determinations differ too widely from each other to be exact. It is obvious that part of the weight muſt be owing to adhering water, and very probably triple ſalts are formed, which muſt render the determination ſtill more erroneous.

Sect. XI. *Of Acetites.*

The compounds which the acetous acid forms are called *acetites*.

777 Acetite of potaſs.

1. Acetite of potaſs. Pliny is ſuppoſed, but probably without any reaſon, to have been acquainted with this ſalt, becauſe he recommends a mixture of vinegar and vine aſhes as a cure for a particular ſpecies of tumor*. It was firſt clearly deſcribed by Raymond Lully. It has received a great number of names; as, for inſtance, *arcanum tartari*, *ſecret foliated earth of tartar*, *eſſential ſalt of wine*, *regenerated tartar*, *diuretic ſalt*, *digeſtive ſalt of Sylvius*.

* Plinii, l. xxiii. *proœmium*.

Its cryſtals are very white, and aſſume the form of thin plates.

It has a ſharp warm taſte.

It is ſoluble in about ten times its weight of water at the temperature of 60° †. It is ſoluble alſo in alcohol.

† Bergman, v. 78.

According to Wenzel, 240 parts of acetous acid require for ſaturation 241$\frac{4}{9}$ths of potaſs. And from the experiments of Dr Higgins, it appears that acetite of potaſs is compoſed of 61,5 parts of alkali and 38,5 of acetous acid and water ‡.

‡ On Acetous Acid, p. 8.

When expoſed to the air it is very deliqueſcent. When heated, it melts as readily as wax; and if a very ſtrong heat be applied, the acid is decompoſed.

The following ſalts decompoſe it by compound affinity:

Sulphat of ſoda,	Nitrat of ammonia,
——— lime,	——— magneſia,
——— ammonia,	——— alumina,
——— magneſia,	——— biſmuth,
——— alumina,	——— mercury,
Nitrat of ſoda,	Muriat of ammonia,
——— lime,	——— alumina.

778 Acetite of ſoda.

2. Acetite of ſoda. This ſalt was firſt deſcribed by Mr Baron.

Its cryſtals are ſtriated priſms, not unlike thoſe of ſulphat of ſoda.

It has a ſharp taſte, approaching to bitter.

It is ſoluble in 2,86 parts of water at the temperature of 60° §.

§ Bergman, ibid.

According to Wenzel, 440 parts of acetous acid require for ſaturation 157$\frac{3}{7}$ths of ſoda.

It is not affected by expoſure to the air.

When heated, it firſt loſes its water of cryſtallization; in

Acetites.

in a ſtrong heat it melts; and in a ſtill ſtronger, its acid is deſtroyed. This ſalt can only be obtained in cryſtals when there is an exceſs of alkali in the ſolution.

The following ſalts decompoſe it by compound affinity:

Sulphat of ammonia,	Nitrat of alumina,
——— alumina,	Muriat of lime,
Nitrat of ammonia,	——— ammonia,
——— magneſia,	——— magneſia.

779 Acetite of ammonia. 3. Acetite of ammonia. This ſalt was formerly called *ſpirit of Mindererus*.

It is too volatile to be eaſily cryſtallized: It may, however, by gentle evaporation, be made to depoſite needle-ſhaped cryſtals. Mr de Laſſone cryſtallized it by ſublimation *. When the ſublimation is ſlow, it forms long, ſlender, flatted cryſtals, terminating in ſharp points, of a pearl white colour, and about an inch and eight-tenths in length †.

It impreſſes the tongue at firſt with a ſenſe of coldneſs, and then of ſweetneſs, which is followed by a taſte reſembling that of a mixture of ſugar and nitre, in which the ſweet does not predominate over the mawkiſh taſte of the nitre ‡.

According to Wenzel, 240 parts of acetous acid ſaturate 244 of ammonia.

It is very deliqueſcent. It melts at 170°, and ſublimes at about 250° §.

When a watery ſolution of this ſalt is diſtilled, there comes over firſt a quantity of ammonia, next a quantity of acetous acid, and at laſt of the neutral ſalt itſelf. No ſuch decompoſition takes place when the cryſtals are diſtilled by a moderate heat ‖.

The following ſalts decompoſe acetite of ammonia by compound affinity:

Sulphat of alumina,	Carbonat of ſoda,
Carbonat of potaſs,	Nitrat of ſilver ¶.

* *Mem. Par.* i. 775.
† *Higgins on Acetous Acid*, p. 188.
‡ *Higgins, ibid*, p. 192.
§ *Ibid.*
‖ *Ibid.*
¶ *Ibid.* p. 193.

780 Acetite of barytes. 4. Acetite of barytes. This ſalt was firſt formed by Mr Morveau.

It is not eaſily cryſtallized. Morveau procured it in long priſms in groups.

It has a pleaſant, ſomewhat acid taſte, and always contains an exceſs of acid.

It is ſoluble in water, and does not deliqueſce when expoſed to the air *.

The following ſalts decompoſe it by compound affinity:

Sulphat of potaſs,	Nitrat of alumina,
——— ſoda,	Muriat of potaſs,
——— lime,	——— ſoda,
——— ammonia,	——— lime,
——— magneſia,	——— ammonia,
——— alumina,	——— magneſia,
Nitrat of potaſs,	——— alumina,
——— ſoda,	Carbonat of potaſs,
——— lime,	——— ſoda,
——— ammonia,	——— ammonia.
——— magneſia,	

* *Morveau, Encyc. Method. Chim.* i. 8.

781 Acetite of lime. 5. Acetite of lime. This ſalt was firſt deſcribed accurately by Crollius. The ancients, however, uſed a mixture of lime and vinegar in ſurgery †.

It cryſtallizes in fine needles, of a gloſſy appearance like ſatin.

Its taſte is bitter and ſour, becauſe it has an exceſs of acid.

It is ſoluble in water.

† *Plinii*, l. xxxvi. c. 24.

According to Wenzel, 240 parts of acetous acid require for ſaturation 125 of lime: according to Maret, 100 parts of acetite of lime contain 50 of lime *. From the experiments of Dr Higgins, it follows, that acetite of lime is compoſed of 35,7 parts of lime and 64,3 of acetous acid and water †.

It is not altered by expoſure to the air; at leaſt Morveau kept ſome of it for a whole year merely covered with paper, and even quite uncovered for a month, without its undergoing any alteration ‡.

Heat decompoſes it, and at the ſame time partly decompoſes its acid.

The following ſalts decompoſe it by compound affinity:

Sulphat of ſoda,	Muriat of alumina,
——— ammonia,	Carbonat of barytes,
——— magneſia,	——— potaſs,
——— alumina,	——— ſoda,
Nitrat of ammonia,	——— ammonia,
——— magneſia,	——— magneſia,
——— alumina,	——— alumina.
Muriat of ammonia,	

* *Encyc. Method. Chim.* i. 9.
† *On Acetous Acid*, p. 47.
‡ *Ibid. Encyc. Method.*

782 Acetite of ſtrontites. 6. Acetite of ſtrontites. This ſalt was firſt formed by Dr Hope. It forms ſmall cryſtals, which are not affected by expoſure to the atmoſphere. 49 parts of it are ſoluble in 120 parts of boiling water: It ſeems to be nearly as ſoluble in cold water. It renders vegetable colours green §.

§ *Dr Hope, Tranſ. Edin.* iv. 14.

783 Acetite of magneſia. 7. Acetite of magneſia. This ſalt was firſt mentioned by Mr Wenzel.

It is not cryſtallizable; but forms by evaporation a viſcid maſs ‖.

It has a ſweetiſh taſte; leaving, however, a ſenſe of bitterneſs ¶.

It is very ſoluble both in water and alcohol *.

According to Wenzel, 240 parts of acetous acid require for ſaturation 123¾ths of magneſia.

When expoſed to the air, it deliqueſces. Heat decompoſes it.

The following ſalts decompoſe it by compound affinity:

Sulphat of ammonia,	Carbonat of barytes,
——— alumina,	——— potaſs,
Nitrat of ammonia,	——— ſoda,
——— alumina,	——— ammonia,
Muriat of ammonia,	——— alumina.
——— alumina,	

‖ *Bergman*, ii. 388.
¶ *Morveau, ibid.*
* *Bergman*, ii. 388.

784 Acetite of alumina. 8. Acetite of alumina. This ſalt can only be formed by digeſting acetous acid on alumina recently precipitated.

By evaporation needle-ſhaped cryſtals are obtained, which are very deliqueſcent. According to Wenzel, 240 parts of acetous acid require 20¾ths of alumina for ſaturation.

This ſalt is decompoſed by compound affinity by the following ſalts:

Nitrat of ammonia,	Carbonat of potaſs,
Muriat of ammonia,	——— ſoda,
Carbonat of barytes,	——— ammonia.

785 Acetite of jargonia. 9. Acetite of jargonia. This ſalt may be formed by pouring acetous acid on newly precipitated jargonia. It has an aſtringent taſte. It does not cryſtallize; but when evaporated to dryneſs, it forms a powder, which does not attract moiſture from the air as acetite of alumina does †. It is very ſoluble in water and in alcohol.

† *Klaproth, Journ. de Phyſ.* xxxvi. 188.

Acetites.

hol. It is not ſo eaſily decompoſed by heat as nitrat of jargonia, probably becauſe it does not adhere ſo ſtrongly to water *.

* Vauquelin, Ann. de Chim. xxii. 206.

786 Acetite of iron.

10. Acetite of iron.—This ſalt was mentioned by Schrœder and Juncker. It is compoſed of acetous acid and brown oxide of iron.

Its ſolution forms by gentle evaporation ſmall oblong cryſtals; but the greateſt part of the ſalt aſſumes the form of a gelatinous maſs †.

† Wenzel.

It has a ſweetiſh ſtyptic taſte.

According to Wenzel, 240 parts of acetous acid require for ſaturation $186\frac{1}{4}$ of iron.

Heat decompoſes this ſalt; and it ſeems alſo to be gradually decompoſed by expoſure to the air.

787 Acetite of zinc.

11. Acetite of zinc.—This ſalt was firſt mentioned by Glauber.

Its cryſtals are rhomboidal, and ſometimes hexagonal plates, of a white colour, and the appearance of talk.

It is ſoluble in water. According to Wenzel, 240 parts of acetous acid require for ſaturation $195\frac{5}{6}$ths of zinc.

It is not altered by expoſure to the air. Heat decompoſes it. When thrown upon burning coals, it explodes with a blue flame.

12. Acetite of mangneſe.—This ſalt is not cryſtallizable; and when evaporated to dryneſs, it deliqueſces. Is it not an acetat?

788 Acetite of cobalt.

13. Acetite of cobalt.—This ſalt is deliqueſcent. Its ſolution is of a fine red colour while cold; but becomes blue by being heated, and it recovers its former colour on cooling. According to Wenzel, 240 parts of acetous acid require for ſaturation $241\frac{5}{7}$ths of cobalt.

789 Acetite of nickle.

14. Acetite of nickel.—This ſalt forms rhomboidal cubes of a green colour ‡: They are not deliqueſcent: Their taſte is ſweet §.

‡ Bergman.
§ Monnet.

790 Acetite of lead.

15. Acetite of lead.—This ſalt is mentioned by Iſaac Hollandus and Raymond Lully. It is compoſed of acetous acid and white oxide of lead.

It was formerly called *ſugar of lead, ſugar of Saturn, ſalt of Saturn, vinegar of Saturn, extract of Saturn,* &c.

Its cryſtals are flat parallelopipeds, terminated by two inclined planes approaching each other.

It has a ſweet and ſomewhat aſtringent taſte.

It is not very ſoluble in water; but acetous acid diſſolves it abundantly.

According to Wenzel, 240 parts of acetous acid require for ſaturation 503 of lead.

When expoſed to the air it becomes yellow, but undergoes no other alteration.

Heat decompoſes it by deſtroying the acid. When diſtilled, the reſiduum takes fire ſpontaneouſly on expoſure to the air. Paper dipped into acetite of lead forms excellent matches, which are not ſubject to go out, and which burn very ſlowly.

The following ſalts decompoſe it by compound affinity:

Muriat of ammonia,	Phoſphat of ammonia,
Sulphat of copper,	Oxalat of potaſs ‖,
Phoſphat of ſoda,	Malat of potaſs ¶.

‖ Scheele.
¶ Id.

791 Acetite of tin.

16. Acetite of tin.—This ſalt was firſt deſcribed by Lemery.

Its cryſtals are priſmatic needles in groups *. According to Wenzel, 240 parts of acetous acid require for ſaturation $3\frac{5}{11}$ of tin.

* Morveau.

17. Acetite of copper.—This ſalt was known to the ancients, and various ways of preparing it are deſcribed by Pliny *. It was formerly known by the names of *cryſtals of Venus and verdigriſe.* 792 Acetite of copper.

* Lib. xxxiv. c. 11.

It is of a deep green colour. Its cryſtals are rhomboids.

It has a diſagreeable coppery taſte.

It is ſoluble in water and in alcohol.

According to Wenzel, 240 parts of acetous acid require $16\frac{1}{8}$th of copper for ſaturation.

It effloreſces when expoſed to the air. Heat decompoſes it. It is uſed in painting.

18. Acetite of biſmuth.—This ſalt ſeems to have been firſt mentioned by Geoffroi. He called it *ſugar of biſmuth.* 793 Acetite of biſmuth.

It is moſt eaſily procured by mixing together the ſolutions of nitrat of biſmuth and acetite of potaſs. It forms brilliant, talky, ſilvery cryſtals.

It has a ſweetiſh taſte. According to Wenzel, 240 parts of acetous acid require for ſaturation $15\frac{5}{9}$ths of biſmuth.

It does not deliqueſce when expoſed to the air. Heat decompoſes it.

19. Acetite of antimony.—It yields with difficulty ſmall cryſtals †. According to Wenzel, 240 parts of acetous acid require for ſaturation $1\frac{1}{3}$d of antimony. 794 Acetite of antimony.

† Wenzel.

20. Acetite of arſenic.—This ſalt forms ſmall cryſtals in grains, hardly ſoluble in water ‡. 795 Acetite of arſenic.

‡ Bergman.

21. Acetite of mercury.—This ſalt is mentioned by Schrœder. 796 Acetite of mercury.

Its cryſtals are ſmall thin plates.

It has a diſagreeable taſte, and excites coughing.

It is hardly ſoluble in water. According to Wenzel, 240 parts of acetous acid require for ſaturation $240\frac{3}{7}$ths of mercury.

When expoſed to the air it becomes black, owing to the reduction of the oxide of mercury. Heat decompoſes it.

22. Acetite of ſilver.—This ſalt was perhaps firſt deſcribed by Margraf. 797 Acetite of ſilver.

It is beſt formed by dropping acetite of ſoda or potaſs into a ſaturated ſolution of nitrat of ſilver §.

§ Maret, ibid.

It forms ſmall oblong cryſtals, eaſily diſſolved in water †. It has a ſharp taſte.

† Margraf.

According to Wenzel, 240 parts of acetous acid require for ſaturation $101\frac{4}{9}$ths of ſilver.

Heat decompoſes it. It is decompoſed by muriat of magneſia ¶.

¶ Bergman.

23. Acetite of gold.—This ſalt is mentioned by Schrœder and Juncker. 798 Acetite of gold.

24. Acetite of uranium.—This ſalt was firſt formed by Klaproth. 799 Acetite of uranium.

Its cryſtals are regular four-ſided ſlender priſms, terminated at both ends by regular quadrilateral pyramids: they are tranſparent, and of a beautiful topaz yellow colour.

Heat decompoſes them: and what is ſingular, if they be heated gradually red hot, the oxide which remains retains nearly the form of the cryſtals *.

* Klaproth on Uranium.

The compounds into which the acetic acid enters are called *acetats*. They are ſo imperfectly known at preſent, that we ſhall not attempt a deſcription of them. 800 Acetats.

Sect. XII. *Of Oxalats.*

The compounds of which oxalic acid forms a part are

Oxalats.

are known by the name of *oxalats*. They were first described by Bergman.

801 Oxalat of potafs.

1. Oxalat of potafs.—This falt cryftallizes with difficulty. It is very foluble in water. When heated it falls to powder *.

* *Bergman*, i. 262.

802 Acidulous oxalat of potafs.

2. Acidulous oxalat of potafs.—The oxalic acid is alfo capable of combining with potafs in excefs, and forming another falt, called *acidulous oxalat* from its acid tafte; or, to fpeak more accurately, this falt is formed by the combination of oxalat of potafs with oxalic acid. This falt exifts ready formed in *oxalis acetofella* or wood-forrel; from which it is extracted in fome parts of Europe in great quantities. Hence it was formerly called falt of wood forrel. It is mentioned by Duclos in the Memoirs of the French Academy for 1668. Margraf first proved that it contained potafs; and Scheele difcovered that its acid is the oxalic. A great many interefting experiments had been previoufly made on it by Wenzel and Wiegleb.

It may be formed, as Scheele has fhown, by dropping potafs very gradually into a faturated folution of oxalic acid and water: as foon as the proper quantity of alkali is added, acidulous oxalat is precipitated. But care muft be taken not to add too much alkali, otherwife no precipitation will take place at all.

Its cryftals are fmall opaque parallelopipeds †.

† *De Lifle.*

It has an acid, poignant, bitterifh tafte.

It is foluble in about ten times its weight of boiling water, but much lefs foluble in cold water.

It is not altered by expofure to the air. Heat decompofes it.

This falt is fold in this country under the name of *effential falt of lemons*.

803 Oxalat of foda.

3. Oxalat of foda.—This falt agrees very much with oxalat of potafs. Its cryftals are fmall, and foluble in water.

From Bergman's defcription, oxalic acid appears alfo capable of combining in excefs with foda, and forming an acidulous oxalat.

804 Oxalat of ammonia.

4. Oxalat of ammonia.—Its cryftals are four-fided prifms, generally diverging from various points. They redden the infufion of turnfole.

They are eafily foluble in water, but not in alcohol ‡.

‡ *Bergman.*

It is decompofed by nitrat of barytes §.

§ *Bergman, ibid.*

805 Earthy oxalats.

5. Oxalat of barytes.—This falt does not cryftallize except with excefs of acid. The addition of potafs, or even of water, deprives it of this excefs, and then it crumbles into powder. It is infoluble in water ‖.

‖ *Bergman, ibid.*

6. Oxalat of lime.—This falt does not cryftallize. It is infoluble in water, but fomewhat foluble in acids. It is compofed of 48 parts of acid, 46 of lime, and 6 of water. Heat decompofes it ¶.

¶ *Bergman, ibid.*

7. Oxalat of ftrontites.—This falt was firft formed by Dr Hope. It is a white infipid powder; foluble in 1920 parts of boiling water. Heat decompofes it by deftroying the acid *.

* *Hope, Tranf. Edin.* iv. 14.

8. Oxalat of magnefia.—This falt is in the form of a white powder. It is fcarcely foluble either in water or alcohol. It is compofed of 35 parts of magnefia and 65 of acid and water. Heat decompofes it †.

† *Bergman, ibid.* and ii. 387.

9. Oxalat of alumina.—It is uncryftallizable; but furnifhes on evaporation a yellowifh pellucid mafs. It is fparingly foluble in alcohol. It has a fweet aftringent tafte. It is compofed of 44 parts of alumina and 56 of acid and water.

When expofed to the air it deliquefces; and if it has been previoufly well dried, its weight is increafed by $\frac{2}{3}$. It reddens turnfole *.

* *Bergman, ibid.*

806 Metallic oxalats.

10. Oxalat of iron.—This falt forms prifmatic cryftals of a yellowifh green colour.

It has an aftringent and fweet tafte. It is very foluble in water.

It is compofed of 45 parts of green oxide, and 55 of acid and water. When expofed to heat it falls to powder †.

† *Ibid.*

From Bergman's defcription, the brown oxide of iron appears alfo capable of combining with oxalic acid. The compound does not cryftallize, and is nearly infoluble in water ‡.

‡ *Ibid.*

11. Oxalat of zinc.—It is hardly foluble in water.

It is compofed of 75 parts of oxide and 25 of acid.

12. Oxalat of manganefe.—It is compofed of oxalic acid and white oxide of manganefe. It appears capable of cryftallizing §.

§ *Ibid.*

13. Oxalat of cobalt.—This is a rofe-coloured powder, infoluble in water, but foluble in oxalic acid; and capable, by that means, of cryftallizing ‖.

‖ *Ibid.*

14. Oxalat of nickel.—This is a green-coloured powder, hardly foluble in water. It is compofed of two parts of acid and one of oxide ¶.

¶ *Ibid.*

15. Oxalat of lead.—It forms fmall cryftalline grains. They are infoluble in alcohol, and nearly infoluble in water. They contain 55 parts of oxide and 45 of acid *.

* *Ibid.*

16. Oxalat of tin.—This falt forms prifmatic cryftals. It has an aufter tafte. If the folution of this falt be quickly evaporated, it affords a mafs refembling horn, and foluble in water †.

† *Ibid.*

17. Oxalat of copper.—This falt is uncryftallizable. It is a bluifh powder, infoluble in water, except with excefs of acid. It is compofed of 21 parts of copper and 29 of acid ‡.

‡ *Ibid.*

18. Oxalat of bifmuth.—This falt may be formed by dropping oxalic acid into a folution of nitrat of bifmuth. It forms pellucid polygonous cryftals. When oxide of bifmuth is diffolved by oxalic acid, the refult is a white powder, fcarcely foluble in water §.

§ *Ibid.*

19. Oxalat of antimony.—This falt forms cryftalline grains, with difficulty foluble in water †.

† *Ibid.*

20. Oxalat of arfenic.—This falt is compofed of oxalic acid and white oxide of arfenic. Its cryftals are prifms very foluble in water and alcohol. It reddens turnfole.

Heat fublimes it; and by a ftrong heat it may be decompofed ¶.

¶ *Ibid.*

21. Oxalat of mercury.—A white powder, hardly foluble in water, except with excefs of acid *.

* *Ibid.*

22. Oxalat of filver.—This falt may be formed by pouring oxalic acid into a folution of nitrat of filver. It is a white powder, fcarcely foluble in water, and not at all in alcohol; but foluble in nitric acid. It becomes black by being expofed to the air, owing to the reduction of the oxide †.

† *Ibid.*

23. Oxalat of platinum.—This falt affords yellow cryftals.

Sect. XIII. *Of Tartrites.*

The falts into which tartarous acid enters as an ingredient are known by the name of *tartrites*.

807 Tartar.

1. Acidulous oxalat of potafs or tartar.—This falt, which is compofed of potafs and an excefs of tartarous acid, or rather of tartrite of potafs and tartarous acid, has

Tartrites. has been long known. It is obtained in a ftate of impurity at the bottom, and adhering to the fides of cafks in which wine has fermented. It is called *tartar*, fays Paracelfus, becaufe it produces the oil, water, limeftone, and falt, which burn the patient as *Hell* does. According to him, it was the principle of every difeafe and every remedy, and all things contain the germ of it.

Margraf and Rouelle firft demonftrated that it contained potafs ready formed: and Scheele firft obtained tartarous acid from it in a ftate of purity.

Its cryftals are very fmall and irregular. According to Montet, they are prifms, fomewhat flat, and moftly with fix fides. It has a ftrong acid tafte. It is foluble in about 30 times its weight of boiling water*. According to Bergman, it contains 23 parts of alkali and 77 of acid.

* Wenzel.

It is not altered by expofure to the air. Heat decompofes it, and at the fame time deftroys the acid. It is capable of forming a great many compounds.

808 Tartrite of potafs.

2. Tartrite of potafs. This falt may be formed by faturating the laft defcribed falt with potafs. It was formerly called *foluble tartar*, becaufe it is much more foluble in water than the acidulous tartrite of potafs. It cryftallizes moft readily when there is a fmall excefs of alkali in the folution. Its cryftals are fmall oblongs.

It has an unpleafant bitter tafte. It is foluble in 4 parts of water at the temperature of 40°.

3. Tartrite of foda. This falt has never been accurately examined.

809 Tartrite of potafs and foda.

4. Tartrite of potafs and foda. This triple falt, formerly known by the name of *falt of Seignette*, becaufe firft formed by Mr Seignette apothecary at Rochelle, is made by faturating tartar with foda.

Its cryftals are prifms of eight or ten unequal fides, having their ends truncated at right angles. They are generally divided into two in the direction of their axes, and the bafe on which they ftand is marked with two diagonal lines, fo as to divide it into four triangles.

It has a bitter tafte. It is almoft as foluble as tartrite of potafs.

It effloresces when expofed to the air. Heat decompofes it.

810 Tartrite of ammonia.

4. Tartrite of ammonia. The cryftals of this falt are polygonous prifms, not unlike thofe of the laft defcribed falt.

It has a cooling bitter tafte like that of nitre. It is eafily foluble in water. Heat decompofes it.

5. Acidulous tartrite of ammonia. This falt may be formed by pouring tartarous acid into a folution of tartrite of ammonia. Like acidulous tartrite of potafs it is very infoluble in water.

6. Tartrite of potafs and ammonia. This triple falt may be formed by pouring ammonia into acidulous tartrite of potafs.

Its cryftals, according to Macquer, are prifms with four, five, or fix fides: according to the Dijon academicians, parallelopipeds, with two alternate floping fides.

It has a cooling tafte. It is foluble enough in water. It effloresces in the air. Heat decompofes it.

811 Earthy tartrites.

7. Tartrite of barytes. Unknown.

8. Tartrite of lime. This falt, firft formed by Scheele, is a taftelefs and almoft infoluble powder. By heat the acid is decompofed, and the pure lime remains behind.

9. Tartrite of ftrontites. This falt was firft formed by Dr Hope. Its cryftals are fmall regular triangular tables, having the edges and angles fharp and well defined. It is infipid. It diffolves in 320 parts of boiling water.

It is not altered by expofure to the air. Heat decompofes it by deftroying the acid*.

* Hope, Edin. Tranf. iv. 15.

10. Tartrite of magnefia. This falt is infoluble in water except there be an excefs of acid prefent. It then affords by evaporation fmall cryftals in the form of hexangular truncated prifms†.

It has a more faline tafte, and is more fufible, than tartrite of lime‡.

Heat firft melts and afterwards decompofes it.

† Bergman, ii. 288.

‡ Von Packen de Sale effent. acid. Tartar.

11. Tartrite of alumina. This falt does not cryftallize, but forms by evaporation a clear tranfparent gummy mafs. Its tafte is aftringent. It is foluble in water. It does not deliquefce in the air §.

§ Von Packen.

12. Tartrite of potafs and alumina. This triple falt is formed by faturating tartar with alumina. It bears a very ftriking refemblance to the laft defcribed falt.

812 Metallic tartrites.

13. Tartrite of iron. This is a grey powder. When tartarous acid is poured into a folution of fulphat of iron, fcaly cryftals are formed by evaporation. Thefe cryftals are doubtlefs compofed of tartarous acid combined with fulphat of iron. This triple falt might be called *tartro-fulphat of iron*.

14. Tartrite of potafs and iron. This triple falt was formerly called *tartarifed tincture of Mars*, *chalybeated tartar*, and *tartarifed iron*. It may be formed by boiling two parts of tartar and one of iron filings, previoufly made up into a pafte, in a proper quantity of water. The liquor by evaporation depofites cryftals, which form the falt wanted.

15. Tartrite of zinc. This falt is not eafily foluble in water.

16. Tartrite of potafs and zinc. This triple falt, formed by combining tartar and oxide of zinc, is very foluble in water ‖.

‖ Elemens. de Chim. Dijon.

17. Tartrite of lead. This falt, which is compofed of tartarous acid and white oxide of lead, is almoft infoluble in water. Nitric acid diffolves it.

18. Tartrite of potafs and lead. This falt, formed by combining white oxide of lead with tartar, is very foluble in water ¶.

¶ Wenzel.

19. Tartrite of tin. Unknown. The tartrite of potafs and tin, compofed of tartar and oxide of tin, is capable of cryftallizing.

20. Tartrite of copper. This falt is beft formed by pouring tartarous acid into the folutions of muriat or fulphat of copper; it precipitates in the form of blue cryftals *.

* Bergman.

This falt forms the beft kind of the pigment called *Brunfwick green* †.

† Leonbardi.

21. Tartrite of potafs and copper. This triple falt is alfo in the form of blue cryftals.

22. Tartrite of bifmuth. Small cryftalline grains ‡.

‡ Bergman.

23. Tartrite of antimony. This falt has never been examined with attention.

24. Tartrite of potafs and antimony, or tartar emetic. To this falt, which is perhaps the moft powerful emetic known, a great deal of attention has been paid, and a vaft number of methods have been tried to prepare it. Thefe methods have been already defcribed in the Encyclopædia. It appears from the experiments of Mr Bindheim,

Citrats.

Bindheim, that if this ſalt be carefully prepared, the difference that reſults from the uſe of different oxides is not ſo great as might have been expected *.

* Ann. de Chim. xiii. 218.

It was firſt made known by Adrian in 1631. It is a triple ſalt, compoſed of tartar and white oxide of antimony.

It is of a white colour and tranſparent. Its cryſtals are trihedral pyramids.

It diſſolves in 60 parts of cold water, and in a ſmaller proportion of hot water. It is decompoſed by lime and alkalies, iron, &c. Care ought therefore to be taken to uſe only diſtilled water when it is adminiſtered as a medicine.

25. Tartrite of arſenic. This ſalt forms priſmatic cryſtals very like thoſe of oxalat of arſenic †.

† Bergman, i. 295.

26. Tartrite of mercury. A yellow powder.

27. Tartrite of potaſs and mercury. This triple ſalt cryſtallizes ‡.

‡ Monnet.

Sect. XIV. *Of Citrats.*

The compounds into which the citric acid enters have been denominated *citrats*.

These ſalts are at preſent very imperfectly known. Mr Dizé has promiſed ſoon to ſupply this defect §.

§ Journ. de Phyſ. 1794, Supplement.

813 Alkaline citrats.

1. Citrat of potaſs. This ſalt does not cryſtallize. It has a cooling ſaline taſte, and deliqueſces when expoſed to the air.

2. Citrat of ſoda. This ſalt does not deliqueſce. It has a mild, pleaſant, cooling taſte ‖. According to Scheele, it does not cryſtallize.

‖ Dr Donald Monro, Phil. Tranſ. 57.

3. Citrat of ammonia. This ſalt cryſtallizes in thin needles. It has a cooling and moderately ſaline taſte ¶. The ammonia is ſeparated by the application of heat *.

¶ Dobſon. * Scheele.

814 Earthy citrats.

4. Citrat of barytes. This ſalt is ſcarcely ſoluble in water. It aſſumes the form of a white powder †. It is ſoluble in citric acid.

† Id.

5. Citrat of lime. This is a white powder, ſcarcely ſoluble in water ‡.

‡ Id.

6. Citrat of magneſia. Does not cryſtallize. It forms a gummy ſaline maſs very ſoluble in water §.

§ Id.

7. Citrat of alumina. This ſalt is ſcarcely ſoluble in water.

815 Metallic citrats.

8. Citrat of iron. A ſolution of a brown colour.

9. Citrat of copper. A green gummy maſs.

10. Citrat of mercury. This ſalt may be formed by pouring citric acid into nitrat or acetite of mercury. It is a flaky ſalt, of a brick-duſt colour, more or leſs red ‖.

‖ Dizé.

Sect. XV. *Of Malats.*

816 Malats.

The compounds into which the malic acid enters are called *malats*. This claſs of ſalts was firſt diſcovered by Scheele. They are no better known than the citrats.

1. Malat of potaſs.
2. Malat of ſoda.
3. Malat of ammonia.

} These ſalts are deliqueſcent ¶.

¶ Scheele.

4. Malat of lime. Small irregular cryſtals. They require a large quantity of boiling water for their ſolution. With exceſs of acid they are readily ſoluble in cold water †. They are inſoluble in alcohol ‡.

† Id. ‡ Id.

5. Malat of barytes. The properties of this ſalt reſemble pretty much thoſe of malat of lime §.

§ Id.

6. Malat of magneſia. Deliqueſcent ‖.

‖ Id.

7. Malat of iron. A brown ſolution, not cryſtallizable *.

Lactats.

8. Malat of zinc. This ſalt forms beautiful cryſtals †.

* Scheele. † Id.

Sect. XVI. *Of Lactats.*

817 Lactats.

The neutral ſalts formed by the combination of the lactic acid with various baſes are called *lactats*. They were firſt diſcovered by Scheele.

1. Lactat of potaſs. A deliqueſcent ſalt, ſoluble in alcohol ‡.

‡ Scheele on Milk.

2. Lactat of ſoda. This ſalt does not cryſtallize. It is ſoluble in alcohol §.

§ Ibid.

3. Lactat of ammonia. Cryſtals which deliqueſce. Heat ſeparates a great part of the ammonia before deſtroying the acid.

4. Lactat of barytes.
5. Lactat of lime.
6. Lactat of alumina.

} These ſalts deliqueſce ‖. The lactat of lime is ſoluble in alcohol ¶.

‖ Ibid. ¶ Ibid.

7. Lactat of magneſia. Small deliqueſcent cryſtals *.

* Ibid.

8. Lactat of iron. A brown ſolution.

9. Lactat of zinc. Cryſtals †.

† Ibid.

Theſe ſalts have a very ſtrong reſemblance to malats. The only difference which Scheele obſerved was, that the malat of lime was inſoluble in alcohol, while alcohol diſſolved lactat of lime.

Sect. XVII. *Of Saccholats.*

818 Saccholats.

The compounds into which the ſaccholactic acid enters are called *ſaccholats*. They alſo were firſt diſcovered by Scheele.

1. Saccholat of potaſs. Small cryſtals, ſoluble in eight times their weight of boiling water ‡.

‡ Scheele on Sugar of Milk.

2. Saccholat of ſoda. The ſame; ſoluble in five times their weight of boiling water §.

§ Ibid.

3. Saccholat of ammonia. A ſalt which has a ſouriſh taſte. Heat ſeparates the ammonia ¶.

¶ Ibid.

4. Saccholat of barytes.
5. Saccholat of lime.
6. Saccholat of magneſia.
7. Saccholat of alumina.

} Theſe ſalts are inſoluble in water *.

* Ibid.

Sect. XVIII. *Of Gallats.*

819 Gallats.

The compounds into which the gallic acid enters are denominated *gallats*. They were firſt attended to by the Dijon academicians and by Scheele.

1. Gallat of potaſs.
2. Gallat of ſoda.
3. Gallat of ammonia.

} We only know that theſe compoſitions are poſſible, and that their properties are different from thoſe of all other ſalts.

4. Gallat of barytes.
5. Gallat of lime.

} Theſe ſalts are ſoluble in water, eſpecially when there is exceſs of acid.

6. Gallat of magneſia. This ſalt is a yellow powder, ſoluble in water and in alcohol *.

* Bartholdi Ann. de Chim. xii. 305.

7. Gallat of alumina. This ſalt, according to Bartholdi, exiſts ready formed in nut galls. It is very ſoluble in water.

8. Gallat of iron. This ſalt, which Mr Prouſt has diſcovered to be formed of gallic acid and brown oxide of iron, is of a black colour, and does not ſeem capable of cryſtallizing. It is ſoluble in the three mineral acids, and by that means is deprived of its black colour. It is to this ſalt that ink partly owes its black colour. Gallat of iron is decompoſed by alkalies.

We ſhall not attempt any farther account of this claſs of

Benzoats. of falts. Scarcely any addition has yet been made to the experiments of Scheele which have been given already in the article CHEMISTRY, *Encycl.*

SECT. XIX. *Of Benzoats.*

820 Alkaline benzoats. THE compounds into which the benzoic acid enters have been called *benzoats*.

1. Benzoat of potafs. This falt forms pointed feathery cryftals. It has a faline fharp tafte. It is very foluble in water. It deliquefces when expofed to the air *.

2. Benzoat of foda. The cryftals of this falt are larger, but its tafte is the fame with that of benzoat of potafs. It is alfo very foluble in water. It effloresces in the air †.

3. Benzoat of ammonia. This falt cryftallizes with difficulty. Its cryftals are feather-fhaped. It deliquefces ‡.

821 Earthy benzoats. 4. Benzoat of lime. This falt forms white, fhining, pointed cryftals, of a fweetifh tafte, and not eafily foluble in water §.

5. Benzoat of magnefia. Feather-fhaped cryftals, of a fharp bitter tafte, and eafily foluble in water †.

6. Benzoat of alumina, an aftringent falt.

822 Metalline benzoats. 7. Benzoat of iron. This falt forms yellow cryftals. It has a fweet tafte. It is foluble in water and alcohol. It efflorefces in the air. Heat difengages the acid ¶.

8. Benzoat of zinc. This falt forms arborefcent cryftals. It is foluble in water and alcohol. When expofed to the air it is diffipated. Heat decompofes it *.

9. Benzoat of manganefe. This falt, which is formed of benzoic acid and white oxide of manganefe, cryftallizes in fmall fcales. It diffolves readily in water; with difficulty in alcohol. It is not altered by expofure to the air †.

10. Benzoat of cobalt. Flat cryftals ‡.

11. Benzoat of lead. Very white cryftals, foluble in water and alcohol. They are not altered by expofure to the air. Heat difengages the acid §.

12. Benzoat of tin. This falt may be formed by pouring benzoat of potafs into a folution of tin in the nitro-muriatic acid. The benzoat of tin is precipitated. It is foluble in hot water, but infoluble in alcohol. Heat decompofes it ||.

13. Benzoat of copper. Small cryftals of a deep green colour. They are with difficulty foluble in water, and not at all in alcohol ¶.

14. Benzoat of bifmuth. This falt forms white needle-fhaped cryftals. They are foluble in water, and in a very fmall proportion in alcohol. They are not altered by expofure to the air. Heat decompofes them *.

15. Benzoat of antimony. Cryftals which efflorefce in the air, and are decompofed by heat †.

16. Benzoat of arfenic. Small feather-fhaped cryftals. It is foluble in hot water, but cryftallizes in the cooling. A moderate heat fublimes it; a ftrong heat decompofes it. Sulphur decompofes it. It is not decompofed by alkalies ‡.

17. Benzoat of mercury. A white powder. It is infoluble in water, but diffolves in a fmall quantity in alcohol. It is not altered by expofure to the air. A fmall heat fublimes it; a greater decompofes it. It is decompofed by fulphur §.

18. Benzoat of filver. This falt is foluble in water, and alfo in a very fmall proportion in alcohol. It is not altered by expofure to the air, but the rays of the fun render it brown. Heat difengages its acid *.

19. Benzoat of gold. Small irregular cryftals, not eafily foluble in water; infoluble in alcohol. It is not altered by expofure to the air. Heat decompofes it †.

20. Benzoat of platinum. This falt forms fmall brownifh cryftals, with difficulty foluble in water; not foluble in alcohol. When expofed to heat, it is decompofed, and there remains behind a brown powder ‡.

SECT. XX. *Of Succinats.*

THE neutral falts, formed by the combination of the fuccinic acid with various bafes, have been called *fuccinats*.

We fhall not defcribe thefe falts, as we could not add much to the account given in the Appendix to the article CHEMISTRY in the *Encycl.* That account was taken from Mr Kier's Chemical Dictionary, and that gentleman borrowed it from Leonhardi.

SECT. XXI. *Of Camphorats.*

THE neutral falts into the compofition of which camphoric acid enters, have been denominated *camphorats*. The only chemift who has hitherto examined them is Bouillon la Grange: his experiments have been publifhed in the 27th volume of the *Annales de Chimie*.

1. Camphorat of potafs. To prepare this falt, carbonat of potafs is to be diffolved in water, and the folution faturated with camphoric acid. When the effervefcence is over, the liquor is to be evaporated by a gentle heat to the proper confiftence, and cryftals of camphorat of potafs will be depofited when the liquor cools. 823 Camphorat of potafs.

Camphorat of potafs is white and tranfparent; its cryftals are regular hexagons. Its tafte is bitterifh and flightly aromatic.

Water at the temperature of 60° diffolves $\frac{1}{100}$th part of its weight of this falt; boiling water diffolves $\frac{1}{4}$th part of its weight.

It is foluble in alcohol, and the folution burns with a deep blue flame.

When expofed to moift air, it lofes a little of its tranfparency, but in dry air it fuffers no change.

When expofed to heat it melts, fwells, and the acid is volatilized in a thick fmoke, which has an aromatic odour. Before the blow-pipe it burns with a blue flame, and the potafs remains behind in a ftate of purity.

By compound affinity this falt is decompofed by

Nitrat of barytes,
All the falts whofe bafe is lime,
Nitrat of filver,
Sulphat of iron,
Muriat of tin,
——— lead §.

2. Camphorat of foda. This falt may be formed precifely in the fame manner with the camphorat of potafs.

824 Camphorat of foda. It is white and tranfparent; its tafte is fomewhat bitter; its cryftals are irregular.

Water at the temperature of 60° diffolves lefs than $\frac{1}{200}$th part of its weight of this falt; boiling water diffolves $\frac{1}{8}$th of its weight.

It is alfo foluble in alcohol.

When expofed to the air it lofes its tranfparency, and efflorefces

§ Bouillon La Grange, Ann. de Chim. xxvii. 24.

Camphorats.

effloresces slightly, but is never completely reduced to powder.

Heat produces the same effect upon it as on camphorat of potass: the acid burns with a blue flame, which becomes reddish towards the end.

By compound affinity it is decomposed by

Nitrat of lime,	Muriat of lime,
——— silver,	——— iron,
Muriat of magnesia,	Sulphat of alumina,
——— barytes,	——— iron: and many other salts with me-
——— alumina,	

tallic bases *.

* Bouillon La Grange, Ann. de Chim. xxvii. 26.

825 Camphorat of ammonia.

3. Camphorat of ammonia. This salt may be prepared by dissolving carbonat of ammonia in hot water, and adding camphoric acid slowly till the alkali is saturated. It must then be evaporated with a very moderate heat, to prevent the disengaging of ammonia.

It is very difficult to obtain this salt in regular crystals. When evaporated to dryness, there is obtained a solid opaque mass of a sharp and bitterish taste.

Water at the temperature of about 60° dissolves nearly $\frac{1}{100}$th part of its weight of this salt; boiling water dissolves $\frac{1}{3}$d of its weight: But this and the two salts above described are a good deal more soluble when there is excess of base.

It is entirely soluble in alcohol.

When exposed to the air it attracts moisture, but not in sufficient quantity to enable it to assume a liquid form.

When exposed to heat it swells, melts, and is converted into vapour; before the blow-pipe it burns with a blue and red flame, and is entirely volatilized.

Most of the calcareous salts form triple salts with camphorat of ammonia.

It decomposes in part all the aluminous salts except the sulphat of alumina †.

† Ibid.

826 Camphorat of barytes.

4. Camphorat of barytes. In order to prepare this salt, barytes is to be dissolved in water, and camphoric acid added to the solution; the mixture is then to be boiled, and afterwards filtered and evaporated to dryness.

Camphorat of barytes does not crystallize; when the evaporation is conducted slowly, the salt is deposited in thin plates one above another, which appear transparent while immersed in the liquor, but become opaque whenever they come into contact with the air.

It has very little taste, though it leaves at last upon the tongue a slight impression of acidity mixed with bitterness.

Water dissolves only a very small quantity of this salt, boiling water being capable of taking up only $\frac{1}{600}$th part of it.

It is not altered by exposure to the air.

When exposed to heat it melts easily, and the acid is volatilized. When the heat is considerable, the acid burns with a lively blue flame, which becomes red and at last white.

It is decomposed by

Nitrat of potass, soda, lime, ammonia, and magnesia.
Muriat of lime, potass, alumina, and magnesia.
All the sulphats.
Carbonat of potass and soda.
Phosphat of potass, soda, and ammonia *.

‡ Bouillon La Grange, ibid. p. 28.

827 Camphorat of lime.

5. Camphorat of lime. This salt may be prepared by dropping into lime-water crystallized camphoric acid. The mixture is then to be made boiling hot, passed through a filter, and evaporated to about $\frac{3}{4}$ths of its volume. On cooling, camphorat of lime is deposited.

It has no regular shape; but if the evaporation has been properly conducted, it is in plates lying one above another. It is of a white colour, and has a taste slightly bitter.

Water at the temperature of 60° dissolves very little of this salt; boiling water is capable of dissolving about $\frac{1}{200}$th part of its weight of it. It is insoluble in alcohol.

It is composed of 43 parts of lime, 50 of acid, and 7 of water.

When exposed to the air it dries and falls into powder.

When exposed to a moderate heat it melts and swells up: when placed on burning coals, or when heated in close vessels, the acid is decomposed and volatilized, and the lime remains pure.

When sulphuric acid is poured into a solution of this salt, it produces an insoluble precipitate; nitric and muriatic acids precipitate the camphoric acid.

It is decomposed by compound affinity by

Carbonat of potass,
Nitrat of barytes,
Muriat of alumina,
Sulphat of alumina,
Phosphat of soda *.

* Bouillon La Grange, Ann. de Chim. xxvii. 21.

828 Camphorat of magnesia.

6. Camphorat of magnesia. This salt may be prepared by pouring water on carbonat of magnesia, and then adding crystallized camphoric acid: heat is then applied, the solution is filtrated, and evaporated to dryness. The salt obtained is dissolved in hot water, passed through a filter, and evaporated by means of a moderate heat till a pellicle forms on the surface of the solution. On cooling, the salt is deposited in thin plates. The second solution is to remove any excess of magnesia that may happen to be present.

This salt does not crystallize. It is white, opaque, and has a bitter taste.

It is scarcely more soluble in water than camphorat of lime.

Alcohol has no action on it while cold, but when hot it dissolves the acid and leaves the magnesia; and the acid precipitates again as the alcohol cools.

When exposed to the air it dries and becomes covered with a little powder; but this effect is produced slowly, and only in a warm place.

When this salt is placed on burning coals, the acid is volatilized, and the magnesia remains pure. Before the blow-pipe it burns like the other camphorats with a blue flame.

The nitrats, muriats, and sulphats, do not completely decompose this salt, if we except the nitrat of lime and muriat of alumina †.

† Id. ibid.

829 Camphorat of alumina.

7. Camphorat of alumina. To prepare this salt, alumina, precipitated by means of ammonia, and well washed, is to be mixed with water, and crystals of camphoric acid added. The mixture is then to be heated, filtered, and concentrated by evaporation.

This salt is a white powder, of an acid bitterish taste, leaving on the tongue, like most of the aluminous salts, a sensation of astringency.

Water at the temperature of 60° dissolves about $\frac{1}{100}$th part of its weight of this salt. Boiling water dissolves it

Suberats.

it in confiderable quantities; but it precipitates again as the folution cools.

Alcohol, while cold, diffolves it very fparingly; but when hot it diffolves a confiderable quantity of it, which precipitates alfo as the folution cools.

This falt undergoes very little alteration in the air; but it rather parts with than attracts moifture.

Heat volatilizes the acid; and when the falt is thrown on burning coals it burns with a blue flame.

It is decompofed by the nitrats of lime and barytes *.

* Bouillon La Grange, Ann. de Chim. xxvii. 34.

Sect. XXII. *Of Suberats.*

The falts formed by the fuberic acid have obtained the appellation of *fuberats*. They have hitherto been examined only by Bouillon la Grange.

830 Suberat of potafs.

1. Suberat of potafs.—This falt ought to be formed by means of cryftallized carbonat of potafs.

It cryftallizes in prifms, having four unequal fides. It has a bitter faltifh tafte, and it reddens vegetable blues. It is very foluble in water. Caloric melts it, and at laft volatilizes the acid.

It is decompofed by moft of the metallic falts, and by fulphat of alumina, muriat of alumina, and of lime; nitrat of alumina and of lime; and phofphat of alumina †.

† Id. ibid. xxiii. 52.

831 Suberat of foda.

2. Suberat of foda.—This falt does not cryftallize. It reddens the tincture of turnfole. Its tafte is flightly bitter. It is very foluble in water and in alcohol. It attracts moifture from the air. Caloric produces the fame effect on it that it does on fuberat of potafs.

It is decompofed by the calcareous, aluminous, and magnefian falts ‡.

‡ Id. ibid. p. 53.

832 Suberat of ammonia.

3. Suberat of ammonia.—This falt cryftallizes in parallelopipeds Its tafte is faltifh, and it leaves an impreffion of bitternefs: It reddens vegetable blues.

It is very foluble in water. It attracts moifture from the air. When placed upon burning coals, it lofes its water of cryftallization, and fwells up; and before the blow-pipe it evaporates entirely.

It is decompofed by the aluminous and magnefian falts §.

§ Id. ibid. p. 55.

833 Suberat of barytes.

4. Suberat of barytes.—This falt does not cryftallize. Heat makes it fwell up, and melts it. It is fcarcely foluble in water except there be an excefs of acid.

It is decompofed by moft of the neutral falts, except the barytic falts and the fluat of lime ||.

|| Id. ibid. p. 52.

834 Suberat of lime.

5. Suberat of lime.—This falt does not cryftallize. It is perfectly white: It has a faltifh tafte: It does not redden the tincture of turnfole.

It is very fparingly foluble in water except when hot; and as the folution cools moft of the falt precipitates again.

When placed upon burning coals it fwells up, the acid is decompofed, and there remains only the lime in the ftate of powder.

It is decompofed by

- The muriat of alumina,
- The carbonats of potafs and foda,
- The fluat of magnefia,
- The phofphats of alumina and foda,
- The borat of potafs,
- All the metallic folutions ¶.

¶ Id. ibid. p. 54.

835 Suberat of magnefia.

6. Suberat of magnefia.—This falt is in the form of a powder:. It reddens the tincture of turnfole. It has a bitter tafte: It is foluble in water, and attracts fome moifture when expofed to the air.

Pruffiats.

When heated it fwells up and melts: before the blow-pipe the acid is decompofed, and the magnefia remains in a ftate of purity.

It is decompofed by

- Muriat of alumina,
- Nitrat of lime and alumina,
- Borat of potafs,
- Fluat of foda,
- Phofphat of alumina *.

* Bouillon La Grange, Ann. de Chim. xxiii. 55.

836 Suberat of alumina.

7. Suberat of alumina.—This falt does not cryftallize. When its folution is evaporated by a moderate heat in a wide veffel, the falt obtained is of a yellow colour, tranfparent, having a ftyptic tafte, and leaving an impreffion of bitternefs on the tongue. When too much heat is employed it melts and blackens. It reddens the tincture of turnfole, and attracts moifture from the air. Before the blow-pipe it fwells up, the acid is volatilized and decompofed, and nothing remains but the alumina.

It is decompofed by

- The carbonats of potafs and foda,
- The fulphat of iron,
- The muriat of iron,
- The nitrats of filver, mercury, and lead †.

† Id. ibid.

Suberic acid forms alfo compounds with the oxides of filver, mercury, lead, copper, tin, iron, bifmuth, arfenic, cobalt, zinc, antimony, manganefe, and molybdenum; moft of which are incryftallizable, and have an excefs of acid ‡.

‡ Id. ibid. p. 57.

Sect. XXIII. *Of Pruffiats.*

The compounds into which the pruffic acid enters are called *Pruffiats*.

Thefe fubftances, the moft important of which are triple falts, have fomething very peculiar in their affinities. The pruffic acid appears to have a ftronger affinity for alkalies and earths than for metals, at leaft thefe fubftances are capable of decompofing metallic pruffiats; yet acids fcarcely decompofe the metallic pruffiats, while the weakeft acid known decompofes the pruffiats of alkalies and earths. Thefe phenomena have not yet been fatisfactorily accounted for.

837 Alkaline pruffiats.

1. Pruffiat of potafs.
2. Pruffiat of foda.

} Thefe falts were firft obtained pure by Mr Scheele. They are foluble in water; but they are of little ufe, as mere expofure to the air decompofes them.

3. Pruffiat of ammonia.—This falt has the fmell of ammonia. It is very volatile and as eafily decompofed as the other two.

838 Earthy pruffiats.

4. Pruffiat of lime.—This falt is foluble in water. It is alfo decompofed by expofure to the air.

5. Pruffiat of barytes.
6. Pruffiat of magnefia.

} Thefe falts are alfo foluble in water, and decompofed by all acids.

Pruffic acid does not combine with alumina.

839 Pruffian blue.

7. Pruffiat of iron, or Pruffian blue.—This fubftance is compofed, as Mr Prouft has fhewn, of the pruffic acid and brown oxide of iron. With the green oxide the pruffic acid forms a white compound, which, however, becomes gradually blue when expofed to the atmofphere, becaufe the oxide abforbs oxygen, and is converted into brown oxide §.

§ Nicholfon's Jour. i. 453.

Pruffiat of iron is a deep blue coloured powder. It is

Pruffiats. is infoluble in water, and fcarcely foluble in acids. It is compofed, according to the moft accurate experiments hitherto made, of equal parts of oxide of iron and pruffic acid. It is not affected by expofure to the air. Heat decompofes it by deftroying the acid, and the oxide of iron remains behind.

The Pruffian blue of commerce, befides other impurities, contains mixed with it a great quantity of alumina. Its ufe as a pigment, and the attempts which have been made to introduce it as a dye, are well known.

Pruffiat of iron may alfo exift in another ftate: It may have a fuperabundance of oxide; its colour is then more or lefs yellow. To this ftate it may be reduced by digefting it with alkalies or any of the alkaline earths. Thefe fubftances deprive it of part of its acid, but not of the whole.

This yellow pruffiat is foluble in acids.

840 Affinities of the pruffic acid explained.

Were we to attempt an explanation of this, and the other phenomena which the pruffic acid difplays in its combinations, we would conjecture, that this yellow pruffiat is the fubftance formed by the direct combination of brown oxide of iron and pruffic acid, and that the blue pruffiat is formed of the yellow pruffiat combined as an integrant with pruffic acid: That the affinity between the pruffic acid and oxide of iron is much ftronger than that between yellow pruffiat of iron and pruffic acid; that therefore alkalies and earths have a ftronger affinity for pruffic acid than the yellow pruffiat has, but a much weaker affinity than oxide of iron, and perhaps every other oxide;—hence the apparent fuperiority of alkalies and earths in fome cafes, while in others they appear very inferior. We would fuppofe, then, that the pruffic acid has a much ftronger affinity for oxide of iron, and perhaps for all other oxides, than for other bodies; that the pruffiats, thus formed, are capable of combining with pruffic acid; but that their affinity for it is much lefs than that of the alkalies and earths. This conjecture is fupported by all the phenomena at prefent known; it would remove all the apparent anomalies which the combinations of this fingular acid prefent, and reduce the whole of them under the known laws of affinity.

841 Properties of Pruffian alkali,

8. Pruffiat of potafs and iron, commonly called *Pruffian alkali*, or *Pruffian teft*. This fubftance is a triple falt, compofed of pruffic acid, potafs, and oxide of iron combined together. To chemifts and mineralogifts it is one of the moft important inftruments ever invented; as, when properly prepared, it is capable of indicating whether any metallic fubftance (platinum excepted) be prefent in any folution whatever, and even of pointing out the particular metal, and of afcertaining its quantity: This it does by means of a compound affinity, which, after what has been faid above, may be eafily underftood. The Pruffian alkali may be conceived to be a combination of two fubftances, pruffiat of potafs and blue pruffiat of iron. Now every metallic oxide has a ftronger affinity for pruffic acid than potafs has (and, in fact, feems to have a ftronger affinity for it than for any other fubftance). If, therefore, there happen to be any oxide in the folution, it immediately feizes the pruffic acid with which the potafs is combined, and by that means decompofes the triple falt. A pruffiat of the particular metal is formed, and, as moft pruffiats of metals are infoluble, it is precipitated; and it indicates by its colour the particular metal, and by its weight the quantity of metal that happens to be prefent. At the fame time the blue pruffiat of iron is alfo precipitated, and its weight muft be deducted from the quantity of the precipitate.

In order to be certain of the accuracy of thefe refults, it is neceffary to have a Pruffian alkali perfectly pure, and to be certain before hand of the quantity, or rather of the proportions of its ingredients. To obtain a teft of this kind has been the object of chemifts ever fince the difcoveries of Macquer pointed out its importance. It is to the ufe of impure tefts that a great part of the contradictory refults of mineralogical analyfes by different chemifts is to be afcribed.

There are two * ways in which this teft may be rendered impure, befides the introduction of foreign ingredients, which we do not mention, becaufe it is obvious that it muft be guarded againft. 1. There may be a fuperabundance of alkali prefent, or, which is the fame thing, there may be mixed with the Pruffian teft a quantity of pure alkali; or, 2. There may be contained in it a quantity of yellow pruffiat of iron, for which pruffiat of potafs has alfo a confiderable affinity.

* See *Kirwan's Min.* i. 487.

842 Liable to impurities.

If the Pruffian teft contain a fuperabundance of alkali, two inconveniences follow. This fuperabundant quantity will precipitate thofe earthy falts which are liable to contain an excefs of acid, and which are only foluble by that excefs: Hence alumina and barytes will be precipitated. It is to the ufe of impure tefts of this kind that we owe the opinion, that barytes and alumina are precipitated by the Pruffian alkali, and the confequent theories of the metallic nature of thefe earths. This miftake was firft corrected, we believe, by Mr Klaproth.

Another inconvenience arifing from the fuperabundance of alkali in the Pruffian teft is, that it gradually decompofes the blue pruffiat which the teft contains, and converts it into yellow pruffiat. In what manner it does this will be underftood, after what has been faid, without any explanation.

On the other hand, when the Pruffian alkali contains a quantity of yellow pruffiat of iron, as great inconveniences follow. This yellow pruffiat has an affinity for pruffic acid, which, though inferior to that of the potafs, is ftill confiderable; and, on the other hand, the potafs has a ftronger affinity for every other acid than for the pruffic. When, therefore, the teft is expofed to the air, the carbonic acid, which the atmofphere always contains, affifted by the affinity between the yellow pruffiat and the pruffic acid, decompofes the pruffiat of potafs in the teft; and the yellow pruffiat is precipitated in the form of Pruffian blue: And every other acid produces the fame effect. A teft of this kind, therefore, would indicate the prefence of iron in every mixture which contains an acid (for a precipitation of Pruffian blue would appear); and could not, therefore, be trufted to with any confidence.

843 Klaproth's method of forming it.

We will not attempt to defcribe the various methods which different chemifts have adopted of preparing this teft; but fhall fatisfy ourfelves with defcribing the method of Klaproth, which anfwers the purpofe completely. This we fhall do nearly in the words of Mr Kirwan.

Prepare a pure potafs, by gradually projecting into a large crucible heated to whitenefs a mixture of equal parts of purified nitre and cryftals of tartar; when the whole is

Prussiats. is injected, let it be kept at a white heat for half an hour, to burn off the coal.

Detach the alkali thus obtained from the crucible, reduce it to powder, spread it on a muffle, and expose it to a white heat for half an hour.

Dissolve it in six times its weight of water, and filter the solution while warm.

Pour this solution into a glass receiver, placed in a sand furnace, heated to 170° or 180°, and then gradually add the best Prussian blue in powder, injecting new portions according as the former becomes grey, and supplying water as fast as it evaporates; continue until the added portions are no longer discoloured, then increase the heat to 212° for half an hour.

Filter the ley thus obtained, and saturate it with sulphuric acid moderately diluted; a precipitate will appear; when this ceases, filter off the whole, and wash the precipitate.

Evaporate the filtered liquor to about one quarter, and set it by to crystallize: after a few days, yellowish crystals of a cubic or quadrangular form will be found mixed with some sulphat of potass and oxide of iron; pick out the yellowish crystals, lay them on blotting paper, and redissolve them in four times their weight of cold water, to exclude the sulphat of potass.

7. Essay a few drops of this solution with barytic water, to see whether it contains any sulphuric acid, and add some barytic water to the remainder if necessary: filter off the solution from the sulphat of barytes, which will have precipitated, and set it by to crystallize for a few days; that the barytes, if any should remain, may be precipitated. If the crystals now obtained be of a pale yellow colour, and discover no bluish streaks when sprinkled over with muriatic acid, they are fit for use; but if they still discover bluish or green streaks, the solutions and crystallizations must be repeated.

These crystals must be kept in a well-stopped bottle, which to preserve them from the air should be filled with alcohol, as they are insoluble in it.

Before they are used, the quantity of iron they contain should be ascertained, by heating 100 grains to redness for half an hour in an *open* crucible: the prussic acid will be consumed, and the iron will remain in the state of a reddish brown magnetic oxide, which should be weighed and noted: This oxide is half the weight of the Prussian blue afforded by the Prussian alkali; its weight must therefore be subtracted from that of metallic precipitates formed by this test. Hence the weight of the crystals, in a given quantity of the solution, should be noted, that the quantity employed in precipitation may be known. Care must be taken to continue the calcination till the oxide of iron becomes brown; for while it is black it weighs considerably more than it should *.

9. Prussiat of soda and iron. The only discernible difference between this salt and the last is, that it crystallizes differently †.

844 Prussiat of ammonia and iron.

10. Prussiat of ammonia and iron. This triple salt has also been employed as a test; but it is not so easy to obtain it in a state of purity as the other two. It was discovered by Macquer, and first recommended by Meyer.

It forms flat hexangular crystals, soluble in water, and deliquesces in the air. Heat decomposes it like the other prussiats ‡.

We shall not give any description of the triple salts formed by digesting the alkaline earths on prussiat of iron; they are sufficiently known, and are not of any use except as tests; and in that respect they are inferior to that above described. They are all soluble in water, and are most of them capable of crystallizing.

845 Prussiat of mercury.

11. Prussiat of mercury. This salt, which was first formed by Scheele, is composed of the prussic acid combined with the red oxide of mercury. It may be formed by boiling the red oxide of mercury with Prussian blue. It crystallizes in tetrahedral prisms, terminated by quadrangular pyramids, the sides of which correspond with the angles of the prism.

This salt is capable of combining with sulphuric and muriatic acids, and forming triple salts, which have not yet been examined *.

* Berthollet.

Sect. XXIV. *Of Formats.*

The compounds into which the formic acid enters are called *formats*. We shall not describe them, as little has been added to the account already given in the Appendix to the article Chemistry in the Encyclopædia.

Sect. XXV. *Of Sebats.*

Sebats.

The compounds into which the sebacic acid enters are called *sebats*. For our knowledge of this class of salts we are chiefly indebted to the celebrated Crell, who published a dissertation on the sebacic acid and its combinations in the Philosophical Transactions for 1780 and 1782.

846 Alkaline sebats.

1. Sebat of potass. This salt is of a white colour. Its crystals are quadrangular pyramids, of which two opposite sides are narrower than the others. It has a sharp saline taste like muriat of ammonia, but milder. It is soluble in water, insoluble in alcohol, and does not deliquesce when exposed to the air. Heat decomposes it.

2. Sebat of soda. This salt is white. Its crystals are pyramids, with three or four sides: a very moderate heat melts them.

3. Sebat of ammonia. This salt in taste and solubility resembles muriat of ammonia, but it differs from it in not being capable of subliming iron.

847 Earthy sebats.

4. Sebat of lime. The crystals of this salt are hexagons, terminated by a plane surface: they have a sharp acrid taste; are very soluble in water, but not in alcohol: they do not deliquesce.

5. Sebat of magnesia. A gummy, saline, uncrystallizable mass.

6. Sebat of alumina. A gummy saline mass, which does not crystallize, and has an austere astringent taste.

848 Metallic sebats.

7. Sebat of iron. Needle-shaped crystals, which deliquesce.

8. Sebat of lead. Needle-shaped crystals, very soluble in water.

9. Sebat of tin. A white deliquescent salt.

10. Sebat of copper. This salt is capable of crystallizing, but is very deliquescent.

11. Sebat of antimony. A crystallizable salt, which does not deliquesce.

12. Sebat of arsenic. Small crystals.

13. Sebat of mercury. A white powder, very difficultly soluble in water.

14. Sebat of gold. Yellow crystals.

15. Sebat of platinum. Brownish yellow crystals.

The bombats or compounds which the bombic acid forms are still unknown.

Metallic Acid Salts.

Sect. XXVI. *Of Arseniats.*

The compounds formed by the combination of the arsenic acid with bases are called *arseniats*. This class of salts was first discovered by Macquer; but little accurate was known concerning it till Scheele made known the arsenic acid.

An abstract of Scheele's experiments has been given in the article Chemistry, *Encycl.*

To his description of arseniats several additions might be made, but not of sufficient consequence to warrant a repetition of what has been given in that article; and without such a repetition these additions would scarcely be intelligible.

Sect. XXVII. *Of Metallic Acid Salts.*

It has been conjectured that all metals may be converted into acids by combining them with a sufficient quantity of oxygen. This conjecture has been verified in a considerable number of instances. We have seen the arsenic acid, the tungstic acid, the molybdic acid, and the new metallic acid of Vauquelin. Berthollet has discovered that platinum becomes an acid; and the same thing has been ascertained with regard to tin. Even those metallic oxides which do not possess many of the characters of acids are capable of combining with alkalies and earths, and of forming peculiar neutral salts. These oxides, therefore, perform the office of acids; and consequently must be considered as partaking of their nature, or rather as a kind of intermediate substances between acids and those bodies which unite only with acids.

Some of these neutral salts we shall proceed to enumerate.

849 Fulminating gold.

1. Aurat of ammonia, or fulminating gold. This salt is composed of the oxide of gold and ammonia. This compound may be formed by precipitating gold from nitro-muriatic acid by ammonia. The precipitate is fulminating gold. Bergman was the first who clearly demonstrated that this powder is composed of oxide of gold and ammonia. When heated a little above the boiling temperature it explodes with astonishing violence. Chemists had made many attempts to explain the cause of this phenomenon, but without success, till Mr Berthollet discovered the composition of ammonia. After making that discovery, he proved, by a number of delicate and hazardous experiments, that during the fulmination the ammonia is decomposed, that its hydrogen combines with the oxygen of the oxide and forms water, while the azot flies off in a gaseous form, and occasions the explosion.

850 Fulminating silver.

2. Argentat of ammonia, or fulminating silver. This substance was discovered by Mr Berthollet. It may be formed by dissolving oxide of silver in ammonia. It is a black powder. It possesses the fulminating property much more powerfully than the last described substance. The slightest friction makes it explode with violence. This property, as Mr Berthollet has proved *, is owing to the same decomposition of ammonia and formation of water that causes the explosion of fulminating gold.

If a small retort be filled with the liquor from which the fulminating silver has been precipitated, and be made to boil, some azot is disengaged, and small opaque crystals are formed consisting of the same substance; which explode when touched, though they be covered with water. Nitrat and muriat of barytes precipitate silver from this salt.

Hydrosulphurets.

851 Mercuriat of lime and of ammonia.

3. Mercuriat of lime. Oxide of mercury boiled with lime-water forms, by evaporation, small transparent yellow crystals *.

4. Mercuriat of ammonia. Oxide of mercury dissolves in ammonia in large quantity, and by evaporation furnishes a white salt †.

* Id. ibid.

† Lavoisier, ibid.

852 Cuprat of ammonia.

5. Cuprat of ammonia. Oxide of copper dissolves in ammonia. Mr Sage has described its crystallization. It is decomposed by lime and potass, and cuprat of lime and potass are formed.

853 Stannat of gold.

6. Stannat of gold. When gold is precipitated by tin it unites with it. Vogel and Beaumé first observed that the precipitate, which is purple, contained tin.

854 Plumbat of lime.

7. Plumbat of lime. Lime-water boiled on the red oxide of lead dissolved it. This solution, evaporated in a retort, gave very small transparent crystals, forming prismatic colours, and not more soluble in water than lime. It is decomposed by all the sulphats of alkalies and by sulphurated hydrogen gas. The sulphuric and muriatic acids precipitate the lead. It blackens wool, the nails, the hair, white of eggs; but it does not affect the colour of silk, the skin, the yoke of eggs, nor animal oil. It is the lead which is precipitated on these coloured substances in the state of oxide; for all acids can dissolve it. The simple mixture of lime and oxide of lead blackens these substances; a proof that the salt is easily formed ‡.

‡ Berthollet, Ann. de Chim. i. 37.

855 Zincat of ammonia.

8. Zincat of ammonia. De Cassone has published a great number of experiments on the property which ammonia has of dissolving oxide of zinc. Lime-water and potass also dissolve it §.

§ Id. ibid. p. 42.

856 Antimoniat of potass.

9. Antimoniat of potass. When antimony is detonated with nitre in a crucible, part of its oxide unites with the potass of the nitre ‖.

‖ Id. ibid.

Chap. III. *Of* Hydrosulphurets.

857 Properties of sulphurated hydrogen gas.

Sulphurated hydrogen gas, which has been described in the first part of this article, possesses almost all the properties of acids. It combines with water, and the solution gives a red colour to vegetable blues. It decomposes soaps and sulphurets, and is capable of combining with alkalies, earths, and metallic oxides, and of forming compounds, to which Mr Berthollet, to whom we are indebted for discovering them, has given the name of *hydrosulphurets* ¶.

Before giving any account of these compounds, which we shall do from the paper of Berthollet just quoted, we beg leave to make a few previous observations, in order to rectify some inaccuracies into which we have fallen from not being acquainted with the experiments of that philosopher.

¶ Ann. de Chim. xxv. 233.

858 Remarks on sulphurets.

Sulphur is capable of combining with alkalies, earths, metals, and metallic oxides, and forming the compounds known by the name of *sulphurets*. The alkaline, earthy, and even some of the metallic sulphurets, can only exist in a state of dryness: the instant they are moistened with water, a quantity of sulphurated hydrogen gas is formed, which combines with the sulphuret, and forms a new compound. To these triple compounds Mr Berthollet has given the name of *hydrogenous sulphurets*. All solutions of sulphurets in water are in fact hydrogenous sulphurets. Were it not for the formation and combination of sulphurated hydrogen, the alkaline sulphurets would

Hydrosul-phurets. would be completely decomposed by water, and their sulphur precipitated; for water has a stronger affinity for the alkalies than sulphur has. This Berthollet proved by the following experiment: To a solution of sulphuret of potass in water (that is, to hydrogenous sulphuret of potass), a quantity of oxy-muriatic acid supersaturated with potass was added, and the sulphur was immediately precipitated. In this experiment the sulphurated hydrogen was destroyed by the oxygen of the oxy-muriatic acid; and the precipitation of the sulphur shews that its affinity for potass was not sufficient to keep it dissolved, or, which is the same thing, that its affinity for potass was inferior to that of water.

859 Hydrogenous sulphuret of mercury. The substance which we described in Part I. chap. iii. sect. 4. of this article, under the name of *Black Sulphuret of Mercury*, is a hydrogenous sulphuret of mercury, and therefore differs from the red sulphuret of mercury or cinnabar by containing a quantity of sulphurated hydrogen. Potass has a stronger affinity for this last substance than the sulphuret; potass therefore, by the assistance of heat, deprives the black or hydrogenous sulphuret of its sulphurated hydrogen, and reduces it to the state of red sulphuret. This explains the method of forming cinnabar described in the section above referred to, and points out a much easier process for obtaining that useful pigment.

860 Method of forming hydrosulphurets. We shall now proceed to the method of forming the hydrosulphurets. Berthollet obtained sulphurated hydrogen gas from sulphuret of iron in the usual manner, by means of sulphuric acid. It was made to pass thro' a vessel filled with water before it entered that in which the combination was to take place. By this method a solution of potass was impregnated with sulphurated hydrogen; and in order to be certain of saturating the alkali completely, the gas was added in excess, and the excess was afterwards driven off by means of heat. By this method hydrosulphurets of potass, soda, and ammonia, may be formed.

In order to form hydrosulphuret of lime, that earth was mixed with distilled water, and sulphurated hydrogen gas passed into this mixture till a sufficient quantity of hydrosulphuret was judged to be formed; the liquid, which contained it in solution, was poured off the undissolved lime, and saturated to excess with sulphurated hydrogen, and this excess was afterwards driven off by means of heat.

Hydrosulphuret of magnesia may be formed by dissolving magnesia in water impregnated with sulphurated hydrogen gas.

If a solution of sulphuret of barytes in water, or, more properly, if hydrogenous sulphuret of barytes be evaporated, a great number of confused crystals are formed; if these be separated quickly by filtration, and placed upon blotting paper to dry, a white crystalline substance is obtained, which is hydrosulphuret of barytes.

861 Affinities of sulphurated hydrogen. The affinities of the alkalies and earths for sulphurated hydrogen appear, from the experiments of Berthollet, to be as follows:

Barytes,
Potass,
Soda,
Lime,
Ammonia,
Magnesia,
Jargonia.

Almost all the metallic oxides have a stronger affinity for sulphurated hydrogen than the earths have.

862 Properties of hydrosulphurets. When the hydrosulphurats are prepared with the necessary precautions to prevent the contact of atmospherical air, they are colourless, but the action of the air renders them yellow.

If they be decomposed while they are colourless, by pouring upon them sulphuric acid, muriatic acid, or any other acid which does not act upon hydrogen, the sulphurated hydrogen gas exhales without the deposition of a single particle of sulphur; but if the hydrosulphuret has become yellow, some sulphur is always deposited during its decomposition, and the quantity of sulphur is proportional to the deepness of the colour.

The yellow colour, therefore, which hydrosulphurets acquire by exposure to the atmosphere is owing to a commencement of decomposition. Part of the hydrogen of the sulphurated hydrogen abandons the sulphur, combines with the oxygen of the atmosphere, and forms water. By degrees, however, a portion of the sulphur is also converted into an acid; and when the proportion of sulphurated hydrogen is diminished, and that of the sulphur increased to a certain point, the sulphur and the hydrogen combine equally with oxygen.

If sulphuric or muriatic acids be poured upon a hydrosulphuret after it has been for some time exposed to the air, a quantity of sulphurated hydrogen gas exhales, sulphur is deposited, and after an interval of time sulphurous acid is disengaged. It is therefore sulphurous, and not sulphuric acid, which is formed while the hydrosulphuret spontaneously absorbs oxygen. This acid, however, is not perceptible till after a certain interval of time when separated from the hydrosulphuret by means of an acid; because as long as it meets with sulphurated hydrogen a reciprocal decomposition takes place. The oxygen of the acid combines with the hydrogen of the gas, and the sulphur of both is precipitated.

Sulphurated hydrogen is capable of combining with several of the metals, mercury, for instance, and silver: it combines with the greater number of the metallic oxides, and forms hydrosulphurets, on which the alkalies have no action at the temperature of the atmosphere: But concentrated acids combine with the oxides of these hydrosulphurets, and separate the sulphurated hydrogen in the form of gas. 863 Metalline hydrosulphurets.

In the greater number of these metallic oxide hydrosulphurets, the tendency which oxygen and hydrogen have to combine occasions a partial decomposition of the sulphurated hydrogen, and brings the oxides nearer to the metallic state. In some of these hydrosulphurets part of the sulphur also combines with oxygen, and forms sulphuric acid.

The alkaline hydrosulphurets precipitate all the metals from their combination with acids; they are therefore very valuable tests of the presence of metals in any solution, as they do not precipitate any of the earths except alumina and jargonia. The following Table exhibits a view of the effect of hydrosulphuret of potass, hydrogenous sulphuret of potass, and water impregnated with sulphurated hydrogen gas, upon various metallic solutions.

Metallic

Hydrosulphurets.

Metallic Solutions.	Solution of Hydrogenous Sulphuret of Potass.	Water impregnated with Sulphurated Hydrogen Gas.	Hydrosulphuret of Potass.
Green sulphat of iron.	A black precipitate, which becomes yellow by the contact of the air.		A black precipitate. The potass separated.
Red oxide of iron.		Becomes black. The liquor remains very deep coloured if there be an excess of sulphurated hydrogen.	Becomes black.
Sulphat of zinc.	A white precipitate.	A white precipitate.	A white precipitate.
Acetite of lead.	A white precipitate, which by an addition becomes black.	A black precipitate.	A black precipitate.
Red oxide of lead.		Becomes black.	The potass separated.
Nitrat of bismuth.		A black precipitate.	A black precipitate.
Oxide of bismuth.		Becomes black.	
Nitrat of silver.	A black precipitate.	A black precipitate.	A black precipitate.
Sulphat of copper.	A brown precipitate.	A black precipitate.	A black precipitate.
Green oxide of copper.		Becomes black.	Separation of the potass.
Nitrat of mercury.	In a great deal of water, a brown colour.	A brownish black precipitate.	A brownish black precipitate.
Oxy-muriat of mercury.	A white precipitate, which becomes black by addition.	A white precipitate, becoming black by an addition.	White, becomes black by addition.
Red oxide of mercury.		Blackish.	A heat produced which caused the hydrosulphuret to boil. The alkali separated (A).
Muriat of tin.			A black precipitate.
Oxy-muriat of tin.	A precipitation of sulphur, and of the oxide.	No change.	A precipitate of white oxide of tin, and a disengagement of sulphurated hydrogen gas.
White oxide of tin.		No change.	Disengagement of sulphurated hydrogen gas.
Sulphat of manganese.		No change.	A white precipitate.
Black oxide of manganese.		The odour disappears. An excess of the water dissolves the oxide.	Ammonia disengaged. Heat. The liquor boils (A).
Nitrat of antimony.			A reddish orange precipitate.
Tartrite of antimony.	A yellow orange precipitate.	An orange colour, but no precipitate.	An orange red precipitate, redissolved by an excess of hydrosulphuret.
White oxide of antimony.		Becomes yellow after some seconds.	The liquor loses its colour (A).

Metallic

(A) In these, hydrosulphuret of ammonia was used instead of hydrosulphuret of potass.

Table continued.

Metallic Solutions.	Solution of Hydrogenous Sulphuret of Potaſs.	Water impregnated with Sulphurated Hydrogen Gas.	Hydroſulphuret of Potaſs.
Oxide of antimony ſublimed.		Scarcely changes colour.	
Solution of oxide of arſenic.	Sulphuret decompoſed as by an acid.	Becomes ſomewhat muddy, and of a yellow colour.	A yellow colour, but no precipitate.
Sulphat of titanium.			A precipitate of a deep green.
Molybdic acid.		A brown precipitate.	A brown precipitate.

CHAP. IV. *Of* CRYSTALLIZATION.

864 Cryſtals

THE word *cryſtal*, in its ſtrict and proper ſenſe, ſignifies a tranſparent body poſſeſſed of a regular figure. But it is now uſed to denote a body which has aſſumed a regular figure whether it be tranſparent or not. *Cryſtallization* is the *act* by which this regular figure is formed.

As the greater number of cryſtals belong to the claſs of neutral ſalts, it may not be improper, before we conclude this part of the article, to make a few obſervations on the phenomena of cryſtallization.

As cryſtallization is confeſſedly nothing elſe than the regular arrangement of the particles of bodies, it is evident that before it can take place the particles of the body to be cryſtallized muſt be at ſome diſtance from each other, and that they muſt be at liberty to obey the laws of attraction. They may be put into this ſituation by three methods, ſolution, ſuſpenſion, and fuſion.

865 Formed by ſolution,

1. Solution is the common method of cryſtallizing ſalts. They are diſſolved in water: The water is ſlowly evaporated, the ſaline particles gradually approach each other, combine together, and form ſmall cryſtals; which become conſtantly larger by the addition of other particles till at laſt they fall by their gravity to the bottom of the veſſel. It ought to be remarked, however, that there are two kinds of ſolution, each of which preſents different phenomena of cryſtallization. Some ſalts diſſolve in very ſmall proportions in cold water, but are very ſoluble in hot water; that is to ſay, water at the common temperature has little effect upon them, but water combined with caloric diſſolves them readily. When hot water ſaturated with any of theſe ſalts cools, it becomes incapable of holding them in ſolution: the conſequence of which is, that the ſaline particles gradually approach each other and cryſtallize. Sulphat of ſoda is a ſalt of this kind. To cryſtallize ſuch ſalts, nothing more is neceſſary than to ſaturate hot water with them, and ſet it by to cool. But were we to attempt to cryſtallize them by evaporating the hot water, we ſhould not ſucceed; nothing would be procured but a ſhapeleſs maſs. Many of the ſalts which follow this law of cryſtallization combine with a great deal of water; or, which is the ſame thing, many cryſtals formed in this manner contain a great deal of water of cryſtallization.

There are other ſalts again which are nearly equally ſoluble in hot and cold water; common ſalt for inſtance. It is evident that ſuch ſalts cannot be cryſtallized by cooling; but they cryſtallize very well by evaporating their ſolution while hot. Theſe ſalts generally contain but little water of cryſtallization.

2. It appears, too, that ſome ſubſtances are capable of aſſuming a cryſtalline form merely by having their particles ſuſpended in water, without any regular ſolution; at leaſt it is not eaſy, on any other ſuppoſition, to explain the cryſtallizations of carbonat of lime ſometimes depoſited by waters that run over quantities of that mineral. 866 Suſpenſion,

3. There are many ſubſtances, however, neither ſoluble in water, nor capable of being ſo minutely divided as to continue long ſuſpended in that fluid; and which, notwithſtanding, are capable of aſſuming a cryſtalline form. This is the caſe with the metals, with glaſs, and ſome other bodies. The method employed to cryſtallize them is *fuſion*, which is a ſolution by means of caloric. By this method the particles are ſeparated from one another; and if the cooling goes on gradually, they are at liberty to arrange themſelves in regular cryſtals. There are many ſubſtances, however, which it has been hitherto impoſſible to reduce to a cryſtalline form, either by theſe or any other method. Whether this be owing to the nature of theſe bodies themſelves, or to our ignorance of the laws by which cryſtals are formed, as is much more likely, cannot be determined. 867 And fuſion.

The phenomena of cryſtallization ſeem to have attracted but little of the attention of the ancient philoſophers. Their theory indeed, that the elements of bodies poſſeſs certain regular geometrical figures, may have been ſuggeſted by theſe phenomena; but we are ignorant of their having made any regular attempt to explain them. The ſchoolmen aſcribed the regular figure of cryſtals to their ſubſtantial forms, without giving themſelves much trouble about explaining the meaning of the term. This notion was attacked by Boyle; who proved that cryſtals were formed by the mere aggregation of particles *. But it ſtill remained to explain, why that aggregation took place? and why the particles united in ſuch a manner as to form regular figures? Theſe queſtions were anſwered by Newton. According to him, the aggregation is produced by the attraction which he had proved to exiſt between the particles of all bodies, and which acts as ſoon as theſe particles are brought within a certain diſtance of each other by the evaporation of the liquid in which they are diſſolved. The regularity of their figures he explained by ſuppoſing, that while in a ſtate of ſolution they were arranged in the liquid in regular rank and file; the conſequence 868 Cryſtallization explained.

* *Treatiſe on the Origin of Forms and Qualities.*

Crystallization.

fequence of which, as they are acted upon by a power which at equal distances is equal, at unequal distances unequal, will be crystals of determinate figures *.

* Optics, p. 363.

This explanation, which is worthy of Newton, is now universally admitted as the true one, and has contributed much towards elucidating this important part of chemistry.

Still, however, there remain various phenomena relating to crystallization, which it is no easy matter to explain.

869
Salts do not easily crystallize in close vessels,

It has been observed, that those salts which crystallize upon cooling, do not assume a crystalline form so readily if they are allowed to cool in close vessels. If a saturated solution of sulphat of soda, for instance, in hot water be put into a phial, corked up closely, and allowed to cool without being moved, no crystals are formed at all; but the moment the glass is opened, the salt crystallizes with such rapidity that the whole of the solution in a manner becomes solid. This phenomenon has been explained by supposing that there is an affinity between the salt and caloric, and that while the caloric continues combined with it the salt does not crystallize; that the caloric does not leave the salt so readily when external air is not admitted, as glass receives it very slowly and parts with it very slowly. In short, the atmospherical air seems to be the agent employed to carry off the caloric; a task for which it is remarkably well fitted, on account of the change of density which it undergoes by every addition of caloric. This is confirmed by the quantity of caloric which always makes its appearance during these sudden crystallizations. This explanation might be put to the test of experiment, by putting two solutions of sulphat of soda in hot water in two similar vessels; one of glass, the other of metal, and both closed in the same manner. If the salt contained in the metallic vessel crystallized, which ought to be the case on account of the great conducting power of metals, while that in the glass vessel remained liquid, this would be a confirmation of the theory, amounting almost to demonstration. On the contrary, if both solutions remained liquid, it would be a proof that the phenomenon was still incompletely understood.

870
And why.

Not only salts, but water itself, which commonly crystallizes at 32°, may be made to exhibit the same phenomenon: it may be cooled much lower than 32° without freezing. This, as Dr Black has completely proved, depends entirely upon the retention of caloric.

871
Variety of forms in crystals accounted for.

If the regular form of crystals depends upon the aggregation of particles, and if during all crystallizations this aggregation goes on in the same manner, why have not all crystals the same form? Some have ascribed these differences to a certain polarity which the particles of bodies are supposed to possess, and which disposes each kind of particles to arrange themselves according to a certain law. Sir Isaac Newton appears rather to have ascribed it to the forms of the particles themselves †; and this seems to be the real solution of the problem. For supposing that all particles have the same form, they must of course possess the same polarity; and therefore every crystal must have the same form. It is impossible, then, to account for the different forms of crystals without supposing that the particles which compose them have also different forms. And if the particles of bodies have different forms, their regular aggregation must produce crystals of various shapes; and therefore their polarity, which is merely a supposition founded on this difference in the appearance of crystals, cannot be admitted. Suppose, for instance, that eight cubic particles were regularly arranged in water, and that by the gradual evaporation of the liquid were to approach, and at last to combine, it is evident that the crystal which they would produce would be a cube. Eight six-sided prisms would also produce a six-sided prism; and eight tetrahedrons would form a very different figure.

† Optics, p. 375.

But it will be asked, if the figure of crystals depends entirely upon the form of the particles that compose them, how comes it that the same substance does not always crystallize in the same way, but presents often such a variety of forms that it is scarcely possible to reckon them? We answer, that these various forms are sometimes owing to variations in the ingredients which compose the integrant particles of any particular body. Alum, for instance, crystallizes in octahedrons; but when a quantity of alumina is added, it crystallizes in cubes; and when there is an excess of alumina, it does not crystallize at all. If the proportion of alumina varies between that which produces octahedrons and what produces cubic crystals, the crystals become figures with fourteen sides; six of which are parallel to those of the cube and eight to those of the octahedron; and according as the proportions approach nearer to those which form cubes or octahedrons, the crystals assume more or less of the form of cubes or octahedrons. What is still more, if a cubic crystal of alum be put into a solution that would afford octahedral crystals, it passes into an octahedron: and, on the other hand, an octahedral crystal put into a solution that would afford cubic crystals, becomes itself a cube *. Now, how difficult a matter it is to proportion the different ingredients with absolute exactness, must appear evident to all.

* Le Blanc, Ann. de Chim. xiv. 149.

Another circumstance which contributes much to vary the form of crystals, is the different degree of concentration to which their solution has been reduced, and the rapidity or slowness with which they are formed. For it is too evident to require illustration, that when crystals are deposited very rapidly they must obstruct one another, and mix together so as very much to obscure the natural regularity of their form.

Even the nature of the vessel in which the crystallization is performed is not without some influence.

872
Hauy's theory of crystals.

But, independent of these accidental circumstances, Mr Hauy has shewn that every particular species of crystals has a primitive figure, and that the variations are owing to the different ways in which the particles arrange themselves. Of this theory, which is certainly exceedingly ingenious, and even satisfactory, we shall attempt to give a short view.

Happening to take up a hexangular prism of calcareous spar, or carbonat of lime, which had been detached from a group of the same kind of crystals, he observed that a small portion of the crystal was wanting, and that the fracture presented a very smooth surface. Let *abcde fgh* (fig. 8.) be the crystal; the fracture lay obliquely as the trapezium *psut*, and made an angle of 135°, both with the remainder of the base *abcsph* and with *tuef*, the remainder of the side *inef*. Observing that the segment *psutin* thus cut off had for its vertex *in*, one of the edges of the base *abcnih* of the prism, he attempted to detach

a

Cryſtallization.

a ſimilar ſegment in the part to which the next edge *c n* belonged, employed for that purpoſe the blade of a knife, directed in the ſame degree of obliquity as the trapezium *p s u t*, and aſſiſted by the ſtrokes of a hammer. He could not ſucceed: But upon making the attempt upon the next edge *b c*, he detached another ſegment, preciſely ſimilar to the firſt, and which had for its vertex the edge *b c*. He could produce no effect on the next edge *a b*; but from the next following, *a h*, he cut a ſegment ſimilar to the other two. The ſixth edge likewiſe proved refractory. He then went to the other baſe of the priſm *d e f g h r*, and found, that the edges which admitted ſections ſimilar to the preceding ones were not the edges *e f*, *d r*, *g k*, correſponding with thoſe which had been found diviſible at the oppoſite baſe, but the intermediate edges *d e*, *k r*, *g f*. The trapezium *l q y v* repreſents the ſection of the ſegment, which had *k r* for its vertex. This ſection was evidently parallel to the ſection *p s u t*; and the other four ſections were alſo parallel two and two. Theſe ſections were, without doubt, the natural joinings of the layers of the cryſtal. And he eaſily ſucceeded in making others parallel to them, without its being poſſible for him to divide the cryſtal in any other direction. In this manner he detached layer after layer, approaching always nearer and nearer the axis of the priſm, till at laſt the baſes diſappeared altogether, and the priſm was converted into a ſolid OX (fig. 9.), terminated by twelve pentagons, parallel two and two; of which thoſe at the extremities, that is to ſay, ASRIO, IGEDO, BAODC at one end, and FKNPQ, MNPXU, ZQPXY at the other, were the reſults of mechanical diviſion, and had their common vertices O, P ſituated at the centre of the baſes of the original priſm. The ſix lateral pentagons RSUXY, ZYRIG, &c. were the remains of the ſix ſides of the original priſm.

By continuing ſections parallel to the former ones, the lateral pentagons diminiſhed in length; and at laſt the points R, G coinciding with the points Y, Z, the points S, R with the points U, Y, &c. there remained nothing of the lateral pentagons but the triangles YIZ, UXY, &c. (fig. 10.). By continuing the ſame ſections, theſe triangles at laſt diſappeared, and the priſm was converted into the rhomboid *a e* (fig. 11.).

So unexpected a reſult induced him to make the ſame attempt upon more of theſe cryſtals; and he found that all of them could be reduced to ſimilar rhomboids. He found alſo, that the cryſtals of other ſubſtances could be reduced in the ſame manner to certain primitive forms; always the ſame in the ſame ſubſtances, but every ſubſtance having its own peculiar form. The primitive form of fluat lime, for inſtance, was an octahedron; of ſulphat of barytes, a priſm with rhomboidal baſes; of field-ſpath, an oblique angled parallelopiped, but not rhomboidal; of adamantine ſpar, a rhomboid, ſomewhat acute; of blende, a dodecahedron, with rhomboidal ſides; and ſo on.

Theſe muſt be conſidered as the real *primitive forms* of the cryſtals; the other forms which they often aſſume may be called *ſecondary forms*.

The primitive cryſtals obtained by the above proceſs may be divided by ſections parallel to their different ſides: all the matter which ſurrounded this primitive cryſtal may alſo be divided by ſections parallel to the ſides of the primitive cryſtal. It follows from this, that the parts detached by means of theſe ſections are ſimilar, and differ from one another only in ſize, which diminiſhes in proportion to the length that the diviſion is carried. But the diviſion of the cryſtals into ſimilar ſolids has a term, beyond which we ſhould come to the ſmalleſt particles of the body, which could not be divided without chemical decompoſition. It is probable, therefore, that the form of the integrant particles of a body is the ſame with the primitive form of its cryſtals. Here, then, we have a method of diſcovering the form of the particles of bodies; and if this method could be applied to all ſubſtances whatever, it would enable us to aſcertain the affinity of all bodies for each other by accurate calculation. It muſt be allowed that ſeveral objections might be made to the concluſions of Mr Hauy; but his theory is, on the whole, ſo plauſible, that it would certainly be worth while to extend it, and apply it to the calculation of affinities as far as it is ſuſceptible of the application. If the cryſtals obtained by the above proceſs be the primitive forms, it becomes a queſtion of ſome conſequence to determine in what manner the ſecondary forms are produced.

According to Hauy, all the parts ſuperadded to the primitive cryſtals, in order to form the ſecondary cryſtal, conſiſt of plates, which decreaſe regularly by the ſubtraction of one or more rows of integrant particles, in ſuch a manner, that the number of theſe ranks, and conſequently the form of the ſecondary cryſtal, may be determined by theory (c).

To explain this, let us ſuppoſe that EP (fig. 12.) repreſents a dodecahedron, terminated by equal and ſimilar rhombs; that this dodecahedron is a ſecondary cryſtal, the primitive form of which is a cube: the ſituation of this cube in the dodecahedron may be conceived from fig. 13. The ſmaller diagonals DC, CG, GF, FD, of four ſides of the dodecahedron, united round the ſame ſolid angle L, form the ſquare CDFG. Now there are ſix ſolid angles, compoſed of four plains, to-wit, the angles L, O, E, N, R, P (fig. 12.); and conſequently, by making ſections through the ſmaller diagonals of the ſides that form theſe angles, ſix ſquares will be made apparent, which are the ſix ſides of the primitive cube, three of which are repreſented in fig. 13. CDFG, ABCD, BCGH.

This cube being compoſed of cubic integrant particles, each of the pyramids, LCDFG for inſtance (fig. 13.) which repoſe upon its ſides, muſt alſo, according to the theory, be compoſed of ſimilar cubic particles. To make this appear, let us ſuppoſe that ABFG (fig. 14.) is a cube compoſed of 729 ſmall cubes: Each of its ſides will conſiſt of 81 ſquares, being the external ſides of as many cubic particles, which together conſtitute the cube. Upon ABCD, one of the ſides of this cube, let us apply a ſquare lamina, compoſed of cubes equal to thoſe of which the primitive cryſtal conſiſts, but which has on each ſide a row of cubes leſs than the outermoſt layer of the primitive cube. It will of courſe be compoſed of 49 cubes, 7 on each ſide; ſo that its lower baſe *o n f g* (fig. 15.) will fall exactly on the ſquare marked with the ſame letters in fig. 14.

Above this lamina let us apply a ſecond *l m p u* (fig. 16.),

(c) The explanation of Bergman is not very different. See his *Opuſc.* vol. ii. diff. 1.

Cryſtallization.

16.), compoſed of 25 cubes; it will be ſituated exactly above the ſquare marked with the ſame letters (fig. 14.) Upon this ſecond let us apply a third lamina *v x y z* (fig. 17.) conſiſting only of 9 cubes; ſo that its baſe ſhall reſt upon the letters *v x y z* (fig. 14.). Laſtly, on the middle ſquare *r* let us place the ſmall cube *r* (fig. 18.), which will repreſent the laſt lamina.

It is evident, that by this proceſs a quadrangular pyramid has been formed upon the face ABCD (fig. 14.), the baſe of which is this face, and the vertex the cube *r* (fig. 18.). By continuing the ſame operation on the other five ſides of the cube, as many ſimilar pyramids will be formed; which will envelope the cube on every ſide.

It is evident, however, that the ſides of theſe pyramids will not form continued planes, but that, owing to the gradual diminution of the laminæ of the cubes which compoſe them, theſe ſides will reſemble the ſteps of a ſtair. We can ſuppoſe, however (what muſt certainly be the caſe), that the cubes of which the nucleus is formed are exceedingly ſmall, almoſt imperceptible; that therefore a vaſt number of laminæ are required to form the pyramids, and conſequently that the channels which they form are imperceptible. Now DCBE (fig. 19.) being the pyramid reſting upon the face ABCD (fig. 14.), and CBOG (fig. 19.) the pyramid applied to the next face BCGH (fig. 14.), if we conſider that every thing is uniform from E to O (fig. 19.) in the manner in which the edges of the *laminæ of ſuperpoſition* (as the Abbé Hauy calls the laminæ which compoſe the pyramids) mutually project beyond each other, it will readily be conceived, that the face CEB of the firſt pyramid ought to be exactly in the ſame plane with the face COB of the adjacent pyramid; and that therefore the two faces together will form one rhomb ECOB. But all the ſides of the ſix pyramids amount to 24 triangles ſimilar to CEB; conſequently they will form 12 rhombs, and the figure of the whole cryſtal will be a dodecahedron, ſimilar to that repreſented in fig. 12. and 13.

If the decreaſe of the laminæ of ſuperpoſition took place according to a more rapid law, if each lamina had on its circumference two, three, or four rows of cubes leſs than the inferior lamina—in that caſe, the pyramids produced being lower, their adjacent faces would no longer form one plane; and therefore the ſurface of the ſecondary cryſtal would conſiſt of 24 iſoſceles triangles, all inclined towards each other.

In this manner Mr Hauy has ſhewn, that a variety of ſecondary cryſtals are formed, and that their forms vary by means of ſlight variations in the ratio of the *decrement*. Dodecahedral ſulphuret of iron, for inſtance, is formed from a cubic nucleus, by the addition of laminæ, decreaſing, as in the example given above, with this difference, that from every lamina laid upon the face ABCD (fig. 14.) only one row of cubes are ſubtracted at the ſides AD and BC reſpectively; whereas two rows are ſubtracted at each of the ſides AB and CD. The conſequence of this more rapid decrement on two parallel ſides than on the other two will be, that the pyramid raiſed on the face ABCD (fig. 14.), inſtead of terminating in a ſingle cube as in the example given above, will terminate in a range of cubes; or (ſuppoſing the cubes infinitely ſmall) inſtead of terminating in a point, it will terminate in a ridge. The pyramid will therefore have for its two ſides, contiguous to AB and DC, two trapeziums, and for its ſides, contiguous to AD and BC, two triangles. Let us ſuppoſe alſo, that with regard to the laminæ of ſuperpoſition which ariſe on the face BCGH (fig. 14.), the decrements follow the ſame law, and that each lamina decreaſes by two rows of cubes towards the lines BC and HG, and only by one row towards the lines CG, BH: The pyramid, in that caſe, will be placed in a direction oppoſite to the pyramid on ABCD, the ridge at the vertex of it running parallel to BC: the vertex of the pyramid raiſed upon CDFG muſt be parallel to CG: the pyramids on the three other ſides of the cube ought to ſtand each like that which ariſes on the oppoſite face.

The ſides of all the ſix pyramids thus formed amount to twelve trapeziums and twelve triangles. Every triangle is evidently contiguous and in the ſame plane with a trapezium of the neareſt pyramid; conſequently the ſecondary cryſtal thus formed conſiſts of twelve ſides, each of which is a pentagon.

Several other examples have been given by Mr Hauy; but theſe are ſufficient to ſhew in what manner the various ſecondary forms of cryſtals are conſtructed, according to the theory of that ingenious philoſopher.

In his reſearches on this ſubject, Mr Hauy perceived, that ſome cryſtals aſſumed ſecondary forms which could not be accounted for by any decrement whatever along the edges. Thus, for inſtance, ſome bodies, the primary form of which is cubic, are ſometimes found cryſtallized in regular octagons. Mr Hauy explains the formation of theſe ſecondary cryſtals, by ſuppoſing that the decrement took place parallel, not to the edges, but to the diagonals of the faces of the primary cubes.

In order to comprehend this, let us ſuppoſe ABCD (fig. 20.) to be the ſurface of a lamina compoſed of ſmall cubes, the baſes of which are repreſented by the little ſquares in the figure. It is evident, that the cubes *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, are in the direction of the diagonal of the ſquare ABCD; that the row of cubes *q*, *v*, *k*, *u*, *x*, *y*, *z*, is parallel to the diagonal; as alſo the row *n*, *t*, *l*, *m*, *p*, *o*, *r*, *s*; and that the whole figure might be divided into rows of ſquares, each of which would be parallel either to the diagonal AC or DB.

Now we may conceive that the laminæ of ſuperpoſition, inſtead of decreaſing by rows of cubes parallel to the edges AB, AD, decreaſe by rows parallel to the diagonals.

Let it be propoſed to conſtruct around the cube ABGF (fig. 21.), conſidered as a nucleus, a ſecondary ſolid, in which the laminæ of ſuperpoſition ſhall decreaſe on all ſides by ſingle rows of cubes, but in a direction parallel to the diagonals. Let ABCD (fig. 22.), the ſuperior baſe of the nucleus, be divided into 81 ſquares, repreſenting the faces of the ſmall cubes of which it is compoſed. Figure 23. repreſents the ſuperior ſurface of the firſt lamina of ſuperpoſition; which muſt be placed above ABCD (fig. 22.) in ſuch a manner that the points *a′*, *b′*, *c′*, *d′*, (fig. 23.) anſwer to the points *a*, *b*, *c*, *d*, (fig. 22.). By this diſpoſition the ſquares A *a*, B *b*, C *c*, D *d* (fig. 22.), which compoſe the four outermoſt rows of ſquares parallel to the diagonals AC, BD, remain uncovered. It is evident alſo, that the borders QV, ON, IL, GF (fig. 23.), project by one range beyond the borders AB, AD, CD, BC (fig. 22.), which is neceſſary, that the nucleus may be enveloped towards theſe edges: For if this were not the caſe,

caſe, re-entering angles would be formed towards the parts AB, BC, CD, DA, of the cryſtal; which angles appear to be excluded by the laws which determine the formation of ſimple cryſtals, or, which comes to the ſame thing, no ſuch angles are ever obſerved in any cryſtal. The ſolid muſt increaſe, then, in thoſe parts to which the decrement does not extend. But as this decrement is alone ſufficient to determine the form of the ſecondary cryſtal, we may ſet aſide all the other variations which intervene only in a ſubſidiary manner, except when it is wiſhed, as in the preſent caſe, to conſtruct artificially a ſolid repreſentation of a cryſtal, and to exhibit all the details which relate to its ſtructure.

The ſuperior face of the ſecond lamina will be A′G′L′K′ (fig. 24.). It muſt be placed ſo that the points a'', b'', c'', d'', correſpond to the points a' b' c' d' (fig. 23.), which will leave uncovered a ſecond row of cubes at each angle parallel to the diagonals AC and BD. The ſolid ſtill increaſes towards the ſides. The large faces of the laminæ of ſuperpoſition, which in fig. 23. were octagons, in fig. 24. arrive at that of a ſquare; and when they paſs that term they decreaſe on all ſides; ſo that the next lamina has for its ſuperior face the ſquare B′M′L′S′ (fig. 25.), leſs by one range in every direction than the preceding lamina (fig. 24.). This ſquare muſt be placed ſo that the points e', f', g', h', (fig. 25.) correſpond to the points e, f, g, h (fig. 24.). Figures 26, 27, 28, and 29, repreſent the four laminæ which ought to riſe ſucceſſively above the preceding; the manner of placing them being pointed out by correſponding letters, as was done with reſpect to the three firſt laminæ. The laſt lamina z' (fig. 30.) is a ſingle cube, which ought to be placed upon the ſquare z (fig. 29.).

The laminæ of ſuperpoſition, thus applied upon the ſide ABCD (fig. 22.), evidently produce four faces, which correſpond to the points A, B, C, D, and form a pyramid. Theſe faces, having been formed by laminæ, which began by increaſing, and afterwards decreaſed, muſt be quadrilaterals of the figure repreſented in fig. 31.; in which the inferior angle C is the ſame point with the angle C of the nucleus (fig. 21. and 22.); and the diagonal LQ repreſents L′G′ of the lamina A′G′L′K′ (fig. 24.). And as the number of laminæ compoſing the triangle L Q C (fig. 31.) is much ſmaller than that of the laminæ forming the triangle ZLQ, it is evident that the latter triangle will have a much greater height than the former.

The ſurface, then, of the ſecondary cryſtal thus produced, muſt evidently conſiſt of 24 quadrilaterals (for pyramids are raiſed on the other 5 ſides of the primary cube exactly in the ſame manner), diſpoſed 3 and 3 around each ſolid angle of the nucleus. But in conſequence of the decrement by one range, the three quadrilaterals which belong to each ſolid angle, as C (fig. 21.) will be in the ſame plane, and will form an equilateral triangle ZIN (fig. 32.). The 24 quadrilaterals, then, will produce 8 equilateral triangles; and conſequently the ſecondary cryſtal will be a regular octagon. This is the ſtructure of the octahedral ſulphuret of lead and of muriat of ſoda.

Decrements which take place in this manner have been called by Mr Hauy *decrements on the angles*.

There are certain cryſtals in which the decrements on the angles do not take place in lines parallel to the diagonals, but parallel to lines ſituated between the diagonals and the edges. This is the caſe when the ſubtractions are made by ranges of double, triple, &c. moleculæ. Fig. 33. exhibits an inſtance of the ſubtractions in queſtion; and it is ſeen that the moleculæ which compoſe the range repreſented by that figure are aſſorted in ſuch a manner as if of two there were formed only one; ſo that we need only to conceive the cryſtal compoſed of parallelopipedons having their baſes equal to the ſmall rectangles $a\,b\,c\,d$, $e\,d\,f\,g$, $h\,g\,i\,l$, &c. to reduce this caſe under that of the common decrements on the angles. To this particular kind of decrement Mr Hauy has given the name of *intermediate*.

In other cryſtals the decrements, either on the edges or on the angles, vary according to laws, the proportion of which cannot be expreſſed but by the fraction $\frac{2}{3}$ or $\frac{3}{4}$. It may happen, for example, that each lamina exceeds the following by two ranges parallel to the edges, and that it may at the ſame time have an altitude triple that of a ſimple molecule. Figure 34. repreſents a vertical geometrical ſection of one of the kinds of pyramids which would reſult from this decrement; the effect of which may be readily conceived, by conſidering that AB is a horizontal line taken on the upper baſe of the nucleus, $b\,a\,z\,r$ the ſection of the firſt lamina of ſuperpoſition, $g\,f\,e\,n$ that of the ſecond, &c. Theſe decrements Mr Hauy has called *mixed*.

Theſe two laſt ſpecies of decrements occur but rarely; Mr Hauy found them only in certain metallic ſubſtances.

All the metamorphoſes to which cryſtals are ſubjected depend, according to Mr Hauy, on the laws of ſtructure juſt explained, and others of the like kind. Sometimes the decrements take place at the ſame time on all the edges; as in the dodecahedron having rhombuſes for its planes, as before mentioned; or on all the angles, as in the octahedron originating from a cube. Sometimes they take place only on certain edges or certain angles. Sometimes there is an uniformity between them; ſo that it is one ſingle law by one, two, three ranges, &c. which acts on the different edges, or the different angles. Sometimes the law varies from one edge to the other, or from one angle to the other; and this happens above all when the nucleus has not a ſymmetrical form; for example, when it is a parallelopipedon, the faces of which differ by their reſpective inclinations, or by the meaſure of their angles. In certain caſes the decrements on the edges concur with the decrements on the angles to produce the ſame cryſtalline form. It happens alſo ſometimes that the ſame edge, or the ſame angle, is ſubjected to ſeveral laws of decrement that ſucceed each other. In ſhort, there are caſes where the ſecondary cryſtal has faces parallel to thoſe of the primitive form, and which combine with the faces produced by the decrements to modify the figure of the cryſtal.

The cryſtals ariſing from a ſingle law of decrement have been called by Mr Hauy *ſimple ſecondary forms*; thoſe which ariſe from ſeveral ſimultaneous laws of decrement he has called *compound ſecondary forms*.

" If amidſt this diverſity of laws (he obſerves), ſometimes inſulated, ſometimes united by combinations more or leſs complex, the number of the ranges ſubtracted were itſelf extremely variable; for example, were theſe decrements by twelve, twenty, thirty, or forty ranges, or more, as might abſolutely be poſſible, the multitude

of

Cryſtallization.

of the forms which might exiſt in each kind of mineral would be immenſe, and exceed what could be imagined. But the power which effects the ſubtractions ſeems to have a very limited action. Theſe ſubtractions, for the moſt part, take place by one or two ranges of molecules. I have found none which exceeded four ranges, except in a variety of calcareous ſpar, forming part of the collection of C. Gillet Laumont, the ſtructure of which depends on a decrement by ſix ranges; ſo that if there exiſt laws which exceed the decrements by four ranges, there is reaſon to believe that they rarely take place in nature. Yet, notwithſtanding theſe narrow limits by which the laws of cryſtallization are circumſcribed, I have found, by confining myſelf to two of the ſimpleſt laws, that is to ſay, thoſe which produce ſubtractions by one or two ranges, that calcareous ſpar is ſuſceptible of two thouſand and forty-four different forms: a number which exceeds more than fifty times that of the forms already known; and if we admit into the combination decrements by three and four ranges, calculation will give 8,388,604 poſſible forms in regard to the ſame ſubſtance. This number may be ſtill very much augmented in conſequence of decrements either mixed or intermediary.

"The ſtriæ remarked on the ſurface of a multitude of cryſtals afford a new proof in favour of theory, as they always have directions parallel to the projecting edges of the laminæ of ſuperpoſition, which mutually go beyond each other, unleſs they ariſe from ſome particular want of regularity. Not that the inequalities reſulting from the decrements muſt be always ſenſible, ſuppoſing the form of the cryſtals had always that degree of finiſhing of which it is ſuſceptible; for, on account of the extreme minuteneſs of the molecules, the ſurface would appear of a beautiful poliſh, and the ſtriæ would elude our ſenſes. There are therefore ſecondary cryſtals where they are not at all obſerved, while they are very viſible in other cryſtals of the ſame nature and form. In the latter caſe, the action of the cauſes which produce cryſtallization not having fully enjoyed all the conditions neceſſary for perfecting that ſo delicate operation of nature, there have been ſtarts and interruptions in their progreſs, ſo that, the law of continuity not having been exactly obſerved, there have remained on the ſurface of the cryſtal vacancies apparent to our eyes. Theſe ſmall deviations are attended with this advantage, that they point out the direction according to which the ſtriæ are arranged in lines on the perfect forms where they eſcape our organs, and thus contribute to unfold to us the real mechaniſm of the ſtructure.

"The ſmall vacuities which the edges of the laminæ of ſuperpoſition leave on the ſurface of even the moſt perfect ſecondary cryſtals, by their re-entering and ſalient angles, thus afford a ſatisfactory ſolution of the difficulty a little before mentioned; which is, that the fragments obtained by diviſion, the external ſides of which form part of the faces of the ſecondary cryſtal, are not like thoſe drawn from the interior part. For this diverſity, which is only apparent, ariſes from the ſides in queſtion being compoſed of a multitude of ſmall planes, really inclined to one another, but which, on account of their ſmallneſs, preſent the appearance of one plane; ſo that if the diviſion could reach its utmoſt bounds, all theſe fragments would be reſolved into molecules ſimilar to each other, and to thoſe ſituated towards the centre.

"The fecundity of the laws on which the variations of cryſtalline forms depend, is not confined to the producing of a multitude of very different forms with the ſame molecules. It often happens alſo, that molecules of different figures arrange themſelves in ſuch a manner as gives riſe to like polyhedra in different kinds of minerals. Thus the dodecahedron with rhombuſes for its planes, which we obtained by combining cubic molecules, exiſts in the granite with a ſtructure compoſed of ſmall tetrahedra, having iſoſceles triangular faces; and I have found it in ſparry fluor *(fluat of lime)*, where there is alſo an aſſemblage of tetrahedra, but regular; that is to ſay, the faces of which are equilateral triangles. Nay more, it is poſſible that ſimilar molecules may produce the ſame cryſtalline form by different laws of decrement. In ſhort, calculation has conducted me to another reſult, which appeared to me ſtill more remarkable, which is, that, in conſequence of a ſimple law of decrement, there may exiſt a cryſtal which externally has a perfect reſemblance to the nucleus, that is to ſay, to a ſolid that does not ariſe from any law of decrement *."

* *Ann. de Chim.* xvii. 225.

Such is a ſhort view of the theory by which Mr Hauy explains the various cryſtalline forms of the ſame ſubſtance. We would with pleaſure have entered more into detail, had not moſt of his examples been deduced from ſubſtances which belong rather to mineralogy than to the elements of chemiſtry. This theory, to ſay no more of it, is, in point of ingenuity, inferior to few; and the mathematical ſkill and induſtry of its author are intitled to the greateſt applauſe.

But what we conſider as the moſt important part of that philoſopher's labours, is the method which they point out of diſcovering the figure of the integrant particles of cryſtals; becauſe it may pave the way for calculating the affinities of bodies, which is certainly by far the moſt important part of chemiſtry. This part of the ſubject, therefore, deſerves to be inveſtigated with the greateſt care.

Mr Hauy has found, that the primitive form of all the cryſtals which he has examined may be reduced to ſix; 1. The parallelopipedon in general, comprehending the cube, the rhomboid, and all ſolids terminated by ſix ſides parallel two and two; 2. The regular tetrahedron; 3. The octahedron with triangular ſides; 4. The hexagonal priſm; 5. The dodecahedron bounded by rhombs; 6. The dodecahedron bounded by iſoſceles triangles. Were we to ſuppoſe that theſe primitive forms are exactly ſimilar to the form of the integrant particles which compoſe them, it would follow, that the integrant particles of all the cryſtals hitherto formed have only ſix different forms. This ſuppoſition, however, is not probable; becauſe the ſame nucleus has been diſcovered in different ſpecies of minerals, and becauſe we can eaſily conceive integrant particles of different forms, combining in ſuch a manner as to compoſe nuclei of the ſame figure, juſt as we have ſeen that different primitive forms are capable of producing the ſame ſecondary form. Still, therefore, in endeavouring to diſcover the integrant particles of bodies, there are difficulties to remove, which hitherto, at leaſt, have been unſurmountable. But the theory of Mr Hauy may be conſidered as a firſt ſtep towards the diſcovery; and a *ſtep* in reſearches of ſo difficult a nature is of very great conſequence.

We

Conclusion.

We have now finished the three first parts of this article, which comprehend all the elementary part of chemistry. We ought now to proceed to the fourth part, which was to consist of a chemical examination of substances as they exist in nature in the mineral, vegetable, and animal kingdoms; but this, for various reasons, we shall defer till we come to the words MINERALOGY, and *Animal and Vegetable* SUBSTANCES.

We shall finish this article with a few remarks upon the chemical nomenclature, which for some time past has been an object of serious attention.

873 Remarks on the chemical nomenclature.

Chemistry was unfortunately first cultivated by a set of ignorant men, filled with the highest notions of their own importance, and buoyed up with the mighty feats which they were to perform by their art. The little which they did know they were anxious to conceal; and their anxiety was no less to inspire the world with high ideas of their knowledge and power. The consequence of this was, that they loaded chemistry with the most ridiculous and whimsical names that can well be conceived. *Liver of sulphur, mercury of life, horned moon, butter of antimony, the double secret, the corraline secret, the secret of vitriol, the wonderful salt, the secret salt, the salt with many virtues, the salt of two ingredients, the foliated earth of tartar*, were the names by which they distinguished some of the most familiar preparations; and, were it worth while, a great many more names of the same stamp might easily be added.

As soon as chemistry had attracted the attention of men of science, the absurdity of its nomenclature was felt, and several partial improvements were at different times made in it. Macquer, in particular, discarded many of the ancient names, and substituted others less exceptionable in their place.

But soon after the publication of the first edition of his Dictionary, an evil began to be felt severely, which never could have occurred to the earlier chemists. Hitherto the number of objects which had engaged the attention of those who cultivated the science had been very limited; the acids amounted only to five, the earths to four, the metals to 12 or 14, and the neutral salts scarcely exceeded 20 or 30. To remember names for so small a number of bodies, however ridiculous they happened to be, was no very difficult matter. But about that time, in consequence chiefly of the discovery of fixed air by Dr Black, which laid the foundation of pneumatic chemistry, the science began to extend itself, and to enlarge its boundaries with inconceivable rapidity. The number of bodies connected with it, and which it had to describe, soon became immense; and if every one of them received names not dependant upon one another, the most retentive memory could not have remembered the thousandth part of them.

The difficulty of studying chemistry from that time till the year 1782 must have been very great: it was even perceived and complained of by the masters of the science. In 1782 Mr de Morveau, who had undertaken the chemical part of the *Encyclopedie Methodique*, published in the *Journal de Physique* a new chemical nomenclature, and at the same time invited all those persons who were fond of chemistry, and interested in its progress, to propose objections and improvements.

This new nomenclature was formed agreeable to the five following rules:

1. Every substance ought to have a name, and not to be denoted by a phrase.
2. Names ought to be as much as possible conformable to the nature of the things signified by them.
3. When the character of a substance is not well enough known to determine the denomination, a name which has no meaning is preferable to one which conveys a false idea.
4. In the choice of new words those ought to be preferred which have their roots in the dead languages most generally known, that the word may be easily suggested by the sense, and the sense by the word.
5. The new words ought to be as suitable as possible to the genius of the languages for which they are formed.

This nomenclature was approved of by Macquer, and by Bergman, who had himself proposed one upon a plan not very different (D). He wrote to Morveau, and exhorted him to prosecute his undertaking with courage. "Do not spare (says he) a single improper denomination; those that are already learned will be always so, and those that are not will learn the sooner*."

* Encycl. Method. Chim. Preface.

This nomenclature was adopted by several chemists, and it was used in the greatest part of the first volume of the chemical part of the *Encyclopedie Methodique*; but the new discoveries in chemistry had produced a more accurate method of reasoning, and had enabled Lavoisier to explain the phenomena of the science without the assistance of the hypothetical principle of phlogiston, which had hitherto been necessary. As the language, even in its improved state, was accommodated to this principle, and presupposed its existence, new changes became evidently necessary, in order that, according to Morveau's rule, the words might denote the most essential properties of the things intended to be signified. Accordingly, when Morveau was in Paris in 1787, Lavoisier, Berthollet, and Fourcroy, agreed to labour in concert with him to bring the chemical nomenclature still nearer to perfection. These philosophers, assisted by the mathematicians of the Royal Academy and by several chemists, formed a new nomenclature, which they made public in 1787.

For some time little attention was paid to this nomenclature by foreign chemists, and it seemed generally to be disapproved. The adherents of the phlogistic system in France, who were exceedingly numerous, viewed it as an engine artfully formed to undermine and destroy their favourite theory. They resolved, therefore, unanimously, to crush, if possible, this new instrument, which they considered as

——— *in nostros fabricata machina muros,*
Inspectura domos, venturaque desuper urbi.

And for this purpose they exerted themselves with a vigour, which was only equalled by the zeal and indefatigable exertions of their antagonists. A kind of civil war was thus kindled in the republic of letters, which was carried on with great animosity: And posterity will see, with regret, men of undoubted genius at times divesting themselves of the armour of truth and of candour, and endeavouring to serve their party, and stab their adversaries with darts steeped in the poison of calumny and falsehood*. This contest, however, which was not confined to France, was productive of good effects, which infinitely surpassed all the bad ones. It occa-

* See the Journ. de Phys. for 1788, 89, 90, 91, passim.

(D) See his thoughts on a natural history of fossils in the 4th vol. of his *Opusc.*

occasioned an accumulation of facts, produced a rigid examination of theories and opinions, introduced an accuracy into chemical experiments which has been of the most essential service, and gave that tone and vigour to the cultivators of chemistry which have brought to light the most sublime and unlooked-for truths. It deserves attention, and the fact is no inconsiderable evidence in favour of the antiphlogistic theory, that almost all the illustrious chemists who at present adhere to it declared originally against it. Berthollet, Morveau, Black, Kirwan, and many other chemists who are now its ablest defenders, were at first its most powerful opponents. "This system had hardly been published in France (says Dr Priestley, who still continues to adhere to the doctrine of phlogiston) before the principal philosophers and chemists of England, notwithstanding the rivalship which has long subsisted between the two countries, eagerly adopted it. Dr Black in Edinburgh, and as far as I hear all the Scots, have declared themselves converts, and, what is more, the same has been done by Mr Kirwan, who wrote a pretty large treatise in opposition to it. The English reviewers of books, I perceive, universally favour the new doctrine. In America, also, I hear of nothing else. It is taught, I believe, in all the schools on this continent, and the old system is entirely exploded. And now that Dr Crawford is dead, I hardly know of any person except my friends of the Lunar Society at Birmingham, who adhere to the doctrine of phlogiston; and what may now be the case with *them* in this age of revolutions, philosophical as well as civil, I will not at this distance answer for.

"It is no doubt *time*, and of course opportunity of examination and discussion, that gives stability to any principles. But this new theory has not only kept its ground, but has been constantly and uniformly advancing in reputation more than *ten years*, which, as the attention of so many persons, the best judges of every thing relating to the subject, has been unremittingly given to it, is no inconsiderable period. Every year of the last twenty or thirty has been of more importance to science, and especially to chemistry, than any ten in the preceding century *."

* *Considerations on the doctrine of phlogiston*, Introduction.

We have endeavoured in the preceding article to state the different theories which have successively made their appearance in *chemistry* with as much fairness as possible. If we have succeeded, the reader will be enabled to judge for himself which of these theories is the most consistent with truth; or rather, if we have succeeded, he will join with us in thinking that the theory of Lavoisier is in most points an accurate account of what takes place in nature.

This we consider as a sufficient reason for having adopted the new nomenclature; for, as Morveau long ago observed, most of the objections that were made to it were rather levelled at the doctrine of those who formed it, than at the nomenclature itself. Its superiority to every other nomenclature cannot be disputed for an instant; and the vast facility which it has added to the acquisition of chemistry, must be acknowledged by every one who knows any thing about the science. The Table of the new nomenclature will not be expected here, as it has been already given in the Appendix to the article CHEMISTRY in the *Encyclopedia*. At any rate, it would have been unnecessary, as we have used the new names all along; and therefore our readers must by this time be well acquainted with them.

Upon the almost infinite number of criticisms which have been made on the new nomenclature, and the many new terms which since its publication have been successively proposed, we do not mean to enter. Few of these terms can bear a comparison with the French nomenclature, and still fewer have any claim to be preferred to it; and the philosophers who persist in these useless innovations, are more probably actuated by the desire of appearing to have a share in the great revolution which chemistry has undergone, than by any hopes of being able to improve the accuracy or the elegance of its language. How few have displayed the magnanimity of an illustrious philosopher of our own country, who, though he had invented a new nomenclature himself, exhorted his pupils not to use it, but to adopt that of the French chemists, which was likely soon to come into universal use.

Even the etymological remarks which have been made on the new nomenclature, we consider as either of little consequence or as ill-founded. The philosophers who formed it have displayed a sagacity and a moderation which could not be excelled, and have, upon the whole, formed a language much more systematic, and much more perfect, than could have been expected; and whoever compares it with the nomenclature proposed in 1782 by Morveau, will see how great a share of it is due to that illustrious philosopher.

Notwithstanding what we have here said, we would not be understood to consider the new nomenclature as already arrived at a state of such absolute perfection, that no alteration whatever can be made in it except for the worse. Such perfection belongs not to the works of man; nor if it did, could it be expected in this case, if we consider for a moment the present state of chemistry. New discoveries must occasion additions and alterations in the nomenclature; but the authors of the new nomenclature have given us the rules by which changes and additions are to be made; and if they are adhered to, we may expect with confidence that the language of chemistry will in its advancement to perfection keep pace with the science. We have in the preceding article ventured in an instance or two to adopt little improvements that have been suggested by later writers. We have taken the liberty, too, of choosing, from the variety which the British chemists have proposed, that mode of spelling each of the terms which appeared to us most agreeable to the English idiom, and most conformable to analogy: Whether or not we have made a proper choice must be left for others to determine.

Cherubim.

CHERUBIM were emblematical figures; of which an account, a very vague one indeed, has been given in the *Encyclopædia Britannica*. We are far from thinking ourselves qualified to improve that account, or to explain emblems in the Jewish worship, which even Josephus did not understand; and we certainly should not have resumed the subject but to gratify a numerous class of our readers, and to comply with the request of some highly respected friends.

The followers of Mr Hutchinson, who are firmly persuaded that their master brought to light from the writings of the Old Testament many important doctrines which had lain concealed from all the piety, all the industry, and all the learning of 1700 years, believe that, among other things, he and they have been able to ascertain the form and the import of the Hebrew Cherubim. Their discoveries on this subject, as we have been told by better judges than we pretend to be, are more clearly stated by Mr Parkhurst in his Hebrew Lexicon, than by any other writer of that school. We shall therefore lay before our readers his doctrine respecting the form of the artificial cherubs, as well as of their emblematical meaning; and subjoin a few remarks, which the nature of his reasoning has forced from us.

" *First*, then, as to the *form* of the artificial cherubs in the tabernacle and temple, Moses (says our author) was commanded (Exod. xxv. 18, 19.) ' Thou shalt make two cherubs: of beaten gold shalt thou make them at the two ends of the mercy-seat. And thou shalt make one cherub at the one end, and the other cherub at the other end: מן הכפרת, out of the mercy-seat (Margin Eng. Traslat. of the matter of the mercy-seat) shall ye make the cherubs at the two ends thereof.' All which was accordingly performed (Exod. xxxvii, 7, 8.), and these cherubs were with the ark placed in the holy of holies of the tabernacle (Exod. xxvi. 33, 34. xl. 20.); as those made by Solomon were afterwards in the holy of holies of the temple (1 Kings vii. 23, 27.)

Cherubim.

We may observe that in Exodus Jehovah speaks to Moses of the cherubs as of figures well known; and no wonder since they had always been among believers in the holy tabernacle from the beginning. (See Gen. iii. 24. Wisd. ix. 8. And though mention is made of their faces (Exod. xxv. 20. 2 Chron. iii. 13.), and of their wings, (Exod. xxv. 20. 1 Kings viii. 7. 2 Chron. iii. 11, 12.); yet neither in Exodus, Kings, nor Chronicles, have we any particular description of their form. This is however very exactly, and, as it were, anxiously supplied by the prophet Ezekiel, ch. i. 5. ' Out of the midst thereof (*i. e.* of the fire infolding itself, ver. 4.) דמות the likeness of four livings creatures or animals; דמות אדם להנה the likeness of a man (being) with them.' This last Hebrew expression cannot mean that they, *i. e.* the four animals, had the likeness of a man, which interpretation would indeed make the prophet contradict himself (comp. ver. 10.); but it imports that the likeness of a man in glory, called (verse 26.) דמות במראה אדם the likeness as the appearance of a man, and

Cherubim. and particularly deſcribed in that and the following verſes, was with them. Ver. 6. ‘ And there were four faces to one (דמות or ſimilitude), and four wings to one, לחם to them. So there were at leaſt two compound figures. Ver. 10. ‘ And the likeneſs of their faces; the face of a man, and the face of a lion, on the right ſide, to them four; and the face of an ox to them four; and the face of an eagle to them four.’ Ezekiel knew (ch. x. 1.—20.) that theſe were cherubs. Ver. 21. ‘ Four faces לאחד to one (cherub) and four wings to one.’ This text alſo proves that the prophet ſaw more cherubs than one, and that each had four faces and four wings. And we may be certain that the cherubs placed in the holy of holies were of the form here deſcribed by the prieſt and prophet of Ezekiel, becauſe we have already ſeen from Exodus, 1 Kings, and 2 Chronicles, that they likewiſe had faces and wings, and becauſe Ezekiel knew what he ſaw to be cherubs, and becauſe there were no four-faced cherubs any where elſe but in the holy of holies; for it is plain from a compariſon of Exod. xxvi. 1, 31. 1 Kings vi. 29, 32. and 2 Chron. iii. 14. with Ezekiel xli. 18, 19, 20. that the artificial cherubs on the curtains and vail of the tabernacle, and on the walls, doors, and vail of the temple, had only two faces; namely, thoſe of a lion and of a man.

“ For it muſt be obſerved further, that, as the word כרוב is uſed for one compound figure with four faces, and כרובים in the plural for ſeveral ſuch compounds (ſee Exod. xxv. 18, 19. xxxvii. 8. 1 Kings vi. 23—26.), ſo is כרוב applied to one of the cherubic animals, as to the ox, Ezek. x. 14.; (compare ch. i. 10.) to the coupled cherub, or lion-man, Ezek. xli. 18.; and כרובים to ſeveral of the cherubic animals, as to ſeveral oxen, 1 Kings vii. 36. (compare ver. 29.) to ſeveral coupled cherubs, Exod. xxvi. 1. 1 Kings vi. 32, 35. & al. I proceed to ſhew.

“ *Secondly*, of what the cherubs were emblems, and with what propriety.

“ That the cherubic figures were emblems or repreſentatives of ſomething beyond themſelves is, I think, agreed by all, both Jews and Chriſtians. But the queſtion is, Of what they were emblematical? To which I anſwer in a word, Thoſe in the holy of holies were emblematical of the ever-bleſſed Trinity in covenant to redeem man, by uniting the human nature to the Second Perſon; which union was ſignified by the union of the faces of the lion and of the man in the cherubic exhibition, Ezek. i. 10. compare Ezek. xli. 18, 19. The cherubs in the holy of holies were certainly intended to repreſent ſome beings in heaven, becauſe St Paul has expreſsly and infallibly determined that the holy of holies was a figure or type of heaven, even of that heaven where is the peculiar reſidence of God (Heb. ix. 24.). And therefore theſe cherubs repreſented either the ever bleſſed Trinity with the man taken into the eſſence, or created ſpiritual angels. The following reaſons will, I hope, clearly prove them to be emblematical of the former, not of the latter:

“ *1ſt*, Not of angels; becauſe (not now to inſiſt on other circumſtances in the cherubic form) no tolerable reaſon can be aſſigned why angels ſhould be exhibited with four faces apiece.

“ *2dly*, Becauſe the cherubs in the holy of holies of the tabernacle were, by Jehovah’s order, ‘ made out of the matter of the mercy-ſeat, or beaten out of the ſame piece of gold as that was’ (Exod. xxv. 18, 19. xxxvii. 9.). Now the mercy-ſeat, made of gold and crowned, was an emblem of the Divinity of Chriſt (See Rom. iii. 25. The cherubs therefore repreſented not the angelic, but the Divine nature.

“ *3dly*, The typical blood of Chriſt was ſprinkled before them on the great day of atonement (compare Exod. xxxvii. 9. Lev. xvi. 14. Heb. ix. 7, 12.): And this cannot in any ſenſe be referred to created angels, but muſt be referred to Jehovah only; becauſe,

“ *4thly*, The high prieſt’s entering into the holy of holies on that day, repreſented Chriſt’s entering with his own blood into heaven ‘ to appear in the preſence of God for us’ (Heb. ix. 7, 24.) And,

5thly, When God ‘ raiſed Chriſt (the humanity) from the dead, he ſet him at his own right hand in the heavenly places, far above, ‘ΥΠΕΡΑΝΩ, all principality and power, and might and dominion, and every name that is named, not only in this world, but alſo in that which is to come (Eph. i. 21.). Angels and authorities and powers being made ſubject unto him’ (1 Peter iii. 22.)

“ *6thly*, The prophet Ezekiel ſaith (ch. x. 20.), ‘ This is the living creature, החיה (which muſt mean one compound figure, comp. ver. 14.) that I ſaw’ תחת inſtead of, a ſubſtitute of ‘ the Aleim of Iſrael. תחת, it is granted, may refer either to ſituation or ſubſtitution, (ſee Gen. xxx. 2. l. 19.) as the ſenſe requires. Here, notwithſtanding what is ſaid ver. 19. the latter ſenſe is preferable; becauſe it was the glory of the God of Iſrael, *i. e.* the God-man in glory, (compare ch. i. 26.) not the Aleim (the Trinity) of Iſrael that were over the cherubim; and the text ſays not, *theſe* were the living *creatures*, but, *this* was the living *creature*, which I ſaw תחת אלהי ישראל. Now the glory was over both the cherubims, ver. 19. but one compound cherub only was a ſubſtitute of the Aleim.

“ If it ſhould be here aſked, Why then were there two compound cherubs in the holy of holies? I anſwer, Had there not in this place been two compound cherubs, it would have been naturally impoſſible for them to repreſent what was there deſigned; for otherwiſe, all the faces could not have looked inwards toward each other, and down upon the mercy-ſeat, and on the interceding high prieſt ſprinkling the typical blood of Chriſt, (ſee Exod. xxxvii. 9.) and at the ſame time have looked outward toward the temple, לבית (Vulg. ad domum exteriorum, to the outer-houſe,) 2 Chron. iii. 13. Or, in other words, the Divine Perſons could not have been repreſented as witneſſing to each other’s voluntary engagements for man’s redemption, as beholding the ſacrifice of Chriſt’s death, typified in the Jewiſh church, and at the ſame time as extending their gracious regards to the whole world. (See Iſa. liv. 5. and Spearman’s Inquiry, p. 382. edit. Edinburgh.

“ The coupled cherub, or lion-man, on the vail and curtains of the outer tabernacle, and on the vail, doors, and walls of the temple, accompanied with the emblematic palm-tree, is ſuch a ſtriking emblem of the lion of the tribe of Judah (Rev. v. 5.) united to the man Chriſt Jeſus, as is eaſy to be perceived, but hard to be evaded. Theſe coupled cherubs appropriate the tabernacle or temple, and their vails, as emblems of Chriſt, and expreſs in viſible ſymbols what he and his apoſtles do in words. See John ii. 19, 21. Heb. viii. 2. ix. 11. x. 20.

x. 20. comp. Matt. xxvii. 51. And as the texts just cited from the New Testament afford us divine anthority for asserting that the outer tabernacle or temple was a type of the body of Christ, so they furnish us with an irrefragable argument to prove that the cherubs on their curtains or walls could not represent angels. For did angels dwell in Christ's body? No, surely: But 'in him dwelt all the fulness of the Godhead bodily.' (Col. ii. 9.)

"I go on to consider the propriety of the animals in the cherubic exhibition representing the Three Persons in the ever-blessed Trinity. And here to obviate any undue prejudice which may have been conceived against the Divine Persons being symbolically represented under any animal forms whatever, let it be remarked that Jehovah appeared as three men to Abraham (Gen. xviii.); that the serpent of brass set up by God's command in the wilderness was a type or emblem of Christ, God-man, lifted up on the cross (comp. Num. xxxi. 1—9. with John iii. 14, 15.); that at Jesus's baptism the Holy Spirit descended in a bodily shape, like a dove, upon him (Luke iii. 21, 22.); that Christ, as above intimated, is expressly called the lion of the tribe of Judah (Rev. v. 5.); and continually in that symbolical book set before us under the similitude of a lamb. All these are plain scriptural representations, each of them admirably suited, as the attentive reader will easily observe, to the particular circumstances or specific design of the exhibition. Why then should it appear a thing incredible, yea why not highly probable, that Jehovah Aleim should, under the typical state, order his own Persons and the union of the manhood with the essence to be represented by animal forms in the cherubim of glory? Especially if it be considered that the three animal forms, exclusive of the man (who stood for the very human nature itself) are the chief of their respective genera: the ox or bull of the tame or graminivorous; the lion, of the wild or carnivorous; and the eagle, of the winged kind.—But this is by no means all: For as the great agents in nature, which carry on all its operations, certainly are the fluid of the heavens, or, in other words, the fire at the orb of the sun, the light issuing from it, and the spirit or gross air constantly supporting, and concurring to the actions and effects of the other two; so we are told (Psal. xix. 1.) that השמים מספרים כבוד אל the heavens (are) the means of declaring, recounting, or particularly exhibiting the glory of God, even his eternal power and godhead, as St Paul speaks, Rom. i. 20. And accordingly Jehovah himself is sometimes, though rarely (I presume for fear of mistakes) called by the very name שמים or שמיא heavens in the Old Testament, see 2 Chron. xxxii. 20. (comp. 2 Kings xix. 14. Isa. xxxvii. 15.) Dan. iv. 23. or 26.; as he is more frequently expressed by Ουρανος heaven in the New. (See Mat. xxi. 25. Mark xi. 30. 31. Luke xv. 18, 21. xx. 4, 5. John iii. 27.) Yea not only so, but we find in the Scriptures both of the Old and New Testament, that the Persons of the eternal Three and their economical operations in the spiritual, are represented by the three conditions of the celestial fluid and their operations in the material world. Thus the peculiar emblem of the Word or Second Person is the שמש or light, and he is and does that to the souls or spirits of men which the material or natural light is and does to their bodies. (See inter al. 2 Sam. xxiii. 4. Isa. xlix. 6. lx. 1. Mal. iv. 2. or iii. 20. Luk i. 78. ii. 32. John i. 4—9. viii. 12. xii. 35, 36, 46.) The Third Person has no other distinctive name in scripture but רוח in Hebrew, and Πνευμα in Greek (both which words in their primary sense denote the material spirit or air in motion), to which appellation the epithet קדש, αγιος holy, or one of the names of God, is usually added: and the actions of the Holy Spirit in the spiritual system are described by those of the air in the natural (See John iii. 8. xx. 22. Acts ii. 2.) Thus, then, the second and Third Persons of the ever-blessed Trinity are plainly represented in scripture by the material light and air. But it is further written, Jehovah thy Aleim is a consuming fire. Deut. iv. 24. (Comp. Deut. ix. 23. Heb. xii. 29. Psal. xxi. 10. lxxviii. 21. Nah. i. 2.) And by fire, derived either immediately or mediately from heaven, were the typical sacrifices consumed under the old dispensation. Since, then, Jehovah is in scripture represented by the material heavens, and even called by their name, and especially by that of fire, and since the Second and Third Persons are exhibited respectively by the two conditions of light and spirit, and since fire is really a condition of the heavenly fluid as much distinct from the other two as they are from each other, it remains that the peculiar emblem of the First Person (as we usually speak) of the eternal Trinity, considered with respect to the other two, be the fire.

"Bearing then in mind that the personality in Jehovah is in scripture represented by the material Trinity of nature; which also, like their divine antitype, are of one substance, that the primary scriptural type of the Father is fire; of the Word, light; and of the Holy Ghost, spirit, or air in motion; we shall easily perceive the propriety of the cherubic emblems. For the ox or bull, on account of his horns, the curling hair on his forehead, and his unrelenting fury when provoked (see Psal. xxii. 13.) is a very proper animal emblem of fire; as the lion from his usual tawny gold-like colour, his flowing mane, his shining eyes, his great vigilancy and prodigious strength, is of light; and thus likewise the eagle is of the spirit or air in action, from his being chief among fowls, from his impetuous motion (see 2 Sam. i. 23. Job ix. 26. Jer. iv. 13. Lam. iv. 19.), and from his towering and surprising flights in the air (see Job xxxix. 27. Prov. xxiii. 5. xxx. 19. Isa. xl. 31. and Bochart, vol. iii. p. 173.) And the heathen used these emblematic animals, or the like, sometimes separate, sometimes joined, in various manners, as representatives of the material Trinity of nature, which they adored. These particulars Mr Hutchinson has proved with a variety of useful learning, vol. vii. p. 381, et seq. and any person who is tolerably acquainted with the heathen mythology will be able to increase his valuable collection with many instances of the same kind from modern as well as ancient accounts of the pagan religions.

"Thus, then, the faces of the ox, the lion, and the eagle, representing at second hand the Three Persons of Jehovah, the Father, the Word, and the Holy Spirit; and the union of the divine light with man being plainly pointed out by the union of the faces of the lion and the man (see Ezek. i. 10. xli. 18.), we may safely assert, that the cherubim of glory (Heb. ix. 5.) in the holy of holies were divinely instituted and proper emblems of the Three Eternal Persons in covenant to

redeem

Cherubim.

redeem man, and of the union of the divine and human natures in the perſon of Chriſt. And we find (Gen. iii. 24.) that immediately on Adam's expulſion from paradiſe, and the ceſſation of the firſt or paradiſiacal diſpenſation of religion, Jehovah Aleim himſelf ſet up theſe emblems, together with the burning flame המתהפכת rolling upon itſelf, to keep the way to the tree of life; undoubtedly, conſidering the ſervices performed before them, not to hinder, but to enable, man to paſs through it."

Thus far Mr Parkhurſt; and to his diſſertation where is the man who will deny the merit of erudition, combined with ingenuity? To the latter part of his reaſoning, however, objections obtrude themſelves upon us of ſuch force, that we know not how to anſwer them. The reader obſerves, that, according to this account, the cherubim are only at *ſecond hand* emblematical of the Holy Trinity, and that the *primary* emblem is that fluid which the author conceives to fill the ſolar ſyſtem, and to be one ſubſtance under the different appearances or modifications of *fire*, *light*, and *groſs air*. But unfortunately for this reaſoning, we are as certain as we can be of any matter of fact, that *fire* and *air* are *not* one ſubſtance; that the *groſs air* itſelf is compounded of very *different* ſubſtances; and that even *light* is a different ſubſtance from that which cauſes in us the ſenſation of heat, and to which modern chemiſts have given the name of *caloric* (See Chemistry-*Index* in this Supplement). We admit, that the *primary atoms* of all matter *may be* ſubſtances of the very ſame kind, though we do not *certainly know* that they are: but this makes nothing for our author's hypotheſis; becauſe the ſun and all the planets muſt, in that caſe, be added to his one ſubſtance, which would no longer appear under a triple form. Could it indeed be proved, that all men from Adam downwards, who made uſe of cherubic figures for the very ſame purpoſe with the ancient Jews, *believed* that fire, air, and light, are different modifications of the ſame ſubſtance, their belief, though erroneous, would be a ſufficient foundation for our author's reaſoning; but of this no proof is attempted, and certainly none that is ſatisfactory could be brought.

Our learned author, indeed, takes much for granted without proof. He has not proved that anywhere the bull was the emblem or hieroglyphic of *fire*, the lion of *light*, or the eagle of *air*. We do not, it muſt be owned, know that ſuch hieroglyphics were *not* uſed in Egypt and other countries before the introduction of alphabetical characters; but unleſs they were ſo uſed by Adam, all that is here ſaid of the *propriety* of theſe emblems muſt go for nothing: Indeed we ſee not their peculiar propriety. The tawny colour, flowing mane, and fierceneſs of the lion, might, for any thing that we can perceive to the contrary, repreſent *fire* as fitly as the horns, curling hair, and fury of the bull; and if it be true, as is generally ſaid, that the eagle can look ſteadily on the ſun, he ſeems, of all the three, to be the fitteſt emblem of light.

But there are other objections to this interpretation of the word cherubim. The four animals in the Revelation, which were undoubtedly cherubim, as well as the four and twenty elders, fell down before the Lamb, and worſhipped God*. Now, ſays Dr Gregory Sharp, "it is ſcarce to be conceived, if theſe four beaſts were repreſentatives of the divine perſons, that they could with any propriety, or without the greateſt ſoleciſm, be ſaid and deſcribed to fall down before and worſhip other emblematical repreſentations of the ſame divine nature and perfections: And therefore, whatever theſe beaſts were emblems of, they could not be cherubim in Mr Hutchinſon's ſenſe of that word; it being as contrary to the rational explanation of a viſion to ſay that one emblem of the divinity ſhould worſhip another emblem of it, as it is contrary to the reaſon of mankind, and to all our notions either of the Godhead or of worſhip, to ſay that the Trinity worſhipped the Trinity, or any one Perſon in the Trinity."

* Ch. v. 8. xix. 4.

This objection is admitted by our learned author to be a very plauſible one. To us it appears unanſwerable. He anſwers it, however, in the following words:

"Let it be carefully obſerved, that theſe repreſentations in Rev. ch. v. and xix. are not only viſional but hieroglyphical, and therefore muſt be explained according to the analogy of ſuch emblematical exhibitions; and as at ver. 6. 'the lamb, as it had been ſlain, having ſeven horns and ſeven eyes, ſtanding in the midſt of the throne, and of the four animals, and of the four-and-twenty elders,' is evidently ſymbolical of the Lamb of God now raiſed from the dead, and inveſted with all knowledge and power both in heaven and in earth; ſo 'the four animals falling down before him' (ver. 8.), and, as it is expreſſed (ch. xix. 4.), 'worſhipping God who ſat upon the throne,' muſt, in all reaſon, be explained ſymbolically likewiſe, not from any abſtract or metaphyſical notions we may have framed to ourſelves of worſhip in general, but from the ſpecific and peculiar circumſtances of the caſe before us. Thus, likewiſe, when in 1 Chron. xxix. 20. 'All the congregation worſhipped Jehovah and the king, namely David, the worſhip to both is expreſſed by the ſame ſtrong phraſe—ישתחו ל proſtrated themſelves to, LXX. προσεκυνησαν; yet ſurely no one will ſay that the people meant to worſhip David as God, but only to acknowledge him as king. So Adonijah, who had conteſted the crown with Solomon, came, וישתחו and worſhipped King Solomon (1 Kings i. 53.), not as God doubtleſs, but as king, thereby ſurrendering his own claim to the throne. However 'contrary therefore it may be to the reaſon of mankind, and to all our notions either of the Godhead or of worſhip, to ſay that the Trinity worſhipped the Trinity, or any one Perſon of the Trinity,' *i. e.* with divine worſhip as a creature worſhips his Creator; yet it is by no means contrary to the rational and ſcriptural explanation of an emblematic viſion, to ſay that the hieroglyphical emblems of the whole ever-bleſſed Trinity fell down and worſhipped the hieroglyphical emblem of the God-man, or God who ſat upon the throne. Since ſuch falling down, proſtration, or worſhipping, was the uſual ſymbolical act, as it ſtill is in the eaſt, not only of divine worſhip, but of acknowledging the regal power to be in the perſon ſo worſhipped; and theſe acts of the cherubic animals in Rev. v. 6. xix. 4. meant nothing more than either a ceſſion of the adminiſtration of all divine power to Chriſt God-man, or a declaration of the divine Perſons, by their hieroglyphical repreſentatives, that He muſt reign till all his enemies were made his footſtool. Comp. Mat. xxviii. 18. 1 Cor. xv. 25."

With every inclination to honour the memory of Mr Parkhurſt, who was certainly a ſcholar, and, which is of of more value, a pious and a good man, we cannot help considering this answer as mere trifling. In the 18th Psalm, the Lord is said to "ride upon a cherub;" and in Ezekiel, chap. i. there is said to have "been over the heads of the cherubim *a throne*, and upon that throne the likeness or appearance of *a man*," whom we take to be the Son of God incarnate. But is there any country in which the regal power of the sovereign is acknowledged by his riding, not upon his subjects, but upon other co-equal sovereigns? or, in which it is the custom for the sovereign to place his viceroy (for such our Saviour in his *human* nature certainly is) in his throne above himself?

We must therefore confess, that we know not of what the cherubic figures were emblematical, and that he who labours to establish the doctrine of the ever blessed Trinity by such criticisms and reasonings as those which we have examined, is either a secret enemy to that doctrine, or a very injudicious friend.

CHESS, the celebrated game, of which a copious account has been given in the Encyclopædia, is affirmed by Sir William Jones to have been invented by the Hindoos. "If evidence were required to prove this fact (says he *), we may be satisfied with the testimony of the Persians, who, though as much inclined as other nations to appropriate the ingenious inventions of a foreign people, unanimously agree that the game was imported from the west of *India* in the sixth century of our era. It seems to have been immemorially known in *Hindostan* by the name of *Cheturanga*, i. e. the four *angá's*, or members of an army; which are these, *elephants*, *horses*, *chariots*, and *foot soldiers*; and in this sense the word is frequently used by epic poets in their descriptions of real armies. By a natural corruption of the pure Sanscrit word, it was changed by the old Persians into *Chetrang*; but the Arabs, who soon after took possession of their country, had neither the initial nor final letter of that word in their alphabet, and consequently altered it further into *Shetranj*, which found its way presently into the modern *Persian*, and at length into the dialects of India, where the true derivation of the name is known only to the learned. Thus has a very significant word in the sacred language of the Brahmins been transformed by successive changes into *axedrez*, *scacchi*, *échecs*, *chess*, and, by a whimsical concurrence of circumstances, has given birth to the English word *check*, and even a name to the *exchequer* of Great Britain."

* *Asiatic Researches*, vol. ii. Mem. 9.

It is confidently asserted that Sanscrit books on *chess* exist in Bengal; but Sir William had seen none of them when he wrote the memoir which we have quoted. He exhibits, however, a description of a very ancient *Indian* game of the same kind, but more complex, and in his opinion more modern, than the simple chess of the *Persians*. This game is also called *Chaturanga*, but more frequently *Chaturaji*, or the *four kings*, since it is played by four persons representing as many princes, two allied armies combating on each side. The description is taken from a book called *Bhawishya Purán*; in which the form and principal rules of this factitious warefare are thus laid down: "Eight squares being marked on all sides, the *red* army is to be placed to the east, the *green* to the south, the *yellow* to the west, and the *black* to the north. Let the *elephant* (says the author of the *Purán*) stand on the left of the *king*; next to him the *horse*; then the *boat*; and before them all, four *foot-soldiers*; but the *boat* must be placed in the angle of the board."

"From this passage (says the president) it clearly appears, that an army with its four *angás* must be placed on each side of the board, since an *elephant* could not stand, in any other position, on the left hand of each *king*; and RADHACANT (a Pandit) informed me, that the board consisted, like our's, of 64 squares, half of them occupied by the forces, and half vacant. He added, that this game is mentioned in the oldest law-books, and that it was invented by the wife of a king, to amuse him with an image of war, while his metropolis was besieged, in the second age of the world. A *ship* or *boat* is absurdly substituted, we see, in this complex game for the *rat'h*, or armed *chariot*, which the *Bengalese* pronounce *rot'h*, and which the Persians changed into *rokh*; whence came the *rook* of some European nations; as the *vierge* and *fal* of the French are supposed to be corruptions of *ferz* and *fil*, the *prime minister* and *elephant* of the Persians and Arabs."

As fortune is supposed to have a great share in deciding the fate of a battle, the use of dice is introduced into this game to regulate its moves; for (says the Purán) "if *cinque* be thrown, the *king* or a *pawn* must be moved; if *quatre*, the *elephant*; if *trois*, the *horse*; and if *deux*, the *boat*. The *king* passes freely on all sides, but over *one* square only; and with the same limitation the *pawn* moves, but he advances straight forward, and kills his enemy through an angle. The *elephant* marches in all directions as far as his driver pleases; the *horse* runs obliquely, traversing the squares; and the *ship* goes over two squares diagonally." The *elephant*, we find, has the powers of our *queen*, as we are pleased to call the *general* or *minister* of the Persians; and the *ship* has the motion of the piece to which we give the unaccountable appellation of *bishop*, but with a restriction which must greatly lessen its value.

In the *Purán* are next exhibited a few general rules and superficial directions for the conduct of the game. Thus, "the *pawns* and the *ship* both kill and may be voluntarily killed; while the *king*, the *elephant*, and the *horse*, may slay the foe, but must not expose themselves to be slain. Let each player preserve his own forces with extreme care, securing his *king* above all, and not sacrificing a superior to keep an inferior piece." Here (says the president) the commentator on the *Purán* observes, that the *horse*, who has the choice of *eight* moves from any central position, must be preferred to the *ship*, which has only the choice of *four*. But the argument would not hold in the common game, where the *bishop* and *tower* command a whole line, and where a knight is always of less value than a tower in action, or the bishop of that side on which the attack is begun. "It is by the overbearing power of the *elephant* (continues the *Purán*) that the king fights boldly; let the whole army, therefore, be abandoned in order to secure the *elephant*. The king must never place one *elephant* before another, unless he be compelled by want of room, for he would thus commit a dangerous fault; and if he can slay one of two hostile elephants, he must destroy that on his left hand."

All that remains of the passage which was copied for Sir William Jones relates to the several modes in which a partial success or complete victory may be obtained by by any one of the four players; for, as in a dispute between two allies, one of the kings may sometimes assume the command of all the forces, and aim at a separate conquest. First, "When any one king has placed himself on the square of another king (which advantage is called *sinhasana* or the *throne*) he wins a stake, which is doubled if he kill the adverse monarch when he seizes his place; and if he can seat himself on the throne of his ally, he takes the command of the whole army." Secondly, "If he can occupy successively the thrones of all the three princes, he obtains the victory, which is named *cheturaji*; and the stake is doubled if he kill the last of the three, just before he takes possession of his throne; but if he kill him on his throne, the stake is quadrupled. Both in giving the *sinhasana* and the *cheturaji* the king must be supported by the *elephants*, or by all the forces united." Thirdly, "When one player has his own king on the board, but the king of his partner has been taken, he may replace his captive ally, if he can seize both the adverse kings; or if he cannot effect their capture, he may exchange his king for one of them, against the general rule, and thus redeem the allied prince, who will supply his place." This advantage has the name of *nripacrishta* or *recovered by the king*. Fourthly, "If a *pawn* can march to any square on the opposite extremity of the board, except that of the king, or that of the ship, he assumes whatever power belonged to that square." Here we find the rule, with a slight exception, concerning the advancement of *pawns*, which often occasions a most interesting struggle at our common chess; but it appears that, in the opinion of one ancient writer on the Indian game, this privilege is not allowable when a player has three pawns on the board; but when only one pawn and one ship remains, the pawn may advance even to the square of a king or a ship, and assume the power of either. Fifthly, According to the people of *Lanee*, where the game was invented, "there could be neither victory nor defeat if a king were left on the plain without force; a situation which they named *cacacasht'ha*." Sixthly, "If three ships happen to meet, and the fourth ship can be brought up to them in the remaining angle, this has the name of *vrihannauca*; and the player of the fourth seizes all the others."

The account of this game in the original Sanscrit is in verse, and there are two or three couplets still remaining, so very dark, either from an error in the manuscript, or from the antiquity of the language, that Sir William Jones could not understand the *Pandit's* explanation of them, and suspects that even to him they gave very indistinct ideas. It would be easy, however, he thinks, if it be judged worth while, to play at the game by the preceding rules; and a little practice would perhaps make the whole intelligible.

CHEVRETTE, in artillery, is an engine employed to raise guns or mortars into their carriage. It is formed of two pieces of wood about four feet long, standing upon a third, which is square. The uprights are about a foot asunder, and pierced with holes exactly opposite to one another, to receive a bolt of iron, which is put in, either higher or lower at pleasure, to serve as a support to a handspike, by which the gun is raised up. By the author of the Military Guide, this is said to be the most useful of all the inventions for raising guns into their carriages; and it seems these inventions have been many.

CHICHA, the name given by the natives to the island of Jesso, which lies to the south of Oku-Jesso, or Segalian island. See SEGALIAN in this Supplement.

CHIMERE, the upper robe worn by bishops in church and in the House of Peers, to which the lawn sleeves are generally sewed. Before the Reformation, and even after it till the reign of Queen Elizabeth, the chimere was always of *scarlet silk*; but bishop Hooper, scrupling first at the robe itself, and then at the colour of it, as too light and gay for the episcopal gravity, the chimere was afterwards made of *black satin*. The archiepiscopal chimere has a long train.

CHIMNEY, a particular part of a house well known, which Professor Beckmann has, in our opinion, proved to be an invention comparatively modern. It would be very unfair dealing in us to give even a large abstract of one of the most curious dissertations of a curious book, which has been but lately published, and thereby injure the interest of him to whom the native of Britain is indebted for the pleasure of perusing it in his own tongue. No man, however, can blame us for here stating, in support of our own opinion, the professor's answer to the passage of Ferrari, which we have quoted under the word CHIMNEY in the Encyclopædia.

"When the triumviri, says Appian *, caused those who had been proscribed by them to be sought for by the military, some of them, to avoid the bloody hands of their persecutors, hid themselves in wells, and others, as Ferrarius translates the words, *in fumaria sub tecto, qua scilicet fumus e tecto evolvitur* (A). The true translation, however (says Mr Beckmann), is *fumosa cœnacula*. The principal persons of Rome endeavoured to conceal themselves in the smoky apartments of the upper story under the roof, which, in general, were inhabited only by poor people; and this seems to be confirmed by what Juvenal † expressly says, *Rarus venit in cœnacula miles*.

* *De bellis civil.* lib. iv. p. 962. edit. Tollii.

† *Sat.* x. ver. 17.

"Those passages of the ancients which speak of smoke rising up from houses, have with equal impropriety been supposed to allude to chimneys, as if the smoke could not make its way through doors and windows. Seneca ‡ writes, 'Last evening I had some friends with me, and on that account a stronger smoke was raised; not such a smoke, however, as bursts forth from the kitchens of the great, and which alarms the watchmen, but such a one as signifies that guests are arrived.' Those whose judgments are not already warped by prejudice, will undoubtedly find the true sense of these words to be, that the smoke forced its way through the kitchen windows. Had the houses been built with chimney-funnels, one cannot conceive why the watchmen should have been alarmed when they observed a stronger smoke than usual arising from them; but as the kitchens had no conveniences of that nature, an apprehension of fire, when extraordinary entertainments were to be provided in the houses of the rich for large companies, seems to have been well founded; and on such occasions people appointed for that purpose were stationed

‡ *Epist.* 64.

(A) Ες καπνωδεις υπωροφια, η των τεγων ταις κεραμισι βυομεναις.

Chimney

stationed in the neighbourhood to be constantly on the watch, and to be ready to extinguish the flames in case a fire should happen. There are many other passages to be found in Roman authors of the like kind, which it is hardly necessary to mention; such as that of Virgil *,

'Et jàm summa procul villarum culmina fumant,'

and the following words of Plautus †, descriptive of a miser:

'Quin divum atque hominum clamat continuo fidem,
'Suam rem periisse, seque eradicarier,
'De suo tigillo fumus si qua exit foras.'

In the *Vespæ* of Aristophanes, referred to in the Encyclopædia, old Philocleon wishes to escape through the kitchen. Some one asks, "What is that which makes a noise in the chimney?" "I am the smoke (replies the old man), and am endeavouring to get out at the chimney." "This passage, however (says the Professor), which, according to the usual translation, seems to allude to a common chimney, can, in my opinion, especially when we consider the illustration of the scholiasts, be explained also by a simple hole in the roof, as Reiske has determined; and indeed this appears to be more probable, as we find mention made of a top or covering ‡ with which the hole was closed."

In the Encyclopædia we have said, that the instances of chimneys remaining among the ruins of ancient buildings are few, and that the rules given by Vitruvius for building them are obscure; but we are now satisfied that there are *no* remains of ancient chimneys, and that Vitruvius gives *no* rules, either obscure or perspicuous, for building what, in the modern acceptation of the word, deserves the name of a chimney.

"The ancient mason-work still to be found in Italy does not determine the question. Of the walls of towns, temples, amphitheatres, baths, aqueducts, and bridges, there are some though very imperfect remains, in which chimneys cannot be expected; but of common dwelling-houses none are to be seen except at Herculaneum, and there no traces of chimneys have been discovered. The paintings and pieces of sculpture which are preserved afford us as little information; for nothing can be perceived in them that bears the smallest resemblance to a modern chimney.

"If there were no funnels in the houses of the ancients to carry off the smoke, the directions given by Columella, to make kitchens so high that the roof should not catch fire, was of the utmost importance. An accident of the kind, which that author seems to have apprehended, had almost happened at Beneventum, when the landlord who entertained Mæcenas and his company was making a strong fire in order to get some birds sooner roasted.

'——————— ubi sedulus hospes
'Pæne arsit, macros dum turdos versat in igne;
'Nam vaga per veterem dilapso flamma culinam
'Vulcano summum properabat lambere tectum §.'

Had there been chimneys in the Roman houses, Vitruvius certainly would not have failed to describe their construction, which is sometimes attended with considerable difficulties, and which is intimately connected with the regulation of the plan of the whole edifice. He does not, however, say a word on this subject; neither does Julius Pollux, who has collected with great care the Greek names of every part of a dwelling-house; and Grapaldus, who in later times made a collection of the Latin terms, has not given a Latin word expressive of a modern chimney *."

Our author admits the derivation of the word *chimney* to be as we have given it in the Encyclopædia; but (say he) "*Caminus* signified, as far as I have been able to learn, first a chemical or metallurgic furnace, in which a crucible was placed for melting and refining metals; secondly, a smith's forge; and, thirdly, a hearth on which portable stoves or fire-pans were placed for warming the apartment. In all these, however, there appears no trace of a chimney." Herodotus relates (lib. viii. c. 137.), that a king of Libya, when one of his servants asked for his wages, offered him in jest the sun, which at that time shone into the house through an opening in the roof, under which the fire was perhaps made in the middle of the edifice. If such a hole must be called a chimney, our author admits that chimneys were in use among the ancients, especially in their kitchens; but it is obvious that such chimneys bore no resemblance to our's, through which the sun could not dart his rays upon the floor of any apartment.

"However imperfect may be the information which can be collected from the Greek and Roman authors respecting the manner in which the ancients warmed their apartments, it nevertheless shews that they commonly used for that purpose a large fire-pan or portable stove, in which they kindled wood, and, when the wood was well lighted, carried it into the room, or which they filled with burning coals. When Alexander the Great was entertained by a friend in winter, as the weather was cold and raw, a small fire bason was brought into the apartment to warm it. The prince, observing the size of the vessel, and that it contained only a few coals, desired his host, in a jeering manner, to bring more wood or frankincense; giving him thus to understand that the fire was fitter for burning perfumes than to produce heat. Anacharsis, the Scythian philosopher, though displeased with many of the Grecian customs, praised the Greeks, however, because they shut out the smoke and brought only fire into their houses †. We are informed by Lampridius, that the extravagant Heliogabulus caused to be burned in these stoves, instead of wood, Indian spiceries and costly perfumes ‡. It is also worthy of notice, that coals were found in some of the apartments of Herculaneum, as we are told by Winklemann, but neither stoves nor chimneys."

It is well known to every scholar, that the useful arts of life were invented in the east, and that the customs, manners, and furniture of eastern nations, have remained from time immemorial almost unchanged. In Persia, which the late Sir William Jones seems to have considered as the original country of mankind, the methods employed by the inhabitants for warming themselves have a great resemblance to those employed by the ancient Greeks and Romans for the same purpose. According to De la Valle, the Persians make fires in their apartments, not in chimneys as we do, but in stoves in the earth, which they call *tennor*. "These stoves consist of a square or round hole, two spans or a little more in depth, and in shape not unlike an Italian cask. That this hole may throw out heat sooner, and with more strength, there is placed in it an iron vessel of the same

fame fize, which is either filled with burning coals, or a fire of wood and other inflammable fubftances is made in it. When this is done, they place over the hole or ftove a wooden top, like a fmall low table, and fpread above it a large coverlet quilted with cotton, which hangs down on all fides to the floor. This covering condenfes the heat, and caufes it to warm the whole apartment. The people who eat or converfe there, and fome who fleep in it, lie down on the floor above the carpet, and lean, with their fhoulders againft the wall, on fquare cufhions, upon which they fometimes alfo fit; for the *tennor* is conftructed in a place equally diftant from the walls on both fides. Thofe who are not very cold only put their feet under the table or covering; but thofe who require more heat can put their hands under it, or creep under it altogether. By thefe means the ftove diffufes over the whole body, without caufing uneafinefs to the head, fo penetrating and agreeable a warmth, that I never in winter experienced any thing more pleafant. Thofe, however, who require lefs heat let the coverlet hang down on their fide to the floor, and enjoy without any inconvenience from the ftove the moderately heated air of the apartment. They have a method alfo of ftirring up or blowing the fire when neceffary, by means of a fmall pipe united with the tennor or ftove under the earth, and made to project above the floor as high as one choofes; fo that the wind, when a perfon blows into it, becaufe it has no other vent, acts immediately upon the fire like a pair of bellows. When there is no longer occafion to ufe this ftove, both holes are clofed up, that is to fay, the mouth of the ftove and that of the pipe which conveys the air to it, by a flat ftone made for that purpofe. Scarcely any appearance of them is then to be perceived, nor do they occafion inconvenience, efpecially in a country where it is always cuftomary to cover the floor with a carpet, and where the walls are plaftered. In many parts thefe ovens are ufed to cook victuals, by placing kettles over them. They are employed alfo to bake bread; and for this purpofe they are covered with a large broad metal plate, on which the cake is laid; but if the bread is thick and requires more heat, it is put into the ftove itfelf."

Our learned author having proved, to our entire fatisfaction, that chimneys, fuch as we have now in every comfortable room, were unknown to the moft polifhed nations of antiquity, fets himfelf to inquire into the era of their invention; and the oldeft account of them which he finds is an infcription at Venice, which relates, that in the year 1347 a great many chimneys were thrown down by an earthquake. It would appear, however, that in fome places they had been in ufe for a confiderable time before that period; for *De Gataris*, in his Hiftory of Padua, relates, that *Francefco de Carraro*, lord of Padua, came to Rome in 1368, and finding no chimneys in the inn where he lodged, becaufe at that time fire was kindled in a hall in the middle of the floor, he caufed two chimneys like thofe which had *long* been ufed at Padua to be conftructed by mafons and carpenters, whom he had brought along with him. Over thefe chimneys, the firft ever feen at Rome, he affixed his arms, which were ftill remaining in the time of De Gataris, who died of the plague in 1405.

Though chimneys have been thus long in ufe, they are yet far enough from being brought to perfection. There is hardly a modern houfe, efpecially if highly finifhed, in which there is not one room at leaft liable to be filled with fmoke when it is attempted to be heated by an open fire; and there are many houfes fo infefted with this plague as to be almoft uninhabitable during the winter months; not to mention other great defects in common chimneys, which not being fo obvious have attracted lefs attention. Many ingenious methods have been propofed to cure fmokey chimneys in every fituation (fee SMOKE, *Encycl.*); but Count Rumford's Effay on this fubject contains the moft valuable directions that we have feen, not only for removing the inconveniency of fmoke, but likewife for increafing the heat of the room by a diminifhed confumption of fuel.

To thofe who are at all acquainted with the nature and properties of elaftic fluids, it muft be obvious, that the whole myftery of curing fmokey chimneys confifts in finding out and removing the accidental caufes which prevent the heated fmoke from being forced up the chimney by the preffure of the cool and therefore heavier air of the room. Though thefe caufes are various, yet, fays our author, that which will moft commonly be found to operate, is the bad conftruction of the chimney *in the neighbourhood of the fire-place.* "The great fault of all the open fire-places or chimneys for burning wood or coals in an open fire now in common ufe is, that they are much too large; or rather it is *the throat of the chimney*, or the lower part of its open canal, in the neighbourhood of the mantle, and immediately over the fire, which is too large."

To this fault, therefore, the attention fhould be firft turned in every attempt which is made to improve the conftruction of chimneys; for however perfect a fire-place may be in other refpects, if the opening left for the paffage of the fmoke is larger than is neceffary for that purpofe, nothing can prevent the warm air of the room from efcaping through it; and whenever this happens, there is not only an unneceffary lofs of heat, but the warm air which leaves the room to go up the chimney being replaced by cold air from without, draughts of cold air cannot fail to be produced in the room, to the great annoyance of thofe who inhabit it. But although both thefe evils may be effectually remedied by reducing the throat of the chimney to a proper fize, yet in doing this feveral precautions will be neceffary. And firft of all, the throat of the chimney fhould be in its proper place; that is to fay, in that place in which it ought to be, in order that the afcent of the fmoke may be moft facilitated: now as the fmoke and hot vapour which rife from a fire naturally tend *upwards*, the proper place for the throat of the chimney is evidently perpendicularly *over the fire*.

But there is another circumftance to be attended to in determining the proper place for the throat of a chimney, and that is, to afcertain its diftance from the fire, or *how far* above the burning fuel it ought to be placed. In determining this point there are many things to be confidered, and feveral advantages and difadvantages to be weighed and balanced.

As the fmoke and vapour which afcend from burning fuel rife in confequence of their being rarefied by heat, and made lighter than the air of the furrounding atmofphere; and as the degree of their rarefaction, and confequently their tendency to rife, is in proportion to the intenfity of their heat; and further, as they are hotter-ter near the fire than at a greater diſtance from it—it is clear that the nearer the throat of a chimney is to the fire, the ſtronger will be what is commonly called its *draught*, and the leſs danger there will be of its ſmoking. But, on the other hand, when the draught of a chimney is very ſtrong, and particularly when this ſtrong draught is occaſioned by the throat of the chimney being very near the fire, it may ſo happen that the draught of air into the fire may become ſo ſtrong as to cauſe the fuel to be conſumed too rapidly. There are likewiſe ſeveral other inconveniences which would attend the placing of the throat of a chimney *very near* the burning fuel.

The poſition of the throat of a chimney being once determined, the next points to be aſcertained are its ſize and form, and the manner in which it ought to be connected with the fire-place below, and with the open canal of the chimney above. But as theſe inveſtigations are intimately connected with thoſe which relate to the form proper to be given to the fire-place itſelf, we muſt conſider them all together.

Now the deſign of a chimney fire being ſimply to warm a room, it is neceſſary, firſt of all, to contrive matters ſo that the room ſhally be actually warmed; ſecondly, that it be warmed with the ſmalleſt expence of fuel poſſible; and, thirdly, that in warming it, the air of the room be preſerved perfectly pure, and fit for reſpiration, and free from ſmoke and all diſagreeable ſmells.

To determine in what manner a room is heated by an open chimney fire, it will be neceſſary firſt of all to find out *under what form* the heat generated in the combuſtion of the fuel exiſts, and then to ſee how it is communicated to thoſe bodies which are heated by it.

In regard to the firſt of theſe ſubjects of inquiry, it is quite certain that the heat which is generated in the combuſtion of the fuel exiſts under *two* perfectly diſtinct and very different forms. One part of it is *combined* with the ſmoke, vapour, and heated air which riſe from the burning fuel, and goes off with them into the upper regions of the atmoſphere; while the other part, which appears to be *uncombined*, or, as ſome ingenious philoſophers have ſuppoſed, combined only with light, and therefore called *radiant heat*, is ſent off from the fire in rays in all poſſible directions.

With reſpect to the ſecond ſubject of inquiry, namely, how this heat, exiſting under theſe two different forms, is communicated to other bodies, it is highly probable that the combined heat can only be communicated to other bodies by *actual contact* with the body with which it is combined; and with regard to the rays which are ſent off by burning fuel, it is certain that *they* communicate or generate heat only *when* and *where* they are ſtopped or abſorbed. In paſſing through air, which is tranſparent, they certainly do not communicate any heat to it; and it ſeems highly probable that they do not communicate heat to ſolid bodies by which they are reflected.

As it is the radiant heat alone which can be employed in warming a room, when fuel is burnt for this purpoſe in an open fire-place, it becomes an object of much importance to determine how the greateſt quantity of it may be generated in the combuſtion of the fuel, and how the greateſt proportion poſſible of that generated may be brought into the room.

Now the quantity of radiant heat generated in the combuſtion of a given quantity of any kind of fuel depends very much upon the management of the fire, or upon the manner in which the fuel is conſumed. When the fire burns bright, much radiant heat will be ſent off from it; but when it is *ſmothered up*, very little will be generated, and indeed very little combined heat that can be employed to any uſeful purpoſe: moſt of the heat produced will be immediately *expended* in giving elaſticity to a thick denſe vapour or ſmoke, which will be ſeen riſing from the fire; and the combuſtion being very incomplete, a great part of the inflammable matter of the fuel being merely rarefied and driven up the chimney without being inflamed, the fuel will be waſted to little purpoſe. And hence it appears of how much importance it is, whether it be conſidered with a view to economy, or to cleanlineſs, comfort, and elegance, to pay due attention to the management of a chimney fire.

Nothing can be more perfectly void of common ſenſe, and waſteful and ſlovenly at the ſame time, than the manner in which chimney fires, and particularly where coals are burned, are commonly managed by ſervants. They throw on a load of coals at once, through which the flame is hours in making its way; and frequently it is not without much trouble that the fire is prevented from going quite out. During this time no heat is communicated to the room; and what is ſtill worſe, the throat of the chimney being occupied merely by a heavy denſe vapour, not poſſeſſed of any conſiderable degree of heat, and conſequently not having much elaſticity, the warm air of the room finds leſs difficulty in forcing its way up the chimney and eſcaping than when the fire burns bright. And it happens not unfrequently, eſpecially in chimneys and fire-places ill-conſtructed, that this current of warm air from the room which preſſes into the chimney, croſſing upon the current of heavy ſmoke which riſes ſlowly from the fire, obſtructs it in its aſcent, and beats it back into the room: hence it is that chimneys ſo often ſmoke when too large a quantity of freſh coals is put upon the fire. So many coals ſhould never be put on the fire at once as to prevent the free paſſage of the flame between them. In ſhort, a fire ſhould never be ſmothered; and when proper attention is paid to the quantity of coals put on, there will be very little uſe for the pocker; and this circumſtance will contribute very much to cleanlineſs, and to the preſervation of furniture.

As we have ſeen what is neceſſary to the *generation* of the greateſt quantity of radiant heat, it remains to be determined how the greateſt proportion of that which is generated and ſent off from the fire in all directions may be made to *enter the room*, and aſſiſt in warming it.

This muſt be done, firſt, by cauſing as many as poſſible of the rays, as they are ſent off from the fire in ſtraight lines, to come *directly* into the room; which can only be effected by bringing the fire as far forward as poſſible, and leaving the opening of the fire-place as wide and as high as can be done without inconvenience: and, ſecondly, by making the ſides and back of the fire-place of ſuch a form, and conſtructing them of ſuch materials, as to cauſe the direct rays from the fire, which ſtrike againſt them, to be ſent into the room by reflection in the greateſt abundance.

Now it will be found upon examination, that the beſt

form

Chimney. form for the vertical ſides of a fire-place, or the *covings* (as they are called), is that of an upright plane, making an angle with the plane of the back of the fire-place of about 135 degrees.—According to the preſent conſtruction of chimneys, this angle is ſometimes only 90, and very ſeldom above 100 or 110 degrees; but it is obvious, that in all theſe caſes the two ſides or coverings of the fire-place are very ill-contrived for throwing into the room by reflection the rays from the fire which fall upon them.

With regard to the materials which ſhould be employed in the conſtruction of fire-places, particularly the backs and covings, it is obvious that thoſe are to be preferred which *abſorb* the *leaſt*, and of courſe *reflect* the greateſt quantity of radiant heat. Iron, therefore, and, in general, metals of all kinds, are the very worſt materials which can poſſibly be employed for the backs and covings of chimneys; whilſt fire-ſtone white-waſhed, or common bricks and mortar, covered with a thin coating of plaſter, and white-waſhed, anſwer the purpoſe extremely well. A white colour ſhould, indeed, be always given to the inſide of a chimney of whatever materials it be conſtructed; and black, which is at preſent ſo common, ſhould be carefully avoided, becauſe white reflects the moſt, and black the leaſt, radiant heat. The grate, however, cannot well be made of any thing elſe than iron; but there is no neceſſity whatever for that immenſe quantity of iron which ſurrounds grates as they are commonly fitted up, and which not only renders them very expenſive, but eſſentially injures the fire-place.

To have only pointed out the faults of the chimneys in uſe, without ſhewing how theſe faults may be corrected, would have been a work of very little value; but the Count's Treatiſe is complete, and contains the plaineſt directions for the conſtruction of fire-places. Theſe directions are introduced by an explanation of ſome technical words and expreſſions. Thus, by the *throat* of a chimney, already mentioned, he means the lower extremity of its canal, where it unites with the upper part of its open fire-place. This throat is commonly found about a foot above the level of the lower part of the mantle, and it is ſometimes contracted to a ſmaller ſize than the reſt of the canal of the chimney, and ſometimes not.

Plate XX. Fig. 1. ſhews the ſection of a chimney on the common conſtruction, in which *de* is the throat.

Fig. 2. ſhews the ſection of the ſame chimney altered and improved, in which *di* is the reduced throat.

The *breaſt* of a chimney is that part of it which is immediately behind the mantle. It is the wall which forms the entrance from below into the throat of the chimney in front, or towards the room. It is oppoſite to the upper extremity of the back of the open fire-place, and parallel to it: in ſhort, it may be ſaid to be the back part of the mantle itſelf.—In the figures 1. and 2. it is marked by the letter *d*. The width of the throat of the chimney (*de* fig. 1. and *di* fig. 2.) is taken from the breaſt of the chimney to the back, and its length is taken at right angles to its width, or in a line parallel to the mantle (*a* fig. 1. and 2.).

The bringing forward of the fire into the room, or rather bringing it nearer to the front of the opening of the fire-place, and the diminiſhing of the throat of the chimney, being two objects principally had in view in the alterations in fire-places propoſed by the Count, it is evident that both theſe may be attained merely by bringing forward the back of the chimney. The only queſtion therefore is, How far it ſhould be brought forward? The anſwer is ſhort, and eaſy to be underſtood; bring it forward as far as poſſible, without diminiſhing too much the paſſage which muſt be left for the ſmoke. Now as this paſſage, which in its narroweſt part he calls *the throat of the chimney*, ought, for reaſons which have been already explained, to be immediately, or perpendicularly over the fire, it is evident that the back of the chimney muſt always be built perfectly upright. To determine, therefore, the place for the new back, or how far preciſely it ought to be brought forward, nothing more is neceſſary than to aſcertain how wide the throat of the chimney ought to be left, or what ſpace muſt be left between the top of the breaſt of the chimney where the upright canal of the chimney begins, and the new back of the fire-place carried up perpendicularly to that height.

Numerous experiments have convinced the Count, that, all circumſtances being well conſidered, and the advantages and diſadvantages compared and balanced, *four inches* is the beſt width that can be given to the throat of a chimney, whether the fire-place be deſtined to burn wood, coals, turf, or any other fuel. In very large halls where great fires are kept up, it may ſometimes, though very rarely, be proper to increaſe this width to four inches and a half, or even to five inches.

The next thing to be conſidered is the width which it will be proper to give to the back of the chimney; and, in moſt caſes, this ſhould be *one-third* of the width of the opening of the fire place in front. It is not indeed abſolutely neceſſary to conform with rigour to this deciſion, nor is it always poſſible; but it ſhould invariably be conformed to as far as circumſtances will permit. Where a chimney, ſays the Count, is deſigned for warming a room of a middling ſize, and where the thickneſs of the wall of the chimney in front, meaſured from the front of the mantle to the breaſt of the chimney, is nine inches, I ſhould ſet off four inches more for the width of the throat of the chimney, which, ſuppoſing the back of the chimney to be built upright, as it always ought to be, will give thirteen inches for the depth of the fire-place, meaſured upon the hearth, from the opening of the fire-place in front to the back. In this caſe, thirteen inches would be a good ſize for the width of the back; and three times thirteen inches, or 39 inches, for the width of the opening of the fire-place in front; and the angle made by the back of the fire-place and the ſides of it, or covings, would be juſt 135 degrees, which is the beſt poſition they can have for throwing heat into the room. This poſition, indeed, it may ſometimes be impoſſible to attain in altering chimneys already built; but a deviation from it of two or three degrees will be of no great conſequence; for the points of by much the greateſt importance in altering fire-places upon the principles here recommended, are the bringing forward the back to its proper place, and making it of the proper width.

Proviſion, however, muſt be made for the paſſage of the chimney-ſweeper up the chimney; and this may eaſily be done in the following manner: In building up the new back of the fire-place; when this wall (which need never be more than the width of a ſingle brick

Chimney.

brick in thicknefs) is brought up fo high that there remains no more than about ten or eleven inches between what is then the top of it and the infide of the mantle, or lower extremity of the breaft of the chimney, an opening or door-way, eleven or twelve inches wide, muft be begun in the middle of the back, and continued quite to the top of it, which, according to the height to which it will commonly be neceffary to carry up the back, will make the opening abundantly fufficient to let the chimney-fweeper pafs. When the fire-place is finifhed, this door-way is to be clofed by a tile or fit piece of ftone placed in it without mortar, and by means of a rabbit made in the brick-work, confined in its place in fuch a manner as that it may be eafily removed when the chimney is to be fwept, and reftored to its place when that work is over. Of this contrivance the reader will be able to form a clear conception from fig. 2. which reprefents the fection of a chimney after it has been properly altered from what is exhibited in fig. 1. In this improved chimney *k l* is the new back of the fire-place; *l i* the tile or ftone which clofes the door-way for the chimney-fweeper; *d i* the throat of the chimney narrowed to four inches; *a* the mantle, and *b* the ftone placed under the mantle, fuppofed to have been too high, in order to diminifh the height of the opening of the fire-place in front.

It has been obferved above, that the new back, which it will always be found neceffary to build in order to bring the fire fufficiently forward, in altering a chimney conftructed on the common principles, need never be thicker than the width of a common brick. The fame may be faid of the thicknefs neceffary to be given to the new fides or covings of the chimney; or if the new back and covings are conftructed of ftone, one inch and three quarters, or two inches in thicknefs, will be fufficient. Care fhould be taken in building up thefe new walls to unite the back to the covings in a folid manner.

Whether the new back and covings are conftructed of ftone or built of bricks, the fpace between them and the old back and covings of the chimney ought to be filled up, to give greater folidity to the ftructure. This may be done with loofe rubbifh, or pieces of broken bricks or ftones, provided the work be ftrengthened by a few layers or courfes of bricks laid in mortar; but it will be indifpenfably neceffary to finifh the work where thefe new walls end, that is to fay, at the top of the throat of the chimney, where it ends abruptly in the open canal of the chimney, by a horizontal courfe of bricks well fecured with mortar. This courfe of bricks will be upon a level with the top of the door-way left for the chimney-fweeper; and the void behind the doorway muft be covered with a horizontal ftone or tile, to be removed at the fame time the door is removed, and for the fame purpofe.

From thefe defcriptions it is clear, that where the throat of the chimney has an end, that is to fay, where it enters into the lower part of the open canal of the chimney, *there* the three walls which form the two covings and the back of the fire-place all end abruptly. It is of much importance that they fhould end in this manner; for were they to be floped outward, and raifed in fuch a manner as to fwell out the upper extremity of the throat of the chimney in the form of a trumpet, and increafe it by degrees to the fize of the canal of the chimney, this manner of uniting the lower extremity of the canal of the chimney with the throat would tend to affift the winds, which may attempt to blow down the chimney, in forcing their way through the throat, and throwing the fmoke backward into the room; but when the throat of the chimney ends abruptly, and the ends of the new walls form a flat horizontal furface, it will be much more difficult for any wind from above to find and force its way through the narrow paffage of the throat of the chimney.

As the two walls which form the new covings of the chimney are not parallel to each other, but inclined, prefenting an oblique furface towards the front of the chimney, and as they are built perfectly upright, and quite flat, from the hearth to the top of the throat, where they end, it is evident that an horizontal fection of the throat will not be an oblong fquare; but its deviation from that form is a matter of no confequence; and no attempts fhould ever be made, by twifting the covings above where they approach the breaft of the chimney, to bring it to that form. All twifts, bends, prominences, excavations, and other irregularities of form in the covings of a chimney, never fail to produce eddies in the current of air which is continually paffing into, and through, an open fire-place in which a fire is burning; and all fuch eddies difturb either the fire or the afcending current of fmoke, or both; and not unfrequently caufe the fmoke to be thrown back into the room. Hence it appears, that the covings of chimneys fhould never be made circular, or in the form of any other curve, but always quite flat.

For the fame reafon, that is to fay, to prevent eddies, the breaft of the chimney, which forms that fide of the throat that is in front or neareft to the room, fhould be neatly cleaned off, and its furface made quite regular and fmooth. This may be eafily done by covering it with a coat of plafter, which may be made thicker or thinner in different parts, as may be neceffary in order to bring the breaft of the chimney to be of the proper form.

With regard to the form of the breaft of a chimney, this is a matter of very great importance, and which ought always to be particularly attended to. The worft form it can have is that of a vertical plane or upright flat; and next to this the worft form is an inclined plane. Both thefe forms caufe the current of warm air from the room, which will, in fpite of every precaution, fometimes find its way into the chimney, to crofs upon the current of fmoke which rifes from the fire in a manner moft likely to embarrafs it in its afcent, and drive it back.

The current of air which, paffing under the mantle, gets into the chimney, fhould be made *gradually to bend its courfe upwards*; by which means it will unite *quietly* with the afcending current of fmoke, and will be lefs likely to check it, or force it back into the room. Now this may be effected with the greateft eafe and certainty, merely by *rounding off* the breaft of the chimney or back part of the mantle, inftead of leaving it flat or full of holes and corners; and this of courfe ought always to be done.

Having thus afcertained the form and pofition of the new covings, the ingenious author next turns his attention to the height to which they fhould be carried. This will depend not only on the height of the mantle, but

but alſo, and more eſpecially, on the height of the breaſt of the chimney, or of that part of the chimney where the breaſt ends and the upright canal begins.—The back and covings muſt riſe a few inches, five or ſix for inſtance, higher than this part, otherwiſe the throat of the chimney will not be properly formed; but no advantage would be gained by carrying them higher.

One important circumſtance reſpecting chimney fire-places ſtill remains to be conſidered; and that is the grate. In placing the grate, the thing principally to be attended to is, to make the back of it coincide with the back of the fire place. But as many of the grates now in common uſe will be found to be too large, when the fire places are altered and improved, it will be neceſſary to diminiſh their capacities by filling them up at the back and ſides with pieces of fire ſtone. When this is done, it is the front of the flat piece of fire-ſtone which is made to form a new back to the grate, which muſt be made to coincide with, and make part of the back of the fire-place.—But in diminiſhing the capacities of grates with pieces of fire-ſtone, care muſt be taken not to make them *too narrow*.

The proper width for grates deſtined for rooms of a middling ſize will be from ſix to eight inches, and their length may be diminiſhed more or leſs according as the room is heated with more or leſs difficulty, or as the weather is more or leſs ſevere.—But where the width of a grate is not more than five inches it will be very difficult to prevent the fire from going out.

It frequently happens that the iron backs of grates are not vertical, or upright, but inclined backwards.—When theſe grates are ſo much too wide as to render it neceſſary to fill them up behind with fire-ſtone, the inclination of the back will be of little conſequence; for by making the piece of ſtone with which the width of the grate is to be diminiſhed in the form of a wedge, or thicker above than below, the front of this ſtone, which in effect will become the back of the grate, may be made perfectly vertical; and the iron back of the grate being hid in the ſolid work of the back of the fire-place, will produce no effect whatever; but if the grate be already ſo narrow as not to admit of any diminution of its width, in that caſe it will be beſt to take away the iron back of the grate entirely, and fixing the grate firmly in the brick-work, cauſe the back of the fire-place to ſerve as a back to the grate.

Where grates, which are deſigned for rooms of a middling ſize, are longer than 14 or 15 inches, it will always be beſt, not merely to diminiſh their lengths, by filling them up at their two ends with fire-ſtone, but, forming the back of the chimney of a proper width, without paying any regard to the length of the grate, to carry the covings through the two ends of the grate in ſuch a manner as to conceal them, or at leaſt to conceal the back corners of them in the walls of the covings.

Had theſe directions been duly attended to by the maſons who in Scotland pretend to alter chimneys on the principles of Count Rumford, we ſhould not have obſerved ſo many of the grates placed by them jutting out beyond the mantle of the chimney; nor of courſe heard ſo many complaints of rooms being rendered more ſmokey, and the conſumption of fuel increaſed by theſe pretended improvements. But when the grate is not ſet in its proper place, when its ſloping iron back is retained, when no pains have been taken to make its ends coincide with the covings of the fire-place, when the mantle, inſtead of having its back rounded off, is a vertical plane of iron cutting the column of ſmoke which riſes beneath it, and, above all, when the throat of the chimney, inſtead of four, is made, as we often ſee, fourteen inches wide; let it be remembered, that not one of Count Rumford's directions has been followed, and that his principles have as little to do with the conſtruction of ſuch a chimney as with the building of the wall of China or the pyramids of Egypt.

To contribute our aid to prevent theſe blunders for the future, we ſhall here ſubjoin the Count's directions for laying out the work; not to inſtruct maſons and bricklayers, to whom we earneſtly recommend the ſtudy of the eſſay itſelf (B), which contains much valuable information that we have omitted; but merely to give the country gentleman an opportunity of diſcovering whether the workmen whom he employs deviates far and needleſsly from the principles which he pretends to follow.

When a chimney is to be altered, after taking away the grate and removing the rubbiſh, firſt draw a ſtraight line with chalk, or with a lead pencil, upon the hearth, from one jamb to the other,—even with the front of the jambs. The dotted line A B, fig. 3. may repreſent this line.

From the middle *c* of this line, (A B) another line *c d* is to be drawn perpendicular to it, acroſs the hearth, to the middle *d*, of the back of the chimney.

A perſon muſt now ſtand upright in the chimney, with his back to the back of the chimney, and hold a plumb-line to the middle of the upper part of the breaſt of the chimney (*d*, fig. 1.), or where the canal of the chimney begins to riſe perpendicularly;—taking care to place the line above in ſuch a manner that the plumb may fall on the line *c d* (fig. 3.) drawn on the hearth from the middle of the opening of the chimney in front to the middle of the back, and an aſſiſtant muſt mark the preciſe place *e*, on that line where the plumb falls.

This being done, and the perſon in the chimney having quitted his ſtation, four inches are to be ſet off on the line *c d*, from *e*, towards *d*; and the point *f*, where theſe four inches end, (which muſt be marked with chalk, or with a pencil), will ſhow how far the new back is to be brought forward.

Through *f*, draw the line *g h* parallel to the line A B, and this line *g h* will ſhow the direction of the new back, or the ground line upon which it is to be built. The line *c f* will ſhow the depth of the new fire-place; and if it ſhould happen that *c f* is equal to about *one-third* of the line A B, and if the grate can be accommodated to the fire-place, inſtead of its being neceſſary to accommodate the fire place to the grate; in that caſe, half the length of the line *c f* is to be ſet off from *f* on the line *g f h*, on one ſide to *k*, and on the other to *i*, and the line *i k* will ſhow the ground line of the fore part of the back of the chimney.

In all caſes where the width of the opening of the fire-place in front (A B) happens to be not greater, or not

(B) It coſts but two ſhillings; and he muſt be a poor bricklayer indeed who cannot afford to pay that ſum for inſtruction in the moſt important, as well as moſt difficult, part of his buſineſs.

not more than two or three inches greater than *three times* the width of the new back of the chimney (*i k*), this opening may be left; and lines drawn from *i* to A, and from *k* to B, will ſhow the width and poſition of the front of the new covings;—but when the opening of the fire-place in front is ſtill wider, it muſt be reduced; which is to be done in the following manner:

From *c*, the middle of the line A B, *c a* and *c b* muſt be ſet off equal to the width of the back (*i k*), added to half its width (*f i*); and lines drawn from *i* to *a*, and from *k* to *b*, will ſhow the ground plan of the fronts of the new covings.

When this is done, nothing more will be neceſſary than to build up the back and covings; and if the fire-place is deſigned for burning coals, to fix the grate in its proper place, according to the directions already given.—When the width of the fire-place is reduced, the edges of the covings *a* A and *b* B are to make a finiſh with the front of the jambs.—And in general it will be beſt, not only for the ſake of the appearance of the chimney, but for other reaſons alſo, to lower the height of the opening of the fire-place whenever its width in front is diminiſhed.

A front view of the chimney, after it has been thus altered, is exhibited in fig. 4. where the under part of the door-way is repreſented, as cloſed by the white dotted lines.

When the wall of the chimney in front, meaſured from the upper part of the breaſt of the chimney to the front of the mantle, is very thin, it may happen, and eſpecially in chimneys deſigned for burning wood upon the hearth, or upon dogs, that the depth of the chimney, determining according to the directions here given, may be too ſmall.

Thus, for example, ſuppoſing the wall of the chimney, in front, from the upper part of the breaſt of the chimney to the front of the mantle, to be only four inches, (which is ſometimes the caſe, particularly in rooms ſituated near the top of a houſe), in this caſe, if we take four inches for the width of the throat, this will give eight inches only for the depth of the fire-place, which would be too little, even were coals to be burnt inſtead of wood.—In this caſe (ſays the Count) I ſhould increaſe the depth of the fire-place at the hearth to 12 or 13 inches, and ſhould build the back perpendicular to the height of the top of the burning fuel (whether it be wood burnt upon the hearth or coals in a grate); and then, ſloping the back by a gentle inclination forward, bring it to its proper place, that is to ſay, *perpendicularly under the back part of the throat of the chimney.* This ſlope, (which will bring the back forward four or five inches, or juſt as much as the depth of the fire-place is increaſed), though it ought not to be too abrupt, yet it ought to be quite finiſhed at the height of eight or ten inches above the fire, otherwiſe it may perhaps cauſe the chimney to ſmoke; but when it is very near the fire, the heat of the fire will enable the current of riſing ſmoke to overcome the obſtacle which this ſlope will oppoſe to its aſcent, which it could not do ſo eaſily were the ſlope ſituated at a greater diſtance from the burning fuel.

Fig. 5, 6, and 7, ſhow a plan, elevation, and ſection of a fire-place conſtructed or altered upon this principle.—The wall of the chimney in front at *a*, fig. 7. being only four inches thick, four inches more added to it for the width of the throat would have left the depth of the fire-place meaſured upon the hearth *b c* only eight inches, which would have been too little;—a niche *c* and *e* was therefore made in the new back of the fire-place for receiving the grate, which niche was ſix inches deep in the centre of it, below 13 inches wide, (or equal in width to the grate,) and 23 inches high; finiſhing above with a ſemicircular arch, which, in its higheſt part, roſe ſeven inches above the upper part of the grate.—The door-way for the chimney-ſweeper, which begins juſt above the top of the niche, may be ſeen diſtinctly in both the figures 6 and 7.—The ſpace marked *g*, fig. 7. behind this door-way, may either be filled with looſe bricks, or may be left void.—The manner in which the piece of ſtone *f*, fig. 7. which is put under the mantle of the chimney to reduce the height of the opening of the fire-place, is rounded off on the inſide in order to give a fair run to the column of ſmoke in its aſcent through the throat of the chimney, is clearly expreſſed in this figure. The plan fig. 5. and elevation fig. 6. ſhow how much the width of the opening of the fire-place in front is diminiſhed, and how the covings in the new fire-place are formed.

A perfect idea of the form and dimenſion of the fire-place in its original ſtate, as alſo after its alteration, may be had by a careful inſpection of theſe figures.

In chimneys, like that repreſented in figure 8, where the jambs A and B project far into the room, and where the front edge of the marble ſlab *o*, which forms the coving, does not come ſo far forward as the front of the jambs, the workmen in conſtructing the new covings are very apt to place them,—not in the line *c A*, which they ought to do,—but in the line *c o*, which is a great fault.—The covings of a chimney ſhould never range *behind* the front of the jambs, however thoſe jambs may project into the room;—but it is not abſolutely neceſſary that the covings ſhould *make a finiſh* with the internal front corners of the jambs, or that they ſhould be continued from the back *c*, quite to the front of the jambs at *A*.—They may finiſh in front at *a* and *b*; and ſmall corners *A*, *o*, *a*, may be left for placing the ſhovels, tongs, &c.

Were the new coving to range with the front edge of the old coving *o*, the obliquity of the new coving would commonly be too great;—or the angle *d c o* would exceed 135 degrees, *which it never ſhould do*,—or at leaſt never be more than a very few degrees. No inconvenience of any importance will ariſe from making the obliquity of the covings *leſs* than what is here recommended; but many cannot fail to be produced by making it much greater.

Theſe extracts, which we have made ſo liberally from Count Rumford's eſſay on chimney fire-places, will be ſufficient, we hope, to bring fully within the comprehenſion of thoſe who are acquainted with pneumatics and pneumatic chemiſtry the principles on which chimneys and fire-places ſhould be conſtructed; but ſuch as are in a great meaſure ſtrangers to theſe ſciences will do well to conſult the eſſay itſelf. With a benevolence which does him honour, the ingenious author has expreſſed a wiſh that his doctrines on this important ſubject may be widely propagated; and to encourage artiſts to ſtudy them, he has declared to the public in general, "that as he does not intend to take out himſelf, Chimney-Sweepers.

or to suffer others to take out, any patent for any invention of his which may be of public utility, all persons are at full liberty to imitate them, and vend them, for their own emolument, when and where, and in any way they may think proper."

Chimney-Sweepers are a class of men who earn their subsistence by clearing chimneys of soot, which occasions them to smoke. While chimneys continued to be built in so simple a manner, and of such a width as they are still observed to be in old houses, they were so easily cleaned that this service could be performed by a servant with a wisp of straw, or a little brushwood fastened to a rope; but after the flues, in order to save room, were made narrower, or when several flues were united together, the cleaning of them became so difficult, that they required boys, or people of small size, accustomed to that employment. The first chimney-sweepers in Germany came from Savoy, Piedmont, and the neighbouring territories. These for a long time were the only countries where the cleaning of chimneys was followed as a trade; and hence Professor Beckmann concludes with great probability, that chimneys were invented in Italy. The Lotharingians, however, undertook the business of chimney-sweeping also; on which account the duke of Lotharingia was styled the *imperial fire-master*. The first Germans who condescended to clean chimneys were miners; and the chimney-sweepers in that empire still procure their boys from the forest of Hartz, where the greatest mines are wrought. Very lately, and perhaps at present, the greater part of the chimney-sweepers in Paris were Savoyards, many of them not above eight years of age, who, for the paltry sum of five sous, which they were obliged to share with their avaricious master, would scramble, at the hazard of their lives, through a narrow funnel fifty feet in length, and with their besoms clean it from soot and dirt. At what precise period chimney-sweeping became a trade in England and Scotland, we have not been able to learn; but among us, as well as elsewhere, young boys are employed in this business, who are said to be very harshly treated by fellows who stole them from the doors of cottages in the country. That children have been sometimes kidnapped by chimney-sweepers, we can have no doubt; but that the practice is frequent, we do not believe. We think however that the business might be wholly abolished; for a narrow funnel might certainly, if not very crooked, be swept by a bundle of straw or brushwood fastened to a rope, as well as one that is wider: and the bricks which separate the contiguous flues we know to be less injured by this method of sweeping, when cautiously gone about, than by sending boys up the chimneys.

On the 4th July 1796, letters patent were granted to Daniel Davis, of the parish of St Giles, Middlesex, for his invention of a machine, by which he proposes to sweep and cleanse chimneys, and extinguish chimneys on fire, without any person going up the same, as is now the practice. The machine consists of an apparatus of rack-work, of various lengths, which, by means of a hand-turn, is made to ascend the chimney. The lengths of the rack-work are joined together by means of mortices and tenons, with a spring which holds them fast. In each length is a joint, by which the rack-work will accommodate itself to angles or turns in the flues. To the first or uppermost length is fixed a brush of hair, or wire, or spunge, or other elastic substance as the occasion may require.

This invention is doubtless well calculated to answer the purpose intended, and may perhaps be the means of diminishing the number of those objects of misery, the unfortunate chimney-sweepers.

China.

CHINA is an empire of such antiquity and extent, the laws and customs of the people are so singular, and the populousness of the country so very great—that it has attracted much of the attention of Europeans ever since it was visited in the 13th century by Marco Paulo the Venetian traveller. Of such a country it would be unpardonable not to give some account in a work of this nature; but we have not, in truth, much to add to what has been said of China and the Chinese in the Encyclopædia Britannica. Since the article China in that work was published, the court of Pekin has indeed been visited by an embassy from Great Britain, and the origin of the people, as well as the antiquity of their empire, has been investigated by Sir William Jones with his usual diligence; but from his memoir, published in the second volume of the Asiatic Researches, and from Sir George Staunton's account of the embassy, there is not much to be extracted which would be either amusing or instructive to our readers.

We have already observed from Grosier and others, that the Chinese not only lay claim to the highest antiquity, but even contend that their first emperor was the first man. Both these positions are controverted by Sir William Jones, who, though he allows the Chinese empire to be very ancient when compared with the oldest European state, is yet decidedly of opinion that it was not founded at an earlier period than the 12th century before the Christian era; and that the people, so far from being aborigines, are a mixed race of Tartars and Hindoos. He begins his investigation with asking, "Whence came the singular people who long had governed China, before they were conquered by the Tartars? On this problem (says he*) four opinions have been advanced, and all rather peremptorily asserted than supported by argument and evidence. By a few writers it has been urged, that the *Chinese* are an original race, who have dwelled for ages, if not from eternity, in the land which they now possess. By others, and chiefly by the missionaries, it is insisted that they sprung from the same stock with the *Hebrews* and the *Arabs*. A third assertion is that of the Arabs themselves, and of M. Pauw, who hold it indubitable, that they were originally *Tartars*, descending in wild clans from the steeps of Imaus: And a fourth, at least as dogmatically pronounced as any of the preceding, is that of the *Brahmans*, who decide, without allowing any appeal from their decision, that the *Chinas* (for so they are named in *Sanscrit*) were Hindoos of the military cast, who, abandoning the privileges of their tribe, rambled in different bodies to the north-east of *Bengal*; and forgetting by degrees the rites and the religion of their ancestors, established separate principalities, which were afterwards united in the plains and valleys which are now possessed by them.

* *Asiatic Researches*, vol. ii. mem. 25.

Of these opinions, Sir William having very completely demolished the first three, proceeds to establish the fourth, which he considers as interesting as well as new in Europe. In the Sanscrit institutes of civil and religious duties, revealed, as the Hindoos believe, by Menu the

China.

the son of Brahma, we find (says he) the following curious passage: 'Many families of the military class, having gradually abandoned the ordinances of the *Veda*, and the company of *Brahmans*, lived in a state of degradation; as the people of *Pundraca* and *Odra*, those of *Dravira* and *Camboja*, the *Yavanas* and *Sacas*, the *Paradas* and *Pahlavas*, the Chinas, and some other nations.' A full comment on this text (continues the president) would be superfluous; but since the testimony of the Indian author, who, though not a divine personage, was certainly a very ancient lawyer, moralist, and historian, is direct and positive, disinterested and unsuspected, it would decide the question before us if we could be sure that the word *China* signifies a *Chinese*." Of this fact Sir William Jones took the very best methods to be satisfied. He consulted a number of Pandits separately, who all assured him that the word *China* has no other signification in *Sanscrit*; that the *Chinas* of Menu settled in a fine country to the north-east of *Gaur*, and to the east of *Camarup* and *Napal*; that they had long been, and still are, famed as ingenious artificers; and that they (the Pandits) had themselves seen old Chinese idols, which bore a manifest relation to the primitive religion of India. He then laid before one of the best informed *Pandits* a map of Asia; and when his own country was pointed out to him, the *Pandit* immediately placed his finger on the north-western provinces of China, as the place where he said the *Chinas* of Menu first established themselves.

In the opinion of Sir William Jones, this is complete evidence that the Chinese are descended from an Indian race; but he does not believe that the Chinese empire, as we now call it, was formed when the laws of Menu were collected; and for his calling this fact in question, he offers reasons, which to us are perfectly satisfactory. By a diligent and accurate comparison of ancient Sanscrit writings, he has been able to fix the period of the compilation of those laws at between 1000 and 1500 years before Christ; but by the evidence of Confucius himself, he proves, that if the Chinese empire was formed, it could be only in its cradle in the 12th century before our era. In the second part of the work, intitled *Lún Yú*, Confucius declares, that "although he, like other men, could relate, as mere lessons of morality, the histories of the first and second imperial houses, yet, *for want of evidence*, he could give no certain account of them." Now, says Sir William, if the Chinese themselves do not pretend that any historical monument existed in the age of Confucius preceding the rise of their third dynasty, about 1100 years before the Christian epoch, we may justly conclude that their empire was then in its infancy, and did not grow to maturity till some ages afterwards. Nay, he is inclined to bring its origin still lower down. "It was not, says he, till the eighth century before the birth of our Saviour, that a small kingdom was erected in the province of *Shen si*, the capital of which stood nearly in the 35th degree of northern latitude, and about five degrees to the west of *Si-gan*. That country and its metropolis were both called *Chin*; and the dominion of its princes was gradually extended to the east and west. The territory of *Chin*, so called by the old Hindoos, by the Persians, and by the Chinese, gave its name to a race of emperors, whose tyranny made their memory so unpopular, that the modern inhabitants of China hold the word in abhorrence, and speak of themselves as the people of a milder and more virtuous dynasty: but it is highly probable that the whole nation descended from the *Chinas* of Menu, and mixing with the *Tartars*, by whom the plains of *Honan* and the more southern provinces were thinly inhabited, formed by degrees the race of men whom we now see in possession of the noblest empire in Asia."

In support of this opinion, which the accomplished author offers as the result of long and anxious inquiries, he observes, that the Chinese have no ancient monuments from which their origin can be traced, even by plausible conjecture; that their sciences are wholly *exotic*; that their mechanic arts have nothing in them which any set of men, in a country so highly favoured by nature, might not have discovered and improved; that their philosophy seems yet in so rude a state as hardly to deserve the appellation; and that their popular religion was imported from *India* in an age comparatively modern. He then institutes a comparison between the mythology of the Chinese and that of the Hindoos; of which the result is, that the former people had an *ancient* system of ceremonies and superstitions which has an apparent affinity with some parts of the oldest Indian worship. "They believed in the agency of genii or tutelary spirits, presiding over the stars and the clouds; over lakes and rivers, mountains, valleys, and woods; over certain regions and towns; over all the elements, of which, like the Hindoos, they reckoned five; and particularly over *fire*, the most brilliant of them. To those deities they offered victims on high places. And the following passage from one of their sacred books, says Sir William, is very much in the style of the Brahmans: 'Even they who perform a sacrifice with due reverence, cannot perfectly assure themselves that the divine spirits accept their oblations; and far less can they, who adore the gods with languor and oscitancy, clearly perceive their sacred illapses.' These (continues the President) are imperfect traces indeed, but they *are* traces of an affinity between the religion of Menu and that of the *Chinas*, whom he names among the apostates from it; and besides them, we discover many other very singular marks of relation between the Chinese and the old Hindoos.

"This relation (he thinks) appears in the remarkable period of 432,000, and the cycle of 60 years; in the predilection for the mystical number *nine*; in many similar fasts and great festivals, especially at the solstices and equinoxes; in the obsequies, consisting of rice and fruits offered to the manes of their ancestors; in the dread of dying childless, lest such offerings should be intermitted; and perhaps in their common abhorrence of *red* objects, which the Indians carried so far, that Menu himself, where he allows a *Brahman* to trade, if he cannot otherwise support life, absolutely forbids his trading in any sort of *red* cloths, whether linen, or woollen, or made of woven bark. In a word, says Sir William Jones, all the circumstances which have been mentioned seem to prove (as far as such a question admits proof), that the Chinese and Hindoos were originally the same people; but having been separated near 4000 years, they have retained few strong features of their ancient consanguity, especially as the Hindoos have preserved their old language and ritual, while the Chinese very soon lost both; and the Hindoos have constantly

China. constantly intermarried among themselves, while the Chinese, by a mixture of Tartarian blood from the time of their first establishment, have at length formed a race distinct in appearance both from Indians and Tartars."

Sir George Staunton, who accompanied the Earl of Macartney on his embassy to the Emperor of China, does not indeed directly controvert this reasoning; but overlooking it altogether, gives to the Chinese a much higher antiquity than Sir William Jones is inclined to allow them. Taking it for granted that their *cycle* is their own, and that it is not the offspring of astronomical science, but of repeated observations, he seems to give implicit credit to those annals of the empire which almost every other writer has considered as fabulous.

"Next to the studies which teach the economy of life, the Chinese (says he) value most the history of the events of their own country, which is, to them, the globe; and of the celestial movements which they had an opportunity of observing at the same time." In regard to the former, he tells us, that "from about *three* centuries before the Christian era the transactions of the Chinese empire have been regularly, and without any intervening chasm, recorded both in official documents and by private contemporary writers. Nowhere had history become so much an object of public attention, and nowhere more the occupation of learned individuals. Every considerable town throughout the empire was a kind of university, in which degrees were conferred on the proficient in the history and government of the state. Historical works were multiplied throughout. The accounts of *recent* events were exposed to the correction of the witnesses of the facts, and compilations of former transactions to the criticisms of rival writers." In regard to the latter, the movements of the heavenly bodies, he thinks that in no country are there stronger inducements or better opportunities to watch them than in China; and hence he infers, that the cycle of sixty years is of Chinese formation. "In a climate (says he) favourable to astronomy, the balance of hours beyond the number of days during which the sun appeared to return opposite to, and to obscure, or to mix among the same fixed stars, might be ascertained in a short time; and occasioned the addition of a day to every fourth year, in order to maintain regularity in the computation of time, in regard to the return of the seasons; but many ages must have past before a period could have been discovered, in which the unequal returns of the sun and moon were so accurately adjusted, that at its termination the new and full moons should return, not only to the same day, but within an hour and a half of the time they had happened, when the period commenced. The knowledge of such a period or cycle could be obtained only by a multiplicity of careful and accurate observations. Many revolutions of those great luminaries must have been completed, and numberless conjunctions have past over, before their returns could be ascertained to happen in the same day, at the end of nineteen years. The small difference of time between the returning periods of this cycle, was partly lessened by the intervention of another of 60 years, or of 720 revolutions of the moon, which, with the settled intercalation of 22 lunations, were at first supposed to bring a perfect coincidence of the relative positions of the sun and moon: but even according to this period, every new year was made constantly to recede, in a very small degree, which the Chinese corrected afterwards from time to time. This cycle answered a double purpose, one as an era for chronological reckoning, and the other as a regulating period for a luni-solar year. Each year of the cycle is distinguished by the union of two characters, taken from such an arrangement of an unequal number of words placed in opposite columns, that the same two characters cannot be found again together for sixty years. The first column contains a series of ten words, the other twelve; which last are, in fact, the same that denote the twelve hours or divisions of the day, each being double the European hour. The first word or character of the first series or column of ten words, joined to the first word of the second series or column of twelve, marks the first year of the cycle; and so on until the first series is exhausted, when the eleventh word of the second series, combined with the first of the first series, marks the eleventh year of the cycle; and the twelfth or last of the second series, joined with the second of the first series, serves for denoting the twelfth year. The third of the first series becomes united in regular progression with the first of the second series, to mark the thirteenth year; and proceeding by this rule, the first character in the first and in the second series cannot come again together for sixty years, or until the first year of the second cycle. The Christian year 1797 answers to the 54th year of the 60th Chinese cycle, which ascertains its commencement to have been 2277 years before the birth of Christ; unless it be supposed that the official records and public annals of the empire, which bear testimony to it, should all be falsified, and that the cycle when first established should have been antidated; which is indeed as little probable as that the period, for example, of the Olympiads should be asserted to have commenced many ages prior to the first Olympic games."

This is a very positive decision against the opinion of a man whose talents and knowledge of oriental learning were such as to give to his opinions on such subjects the greatest weight. If the statements and reasonings of Sir George Staunton be accurate, the Chinese empire must have subsisted at least 3000 years before the Christian era; for he says expressly, that *many ages* must have elapsed before the commencement of that cycle, which, according to him, commenced 2277 years before the birth of Christ. But surely Confucius was as well acquainted with the ancient annals of his own country, and the credibility which is due to them, as any man of the present age, whether Chinese or European; and we have seen, that he considered none of them as authentic which relate events previous to the 11th century before our era. Even this is by much too early a period at which to rely upon them with implicit confidence, if it be true, as Sir George informs us, that the transactions of the empire have been regularly recorded only from about *three* centuries before the birth of Christ. With respect to the cycle, there is every probability that it was derived from India, where we know that astronomy has been cultivated as a science from time immemorial, and where, we have shewn in another place, that the commencement of the cycle was actually antedated (see PHILOSOPHY, n° 9. *Encycl.*) We have therefore no hesitation in preferring Sir William Jones's opinion of the origin of the Chinese empire to Sir George Staunton's; not merely because we believe the

China.

the former of these gentlemen to have been more conversant than the latter with Chinese literature, but because we think his reasoning more consistent with itself, and his conclusion more consonant to that outline of chronology, which, as he observes, has been so correctly traced for the last 2000 years, that we must be hardy sceptics to call it in question.

There is another point very nearly related indeed to this, about which these two learned men likewise differ. Sir George Staunton informs us, that "no accounts of a general deluge are mentioned in Chinese history." Sir William Jones, on the other hand, in the discourse already quoted, says, "I may assure you, after full inquiry and consideration, that the Chinese, like the Hindoos, believe this earth to have been wholly covered with water, which, in works of undisputed authenticity, they describe as *flowing abundantly, then subsiding, and separating the higher from the lower age of mankind.*" To which of these authors shall we give credit? The high antiquity which Sir George Staunton assigns to the Chinese empire, rendered it necessary for the persons from whom he drew his information to get quit by any means of an universal deluge. The system of Sir William Jones left him at liberty to admit or reject that event according to evidence; and in addition to the authentic records to which he appeals, he quotes a mythological fable of the Chinese, and another of the Hindoos, which, though he lays not upon them any great stress, appear to us, when compared together, not only to corroborate his opinion respecting the descent of the Chinese, but likewise to shew that both they and the Hindoos have preserved a traditionary account of the deluge very similar to that which is given by Moses. The Chinese fable is this: "The mother of Fo-hi was the *daughter of Heaven*, surnamed *Flower-loving*; and as the nymph was walking alone on the brink of a river with a similar name, she found herself on a sudden encircled with a *rainbow*; soon after which she became pregnant, and at the end of twelve years was delivered of a son, radiant as herself, who, among other titles, had that of *Sui*, or *the Star of the Year*." In the mythological system of the Hindoos, "the nymph Rohini, who presides over the fourth lunar mansion, was the favourite mistress of Soma or the Moon, among whose numerous epithets we find *Cumudanáyaca*, or delighting in a species of *water-flower* that blossoms at night. The offspring of Rohini and Soma was Budha, regent of a planet; and he married Ila, whose father was preserved in a miraculous ark from an universal deluge." The learned president shews, that, according to the Brahams, the Chinese descended from Buda; and he mentions a divine personage connected with the Chinese account of the birth of Fo-hi, whose name was Niu-va. But if all these circumstances be laid together, it will appear, we think, pretty evident, that the two ancient nations have preserved the same tradition of an universal deluge, and that the Chinese rainbow and Niu-va, with the Indian ark, point to the flood of Noah.

To Sir William Jones's derivation of the Chinese from the Hindoos, the state of their written language may occur as an objection; for since it is certain that alphabetical characters were in use among the Hindoos before the period at which he places the emigration of the *Chinas*, how, it may be asked, came these people to drop the mode of writing practised by their ancestors, and to adopt another so very inconvenient as that which the Chinese have used from the foundation of their empire? The force of this objection, however, will vanish, when it is remembered that the *Chinas* were of the military cast; that they had gradually abandoned the ordinances of the Veda, and were in consequence degraded; and that they rambled from their native country in small bodies. We do not know that the military cast among the Hindoos was ever much devoted to letters; there is the greatest reason to believe that a degraded cast would neglect them; and it is certain that small bodies of men, wandering in deserts, would have their time and their attention completely occupied in providing for the day that was passing over them. That the *Chinas* should have forgotten the alphabetical characters of the Hindoos, is therefore so far from being an objection to Sir William Jones's account of their descent from that people, that it is the natural consequence of the manner in which he says they rambled from Hindostan to the northern provinces of what now constitutes the Chinese empire.

Of the origin of the characters which are used by this singular people, the illustrious president of the Asiatic Society gives the following account from a Chinese writer named Li Yang Ping. "The earliest of them were nothing more than the outlines of visible objects, earthly and celestial; but as things merely intellectual could not be expressed by those figures, the grammarians of *China* contrived to represent the various operations of the mind by metaphors drawn from the productions of nature. Thus the idea of roughness and of rotundity, of motion and rest, were conveyed to the eye by signs representing a mountain, the sky, a river, and the earth. The figures of the sun, the moon, and the stars, differently combined, stood for smoothness and splendour, for any thing artfully wrought, or woven with delicate workmanship. Extension, growth, increase, and many other qualities, were painted in characters taken from the clouds, from the firmament, and from the vegetable part of the creation. The different ways of moving, agility and slowness, idleness and diligence, were expressed by various insects, birds, fishes, and quadrupeds. In this manner passions and sentiments were traced by the pencil, and ideas not subject to any sense were exhibited to the sight; until by degrees new combinations were invented, new expressions added, the characters deviated imperceptibly from their primitive shape, and the Chinese language became not only clear and forcible, but rich and elegant in the highest degree *."

Of this language, both as it is spoken and written, Sir George Staunton has given an account so clear and scientific, that it will undoubtedly place him high among the most eminent philologists of the 18th century. As there is nothing relating to the Chinese more wonderful than their language, which is very little understood in Europe, we shall lay before our readers a pretty copious abstract of what he says on the subject, referring them for further information to his account of Lord Macartney's Embassy to China.

"In the Chinese tongue (says Sir George) the sounds of several letters in most alphabets are utterly unknown, and the organs of a native advanced in life cannot pronounce them. In endeavouring to utter the

* *Asiatic Researches*, vol ii. Memoir 13.

China.

founds of B, D, R, and X, for inftance, he fubftitutes fome other founds to which the fame organ has been accuftomed; L for R, and, as we have reafon to think from fome expreffions of Sir William Jones's, F for B. The nice diftinctions between the tones and accents of words nearly refembling each other in found, but varying much in fenfe, require a nicety of ear to diftinguifh, and of vocal powers to render them exactly. Synonymous words are therefore frequently introduced in Chinefe dialogue to prevent any doubt about the intended fenfe; and if in an intricate difcuffion any uncertainty fhould ftill remain as to the meaning of a particular expreffion, recourfe is had to the ultimate criterion of tracing with the finger in the air, or otherwife, the form of the character, and thus afcertaining at once which was meant to be expreffed. In a Chinefe fentence there is no marked diftinction of fubftantives, adjectives, or verbs; nor any accordance of gender, number, and cafe. A very few particles denote the paft, the prefent, and the future; nor are thofe auxiliaries employed when the intended time may be otherwife inferred with certainty. A Chinefe who means to declare his intention of departing to-morrow, never fays that he *will* depart to-morrow; becaufe the expreffion of the morrow is fufficient to afcertain that his departure muft be future. The plural number is marked by the addition of a word, without which the fingular always is implied. Neither the memory nor the organs of fpeech are burthened with the pronunciation of more founds to exprefs ideas than are abfolutely neceffary to mark their difference. The language is entirely monofyllabic. A fingle fyllable always expreffes a complete idea. Each fyllable may be founded by an European confonant preceding a vowel, fometimes followed by a liquid. Such an order of words prevents the harfhnefs of fucceeding confonants founding ill together; and renders the language as foft and harmonious as the Italian is felt to be, from the rarity of confonants, and the frequency of its vowel terminations.

"The names or founds, by which men may be firft fuppofed to have diftinguifhed other animals, when occafion offered to defignate them in their abfence, were attempts at an imitation of the founds peculiar to thofe beings; and ftill, in Chinefe, the name, for example, of a cat, is a pretty near refemblance of its ufual cry. It occurred as naturally to endeavour, in fpeaking, to imitate the voice, if practicable, as it was in writing to fketch a rude figure of the object of defcription. It is obfervable, that the radical words of moft languages, feparated from the fervile letters which mark their inflections, according to their conjugations or declenfions, are monofyllabic. A part of each radical word is retained in compofition to denote the meaning and etymology of the compound, which thus becomes polyfyllabic; but the Chinefe grammarians, aware of the inconvenience refulting from the length and complication of founds, confined all their words, however fignificant of combined ideas, to fingle founds; and retained only in writing, fome part at leaft of the form of each character denoting a fimple idea, in the compound characters conveying complex ideas."

This is a very plaufible, and perhaps the true, account of the monofyllabic form of the Chinefe language; but it is proper to ftate the different account which is given of this peculiarity by Sir William Jones. "It has arifen, according to him, from the fingular habits of the people; for though their common tongue be fo *mufically* accented as to form a kind of recitative, yet it wants thofe *grammatical* accents without which all human tongues would appear monofyllabic. Thus *Amita*, with an accent on the firft fyllable, means, in the *Sanfcrit* language, *immeafurable*, and the natives of Bengal pronounce it *Omito;* but when the religion of BUDDHA, the fon of Máyá, was carried into *China*, the people of that country, unable to pronounce the name of their new god, called him FOE, the fon of MO-YE; and divided his epithet *Amita* into three fyllables O-MI-TO, annexing to them certain ideas of their own, and expreffing them in writing by three diftinct fymbols. Hence it is that they have clipped their language into monofyllables, even when the ideas expreffed by them, and the written fymbols for thofe ideas, are very complex."

"In the Chinefe language Sir George Staunton informs us, that there is a certain order, or fettled fyntax, in the fucceffion of words in the fame fentence; a fucceffion fixed by cuftom, differently in different languages, but founded on no rule or natural order of ideas, as has been fometimes fuppofed; for though a fentence confifts of feveral ideas, to be rendered by feveral words, thefe ideas all exift and are connected together in the fame inftant; forming a picture or image, every part of which is conceived at once. The formation of Chinefe fentences is often the fimpleft and moft artlefs poffible, and fuch as may naturally have occurred at the origin of fociety. To interrogate, for example, is often at leaft to require the folution of a queftion, whether the fubject of doubt be in a particular way or the contrary; and accordingly a Chinefe inquiring about his friends health, will fometimes fay, *hou, poo hou?* The literal meaning of which words is, "well, not well?" A fimple character repeated ftands fometimes for more than one of the objects which fingly it denotes, and fometimes for a collective quantity of the fame thing. The character of *moo* fingly is a tree, repeated is a thicket, and tripled is a foreft.

"In Chinefe there are fcarcely fifteen hundred diftinct founds. In the written language there are at leaft eighty thoufand characters or different forms of letters, which number divided by the firft gives nearly fifty fenfes or characters upon an average to every found expreffed; a difproportion, however, that gives more the appearance than the reality of equivocation and uncertainty to the oral language of the Chinefe.

"The characters of the Chinefe language were originally traced, in moft inftances, with a view to exprefs either real images, or the allegorical figns of ideas: a circle, for example, for the fun, and a crefcent for the moon. A man was reprefented by an erect figure, with lines to mark the extremities. It was evident that the difficulty and tedioufnefs of imitation will have occafioned foon a change to traits more fimple and more quickly traced. Of the entire figure of a man, little more than the lower extremities only continue to be drawn, by two lines forming an angle with each other. A faint refemblance, in fome few inftances, ftill remains of the original forms in the prefent hieroglyphic characters; and the gradation of their changes is traced in feveral Chinefe books. Not above half a dozen of the prefent characters confift each of a fingle line; but moft of of them confift of many, and a few of fo many as feventy different ftrokes. The form of thofe characters has not been fo flux as the found of words, as appears in the inftance of almoft all the countries bordering on the Chinefe Sea or Eaftern Afia, where the Chinefe written, but not the oral language, is underftood; in like manner, as one form of Arabic figures to denote numbers, and one fet of notes for mufic, are uniform and intelligible throughout Europe, notwithftanding the variety of its languages.

" A certain order or connection is to be perceived in the arrangement of the written characters of the Chinefe; as if it had been formed originally upon a fyftem to take place at once, and not grown up, as other languages, by flow and diftant intervals. Upwards of two hundred characters, generally confifting each of a few lines or ftrokes, are made to mark the principal objects of nature, fomewhat in the manner of Bifhop Wilkin's divifions, in his ingenious book on the fubject of univerfal language, or real character. Thefe may be confidered as the genera or roots of language, in which every other word or fpecies, in a fyftematic fenfe, is referred to its proper genus. The heart is a genus, of which the reprefentation of a curve line approaches fomewhat to the form of the object; and the fpecies referable to it include all the fentiments, paffions, and affections, that agitate the human breaft. Each fpecies is accompanied by fome mark denoting the genus or heart. Under the genus *hand* are arranged moft trades and manual exercifes. Under the genus *word* every fort of fpeech, ftudy, writing, underftanding, and debate. A horizontal line marks a unit; croffed by another line it ftands for ten, as it does in every nation which repeats the units after that number. The five elements, of which the Chinefe fuppofe all bodies in nature to be compounded, form fo many genera, each of which comprehends a great number of fpecies under it. As in every compound character or fpecies, the abridged mark of the genus is difcernible by a ftudent of that language, in a little time he is enabled to confult the Chinefe dictionary, in which the compound characters or fpecies are arranged under their proper genera. The characters of thefe genera are placed at the beginning of the dictionary, in an order which, like that of the alphabet, is invariable, and foon becomes familiar to the learner. The fpecies under each genus follow each other, according to the number of ftrokes of which each confifts, independently of the one or few which ferve to point out the genus. The fpecies wanted is thus foon found out. Its meaning and pronunciation are given through other words in common ufe; the firft of which denotes its fignification and the other its found. When no one common word is found to render exactly the fame found, it is communicated by two words with marks, to inform the inquirer that the confonant of the firft word and the vowel of the fecond joined together form the precife found wanted.

" The compofition of many of the Chinefe characters often difplays confiderable ingenuity, and ferves alfo to give an infight into the opinions and manners of the people. The character expreffive of happinefs includes abridged marks of land, the fource of their phyfical, and of children that of their moral, enjoyments. This character, embellifhed in a variety of ways, is hung up almoft in every houfe. Sometimes written by the hand of the emperor, it is fent by him as a compliment, which is very highly prized, and fuch as he was pleafed to fend to the embaffador.

" Upon the formation, changes, and allufions of compound characters, the Chinefe have publifhed many thoufand volumes of philological learning. Nowhere does criticifm more abound, or is more ftrict. The introduction or alteration of a character is a ferious undertaking, and feldom fails to meet with oppofition. The moft ancient writings of the Chinefe are ftill claffical amongft them. The language feems in no inftance to have been derived from or mixed with any other. The written feems to have followed the oral language foon after the men who fpoke it were formed into a regular fociety. Though it is likely that all hieroglyphical languages were originally founded on the principles of imitation, yet in the gradual progrefs towards arbitrary forms and founds, it is probable that every fociety deviated from the originals in a different manner from the others; and thus for every independent fociety there arofe a feparate hieroglyphic language. As foon as a communication took place between any two of them, each would hear names and founds not common to both; each reciprocally would mark down fuch names in the founds of its own characters, bearing, as hieroglyphics, a different fenfe. In that inftance, confequently, thofe characters ceafe to be hieroglyphics, and were merely marks of found. If the foreign founds could not be expreffed but by the ufe of a part of two hieroglyphics, in the manner mentioned to be ufed fometimes in Chinefe dictionaries, the two marks joined together become in fact a fyllable. If a frequent intercourfe fhould take place between communities fpeaking different languages, the neceffity of ufing hieroglyphics merely as marks of found would frequently recur. The practice would lead imperceptibly to the difcovery that, with a few hieroglyphics, every found of the foreign language might be expreffed; and the hieroglyphics which anfwered beft this purpofe, either as to exactnefs of found or fimplicity of form, would be felected for this particular ufe; and ferving as fo many letters, would form in fact together what is called an alphabet. Thus, the paffage from hieroglyphic to alphabetic writing may naturally be traced, without the neceffity of having ' recourfe to divine inftruction, as fome learned men have conjectured, on the ground that the art of writing by an alphabet is too refined and artificial for untutored reafon.'

" The Chinefe printed character is the fame as is ufed in moft manufcripts, and is chiefly formed of ftraight lines in angular pofitions, as moft letters are in Eaftern tongues, efpecially the Sanfcrit; the characters of which, in fome inftances, admit of additions to their original form, producing a modification of the fenfe. A running hand is ufed by the Chinefe only on trivial occafions, or for private notes, or for the eafe and expedition of the writer; and differs from the other as much as an European manufcript does from print. There are books with alternate columns of both kinds of writing for their mutual explanation to a learner.

" The principal difficulty in the ftudy of Chinefe writings arifes from the general exclufion of the auxiliary particles of colloquial language, that fix the relation between indeclinable words, fuch as are all thofe of the Chinefe language. The judgment muft be conftantly exercifed

China.

exercifed by the ftudent, to fupply the abfence of fuch affiftance. That judgment muft be guided by attention to the manners, cuftoms, laws, and opinions of the Chinefe, and to the events and local circumftances of the country, to which the allufions of language perpetually refer. If it in general be true, that a language is difficult to be underftood in proportion to the diftance of the country where it is fpoken, and that of him who endeavours to acquire it, becaufe in that proportion the allufions to which language has continually recourfe are lefs known to the learner, fome idea may be conceived of the obftacles which an European may expect to meet in reading Chinefe, not only from the remotenefs of fituation, but from the difference between him and the native of China in all other refpects. The Chinefe characters are in fact fketches or abridged figures, and a fentence is often a ftring of metaphors. The different relations of life are not marked by arbitrary founds, fimply conveying the idea of fuch connection; but the qualities naturally expected to arife out of fuch relations become frequently the name by which they are refpectively known. Kindred, for example, of every degree is thus diftinguifhed with a minutenefsunknown in other languages. That of China has diftinct characters for every modification known by them of objects in the phyfical and intellectual world. Abftract terms are no otherwife expreffed by the Chinefe than by applying to each the name of the moft prominent objects to which it might be applied, which is likewife indeed generally the cafe of other languages. Among the Latins the abftract idea of virtue, for example, was expreffed under the name of valour or ftrength (*virtus*), being the quality moft efteemed among them, as filial piety is confidered to be in China. The words of an alphabetic language being formed of different combinations of letters or elemental parts, each with a diftinct found and name, whoever knows and combines thefe together, may read the words without the leaft knowledge of their meaning; not fo hieroglyphic language, in which each character has indeed a found annexed to it, but which bears no certain relation to the unnamed lines or ftrokes of which it is compofed. Such character is ftudied and beft learned by becoming acquainted with the idea attached to it; and a dictionary of hieroglyphics is lefs a vocabulary of the terms of one language with the correfpondent terms in another, than an encyclopædia containing explanations of the ideas themfelves reprefented by fuch hieroglyphics. In fuch fenfe only can the acquifition of Chinefe words be juftly faid to engrofs moft of the time of men of learning among them. The knowledge of the fciences of the Chinefe, however imperfect, and of their moft extenfive literature, is certainly fufficient to occupy the life of man. Enough, however, of the language is imperceptibly acquired by every native, and may, with diligence, be acquired by foreigners for the ordinary concerns of life; and further improvements muft depend on capacity and opportunity."

Next to the fingular ftructure of the oral and written language of the Chinefe, there is perhaps nothing in their hiftory more furprifing to a native of Europe than the number of the people, and the means by which they contrive to procure fubfiftence, without foreign trade, in a country fo crouded, and at the fame time not everywhere of a fertile foil. In the Encyclopædia, the population of this vaft empire is ftated, from M. Grofier, at 200 millions: but great as this is, when compared with the population of every other extenfive country, it appears to be far fhort of the truth. Sir George Staunton has publifhed a ftatement, taken from one of the public offices in the capital, and given by a great and refpectable manderin to Lord Macartney, in which it is fhewn that China Proper contains not fewer than 333 millions of inhabitants. As the extent of the country is 1,297,999 fquare miles, there are of courfe very near 260 inhabitants to every fquare mile; and of thefe miles a very confiderable proportion confifts of nothing but barren rocks. That this account is accurate there can be little doubt; for the extent of the provinces was afcertained by aftronomical obfervations, as well as by admeafurement; and the number of individuals is regularly taken in each divifion of a diftrict by a tythingman, or every tenth mafter of a family. Thefe returns are collected by officers refident fo near as to be capable of correcting any grofs miftake, and are all lodged in the great regifter of Pekin.

For this exceffive population our author fatisfactorily accounts. Celibacy, fays he, is rare in China, even in the military profeffion; the marriages are prolific as well as early, and the influence of the patriarchal fyftem, to be explained afterwards, is fuch, that a man's children adds to his wealth. It is reckoned a difcredit to be without offspring; and they who have none adopt others, who become theirs exclufively. In cafe of marriage, fhould a wife prove barren, a fecond may be efpoufed in the lifetime of the firft. The opulent, as in moft parts of the Eaft, are allowed, without reproach, to keep concubines, of whom the children are confidered as being thofe of the legitimate wife, and partake in all the rights of legitimacy. "Accidents fometimes of extraordinary drought, and fometimes of exceffive inundations, occafionally produce famine in particular provinces, and famine difeafe; but there are few drains from moral caufes either of emigration or foreign navigation. The number of manufactures, whofe occupations are not always favourable to health, whofe conftant confinement to particular fpots, and fometimes in a clofe or tainted atmofphere, muft be injurious, and whofe refidence in towns expofes them to irregularities, bears but a very fmall proportion to that of hufbandmen in China. In general there feems to be no other bounds to Chinefe populoufnefs than thofe which the neceffity of fubfiftence may put to it. Thefe boundaries are certainly more enlarged than in other countries. The whole furface of the empire is, with trifling exceptions, dedicated to the production of food for man alone. There is no meadow, and very little pafture; nor are fields cultivated in oats, beans, or turnips, for the fupport of cattle of any kind. Few parks or pleafure grounds are feen, excepting thofe belonging to the emperor. Little land is taken up for roads, which are few and narrow, the chief communication being by water. There are no commons, or lands fuffered to lie wafte by the neglect, or the caprice, or for the fport of great proprietors. No arable land lies fallow. The foil, under a hot and fertilizing fun, yields annually, in moft inftances, double crops, in confequence of adapting the culture to the foil, and of fupplying its defects by mixture with other earths, by manure, by irrigation, by careful and judicious induftry of every kind. The labour of man is little diverted from that induftry

to

to minifter to the luxuries of the opulent and powerful, or in employments of no real ufe. Even the foldiers of the Chinefe army, except during the fhort intervals of the guards which they are called to mount, or the exercifes, or other occafional fervices which they perform, are moftly employed in agriculture. The quantity of fubfiftence is increafed alfo, by converting more fpecies of animals and vegetables to that purpofe than is ufual in other countries. And even in the preparation of their food the Chinefe have economy and management."

The government of China is defpotic; and it is a curious fpectacle to behold fo large a proportion of the whole human race, connected together in one great fyftem of polity, fubmitting quietly, and through fo confiderable an extent of country, to one great fovereign; and uniform in their laws, their manners, and their language, but differing effentially in each of thefe refpects from every other portion of mankind: and neither defirous of communicating with nor forming any defigns againft the reft of the world. To produce fuch a phenomenon, many caufes muft be combined; but perhaps the principal are to be found in the patriarchal fyftem already mentioned, in the laws and cuftoms of the empire, and in the belief that the emperor is the vicegerent of heaven, and guided in all his actions by divine infpiration.

The patriarchal fyftem is founded upon that filial piety which the philofophers of China have uniformly reprefented as the greateft of human virtues. Thefe fages, while they fuccefsfully inculcated this duty, have left parental affection to its own natural influence; and hence in China parents are lefs frequently neglected than infants are expofed. The laws of the empire, to corroborate the difpofition to filial obedience, furnifh an opportunity for punifhing any breach of it, by leaving a man's offspring entirely within his own power: and hence it is, that with the poor, marriage, as we have faid, is a meafure of prudence; becaufe the children, particularly the fons, are bound to maintain their parents.

A Chinefe dwelling is generally furrounded by a wall fix or feven feet high. Within this inclofure a whole family, of three generations, with all their refpective wives and children, will frequently be found. One fmall room is made to ferve for the individuals of each branch of the family, fleeping in different beds, divided only by mats hanging from the ceiling. One common room is ufed for eating.

The prevalence of this cuftom, of retaining the feveral branches of a family under the fame roof, is attended with important effects. It renders the younger temperate and orderly in their conduct under the authority and example of the older; and it enables the whole to fubfift, like foldiers in a mefs, with more economy and advantage. As the venerable patriarch of each habitation prefides over his defcendants with the authority of a magiftrate; fo the different orders of magiftrates are, in their different diftricts and provinces, looked up to with the veneration due from children to their parents, while the emperor is revered as the grand patriarch of the whole empire.

Another thing which contributes much to the permanency of the government and the internal quiet of the empire is, that in China there is lefs inequality in the fortunes than in the conditions of men. The ancient annals of the empire teftify, that for a long period of time, the earth, like the other elements of nature, was enjoyed by its inhabitants almoft in common. Their country was divided into fmall equal diftricts; every diftrict was cultivated conjointly by eight labouring families, which compofed each hamlet; and they enjoyed all the profit of their labours, except a certain fhare of the produce referved for public expences. It is true, indeed, that after a revolution, deplored in all the Chinefe hiftories, which happened prior to the Chriftian era, the ufurper granted all the lands away to the partners of his victories, leaving to the cultivators of the foil a fmall pittance only out of the revenue which it yielded. Property in land alfo became hereditary: but in procefs of time, the moft confiderable domains were fubdivided into very moderate parcels by the fucceffive diftribution of the poffeffions of every father equally among all his fons; the daughters being always married without dower. It very rarely happened that there was but an only fon to enjoy the whole property of his deceafed parents; and it could fcarcely be increafed by collateral fucceffion.

From the operations of all thofe caufes, there was a conftant tendency to level wealth; and few could fucceed to fuch an accumulation of it as to render them independent of any efforts of their own for its increafe. Befides, wealth alone confers in China but little importance, and no power; nor is property, without office, always perfectly fecure. There is no hereditary dignity, which might accompany, and give it pre-eminence and weight. The delegated authority of government often leans more heavily on the unprotected rich than on the poor, who are lefs objects of temptation. And it is a common remark among the Chinefe, that fortunes, either by being parcelled out to many heirs, or by being loft in commercial fpeculations, gaming, or extravagance, or extorted by oppreffive mandarines, feldom continue to be confiderable in the individuals of the fame family beyond the third generation. To afcend again the ladder of ambition, it is neceffary, by long and laborious ftudy, to excel in the learning of the country, which alone qualifies for public employments.

There are properly but three claffes of men in China: men of letters, from whom the mandarines are taken; cultivators of the ground; and mechanics, including merchants. In Pekin alone is conferred the higheft degree of literature upon thofe who, in public examinations, are found moft able in the fciences of morality and government as taught in the ancient Chinefe writers; with which ftudies the hiftory of their country is intimately blended. Among fuch graduates all the civil offices in the ftate are diftributed by the emperor; and they compofe all the great tribunals of the empire. The candidates for thofe degrees are fuch as have fucceeded in fimilar examinations in the principal city of each province. Thofe who have been chofen in the cities of the fecond order, or chief town of every diftrict in the province, are the candidates in the provincial capital. They who fail in the firft and fecond claffes have ftill a claim on fubordinate offices, proportioned to the clafs in which they had fucceeded. Thofe examinations are carried on with great folemnity, and apparent fairnefs. Military rank is likewife given to thofe who are found upon competition to excel in the military art, and in warlike exercifes. This diftribution

China.

of offices contributes greatly to the peace of the empire; for the people cheerfully submit to the authority of those whom they believe to be placed over them by merit alone, and love that constitution which brings within the reach of the meanest subject, who has talents and industry, the highest station next to the supreme.

"The great tribunals are situated, for the sake of convenience, near the southern gate of the imperial palace at Pekin. To them accounts of all the transactions of the empire are regularly transmitted. They are councils of reference from the emperor, to whom they report every business of moment, with the motives for the advice which they offer on the occasion. There is a body of doctrine composed from the writings of the earliest ages of the empire, confirmed by subsequent lawgivers and sovereigns, and transmitted from age to age with increasing veneration, which serves as rules to guide the judgment of those tribunals. This doctrine seems, indeed, founded on the broadest basis of universal justice, and on the purest principles of humanity.

"His imperial majesty generally conforms to the suggestions of those tribunals. One tribunal is directed to consider the qualifications of the different mandarines for different offices, and to propose their removal when found incapable or unjust. One has for object the preservation of the manners or morals of the empire, called by Europeans *the tribunal of ceremonies*, which it regulates on the maxim, that exterior forms contribute not a little to prevent the breach of moral rules. The most arduous and critical is the tribunal of censors; taking into its consideration the effect of subsisting laws, the conduct of the other tribunals, of the princes and great officers of state, and even of the emperor himself. There are several subordinate tribunals; such as those of mathematics, of medicine, of public works, of literature and history. The whole is a regular and consistent system, established at a very early period, continued with little alterations through every dynasty, and revived after any interruption from the caprice or passions of particular princes. Whatever deviation has been made by the present family on the throne, arises from the admission of as many Tartars as Chinese into every tribunal." The opinions of the former are supposed always to preponderate; and many of them are indeed men of considerable talents and strength of mind, as well as polished manners. They are, however, in general, fitter for military than civil offices. The hardy education, the rough manners, the active spirit, the wandering disposition, the loose principles, and the irregular conduct, of the Tartar, fit him better for the profession, practice, and pursuits of war, than the calm, regulated, and domestic habits of the Chinese. Warriors seem naturally the offspring of Tartary, as literati are of China; and accordingly, the principal military commands are conferred on natives of the former country, as, with many exceptions indeed, the chief civil offices are on those of the latter.

A military mandarin, who was much with Lord Macartney, and was himself a distinguished officer, asserted that, "including Tartars, the total of the army in the pay of China amounted to 1,000,000 infantry and 800,000 cavalry. From the observations made by the embassy in the course of their travels through the empire, of the garrisons in the cities of the several orders, and of the military posts at small distances from each other, there appeared nothing unlikely in the calculation of the infantry; but they met few cavalry. If the number mentioned really do exist, a great proportion of them must have been in Tartary, or on some service distant from the route of the embassy.

"Of the troops, especially cavalry, a vast number are Tartars, who have a higher pay than their Chinese fellow-soldiers. The principal officers of confidence in the army are Tartars also. None of either nation are received into the service but such as are healthy, strong, and sightly. The pay and allowances of a Chinese horseman are three Chinese ounces, heavier than European ounces, and three-tenths of an ounce, of silver, and fifteen measures or rations (the weight not mentioned) of rice every lunar month. A Tartar horseman, seven similar ounces of silver, and 20 measures of rice for the same period. A Chinese foot soldier has one ounce and six-tenths of an ounce of silver, and ten measures of rice; and a Tartar of the same description has two ounces of silver and ten measures of rice every lunar month. The Emperor furnishes the arms, accoutrements, and the upper garment, to all the soldiers. Beside their ordinary pay and allowances, they also receive donations from the Emperor on particular occasions; as when they marry, and when they have male children born. On the death of their parents they obtain 'a gift of consolation;' as do their families when the soldiers themselves die.

"The public revenues of China Proper are said to be little less than 200,000,000 of ounces of silver, which may be equal to about 66,000,000 of pounds sterling; or about three times those of France before the late subversion. From the produce of the taxes all the civil and military expences, and the incidental and extraordinary charges, are first paid upon the spot out of the treasuries of the respective provinces where such expences are incurred; and the remainder is remitted to the Imperial treasury at Pekin. This surplus amounted in the year 1792 to the sum of 36,614,328 ounces of silver, or 12,204,776 pounds sterling, according to an account taken in round numbers. In case of insurrections, or other occurrences requiring extraordinary expences, they are generally levied by additional taxes on the provinces adjacent to the scene of action, or connected with the occasion of the expence.

"In the administration of the vast revenue of the state, the opportunities of committing abuses are not often neglected; as may be inferred from the frequent confiscation to the Emperor in consequence of such transgressions. It is indeed affirmed, that much corruption and oppression prevail in most of the public departments, by which considerable fortunes are acquired, notwithstanding the modicity of the public salaries."

With such a standing army and so vast a revenue, it will no longer appear wonderful that one man should govern with despotic sway even the immense multitude of people who inhabit the empire of China, especially trained up as those people are in habits of filial submission to their superiors. But there are some circumstances in the system of Chinese policy, not yet mentioned, which contribute perhaps more than even these habits and that power to preserve the stability of the government. The Emperor reserves to himself alone the right of relieving the wants of the poor, produced by famine or any other unforeseen calamity. On such occasions he he always comes forward. He orders the public granaries to be opened; remits the taxes to thoſe who are viſited with misfortune; affords aſſiſtance to enable them to retrieve their affairs; and appears to his ſubjects as ſtanding almoſt in the place of Providence in their favour. He is perfectly aware by how much a ſtronger chain he thus maintains his abſolute dominion, than the mere dread of puniſhment would afford. The emperor, to whom the Britiſh embaſſy was ſent, ſhewed himſelf ſo jealous of retaining the excluſive privilege of benevolence to his ſubjects, that he not only rejected, but was offended at, a propoſal once made to him by ſome conſiderable merchants, to contribute towards the relief of a ſuffering province; whilſt he ſcrupled not, at the ſame time, to accept the donation of a rich widow towards the expences of a war in which he was engaged.

This veneration, excited towards the emperor by his apparent benevolence, is increaſed by an opinion zealouſly inſtilled into the people, that he has the faculty of predicting future events of the greateſt importance. The Chineſe, given up to the dotages of judicial aſtrology, are firmly perſuaded that eclipſes of the ſun and moon have a powerful influence on the operations of nature and the tranſactions of mankind; and the periods of their occurrence become, of courſe, objects of attention and ſolicitude. The government of the country, ever anxious to eſtabliſh its authority in the general opinion of its ſuperior wiſdom and conſtant care for the welfare of the people, employs the European miſſionaries at Pekin (for it is doubtful if any one of the natives has ſo much ſcience) to calculate eclipſes, and then announces them to the people with that ſolemnity which is fitted to enſure veneration for the ſuperintending power whence ſuch knowledge is immediately derived to them. Eclipſes of the ſun, in particular, are conſidered as omenous of ſome general calamity; and as great pains are taken to inſpire them with a belief that their proſperity is owing to the wiſdom and virtues of their ſovereign, ſo they are tempted to attribute to ſome deficiency on his part whatever they think portentous. To this prejudice the emperor finds it prudent to accommodate his conduct. He never ventures on any undertaking of importance at the approach of a ſolar eclipſe, but affects to withdraw himſelf from the preſence of his courtiers, to examine ſtrictly into his late adminiſtration of the empire, in order to correct any error, for the commiſſion of which the eclipſe may have been an admonition. On theſe occaſions he invites his ſubjects to give him freely their advice: but it is plain that advice muſt be offered with great deference to a being for whoſe admonition the motions of the ſun and moon are believed to be regulated; and while ſuch notions are implicitly admitted, the perſon of the Chineſe emperor, as well as his authority, muſt be looked upon by his ſubjects as ſomething more than human.

This is in fact the caſe. He is not only approached in perſon with teſtimonies of the utmoſt reſpect, but is adored when abſent with all the rites and ceremonies which are uſed by the Chineſe in the worſhip of their divinities. On his birth-day, at the new and full moon, and probably on other feſtivals, all the mandarines reſident in the neighbourhood of any of his numerous palaces aſſemble about noon, and repairing to the palace, ſolemnly proſtrate themſelves nine times before the throne, their foreheads ſtriking the floor each time; whilſt incenſe is burning on tripods on each ſide of it, and offerings are made, on an alter before it, of tea and fruits to the ſpirit of the abſent emperor. Over the throne are ſeen the Chineſe characters of glory and perfection; and the name of the Deity is given to the emperor, who is conſidered by his votaries as poſſeſſing in ſome ſenſe the attribute of ubiquity. Mr Barrow, one of the gentlemen of the embaſſy, was preſent at *Yuen-min-yuen*, one of the imperial palaces, when theſe idolatrous rites of adoration were performed; and he was aſſured that they took place on that day in all parts of the empire, the proſtraters being everywhere attentive to turn their faces towards the capital.

That he who claims adoration in his abſence does not appear on his birth-day to receive the compliments of his ſubjects, will not ſurpriſe the reader. The manner in which that feſtival is celebrated at the palace, where the emperor happens to be reſident, is thus deſcribed by Sir George Staunton, who witneſſed this more than auguſt ceremony at the palace of *Zhe-hal* in Tartary. "The princes, tributaries, ambaſſadors, great officers of ſtate, and principal mandarines, were aſſembled in a vaſt hall; and upon particular notice, were introduced into an inner building, bearing, at leaſt, the ſemblance of a temple. It was chiefly furniſhed with great inſtruments of muſic, among which were ſets of cylindrical bells, ſuſpended in a line from ornamented frames of wood, and gradually diminiſhing in ſize from one extremity to the other, and alſo triangular pieces of metal arranged in the ſame order as the bells. To the ſound of theſe inſtruments a ſlow and ſolemn hymn was ſung by eunuchs, who had ſuch a command of their voices as to reſemble the effect of the muſical glaſſes at a diſtance. The performers were directed, in gliding from one tone to another, by the ſtriking of a ſhrill and ſonorous cymbal; and the judges of muſic among the gentlemen of the embaſſy were much pleaſed with their execution. The whole had indeed a grand effect. During the performance, and at particular ſignals, nine times repeated, all the perſons proſtrated themſelves nine times, except the ambaſſador and his ſuit, who made a profound obeiſance (A). But he whom it was meant to honour, continued, as if it were in imitation of the Deity, inviſible the whole time."

That the awful impreſſion meant to be made upon the

(A) The Chineſe court, which conſiders all other ſovereigns as ſubordinate to their own, exacts from foreign miniſters, as well as from natives of the empire, nine proſtrations upon their firſt introduction to the emperor. This demand was made, in the laſt century, of the Dutch, who inſtantly complied with it in hopes of obtaining in return ſome lucrative advantages; and the conſequence was, that their ambaſſador was treated with neglect, and diſmiſſed without promiſe of the ſmalleſt favour. It was likewiſe made of a Ruſſian ambaſſador in the preſent century; but he would not comply with it, until a regular agreement was made for its return, on a like occaſion, to his own ſovereign. Lord Macartney, who was repeatedly urged to go through the ſame abject ceremony, diſplayed ſuch firmneſs and addreſs, that after much evaſion it was at laſt announced to him, that his imperial majeſty would be ſatisfied with the ſame form of reſpectful obedience that the Engliſh are in the habit of paying to their own ſovereign; and upon theſe terms his lordſhip was introduced and graciouſly received.

China.

the minds of men by this apparent worſhip of a fellow-mortal might not be too quickly effaced, all ſcenes of ſport and gaiety were poſtponed to the next day, when a variety of entertainments was exhibited in the preſence of the emperor, ſurrounded by his court and tributary princes.

Notwithſtanding the general veneration of the Chineſe for the perſon and government of their emperor, the mandarines aſſerted that a ſect had for ages ſubſiſted in the country, whoſe chief principles were founded on an antipathy to monarchy, and who nouriſhed hopes of at laſt ſubverting it. Their meetings were held in the utmoſt ſecrecy, and no man avowed any knowledge of them; but a ſort of inquiſition was ſaid to be eſtabliſhed in order to find them out, and they who were ſuſpected of ſuch ſentiments were cut off, or hunted out of ſociety. Should the French declaration of the rights of man, which, through the zeal of its authors, has been tranſlated into one of the languages of India, find its way into China (of which the court is ſaid to be much afraid), it would indeed be a powerful engine in the hands of this ſecret ſect to ſap the foundations of the ancient government. The minds of many of the Chineſe are far from ſatisfied with their condition, which lays both their perſons and their fortunes at the mercy of the mandarines. No private man in China is exempted from corporal puniſhment, which may be inſtantly inflicted on him at the nod of a magiſtrate; and when he has occaſion to ſpeak to a great mandarine, he is obliged, by the police of the country, to throw himſelf on his knees, and in that poſture to communicate his buſineſs. The mandarine himſelf, on the other hand, lies under the hardſhip of being frequently reſponſible for events which he could not controul. Upon the general principle that it is his duty to watch over the morals of the people, he is in many caſes conſidered as a criminal for not preventing crimes which he had not been able to prevent. The mandarines are thus aware of not being guaranteed by good conduct againſt diſgrace; and feeling the chagrin of inſecurity, many of them muſt doubtleſs be ripe for a revolt. Fear may keep them quiet during the reign of a ſovereign poſſeſſed of abilities and vigilance; but the maxims which regulate the imperial ſucceſſion are ſuch, that a firm confederacy could hardly fail at the death of an emperor to introduce great changes into the conſtitution. The throne of China is neither hereditary nor elective. The choice of a ſucceſſor is left entirely to the reigning prince, who may exclude, as has been inſtanced, even his own offſpring and family. To prevent commotions and fraud, it is no uncommon practice for the emperor, during his lifetime, to declare his ſucceſſor; for when his ſucceſſion is ſettled by a written teſtament, the throne is not always filled by him for whom it was deſtined. The father of the emperor to whom the Britiſh embaſſy was ſent, is ſaid to have obtained poſſeſſion of the throne by ſuddenly entering the palace in the laſt moments of his predeceſſor, and ſubſtituting his own name in a teſtament intended for the exaltation of another.

To what has been ſaid in the Encyclopædia of the religion of the Chineſe, we have here very little to add. Various deities are worſhipped in the empire by very different rites and ceremonies; but there is in China no ſtate religion. None is paid, preferred, or encouraged by it. The emperor is of one faith; many of the mandarines of another; and the majority of the common people of a third, which is that of Fo. The men of letters venerate rather than adore Confucius; and meet to honour and celebrate his memory in halls of a ſimple but neat conſtruction. The numerous and lower claſſes of the people are leſs able than inclined to contribute much towards the erection of large and coſtly edifices for public worſhip: their attention is almoſt wholly engaged by their houſhold gods; for every houſe has its altar and its deities.

"No people are, in fact, more ſuperſtitious than the common Chineſe. Beſide the habitual offices of devotion on the part of the prieſts and females, the temples are particularly frequented by the diſciples of Fo previouſly to any undertaken of importance; whether to marry, or go a journey, or conclude a bargain, or change ſituation, or for any other material event in life, it is neceſſary firſt to conſult the ſuperintendant deity. This is performed by various methods. Some place a parcel of conſecrated ſticks, differently marked and numbered, which the conſultant, kneeling before the altar, ſhakes in a hollow bamboo, until one of them falls on the ground; its mark is examined, and referred to a correſpondent mark in a book which the prieſt holds open, and ſometimes even it is written upon a ſheet of paper paſted upon the inſide of the temple. Polygonal pieces of wood are by others thrown into the air. Each ſide has its particular mark; the ſide that is uppermoſt when fallen on the floor is in like manner referred to its correſpondent mark in the book or ſheet of fate. If the firſt throw be favourable, the perſon who made it proſtrates himſelf in gratitude, and undertakes afterwards with confidence the buſineſs in agitation. But if the throw ſhould be adverſe, he tries a ſecond time, and the third throw determines, at any rate, the queſtion. In other reſpects, the people of the preſent day ſeem to pay little attention to their prieſts. The temples are, however, always open for ſuch as chooſe to conſult the decrees of heaven. They return thanks when the oracle proves propitious to their wiſhes. Yet they oftener caſt lots to know the iſſue of a projected enterpriſe than ſupplicate for its being favourable; and their worſhip conſiſts more in thankſgiving than in prayer.

"The Chineſe are ſeldom ſaid to carry the objects to be obtained by their devotion beyond the benefits of this life. Yet the religion of Fo profeſſes the doctrine of the tranſmigration of ſouls, and promiſes happineſs to the people on conditions, which were no doubt originally intended to conſiſt in the performance of moral duties; but in lieu of which are too frequently ſubſtituted thoſe of contributions towards the erection or repair of temples, the maintenance of prieſts, and a ſtrict attention to particular obſervances. The neglect of theſe is announced as puniſhable by the ſouls of the defaulters paſſing into the bodies of the meaneſt animals, in whom the ſufferings are to be proportioned to the tranſgreſſions committed in the human form."

Though the Chineſe artiſts are very ingenious as mere workmen, there is hardly any thing which deſerves the name of ſcience in the whole empire. So little is the ſtudy of mathematics cultivated, that there are few ſhopkeepers in China who can perform the ordinary operations of arithmetic; but caſt up their accounts by means of an inſtrument called *ſwanpan* (See Swan-

China. SWANPAN, *Encycl.*). Though the compoſition of gun-powder was certainly known in China much earlier than in Europe, and though the Chineſe had employed it from the beginning in blaſting rocks, and in making a vaſt variety of fire-works; yet Sir George Staunton ſeems convinced, that they never thought of the invention of guns till they were taught by the Europeans to introduce them into their armies.

The ſtate of phyſic in this vaſt country is extremely low, being nowhere taught in public ſchools or colleges. "A young man who wiſhes to become a phyſician, has no other way of acquiring medical knowledge than by engaging himſelf to ſome practitioner as an apprentice. He has thus the opportunity of ſeeing his maſter's practice, of viſiting his patients with him, and of learning ſuch parts of his knowledge and ſecrets as the other chooſes to communicate to him. The emoluments of the profeſſion ſeldom exceed the ſkill of the practitioner. As many copper coin as ſcarcely are equal to ſixpence ſterling is ſaid to be the uſual fee among the people; and perhaps quadruple among the mandarines. Medicine is not divided in China into diſtinct branches as in moſt parts of Europe. The ſame perſon acts as phyſician, ſurgeon, and apothecary. The ſurgical part of the profeſſion is ſtill more backward than the others. Amputation, in caſes of compound fracture and gangrene, is utterly unknown; and death is the ſpeedy conſequence of ſuch accidents. The Chineſe method of inoculation, which was introduced into the empire about the beginning of the tenth century of our era, is as follows: When the diſeaſe breaks out in any diſtrict, the phyſicians of the place carefully collect a quantity of ripe matter from puſtules of the proper ſort; which being dried and pulveriſed, is cloſely ſhut up in a porcelain jar, ſo as to exclude from it the atmoſpheric air; and in this manner it will retain its properties for many years. When the patient has been duly prepared by medicines, generally of an aperient kind, and ſtrictly dieted for a ſhort time, a lucky day is choſen to ſprinkle a little of the variolus powder upon a ſmall piece of fine cotton wool, and to inſert it into the noſtrils of the patient.

"No male phyſician is allowed to attend a pregnant woman, and ſtill leſs to practiſe midwifery; in the indelicacy of which both ſexes ſeem to agree in China. There are books written on that art for the uſe of female practitioners, with drawings of the ſtate and poſition of the infant at different periods of geſtation; together with a variety of directions and preſcriptions for every ſuppoſed caſe that may take place: the whole mixed with a number of ſuperſtitious obſervances.

Many practitioners of phyſic take the advantage, as elſewhere, of the obſcurity in which that art is involved, and of the ignorance and credulity of the people, to gain money by the ſale of noſtrums and ſecrets of their own. They diſtribute hand bills, ſetting forth the efficacy of their medicines, with atteſted cures annexed to them. And there is one ſect which boldly arrogates to itſelf the poſſeſſion of a medical ſecret *not to die!* To thoſe who had all the enjoyments of this life, there remained unaccompliſhed no other wiſh than that of remaining for ever in it. And accordingly ſeveral ſovereigns of China have been known to cheriſh the idea of the poſſibility of ſuch a medicine. They had put themſelves, in full health, under the care of thoſe religious empirics, and took large draughts of the boaſted beverage of immortality. The compoſition did not conſiſt of merely harmleſs ingredients; but probably of ſuch extracts and proportions of the poppy, and of other ſubſtances and liquors, as occaſioning a temporary exaltation of the imagination, paſſed for an indication of its vivifying effects. Thus encouraged, they had recourſe to frequent repetitions of the doſe, which brought on quickly languor and debility of ſpirits: and the deluded patients often became victims to deceit and folly in the flower of their age. China, Chineſe.

"There are in China no profeſſors of the ſciences connected with medicine. The human body is never, unleſs privately, diſſected there. Books, indeed, with drawings of its internal ſtructure are ſometimes publiſhed; but theſe are extremely imperfect, and conſulted, perpaps, oftener to find out the name of the ſpirit under whoſe protection each particular part is placed, than for obſerving its form and ſituation.

"It is a matter of doubt, whether natural hiſtory, natural philoſophy, or chemiſtry, be, as ſciences, much more improved than anatomy in China. There are ſeveral treatiſes, indeed, on particular ſubjects in each. The Chineſe likewiſe poſſeſs a very voluminous Encyclopædia, containing many facts and obſervations relative to them; but from the few reſearches which the gentlemen of the embaſſy had leiſure or opportunity to make during their ſhort viſit to the country, they perceived no traces of any general ſyſtem or doctrine by which ſeparate facts or obſervations were connected and compared, or the common properties of bodies aſcertained by experiment; or where kindred arts were conducted on ſimilar views, or rules framed, or deductions drawn from analogy, or principles laid down to conſtitute a ſcience."

Of all people the Chineſe are perhaps the moſt eager in their curioſity about foreigners coming among them, and the moſt indifferent about the countries of ſuch foreigners. They have been always in the habit of confining their ideas to their own country, emphatically ſtyled *the middle kingdom*. No Chineſe ever thinks of quitting it, except a few of deſperate fortunes reſiding near the ſea-coaſt, or ſea-faring men, who form a claſs, in a great meaſure, apart from ſociety. Even foreign commodities conſumed in China remind them only of Canton, whence they received them, as if produced in it; and theſe commodities they conſider, perhaps properly, as of no real benefit to the empire. Regions out of Aſia are ſcarcely mentioned in their books, or noticed in their diſtorted maps; and the great body of the people would be little gratified with accounts of ſuch regions, which did not contain tales of wonders not performed at home, or of powers exerted beyond the ordinary boundaries of nature.

CHINESE PUMP. See PUMP in this Supplement.

CHINESE *Weights* are ſo very different in many reſpects from thoſe in uſe elſewhere, that it will at leaſt gratify the curioſity of our readers to take ſome notice of them in this Work. Of theſe weights Charles Coquebert has preſented a ſpecimen to the Philomathematical Society in Paris. They are made of copper, and bear a great reſemblance in form to the body of a violin. Like that inſtrument, they are rounded off at the extremities, and indented on the ſides to admit the fingers. The faces are flat and parallel, and have Chineſe characters

racters

Chineſe. racters engraven on the upper ſurface. They advance in a regular decimal progreſſion, of which Coquebert has diſcovered four diſtinct ſeries, the units of which are in the proportion of 1, 10, 100, 1000. Inſtead of employing a combination of one, two, four, and eight units, or after the new ſyſtem of one, two, and five units, the Chineſe have a diſtinct weight for every intermediate number between one and ten. Thus they have weights of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, &c. Of courſe, thoſe weights which ſtand related to each other in the proportion of 6 to 7, 7 to 8, 8 to 9, 9 to 10, differ ſo little in ſize, that it would be impoſſible to diſtinguiſh them without the help of the characters which are engraven upon the face. This is confeſſedly a defect in the ſyſtem. Of the four different ſeries exhibited to the ſociety, the higheſt bears in China the name of *kin*, and is nearly of equal value with a pound avoirdupois. The kin contains ten times the number of units of the next inferior weight, which the Chineſe denominate *leang* or *loam*, and which the Europeans call *tael*, *taille*, or Chineſe *ounce*. This ounce is divided into ten *tſien*, which anſwers nearly to our drachm. The tſien is again ſubdivided into ten *fen*. The Chineſe extend the decimal ſubdiviſion of their weights conſiderably farther. They have diſtinct names, which are all monoſyllabic, for nine ſeries below the fen. Suppoſing the kin to ſtand for unity, they have,

1,	0	0	0	0	0	0	0	0	0	0	0	0
kin,	leang	tſien	fen	li	hav	ſen	tchin	yai	miao	mo	tſun	ſun

The Chineſe weights, compared with the greateſt preciſion, and with the help of the beſt inſtruments, bear the following proportion to our weights: The kin is equal to 1 pound 12 ounces 2 drachms 24 grains; the leang 1 ounce 1 drachm 60 grains; the tſien 70 grains $\frac{8}{10}$; the fen 7 grains $\frac{8}{100}$. Conſequently the laſt of this ſeries, the ſun, amounts to no more than 0 grains 0000000708.

Chinese Wheel is an engine employed in the province of *Kiang-ſee*, and probably through the whole empire, for raiſing water from rivers to irrigate plantations of ſugar canes, on a ſandy ſoil, conſiderably elevated above the level of the river. By Sir George Staunton, who ſays that it is ingenious in its contrivance, cheap in its materials, eaſy in its operation, and effectual to its purpoſe, it is thus deſcribed:

"Two hard wood-poſts or uprights are firmly fixed in the bed of the river, in a line perpendicular to its bank. Theſe poſts ſupport the axis, about ten feet in length, of a large and durable wheel, conſiſting of two unequal rims, the diameter of one of which, cloſeſt to the bank, being about fifteen inches ſhorter than that of the outer rim; but both dipping in the ſtream, while the oppoſite ſegment of the wheel riſes above the elevated bank. This double wheel is connected with the axis, and is ſupported by 16 or 18 ſpokes obliquely inſerted near each extremity of the axis, and croſſing each other at about two-thirds of their length. They are there ſtrengthened by a concentric circle, and faſtened afterwards to the rims: the ſpokes inſerted in the interior extremity of the axis reaching the outer rim, and thoſe proceeding from the exterior extremity of the ſame axis, reaching the inner and ſmaller rim. Between the rims and the croſſing of the ſpokes is woven a kind of cloſe baſket-work, ſerving as laddle-boards or floats, which meeting ſucceſſively the current of the ſtream, obey its impulſe, and turn round the wheel. To both its rims are attached ſmall tubes or ſpouts of wood, with an inclination of about 25 degrees to the horizon, or to the axis of the wheel. The tubes are cloſed at their outer extremity, and open at the oppoſite end. By this poſition the tubes, which happen in the motion of the wheel to be in the ſtream with their mouths or open ends uppermoſt, fill with water. As that ſegment of the wheel riſes, the mouths of the tubes attach to it, alter their relative inclination, but not ſo much as to let their contents flow out till ſuch ſegment of the wheel becomes the top. The mouths of thoſe tubes are then relatively depreſſed, and pour the water into a wide trough placed on poſts, from whence it is conveyed as may be wanted among the canes.

"The only materials employed in the conſtruction of this water-wheel, except the nave or axis, and the poſts on which it reſts, are afforded by the bamboo. The rims, the ſpokes, the laddle-boards or floats, and the tubes or ſpouts, and even the cords, are made of entire lengths, or ſingle joints, or large pieces, or thin ſlices, of the bamboo. Neither nails, nor pins, nor ſcrews, nor any kind of metal, enters into its conſtruction. The parts are bound together firmly by cordage, alſo of ſlit bamboo. Thus, at a very trifling expence, is conſtructed a machine which, without labour or attendance, will furniſh, from a conſiderable depth, a reſervoir with a conſtant ſupply of water adequate to every agricultural purpoſe.

"Theſe wheels are from 20 to 40 feet in diameter, according to the height of the bank and conſequent elevation to which the water is to be raiſed. Such a wheel is capable of ſuſtaining with eaſe 20 tubes or ſpouts, of the length of four feet, and diameter two inches in the clear. The contents of ſuch a tube would be equal to ſix-tenths of a gallon, and a periphery of 20 tubes, twelve gallons. A ſtream of a moderate velocity would be ſufficient to turn the wheel at the rate of four revolutions in one minute, by which would be lifted 48 gallons of water in that ſhort period; in one hour, 2880 gallons; and 69120 gallons, or upwards of 300 tons of water, in a day."

Sir George, who ſaw this wheel in motion, thinks it preferable in many reſpects to any machine yet in uſe for ſimilar purpoſes. He obſerves, that, while it approaches near to the Perſian wheel, of which a deſcription and figure is given in the article Hydrostatics, *Encycl.* it is more ſimple than that wheel in its contrivance, and much leſs expenſive. This is indeed true; but the ſimpleſt engine of the kind, and therefore the beſt that has yet been invented, is perhaps that which is employed to throw water into the moſs of Blair Drummond in Perthſhire. See Moss, *Encycl.*

Chineſe, Chopine.

CHOPINE, Choppine, or *Chopeene*, a high ſhoe, or rather clog, worn 200 years ago by the Italians.

Tom Coryat, in his Crudities 1611. p. 262, calls them *chapineys*, and gives the following account of them: "There is one thing uſed of the Venetian women, and ſome others dwelling in the cities and towns ſubject to the ſigniory of Venice, that is not to be obſerved, I thinke, amongſt any other women in Chriſtendome, which is ſo common in Venice, that no women whatſoever goeth without it, either in her houſe or abroad, *a thing made of wood and covered with leather of sundry colors, some with white, some redde, some yellow. It is called a* chapiney, *which they wear under their shoes.* Many of them are curiously painted; some also of them I have seen fairly gilt; so uncomely a thing, in my opinion, that it is pitty this foolish custom is not cleane banished and exterminated out of the citie. *There are many of these chapineys of a great height, even half a yard high,* which maketh many of their women that are very short seeme much taller than the tallest women we have in England. Also I have heard it observed among them, that by how much the nobler a woman is, by so much the higher are her *chapineys*. All their gentlewomen, and most of their wives and widowes that are of any wealth, are assisted eyther by men or women when they walke abroad, to the end they may not fall. They are borne up most commonly by the left arme, otherwise they might quickly take a fall."

CHOWDRY, in Bengal, the possessor of several *Talooks*. It is also used as synonymous with *Talookdar*, anciently a collector. See TALOOK in this Supplement.

CHRISOM was not, as is said in the Encyclopædia, a face-cloth or piece of linen laid over the child's head when it was baptized; but it was a white vesture or garment, which, immediately after it was baptised, the priest put upon it, saying, "Take this white vesture as a token of the innocency, which, by God's grace in this holy sacrament of baptism, is given unto thee, and for a sign whereby thou art admonished, so long as thou livest, to give thyself to innocence of living, that after this transitory life thou mayest be partaker of life everlasting. Amen."

As soon as the priest had pronounced these words, he anointed the infant upon the head, saying, "Almighty God, the Father of our Lord Jesus Christ, who hath regenerated thee by water and the Holy Ghost, and hath given unto thee the remission of all thy sins; he vouchsafe to anoint thee with the unction of his Holy Spirit, and bring thee to the inheritance of everlasting life. Amen."

It was from this anointing or *chrism* that the white garment got the name of *chrisom*, which, after being worn a few days, was offered to the priest to be kept in the church or vestry, in order to be produced as evidence against the person whose chrisom it was, should he afterwards deny the faith in which he had been baptized. These ceremonies were retained, for some time after the reformation, in the church of England, which ordered the mother of the child (if the child was then alive) to offer, when she was churched, the *chrisom* and other accustomed offerings. If the child died before its mother was churched, the *chrisom* was not given to the priest, but employed as a shroud, in which the body was buried; and hence it is that chrisoms are now enumerated, most absurdly indeed, in the weekly bills of mortality. We say absurdly; because children who die unbaptized are called *chrisoms*, though the chrisom, when it was used, was never put on till baptism. See *Whitby on the Book of Common Prayer, &c.*

CHRONOLOGICAL CHARACTERS are characters by which times are distinguished. Of these some are natural or astronomical; others, artificial or historical. The natural characters are such as depend on the motions of the stars or luminaries, as *eclipses, solstices, equinoxes,* the *different aspects of the planets,* &c. The artificial characters are those that have been invented and established by men; as the *solar cycle*, the *lunar cycle*, &c. Historical chronological characters are those supported by the testimony of historians, when they fix the *dates* of certain *events* to certain *periods*. *Hutton's Mathematical Dictionary.*

CHRONOSCOPE, a word sometimes used to denote a pendulum or machine to measure time.

CHUCKIAH, in Bengal, the jurisdiction of a *Fogedar*. See FOGEDAR in this Supplement.

CHURCH is a word which has many different significations, all sufficiently explained in the Encyclopædia Britannica, where there is likewise given a concise *history* of the Christian church (see HISTORY, Sect. ii.), defective, indeed, but perhaps not more so than was to be expected from the limits of the work and the extent of the subject.

Of the constitution of the primitive and apostolical church, no man can have a correct notion who has not taken the trouble to consult the primitive and apostolical writers; for, as we have elsewhere observed, all modern compilers of ecclesiastical history are more or less prejudiced in behalf of the particular church to which they belong, and wrest the language of the original writers so as to make them bear witness to the antiquity of *modes of faith* and *ecclesiastical polity*, which are not perhaps a hundred years old.

On this account we shall not here attempt to correct what we really think the mistakes of him who compiled the section of ecclesiastical history in the Encyclopædia. Mosheim and Sir Peter King, whom he seems to have implicitly followed, were indeed great men; and it would be folly to deny that the *History* of the former, and the *Inquiry* of the latter *into the Constitution of the Primitive Church*, are works of learning and ingenuity; but it is not perhaps too much to say, that both authors wrote under the influence of prejudice. Our readers will discover how closely either the one or the other has adhered to truth, by studying the ecclesiastical writers of the first four centuries. Such a study will make them acquainted with the doctrines, discipline, and worship of the church before it was incorporated with the state; and we know not that kind of knowledge which is of more importance to the divine, however much it may be despised in this age of affected science and real ignorance.

Of the principal churches at present existing, a pretty full account is given in the Encyclopædia, either under their different denominations, or under the titles of those tenets by which they are chiefly distinguished; so that from that Work alone a reader may form a tolerably accurate notion of the faith, worship, constitution, and discipline of the church of Rome, the churches of England and Scotland, the Lutheran and Calvinistical churches on the continent of Europe, as well as of the various sects which have arisen in these kingdoms during the course of the last and present centuries. There is, however, one church which boasts of a very high antiquity, and is certainly spread over a larger extent of country than all the other churches that we have mentioned, of which the account given in the Encyclopædia is exceedingly defective. Our readers will perceive that the church to which we allude is

The

Church.

1 The Greek church.

The Greek Church, which comprehends in its bosom (A) a considerable part of Greece, the Grecian isles, Wallachia, Moldavia, Egypt, Abyssinia, Nubia, Lybia, Arabia, Mesopotamia, Syria, Cilicia, and Palestine, which are all under the jurisdiction of the patriarchs of Constantinople, Alexandria, Antioch, and Jerusalem. If to these we add the whole of the Russian empire in Europe, great part of Siberia in Asia, Astracan, Casan, and Georgia—it will be evident that the Greek church has a wider extent of territory than the Latin, with all the branches which have sprung from it; and that it is with great impropriety that the church of Rome is called by her members the *catholic* or universal church. That in these widely distant countries the professors of Christianity are agreed in every minute article of belief, it would be rash to assert; but there is certainly such an agreement among them with respect both to faith and to discipline, that they mutually hold communion with each other, and are in fact but one church.

2 The faith of that church.

As the Greek church has no public or established articles, like those of the churches of England and Scotland, we can collect what is its doctrine only from its creeds, from the councils whose decrees it receives (B), from the different offices in its liturgies, and from the catechisms which it authorises to be taught. "The doctrine of the Trinity, and the articles of the Nicene and Athanasian creeds, are received by the Greeks in common with other Christians. In one particular, indeed, they differ from the other churches of Europe, whether Romish or reformed. They believe that the Holy Spirit proceeds from the father only, and not from the Father and the Son; and in defence of this opinion they appeal to ecclesiastical history, the acts of councils, the writings of the fathers, ancient manuscripts, and especially to a copy of the creed of Constantinople, engraven on two tables of silver, and hung up in the church of St Peter at Rome by order of Leo III. Of the Nicene or Constantinopolitan creed, therefore, as it is received by them, the eighth article runs in these words, 'I believe in the Holy Ghost, the Lord and Giver of life, who proceedeth from the Father, and with the Father and the Son together is worshipped and glorified:' And the corresponding article of the Athanasian creed is of course, "The Holy Ghost is of the Father, neither made, nor created, nor begotten, but proceeding †."

† Dallaway's *Constantinople, Ancient and Modern*, and King's *Rites and Ceremonies*, &c

3 It admits of pictures, but not of graven images.

Though the bishops and clergy of the Greek church abhor the use of images, which they pretend to be one cause of their separation from the see of Rome, they admit into their churches the pictures of saints to instruct, they say, the ignorant, and to animate the devotion of others. This practice they consider as by no means contrary to the second commandment of the decalogue, which, according to them, prohibits only the worshipping of such idols as the Gentiles believed to be gods; whereas their pictures, being used merely as remembrancers of Christ and the saints, have written on each of them the name of the person whom it is meant to represent. Dr King assures us that the more learned of the Russian clergy would willingly allow no representation whatever of God the Father; and that, during the reign of Peter the Great, the synod not only censured the use of such pictures in churches, but petitioned the emperor that they might be everywhere taken down. Peter, however, though he fully concurred in opinion with the synod, thought this a measure for which the minds of his subjects were not ripe, and dreaded, that if carried into execution it would occasion a general insurrection. Such pictures, therefore, though not more impious than absurd, are still in use; and in many churches, as well ancient as modern, the figure of Daniel's *Ancient of Days*, together with that of *Christ* and a *dove*, are painted in one group to signify the Holy Trinity. Nay, when our author was in St Petersburg, not thirty years ago, there was in the church of St Nicholas the picture of an old man holding a globe, and surrounded with angels, on which God the Father was inscribed; and we have not heard that the picture has been since taken down.

4 Invocation of saints.

In the Greek as well as in the Roman church, the invocation of saints is practised, but they are not invoked in either as deities, but merely as intercessors with the Supreme God, "it being more modest (say the Greeks), as well as more available, to apply to them to intercede with God, than to address ourselves immediately to the Almighty." Plausible as this reasoning may at first sight appear, it ascribes to the saints the divine attribute of ubiquity, and is likewise in direct contradiction to the doctrine of St Paul, who hath taught us, that as "there is one God, so there is but one mediator between God and man, the man Christ Jesus."

5 Prayers for the dead.

The Greek church, at the celebration of the Lord's Supper, commemorates the faithful departed, and even prays for the remission of their sins; but she allows not of purgatory, nor pretends to determine dogmatically concerning the state or condition of departed souls. She must, however, believe that no final judgment is passed upon the great body of mankind (C) till the consummation of all things, otherwise such prayers could not be offered without absurdity; and in this part of her doctrine she is certainly countenanced by all the writers of the primitive church, if not by some passages of the sacred scriptures *. The practice of praying for the dead is loudly condemned in every Protestant country, and yet there is no Christian who does not in effect pray

* *Math.* xxv. 19, 20, —31—34. 2 *Tim.* i. 18. iv. 8.

(A) King's *Rites and Ceremonies of the Greek Church*—Bruce's *Travels to the Source of the Nile*—and Lobo's *Voyage to Abyssinia*.

(B) in the Greek church seven general councils are received, and nine provincial ones. The seven general councils are, 1. The council of Nice, held in the year 325, under Constantine. 2. The first council of Constantinople, held A. D. 381, under Theodosius the Great. 3. The council of Ephesus, A. D. 431, in the reign of Theodosius Minor. 4. The council of Calcedon, A. D. 451, in the reign of Marcian. 5. The second council of Constantinople, A. D. 553, in the reign of Justinian. 6. The third council of Constantinople in Trull, A. D. 680, in the reign of Constantine Pagonatus. 7. The second council of Nice, A. D. 787.

(C) We say the great body of mankind, because she doubtless believes that Enoch, Elias, and those saints who rose with our Saviour, have been already judged, and now enjoy their reward in heaven.

pray for his departed ſriends. This may appear a paradox, but it is an obvious and a certain truth; for where is the man who believes in a general judgment, and does not *wiſh* that his deceaſed wife, or parent, or child, or friend, "may find mercy of the Lord in that day?" Such a wiſh is the eſſence of a prayer; which conſiſts not of the ſounds in which our ſentiments are cloathed, but in the aſpirations of a devout heart.

6 Grants no indulgencies.

Supererogation, with its conſequent indulgencies and diſpenſations, which were once ſo profitable, and afterwards ſo fatal to the intereſts of the court of Rome, are utterly diſallowed in the Greek church, which likewiſe lays no claim to the character of infallibility. She is indeed, like ſome other churches, very inconſiſtent on this laſt topic; for whilſt ſhe pretends not to an abſolute exemption from error, her clergy ſeem to conſider their own particular mode of worſhip as that which alone is acceptable to God.

7 Predeſtination.

Predeſtination is a dogma of the Greek church, and a very prevailing opinion amongſt the people of Ruſſia; "and I muſt do the juſtice (ſays Dr King) to thoſe who have written upon it, eſpecially the lateſt authors of that country, to ſay that they have treated it, as depending on the attribute of preſcience in the divine nature, with a much better kind of logic than that with which ſuch points are generally diſcuſſed." As our author has not given us the reaſoning of the Ruſſian doctors on this difficult ſubject, we cannot hazard any opinion of our own on the ſoundneſs of their logic; but from the ſtate of ſcience in that vaſt empire, as it was repreſented to us by an abler judge than he, we doubt of its being entitled to the praiſe which he beſtows on it. (See Russia, n° 104. *Encycl.*)

8 Seven ſacraments.

In the Greek church there are ſeven *ſacraments*; or, as they are there termed, *myſteries*, viz. *baptiſm*; the *chriſm*, or baptiſmal unction; the *euchariſt*; *confeſſion*; *ordination*; *marriage*; and the myſtery of *the holy oil*, or *euchelaion*. By the Greeks a myſtery is defined to be "a ceremony or act appointed by God, in which God giveth or ſignifieth his grace; and of the ſeventh which they celebrate, four are to be received by all Chriſtians, viz. *baptiſm*, the *baptiſmal unction*, the *euchariſt*, and *confeſſion*. Of theſe, *baptiſm* and the *euchariſt* are deemed the chief; and of the other three, none, not even the *euchelaion*, is conſidered as obligatory upon all.

With reſpect to baptiſm, we know not that they hold any peculiar opinions. They conſider it indeed as ſo abſolutely neceſſary to ſalvation, that in caſes of extremity, when a prieſt or deacon cannot be had, it may be adminiſtered by a midwife or any other perſon, and is not to be repeated on any occaſion whatever. In this opinion, as well as in the practice founded on it, they are in perfect harmony with the church of Rome, which, as every perſon knows, has for many ages allowed the validity of lay-baptiſm in caſes of neceſſity. The Portugueſe Jeſuits, who in the laſt century viſited Abyſſinia in the capacity of miſſionaries, have maintained that, once every year, all grown people are in that country baptiſed: but Mr Bruce has ſhewn, by the moſt incontrovertible evidence, that this was a mere fiction, invented to throw odium upon what the church of Rome calls the eaſtern chiſm, and abhors perhaps more than paganiſm itſelf.

9 Daily ſervice of the church,

The daily ſervice of the Greek church is ſo long and ſo complicated, that it is impoſſible for us to give an adequate account of it without ſwelling this article far beyond its due proportion. Of this the reader will be convinced, when he is informed that the ſeveral books containing the church ſervice for all the days in the year, amount to more than twenty volumes in folio, beſides one large volume called *the regulation*, which contains the directions how the reſt are to be uſed.

10 Intricate and tedious.

The four goſpels make one volume by themſelves; and whenever the goſpel is read in any ſervice, the deacon exclaims; "Wiſdom, ſtand up. Let us hear the holy goſpel." The prieſt then ſaith, "The leſſon from the goſpel according to St Matthew, St Mark, &c." The deacon ſays again, "Let us ſtand." The choir, at the beginning and end of the goſpel, always ſays, "Glory be to thee, O Lord, glory be to thee." From the old teſtament and the epiſtles extracts only are uſed in the ſervice; and when they are to be read, the deacon calls out, "Attend."

The ſervice of this church as it now ſtands, and was at firſt drawn up in writing, is calculated for the uſe of monaſteries; and when it was afterwards applied to parochial churches, many of the offices or forms, which were compoſed for different hours of the day and night, were uſed as one ſervice, without the ſlighteſt alteration being made to avoid repetitions. Something of this kind has taken place in the church of England, where the matins, the litany, and the communion, which were formerly three diſtinct ſervices, read at different times of the day, are now run into one ſervice; which by thoſe not accuſtomed to it is therefore deemed long, as well as deformed by needleſs repetitions.

11 Begins in the evening.

The ſervice of every day, whether it has a vigil or not, begins in the evening of what we would call the preceding day, as among the Jews; and for the ſame reaſon, becauſe it is ſaid in the Moſaic account of the creation, that "the evening and the morning were the firſt day." The ſeveral ſervices, according to the original or monkiſh inſtitution, are, 1. *The veſpers*, which uſed to be celebrated a little before ſun-ſet; 2. *The after-veſpers*, anſwering to the *completorium* of the Latin church, which uſed to be celebrated after the monks had ſupped, and before they went to bed; 3. *The meſonyecticon*, or midnight ſervice; 4. *The matins* at break of day, anſwering to the *laudes* of the Romiſh church; 5. The *firſt hour* of prayer, or *prima*, at ſun-riſe; 6. The *third hour*, or *tertia*, at the third hour of the day; 7. The *ſixth hour*, or *ſexta*, at noon; 8. The *ninth hour*, or *nona*, in the afternoon at the ninth hour of the day. Theſe are called the canonical hours; but it is to be obſerved, that the *after-veſpers* were not added till a late period, before which the reaſon aſſigned for the number of ſervices being ſeven, was, that David ſaith, "Seven times a-day will I praiſe thee." When all the pſalms and hymns were ſung, theſe daily ſervices could not poſſibly have been performed in leſs than twelve or fourteen hours. In the church of Ruſſia, and probably in other branches of the Greek church, there are at preſent but three ſervices in the day: the *ninth hour*, the *veſpers*, and the *after-veſpers* making one; the *meſonyecticon*, the *matins*, and *prima*, another; and the *third* and *ſixth hour*, with the *communion*, the laſt. In all the ſervices, except the communion, prayers and praiſes are offered to ſome ſaint; and to the Virgin Mary, almoſt as often as to God; and in ſome of the ſervices, after every ſhort prayer uttered by the deacon or the prieſt, the

choir

choir chaunts "Lord have mercy upon us," thirty, forty, or fifty times, ſucceſſively.

Though the number of ſervices is the ſame every day, the ſervices themſelves are conſtantly varying in ſome particular or other, as there is not a day which, in the Greek church, is not either a faſt or a feſtival. Beſides the ſaints, whoſe feſtivals are marked in the calendar, and who are ſo very numerous that there are more than one for every day in the year, there are other ſaints and feſtivals, to which ſome portion of the ſervice for every day of the week is appropriated. Thus, Sunday is dedicated to the reſurrection: Monday, to the angels; Tueſday, to St John Baptiſt; Wedneſday, to the Virgin and the croſs; Thurſday, to the apoſtles; Friday, to the paſſion of Chriſt; and Saturday, to the ſaints and martyrs. For theſe days there are particular hymns and ſervices, in two volumes folio, to which there is a ſupplement containing ſervices for the ſaints and feſtivals, as they occur in the calendar throughout the year. Theſe different ſervices are mixed together, and adjuſted by the directions contained in the book of *regulation*; and it is the difficulty of this adjuſtment which makes the public worſhip of the Greek church ſo very intricate, that, as was ſaid of the ſervice of the Engliſh church before the Reformation, "there is more buſineſs to find out what ſhould be read, than to read it when found out."

12 Mode of adminiſtering baptiſm.

We have obſerved, that the Greeks have no peculiar opinions reſpecting the nature of baptiſm; but the rites and ceremonies with which that ordinance is adminiſtered will appear to our unlearned readers very extraordinary. On the day that a woman is delivered, the prieſt goes to the houſe, and uſes a form of prayer for her and for the child. On the eighth day the child ſhould be regularly carried to the church, where the prieſt having ſigned it with the ſign of the croſs on the forehead, on the mouth, and on the breaſt, offers up for it a prayer, in which he firſt gives it a name, commonly the name of the ſaint for that day in the calendar; he then takes it from the midwife, and ſtanding before the picture of the bleſſed Virgin, he makes the ſign of the croſs with the infant, uttering a kind of hymn in honour of the Virgin and of Simeon, who held in his boſom the Saviour of our ſouls. He then diſmiſſes the company with an exhortation not to delay the baptiſing of the infant, ſhould it appear in danger of death before the regular time for its baptiſm.

On the fortieth day after her delivery, the mother ſhould attend the church to be purified, and carry the child again to be preſented, the perſon who is to be ſponſor being preſent. Upon their arrival at the church door, the prieſt utters ſome pious exclamations; and then, the mother holding the child in her arms and bowing down her head, he makes the ſign of the croſs upon her and the child, and laying his hand upon its head, he prays that the woman may be cleanſed from every ſin and from every defilement, and that the child may be ſanctified and endued with underſtanding, with wiſdom, and with gentleneſs of manners. He then ſigns it again, and again prays for it, for its parents, and for its ſponſor; after which, if it has been privately baptiſed, he takes it in his arms, and makes with it the ſign of the croſs before the door of the church, ſaying, "N. N. the ſervant of God, enters into the church, in the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen." He then carries the child into the church, ſaying, "he ſhall go into thine houſe, and ſhall worſhip toward thy holy temple;" and advancing into the middle of the church, he ſays, "In the midſt of thy church ſhall he praiſe thee." Then, if the child be a boy, he carries him within the rails of the altar; but if a girl, only to the door, and ſays "*Nunc dimittis* (D);" after which he delivers it to the ſponſor, who makes three reverences, and retires.

This is called the preſentation of the child in the temple, and can only be performed after it has been baptized. In the detail we have given, we have ſuppoſed that it was baptized privately before the purification of the mother, which is now indeed commonly the caſe. Such baptiſm, however, is not regular, being allowed only in caſes of neceſſity; and when it has not taken place, the mother and child are diſmiſſed as ſoon as ſhe is purified, and return at ſome other time, not fixed, in order that the child may be publicly baptized.

Previous to baptiſm, the child, though not two months old, muſt be ſolemnly initiated into the church as a catechumen (See CATECHUMEN, *Encycl.*) By thoſe whoſe religion is a reaſonable ſervice, ſuch initiation of an infant will be conſidered as a very idle ceremony; and the rites with which it is performed are not well calculated to give it even a fictitious importance. At the door of the church the prieſt unties the girdle of the infant; takes off all his clothes but one looſe garment; turns him towards the eaſt, with his head uncovered, his feet naked, and his hands held down; blows thrice in his face; ſigns him thrice with the ſign of the croſs on the forehead and on the breaſt, and lays his hand upon his head, praying that his "*ancient* error may be put away from him; that his heart may be filled with faith, hope, and charity; and that he may walk in the ways of God's commandments." The prieſt then four times exorciſes the infant, commanding Satan, in the firſt exorciſm, to "tremble, depart, and flee from Chriſt's creature, nor dare to return again, nor dare to lurk concealed within him, or to meet him, or to meditate againſt him, either in the evening or the morning, at midnight or at noon-day." In the laſt exorciſm he blows thrice upon the child's mouth, upon his forehead, and upon his breaſt; ſaying, each time, "Drive away from him every evil and unclean ſpirit that lurks in him, and hath made itſelf a neſt in his heart." The child is now become a catechumen, and, being turned to the weſt, uncovered, without ſhoes, and his hands lifted up, the prieſt repeatedly aſks him if he *renounces* and *has* renounced the Devil and all his works? and receiving from the ſponſor the proper anſwer, he ſays, "Blow and ſpit upon him;" and having blown and ſpit upon the catechumen, he turns him to the eaſt, and holding down his hands, aſks him repeatedly if he be joined to Chriſt, and if he believes in him? The catechumen or his ſponſor replies to each queſtion, that he is, and has been, joined to Chriſt; and as a proof of his

(D) We quote the words of Dr King. Is it poſſible that in the Greek church Latin hymns are uſed, or that Greek hymns have Latin deſignations?

Church. his faith he repeats, from beginning to end, the Nicene creed. After a repetition of the formerly repeated questions and answers, the priest prays that the catechumen may be called to God's holy sanctification, and receive the grace of God's holy baptism.

Baptism may be celebrated immediately after the candidate has been made a catechumen, or on any subsequent day at no great distance. In the first part of the form there is not much that is singular, or with which every scholar is not acquainted. After praying that the water may be sanctified, in terms differing little from those which are used in the most respectable Protestant churches, the priest dips his fingers in it, signs it thrice with the sign of the cross; and then blowing upon it, says three times, "Let every adverse power be confounded under the sign of the cross." He then solemnly exorcises it of the dæmon of darkness and all evil spirits; and prays, that "the person to be baptised therein may put off the old man, which is corrupt after the lust of fraud, and may put on the new man after the image of Him that made him. After this, he blows thrice into a vessel of oil of olives held by the deacon, signs it thrice with the sign of the cross; and prays fervently, that it may "become to those who are anointed with faith, and are partakers thereof, the unction of incorruption, the armour of righteousness, the renewing of soul and body, for turning aside all machinations of the devil, and for deliverance from all evil." He then sings allelujah thrice with the people, and pours the oil on the top of the water; and making three crosses with it, says aloud, "Blessed be God, who enlighteneth and sanctifieth every man that cometh into the world, now and forever, even unto ages of ages." The person to be baptized is then presented; and the priest, taking some of the oil with two fingers, and making the sign of the cross on his forehead, on his breast, and betwixt his shoulders, says, "N the servant of God is anointed with the oil of gladness, in the name of the Father, and of the Son, and of the Holy Ghost, now and forever, even unto ages of ages. Amen." He then signs him on the breast and the middle of the back, saying, "For the healing of his soul and body;" then on the ears, saying, "For hearing the faith;" then on the palms of the hands, saying, "Thy hands have made me and fashioned me;" then on the feet, "That he may walk in the way of thy commandments." After the whole body is thus anointed, the priest baptizes him, using the trine immersion; which is unquestionably the most primitive manner. He takes the child in his arms, and holding him upright with his face towards the east, he says, "N the servant of God is baptized (*dipping him the first time*), in the name of the Father, Amen; in the name of the Son (*dipping him again*), Amen; and of the Holy Ghost (*dipping him the third time*), Amen, now and for ever, even unto ages of ages. Amen." After the baptism, the priest wipes his hands, and with the people sings thrice, from beginning to end, the 32d Psalm; he then puts upon the baptized person a white garment; saying, "N the servant of God is clothed with the garment of righteousness, in the name of the Father, and of the Son, and of the Holy Ghost, now and for ever, even unto ages of ages (E)." He then prays that he may be delivered from the evil one, and all his insidious snares; that he may be confirmed in the true faith; and that he may preserve his soul in purity and righteousness: and proceeds immediately to anoint him with the *Holy Chrism*.

13 The baptismal chrism.

This chrism is a very different thing from the oil with which he was anointed previous to baptism, and which was used in the consecration of the baptismal water. It can be prepared only by a bishop, and only on one day in the year, *viz.* Thursday in Passion-week; and as the anointing with it is substituted in place of the apostolical rite of laying on hands, called *confirmation* in the western churches, great quantities of it are of course prepared at once, and distributed through the different churches of each diocese. The chrism consists of the following ingredients, which in different proportions are all boiled together, and afterwards solemnly consecrated by the bishop: Fine oil (we suppose of olives), white wine, styrax calamita (F), palm-dew, rose-flowers, black palm-gum, Basil-gum, marjoram, thick and thin oil of nutmegs in very different quantities, oil of cinnamon, oil of cloves, lignum Rhodii, oil of oranges, oil of marjoram, oil of lavendar, oil of rosemary, essence of rosemary, cedar, black balsam of Peru, sandarac, whitest mastic, and Venice turpentine. With this holy mixture the baptized person is anointed, the priest making with it the sign of the cross on his forehead, on his eyes, his nostrils, his mouth, both ears, his breast, his hands, and his feet; saying at each part, "The seal of the gift of the Holy Ghost. Amen." Then with the sponsor and the child he goes thrice round the font, turning from the right to the left; the choir, in the mean time, singing, "As many of you as are baptized unto Christ have put on Christ, allelujah."

Seven days after this ceremony is performed, the child is again brought to the church; when the priest, after praying for him, unties his girdle and linen clothes, washes him with clean water, and, sprinkling him, says, "Thou hast been justified, enlightened, sanctified in the name of our Lord Jesus Christ, and with the Spirit of our God." Then taking a new sponge moistened with water, he washes his face, breast, &c.; saying, "Thou hast been baptized, enlightened, anointed, sanctified, washed, in the name of the Father, and of the Son, and of the Holy Ghost, now and for ever, even unto ages of ages. Amen."

14 The tonsure.

The last ceremony appended to baptism is that of the tonsure, or shaving the head of the child in the form of the cross. At what time this rite crept into the church it would not be easy to discover. Some think it received its origin from the religious ceremonies of the Heathen, who certainly rounded the corners of

(E) The reader will perceive, that many of these rites and ceremonies are common to the Greek church and the church of Rome in the celebration of the sacrament of baptism.

(F) We quote the words of Dr King, taking it for granted that our readers will pardon our not giving ourselves much trouble to discover, on the present occasion, what particular species or variety of the storax he means by this designation. See Styrax, *Encycl.*

Church.

of their heads, and marred their beards, at a very early period, in honour of their idols (See THEOLOGY, n° 155. *Encycl,*); and some pious, but foolish Christians, esteemed it highly commendable to transfer to the true God that worship, in a different form, which had been rendered by their ancestors to false deities. Others will have the tonsure to typify the dedication of the person to the service of God; the cutting off of the hair being always considered as a mark of servitude. Be these conjectures as they may, the priest, after the child is baptized, offers up for him several prayers, all alluding to the rite to be performed; and then cuts his hair crosswise, saying, "N the servant of God is shorn, in the name of the Father, and of the Son, and of the Holy Ghost, now and for ever, even unto ages of ages. Amen."

We have given a full account of the manner in which the sacrament of baptism is celebrated among the Greeks, that the reader may have some notion of the childish superstition of that church, with which certain zealous Protestants in England were very desirous, at the beginning of this century, to form a union. There is no occasion for dwelling so long upon their other offices.

15
The Greeks have three communion-offices.

For the celebration of the Lord's Supper they have three liturgies that are occasionally used, *viz.* that of St Chrysostom, which is in ordinary daily use; that of St Basil, used on particular days; and that of the *presanctified*, as it is called, which is used on the Wednesdays and Fridays during the great fast before Easter. Between the liturgies of St Chrysostom and St Basil there is no essential difference; and the office of the presanctified is merely a form of dispensing the communion with elements which had been consecrated on the preceding Sunday. We would gladly insert the liturgy of St Chrysostom, or at least such an abstract of it as we have given of the form of administering baptism; but as our limits will not permit us to do so, we must refer such of our readers as have any curiosity respecting subjects of this nature to *Dr King's Rites and Ceremonies of the Greek Church.*

It is proper, however, to observe here, that many superstitious ceremonies have been added to the service since the age of St Chrysostom, and that no man can compare his genuine works with the liturgy which now goes under his name, and entertain the smallest doubt but that the latter has been greatly, though gradually, corrupted.

16
Strange ceremony at the offertory.

In the offertory there is a strange ceremony, called *the slaying of the Holy Lamb*, when the priest, taking into his left hand one of the five loaves which are to be consecrated, thrusts a spear into the right side of it; saying, "He was led as a lamb to the slaughter;" then into the left side, adding, "And as a blameless lamb before his shearers is dumb, so he openeth not his mouth:" then into the upper part of the loaf; saying, "In his humiliation his judgment was taken away:" and into the lower part; adding, "And who shall declare his generation?" He then thrusts the spear obliquely into the loaf, lifting it up, and saying, "For his life was taken away from the earth." After this he lays down the loaf, and cutting it crosswise, says, "The Lamb of God, which taketh away the sins of the world, is slain for the life and salvation of the world." All this, and more to the same purpose, is unquestionably modern; but we have no doubt but that the priest uses the words of Chrysostom himself, when, in the consecration of the elements, he says, "We offer unto thee this reasonable, this unbloody sacrifice; and we implore, we pray thee, we humbly beseech thee, to send down the Holy Spirit upon us, and those oblations presented unto thee; and make this bread the precious body of thy Christ; and that which is in this cup the precious blood of thy Christ, changing them by thy Holy Spirit."

17
The consecration of the elements.

Dr King observes, that this invocation of the Holy Spirit upon the elements, which in the eastern church is always used after the words of Christ, "This is my body, this is my blood, &c." is inconsistent with the Popish doctrine of transubstantiation: and he is undoubtedly right; for the church of Rome teaches, that the change is made about the middle of the mass, when the priest, taking into his hand first the bread and then the wine, pronounces over each separately the sacred words of consecration; *i.e.* the words of Christ. "It is the office of the priest, in this and in all other sacraments (says a dignitary of that church), only to perform the outward sensible part; but the inward invisible effect is the work of the great God, who accordingly changes the substance of the bread and wine into the body and blood of Christ the very instant that the sacred words of consecration are pronounced by the priest over them." But if this be so, it would be impious, and we believe that by the church of Rome it is deemed impious, to pray afterwards, that God would send down his Holy Spirit to change into the body and blood of Christ elements which he had already changed into that body and blood, in consequence of the priest's pronouncing over them the all-powerful words of Christ. Yet is it certain, that in the present Greek church transubstantiation is as much an article of faith as in the church of Rome; for now every bishop at his consecration declares, in the most solemn manner, that he believes and "understands that the transubstantiation of the body and blood of Christ, in the holy supper, is effected by the influence and operation of the Holy Ghost, when the bishop or priest invokes God the Father in these words, *and make this bread the precious body of thy Christ*, &c." This is indeed a different account from that of the Latin church of the time at which this portentous change is wrought; but such difference is a matter of very little importance (G). If the change itself be admitted, the consequence must be the same, whether it be supposed to take place when the

18
Transubstantiation.

(G) Mr Bruce seems to doubt whether transubstantiation be the doctrine of the Abyssinian church, and relates a conversation which he had on the subject with a priest; who solemnly affirmed, that he never believed in the conversion of the substance of the bread and wine into the substance of our Saviour's body and blood. It must be remembered, however, that the priest had at the time a powerful reason for wishing that doctrine not to be true. The Jesuits uniformly attest, that the Abyssinians believe in the real presence; though it must not be forgotten that Ludolf was of a different opinion, and that no man had studied the language of Abyssinia more successfully than he.

the prieſt pronounces the words of inſtitution, or after he has invoked the deſcent of the Holy Ghoſt; in either caſe it leads to idolatry. It may be proper to mention, that in the Greek church it is deemed eſſential to the validity of this holy ſacrament, that a little warm water be mixed with the wine; that the napkin, which is ſpread over the holy table, and anſwers to the *corporale* of the church of Rome, be conſecrated by a biſhop, and that it have ſome ſmall particles of the reliques of a martyr mixed in the web, otherwiſe the euchariſt cannot be adminiſtered.

19 The laity communicate in both kinds.

In this church children may receive the communion immediately after baptiſm; and the lay communicants, of whatever age, receive both the elements together, the bread being ſopped in the cup: The clergy receive them ſeparately.

20 Confeſſion in the Greek church.

We have obſerved, that one of the ſeven *myſteries* or ſacraments of the Greek church is *confeſſion;* but among the Greeks it is a much more rational and edifying ſervice than in the church of Rome. In the Greek church the end of confeſſion is the amendment of the penitent; in the church of Rome it is to magnify the glory of the prieſt. In the former church, the confeſſors pretend only to abate or remit the penance, declaring the pardon from God alone; in the latter, they take upon them to forgive the ſin itſelf. The Greek church preſcribes confeſſion four times in the year to all her members; but the laity, for the moſt part, confeſs only once a year previous to receiving the holy communion; and to this they are in Ruſſia obliged by the laws of the empire.

21 Matrimony.

The ceremonies with which matrimony is performed in the Greek church conſiſt of three diſtinct offices, formerly celebrated at different times, after certain intervals, which now make but one ſervice. Firſt, there was a ſolemn ſervice, when the parties betrothed themſelves to each other, by giving and receiving rings or other preſents, as pledges of their mutual fidelity and attachment. The ancient uſage was for the man to receive a gold ring and the woman a ſilver one, which is ſtill alluded to in the rubric, though, in the preſent practice, the rings are generally both of gold. At this time the dowry was paid, and certain obligations were entered into to forfeit ſums in proportion to it, if either of the parties ſhould refuſe to ratify the engagement. At this ceremony, called the μνηστρον, or *recording of the pledges before witneſſes,* the prieſt gives lighted tapers to the parties to be contracted, making the ſign of the croſs on the forehead of each with the end of the taper before he deliver it.

The ſecond ceremony, which is properly the marriage, is called the office of *matrimonial coronation,* from a ſingular circumſtance in it, that of *crowning* the parties. This is done in token of the triumph of continence; and therefore it has, in ſome places, been omitted at ſecond marriages. Formerly theſe crowns were garlands made of flowers or ſhrubs; but now there are kept, in moſt churches, crowns of ſilver or ſome other metal for the celebration of matrimony. At the putting of them on, the prieſt ſays, "N, the ſervant of God, is crowned for the handmaid of God; and "N, handmaid of God, is crowned for the ſervant of God, in the name of the Father, and of the Son, and of the Holy Ghoſt;" adding thrice, "O Lord our God, crown them with glory and honour."

The third ceremony is that of diſſolving the crowns on the eighth day; after which the bride is conducted to the bridegroom's houſe, immediately to enter on the cares of his family.

22 Regular and ſecular clergy.

With reſpect to diſcipline and government, the Greek church bears a ſtriking reſemblance to that of Rome. In both there is the ſame diviſion of the clergy into regular and ſecular; the ſame ſpiritual juriſdiction of biſhops and their officials, and the ſame diſtinction of ranks and offices. In ſome points the diſcipline of the Greeks differs from that of the Romans. All orders of ſecular clergy in the Greek church inferior to biſhops are permitted to marry; but celibacy, and the aſſumption of the monaſtic habits, are indiſpenſably requiſite in thoſe who are candidates for the mitre. The regular clergy, ſays Mr Dallaway, are generally men of a certain education; whereas the ſeculars are of the meaner ſort, and illiterate in the extreme.

23 Five orders of clergy.

In the Greek church there are five orders of clergy promoted by the impoſition of hands; but it does not appear that the ordination of the reader, or of the ſubdeacon, is conſidered as a ſacrament. The forms uſed in the ordination of deacons, preſbyters, and biſhops, are ſerious and ſignificant (H), bearing in themſelves evidence of great antiquity. The candidate for the deaconate or prieſthood kneels before the holy table, and the biſhop, laying his right hand on his head, ſaith,

24 Form of ordination.

"The divine grace, which healeth our infirmities, and ſupplieth our defects, promoteth N, the moſt pious *ſubdeacon,* to the order of *deacon;*" or, in the caſe of the prieſthood, "The moſt pious *deacon* to the order of a *preſbyter;* let us pray for him, that the Grace of the Holy Spirit may come upon him." It does not appear, from Dr King's account of theſe offices, that in the Greek church the attending preſbyters lay on their hands together with the biſhop at the ordination of a preſbyter,

(H) We muſt except thoſe uſed in the church of Abyſſinia, which, according to Mr Bruce, are ſhamefully indecent. "A number of men and children preſent themſelves at a diſtance, and there ſtand, from humility, not daring to approach the *abuna* or biſhop. He then aſks who theſe are? and they tell him that they want to be deacons. On this, with a ſmall iron croſs in his hand, after making two or three ſigns, he blows with his mouth twice or thrice upon them; ſaying, *Let them be deacons.* I ſaw once (ſays our author) all the army of Begemder made deacons, juſt returned from ſhedding the blood of 10,000 men. With thoſe were mingled about 1000 women, who conſequently having part of the ſame blaſt and brandiſhment of the croſs, were as good deacons as the reſt. In the ordination of prieſts a little more ceremony is uſed; for they muſt be able to read a chapter of St Mark, which they do in a language of which the abuna underſtands not one word. They then give him a brick of ſalt, to the value perhaps of ſixpence, for their ordination; which, on account of this preſent, the Jeſuits maintained to be Simoniacal." There is but one biſhop or abuna in Abyſſinian, and he is always a foreigner, ſubordinate in his juriſdiction to the patriarch of Alexandria.

preſbyter, as is practiſed in the church of England; but ſeveral biſhops lay on their hands together with the archbiſhop at the conſecration of a biſhop.

25 Solemn conſecration of biſhops.

This is indeed a very ſolemn ceremony. The candidate for the epiſcopate, who is always an *archimandrite* or *hieromonachus*, i. e. an abbot or chief monk in ſome monaſtery, being named to the vacant ſee, and the election being confirmed, repairs, at the time appointed, to the church where the conſecration is to be performed. Being arrived, he is introduced by the proto-pope (I) and proto-deacon to the archbiſhop and biſhops, who are arranged in proper order on a temporary theatre or platform erected in the church for the occaſion. He there gives an account of his faith; declares ſolemnly that he has neither given nor promiſed money, or any bribe-worthy ſervice, for his dignity; and promiſes to adhere ſteadily to the traditions and canons of the eaſtern church, to viſit his dioceſe regularly, and to oppoſe ſtrenuouſly all innovations and hereſies, particularly the errors of the Latin church. This being done, the archbiſhop ſays, "The grace of the Holy Spirit, through my humility, exalts thee N. archimandrite or hieromonachus, beloved of God, to be biſhop of the cities N. N. which God preſerve." With much ceremony the biſhop elect is then conducted from the theatre, within the rails of the holy altar, where he kneels down with the other biſhops, who hold open over his head the holy goſpel with the letters inverted, the archbiſhop ſaying aloud, "The divine grace, which always healeth our infirmities, and ſupplieth our defects, by my hand conducteth thee N. archimandrite or hieromonachus, beloved of God, biſhop elect of the cities of N. N. which God preſerve!—Let us pray therefore for him, that the Grace of the moſt Holy Spirit may come upon him." Then the prieſts ſay thrice, "Lord have mercy upon us;" and while the biſhops continue to hold the goſpel, the archbiſhop ſigns the newly conſecrated biſhop thrice with the ſign of the croſs, ſaying, "In the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen." Then all the biſhops putting their right hands on his head, the archbiſhop prays that he may be confirmed in the office of which they have judged him worthy, that his prieſthood may be rendered irreproachable, and that he himſelf may be made holy and worthy to be heard of God. After this, one of the aſſiſting biſhops reads a ſhort litany in a low voice, to be heard only by thoſe within the altar, and the other biſhops make the reſponſes. At the end of the litany the archbiſhop, laying his hand again upon the head of the newly conſecrated biſhop, prays in very decent and devout terms, that Chriſt will render him an imitator of himſelf, the true Shepherd; that he will make him a leader of the blind, a light to thoſe who walk in darkneſs, and a teacher of infants; that he may ſhine in the world, and receive at laſt the great reward prepared for thoſe who contend boldly for the preaching of the goſpel. After this the paſtoral-ſtaff is delivered to the new biſhop, with a very proper and ſolemn exhortation from the archbiſhop, to feed the flock of Chriſt committed to his care.

The laſt ſacrament of the Greek church is that of the holy oil or euchelaion, which is not confined to perſons *perículoſe ægrotantibus, et mortis periculo imminente*, like the extreme unction of the Romiſh church; but is adminiſtered, if required, to devout perſons upon the ſlighteſt malady. Though this ordinance is derived from St James, chap. v. ver. 14, 15. it is by no means deemed neceſſary to ſalvation, or obligatory upon all Chriſtians; and it is well that it is not, for ſeven prieſts are required to adminiſter it regularly, and it cannot be adminiſtered at all by leſs than three. The oil is conſecrated with much ſolemnity; after which each prieſt, in his turn, takes a twig, and dipping it in the oil now made holy, anoints the ſick perſon croſs-wiſe, on the forehead, on the noſtrils, on the paps, the mouth, the breaſt, and both ſides of the hands, praying that he may be delivered from the bodily infirmity under which he labours, and raiſed up by the grace of Jeſus Chriſt.

26 The lavipedium.

In the Greek, as well as in the Latin church, there is a ſervice, called the divine *lavipedium*, obſerved on the Thurſday of paſſion-week, in imitation of our Saviour's humility. At Conſtantinople Jeſus Chriſt is, on this occaſion, perſonified by the Patriarch, and everywhere elſe by the biſhop of the dioceſe, and the twelve apoſtles by twelve regular prieſts, when a ludicrous conteſt ariſes who ſhall repreſent Judas; for the name attaches for life. This office is performed at the weſt end of the church, where an arm-chair is ſet at the bottom, facing the eaſt, for the biſhop; and on each ſide are placed twelve chairs for the twelve prieſts, who are to repreſent the twelve apoſtles. The prayers and hymns uſed on this occaſion are exceedingly beautiful and appropriate; and when the firſt goſpel, relating our Saviour's waſhing of his diſciples feet, begins to be read, the biſhop or patriarch riſes up, and takes off his pontifical veſtments by himſelf without aſſiſtance. He then girds himſelf with a towel, and taking a baſon of water in his hand, kneels down and waſhes one foot of each prieſt, beginning with the youngeſt; and after having waſhed it he kiſſes it. All this is done as the ſeveral circumſtances are read; and when he comes to the laſt prieſt, who is ſuppoſed to repreſent Peter, that prieſt riſeth up and ſaith, "Lord, doſt thou waſh my feet?" &c. The biſhop anſwers in the words of our Saviour; and having finiſhed the whole, puts on his garments again, and ſits down; and as the ſecond goſpel is read (K), repeats the words of our Saviour, "Know ye what I have done unto you?" &c. The office is certainly ancient, and, if decently performed, muſt be affecting.

27 The privileges of the patriarch of Conſtantinople.

Under the word Patriarchs, *Encycl.* we have given a ſufficient account of the riſe of the patriarchates, as well as of the various degrees of rank and authority claimed by the biſhops of ſeveral other ſees in the Greek church. It may be proper to add here, that after the taking of Conſtantinople by Mohammed II. he continued to the patriarch of that city the ſame preſent which the Greek emperors had been accuſtomed to make—a paſtoral ſtaff, a white horſe, and four hundred ducats in gold. To the Greek church and the maintenance of its clergy he left indeed ample revenues, which they have gradually ſacrificed to their inconſtancy,

(I) In the Greek church all pariſh prieſts are called *papas* or popes; and the proto-pope is an archpreſbyter.
(K) The firſt goſpel is John xiii. 3—12. The ſecond goſpel is John xiii. 12—18.

cy, their ambition, and their private jealouſy. Still, however, the patriarch of Conſtantinople fills a very lucrative and high office. "Beſides the power of nominating the other three patriarchs, and all epiſcopal dignitaries (ſays Mr Dallaway), he enjoys a moſt extenſive juriſdiction, compriſing the churches of Anatolia, Greece, Wallachia, Moldavia, and the iſlands of the Archipelago. Since the cloſe of the ſixteenth century, the Ruſſian church has claimed a juriſdiction independent of the ſee of Conſtantinople; though appeals have been made to that ſee in caſes of extraordinary importance. The influence of the patriarch with the Porte is very extenſive, as far as his own nation is concerned. His memorials are never denied; and he can, in fact, command the death, the exile, impriſonment for life, depoſition from offices, or pecuniary fine, of any Greek whom he may be inclined to puniſh with rigour, or who has treated his authority with contempt. On the death of the patriarch the moſt eager competition is exerted to fill the vacant throne; which, as it is obtained by bribery and intrigue, is of courſe a very unſtable ſeat to the ſucceſsful candidate, ſhould another offer to accept the appointment at a lower ſalary." For a fuller account of the doctrines, diſcipline, and worſhip of the Greek church at preſent, we refer the reader to *King's Rites and Ceremonies of the Greek Church in Ruſſia*, and to *Dallaway's Conſtantinople ancient and modern* (publiſhed in 1797); from which two works this abſtract has been moſtly taken.

CHUSAN-Islands, a cluſter of ſmall iſlands on the eaſt coſt of China, which were viſited by Lord Macartney in his courſe to Pekin. Moſt of theſe iſlands ſeem to be hills riſing regularly out of the ſea, and rounded at top, as if any points or angles exiſting in their original formation had been gradually worn off into a globular and uniform ſhape. Many of them, though cloſe to each other, are divided by channels of great depth. They reſt upon a foundation of grey or red granite, ſome part reſembling porphyry, except in hardneſs. They were, certainly, not formed by the ſucceſſive alluvian from the earth brought into the ſea by the great river at whoſe mouth they are ſituated, like the numerous low and muddy iſlands at the mouth of the Po, and many others; but ſhould rather be conſidered as the remains of part of the continent thus ſcooped and furrowed, as it were, into iſlands, by the force of violent torrents carrying off, further into the ſea, whatever was leſs reſiſtable than the rocks juſt mentioned. Some of them wore a very inviting aſpect; one in particular, called Poo-too, is deſcribed as a perfect paradiſe. This ſpot was choſen, no doubt, for its natural beauties, and afterwards embelliſhed, by a ſet of religious men, who, to the number of three thouſand, poſſeſs the whole of it, living there in a ſtate of celibacy. It contains four hundred temples, to each of which are annexed dwelling-houſes and gardens for the accommodation of thoſe monks. This large monaſtery, as it may be called, is richly endowed, and its fame is ſpread throughout the empire.

The Engliſh Eaſt India Company had once a factory at Chuſan, the principal of theſe iſlands, from which they were many years ago interdicted. This, according to the account of a Chineſe merchant who remembered the factory, was not occaſioned by any offence given by the Engliſh, but by the avarice of the officers governing at Canton, who draw large ſums from the accumulation of foreign trade in that port. Perhaps, too, the exceſſive jealouſy of the Chineſe government might fancy danger in the unreſtrained communication between foreigners and the ſubjects of that empire in ſeveral of its ports at the ſame time.

Ting-hai, the chief town of Chuſan, reſembles Venice, but on a ſmaller ſcale. It is ſurrounded, as well as interſected, by canals, over which are thrown ſteep bridges, aſcended by ſteps like the Rialto. The ſtreets are narrow, and paved with ſquare flat ſtones; but the houſes, unlike the Venetian buildings, are low and moſtly of one ſtory. The ornaments of theſe buildings are confined chiefly to the roofs, on the ridges of which are uncouth figures of animals in clay, ſtone, or iron. The town is full of ſhops, containing chiefly articles of clothing, food, and furniture, diſplayed to full advantage. Even coffins are painted in a variety of lively and contraſting colours. The ſmaller quadrupeds, including dogs, intended for food, are expoſed alive for ſale, as well as poultry, and fiſh in tubs of water, with eels in ſand. When the gentlemen belonging to the embaſſy were at Ting-hai, they were ſtruck with the number of places where tin-leaf and ſticks of odoriferous wood were ſold for burning in the temples, which indicated no ſlight degree of ſuperſtition in the people. Superſtition, however, made them not idle; for throughout the whole place there was a quick and active induſtry. Men paſſed buſily through the ſtreets, while not an individual was ſeen aſking alms; and the women were employed in the ſhops. At Chuſan, the number of valuable harbours, or places of perfect ſecurity for ſhips of any burden, is almoſt equal to the number of iſlands. This advantage, together with that of their central ſituation, in reſpect to the eaſtern coſt of China, and the vicinity of Corea, Japan, Leoo-keoo, and Formoſa, attract conſiderable commerce, eſpecially to Ning-poo, a city of great trade in the adjoining province of Che-chiang, to which all the Chuſan iſlands are annexed. From one port in that province twelve veſſels ſail annually for copper to Japan.

According to Brookes, Chuſan is in N. Lat. 30. 0. E. Long. 124. 0.

CINARA, or Cynara, which we tranſlate *artichoke*, is, according to Profeſſor Beckmann, the name which was given by the ancients to a plant very different from the artichoke of our kitchen gardens, though he admits that they belong to the ſame genus. The proofs which he adduces for the truth of his opinion are too tedious to be introduced into this Work, eſpecially as they appear not to us to be abſolutely concluſive. We muſt therefore refer the reader to his Hiſtory of Inventions. The *cinara*, *carduus*, and *ſcolymus* (ſee Scolymus in this Supplement), were in his opinion ſpecies of the *thiſtle*, of which the *roots* and young *ſhoots*, as well as the bottom of the *calyx* of the laſt, were eaten. He has proved indeed, he thinks, that the Greeks and Romans uſed the pulpy bottom of the calyx, and the tendereſt ſtalks and young ſhoots of many plants belonging to the thiſtle kind, in the ſame manner as we uſe artichokes and cardoons, but that theſe latter were unknown to them.

"It appears probable (ſays he) that the uſe of theſe thiſtles, at leaſt in Italy and Europe in general, was in the courſe of time laid aſide and forgotten, and that the

arti-

artichoke, when it was firſt brought to Italy from the Levant, was conſidered as a new ſpecies of food. It is undoubtedly certain that our artichoke was firſt known in that country in the 15th century. Hermolaus Barbarus, who died in 1494, relates that this plant was firſt ſeen at Venice in a garden in 1473, at which time it was very ſcarce. About the year 1466, one of the family of Strozza brought the firſt artichokes to Florence from Naples. Politian, in a letter in which he deſcribes the diſhes he found at a grand entertainment in Italy in 1488, among theſe mentions artichokes. They were introduced into France in the beginning of the 16th century, and into England in the reign of Henry VIII."

The original country of the artichoke is unknown. Linnæus ſays that it grew wild in Narbonne, Italy, and Sicily, as the cardoon did in Crete; but our author has proved very ſufficiently, that with reſpect to both theſe facts the great botaniſt was miſinformed. The artichoke is certainly known in Perſia; but Tavernier ſays expreſsly, that it was carried thither, like aſparagus and other European vegetables of the kitchen garden, by the Carmelite and other monks; and that it was only in latter times that it became common.

CINNABAR. See CHEMISTRY in this Supplement, n° 91.

CIRCLE OF CURVATURE, or circle of equicurvature, is that circle which has the ſame curvature with a given curve at a certain point; or that circle whoſe radius is equal to the radius of curvature of the given curve at that point.

CIRCLES *of Declination* are great circles interſecting each other in the poles of the world.

CIRCLE *of Diſſipation*, in optics. See OPTICS, *Encycl.* n° 253.

CIRCLE *Equant*, in the Ptolemaic aſtronomy, is a circle deſcribed on the centre of the equant. Its chief uſe is to find the variation of the firſt inequality.

CIRCLES *of Excurſion* are little circles parallel to the ecliptic, and at ſuch a diſtance from it, as that the excurſions of the planets towards the poles of the ecliptic may be included within them; being uſually fixed at about 10 degrees.

CIRCLES *of Poſition*, are circles paſſing through the common interſections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any ſtar, or other point in the heavens; and are uſed for finding out the ſituation or poſition of any ſtar. Theſe are uſually ſix in number, cutting the equinoctial into 12 equal parts, which the aſtrologers call the *celeſtial houſes*, and hence they are ſometimes called *circles of the celeſtial houſes.*

CIRCULAR LINES, a name given by ſome authors to ſuch ſtraight lines as are divided by means of the diviſions made in the arch of a circle; ſuch as the ſines, tangents, ſecants, &c.

CIRCULAR *Parts*, called, from the uſe which he firſt made of them, *Napier's* circular parts, are the five parts of a right-angled or a quadrantal ſpherical triangle; they are the two legs, the complement of the hypothenuſe, and the complements of the two oblique angles.

Concerning theſe circular parts, Napier gave a general rule in his *Logarithmorum Canonis Deſcriptio*, which is this; "The rectangle under the radius and the ſine of the middle part is equal to the rectangle under the tangents of the adjacent parts, and to the rectangle under the coſines of the oppoſite parts. The right angle or quadrantal ſide being neglected, the two ſides and the complements of the other three natural parts are called the *circular parts*, as they follow each other as it were in a circular order. Of theſe, any one being fixed upon as the middle part, thoſe next it are the adjacent, and thoſe fartheſt from it the oppoſite parts."

This rule contains within itſelf all the particular rules for the ſolution of right-angled ſpherical triangles, and they were thus brought into one general comprehenſive theorem, for the ſake of the memory; as thus, by charging the memory with this one rule alone: All the caſes of right-angled ſpherical triangles may be reſolved, and thoſe of oblique ones alſo, by letting fall a perpendicular, excepting the two caſes in which there are given either the three ſides, or the three angles. And for theſe a ſimilar expedient has been deviſed by Lord Buchan and Dr Minto, which may be thus expreſſed: "Of the circular parts of an oblique ſpherical triangle, the rectangle under the tangents of half the ſum and half the difference of the ſegments at the middle part (formed by a perpendicular drawn from an angle to the oppoſite ſide), is equal to the rectangle under the tangents of half the ſum and half the difference of the oppoſite parts." By the circular parts of an oblique ſpherical triangle are meant its three ſides and the ſupplements of its three angles. Any of theſe ſix being aſſumed as a middle part, the oppoſite parts are thoſe two of the ſame denomination with it, that is, if the middle part is one of the ſides, the oppoſite parts are the other two, and, if the middle part is the ſupplement of one of the angles, the oppoſite parts are the ſupplements of the other two. Since every plane triangle may be conſidered as deſcribed on the ſurface of a ſphere of an infinite radius, theſe two rules may be applied to plane triangles, provided the middle part be reſtricted to a ſide.

Thus it appears that two ſimple rules ſuffice for the ſolution of all the poſſible caſes of plane and ſpherical triangles. Theſe rules, from their neatneſs, and the manner in which they are expreſſed, cannot fail of engraving themſelves deeply on the memory of every one who is a little verſed in trigonometry. It is a circumſtance worthy of notice, that a perſon of a very weak memory may carry the whole art of trigonometry in his head.

CIRCULATING DECIMALS. See DECIMALS in this Supplement.

CLOCK, a machine for meaſuring time, of which a deſcription is given in the Encyclopædia. For the ſcientific principles of *clock* and *watch-making*, as well as for a ſhort account of the moſt valuable conſtructions, ſee WATCH-*Making* in this Supplement.

COACH, as we have obſerved in the Encyclopædia, is a very modern invention, if by that word be meant a covered carriage ſuſpended on ſprings. We learn, indeed, from the laborious reſearches of Profeſſor Beckmann, that coaches of ſome kind were known in the beginning of the 16th century; but they were uſed only by women of the firſt rank, for the men thought it diſgraceful to ride in them. At that period, when the electors and princes did not chooſe to be preſent at the meetings of the ſtates, they excuſed themſelves by informing the emperor that their health did not permit them

Coach. them to ride on horfeback; and it was confidered as a point eftablifhed, that it was unbecoming for them to ride like women. It is certain, however, that, about the end of the 15th century, the emperor, kings, and princes, began to employ covered carriages on journeys, and afterwards on public folemnities.

The wedding carriage of the firft wife of the Emperor Leopold, who was a Spanifh princefs, coft, together with the harnefs, 38,000 florins. The coaches ufed by that Emperor are thus defcribed by Kink: "In the imperial coaches no great magnificence was to be feen; they were covered over with red cloth and black nails. The harnefs was black, and in the whole work there was no gold. The pannels were of glafs, and on this account they were called the *imperial glafs coaches*. On feftivals the harnefs was ornamented with red filk fringes. The imperial coaches were diftinguifhed only by their having leather traces; but the ladies in the imperial fuite were obliged to be contented with carriages, the traces of which were made of ropes." At the magnificent court of Duke Erneft Auguftus of Hanover, there were in the year 1681 fifty gilt coaches with fix horfes each. So early did Hanover begin to furpafs other cities in the number of its carriages. The firft time that ambaffadors appeared in coaches on a public folemnity was at the imperial commiffion held at Erfurth in 1613 refpecting the affair of Juliers.

In the hiftory of France we find many proofs that at Paris, in the 14th, 15th, and even 16th centuries, the French monarchs rode commonly on horfes, the fervants of the court on mules, and the princeffes, together with the principal ladies, fometimes on affes. Perfons of the firft rank often fat behind their equerry, and the horfe was often led by fervants. Carriages, however, of fome kind appear to have been ufed very early in France. An ordinance of Philip the Fair, iffued in 1294 for fuppreffing luxury, and in which the citizens wives are forbid to ufe carriages (*cars*), is ftill preferved. Under Francis I. or rather about 1550, fomewhat later, there were in Paris for the firft time only three coaches.

The oldeft carriages ufed by the ladies in England were known under the now forgotten name of *whirlicotes*. When Richard II. towards the end of the 14th century, was obliged to fly before his rebellious fubjects, he and all his followers were on horfeback; his mother only, who was indifpofed, rode in a carriage. This, however, became afterwards fomewhat unfafhionable, when that monarch's queen, Ann, the daughter of the Emperor Charles IV. fhewed the Englifh ladies how gracefully and conveniently fhe could ride on a fidefaddle. Whirlicotes were laid afide, therefore, except at coronations and other public folemnities. Coaches were firft known in England about the year 1580, and, as Stow fays, were introduced from Germany by Fitzallen, earl of Arundel. In the year 1598, when the Englifh ambaffador came to Scotland, he had a coach with him. Anderfon places the period when coaches began to be in common ufe about the year 1605. The celebrated duke of Buckingham, the unworthy favourite of two kings, was the firft perfon who rode with a coach and fix horfes, in 1619. To ridicule this new pomp, the earl of Northumberland put eight horfes to his carriage.

Refpecting the progrefs of luxury with regard to coaches, the reader will find much curious information in the firft volume of Profeffor Beckmann's *Hiftory of Inventions*. It is perhaps one of the moft entertaining articles in that very learned work. The author, however, with all his labour, has not been able to afcertain the country in which coaches hung on fprings were firft ufed; but he feems inclined to give the credit of the invention to Hungary.

Cobalt. COBALT (fee CHEMISTRY-*Index*, in this Supplement), is a valuable article to potters and dyers. To fit it for their ufe, it is firft roafted and freed from the foreign mineral bodies with which it is united: it is then well calcined, and fold either mixed or unmixed with fine fand under the name of zaffer (*zaffera*); or it is melted with filiceous earth and potafhes to a kind of blue glafs called *fmalt*, which when ground very fine is known in commerce by the name of *powder blue*. All thefe articles, becaufe they are moft durable pigments, and thofe which beft withftand fire, and becaufe one can produce with them every fhade of blue, are employed above all for tinging cryftal and for enamelling; for counterfeiting opaque and tranfparent precious ftones, and for painting and varnifhing real porcelain and earthen and potters ware. This colour is indifpenfably neceffary to the painter when he is defirous of imitating the fine azure colour of many butterflies and other natural objects; and the cheaper kind is employed to give a blueifh tinge to new-wafhed linen, which fo readily changes to a difagreeable yellow, though not without injury to the health as well as to the linen.

Profeffor Beckmann, in his *Hiftory of Inventions*, gives the following account of the paint prepared from cobalt. "About the end of the 15th century cobalt appears to have been dug up in great quantity in the mines on the borders of Saxony and Bohemia, difcovered not long before that period. As it was not known at firft to what ufe it could be applied, it was thrown afide as a ufelefs mineral. The miners had an averfion to it, not only becaufe it gave them much fruitlefs labour, but becaufe it often proved prejudicial to their health by the arfenical particles with which it was combined; and it appears even that the mineralogical name *cobalt* then firft took its rife. At any rate, I have never met with it before the beginning of the 16th century; and Mathefius and Agricola feem to have firft ufed it in their writings. Frifch derives it from the Bohemian word *kow*, which fignifies *metal;* but the conjecture that it was formed from *cobalus*, which was the name of a fpirit that, according to the fuperftitious notions of the times, haunted mines, deftroyed the labours of the miners, and often gave them a great deal of unneceffary trouble, is more probable; and there is reafon to think that the latter is borrowed from the Greek. The miners, perhaps, gave this name to the mineral out of joke, becaufe it thwarted them as much as the fuppofed fpirit, by exciting falfe hopes, and rendering their labour often fruitlefs. It was once cuftomary, therefore, to introduce into the church fervice a prayer that God would preferve miners and their works from *kobolts* and fpirits.

"Refpecting the invention of making an ufeful kind of blue glafs from cobalt, we have no better information than that which Klotzfch has publifhed from the papers of Chriftian Lehmann. The former, author of an hiftorical work refpecting the upper diftrict of the mines in Mifnia, and a clergyman at Scheibenberg, collected with

Cobalt.

with great diligence every information that respected the history of the neighbouring country, and died at a great age in 1688. According to his account, the colour-mills at the time when he wrote were about 100 years old; and as he began first to write towards the end of the thirty years war, the invention seems to fall about 1540 or 1560. He relates the circumstance as follows: 'Christopher Schurer, a glass-maker at Platten, a place which belongs still to Bohemia, retired to Neudeck, where he established his business. Being once at Schneeberg, he collected some of the beautiful coloured pieces of cobalt which were found there, tried them in his furnace; and finding that they melted, he mixed some cobalt with glass metal, and obtained fine blue glass. At first he prepared it only for the use of the potters; but in the course of time it was carried as an article of merchandise to Nuremberg, and thence to Holland. As painting on glass was then much cultivated in Holland, the artists there knew better how to appreciate this invention. Some Dutchmen therefore repaired to Neudeck, in order that they might learn the process used in preparing this new paint. By great promises they persuaded the inventor to remove to Magdeburg, where he also made glass from the cobalt of Schneeberg; but he again returned to his former residence, where he constructed a handmill to grind his glass, and afterwards erected one driven by water. At that period the colour was worth $7\frac{1}{2}$ dollars per cwt. and in Holland from 50 to 60 florins. Eight colour mills of the same kind, for which roasted cobalt was procured in casks from Schneeberg, were soon constructed in Holland; and it appears that the Dutch must have been much better acquainted with the art of preparing, and particularly with that of grinding it, than the Saxons; for the Elector John George sent for two colour makers from Holland, and gave a thousand florins towards the enabling them to improve the art. He was induced to make this advance chiefly by a remark of the people of Schneeberg, that the part of the cobalt which dropped down while it was roasting contained more colour than the roasted cobalt itself. In a little time more colour-mills were erected around Schneeberg. Hans Burghard, a merchant and chamberlain of Schneeberg, built one, by which the eleven mills at Platten were much injured. Paul Nordhoff, a Frieslander, a man of great ingenuity, who lived at the Zwittermill, made a great many experiments in order to improve the colour; by which he was reduced to so much poverty that he was at length forced to abandon that place, where he had been employed for ten years in the colour-manufactory. He retired to Annaberg, established there in 1649, by the assistance of a merchant at Leipsic, a colour-manufactory, of which he was appointed the director; and by these means rendered the Annaberg cobalt of utility. The consumption of this article, however, must have decreased in the course of time; for in the year 1659, when there were mills of the same kind at more of the towns in the neighbourhood of mines, he had on hand above 8000 quintals.' Thus far Lehmann."

Kossler says, that the Bohemian cobalt is not so good as that of Misnia, and that its colour is more like that of ashes. We trust, however, that the qualities of foreign cobalt shall soon be a matter of little importance to the British artist, as a rich mine of this mineral has lately been discovered near Penzance in Cornwal.

Coffea.

COFFEA, the *Coffee-Tree*, is a plant which has been botanically described in the Encyclopædia Britannica, where some account is likewise given of the modes of cultivating it, as well as of the qualities of its fruit. Since that account, however, was published, two works have fallen into our hands, from which we deem it our duty to make such extracts as may not only correct some mistakes which we had committed, but also communicate useful information to the public.

In our former article we adopted the common opinion, that the coffee produced in Arabia is so greatly superior to that which is raised everywhere else, that it is vain to think of cultivating the plant to any extent in the West India islands. We are happy to find that this is a vulgar error. In the year 1783, when the cultivation of coffee was not so well understood in Jamaica as at present, some samples from that island were produced in London, and pronounced by the dealers to be equal to the very best brought from the East. "Two of the samples were equal to the best Mocha coffee, and two more of them superior to any coffee to be had at the grocers shops in London, unless you will pay the price of *picked* coffee for it, which is two shillings per pound more than for that which they call the *best* coffee. All the rest of the samples were far from bad coffee, and very little inferior, if at all, to what the grocers call *best* coffee *."

* *Moseley's Treatise on Coffee.*

If this be so, it surely becomes the legislature of Great Britain to encourage the cultivation of coffee in the West Indies, especially as it thrives best in soil which is not fit for the sugar-cane, and may be raised in considerable quantities by those who are not able to stock a sugar plantation. The encouraging every article which increases the intercourse with our colonies is increasing our commerce. The payment for all the staples of the West Indies is made in our manufactures; the sale of which must increase in proportion to the numbers that are employed in the cultivation of what is bartered for them. Our West India islands, without draining us of specie or bullion, can supply us with many of those very articles for which we are drained in other parts of the world, and particularly with coffee.

To give a detailed account of the introduction of the coffee-tree into the West Indies, would swell this article to very little purpose. According to Boerhaave, a Dutch governor was the first person who procured fresh berries from Mocha, and planted them in Batavia; and in the year 1690 sent a plant from thence to Amsterdam, which came to maturity, and produced those berries which have since furnished all that is now cultivated in the West Indies.

In 1714 a plant from the garden of Amsterdam was sent by Mr Pancras, a burgomaster and director of the botanic garden, as a present to Louis XIV. which was placed in the garden at Marly. In 1718, the Dutch began to cultivate coffee in Surinam; in 1721, the French began to cultivate it at Cayenne; in 1727, at Martinico; and in 1728, the English began to cultivate it in Jamaica.

As it has been more cultivated in the French West India islands than in the British, it may be of importance to our colonists to be made acquainted with the practice of the French planters. Accordingly Dr Laborie, a royalist of St Domingo, has lately published a volume for their instruction on this subject; in which are

are many judicious obfervations, the refult of long experience, refpecting the foil fit for a coffee plantation; the various eftablifhments neceffary; the cultivation of the coffee-tree through the feveral ftages of its growth and duration; and the management and ufe of the negroes and cattle.

With refpect to foil, it is a fact, fays he, beyond contradiction, that low lands, and even the mountains near the champaign country, are lefs proper for the production of coffee, than lands which are high and at a diftance from the fea. The coffee-tree delights in a comparatively cool climate, and in an open and permeable virgin foil; and is hurt by the parching deftructive air of the fea. The foil on the mountains of St Domingo confifts generally of a bed of mould more or lefs deep; but which, for the production of coffee-trees, ought not to be lefs than four or five feet. If the declivity be gentle, the fofteft and moft friable earth is preferable to all others; but in fteep grounds a firm though not clayey foil, mixed with a proportion of gravel or fmall ftones, through which the water may find an eafy way, is the moft defirable. The colour of the ground is of little confequence, though fuch as is fomewhat reddifh is generally to be preferred. With regard to expofure, the north and weft are the moft eligible in low and hot fituations, becaufe thefe expofures are the cooleft; and on the higheft mountains the fouth and eaft are to be chofen, becaufe they are the hotteft. On the whole, neither the higheft nor the loweft fituations are the beft, but thofe which are confiderably above the middle of the mountains.

Whatever be the planter's circumftances in point of fortune, and our author thinks that he ought not to undertake a fettlement without the command of 3000 or 4000 pounds fterling, he ought not to fet out with a great number of negroes. If he cannot command a plentiful fupply of victuals from fome contiguous plantation, fix, or at the moft twelve, male negroes, with one or two women, will be found fufficient to make the firft effay. After building two huts, one for the mafter or overfeer and the other for the flaves, they are to commence their operations by cutting away the underwood and creeping plants with the bill, and felling the trees. The trees are to be cut as low as poffible, but the roots are to be left in the ground, becaufe they preferve the foil during the firft period of culture; and in burning this mafs of wood and fhrubs, the only way fometimes of clearing the ground, care muft be taken that the fire be nowhere fo violent as to convert the foil into the confiftence of brick, which it is very apt to do if the foil be clayey. Amid the coffee-trees, after they are planted, may be fown beans, maize, and all kinds of efculent plants, pot herbs, and roots; but particular care muft be taken to remove from thefe plantations all creeping plants, fuch as melons, yams, potatoes, gourds, and more efpecially tobacco, which multiplies to a vaft extent, and exhaufts the ground.

In St Domingo the moft approved method of planting the coffee-tree is in ftraight rows croffing each other at right angles, and the diftance between the plants is regulated by the quality and expofure of the ground. The richer the foil, the expofures being the fame, and the cooler the expofure, the quality of the foil being the fame, the farther muft the trees be planted afunder. If on the north and weft the ground be good, plant ftill farther; but, on the contrary, if to the eaft or fouth it be light (which it generally is), plant ftill nearer. Thus if it be proper on a fouth or eaft expofure to plant at the diftance of fix feet, it will be neceffary to plant at the diftance of feven on a weft or north expofure, if the ground be of the fame quality as in the other fituations.

Though coffee, like all other vegetables, grows from the feed, Dr Laborie advifes, in the forming of large plantations, to make ufe of faplings reared in nurferies; and the fituation fitteft for a nurfery is a plain, or at leaft a ground of gentle afcent, where the mould is crumbly. In forming a nurfery, fome plant the whole cherry; but our author recommends the taking off the fkin, and wafhing the feparated feeds; in which we fufpect that he is miftaken, as his practice is certainly a deviation from nature. The nurfery muft be kept very clear of weeds, and neither corn nor any thing elfe fown in it.

The beft feafon for tranfplanting the faplings is during the genial rains of April and May, when great attention is required, as the treafures of future harvefts are at ftake. Thofe plants are the fitteft for being removed which, in the language of our author, are *crowned*, or have each four little boughs; and, if the feeds were frefh and fown in furrows about an inch from each other, this perfection is generally attained in the courfe of a year. The faplings muft not be pulled up by force, but carefully raifed by means of a flat, fharp, iron fhovel, thruft deep under their roots; and the fooner they are planted, after being taken up, the better.

In planting, the firft thing to be done is to thruft into the ground a dibble, or fharp pointed ftick, round which a hole is dug from nine to twelve inches in diameter, and from fifteen to eighteen in depth. Then a quantity of the mould taken out of the hole is thrown back into it, till its depth be diminifhed about four or fix inches; and the plant being fupported with the left hand, in the middle of the hole, while the end of its ftraight root, which our author calls its pivot, touches lightly the new bed, the furrounding mould is with the right hand thrown in, to the height of fix inches. This being lightly preffed down with both hands, more earth is thrown in and preffed in the fame manner, care being taken not to hurt, or bend, or difplace the fapling, which muft be fet fo deep that its two inferior branches be rather below the level of the ground. On this account three or four inches of the hole are left open, which, by the time that thefe branches rife above its margin, are filled up by the furrounding earth. The bufinefs is finifhed by finking the fharp-pointed ftick at the upper margin of the hole, where it ferves as a fmall fence to the infant tree. In hot fituations plantain trees are intermingled with the coffee trees for the purpofe of fhade and coolnefs. They are ufually placed in every fourth or fixth row, as the trees are more or lefs diftant, and the expofure more or lefs hot.

To the bufinefs of planting very foon fucceeds that of weeding; for there is hardly any plant to which weeds are fo pernicious as the coffee-tree: they caufe it to grow yellow, fade, wither, and perifh. Where the ground flopes much, efpecially if the foil be foft and friable, the weeds muft be taken up by the hand; for if they be rooted out by the hoe, the foil will be fo loofened that the rains will fweep it away. Some weeds,

weeds, however, from the depth of their roots muſt be dug up; and when that is the caſe the earth muſt be carefully returned and preſſed down. If, in weeding, any ſaplings be found withered, others of the ſame ſize muſt be brought from the nurſery and planted in their ſtead, with what our author calls their clod, *i. e.* with the earth of the nurſery adhering to their roots. If any ſapling be found broken or twiſted, it muſt be cut cloſe by the ground in a ſloping direction, the cut ſurface facing the north, and it will ſoon put forth ſuckers, of which the beſt only need be preſerved. In plantations of eighteen or twenty months old trees are often found with yellow, withered leaves, of which the cauſe is ſometimes a premature load of fruit, which muſt therefore be inſtantly removed or the tree will periſh. If, after this, it begin not in a few days to recover, it is probably eaten at the roots by a large white worm reſembling a ſlug. In that caſe the tree muſt be removed, the worm taken out, and before another tree be planted in its ſtead, a large hole muſt be made in the ground, expoſed to the influence of the ſun at leaſt for a fortnight.

The natural height of the coffee tree is from 15 to 18 feet; and if left to itſelf it would have the form of moſt other trees, *i. e.* a naked trunk and a branchy head. This is prevented by what the planters call *ſtopping*; which is performed by cutting off the top of the tree when it has arrived at the proper height, which varies according to circumſtances. In the beſt ſoil and moſt genial expoſure, it is ſuffered to grow to the height of five feet, and in the worſt ſtopped at two; but under the ſame aſpect, and on ground of the ſame quality, all the trees ought to be ſtopped at the ſame height. This operation of ſtopping is very apt to make the trees put forth ſuperfluous branches, which renders them inacceſſible to the genial warmth of the ſun, and, of courſe, deficient in the powers of fructification. Theſe muſt be *plucked* away while yet tender; for if they be ſuffered to grow till it become neceſſary to cut them, a number of ſprouts ſucceed; whereas, when they are plucked, the wound ſoon cicatrizes, and nothing follows.

The ſaw and the knife, however, muſt ſometimes be uſed; for when trees grow old their heads are apt to ſpoil; ſuperfluous branches may have been left upon them through neglect; a bough may have been broken by accident; or branches may be ſpent by too great a load of fruit. In all theſe caſes recourſe muſt be had to pruning, which ſhould be performed immediately after crop, and in ſuch a manner as that the tree, when it puts forth its new branches, may ſtill have as much as poſſible its natural or former appearance. This will be accompliſhed by cutting the withered bough immediately above a knot, whence a good ſecondary branch is put forth, which may be eaſily trained into the proper ſhape. Our author directs the cut to be always made ſo as that the ſloping ſurface ſhall face the north; by which expoſure it will eſcape the injury which it would otherwiſe receive from the exceſſive heat of the ſun. This is a good advice; but it would ſtill be an improvement on it to treat the wound with Forſyth's or Hit's plaſter, which we have deſcribed elſewhere (See *Encycl.* Vol. XVIII. page 562). When the tree is completely pruned, the moſs and other excreſcences muſt be ſcraped from the trunk with a wooden knife, great care being taken not to injure the bark.

After pruning follows what is called *nipping*. This is nothing more than the removal of thoſe ſuperfluous ſmall twigs which are ſent forth from every cut ſurface in ſuch numbers as would ſoon exhauſt the tree; and it is called nipping, becauſe they are plucked away by the hand, and not cut by the knife. It is needleſs to add, that when the ground begins to be impoveriſhed, it muſt be enriched by proper manure. This is known to every huſbandman both in Europe and in the Weſt Indies; but it is not perhaps ſo generally known that the weedings, and chiefly the red ſkins of coffee, when gathered into pits, are, in proceſs of time, converted into a black mould, which our author ſays makes the very beſt manure.

"The fruit of the coffee, when perfectly ripe, appears like a ſmall oval cherry. Under a red and ſhining ſkin a whitiſh clammy luſcious pulp preſents itſelf, which generally incloſes two ſeeds. Theſe ſeeds have one ſide flat, the other hemiſpherical. The firſt is marked with a longitudinal fiſſure, and the flat ſides are applied to each other. When the ſeeds are opened, they are found covered with a white, ligneous, brittle membrane, denominated *parchment*; on the inſide of which is another ſilver-coloured membrane, exceedingly thin, and ſeeming to originate from the fiſſure of the ſeeds. Sometimes the cherry has but one ſeed or grain, which then is in the form of a ſmall egg. This is peculiar to old decayed trees, or to the extremities of ſome ſmall branches."

The buſineſs of preparation conſiſts in taking the ſeed from its covering, in drying, and in cleaning it ſo as to have every advantage at market. Our author thinks that the beſt method of preparing the coffee is to ſtrip the ſeed of its outer ſkin immediately on its being pulled, and to dry it in its parchment. The proceſs has been already deſcribed in the Encyclopædia; but we believe it to be an injudicious one. We have the authority of a very eminent botaniſt *, well acquainted with all the vegetable productions of the Weſt Indies, to ſay, that the improvement which we have there mentioned, as propoſed by Mr Miller, is greatly preferable to Dr Laborie's practice. Indeed he himſelf admits, that coffee dried in the cherry is more heavy than when dried in parchment, and that it generally has a higher flavour. Nay, he ſays expreſsly, that "if a planter wants to have coffee of the firſt quality, either for himſelf or for his friends, he muſt ſet a part a number of his oldeſt trees, and not gather the fruit till it is ripened into *dryneſs*. It is in that manner, he believes, that the Arabians in Yemen make their little harveſts; and he declares, that coffee thus nouriſhed on the tree to the laſt moment, muſt have every perfection of which it is capable." His only plauſible objection is, that the trees are ſoon exhauſted when the fruit is left ſo long upon them; but doubtleſs this exhauſtion might be retarded by proper manure.

* *Dr Wright.*

The chemical analyſis of coffee evinces that it poſſeſſes a great portion of mildly bitter and lightly aſtringent gummous and reſinous extract; a conſiderable quantity of oil; a fixed ſalt; and a volatile ſalt.—Theſe are its medicinal conſtituent principles. The intention of torrefaction is not only to make it deliver thoſe principles, and make them ſoluble in water, but to give it a property it does not poſſeſs in the natural ſtate of the berry. By the action of fire, its leguminous taſte and the

the aqueous part of its mucilage are deftroyed ; its faline properties are created and difengaged, and its oil is rendered empyreumatic.—From thence arifes the pungent fmell, and exhilarating flavour, not found in its natural ftate.

The roafting of the berry to a proper degree requires great nicety : Du Four juftly remarks, that the virtue and agreeablenefs of the drink depend on it, and that both are often injured in the ordinary method. Bernier fays, when he was at Cairo, where it is fo much ufed, he was affured by the beft judges, that there were only two people in that great city, in the public way, who underftood the preparing it in perfection. If it be under-done, its virtues will not be imparted, and in ufe it will load and opprefs the ftomach :—If it be overdone, it will yield a flat, burnt, and bitter tafte, its virtues will be deftroyed, and in ufe it will heat the body, and act as an aftringent.

Fourteen pounds weight of raw coffee is generally reduced, at the public roafting houfes in London, to eleven pounds by the roafting ; for which the dealer pays feven pence half-penny, at the rate of five fhillings for every hundred weight. In Paris, the fame quantity is reduced to ten pounds and an half. But the roafting ought to be regulated by the age and quality of the coffee, and by nicer rules than the appearance of the fumes, and fuch as are ufually practifed : therefore the reduction muft confequently vary, and no exact ftandard can be afcertained. Befides, by mixing different forts of coffee together, that require different degrees of heat and roafting, coffee has feldom all the advantages it is capable of receiving to make it delicate, grateful, and pleafant. This indeed can be effected no way fo well as by people who have it roafted in their own houfes, to their own tafte, and frefh as they want it for ufe. The clofer it is confined at the time of roafting, and till ufed, the better will its volatile pungency, flavour, and virtues, be preferved.

The mode of preparing this beverage for common ufe differs in different countries, principally as to the additions made to it.—But though that is generally underftood, and that tafte, conftitution, the quality of the coffee, and the quantity intended to be drunk, muft be confulted, in regard to the proportion of coffee to the water in making it—yet there is one material point, the importance of which is not well underftood, and which admits of no deviation.

The prefervation of the virtues of coffee, particularly when it is of a fine quality, and exempt from ranknefs, as has been faid, depends on carefully confining it after it has been roafted ; and not powdering it until the time of ufing it, that the volatile and ethereal principles, generated by the fire, may not efcape. But all this will fignify nothing, and the beft materials will be ufelefs, unlefs the following important admonition is ftrictly attended to ; which is, that after the liquor is made, it fhould be bright and clear, and entirely exempt from the leaft cloudinefs or foul appearance, from a fufpenfion of any of the particles of the fubftance of the coffee.

There is fcarcely any vegetable infufion or decoction whofe effects differ from its grofs origin more than that of which we are fpeaking. Coffee taken in fubftance caufes oppreffion at the ftomach, heat, naufea, and indigeftion : confequently a continued ufe of a preparation of it, in which any quantity of its fubftance is contained, befides being difgufting to the palate, muft tend to produce the fame indifpofitions. The refiduum of the roafted berry, after its virtues are extracted from it, is little more than an earthy calx, and muft therefore be injurious.

The want of attention to this circumftance has been the caufe of many of the complaints againft coffee, and of the averfion which fome people have to it ; and it is from this confideration that coffee fhould not be prepared with milk inftead of water, nor fhould the milk be added to it on the fire, as is fometimes the cafe, for economical dietetic purpofes, where only a fmall quantity of coffee is ufed, as the tenacity of the milk impedes the precipitation of the grounds, which is neceffary for the purity of the liquor, and therefore neither the milk nor the fugar fhould be added until after it is made with water in the ufual way, and the clarification of it is completed (A).—The milk fhould be hot when added to the liquor of the coffee, which fhould alfo be hot, or both fhould be heated together, in this mode of ufing coffee as an article of fuftenance.

If a knowledge of the principles of coffee, founded on examination and various experiments, added to obfervations made on the extenfive and indifcriminate ufe of it, cannot authorife us to attribute to it any particular quality unfriendly to the human frame ; if the unerring teft of experience has confirmed its utility, in many countries, not exclufively productive of thofe inconveniences, habits, and difeafes, for which its peculiar properties feem moft applicable—let thofe properties be duly confidered ; and let us reflect on the ftate of our atmofphere, the food and modes of life of the inhabitants, and the chronical infirmities which derive their origin from thefe fources, and it will be evident what falutary effects might be expected from the general dietetic ufe of coffee in Great Britain.

COFFER-DAMS, or *Batardeaux*, in bridge-building, are enclofures formed for laying the foundation of piers, and for other works in water, to exclude the furrounding water, and fo prevent it from interrupting the workmen.

COLCHESTER, the chief town in Effex, is defcribed in the Encyclopædia Britannica ; but the defcription is in many refpects erroneous. The following account of it was fent to us by an obliging correfpondent, who is defirous that the place of his nativity may be accurately defcribed in this Supplement.

Colchefter is pleafantly fituated upon an eminence, gradually rifing on the fouth fide of the river Colne. It is the ancient *Colonia Camulodunum*, from which word Colonia, both the town and the river Colne received their names. The Saxons called it *Colneceafter*. That it flourifhed under the Romans, feveral buildings full of their bricks, and innumerable quantities of coin dug

(A) It is not to coffee alone that this reflection is confined ; every article we ufe as a diluter demands the fame attention. Malt liquors, particularly fmall beer, which in this refpect is much neglected, ought always to be carefully fined. The fæculent matter entangled by the mucilage of the malt is hurtful to digeftion, and detrimental to health.

dug up in and about it, fully evince. In the year 1763, a curious tessellated or mosaic pavement was found in the garden of the late Mr Barnard, surgeon in the High Street, now the property of Mr John Wallis, about three feet under the surface of the earth. The emperor Constantine the Great was born here, his mother Helen being daughter of Cool, governor or king of this district under the Romans. She is said to have found out the cross of Christ at Jerusalem; and on that account the arms of this town are a cross regulee between three ducal coronets, two in chief and one in base, the coronet in base passing through the cross.

The walls wherewith the town was encompassed are still tolerably entire on the south, east, and west sides, but much decayed on the north side: they are generally about nine feet thick. By a statute of King Henry VIII. this town was made the see of a suffragan bishop.

This town is the most noted in England for making of baize; it is also of special note for candying the eringo roots, and for oysters.

In the conclusion of the civil war 1648, this town suffered a severe siege of ten weeks; and the besieged making a very resolute defence, the siege was turned into a blockade, wherein the garrison and inhabitants suffered the utmost extremity of hunger, being reduced to eat horse-flesh, dogs, and cats, and were at last obliged to surrender at discretion, when their two valiant chief officers, Sir Charles Lucas and Sir George Lisle, were shot under the castle walls in cold blood. Colchester is a borough by prescription, and under that right sends two members to parliament, all their charters being silent upon that head. The charter was renewed in 1763. The town is now governed by a mayor, recorder, 12 aldermen, 18 assistants, and 18 common-council men. Quarter-sessions are held here four times in the year.

The famous abbey gate of St John is still standing, and allowed to be a surprising, curious, and beautiful piece of Gothic architecture, great numbers of persons coming from remote parts to see it. It was built, together with the abbey, in 1097, and Gudo, steward to King William Rufus, laid the first stone.

St Ann's chapel, standing at the east end of the town, is valuable in the esteem of antiquarians as a building of great note in the early days of Christianity, and made no small figure in history many centuries past. It is now pretty entire.

St Botoph's priory was founded by Ernulphus in the reign of Henry I. in the year 1110. It was demolished in the wars of Charles I. by the parliament army under Sir Thomas Fairfax. The ruins still exhibit a beautiful sketch of ancient masonry, much admired by the lovers of antiquities. The castle is still pretty entire, and is a magnificent structure, in which great improvements have of late been made. Here is an excellent and valuable library.

The markets, which are on Wednesday and Saturday, are very well supplied with all kinds of provisions. There are no less than six dissenting meeting-houses in this town. Colchester is 51 miles from London. It had 16 parish churches, in and out of the walls, but now only 12 are used, the rest being damaged at the siege in 1648.

COLOURS. See PIGMENTS in this Supplement.

Accidental COLOURS, a name given to a very curious optical phenomenon, which was first, we believe, attended to by Buffon. That philosopher wrote a short paper on it, which was published in the Memoirs of the Academy of Sciences for the year 1743.

If a person look stedfastly and for a considerable time at a small *red* square painted upon *white* paper, he will at last observe a kind of green-coloured border surround the red square. If he now turn his eyes to some other part of the paper, he will see an imaginary square of a delicate green bordering on blue, and corresponding exactly in point of size with the red square. This imaginary square continues visible for some time, and indeed does not disappear till the eye has viewed successively a number of new objects. It is to this imaginary square that the improper name of *accidental colour* has been given. If the small square be *yellow*, the imaginary square or accidental colour is blue: the accidental colour of green is red; of blue, yellow; of white, black; and on the contrary, that of black is white.

The first person, as far as we know, who gave a satisfactory explanation of these phenomena was Professor Scherffer of Vienna, whose dissertation, translated by Mr Bernoulli, has been published in the 26th volume of the Journal de Physique.

In order to understand these phenomena, let us recollect, in the first place, that light consists of seven rays, namely, red, orange, yellow, green, blue, indigo, violet; that whiteness consists in a mixture of all these rays: and that those bodies which reflect but very little light are black. Those bodies that are of any particular colour, reflect a much greater quantity of the rays which constitute that particular colour than of any other rays. Thus red bodies reflect most red rays; green bodies, most green rays, and so on.

Let us recollect, in the second place, that when two impressions are made at the same time upon any of our organs of sensation, one of which is strong and the other weak, we only perceive the former. Thus if we examine by the prism the rays reflected by a red rose, we shall find that they are of four kinds; namely red, yellow, green, and blue. In this case, the impression made by the red rays makes that made by the others quite insensible. For the same reason, when a person goes from broad day light into an ill-lighted room, it appears to him at first perfectly dark, the preceding strong impression rendering him for sometime incapable of feeling the weaker impression.

With the assistance of these two remarks, it will not be difficult to explain the phenomena of accidental colours. When a person considers attentively for some time a white square lying on any black substance (paper for instance), it is evident that the part of the retina on which the white square is painted, receives a stronger impression than any other part; at least the greatest number of rays strike upon it. A weaker impression, therefore, will act on it with much less force than upon the rest of the retina. Consequently, when the eye is turned from the white square to some other part of the black paper, a square is perceived of the same size with the white square, and much blacker than any other part of the paper: this is evidently in consequence of the weaker impression made by the rays reflected by the black paper upon that part of the eye previously fatigued by the copious reflection from the white square. For the very same reason, if, after looking for a sufficient

cient time at a white ſquare lying on a black ground, we turn our eyes upon a ſheet of white paper, we perceive a very well defined black ſquare. In this caſe, the part of the retina already fatigued is not ſo ſenſible to the rays reflected by the white paper as the other parts of it which have not been fatigued. The reaſon then that *black* is the accidental colour of white is ſufficiently evident.

On the contrary, when we look a ſufficient time at a black ſquare lying upon a white ground, if we turn our eyes to any other part of the white paper, or even upon black paper, we ſhall perceive a ſmall ſquare anſwering to the black ſquare, and much brighter than any other part of the paper: evidently becauſe that part of the retina on which the black ſquare was painted being leſs fatigued is more ſuſceptible of impreſſions than any other part of the eye. Thus we ſee why the accidental colour of black is white, and why that of white on the contrary is black. Theſe facts, indeed, have been long known, and they have been generally explained in this manner.

When a perſon has looked for a ſufficient time at a red ſquare placed on a ſheet of white paper, and then turns his eyes to another part of the paper, that part of the retina on which the red was painted being fatigued, the red rays reflected from the white paper ceaſe to make any ſenſible impreſſion on it, and conſequently there will be ſeen upon the white paper a ſquare ſimilar to the red ſquare, and the colour of which is that which would reſult from the mixture of all the rays of light except the red. In general, therefore, the *accidental colour* is the colour which reſults from the mixture of all the rays of light, thoſe rays excepted which are the ſame with the primitive colour.

Now, in order to diſcover the accidental colours, let us recollect the manner which Newton employed to determine the colour which reſults from the mixture of ſeveral others, the ſpecies and quantity of which are known. He did it by dividing the circumference of a circle, ſo that the arches are to one another in the proportion of a ſtring ſhortened by degrees, in order to ſound one after another the notes of an octave; which is nearly the proportion that the different rays occupy when light is decompoſed by means of the priſm. Or ſuppoſe the circumference of the circle, as uſual, divided into 360 degrees, the different rays, according to Benvenut, ſhould occupy the following arches:

Red, - - - - - -	45°
Orange, - - - - -	27
Yellow, - - - - - -	48
Green, - - - - - -	60
Blue, - - - - - -	60
Indigo, - - - - - -	40
Violet, - - - - - -	80

Let us now compare the action of colours on one another with that of different weights; and for that purpoſe let us ſuppoſe each colour concentrated in the centre of gravity of its arch. In order to find the colour reſulting from any mixture, we have only to find the common centre of gravity of the arches which repreſent the different colours: The colour reſulting from the mixture will be that of the arch to which the common centre of gravity approaches neareſt. And if that common centre of gravity is not in the ſtraight line which joins the centre of the circle, and the centre of gravity of the arch to which it is moſt contiguous, the reſulting colour will approach more or leſs to the colour of the contiguous arch towards which the line, paſſing through the centre of the circle, and the common centre of gravity of the arches, falls. And farther, the reſulting colour will be more or leſs deep according to the diſtance of the common centre of gravity from the centre of the circle.

In the caſe under conſideration at preſent, namely, to determine the different accidental colours, the application of this method is remarkably eaſy; becauſe only one of the ſeven primitive colours is excluded, and conſequently the ſix colours from the mixture of which we wiſh to know the reſulting colour are all contiguous. For it is evident, that the ſum of the ſix arches, repreſenting theſe ſix colours, will be divided into two equal parts by the line which paſſes through the centre of the circle and their common centre of gravity; and that if the ſame line be produced till it reaches the circumference of the circle on the other ſide, it will alſo divide the arch repreſenting the ſeventh or omitted colour into two equal parts. Let us ſuppoſe, for inſtance, that the violet is omitted, and that we wanted to know the colour reſulting from the mixture of the other ſix colours, we have only to biſect the arch repreſenting the violet, and from the point of ſection to draw a diameter to the circle, the arch of the circle oppoſite to the violet through which the diameter paſſes will indicate the colour of the mixture. The arch repreſenting the violet being 80°, let us take the half of it, which is 40°, and let us add to it 45° for the red, 27° for the orange, and 48° for the yellow, we ſhall have 160°, which wants 20° of half the circumference of the circle. If now we add the 60° for the green, the ſum total will be 220°, conſiderably more than half the circumference; conſequently the common centre of gravity is neareſt the green arch; but it falls 10° nearer the yellow than the ſtraight line which joins the centre of the circle and the centre of gravity of the green arch. Hence we ſee that the reſulting colour will be green, but that it will have a ſhade of yellow.

It is evident, then, that the accidental colour of violet muſt be green with a ſhade of yellow; and this is actually the caſe, as any one may convince himſelf by making the experiment.

Suppoſe, now, we wanted to know the accidental colour of *green*, or, which is the ſame thing, the colour reſulting from the mixture of all the primitive rays except the green. The green arch is 60°, the half of which is 30°; if to this we add 60° for the blue arch, and 40° for the indigo arch, we ſhall have 130°, or 50° degrees leſs than a ſemicircle. If to this we add the violet arch, which is 80°, we ſhall have 30° more than the ſemicircle; conſequently the common centre of gravity falls neareſt the violet, and it is 10° nearer the red arch than is the centre of gravity of the violet arch. Hence we know that the accidental colour of green will be violet or purple, with a ſhade of red: And experiment confirms this.

Buffon obſerved that the accidental colour of blue was reddiſh and pale. Let us ſee whether we ſhall obtain the ſame reſult from our method. Let us ſuppoſe that Buffon employed a light blue. In that caſe, if to 30, the half of the blue arch, we add 60 for the green, 48 for the yellow, and 27 for the orange, we ſhall have 165°, or 15° leſs than half the circumference of the

circle:

circle: Consequently the common centre will fall neareſt the red arch, but within 15° of the orange. The accidental colour muſt therefore be red, with a ſhade of orange; or, which is the ſame thing, it muſt be a pale red.

In the ſame manner we may diſcover, that the accidental colour of indigo is yellow, inclining a good deal to orange; and that the accidental colour of indigo and blue together is orange, with a ſtrong ſhade of red. Both of which correſpond accurately with experiment.

It would be eaſy to indicate, in the ſame manner, the accidental colour of any primitive colour, if what has been ſaid were not ſufficient to explain the cauſe of accidental colours, and to ſhow that their phenomena correſpond exactly, both with the Newtonian theory of optics, and with what we know to be laws of our ſenſations in other particulars.

From the theory above given, which is that of Profeſſor Scherffer, the following conſequences may be deduced: 1. The accidental colour of a red ſquare, lying upon a white or a black ground, ought to be blackiſh, if we caſt our eyes upon a red coloured ſurface. 2. If the ſurface upon which we look at a red ſquare be itſelf coloured, if it be yellow, for inſtance, the white paper upon which we afterwards caſt our eyes will appear blue, with a green ſquare in it correſponding to the original red ſquare. And, in general, we ought to perceive the accidental colour of the ground on which the ſquare is placed, as well as the ſquare itſelf. 3. If while we are looking at the little ſquare we change the ſituation of the eye, ſo that its image ſhall occupy a different place on the retina, when we turn our eyes to the white paper we ſhall ſee two ſquares, or at leaſt one unlike the figure of the original one. 4. If the white paper on which we look be farther diſtant than the little ſquare was, the imaginary ſquare will appear conſiderably larger than the true one. 5. If while we are looking at the little ſquare, we gradually make the eye approach to it, without altering its ſituation, the imaginary ſquare will appear with a pale border. Theſe, and many other conſequences that might eaſily be deduced, will be found to take place conſtantly and accurately, if any one chooſes to put them to the teſt of experiment; and therefore may be conſidered as a complete confirmation of the theory given above of the cauſe of accidental colours.

There is another circumſtance reſpecting accidental colours which deſerves attention. If we continue looking ſtedfaſtly at the little ſquare longer than is neceſſary, in order to perceive its accidental colour, we ſhall at laſt ſee its border tinged with the accidental colour of the ground on which the ſquare is lying. For inſtance, if a white ſquare be placed upon blue paper, its border becomes yellow; if upon red paper, it becomes green; and it becomes reddiſh upon green. In like manner, the border of a yellow ſquare becomes greeniſh upon a red ground, and that of a red ſquare on a green ground becomes purple.

The cauſe of this phenomenon ſeems to depend upon the contraction and extenſion of the image of the ſquare painted on the retina. We know for certain, that the diameter of the pupil changes during our inſpecting the ſquare; at firſt it becomes leſs, and afterwards increaſes. And though we cannot ſee what paſſes in the bottom of the eye, we can ſcarcely doubt that ſimilar movements are going on there, if we attend to the changes that are continually taking place in the border of our little ſquare; ſometimes it is large, ſometimes ſmall; at one time it diſappears altogether, and the next moment makes its appearance again.

There is another phenomenon connected with accidental colours, which it is not ſo eaſy to explain; namely, that if we look at theſe little ſquares for a very long time, till the eye is very much fatigued, their accidental colours will appear even after we ſhut our eyes. The very ſame thing takes place if we attempt to look at a very luminous object; as the ſun, for inſtance. Profeſſor Scherffer thinks that this may be partly owing to the light which ſtill paſſes through the eye-lids. That ſome light paſſes through the eye-lids is evident, becauſe when we look towards a ſtrong light with our eye-lids ſhut, we ſee diſtinctly their colour, derived from the blood-veſſels with which they are filled; and if we paſs our finger before our eyes, we ſee the ſhadow of the finger though our eye-lids be ſhut, provided our eyes be turned towards the window. But that this light is not ſufficient to explain the phenomenon in queſtion is evident from this circumſtance, that the ſame accidental colours make their appearance though we go immediately into the darkeſt place. Perhaps we have accounted for the phenomenon elſewhere (See METAPHYSICS, *Encycl.* n° 54.) We paſs over the other conjectures of Profeſſor Scherffer, which are exceedingly ingenious, but not ſufficiently ſupported by facts to be admitted.

COLUMBA NOACHI, *Noah's Dove*, a ſmall conſtellation in the ſouthern hemiſphere, conſiſting of 10 ſtars.

COMAR, or KHOMAR, a Zemindar's demeſne of land.

COMBUSTION is an operation of nature, which, though of the higheſt importance, ſeems not to have attracted much of the attention of philoſophers previous to the ſeventeenth century. Since that period indeed, the labours of Bacon and Boyle, and Hooke and Mayow, together with thoſe of Stahl and Lavoiſier, have thrown much light on the ſubject; as the reader will find by conſulting the articles CHEMISTRY both in this Supplement and in the Encyclopædia. The theory of Lavoiſier is by far the moſt rational that has yet been offered to the public, and places its author in the firſt ranks of philoſophy. He corrects the errors of his predeceſſors, and has advanced before them one very important ſtep; but, as we have elſewhere obſerved, many new ſteps are ſtill wanting to render his theory of combuſtion complete. It explains indeed, in a ſatisfactory manner, why, during the proceſs of combuſtion, the burning body gradually waſtes away; but it gives no explanation of the conſtant emiſſion of heat and light, though a circumſtance as worthy of attention as the waſting of the body.

The emiſſion of light and heat the French chemiſts ſeem indeed to have conſidered as of no importance; for rather than acknowledge that the theory of their juſtly admired and ill-fated aſſociate is incomplete, they have choſen to give a new meaning to the word *combuſtion*; and to make it ſignify the *combination of a body with oxygen*, whether during that proceſs light and heat be evolved or not. Surely ſuch conduct is unphiloſophical; and yet our own chemiſts, with a ſervility which ill becomes the countrymen of Bacon and Newton, Combustion.

ton, have, for the most part, acquiesced in this absurd definition of combustion.

From the class of idolaters of the science of the *great nation* must be excepted Dr Thomson, the author of the article Chemistry in this Supplement. Sensible that *combustion*, in the sense usually affixed to that word, denotes a phenomenon very different from many of those which are included under the term in its new acceptation, he acknowledges the theory of Lavoisier to be defective; but influenced by that diffidence which is the inseparable attendant on the spirit of true philosophy, he has not ventured to complete it in the article to which we have referred. He has indeed formed a theory of his own, and submitted it to public discussion; but, with great propriety, gives it no place in his System of the Science, till it shall have undergone the examination of other chemists.

The conductor of this work, however, persuaded that, while gratifying his readers in general, he shall not injure his friend's fame, embraces with pleasure the opportunity afforded him, by a new edition, of laying before them a concise view of this very ingenious theory.

Dr Thomson, then, admitting the truth and accuracy of the Lavoiserian theory as far as it proceeds, divides the bodies which occupy the attention of chemists into, 1. *Combustibles;* 2. *Supporters of combustion;* and, 3. *Incombustiblts.*

The combustibles, or those bodies which, in common language, are said to *burn*, may be divided into, 1. *Simple* combustibles; 2. *Compound* combustibles; and, 3. Combustible *oxides*. *Simple* combustibles are, *sulphur, phosphorus, carbon, hydrogen*, and all the *metals*, except perhaps *gold, silver*, and *mercury*. *Compound* combustibles consist of compounds formed by the simple combustibles uniting together two and two; and combustible *oxides* are composed of one or more simple combustibles combined with a dose of *oxygen*. These oxides may be arranged under two heads: viz. those which containing only a *single base* combined with oxygen, may therefore be termed *simple* combustible *oxides;* and those which containing *more than one base*, may therefore be termed *compound* combustible oxides. The simple combustible oxides are only four in number; namely, *oxide of sulphur, oxide of phosphorus, charcoal*, and *carbonic oxide gas*. All the simple combustible oxides are by combustion converted into *acids*. The compound combustible oxides include by far the greater number of combustible bodies; for almost all the animal and vegetable substances belong to them, and the double base is usually *carbon* and *hydrogen*.

The supporters *of combustion* are a set of bodies which are not of themselves, strictly speaking, capable of undergoing combustion, but which are absolutely necessary for the process. All the supporters known at present are six; viz. 1. *Oxygen gas;* 2. *Air;* 3. *Gaseous oxide of azot;* 4. *Nitrous gas;* 5. *Nitric acid;* and, 6. *Oxy-muriatic acid.* There are other substances, to be mentioned afterwards, to which the author gives the name of *partial supporters;* but *all* supporters contain one common principle, namely *oxygen.*

The incombustible bodies are neither capable of undergoing combustion themselves, nor of supporting the combustion of bodies that are. Of course, they are not immediately connected with combustion; but they are noticed here, because some of the alkalies and earths, which belong to this class, possess certain properties in common with combustibles, and are capable of exhibiting phenomena somewhat analogous to combustion; phenomena which the author describes under the title of *semi-combustion.*

From the preceding observations it is obvious, that, in every case of combustion, there must be present a *combustible* and a *supporter;* and Lavoisier ascertained beyond a doubt, that, during the process, the combustible always unites with the oxygen of the supporter. This new compound our author calls *a product of combustion;* and maintains that every such product is either *water*, or an *acid*, or a *metallic oxide*. He admits, indeed, that other bodies sometimes make their appearance during combustion; but affirms that these, upon examination, will be found neither to be products, nor to have undergone combustion.

But though the combination of the combustible with oxygen be a constant part of combustion, yet the facility with which combustibles burn is not in proportion to their apparent affinity for that gas. Phosphorus, for instance, burns more readily than charcoal; yet charcoal is capable of abstracting oxygen from phosphorus. The combustible oxides take fire more readily than some of the simple combustibles. Thus, charcoal burns more easily than carbon or diamond; and alcohol, ether, and oils, which are all compound combustible oxides, are exceedingly combustible; whereas the metals, which are simple combustibles, do not burn, when air is the supporter, but at a very high temperature. This facility of burning combustible oxides is probably owing to the weak affinity by which their particles are united; and to the same cause, viz. the inferiority of the cohesion of heterogeneous particles, is to be attributed the fact, that some of the *compound supporters* occasion combustion in circumstances when the combustibles would not be acted on by *simple supporters.*

None of the *products* of combustion are themselves combustible, in the usual and proper acceptation of that word. This, however, is not owing to their being saturated with oxygen, for several of them are capable of combining with an additional dose of it; but during this new combination no caloric nor light is ever emitted, and the compound formed differs essentially from a mere *product* of combustion, being by the additional dose of oxygen converted into a *supporter.*

When the *supporters*, thus formed by the combination of oxygen with *products*, are made to support combustion, they do not lose *all* their oxygen, but only the *additional dose* which constituted them supporters. Of course they are again reduced to their original state of products of combustion; and as they owe their properties as supporters, not to the whole of the oxygen which they contain, but to the additional dose, the author calls them *partial supporters.*

All the partial supporters with which we are acquainted contain a metallic basis; for metallic oxides are the only products at present known capable of combining with an additional dose of oxygen. The following oxides, which are products of combustion, combined each with an additional dose of oxygen, are *partial supporters:* 1. Red oxide of iron; 2. Yellow oxide of gold; 3. White oxide of silver; 4. Red oxide of mercury; 5. Arsenic acid; 6. Red and brown oxides of

Combustion. of lead; 7. Black oxide of manganese; 8. Acidulous oxide of antimony? 9. White oxide of tin.

Thus it appears that several of the products of combustion are capable of combining with oxygen; and hence it follows that the incombustibility of products is not owing to their want of affinity for oxygen, but to some other cause.

Though no *mere product* of combustion is capable of *supporting* combustion, this is not occasioned by any want of affinity for combustible bodies; for several of these products are capable of combining with an additional dose of their bases. By this combination, however, they lose their properties as products, and are converted into *combustibles*; whence it follows that the process must differ essentially from that of combustion. Thus sulphuric acid, a *product* of combustion, by combining with an additional dose of sulphur or its oxide, is converted into *sulphurous acid*; a substance which, from many of its properties, Dr Thomson concludes to be *combustible*. Thus also phosphoric acid, a product of combustion, is capable of combining with phosphorated hydrogen, and forming *phosphorous acid*, a combustible body. When this last acid is heated in contact with a supporter, it undergoes combustion; but it is only the additional dose of the combustible which burns, and the whole is converted into phosphoric acid. Hence we see that it is not the whole basis of these compounds that is combustible, but merely the additional dose; and therefore the compounds themselves may be termed *partial combustibles*, to indicate, that *part* only of the base is capable of undergoing combustion. Now, since the products of combustion are capable of combining with oxygen, but never exhibit the phenomena of combustion, except when they are in the state of partial combustibles, combustible bodies must contain some principle, which they lose during combustion, and to which they owe their combustibility; for after they have lost it, they unite to oxygen without exhibiting the phenomena of combustion.

Though the *products* of combustion are not capable of *supporting* combustion, they not unfrequently part with their oxygen just as supporters do, give it out to combustibles, and convert them into products; but during this process no heat nor light is ever evolved. Water, for instance, gives out its oxygen to iron, and converts it into *black oxide*, a product; and sulphuric acid gives out its oxygen to phosphorus, and converts it into phosphoric acid. Thus we see that the oxygen of products is capable of converting combustibles into products, just as the oxygen of supporters; but during the combination of the last only are heat and light emitted. The oxygen of supporters, then, contains something which the oxygen of products wants.

Whenever the whole of the oxygen is abstracted from products, the combustibility of their base is restored as completely as before combustion; but no substance is capable of abstracting the whole of oxygen, except a *combustible* or a *partial combustible*; and when this is done, the combustible or partial combustible loses its own combustibility by the process, and is converted into a product.

From these facts, which have been all established by Stahl, Lavoisier, and our author, it follows that the products of combustion may be formed without actual combustion: but in these cases a *new combustible* is always evolved. The process is merely an interchange of combustibility; for the combustible is converted into a product only by means of a product. Both the oxygen and the base of the product having undergone combustion, have lost something which is essential to combustion. The process is merely a double decomposition. The product yields its oxygen to the combustible, while, at the same time, the combustible gives out something to the base of the product. The combustibility of that base, then, is restored by the loss of its oxygen, and by the restoration of something which it receives from the other combustible thus converted into a product.

No *supporter* can be produced by combustion, or by any equivalent process. Now as all the supporters, except oxygen gas, consist of oxygen combined with a base, it follows as a consequence, that oxygen may combine with a base, without losing that ingredient, whatever it is, which gives occasion to combustion. The mere act of combination of oxygen with a base, therefore, is by no means the same with combustion.

Several of the supporters and partial supporters are capable of combining with combustibles, without undergoing decomposition, or exhibiting the phenomena of combustion. In this manner the yellow oxide of gold, and the white oxide of silver, combine with ammonia; the red oxide of mercury with oxalic acid; and oxy-muriatic acid with ammonia. Thus also nitre and oxy-muriat of potash may be combined, or at least intimately mixed with several combustible bodies, as in gunpowder, &c. In all these compounds the oxygen of the supporter retains each the ingredients proper to itself, which render them susceptible of combustion; and hence the compound is still combustible. They burn indeed with amazing facility, not only when heated, but when triturated or struck smartly with a hammer; and have received, in consequence, the name of *detonating* or *fulminating* bodies.

Such are the properties of the combustibles, the supporters, and the products; and such the phenomena which they exhibit when made to act upon each other. If we compare together the *supporters* and the *products*, we shall find that they resemble each other in several respects. Both of them contain oxygen as an essential part; both are capable of converting combustibles into products; and of both several combine with combustibles and with additional doses of oxygen. But they differ widely from each other in the phenomena which accompany their action on combustibles. The supporters convert these bodies into products; and at the same time combustion, or the emission of light and heat, takes place; whereas the products convert combustibles into products without any such emission. Now as the ultimate change produced upon combustibles by both these sets of bodies is the same, and as the substance which combines with the combustibles is in both cases the same, namely oxygen, we must conclude that this oxygen in the supporters contains something which the oxygen of the products wants; something which seperates during the passage of the oxygen from the supporter to the combustible, and occasions the combustion, or emission of fire, which accompanies this passage. The oxygen of supporters, then, contains some ingredient

Combustion.

dient which the oxygen of products wants. Many circumstances concur to render it probable that this ingredient is CALORIC.

The *combustibles* and the *products* also resemble each other in several respects. Both of them contain the same or a similar base; both frequently combine with combustibles, and likewise with oxygen: but they differ essentially in the phenomena which accompany their combination with oxygen. In the one case, *fire* is emitted; in the other, not. If we recollect that no substance but a combustible is capable of restoring combustibility to the base of a product, and that at its doing so, it always loses its own combustibility; and if we recollect farther, that the base of the product does not exhibit the phenomenon of combustion even when it combines with oxygen—we cannot avoid concluding, that all combustibles contain an ingredient which they lose when converted into products, and that this loss contributes to the fire which makes its appearance during the conversion. Many circumstances concur to render it probable that this ingredient is LIGHT.

If we suppose that the oxygen of *supporters* contains *caloric* as an essential ingredient, and that *light* is a component part of all *combustibles*, the phenomena of combustion, numerous and intricate as they are, admit of an easy and obvious explanation. The component parts of the oxygen of supporters are two; namely, 1. A *base*; and, 2. *Caloric*. The component parts of combustibles are likewise two; namely, 1. A *base*; and, 2. *Light*. During combustion the base of the oxygen combines with the base of the combustible, and forms the product; while at the same time the caloric of the oxygen combines with the light of the combustible, and the compound flies off in the form of fire. Thus combustion is a double decomposition; the oxygen and combustible divide themselves each into two portions, which combine in pairs; the one compound is the *product*, and the other the *fire*, which escapes. Hence the reason that the oxygen of products is unfit for combustion: It wants its *caloric*. Hence the reason that combustion does not take place when oxygen combines with products, or with the base of supporters: These bodies contain no *light*. The caloric of the oxygen of course is not separated, and no *fire* appears. Hence also the reason why a combustible alone can restore combustibility to the base of a product. In all such cases a double decomposition takes place. The oxygen of the product combines with the base of the combustible, while the light of the combustible combines with the base of the product."

Such is the theory of Dr Thomson, proposed to the public* under the humble title of *Remarks on Combustion*. As the author completely establishes the facts on which his reasoning rests, we can conceive to it but one plausible objection. Why is not the caloric of the oxygen separated when that gas combines with bodies destitute of light? That there is caloric emitted on many occasions, when no light *appears* with it, is incontrovertible; but perhaps the matter of light is chemically combined with all bodies which emit heat, though it never flies off but when the heat is great. If this be a fact, and it is not improbable, the theory before us seems to be established; for it not only completes the theory of Lavoisier, but affords an easy solution to some phenomena which have been thought inconsistent with that theory.

* *Nicholson's Journal*, vol. ii. Second series.

In the year 1793, the associated Dutch chemists drew the attention of philosophers to a curious phenomenon which accompanies the formation of some of the sulphurets. When eight parts of copper, iron, lead, tin, or zinc filings, and three parts of flowers of sulphur, are mixed together in a glass receiver, and the vessel placed upon burning coals, the mixture melts, a kind of explosion takes place, it becomes suddenly red hot, and a glow, like that of a piece of red hot charcoal fanned with bellows, rapidly pervades the whole. When this disappears, the mixture is found in the state of solid sulphuret of copper, or iron, &c. The experiment succeeds whether the vessel be filled with air, or with azotic or hydrogen gas, or even with water or mercury. What is singular in this experiment is the glowing *red heat*, or the emission of fire, which accompanies the combination of the sulphur and metal. This emission being the same which takes place during combustion, the process has been considered as a combustion, and stated as such, by the German chemists, as an objection to Lavoisier's theory. But our author shews that no objection can be urged from this experiment against the truth of that theory as far as it goes; and that all the phenomena are fully explained by the additions which he has made to it. Thus, we have only to recollect, 1. That the sulphur is in a melted state, and therefore contains caloric as an ingredient; 2. That the metals which produce the phenomenon contain light as an essential ingredient; and, 3. That the sulphuret produced is always in a solid state—and the explanation is simple and obvious. The *sulphur* combines with the *base* of the metal, while the *caloric*, to which the sulphur owed its fluidity, combines with the *light* of the metal, and the compound flies off under the form of *fire*.

Thus the process is exactly the same with combustion, excepting what regards the product. The melted sulphur acts the part of the *supporter*, while the metal occupies the place of the *combustible*. The first furnishes caloric, the second light, while the bases of both combine together. Hence we see that the base of sulphurets (and the same thing holds of some phosphurets) resembles the base of products in being destitute of light, the formation of these bodies exhibiting the separation of fire like *combustion*; but the product, differing from a product of combustion in being destitute of oxygen, our author proposes to distinguish the process by the title of *semi-combustion*, to indicate that it possesses one half of the characteristic marks of combustion, but is destitute of the other half.

COMPASS, or MARINER'S STEERING COMPASS, is an instrument of so great value, that every improvement of it, proposed by men of science or of experience, is entitled to notice. We shall therefore lay before our readers some observations on the defects of the compass in common use, which have fallen into our hands since the article in the Encyclopædia was published. The first is by Captain O'Brien Drury of the royal navy, and relates entirely to the needle.

"Experience (says this officer) shews us, that the needle of a compass, as well as all other magnets, whether artificial or real, perpetually loses something of its magnetic

magnetic powers, which often produces a difference exceeding a point; and I am well convinced that the great errors in fhip-reckonings proceed more frequently from the incorrectnefs of the compafs than from any other caufe.

"Steel cannot be too highly tempered for the needle of a fea-compafs, as the more it is hardened the more permanent is the magnetifm it receives; but, to preferve the magnetifm, and confequently the polarity of the needle, I recommend to have the needle cafed with thin, well-polifhed, foft iron; or elfe to have it armed at the poles with a bit of foft iron. I have found, from many experiments, that the cafed needle preferved its magnetifm in a much more perfect degree than the needle not cafed; and I have fometimes thought that the magnetic power of the cafed needle had inreafed, while the magnetic power of the uncafed and unarmed needle always lofes of its polarity."

This is not an opinion taken up at random, but is the refult of what appears to have been a fair and judicious experiment; for our author placed a cafed needle, an armed needle, and one without either cafe or armour, in a room for three months; each having at that time precifely the fame direction, and nearly the fame degree of force. At the expiration of the three months, he found that the cafed needle and the armed needle had not in the leaft changed their direction; but the other had changed two degrees, and had loft very confiderable of its magnetic power. If there was any change in either of the other needles, it was too inconfiderable to be perceived.

Thefe obfervations feem to be new, and may tend to the improvement of the compafs. But it is not with refpect to the needle only that this inftrument is defective. Mr Bernard Romans of Penfacola well obferves, that, on another account, the heavieft brafs compaffes now in ufe are by no means to be relied on in a hollow or high fea. This is owing to the box hanging in two brafs rings, confining it to only two motions, both vertical and at right angles with each other; by which confinement of the box, upon any fuccuffion, more efpecially fudden ones, the card is always put into too much agitation, and, before it can well recover itfelf, another jerk prevents its pointing to the pole; nor is it an extraordinary thing to fee the card unfhipped by the violence of the fhip's pitching.

All thefe inconveniences are remedied to the full by giving the box a vertical motion at every degree and minute of the circle, and compounding thefe motions with a horizontal one of the box as well as of the card. By this unconfined difpofition of the box, the effects of the jerks on the card are avoided, and it will always very fteadily point to the pole. "Experience (fays our author) has taught me, that the card not only is not in the fmalleft degree affected by the hollow fea, but that, in all the violent fhocks and whirlings the box can receive, the card lies as ftill as if in a room unaffected by the leaft motion.

"Lately a compafs was invented and made in Holland, which has all thefe motions. It is of the fize of the common brafs compaffes; the bottom of the brafs box, inftead of being like a bowl, muft be raifed into a hollow cone, like the bottom of a common glafs bottle; the vertex of the cone muft be raifed fo high as to leave but one inch between the card and the glafs; the box muft be of the ordinary depth, and a quantity of lead muft be poured in the bottom of the box, round the bafe of the cone; this fecures it on the ftile whereon it traverfes.

"This ftile is firmly fixed in the centre of a fquare wooden box, like the common compafs, except that it requires a thicker bottom. The ftile muft be of brafs, about fix inches long, round, and of the thicknefs of one-third of an inch; its head blunt, like the head of a fewing-thimble, but of a good polifh: the ftile muft ftand perpendicular. The inner vertex of the cone muft alfo be well polifhed; the vertical part of the cone ought to be thick enough to allow of a well-polifhed cavity, fufficient to admit a fhort ftile, proceeding from the centre of the card whereon it traverfes. The compafs I faw was fo conftructed; but I fee no reafon why the ftile might not proceed from the centre of the vertex of the cone, and fo be received by the card the common way. The needle muft be a magnetic bar, blunt at each end; the glafs and cover are put on in the common way."

A compafs of this kind was fubmitted to our author's examination by the captain of a floop of war, who affured him, that in a hard gale, which lafted fome days, there was no other compafs of the fmalleft fervice. Mr Romans was fatisfied that the officer did not praife the apparatus more than it deferved; and we feel ourfelves ftrongly inclined to be of the fame opinion.

It muft not be concealed, however, that the ingenious Mr Nicholfon feems to think very differently of all fuch contrivances. In a paper publifhed in the ninth number of his valuable Journal, he labours to prove, that the compafs is very little difturbed by tilting the box on one fide, but very much by fudden horizontal changes of place; that a fcientific provifion againft the latter is therefore the chief requifite in a well made inftrument of this kind; and that no other provifion is requifite or can eafily be obtained, than good workmanfhip according to the common conftruction, and a proper adjuftment of the weight with regard to the centres or axes of fufpenfion. The fame author is of opinion, that it would greatly improve the compafs to make the needle flat and thin, and to fufpend it, not, as is moft commonly done, with its flat fide, but with its edge uppermoft; for it being a well-known fact, that foft fteel lofes its magnetifm fooner than hard, it is obvious, that unlefs both fides of a needle be equally hard (which is almoft impoffible if they be diftant from each other), the magnetic power will, in procefs of time, deviate towards the harder fide.

The Chinefe COMPASS has fome advantages over the European compafs, from which it differs with refpect to the length of the needle, and the manner in which it is fufpended. In the compafs of China, the magnetic needle is feldom above an inch in length, and is lefs than a line in thicknefs. It is poifed with great nicety, and is remarkably fenfible, or, in other words, points fteadily towards the fame portion of the heavens. This fteadinefs is accomplifhed by the following contrivance: "A piece of thin copper is ftrapped round the centre of the needle. This copper is rivetted by its edges to the upper part of a fmall hemifpherical cup, of the fame metal, turned downwards. The cup fo inverted ferves as a focket to receive a fteel pivot rifing from a cavity made into a round piece of light wood or cork, which thus

thus forms the compass-box. The surfaces of the socket and pivot, intended to meet each other, are perfectly polished, to avoid, as much as possible, all friction. The cup has a proportionably broad margin, which, beside adding to its weight, tends, from its horizontal position, to keep the centre of gravity, in all situations of the compass, nearly in coincidence with the centre of suspension. The cavity, in which the needle is thus suspended, is in form circular, and is little more than sufficient to remove the needle, cup, and pivot. Over this cavity is placed a thin piece of transparent talc, which prevents the needle from being affected by any motion of the external air; but permits the apparent motion of the former to be easily observed. The small and short needle of the chinese has a material advantage over those of the usual size in Europe, with regard to the inclination or dip towards the horizon; which, in the latter, requires that one extremity of the needle should be made so much heavier than the other as will counteract the magnetic attraction. This being different in different parts of the world, the needle can only be accurately true at the place for which it had been constructed. But in short and light needles, suspended after the Chinese manner, the weight below the point of suspension is more than sufficient to overcome the magnetic power of the dip or inclination in all situations of the globe; and therefore such needles will never deviate from their horizontal position."

COMPLEMENT, in general, is what is wanting, or necessary, to complete some certain quantity or thing.

Arithmetical COMPLEMENT, is what a number or logarithm wants of unity or 1 with some number of cyphers. It is best found by beginning at the left hand side, and subtracting every figure from 9, except the last, or right hand figure, which must be subtracted from 10. So, the arithmetical comp. of the log. 9·5329714,
by subtracting from 9's, &c. is 0·4670286.

The arithmetical complements are much used in operations by logarithms, to change subtractions into additions, which are more conveniently performed, especially when there are more than one of them in the operation.

COMPLEMENT, in astronomy, is used for the distance of a star from the zenith; or the arc contained between the zenith and the place of a star which is above the horizon. It is the same as the complement of the altitude, or co-altitude, or the zenith distance.

COMPLEMENT *of the Course*, in navigation, is the quantity which the course wants of 90°, or 8 points, viz. a quarter of the compass.

COMPLEMENT *of the Curtain*, in fortification, is that part of the anterior side of the curtain which makes the demigorge.

COMPLEMENT *of the Line of Defence*, is the remainder of that line, after the angle of the flank is taken away.

COMPLEMENTS *of a Parallelogram*, or *in a Parallelogram*, are the two lesser parallelograms, made by drawing two right lines parallel to each side of the given parallelogram, through the same point in the diagonal.

COMPLEMENT *of Life*, a term much used, in the doctrine of life annuities, by De Moivre; and, according to him, it denotes the number of years which a given life wants of 86, this being the age which he considered as the utmost probable extent of life. So 56 is the complement of 30, and 30 is the complement of 56.

COMPOSITION OF PROPORTION, according to the 15th definition of the 5th book of Euclid's Elements, is when, of four proportionals, the sum of the first and second is to the second, as the sum of the third and fourth is to the fourth.

COMPOSITION *of Ratios*, is the adding of ratios together: which is performed by multiplying together their corresponding terms, viz. the antecedents together, and the consequents together, for the antecedent and consequent of the compound ratio; like as the addition of logarithms is the same thing as the multiplication of their corresponding numbers. Or, if the terms of the ratios be placed fraction-wise, then the addition or composition of the ratios is performed by multiplying the fractions together.

COMPOUND INTEREST. See ALGEBRA, *Encycl.* and *Compound* INTEREST in this *Supplement*.

CONCEPTION, a city of Chili in South America, was visited in 1786 by the celebrated, though unfortunate, navigator La Perouse, who gives an account of some particulars relating to it very different from what we have given of it under the article CONCEPTION, *Encycl.* So far are the Spaniards from living in security with respect to the Indians, that, according to him, they are under continual alarms of being attacked by those bold and enterprising savages. "The Indians of Chili (says he) are no longer those Americans who were inspired with terror by European arms. The increase of horses, which are dispersed through the interior of the immense deserts of America, and that of oxen and sheep, which has also been very great, have converted these people into a nation of Arabs, in every thing resembling those who inhabit the deserts of Arabia. Constantly on horseback, they consider an excursion of two hundred leagues as a very short journey. They march accompanied by their flocks; feed upon their flesh and milk, and sometimes upon their blood; and cover themselves with their skins, of which they make helmets, cuirasses, and bucklers. All their old customs are laid aside. They no longer feed upon the same fruits, nor wear the same dress; but have a more striking resemblance to the Tartars, or to the inhabitants of the banks of the Red Sea, than to their ancestors, who lived two centuries ago. So decisive an influence has the introduction of two domestic animals had upon the manners of that once timid people. It is easy to conceive what formidable enemies they must now be to the Spaniards; for supposing them defeated in battle, how is it possible to follow them in such long excursions? How is it possible to prevent assemblages, which bring together in a single point nations scattered over 400 leagues of country, and thus form armies of 30,000 men?"

Of these people M. Rollin, surgeon-major of the frigate *la Bussale*, gives the following physiological particulars: "They are, in general (says he), of lower stature, and less robust, than Frenchmen, though they endure with great courage the fatigues of war and all its attendant privations. There is a great sameness in the physiognomy of most individuals. The face is larger and rounder than that of Europeans. The features are more strongly marked. The eyes are small, dull, black, and deeply seated. The forehead is low; the eyebrows black and shaggy; the nose short and flattened; the cheek-bones high; the lips thick; the mouth wide;

 and

Conception. and the chin diminutive. The women are ſhort, ill-made, and with diſguſting countenances. Both men and women bore their noſe and ears, which they adorn with glaſs or mother-of-pearl trinkets. The colour of their ſkin is a reddiſh brown: That of their nails is ſimilar, but not ſo deep. The hair of both is black, coarſe, and very thick. The men have little beard; but their arm-pits and parts of ſex are well furniſhed with hair, which parts, in moſt of the women, have none."

The military governor of Conception, who was an Iriſhman, returned, while M. de la Perouſe was there, from the frontiers of the Spaniſh ſettlements, where he had juſt concluded a glorious peace with the Indians. This peace was highly neceſſary to the people of his government, whoſe diſtant habitations were expoſed to the inroads of ſavage cavalry, whoſe practice it is to maſſacre the men and children, and to make the women priſoners. This amiable man, whoſe name was *Higguins* (probably *Higgins*), had ſucceeded in gaining the good-will of theſe ſavages, and thereby rendered the moſt ſignal ſervice to the nation that had adopted him. For while the Indians and Spaniards are at variance, an alliance with the former by any of the maritime powers of Europe would become ſo formidable to the latter, as to induce them, for fear of their lives, to abandon their ſettlements in Chili, and retire to Peru. This was clearly ſeen by *Monneron* the engineer on the expedition, who, with the true ſpirit of a Frenchman, pointed out to his government the method of wreſting from its moſt faithful ally one of the moſt valuable provinces of the Spaniſh empire.

La Perouſe deſcribes the common people of Conception as much addicted to thieving, and the women as exceedingly eaſy of acceſs. "They are a degenerated and mongrel race (ſays he); but the inhabitants of the firſt claſs, the true bred Spaniards, are polite and obliging in the extreme. The biſhop was a man of great ſenſe, of agreeable manners, and of a charity of which the Spaniſh prelates afford frequent examples." He was a Creole, and had never been in Europe. Of the monks our author gives a very different character. "The misfortune (ſays he) of having nothing to do, the want of family ties, the profeſſion of celibacy, without being ſeparated from the world, and their living in the convenient retirement of their cells, has rendered, and could not fail to render, them the greateſt profligates in America. Their effrontery is inconceivable. I have ſeen ſome of them ſtay till midnight at a ball; aloof, indeed, from the good company, and ſeated among the ſervants. Theſe ſame monks gave our young men more exact information than they could get elſewhere, concerning places with which prieſts ought to have been acquainted only in order to interdict the entrance."

M. de la Perouſe repreſents that part of Chili, which is called *the Biſhopric of Conception*, as one of the moſt fertile countries in the univerſe. Corn yields ſixty to one; the vineyards are equally productive; and the plains are covered with innumerable flocks, which, tho' left to themſelves, multiply beyond all imagination. Yet this colony is far from making the progreſs that might be expected from a ſituation ſo favourable to an increaſe of population. The influence of the government inceſſantly counteracts the climate and the ſoil. Prohibitory regulations exiſt from one end of Chili to the other; and this kingdom, of which the productions, if carried to their higheſt pitch, would feed the half of Europe; of which the wool would ſuffice for the manufactures of Great Britain and France, even when manufactures flouriſhed in the latter country; and of which the cattle, if ſalted down, would produce an immenſe revenue—is entirely deſtitute of commerce, and its inhabitants ſunk in ſloth and indolence. Unleſs, therefore, Spain change its ſyſtem entirely, Chili will never reach that pitch of proſperity which might be expected from its ſituation and fertility. For the latitude and longitude of Conception, ſee *Encycl.*

Condorcet. CONDORCET (Jean-Antoine Nicolas Caritat de), was born at Ribemont in Picardy, the 17th of September 1743, of a noble and very ancient family. At the age of 15 he was ſent to ſtudy philoſophy at the college of Navarre, and had the good fortune to fall into the hands of an able profeſſor, who has ſince diſtinguiſhed himſelf by his geometrical works. The young Condorcet had no reliſh for the buſineſs of the firſt courſe, for the quibbles of ontology and pneumatology, and all the wretched appendages of ſchool metaphyſics: But in the following year, his ſtudies, being directed to the mathematical and phyſical ſciences, were entirely congenial to his taſte; and though there were upwards of 120 ſcholars, he diſtinguiſhed himſelf above them all. At Eaſter he held a public theſis, at which Clairaut, D'Alembert, and Fontaine, aſſiſted. He now returned home, but continued to cultivate geometry. To enjoy more opportunities of improvement, he removed in 1762 to Paris; where he attended the chemical courſe of Macquer and Beaumé, and frequented the literary ſocieties which D'Alembert had formed at the houſe of Mademoiſelle de Leſpinaſſe.

In 1765, when only 22 years old, he publiſhed a work on the Integral Calculus, which diſcovered vaſt extent and originality of views. Condorcet was already numbered with the foremoſt mathematicians in Europe. "There was not (ſays La Lande) above ten of that claſs; one at Peterſburgh, one at Berlin, one at Baſle, one at Milan, and five or ſix at Paris; England, which had ſet ſuch an illuſtrious example, no longer produced a ſingle geometer that could rank with the former." It is mortifying to us to confeſs that this remark is but too much founded in truth. We doubt not but there are in Great Britain at preſent mathematicians equal in profundity and addreſs to any who have exiſted ſince the illuſtrious Newton; but theſe men are not known to the learned of Europe, becauſe they keep their ſcience to themſelves. They have no encouragement, from the taſte of the nation, to publiſh any thing in thoſe higher departments of geometry which have ſo long occupied the attention of the mathematicians on the continent.

In 1767 Condorcet publiſhed his ſolution of the problem of three bodies; and in the following year, the firſt part of his Analytical Eſſays; in which he entered very profoundly into thoſe arduous queſtions. He was received into the academy on the 8th of March 1769; and from that time till 1773 he enriched their annual volumes with memoirs on infinite ſeries, on partial and finite differences on equations of condition, and on other objects of importance in the higher calculus. It muſt be regretted, that he indulged ſpeculation perhaps to exceſs; the methods that he propoſes for integration

gration are ſometimes of a nature ſo extremely general, as to refuſe to be accommodated to practice. Proſecuting thoſe reſearches for ſeveral years longer, he compoſed an ample Treatiſe on the Integral Calculus, in five parts, compriſing the doctrines and their application. It was afterwards copied out for the preſs in 1785 by Keralio, formerly governor to the Infant of Parma. Only 128 pages were printed; but the manuſcript ſtill exiſts; as does that of an elementary Treatiſe on Arithmetic. It is to be hoped that both of theſe will yet be given to the public.

His attention was not, however, entirely abſorbed in thoſe recondite ſtudies. He publiſhed about this time an anonymous pamphlet, intitled *A Letter to a Theologian;* in which he replied with keen ſatire to the attacks made by the author of the *Three Centuries of Literature* againſt the philoſophical ſect. "But (ſubjoins the prudent La Lande) he puſhed the matter ſomewhat too far; for, admitting the juſtneſs of his ſyſtem, it was more prudent to confine within the circle of the initiated thoſe truths which are dangerous for the multitude, who cannot replace by ſound principles what they would loſe of fear, of conſolation, and of hope." Condorcet was now leagued with the atheiſts; and *La Lande*, who wiſhes well to the ſame ſect, cenſures not his principles, but only regrets his raſhneſs. He was indeed, as Mr Burke obſerved, a fanatic atheiſt and furious democratic republican.

On the 10th of June 1773 he was made ſecretary of the academy of ſciences; and that important truſt he diſcharged through the reſt of his life with great ability and uncommon reputation. The duties of his office required him to write the lives of the deceaſed academicians, which he performed with diligence, judgment, and univerſal applauſe: And what ſpecies of compoſition is capable of being rendered ſo extenſively uſeful as biography? In the moſt inſinuating form it conveys inſtruction; and, beſtowing vitality and action on the rules of conduct and on the leſſons of virtue, it fires the breaſt with the nobleſt emulation. The life of a philoſopher muſt alſo include a portion of the hiſtory of ſcience. We there trace the ſucceſſive ſteps which led to diſcoveries, and learn to eſtimate the value of thoſe acquiſitions by the efforts that were made, and the obſtacles that were ſurmounted. The literati of France have long excelled in the compoſition of *Eloges:* but thoſe of Condorcet are of a very ſuperior caſt. Replete with information and genuine ſcience, they maintain a dignified impartiality, and diſplay vigour of imagination, with boldneſs and energy of ſtyle. The intrepidity (ſay his Panegyriſts) with which he uttered the ſentiments of truth and of freedom, could not have been expected from the mouth of an academician under an abſolute monarchy. It could not, indeed, till the preſent eventful age, have been expected under any government whatever; for what he called the ſentiments of truth were the dogmas of debaſing irreligion, which would not have been permitted in the far-famed republics of Greece and Rome; and what he dignified with the appellation of the principles of freedom, experience has ſhown to have been the immediate ſource of anarchy, out of which has ſprung a deſpotiſm, the heavieſt under which any people have groaned ſince the creation of the world.

Beſides the eloges, which properly belonged to his province, Condorcet publiſhed in a ſeparate volume the lives of thoſe *ſavants*, who, having died before the renewal of the academy in 1699, did not fall in with the plan of Fontenelle. The ſuppreſſion of the hiſtory of the academy, or the regular abſtracts of the printed memoirs, which he effected in 1783, afforded him more leiſure. In 1787 appeared, yet without a name, his account of Turgot; an ineſtimable piece, which, in developing the beneficial views of a virtuous and enlightened miniſter, exhibits the neateſt abſtract of the principles of political economy that is extant in any language. Nearly about the ſame time he compoſed that elegant life which is prefixed to the ſplended edition of the works of Voltaire. Condorcet had been elected member of the *Academie Françaiſe* in 1782; and his reputation as a fine writer was ſo well eſtabliſhed, that bookſellers were ſolicitous to cover their undertakings with the ſanction of his name. He promiſed an additional volume to the tranſlation of Euler's Letters to a German Princeſs; but it was never finiſhed. The part which was printed, amounting to only 112 pages, contains the elements of the calculation of probabilities, and a curious plan of a dictionary, in which objects ſhould be arranged by their qualities merely. A new tranſlation of Smith's celebrated *Wealth of Nations* was likewiſe announced with the notes of Condorcet, tho' he was never heartily engaged about it. On equally ſlight grounds, his name was lent to the *Bibliotheque de l' Homme Public;* and the facility of his temper laid him but too open, at this period, to ſuch diſingenuous arts. Indeed diſingenuous arts ſeem to be the natural offspring of the preſent philoſophy of France; for the tricks played by Voltaire to his bookſellers, which are well known, would in this country have ſunk into diſgrace the greateſt genius that ever lived; and the attempt of Diderot to cheat the late empreſs of Ruſſia, by ſelling to her, at an immenſe price, a library, which he pretended to be one of the moſt valuable in Europe, when he poſſeſſed not perhaps one hundred volumes, was diſingenuity ingrafted on impudence. But to return from this ſhort digreſſion.

Theſe literary purſuits did not entirely ſeduce Condorcet from more profound ſtudies. At the inſtigation of Turgot, he ſought to apply analyſis to queſtions of politics and morality. His firſt Memoir on Probabilities was read to the academy in 1781. He afterwards extended his reſearches to the conſideration of elections, ſales, and ſucceſſions; and digeſting thoſe remarks and calculations into a ſyſtematic ſhape, he publiſhed in 1785 a quarto volume, containing the elements of a new and important ſcience.

It is eaſy to conceive the intereſt that Condorcet would take in the ſucceſs of the revolution. Aware of the prodigious influence of newſpapers, he contributed largely to the *Journal de Paris*, and the *Chronique*, which acquired great celebrity from the elegance of his pen; and not very long before his death, he began, in concert with the famous Sieyes, a Journal of Social Inſtruction. In 1791 he wrote a pamphlet in favour of republican government, which procured him a ſeat in the Legiſlative Aſſembly, and the academy permitted him ſtill to retain the office of ſecretary. He drew up a manifeſto on the ſubject of the war menaced by the crowned heads; and a very ample report on public inſtruction, which has in part been lately adopted by the councils of France. He was an early member of the

Jacobin

Condorcet.

Jacobin club, that active inſtrument of the revolution: but perceiving the progreſſive ferocity of its meaſures, he forſook it in March 1792.

On the 13th of Auguſt, when the king was conducted to the temple, Condorcet was named by the Aſſembly to draw up a juſtificatory memorial addreſſed to all Europe. At the diſſolution of that Aſſembly, he was choſen deputy to the National Convention, and for ſome time acted a diſtinguiſhed part in its deliberations. He was at the head of the committee appointed to prepare the plan of a republican conſtitution. But, in the meanwhile, the faction of the Mountain, with a peculiar energy of character, was rapidly acquiring ſtrength. The report of the committee was coldly received—was even treated with contempt; and, on the 31ſt of May 1793, Robeſpierre completely triumphed.

During the conteſt between the Mountain and the Briſſotines, Condorcet maintained a cautious ſilence. For eight months he hardly ſpoke in the Convention; and ſeems to have been ſingularly wary in not riſking an opinion on any party queſtion. At length he was ſo far rouſed by the indignities which the legiſlative body daily endured, that he propoſed the diſſolution of the Convention, and the calling of a new one. This probably exaſperated the Mountain to ſuch an exceſs, that in a ſubſequent inſurrection his printing-office was deſtroyed. He was not, however, included in the liſt of proſcribed deputies; nor was he one of the members who ſigned the famous proteſt againſt the proceedings on the 31ſt of May. See REVOLUTION (*Encycl.*), n° 159.

But though he could conquer every ſentiment of friendſhip, and ſtifle every indignant ſenſation at the deſtruction of his party, his vanity as an author propelled him to a fatal exertion. When the conſtitution of 1793 was accepted, he publiſhed *An Addreſs to all French Citizens;* reprobating the extreme rapidity and want of conſideration with which it had been framed and accepted, and detailing the numerous acts of violence by which the prevailing party in the Convention had eſtabliſhed their influence. This raſh act placed him in the power of the Mountain: Chabot denounced the publication, and moved for a decree of accuſation againſt Condorcet; which was immediately granted.

He eſcaped from the arreſt, and concealed himſelf nine months in the houſe of a woman in Paris, who, though ſhe knew him only by name, had the generoſity to riſk her life, and ſuſtain all the inconveniences ariſing from her harbouring ſuch a gueſt. At length a domiciliary viſit was threatened, and he was obliged to quit his aſylum. He had the good fortune, though unprovided with a paſſport or civic card, to eſcape through the barrier; when he went to the country-houſe of a friend on the plain of Mont-Rouge. Unfortunately his friend was at Paris, and not expected to return in leſs than three days; during which the fugitive was obliged to wander about, expoſed to hunger, cold, ſuſpenſe, and the pain ariſing from a wound in his foot. At length his friend returned into the country, and found him; but conſidering it dangerous to take him to his houſe in the day-time, requeſted him to wait till night, when he would receive and conceal him. Condorcet, on that day which his friend had fixed as the end of his miſeries, forgot the dictates of prudence, and went to an inn at Chemars, where he ordered an amelette. His ſqualid appearance, dirty cap, torn clothes, leanneſs, and voracity, fixed the attention of a municipal officer, who aſked him whence he came, whither he was going, and if he had a paſſport? His confuſion at theſe interrogatories betrayed him, and he was inſtantly apprehended. He was confined that night in a dungeon, and in the morning was found dead. He always carried about him a doſe of poiſon, with which he terminated his life, to avoid a trial before the revolutionary tribunal, and ſhun the *gradual approach* of inevitable deſtruction.

Condorcet.

Thus miſerably periſhed a philoſopher, whoſe "genius (ſays Madame Roland) was equal to the comprehenſion of the vaſteſt ſubjects; but he had no other characteriſtic beſides fear. It may be ſaid of his underſtanding, combined with his perſon, that it was a fine eſſence abſorbed in cotton. No one could ſay of him, that in a feeble body he diſplayed great courage; for his heart and his conſtitution were equally weak. After having deduced a principle, or demonſtrated a fact, in the Aſſembly, he would give a vote decidedly oppoſite; overawed by the thunder of the tribunes, armed with inſults, and prodigal of threats."

It was during the period of his concealment at Paris, uncertain of a day's exiſtence, that he wrote his Sketch of the Progreſs of the Human Mind; a production which undoubtedly diſplays genius, though it contains ſome of the moſt extravagant paradoxes that ever fell from the pen of a philoſopher. Among other wonderful things, the author inculcates the poſſibility, if not the probability, that the nature of man may be improved to abſolute perfection in body and mind, and his exiſtence in this world protracted to immortality. So firmly does he ſeem to have been perſuaded of the truth of this unphiloſophical opinion, that he ſet himſelf ſeriouſly to conſider how men ſhould conduct themſelves when the population ſhould become too great for the quantity of food which the earth can produce; and the only way which he could find for counteracting this evil was, to check population by promiſcuous concubinage and other practices, with an account of which we will not ſully our pages. Yet we are told by La Lande, that this ſketch is "only the outline of a great work, which, had the author lived to complete it, would have been conſidered as a monument erected to the *honour* of human nature!!!" La Lande, indeed, ſpeaks of the author in terms of high reſpect; and his abilities are certainly unqueſtionable: but what ſhall we think of the morals of that man, who firſt purſued with malicious reports, and afterwards hired ruffians to aſſaſſinate *, the old Duke of Rocheſoucalt, in whoſe houſe he had been brought up; by whom he had been treated as a ſon; and at whoſe ſolicitation Turgot created for him a lucrative office; and by the power of the court raiſed him to all his eminence? There is a living Engliſh writer, who has laboured hard to prove that gratitude is a crime. Condorcet muſt ſurely have held the ſame opinion; and therefore could not blame thoſe low-born tyrants who paſſed againſt him what we muſt think an unjuſt decree of accuſation; for it was in ſome degree to his writings that thoſe tyrants were indebted for their power.

* *Jour. de Phyſ.* Nov. 1792.

About the end of the year 1786, Condorcet married Marie-Louiſe Sophie de Grouchy, whoſe youth, wit, and beauty, were leſs attractive in the eyes of a philo-

ſopher

fopher than the tender and courageous anxiety with which fhe watched the couch, and affuaged the fufferings, of the fon of the prefident du Paty, who had been bitten by a mad dog. This union, however, we are told, was fatal to his repofe; it tempted him into the dangerous road of ambition; and the idea of providing for a wife and daughter induced him to feek for offices which once he would have defpifed.

CONFERVA JUGALIS (fee CONFERVA, *Encycl.*) is introduced here merely on account of a curious circumftance refpecting it, which was communicated, not long ago, to the Philomatic Society at Paris. Citizens Charles and Romain Coquebert having collected fome of this *Conferva* in the neighbourhood of Paris, afcertained, by means of an excellent microfcope, conftructed by Nairne and Blunt, that, in this fpecies, there are male and female filaments, which unite by an actual copulation; that certain globules contained in the male filaments pafs into the interior part of the female filaments; and that by this union there are formed in the latter feeds, or, if we may ufe the expreffion, fmall *ova*, which reproduce the fpecies. This is the firft inftance, in the vegetable kingdom, of a reproduction abfolutely analogous to that which we find among animals.—*Philofophical Magazine*, N° 3.

May this fact be depended on? We queftion not, in the flighteft degree, the veracity of the editor of the very refpectable mifcellany from which we have copied it; but we confefs ourfelves inclined to admit the phyfiological difcoveries of citizen philofphers with great hefitation. The fact, if real, is certainly curious, and may lead to important conclufions; and we therefore recommend an inveftigation of its truth to our botanical readers.

CONGELATION. See CHEMISTRY in this Supplement, n° 280—283.

CONTAGION (fee *Encycl.*) is a fubject on which much has been written to very little purpofe. Of all the attempts which have been made to account for it, there is not one that can be thought fatisfactory. This, however, is not perhaps a matter of great importance, if a method could only be difcovered to ftop the progrefs of contagion where it is known to have place. Among the many benefits which may be reaped from the late difcoveries in chemiftry, even this defideratum promifes to be one; and we furely need not add one of the greateft. Dr James Carmichael Smyth, phyfician extraordinary to his Majefty, fuggefted, in the year 1795 or 1796, a procefs for determining the effect of the nitric acid in deftroying contagion; and experiments, according to his directions, were made on board the *Union* and other fhips at Sheernefs.

The Union was an hofpital fhip, and the experiment on board her was conducted by Mr Menzies, late furgeon to his Majefty's floop Difcovery, and by Mr Baffan, furgeon of the Union; and when it is confidered that frefh contagion was daily pouring into the hofpital from the Ruffian veffels, which were at that time lying in the Downs, and which had brought with them a fpecies of fever that might in every fenfe of the word be termed an epidemy, it will be allowed, that the fuccefs which attended it was fuch that it cannot be too generally known.

The wards were extremely crowded, and the fick of every defcription lay in cradles, promifcuoufly arranged, to the number of nearly two hundred; of which about one hundred and fifty were in different ftages of the above malignant fever, which was extremely contagious, as appeared evident from its rapid progrefs and fatal effects among the attendants on the fick and the fhip's company.

The utenfils and materials provided for the procefs were the following: A quantity of fine fand, about two dozen quart earthen pipkins, as many common teacups, fome long flips of glafs to be ufed as fpatulas, a quantity of concentrated vitriolic (fulphuric) acid, and a quantity of pure nitre (nitrat of potafh).

The procefs was conducted in the following manner: *1ft*, All the ports and fcuttles were fhut up; the fand, which had been previoufly heated in iron pots, was then fcooped out into the pipkins by means of an iron ladle; and in this heated fand, in each pipkin, a fmall tea-cup was immerfed, containing about half an ounce of the fulphuric acid, to which, after it had acquired a proper degree of heat, an equal quantity of nitrat of potafh in powder was gradually added, and the mixture ftirred with a glafs fpatula till the vapour arofe from it in confiderable quantity (A). The pipkins were then carried through the wards by the nurfes and convalefcents, who kept walking about with them in their hands, occafionally putting them under the cradles of the fick, and in every corner where any foul air was fupected to lodge. In this manner they continued fumigating, until the whole fpace between decks was fore and aft filled with the vapour, which appeared like a thick haze.

The vapour at firft excited a good deal of coughing among the patients, which gradually ceafed as it became more generally diffufed through the wards; part of this effect, however, was to be attributed to the inattention of thofe who carried the pipkins, in putting them too near the faces of the fick; which caufed them to inhale the ftrong vapour as it immediately iffued from the cups.

The body-clothes and bed-clothes of the fick were as much as poffible expofed to the nitrous vapour during the fumigation; and all the foul linen removed from them was immediately immerfed in a tub of cold water, afterwards carried on deck, rinfed out, and hung up till nearly dry, and then fumigated before it was taken to the wafh-houfe: a precaution extremely neceffary in every cafe of infectious diforder. Due attention was alfo paid to cleanlinefs and ventilation.

It took about three hours to fumigate the fhip. In about an hour after, the vapour having entirely fubfided, the ports and fcuttles were thrown open for the admiffion of frefh air. It could plainly be perceived that

(A) That the fumes of the mineral acids poffeffed the property of ftopping contagion was proved by Morveau as far back as the year 1773, who, by means of the fumes of muriatic acid extricated from the muriat of foda (fea falt) by the fulphuric acid, purified the air of the cathedral of Dijon, which had been fo much infected by exhumations that they were obliged to abandon the building. See CHEMISTRY, n 426. in this *Suppl.*

that the air of the hoſpital was greatly ſweetened even by this firſt fumigation. The proceſs was repeated again next morning; and the people employed, being now better acquainted with it, were more expert, and finiſhed the whole in about an hour's time. In an hour afterwards, the vapour having entirely ſubſided, the freſh air was freely admitted into the hoſpital as before. Fewer pipkins were employed for the evening fumigations than for thoſe of the mornings, as the freſh air could not be admitted ſo freely after the former as the latter.

The pleaſing and immediate effect of the fumigation in deſtroying the offenſive and diſagreeable ſmell, ariſing from ſo many ſick crowded together, was now very perceptible, even to the nurſes and attendants; the conſequence of which was, that they began to place ſome degree of confidence in its efficacy, and approached the cradles of the infected with leſs dread of being attacked with the diſorder: ſo that the ſick were better attended, and the duty of the hoſpital was more regularly and more cheerfully performed. In ſhort, a pleaſing gleam of hope ſeemed now to caſt its cheering influence over that general deſpondency, which was before evidently pictured in every countenance, from the dread and horror each individual naturally entertained of being, perhaps, the next victim to the malignant powers of a virulent contagion.

It is a remarkable fact, that from the 26th of November 1795, when the fumigation was firſt reſorted to, till the 25th of December, not a perſon on board was attacked with the fever, though, in the three months preceding, more than one-third of all the people in the ſhip had been ſeized with the diſtemper, and of theſe more than one in four were carried off by it; and the probability is, that the ſickneſs and mortality would have gone on, increaſing in proportion to the diffuſion of the contagion, and to the increaſing deſpondency of the people, who conſidered themſelves as ſo many devoted victims.

The advantage of the fumigation was not felt by the ſhip's company and attendants alone, whom it preſerved from the baneful effects of the fever: the ſick and convaleſcents derived almoſt an equal benefit from it. The ſymptoms of the diſeaſe were meliorated, and loſt much of their malignant appearance; and the advantage of a pure air, and free from ſtench, to convaleſcents, may be readily conceived.

Great confidence is always dangerous. It proved ſo on the preſent occaſion. On the 17th of December they imagined themſelves ſo ſecure, that they diſcontinued the cuſtom of fumigating morning and evening, thinking that once a day was ſufficient. On the 25th, one of the nurſes ſuffered a ſlight attack; and on the 26th, a marine, who, for a week before, had been in a ſtate of intoxication, was ſeized with the fever, of which he died. Theſe two accidents gave immediate alarm: they returned again to the practice of fumigating twice a-day; and from that time to the extermination of the diſorder, there was not an inſtance of a perſon ſuffering from contagion on board the ſhip.

The ſucceſs of the experiment was not confined to the Union: the power of the nitrous vapour to deſtroy contagion was equally diſplayed on board the Ruſſian ſhips in which it was employed. The ſafety, too, with which it may be employed, in any ſituation, without inconvenience or riſk of fire, is another great recommendation in its favour.

From the deſcription that has been given of the proceſs, no perſon can be at any loſs in reſorting to the ſame kind of fumigation. It is only neceſſary to obſerve, for the ſake of thoſe who may not be verſant in chemical purſuits, that the ingredients ought to be pure, and that metal veſſels or rods muſt not be employed. Any kind of metal getting among the ingredients would cauſe the vapour to be very noxious inſtead of ſalutary. The fumes that riſe ſhould be white; if they are of a red colour, there is reaſon to ſuſpect the purity of the ingredients.

The importance of this diſcovery need not be inſiſted on: it is equally applicable to every ſpecies of putrid contagion, even to the plague itſelf. It ſhould therefore be uſed in all hoſpitals and pariſh workhouſes; and ſhould be conſtantly reſorted to by the proprietors of all large works, on the firſt appearance of infectious diſeaſe among the people employed in them:—Indeed, it ſhould be employed even as a preventive in all ſituations where a number of people, from the nature of their buſineſs, are obliged to be crowded together, or where, from local circumſtances, there are reaſons for ſuſpecting that the purity of the air is injured by noxious exhalations or other cauſes. If there be any circumſtances in which its utility may be called in queſtion, it can only be in caſes of inflammatory diſeaſes; for in ſuch ſuperoxygenation has been found hurtful.

CONTRA-HARMONICAL *Proportion*, that relation of three terms, in which the difference of the firſt and ſecond is to the difference of the ſecond and third, as the third is to the firſt. Thus, for inſtance, 3, 5, and 6, are numbers contra-harmonically proportional; for $2 : 1 :: 6 : 3$.

Contra-Mure, in fortification, is a little wall built before another partition wall, to ſtrengthen it, ſo that it may receive no damage from the adjacent buildings.

COOPER, an artificer who makes coops, caſks, tubs, or barrels, *i. e.* all kinds of wooden veſſels bound together by hoops. See *Encycl.*

The art of the cooper appears to be of great antiquity, and to have very ſoon attained to all the perfection which it poſſeſſes at preſent. This being the caſe, it is obvious that we can communicate no inſtruction to the cooper himſelf, and, on the ſubject of his art, very little that could be intereſting to our other readers. In the *Encyclopedie Methodique* there is a long and verboſe account of the tools or inſtruments employed by the cooper; of the kinds of timber proper for the different kinds of caſks; of the methods of preparing the wood for his various purpoſes; of the manner in which he ought to *hold the plane* when dreſſing the ſtaves; and of the time when it is proper to put the ſtaves together, or, in other words, to mount the caſk. From this detail we ſhall extract ſuch particulars as appear to us to be leaſt generally known, though perhaps of no great importance in themſelves.

Notwithſtanding the antiquity of the art of *caſk-building*, there are ſome countries in which even now it is wholly unknown; and others where, though it is ſufficiently known, yet, from the ſcarcity of wood or ſome other cauſe, earthen veſſels, and ſkins lined with pitch,

pitch, are preferred to wooden barrels for the holding and transporting of liquors. The Latin word *dolium*, which we translate "a cask," was employed by the Romans to denote earthen vessels used for this purpose; though the word *dolare*, from which it is derived, applies very well to our casks, which are composed of several pieces of wood hewn from the same tree, and fitted by planes before they be joined together. We are indeed certain that casks of the same kind with our own were in use among the Romans before the Christian era; for both Varro and Columella, in treating of the rural economy of their days, speak of vessels formed of several staves of wood bound together by circles or hoops. The merit of having invented such vessels is given by Pliny to certain people who lived at the foot of the Alps, and who in his days lined their casks with pitch.

At what period the fabrication of casks was introduced into Britain is unknown to us, though it is probable that we derived the art from the French, who might have it from the Romans.

We need hardly inform any of our readers, that a cask has the appearance of two truncated cones joined at their bases, or that the part where the junction appears to be made being the most capacious, or that of which the diameter is the largest, is vulgarly called the belly of the cask. These cones, however, were they completed, would not be regular, but rather *conoids*, being formed of pieces of timber, or staves, which are not straight lines as in the cone, but are curved from the vertex to the base.

In choosing his wood, if he can have a choice, the cooper prefers old and thick and straight trees, from which he hews thin planks to be formed into staves; and in France, where this art is practised on a large scale, the winter months are allotted for the preparation of the staves and bottoms, and the summer for putting them together or mounting the cask. The author of the article in the *Encyclopedie Methodique* directs the cooper, when dressing the staves with the plane, to cut the wood always across; a practice which we doubt not is proper, though we think it would not be easy to assign the reason of it. Plaining is the most laborious and difficult part of the work; and there are but few coopers who plane quickly, and at the same time well. In shops where the work is distributed into parts, plaining is reckoned a great object; and in France, before the revolution, a good plainer gained from three shillings and threepence sterling to four shillings and three farthings a-day.

In forming the staves, it must never be forgotten that each is to constitute part of a double conoid; that it must therefore be broadest at the middle, becoming gradually, though not in straight lines, narrower towards the extremities; that the outside across the wood must be wrought into the segment of a circle; and that the stave must be thickest near the middle, growing thinner, by very gentle degrees, towards the ends. To adjust accurately these different curves (for even the *narrowing* of the staves must be in a curve) to the size and intended shape of the cask, would require either great experience, or a larger portion of mathematical science than we have reason to think that many coopers possess. With respect to the inside of the stave, it is of little consequence whether it be rounded into the segment of a circle or not, and therefore the cooper very seldom takes that trouble.

The staves being all dressed and ready to be arranged in a circular form, it might be thought necessary, in order to make the seams tight, to trim the thin edges, which are to be joined together, in such a manner as that a ray passing from the outside of the cask through a seam to the centre, should touch the contiguous staves from the exterior to the interior side; in other words, that the thin edges should be sloped as the archstones of a bridge are sloped, so that the contiguous staves may be brought into firm contact throughout the whole joint. This, however, is not the practice of the cooper. With great propriety he brings the contiguous staves into contact at their inner surfaces only; so that by driving the hoops hard, he can make the joints much closer than he could possibly have done had the edges of the staves been so sloped as to permit them to touch each other throughout before being drove together by the compression of the hoops. This, together with giving to the staves the proper curvature, seems to be the only part of the cooper's work which deserves the name of art; for the driving of the hoops and the forming of the bottoms could certainly be accomplished by any carpenter, we had almost said by any man, though he had never seen a hoop driven or a bottom formed.

In many parts of Scotland, instead of ale or beer mugs, they use small hooped wooden vessels, of which the staves are feather-edged or dove-tailed into one another. This, as the staves are of different colours, increases the beauty of the vessel, and to a superficial observer appears to be an ingenious contrivance; but it adds nothing to the strength or tightness of the seam, and cannot be attended with the smallest difficulty. We think, indeed, that in a large cask or tub it would prove injurious to the seam; for either these dove-tails must be very thin slips raised from the interior edges of the staves, which in many cases could not be done if the wood were thoroughly seasoned; or if they be cut out like inverted wedges, the contiguous staves must be brought into contact from the interior to the exterior side previous to the driving of the hoops; and in that case, as we have seen, the seams could not be made completely tight.

COPERNICUS (Nicolaus), the restorer, if not the inventor, of the true system of the sun, holds so conspicuous a place in the republic of science, that every man of a liberal education must be interested both in the events of his life and in the history of his discoveries. Accordingly, in the Encyclopædia, we have given a short sketch of his history, as well as an account of what led him to suppose the sun placed in the centre of our system (see Copernicus, and Astronomy, n° 22. *Encycl.*) Since these articles were published, Dr Adam Smith's *Essays on Philosophical Subjects* have been given to the world; and in that which is intitled *The History of Astronomy*, we have an account of Copernicus's discoveries, so much more perspicuous and satisfactory than any thing which we have elsewhere seen on the subject, that we are persuaded our readers will be pleased to meet with it here.

"The confusion (says Dr Smith) in which the old hypothesis represented the heavenly bodies, was, as Copernicus himself tells us, what first suggested to him the design

Copernicus.

design of forming a new ſyſtem, that theſe, the nobleſt works of Nature, might no longer appear devoid of that harmony and proportion which diſcover themſelves in her meaneſt productions. What moſt of all diſſatisfied him was, the notion of the equalizing circle, which, by repreſenting the revolutions of the celeſtial ſpheres as equable only, when ſurveyed from a point that was different from their centres, introduced a real inequality into their motions; contrary to that moſt natural, and indeed fundamental idea, with which all the authors of aſtronomical ſyſtems, Plato, Eudoxus, Ariſtotle, even Hipparchus and Ptolemy themſelves, had hitherto ſet out, that the real motions of ſuch beautiful and divine objects muſt neceſſarily be perfectly regular, and go on in a manner as agreeable to the imagination as the objects themſelves are to the ſenſes. He began to conſider, therefore, whether, by ſuppoſing the heavenly bodies to be arranged in a different order from that in which Ariſtotle and Hipparchus had placed them, this ſo much ſought for uniformity might not be beſtowed upon their motions. To diſcover this arrangement, he examined all the obſcure traditions delivered down to us, concerning every other hypotheſis which the ancients had invented for the ſame purpoſe. He found, in Plutarch, that ſome old Pythagoreans had repreſented the earth as revolving in the centre of the univerſe, like a wheel round its own axis; and that others, of the ſame ſect, had removed it from the centre, and repreſented it as revolving in the ecliptic like a ſtar round the central fire. By this central fire he ſuppoſed they meant the ſun; and though in this he was very widely miſtaken, it was, it ſeems, upon this interpretation that he began to conſider how ſuch an hypotheſis might be made to correſpond to the appearances. The ſuppoſed authority of thoſe old philoſophers, if it did not originally ſuggeſt to him his ſyſtem, it ſeems at leaſt to have confirmed him in an opinion which, it is not improbable, he had before-hand other reaſons for embracing, notwithſtanding what he himſelf would affirm to the contrary.

" It then occurred to him, that if the earth was ſuppoſed to revolve every day round its axis, from weſt to eaſt, all the heavenly bodies would appear to revolve, in a contrary direction, from eaſt to weſt. The diurnal revolution of the heavens, upon this hypotheſis, might be only apparent; the firmament, which has no other ſenſible motion, might be perfectly at reſt; while the ſun, the moon, and the five planets, might have no other movement beſide that eaſtward revolution which is peculiar to themſelves. That, by ſuppoſing the earth to revolve with the planets round the ſun, in an orbit, which comprehended within it the orbits of Venus and Mercury, but was comprehended within thoſe of Mars, Jupiter, and Saturn, he could, without the embarraſſment of epicycles, connect together the apparent annual revolutions of the ſun, and the direct, retrograde, and ſtationary appearances of the planets; that while the earth really revolved round the ſun on one ſide of the heavens, the ſun would appear to revolve round the earth on the other; that while ſhe really advanced in her annual courſe, he would appear to advance eaſtward in that movement which is peculiar to himſelf. That, by ſuppoſing the axis of the earth to be always parallel to itſelf, not to be quite perpendicular, but ſomewhat inclined to the plane of her orbit, and conſequently to preſent to the ſun, the one pole when on the one ſide of him, and the other when on the other, he would account for the obliquity of the ecliptic; the ſun's ſeemingly alternate progreſſion from north to ſouth, and from ſouth to north, the conſequent change of the ſeaſons, and different lengths of days and nights in the different ſeaſons.

" If this new hypotheſis thus connected together all theſe appearances as happily as that of Ptolemy, there were others which it connected together much better. The three ſuperior planets, when nearly in conjunction with the ſun, appear always at the greateſt diſtance from the earth, are ſmalleſt, and leaſt ſenſible to the eye, and ſeem to revolve forward in their direct motion with the greateſt rapidity. On the contrary, when in oppoſition to the ſun, that is, when in their meridian about midnight, they appear neareſt the earth, are largeſt, and moſt ſenſible to the eye, and ſeem to revolve backwards in their retrograde motion. To explain theſe appearances, the ſyſtem of Ptolemy ſuppoſed each of theſe planets to be at the upper part of their ſeveral epicycles in the one caſe, and at the lower in the other. But it afforded no ſatisfactory principle of connection, which could lead the mind eaſily to conceive how the epicycles of thoſe planets, whoſe ſpheres were ſo diſtant from the ſphere of the ſun, ſhould thus, if one may ſay ſo, keep time to his motion. The ſyſtem of Copernicus afforded this eaſily, and like a more ſimple machine, without the aſſiſtance of epicycles, connected together, by fewer movements, the complex appearances of the heavens. When the ſuperior planets appear nearly in conjunction with the ſun, they are then in the ſide of their orbits, which is almoſt oppoſite to, and moſt diſtant from, the earth, and therefore appears ſmalleſt and leaſt ſenſible to the eye. But as they then revolve in a direction which is almoſt contrary to that of the earth, they appear to advance forward with double velocity; as a ſhip that ſails in a contrary direction to another, appears from that other to ſail both with its own velocity and the velocity of that from which it is ſeen. On the contrary, when thoſe planets are in oppoſition to the ſun, they are on the ſame ſide of the ſun with the earth, are neareſt it, moſt ſenſible to the eye, and revolve in the ſame direction with it; but as their revolutions round the ſun are ſlower than that of the earth, they are neceſſarily left behind by it, and therefore ſeem to revolve backwards; as a ſhip which ſails ſlower than another, though it ſails in the ſame direction, appears from that other to ſail backwards. After the ſame manner, by the ſame annual revolution of the earth, he connected together the direct and retrograde motions of the two inferior planets, as well as the ſtationary appearances of all the five.

" Thus far did this new account of things render the appearances of the heavens more completely coherent than had been done by any of the former ſyſtems. It did this, too, by a more ſimple and intelligible, as well as more beautiful machinery. It repreſented the ſun, the great enlightener of the univerſe, whoſe body was alone larger than all the planets taken together, as eſtabliſhed immoveable in the centre, ſhedding light and heat on all the worlds that circulated around him in one uniform direction, but in longer or ſhorter periods, according to their different diſtances. It took away the diurnal revolution of the firmament, whoſe rapidity, upon

upon the old hypothesis, was beyond what even thought could conceive. It not only delivered the imagination from the embarrassment of epicycles, but from the difficulty of conceiving these two opposite motions going on at the same time, which the system of Ptolemy and Aristotle bestowed upon all the planets; I mean, their diurnal westward, and periodical eastward revolutions. The earth's revolution round its own axis took away the necessity for supposing the first, and the second was easily conceived when by itself. The five planets, which seem, upon all other systems, to be objects of a species by themselves, unlike to every thing to which the imagination has been accustomed, when supposed to revolve along with the earth round the sun, were naturally apprehended to be objects of the same kind with the earth, habitable, opaque, and enlightened only by the rays of the sun. And thus this hypothesis, by classing them in the same species of things, with an object that is of all others the most familiar to us, took off that wonder and uncertainty which the strangeness and singularity of their appearance had excited; and thus far, too, better answered the great end of philosophy.

"Neither did the beauty and simplicity of this system alone recommend it to the imagination; the novelty and unexpectedness of that view of nature which it opened to the fancy, excited more wonder and surprise than the strangest of those appearances, which it had been invented to render natural and familiar, and these sentiments still more endeared it. For though it is the end of philosophy to allay that wonder which either the unusual or seemingly disjointed appearances of Nature excite, yet she never triumphs so much as when, in order to connect together a few, in themselves perhaps inconsiderable objects, she has, if I may say so, created another constitution of things, more natural indeed, and such as the imagination can more easily attend to, but more new, more contrary to common opinion and expectation, than any of those appearances themselves. As in the instance before us, in order to connect together some seeming irregularities in the motions of the planets, the most inconsiderable objects in the heavens, and of which the greater part of mankind have no occasion to take any notice during the whole course of their lives, she has, to talk in the hyperbolical language of Tycho Brahé, moved the earth from its foundations, stopt the revolution of the firmament, made the sun stand still, and subverted the whole order of the universe.

"Such were the advantages of this new hypothesis, as they appeared to its author when he first invented it. But though that love of paradox, so natural to the learned, and that pleasure which they are so apt to take in exciting, by the novelty of their supposed discoveries, the amazement of mankind, may, notwithstanding what one of his disciples tells us to the contrary, have had its weight in prompting Copernicus to adopt this system; yet when he had completed his Treatise of Revolutions, and began coolly to consider what a strange doctrine he was about to offer to the world, he so much dreaded the prejudice of mankind against it, that, by a species of continence of all others the most difficult to a philosopher, he detained it in his closet for thirty years together. At last, in the extremity of old age, he allowed it to be extorted from him, but died as soon as it was printed, and before it was published."

This noble theory, however, being repugnant to the prejudices of habit and education, was at first coldly received, or utterly rejected, by every class of men. The astronomers alone favoured it with their notice, though rather as a convenient hypothesis than an important truth. By the vulgar it was considered as a chimera, belied by the clearest evidence of our senses; while the learned beheld it with disdain, because it militated against the fanciful distinctions and the vague erroneous tenets of the Peripatetic philosophy, which no one had ventured to call in question; and it is amusing to observe with what dexterity the Copernicans, still using the same weapons, endeavoured to parry the blows of their antagonists. Its real merits and blemishes appear to have been overlooked by both parties. Brahé framed a sort of intermediate system; but this Danish astronomer was more remarkable for his patience and skill in observing the heavens, than for his talents of philosophical investigation. Towards the commencement of the 16th century, a new order of things emerged. The system of Copernicus became generally known and daily made converts. Its reception alarmed the ever-watchful authority of the church, roused her jealousy, and at length provoked her vindictive artillery. The *ultima ratio theologorum* was pointed at the head of the illustrious Galileo, whose elegant genius discovered the laws of motion, extended the science of mechanics, and added lustre and solidity to the true system of the universe. From the storms of persecution Copernicus himself had been exempted only by a timely death.

COPPER, one of the metals; for the properties of which, see Chemistry-*Index* in this Supplement.—The Chinese have a metal which they call *pe-tung*, but which Sir George Staunton denominates

White Copper. This metal has a beautiful silver-like appearance, and a very close grain. It takes a fine polish, and many articles of neat workmanship, in imitation of silver, are made of it. An accurate analysis has determined it to consist of copper, zinc, a little silver; and in some specimens a few particles of iron and of nickel have been found. From this account it would appear that white copper is not an artificial mixture of metals, but is found native in the mine. Yet in the very same page and paragraph, Sir George proceeds to say that Dr Gallan was informed at Canton, that the artists, in making their pe-tung, reduce the copper into as thin sheets or laminæ as possible, which they make red-hot, and increase the fire to such a pitch as to soften in some degree the laminæ, and to render them ready almost to flow. In this state they are suspended over the vapour of their purest tu-te-nag or zinc, placed in a subliming vessel over a brisk fire. The vapour thus penetrates the heated laminæ of the copper, so as to remain fixed with it, and not to be easily dissipated or calcined by the succeeding fusion it has to undergo. The whole is suffered to cool gradually, and is then found to be of a brighter colour, and of a closer grain, than when prepared in the European way. Surely this is not the white copper, which consists of copper, zinc, silver, iron, and nickel.

CORK is the exterior bark of a tree which has been described in the Encyclopædia. When the tree is about 15 years old it is fit to be barked, and this can be done successively for eight years. The bark always grows up again, and its quality improves as the age of the tree increases. It is commonly singed a little over a

Cornua.

ſtrong fire or glowing coals, or laid to ſoak a certain time in water; after which it is placed under ſtones in order to be preſſed ſtraight. We were wont to procure the greater part of our cork from the Dutch, who brought it principally from France; but they imported ſome alſo from Portugal and Spain.

This tree, as well as the uſes to which its bark is put, was known to the Greeks and the Romans; by the former of whom it was called φελλος, and by the latter *ſuber*. By the Romans, as we learn from Pliny, it was even employed to ſtop veſſels of every kind; but its application to this uſe ſeems not to have been very common till the invention of glaſs bottles, of which Profeſſor Beckmann finds no mention before the 15th century.

In later times, ſome other vegetable productions have been found which can be employed inſtead of cork for the laſt mentioned purpoſe. Among theſe is the wood of a tree common in South America, particularly in moiſt places, which is called there *monbin* or *monbain*, and by botaniſts *ſpondias lutea*. This wood is brought to England in great abundance for that uſe. The ſpongy root of a North American tree, known by the name of *nyſſa*, is alſo uſed for the ſame end, as are the roots of liquorice, which, on that account, is much cultivated in Sclavonia, and exported to other countries.

CORNUA Ammonis, in natural hiſtory, are foſſil ſhells, of which a pretty full account is given in the Encyclopædia. See Cornu *Ammonis* and Snake-*Stones*. It was obſerved in the laſt of theſe articles, that few, if any, of theſe ſhells are known in their recent ſtate, or as occupied by the living animal; but ſome authors have aſſerted, on the authority of Linnæus, that *ammonites*, with ſhells ſimilar to all the varieties of the foſſil ones, are yet found alive in the depth of the ſea. We are much inclined to embrace this opinion; but it has been controverted by *M. de Lamanon*, who accompanied *La Perouſe* on his voyage of diſcovery, by ſuch arguments as we know not how to anſwer. This unfortunate naturaliſt (ſee Lamanon in this Supplement) allows that there are ſtill in the ſea living *cornua ammonis;* but he thinks that they are in very ſmall numbers, and materially different from the greater part of the foſſil ones. According to him, theſe laſt ought to be conſidered as a race, formerly the moſt numerous of all, of which, either there are no deſcendants, or thoſe deſcendants are reduced to a few degenerate individuals. That there are no living animals with ſhells of the very ſame kind with ſome of the foſſil *cornua ammonis*, the following obſervations he conſiders as a ſufficient proof.

"The foſſil ſhells are very light and thin, whereas the ſhells of thoſe animals that live in very deep water are always thick and ponderous; beſides, the form of the foſſil cornua ammonis points out to us, in ſome meaſure, the organization of the animal which inhabited it. The celebrated Juſſieu proved, in 1721, that there exiſted a very cloſe analogy between the ammonite and nautilus (A). It is well known that the nautilus, by filling or emptying a part of its ſhell, has the power of remaining ſtationary in any depth it pleaſes: the ſame was doubtleſs the caſe with the ammonite; and if this ſpecies ſtill abounds in the ſea, it would ſurely be occaſionally diſcovered by ſailors.

"The waves alſo would throw fragments of it on the ſhore; fiſhermen might ſometimes entangle it in their nets; or, at leaſt, there would be fragments ſticking to the lead of the ſounding line when aſcertaining great depths. It may alſo be added, that if the ammonites never quitted the abyſs of the ſea, thoſe which are found petrified would not be conſtantly met with on the ſame level, and in the ſame bed, as thoſe ſhell-fiſh that only inhabit the ſhallows. There are, however, found in Normandy, Provence, Touraine, and a multitude of other places, ammonites mixed with turbines, buccina (whelks), and other littoral ſhells. They are found, beſides, at every degree of elevation from below the level of the ſea to the ſummits of the higheſt mountains. Analogy alſo leads us to ſuppoſe, that Nature, who has given eyes to the nautilus, has not refuſed them to the ammonite: now what uſe could theſe be of if they remained confined to thoſe depths which the light is unable to penetrate?

"The extinction of the ancient race of ammonites is therefore an eſtabliſhed fact, which no rational ſuppoſition can deſtroy; and this fact is undoubtedly the moſt ſurpriſing of any that is preſented to us in the hiſtory of aquatic animals. The diſcovery of a few living ſpecies of cornua ammonis does not deſtroy the truth of this, for theſe ammonites are very different from thoſe which are found petrified. They are extremely rare, and cannot be looked up to as the repreſentatives of the old ammonites, ſo varied in their ſpecies, and the number of which in the ancient ocean was probably far more conſiderable than that of all the other ſhells beſides."

To every univolve ſhell, rolled in a ſpiral, ſo as that a horizontal plane will divide it into two equal parts, formed of united ſpirals, and bearing a certain proportion to each other, our author gives the name of an *ammonite*. "I thought it abſolutely neceſſary (ſays he) to aſcertain the preciſe meaning of the term *ammonite*, previous to deſcribing that which I found during our voyage round the world. The form of this is almoſt orbicular, the long diameter being to the ſhort one as three lines to two lines and three quarters. The firſt ſpire is by far the largeſt, occupying nearly half of the longitudinal diameter. The ſummit is placed at the diſtance of about two-thirds of this diameter; it is terminated on the right ſide by a very ſmall knob viſible only through a magnifier, thus differing from the ammonite of Rimini, which beſides is microſcopical and celled, the inſide of this which we are now ſpeaking of being entirely plain. The number of ſpiral circumvolutions is four and a half; they are equally convex on both ſides, and are fixed on a plane, dividing the ſhell into

(A) There are, however, ſome ſtriking internal differences: firſt, the partitions in the ſhell of the nautilus are more curved than thoſe of the ammonite: ſecondly, the ammonite wants the ſmall hole which communicates from one cell to the other.

Cornua.

into two equal parts: there is on each ſide a kind of boſs formed by the increaſe of the perpendicular diameter of the ſpires, in proportion as they recede from the centre. The ſurface is ſmooth; the back is armed with a flat, even, brittle creſt, as thin as paper, ſurrounding it on every ſide like a ruff: it is about half a line broad, extends over the ſummit of the ſpires, and ſerves to join them together. The mouth of the ſhell is nearly triangular; its edges project in the form of lips, and are rounded at the border. I have often found this ammonite encloſed in the ſtomach of the bonetta (ſcomber pelamis, Linn.), caught in the South Sea, between the tropics, where no bottom was found with a line of more than two hundred fathoms. Theſe ſhells were covered with a black clayey mud. Their ſize varies from one to four lines acroſs; they are conſequently the largeſt living ammonites that have yet been diſcovered."

It is well known for what purpoſe the modern philoſophers of France have been ſo indefatigable in the ſtudy of natural hiſtory; and there can be little doubt but that it is to ſerve the ſame purpoſe that Lamanon thus reaſons for the deſtruction of the ancient race of ammonites in ſome univerſal convulſion of the world. But ſuppoſing his arguments concluſive, they affect not the truth of the Jewiſh and Chriſtian ſcriptures. It is nowhere ſaid in the Bible, that the *matter* of this globe was brought into being at the moment when Moſes repreſents the Creator as beginning to reduce the chaos into order; and it is more than inſinuated that there will be a *new earth* after the preſent ſyſtem of things ſhall be diſſolved. That *new* earth will certainly be ſtored with ſome kind of inhabitants; and could it be demonſtrated that there was an *old* earth, previous to the era of the Moſaic coſmogany, inhabited by creatures rational and irrational, and that the foſſil *cornua ammonis* make part of the wreck of that ſyſtem, the cauſe of revelation would remain uninjured. "Moſes, as a real philoſopher * has well obſerved, writes the hiſtory, not of this globe through all its revolutions, but of the race of Adam."

* *Profeſſor Robiſon of Edinburgh.*

This ſecret attack, therefore, made by Lamanon againſt that religion of which he once profeſſed to diſcharge the duties of a prieſt, is nothing more than *telum imbelle ſine ictu.* Yet it may be worth ſome naturaliſt's while to enquire, whether, though feeble, it has been fairly made. We confeſs that our own ſuſpicions of unfair dealing are ſtrong; for when a man of ſcience contradicts himſelf in the courſe of two pages, the blunder muſt be attributed to ſome other ſource than mere inadvertency. M. de Lamanon wiſhes to prove, among other things, that the ancient ammonites did not inhabit great depths of the ſea; and that Linnæus was miſtaken when he ſuppoſed that in great depths they may ſtill be found. Yet he himſelf tells us, that he frequently caught ammonites in the South Sea, where no bottom was to be found with a line of *more than* 200 *fathoms;* and to put it beyond a doubt that the animals had been at that bottom, he informs us, that their ſhells were covered with a *black clayey mud.* It is true theſe ammonites were but ſmall; while of 300 varieties of foſſil ammonites which he mentions, ſome, he ſays, have been found ten feet in circumference. But is it certain that theſe large ſhells were real *cornua ammonis?* If they agree not exactly with our author's deſcription of the ſhell of the ammonite (a fact into which we have had no opportunity of inquiring), his arguments for the extinction of the ancient race are groſs ſophiſms, unworthy of a man either of ſcience or of candour.

Correction.

CORRECTION-HOUSE is a priſon where idle vagrants are compelled to work, and where perſons guilty of certain crimes ſuffer puniſhment and make reparation to the public. Of the former kind of *correction-houſes*, perhaps enough has been ſaid in the Encyclopædia under the title WORK-*Houſe;* but of the latter very little will be found in that work under the titles BRIDEWELL and IDLENESS.

Perhaps houſes of correction, as means of puniſhment, are not, in this country, employed ſo frequently as juſtice and expediency ſeem to require. In the opinion of Dr Paley, whoſe opinions are always worthy of attention, it is one of the greateſt defects of the laws of England (and we may ſay the ſame thing of the laws of Scotland), that "they are not provided with any other puniſhment than that of death, ſufficiently terrible to keep offenders in awe. Tranſportation, which is the puniſhment ſecond in the order of ſeverity, anſwers the purpoſe of example very imperfectly; not only becauſe exile is in reality a ſlight puniſhment to thoſe who have neither property, nor friends, nor regular means of ſubſiſtence at home, but becauſe the puniſhment, whatever it be, is unobſerved and unknown. A tranſported convict *may* ſuffer under his ſentence, but his ſufferings are removed from the view of his countrymen; his miſery is unſeen; his condition ſtrikes no terror into the minds of thoſe for whoſe warning and admonition it was intended. This chaſm in the ſcale of puniſhment produces alſo two farther imperfections in the adminiſtration of penal juſtice; of which the firſt is, that the ſame puniſhment is extended to crimes of very different characters and malignancy; and the ſecond, that puniſhments, ſeparated by a great interval, are aſſigned to crimes hardly diſtinguiſhable in their guilt and miſchief."

Perhaps this chaſm might be properly filled up by houſes of correction under judicious management, which might likewiſe promote another important purpoſe, better than the puniſhments in common uſe.

The end of puniſhment is twofold, *amendment* and *example.* In the firſt of theſe, the *reformation* of criminals, little has ever been effected, and little indeed ſeems practicable by the puniſhments known to the laws of Britain. From every ſpecies of puniſhment inflicted among us, from impriſonment and exile, from pain and infamy, malefactors return more hardened in their crimes, and more inſtructed. The caſe we think would often be different when they returned to the world from a well-regulated houſe of correction. As experience is the only ſafe guide in matters of legiſlation and police, we ſhall lay before our readers *M. Thouin*'s account of the houſe of correction at Amſterdam, which ſeems to corroborate our opinion.

The Amſterdam correction houſe, from the employment of the priſoners confined in it, is called the *raſping-houſe*, and is deſtined to the reception of thoſe malefactors whoſe crimes do not amount to a capital offence. Their puniſhment cannot ſo properly be denominated ſolitary confinement as a ſequeſtration from ſociety during a limited term of years. The building is ſituated in a part of the ſuburbs to the north-eaſt of the city.

The

Correction. The exterior has nothing remarkable, either with reſpect to form or extent. It is detached from the ſtreet by a ſpacious court, which contains the keeper's lodge, together with apartments for the different ſervants belonging to the eſtabliſhment. Over the gate, which opens from this court into the priſon, are placed two ſtatues, as large as life, repreſenting two men in the act of ſawing a piece of logwood.

The inner court is in the form of a ſquare, round which are arranged the apartments of the priſoners, together with the neceſſary warehouſes. One part of the ground ſtory is divided into different chambers; the other ſerves as a depot for the logwood, and the implements employed in its preparation.

The keeper, whoſe countenance, contrary to the general cuſtom of perſons of his profeſſion, was ſtrongly indicative of urbanity and gentleneſs, introduced M. Thouin into an apartment where two priſoners were at work in ſawing a large log of Campeachy wood. The ſaw is compoſed of four blades joined together, with very ſtrong, large, and ſharp teeth, which make a ſciſſure in the wood of nearly two inches in breadth. The operation is repeated, till the pieces become too ſmall to undergo the ſaw, when they are ground in mills peculiarly conſtructed for this purpoſe.

This employment requires an extraordinary exertion of ſtrength, and is at firſt a ſevere penance even to robuſt perſons; but habit, addreſs, and practice, ſoon render it eaſy; and the priſoners in a ſhort time become competent to furniſh, without painful exertion, their weekly contingent of 200 lb. weight of ſawed pieces. After completing this taſk, they even find time to fabricate a variety of little articles in wood and ſtraw, which they ſell to thoſe who viſit the priſon, or diſpoſe of, by means of agents, in the town.

M. Thouin next inſpected three apartments of different dimenſions, which opened into the inner court. The one was inhabited by four, the ſecond by ſix, and the third by ten priſoners. The furniture of the rooms conſiſted in hammocks, with a matraſs, a blanket, and a coverlid to each, tables, chairs, and ſtools, glaſs, &c. earthen veſſels, and various other articles of convenience. Every thing in theſe apartments was diſtinguiſhed by neatneſs and propriety; and notwithſtanding the number of inhabitants allotted to each, was fully adequate to the dimenſions of the rooms; the ſenſes were not offended with any diſagreeable ſcent, and the air was in every reſpect as pure and wholeſome as the ſurrounding atmoſphere.

In an obſcure part of the building are a number of cells, in which formerly thoſe priſoners who revolted againſt the proper ſubordination of the place, or ill-treated their comrades, were confined for a few days. But the keeper aſſured M. Thouin that theſe cells had not been made uſe of for upwards of 10 years. They are dark gloomy dungeons, with only a ſmall aperture for the admiſſion of light and air. The ſuppreſſion of this barbarous and coercive puniſhment does honour to the humanity of government.

The ſtore-rooms are filled with various kinds of wood for the purpoſes of dyeing; as the haemotoxylum campechianum, the morus tinctoria, the caeſalpinia ſappan, &c. They are all exotics, with the exception of the Evonymus Europæus. The warehouſes were not of ſufficient extent to contain the quantity of wood, which was depoſited in piles in different parts of the court. Correction.

The priſoners, amounting to 76 in number, were uniformly habited in coarſe woollens; wear very good ſtockings, large leather ſhoes, white ſhirts, and caps or hats. They are, by the rules of the houſe, obliged to frequent ablutions, which greatly contribute to the preſervation of their health. There was only one ſick perſon amongſt them; and, what is not a little remarkable, almoſt all the priſoners had formerly lived in large commercial towns; very few villagers were amongſt them. They had all been ſentenced to impriſonment for theft; but it depends upon themſelves, by reformation and good behaviour, to ſhorten the term of their confinement, which many of them frequently do.

The keeper, whoſe humanity to the unfortunate perſons committed to his care entitles him rather to the title of their protector than their gaoler (and M. Thouin informs us, that the priſoners generally called him by no other name than *father)*, aſſiſts them with his counſels and friendly admonitions. He regiſters every week, in a book appropriated to this purpoſe, both the inſtances of good and bad behaviour, which is annually ſubmitted to the examination of the magiſtracy, who, from this report, abridge or prolong the term of confinement, according to the degree of indulgence which each priſoner appears to merit. Caſes frequently happen where a malefactor, condemned to an impriſonment of eight years, by his good behaviour procures his enlargement at the expiration of four; and ſo in proportion for a ſhorter term. But great attention is paid to diſcriminate between actual reform and hypocritical artifice.

The reward of good behaviour is not, however, confined to, or withheld till, the period of actual liberation. Their reſtoration to ſociety is preceded by a progreſſive amelioration of their lot. Their work is gradually rendered leſs laborious, they are accommodated with ſeparate apartments, and employed in the ſervices of domeſtic economy. The keeper even entruſts them with commiſſions beyond the precincts of the priſon; and ſcarce a ſingle inſtance has occurred of their abuſing this indulgence. By this prudent management, a conſiderable ſaving is effected in the expence of the eſtabliſhment, at the ſame time that it tends to wear away prejudice, and to initiate the priſoners by gradual advances into the reciprocal duties of ſocial life.

M. Thouin made particular inquiries whether it was cuſtomary for perſons after their diſcharge to be confined a ſecond and third time, as is but too often the caſe in many countries, for a repetition of their offence. He was informed, that ſuch inſtances very rarely occur; but the caſe is not without precedent, as he obſerved in the perſon of a young Jew, who was then in the raſping-houſe for the third time. The caſe of this man is ſomewhat extraordinary. During the period of his detention, he always conforms, with the moſt ſcrupulous obſervance, to the rules of the place, and gives general ſatisfaction by his exemplary conduct. But ſuch, as he himſelf avowed to our traveller, is his conſtitutional propenſity to thieving, that no ſooner is the term of his impriſonment elapſed, than he returns with redoubled ardour to his lawleſs courſes. It is not ſo much for the ſake of plunder, as to gratify his irreſiſtible impulſe, that he follows this vicious life; and M. Thouin adds, that he recounted his different exploits with as much exultation

Correction. exultation and triumph as a veteran displays when rehearsing his warlike atchievements.

Another salutary regulation in this institution, from which the best consequences result, is the indulgence granted to the prisoners of receiving the visits of their wives and mistresses twice every week. Proper care, however, is taken to guard against the introduction of disease; and the ladies, in one sense, purchase their admission by giving a trifling sum of money at the gate, which becomes the perquisite of the aged prisoners, whose wants are of a different nature from their youthful comrades. Thus the pleasures of one class contribute to the comforts of the other; and the entrance money, trifling as it is, keeps away a croud of idle vagabonds, who have no acquaintance with the prisoners. The ladies at their visits are permitted to eat and drink with their lovers; and when the conversation becomes too animated for a third person to be present, the rest of the company obligingly take the hint, and leave them to enjoy a *tete-a-tete*.—By this prudent regulation, many hurtful consequences attendant on a total seclusion from female society are guarded against.

M. Thouin concludes his account with observing, that the rasping-house at Amsterdam bears a greater resemblance to a well-ordered manufactory than to a prison. It were to be wished that all similar institutions were conducted upon a similar plan (A).

So says our author: But though we have admitted experience to be the only safe guide in regulating institutions of this kind, we cannot help thinking that the plan is susceptible of improvement. We do not see the propriety of locking up four, six, or ten thieves in the same apartment. The uncommon attention to cleanliness, which distinguishes all ranks among the Dutch, may indeed prevent the room from having an offensive scent; but what can prevent such a number of unprincipled persons from corrupting each other in Holland, as we know that they do in Great Britain? The introduction of females of loose character to felons suffering punishment for their offences in a prison, is a practice which we trust will be approved only by philosophers of the French school. The British philosopher, whom we have already quoted with approbation, is of opinion, and we heartily agree with him, that "of reforming punishments, none promises so much success as that of solitary imprisonment, or the confinement of criminals in separate apartments. This improvement of the Amsterdam house of correction would augment the terror of the punishment, would seclude the criminal from the society of his fellow-prisoners, in which society the worse are sure to corrupt the better; would wean him from the knowledge of his companions, and from the love of that turbulent pernicious life in which his vices had engaged him; would raise up in him reflections on the folly of his choice, and dispose his mind to such bitter and continued penitence, as might produce a lasting alteration in the principles of his conduct."

In some houses of correction, the prisoners are subjected to the discipline of flagellation at stated intervals. We will not take it upon us to say that this punishment is never proper; but we are fully convinced that it is not often so; and that flagellation, if it can at all produce any good effect, must be administered in private. It is observed by Fielding, who well understood human nature, that fasting is the proper punishment of profligacy, not any punishment that, like flagellation, is attended with shame. Punishment (says he) that deprives a man of all sense of honour, never will contribute to make him virtuous; and we believe it is generally admitted by the gentlemen of the army, that a soldier who has suffered the punishment of whipping seldom proves good for any thing.

Courtesey || Crane.

COURTESEY OF SCOTLAND. See LAW (*Encycl.*), Part III. sect. ix. § 28.

COWRY-SHELLS, the lowest money in some parts of the East. See MONEY (*Encycl.*), where they are called *karis*.

CRANE, in mechanics, a machine used for raising or lowering great weights. For the principles on which these machines act, see DYNAMICS in this *Supplement*, and likewise MECHANICS, *Encycl.* where descriptions are given of several very powerful cranes.

The crane in common use is employed with some danger to those who work it; and therefore a machine of this kind, acting upon a simple and certain principle, by which the men walking in the wheel can lower goods with safety as well as expedition, has long been considered as a great desideratum in mechanics. Repeated premiums have been offered by the *Society for the Encouragement of Arts* to induce ingenious men to attempt the invention of such a machine; and various have been the contrivances for accomplishing so desirable a purpose. A clergyman, who subscribes E. C. we suppose as the initials of his name, proposes, through the medium of the Repertory of Arts, to accomplish it merely by introducing the action of a worm or screw into the crane.

Whenever a worm of two threads is introduced into a machine, all retrograde motion is stopped, unless that worm receive its reaction from the first moving force; for, powerfully as a worm acts upon a wheel, a wheel has no power upon a worm, whatever force may be applied to it. Suppose, then, the first motion in a crane were given by a worm upon the axis of the wheel in which the man walks, the man would have perfect command of the machine, to raise or lower the goods at pleasure, with the remotest possibility of being overpowered by the descending weight.

"Were I to construct (says the author) a crane upon this principle, I would have the axis of the wheel in which the man walks, and the axis of the worm, in separate parts, and occasionally united by a coupling-box. When goods were to be raised, the two axes should be connected; when lowered, they might be disunited, and the worm turned by a winch, which would be done much more expeditiously that way than by the wheel. For the reasons before suggested, the descent of the weight could be accelerated or stopped at pleasure, at the discretion of the person turning the winch.

"This contrivance might be not inconveniently applied

(A) We do not know that M. Thouin's journal of his travels has been yet published. Extracts from it have been inserted into the *Decade*, a periodical publication at Paris, whence this account of the *Amsterdam house of correction* was first copied into the Monthly Magazine for June 1798.

plied to a crane already erected upon the common principle: Let there be a wheel put upon any convenient axis in the machine as it now ſtands; upon this let there lie a worm, that can be thrown in or out of gear at pleaſure; and let the lever by which it is done lie within reach of the man's hand in the wheel. The goods being faſtened to the crane, and raiſed off the floor of the warehouſe ready for letting down, the man puts the worm into gear, leaves the wheel, and lets the goods down by the winch. Provided it can be conveniently done, it would be adviſable to throw the wheel in which the man walks out of gear when the winch is made uſe of; this, however, I ſhould apprehend, would not be a matter of abſolute neceſſity."

Our author is aware of two objections which may be urged againſt the introduction of a worm into a crane in the manner which he propoſes. The firſt ariſes from the ſlowneſs of the motion produced by the turning of a ſcrew, which he conſiders as unworthy of regard; becauſe the neceſſary ſpeed is to be gained by the firſt pair of wheels and the diameter of the barrel of the windlaſs.

To the ſecond, ariſing from the ſuppoſed greater friction between a worm and wheel, he replies, that as the friction between the teeth of two wheels (if not formed on the true epicycloidal principle) muſt, while it laſts, be greater than between a worm and wheel for the ſame ſpace of time, it ſeems no unreaſonable ſuppoſition that the aggregate of friction will, in the two caſes, nearly balance each other; eſpecially if it be taken into the account, that to obtain the power of one worm and wheel, there will be, in moſt caſes, required two pair of wheels, and two additional axes—all which will add to the friction. But, granting the balance of friction to be againſt the action of the worm, the power to overcome it is greater in proportion than to overcome the friction of two wheels.

Mr James Whyte of Chevening, in the county of Kent, whoſe improvement in the conſtruction of pullies has, with due reſpect, been noticed elſewhere *, gives, in *the Tranſactions of the Society for the Encouragement of Arts*, &c. the following deſcription of a new crane for wharfs:

* See *Mechanics*, nº 27. *Encycl.*

Plate XX.

A (fig. 1.), a circular inclined plane, moving on a pivot underneath it, and carrying round with it the axis E. A perſon walking on this plane, and preſſing againſt the lever B, throws off the gripe D, by means of an iron rod C; and thus admits the plane and its axis to move freely, and raiſe the weight G by the coiling of the rope F round the axis E.

To ſhew more clearly the conſtruction and action of the lever and gripe, a plan of the circular inclined plane, with the lever and gripe, is added (ſee fig. 2.), where B repreſents the lever, D the ſpring or gripe. In this plan, when the lever B is in the ſituation in which it now appears, the ſpring or gripe D preſſes againſt the periphery of the plane, as ſhewn by the double line, and the machine cannot move; but when the lever B is preſſed out to the dotted line H, the gripe is alſo thrown off to the dotted line I, and the whole machine left at liberty to move. One end of a rope or cord, of a proper length, is fixed near the end of the lever B, and the other end made faſt to one of the uprights, ſerving to prevent the lever moving too far when preſſed by the man.

The properties of this crane, for which the premium of 40 guineas was adjudged by the ſociety to the inventor, are as follows:

1. It is ſimple, conſiſting merely of a wheel and axle. 2. It has comparatively little friction, as is obvious from the bare inſpection of the figure. 3. It is durable, as is evident from the two properties above mentioned. 4. It is ſafe; for it cannot move but during the pleaſure of the man, and while he is actually preſſing on the gripe-lever. 5. This crane admits of an almoſt infinite variety of different powers; and this variation is obtained without the leaſt alteration of any part of the machine. If, in unloading a veſſel, there ſhould be found goods of every weight, from a few hundreds to a ton and upwards, the man that does the work will be able ſo to adapt his ſtrength to each as to raiſe it in a ſpace of time proportionate to its weight; he walking always with the ſame velocity as nature and his greateſt eaſe may teach him.

It is a great diſadvantage in ſome cranes, that they take as long time to raiſe the ſmalleſt as the largeſt weight, unleſs the man who works them turn or walk with ſuch velocity as muſt ſoon tire him. In other cranes, perhaps, two or three different powers may be procured; to obtain which, ſome pinion muſt be ſhifted, or freſh handle applied or reſorted to. In this crane, on the contrary, if the labourer find his load ſo heavy as to permit him to aſcend the wheel without its turning, let him only move a ſtep or two toward the circumference, and he will be fully equal to the taſk. Again, if the load be ſo light as ſcarcely to reſiſt the action of his feet, and thus to oblige him to run through ſo much ſpace as to tire him beyond neceſſity, let him move laterally towards the centre, and he will ſoon feel the place where his ſtrength will ſuffer the leaſt fatigue by raiſing the load in queſtion. One man's weight applied to the extremity of the wheel would raiſe upwards of a ton; and it need not be added, that a ſingle-ſheaved block would double that power. Suffice it to ſay, that the ſize may be varied in any required *ratio*; and that this wheel will give as great advantage at any point of its plane as a common walking-wheel of equal diameter, as the inclination can be varied at pleaſure, as far as expediency may require. It may be neceſſary to obſerve, that what in the figure is the frame, and ſeems to form a part of the crane, muſt be conſidered as a part of the houſe in which it is placed; ſince it would be moſtly unneceſſary ſhould ſuch cranes be erected in houſes already built. With reſpect to the horizontal part, by walking on which the man who attends the gib occaſionally aſſiſts in raiſing the load, it is not an eſſential part of this invention, where the crane is not immediately contiguous to the gib, although, where it is, it would be certainly very convenient and economical.

Crane is alſo a popular name for a ſyphon, employed in drawing off liquors.

CROSS, *in ſurveying*, is an inſtrument conſiſting of a braſs circle, divided into four equal parts by two lines croſſing each other in the centre. At each extremity of theſe lines is fixed a perpendicular ſight, with ſmall holes below each ſlit, for the better diſcovering of diſtant objects. The croſs is mounted on a ſtaff or ſtand, to fix it in the ground, and is very uſeful for meaſuring ſmall pieces of land, and taking offsets, &c.

Cross-ſtaff, or *Fore-ſtaff*, is a mathematical inſtrument of

of box or pear-tree, confifting of a fquare ftaff of about three feet long, having each of its faces divided like a line of tangents, and having four crofs pieces of unequal lengths to fit on the ftaff, the halves of thefe being as the radii to the tangent lines on the faces of the ftaff.—The inftrument was ufed in taking the altitudes of the celeftial bodies at fea.

CROWN, in aftronomy, a name given to two conftellations, the fouthern and the northern.

Crown, in geometry, a plane ring included between two parallel or concentric peripheries of unequal circles.

Crown-Poft, is a poft in fome buildings ftanding upright in the middle between two principal rafters; and from which proceed ftruts or braces to the middle of each rafter. It is otherwife called a *king-poft*, or *king's-piece*, or *joggle-piece*.

La CRUZ, an excellent harbour on the north-weft coaft of America, difcovered by the Spaniards in 1779. They were introduced into it by a paffage which they called *Bucarelli's Entrance*, and which they placed in 55° 18′ N. Lat. and 139° 15′ W. Long. from the meridian of Paris. There is no good reafon to queftion the exactnefs of the latitude of this paffage as laid down by the Spaniards; but the editor of Peroufe's voyage juftly concludes, from the furvey made by our celebrated navigator Captain Cook on the coafts adjacent to the entrance of Bucarelli, that this entrance is about 135° 20′ to the weft of Paris, or very nearly 133° weft of Greenwich.

The Spaniards were not long in the harbour of *La Cruz* before they received a vifit from the inhabitants in its neighbourhood. Bartering took place. The Indians gave their peltry, and various trifles, for glafs beads, bits of old iron, &c. By this traffic the Spaniards were enabled to gain a fufficiently exact knowledge of their genius, of their offenfive and defenfive arms, of their manufactures, &c.

Their colour is a clear olive; many among them have, however, a perfectly white fkin: their countenance is well proportioned in all its parts. They are robuft, courageous, arrogant, and warlike.

They clothe themfelves in one or two undreffed fkins (with the fur apparently); thefe are the fkins of otters, of fea-wolves, of benades (a fpecies of deer), of bears, or other animals, which they take in hunting. Thefe dreffes cover them from the neck to the middle of the leg; there are, however, many among them who wear boots of fmooth fkin, refembling Englifh boots, only that thofe of the Indians open before, and are laced tight with a ftring. They wear hats woven from the fine bark of trees, the form of which refembles that of a funnel or a cone. At the wrifts they have bracelets of copper or iron, or for want of thefe metals the fins of whales; and round the neck, necklaces of fmall fragments of bones of fifhes and other animals, and even copper collars of the bignefs of two fingers. They wear in their ears pendants of mother-of-pearl, or flat pieces of copper, on which is emboffed a refin of a topaz colour, and which are accompanied with jet beads. Their hair is long and thick, and they make ufe of a comb to hold it together in a fmall queue from the middle to the extremity; a narrow ribbon of coarfe linen, woven for this purpofe, ferves as a ligament. They wear alfo as a covering a kind of fcarf, woven in a particular manner, fomething more than a yard and a half long, and about half a yard broad, round which hangs a fringe fomething more than half a quarter of a yard deep, of which the thread is regularly twifted.

The women give proofs of their modefty and decency by their drefs. Their phyfiognomy is agreeable, their colour frefh, their cheeks vermilioned, and their hair long; they plait it together in one long trefs. They wear a long robe of a fmooth fkin tied round the loins, like that of a nun; it covers them from the neck as low as the feet; the fleeves reach down to the wrifts. Upon this robe they put divers fkins of otters or other animals to defend themfelves from the inclemency of the weather. Better dreffed, many of them might difpute charms with the moft handfome Spanifh women; but diffatisfied with their natural charms, they have recourfe to art, not to embellifh, but to disfigure themfelves. All the married women have a large opening in the under lip, and this opening or orifice is filled up by a piece of wood cut in an oval fhape, of which the fmalleft diameter is almoft an inch; the more a woman is advanced in years, the more this curious ornament is extended: it renders them frightful, the old women efpecially, whofe lip, deprived of its wonted fpring, and dragged by the weight of this extraordinary jewel, neceffarily hangs in a very difagreeable manner. The girls wear only a copper needle, which croffes the lip in the place where the ornament is intended hereafter to be placed.

Thefe Indians in war make ufe of cuiraffes and fhoulder pieces of a manufacture like that of the whalebone ftays among the Europeans. Narrow boards or fcantlings form, in fome fort, the woof of the texture, and threads are the warp: in this manner the whole is very flexible, and leaves a free ufe to the arms for the handling of weapons. They wear round the neck a coarfe and large gorget which covers them as high as below the eyes, and their head is defended by a morion, or fkull-piece, ufually made of the head of fome ferocious animal. From the waift downwards, they wear a kind of apron, of the fame contexture as their cuirafs. Laftly, a fine fkin hangs from their fhoulders down to the knee. With this armour they are invulnerable to the arrows of their enemies; but thus armed, they cannot change pofition with fo much agility as if they were lefs burdened.

Their offenfive arms are arrows; bows, of which the ftrings are woven like the large cords of our beft mufical inftruments; lances, four yards in length, tongued with iron; knives, of the fame metal, longer than European bayonets, a weapon, however, not very common among them; little axes of flint, or of a green ftone, fo hard that they cleave the moft compact wood without injury to their edge.

The pronunciation of their language is extremely difficult; they fpeak from the throat, with a movement of the tongue againft the palate. The little ufe the women make of the inferior lip greatly injures the diftinctivenefs of their language. The Spaniards could neither pronounce nor write the words which they heard.

From the vivacity of fpirit in thefe Indians, and from their attention amply to furnifh the market eftablifhed in the harbour, it may be concluded that they are pretty laborious. They continually brought ftuffs well woven and fhaded by various colours, the fkins of land and fea wolves, of otters, bears, and other fmaller animals;

mals; of these some were raw, and others dressed. There were to be found at this market also coverlets of coarse cloth, shaded with white and brown colours, very well woven, but in small quantities: large ribbons of the same linen which might match with that of the Spanish officers mattresses; skeins of thread such as this cloth was made of; wooden plates or bowls neatly worked; small boats, or canoes, painted in various colours, the figures of which represented heads with all their parts; frogs in wood, nicely imitated, which opened like tobacco boxes, and which they employed to keep their trinkets in: boxes made of small planks, of a cubical form, being three quarters of a yard on each side, with figures well drawn, or carved on the outside, representing various animals; the covers fabricated like Flanders etwees, with rabbeted edges, formed so as to shut into the body of the box; animals in wood, as well those of the earth as of the air; figures of men of the same material, with skull-caps representing the heads of various fierce animals; snares and nets for fishing; copper collars for the neck, and bracelets of iron for the wrist, but which they would not part with except at a very high price; beak-like instruments, from which they drew sounds as from a German flute. The principal officers took such of these merchandizes as were most agreeable to them, and left the remainder to the ships crews.

As the Indians discovered that the Spaniards were very dainty in their fish, they did not let them want for choice: the greatest abundance was in salmon, and a species of sole or turbot three yards and a quarter long, broad and thick in proportion; cod and pilchards were also brought to market, and fishes resembling trout. From all this it may be inferred, that this gulf is full of fish; the banks too are covered with shells.

The quantity of mother-of-pearl that these Indians cut to pieces for making ear-rings awakened the curiosity of the Spaniards: they tried to discover whether these people had not in their possession, or whether their country did not produce pearls, or some precious stones: their researches were fruitless; they only found some stones which they judged to be metallic, and which they carried on board, not having the necessary means for extracting the metal they might contain.

These Indians feed upon fish, fresh or dry, boiled or roasted; herbs and roots which their mountains yielded them, and particularly that which in Spain is called sea parsley; and, lastly, upon the flesh of animals which they take in hunting: the productions of the chase are undoubtedly abundant, seeing the number of dogs they keep for this purpose.

These Indians appeared to the Spaniards to worship the sun, the earliest and most natural of all idolatrous worship; and they paid a decent respect to the remains of their dead. Don Maurelle, one of the Spanish officers, in an expedition round the gulf, found in two islands three dead bodies laid in boxes of a similar form to those which have been described above, though considerably larger, and decked in their furs. These biers were placed in a little hut upon a platform, or raised floor, made of the branches of trees.

The country is very hilly, the mountains are lofty, and their slope extends almost every where to the sea. The soil, limestone; it is nevertheless covered with an impenetrable forest of tall fir trees, very large and very strait. As these trees cannot strike very deep into the earth, the violence of the wind often tears them up by the roots: they rot and become a light mould, upon which grows a bushy thicket; and in this are found nettles, camomile, wild celery, anise, a species of cabbage, celandine, elder, wormwood, sorrel; and without doubt there are other plants along the rivers.

The Spaniards saw ducks, gulls, divers, kites, ravens, geese, storks, gold-finches, and other little birds unknown to them.

The commerce between the Spaniards and the Indians was quite undisturbed; and so desirous were the latter to obtain iron, cloth, and other stuffs, that they sold their children for broken iron hoops and other wares. The Spaniards in this manner bought three young lads, one from five to six years old, another of four, and the third from nine to ten, not to make slaves, but Christians of them; they hoped besides to derive useful information from them as to the nature of the country and its inhabitants. These youths were so contented in being with the Spaniards, that they hid themselves when their parents came on board, from the apprehension of being again restored to them. Two young girls were also purchased with the same view; one very ugly, seven years of age; the other younger, better made, but sickly, and almost at the gates of death.

At the full and change of the moon, the sea rises in the harbour of La Cruz seventeen feet three inches English; it is then high water at a quarter after 12 at noon: the lowest tides are fourteen feet three inches; the night tides exceed by one foot nine inches those of the day.

CRYSTAL, CRYSTALLIZATION, and *Rock*-CRYSTAL. } See CRYSTAL and CRYSTALLIZATION, *Encycl.* and CHEMISTRY-*Index* in this Supplement.

CUBIC HYPERBOLA, is a figure expressed by the equation $xy^2=a$, having two asymptotes, and consisting of two hyperbolas, lying in the adjoining angles of the asymptotes, and not in the opposite angles, like the Apollonian hyperbola; being otherwise called by Newton, in his *Enumeratio Linearum Tertii Ordinis*, an hyperbolismus of a parabola; and is the 65th species of those lines according to him.

CUBIC *Parabola*, a curve of the second order, having two infinite legs tending contrary ways. The curve of this parabola cannot be rectified even by means of the conic sections.

CULLEN (Dr William) was a man to whom physical science is so deeply indebted, that it has often struck us with wonder that no account of him has yet been given to the public, which deserves to be classed with British biography. We know, indeed, that a life of him has been written by an eminent physician well qualified and strongly inclined to do justice to the merits of his revered preceptor; but that life has been withheld from us by him who has certainly the best right to consider himself as the guardian of the Doctor's fame, and who, we have been told, is to enlarge and publish it himself. In this state of things our readers must pardon us for laying before them a very imperfect account of this eminent man, to whom we were ourselves almost strangers. There is a character of him in the periodical publication called *The Bee*, which we shall

Cullen.

ſhall appropriate to our own uſe, we are perſuaded, with the entire approbation of its author, though ſometimes we may expreſs our ſuſpicions that his praiſe is exaggerated.

Dr William Cullen was born in Lanarkſhire, in the weſt of Scotland, 11th December 1712. His father was for ſome time chief magiſtrate of the town of Hamilton; but though a very reſpectable man, his circumſtances were not ſuch as to permit him to lay out much money on the education of his ſon. William therefore, after ſerving an apprenticeſhip to a ſurgeon apothecary in Glaſgow, went ſeveral voyages to the Weſt Indies as a ſurgeon in a trading veſſel from London: but of this employment he tired, and ſettled himſelf, at an early period of life, as a country ſurgeon in the pariſh of Shotts, where he ſtaid a ſhort time practiſing among the farmers and country people, and then went to Hamilton with a view to practiſe as a phyſician, having never been fond of operating as a ſurgeon.

While he reſided near Shotts, it chanced that Archibald Duke of Argyle, who at that time bore the chief political ſway in Scotland, made a viſit to a gentleman of rank in that neighbourhood. The Duke was fond of literary purſuits, and was then particularly engaged in ſome chemical reſearches, which required to be elucidated by experiment. Eager in theſe purſuits, his Grace, while on this viſit, found himſelf much at a loſs for the want of ſome ſmall chemical apparatus, which his landlord could not furniſh: but happily recollecting young Cullen in the neighbourhood, he mentioned him to the Duke as a perſon who could probably furniſh it. He was accordingly invited to dine; was introduced to his Grace,—who was ſo much pleaſed with his knowledge, his politeneſs, and addreſs, that he formed an acquaintance which laid the foundation of all Dr Cullen's future advancement.

The name of Cullen by this time became familiar at every table in that neighbourhood; and thus he came to be known, by character, to the Duke of Hamilton, who then reſided, for a ſhort time, in that part of the country: and that nobleman having been ſuddenly taken ill, the aſſiſtance of young Cullen was called in; which proved a fortunate circumſtance in ſerving to promote his advancement to a ſtation in life more ſuited to his talents than that in which he had hitherto moved.

The character of the Douglaſſes, of which name the family of Hamilton now forms a principal branch, has always been ſomewhat of the ſame ſtamp with that of the riſing Cullen. Genius, benevolence, frankneſs, and conviviality of diſpoſition, have been, with them in general, very prominent features; and if to that be added a ſpirit of frolic and diſſipation, theſe will be accounted as only natural conſequences of thoſe youthful indulgences that ſpring from an exceſs of wealth at an early period of life, and the licence allowed to people of elevated rank. The Duke was therefore highly delighted with the ſprightly character and ingenious converſation of his new acquaintance. Receiving inſtruction from him in a much more pleaſing, and an infinitely eaſier way than he had ever before obtained, the converſation of Cullen proved highly intereſting to his Grace.—No wonder then that he ſoon found means to get his favourite Doctor, who was already the eſteemed acquaintance of the man through whoſe hands all preferments in Scotland were obliged to paſs, appointed to a place in the univerſity of Glaſgow, where his ſingular talents for diſcharging the duties of the ſtation he now occupied ſoon became very conſpicuous (A).

During his reſidence in the country, however, ſeveral important incidents occurred, that ought not to be paſſed over in ſilence. It was during this time that was formed a connection in buſineſs in a very humble line between two men, who became afterwards eminently conſpicuous in much more exalted ſtations. William, afterwards Doctor, Hunter, the famous lecturer on anatomy in London, was a native of the ſame part of the country; and not being in affluent circumſtances more than Cullen, theſe two young men, ſtimulated by the impulſe of genius to proſecute their medical ſtudies with ardour, but thwarted by the narrowneſs of their fortune, entered into a copartnery buſineſs as ſurgeons and apothecaries in the country. The chief end of their contract being to furniſh the parties with the means of proſecuting their medical ſtudies, which they could not ſeparately ſo well enjoy, it was ſtipulated, that one of them alternately ſhould be allowed to ſtudy in what college he inclined, during the winter, while the other ſhould carry on the buſineſs in the country for their common advantage. In conſequence of this agreement, Cullen was firſt allowed to ſtudy in the univerſity of Edinburgh for one winter; but when it came to Hunter's turn next winter, he, preferring London to Edinburgh, went thither. There his ſingular neatneſs in diſſecting, and uncommon dexterity in making anatomical preparations, his aſſiduity in ſtudy, his mildneſs of manner, and pliability of temper, ſoon recommended him to the notice of Dr Douglaſs, who then read lectures upon anatomy and midwifery there; who engaged Hunter as an aſſiſtant, and whoſe chair he afterwards filled with ſo much honour to himſelf and ſatisfaction to the public.

Thus was diſſolved, in a premature manner, a copartnery perhaps of as ſingular a kind as is to be found in the annals of literature: nor was Cullen a man of that diſpoſition to let any engagement with him prove a bar to his partner's advancement in life. The articles were freely departed from by him; and Cullen and Hunter ever after kept up a very cordial and friendly correſpondence; though, it is believed, they never from that time had a perſonal interview.

During the time that Cullen practiſed as a country ſurgeon and apothecary, he formed another connection of a more permanent kind, which, happily for him, was not diſſolved till a very late period of his life. With the

(A) It was not, however, ſolely to the favour of theſe two great men that Cullen owed his literary fame. He was recommended to the notice of men of ſcience in a way ſtill more honourable to himſelf. The diſeaſe of the Duke of Hamilton having reſiſted the effect of the firſt applications, Dr Clarke was ſent for from Edinburgh; and he was ſo much pleaſed with every thing that Cullen had done, that he became his eulogiſt upon every occaſion. Cullen never forgot this; and when Clarke died, gave a public oration in his praiſe in the Univerſity of Edinburgh; which, it is believed, was the firſt of the kind in this country.

Cullen.

the ardour of difpofition he poffeffed, it cannot be fuppofed he beheld the fair fex with indifference. Very early in life he took a ftrong attachment to an amiable woman, a Mifs Johnfton, daughter to a clergyman in that neighbourhood, nearly of his own age, who was prevailed on to join with him in the facred bonds of wedlock, at a time when he had nothing elfe to recommend him to her except his perfon and difpofitions; for as to riches and poffeffions he had little of thefe to boaft of. She was beautiful, had great good fenfe, equanimity of temper, an amiable difpofition, and elegance of manners, and brought with her a little money, which, though it would be accounted nothing now, was fomething in thofe days to one in his fituation in life. After giving to him a numerous family, and participating with him the changes of fortune which he experienced, fhe peacefully departed this life in fummer 1786.

In the year 1746, Cullen, who had now taken the degree of doctor in phyfic, was appointed a lecturer in chemiftry in the univerfity of Glafgow: and in the month of October began his lectures in that fcience. His fingular talents for arrangement, his diftinctnefs of enunciation, his vivacity of manner, and his knowledge of the fcience he taught, rendered his lectures interefting to the ftudents to a degree that had been till then unknown at that univerfity. He became, therefore, in fome meafure, adored by the ftudents. The former profeffors were eclipfed by the brilliancy of his reputation; and he had to experience all thofe little rubs that envy and difappointed ambition naturally threw in his way. Regardlefs, however, of thefe fecret fhagreens, he preffed forward with ardour in his literary career; and, fupported by the favour of the public, he confoled himfelf for the contumely he met with from a few individuals. His practice as a phyfician increafed from day to day; and a vacancy having occurred in the year 1751, he was then appointed by the king profeffor of medicine in that univerfity. This new appointment ferved only to call forth his powers, and to bring to light talents that it was not formerly known he poffeffed; fo that his fame continued to increafe.

As, at that period, the patrons of the univerfity of Edinburgh were conftantly on the watch for the moft eminent medical men to fupport the rifing fame of the college, their attention was foon directed towards Cullen; who, on the death of Dr Plumber, profeffor of chemiftry, was, in 1756, unanimonfly invited to accept the vacant chair. This invitation he accepted: and having refigned all his employments in Glafgow, he began his academical career in Edinburgh in the month of October of that year; and there he refided till his death.

If the admiffion of Cullen into the univerfity of Glafgow gave great fpirit to the exertions of the ftudents, this was ftill, if poffible, more ftrongly felt in Edinburgh. Chemiftry, which had been till that time of fmall account in that univerfity, and was attended to by very few of the ftudents, inftantly became a favourite ftudy; and the lectures upon that fcience were more frequented than any others in the univerfity, anatomy alone excepted. The ftudents, in general, fpoke of Cullen with the rapturous ardour that is natural to youth when they are highly pleafed. Thefe eulogiums appeared extravagant to moderate men, and could not fail to prove difgufting to his colleagues. A party was formed among the ftudents for oppofing this new favourite of the public; and thefe ftudents, by mifreprefenting the doctrines of Cullen to others who could not have an opportunity of hearing thefe doctrines themfelves, made even fome of the moft intelligent men in the univerfity think it their duty publicly to oppofe thefe imaginary tenets. The ferment was thus augmented; and it was fome time before the profeffors difcovered the arts by which they had been impofed upon, and univerfal harmony reftored.

During this time of public ferment, Cullen went fteadily forward, without taking any part himfelf in thefe difputes. He never gave ear to any tales refpecting his colleagues, nor took any notice of the doctrines they taught: That fome of their unguarded ftrictures might at times come to his knowledge, is not impoffible; but if they did, they feemed to make no impreffion on his mind.

Thefe attempts of a party of ftudents to lower the character of Cullen on his firft outfet in the univerfity of Edinburgh having proved fruitlefs, his fame as a profeffor, and his reputation as a phyfician, became more and more refpected every day. Nor could it well be otherwife: Cullen's profeffional knowledge was always great, and his manner of lecturing fingularly clear and intelligible, lively and entertaining; and to his patients, his conduct in general as a phyfician was fo pleafing, his addrefs fo affable and engaging, and his manner fo open, fo kind, and fo little regulated by pecuniary confiderations, that it was impoffible for thofe who had occafion to call once for his medical affiftance, ever to be fatisfied on any future occafion without it. He became the friend and companion of every family he vifited; and his future acquaintance could not be difpenfed with.

But if Dr Cullen in his public capacity deferved to be *admired*, in his private capacity by his ftudents he deferved to be *adored*. His conduct to them was fo attentive, and the intereft he took in the private concerns of all thofe ftudents who applied to him for advice, was fo cordial and fo warm, that it was impoffible for any one who had a heart fufceptible of generous emotions, not to be enraptured with a conduct fo uncommon and fo kind. Among ingenuous youth, gratitude eafily degenerates into rapture—into refpect nearly allied to adoration. Thofe who advert to this natural conftruction of the human mind, will be at no lofs to account for that popularity that Cullen enjoyed—a popularity, that thofe who attempt to weigh every occurrence by the cool ftandard of *reafon* alone, will be inclined to think exceffive. It is fortunate, however, that the bulk of mankind will ever be influenced in their judgment not lefs by feelings and affections than by the cold and phlegmatic dictates of *reafon*. The adoration which generous conduct excites, is the reward which nature hath appropriated exclufively to difinterefted beneficence. This was the fecret charm that Cullen ever carried about with him, which fafcinated fuch numbers of thofe who had intimate accefs to him. This was the power which his envious opponents never could have an opportunity of feeling.

The general conduct of Cullen to his ftudents was thus. With all fuch as he obferved to be attentive and diligent, he formed an early acquaintance, by inviting them by twos, by threes, or by fours at a time, to fup with him, converfing with them on thefe occafions with the

the moft engaging eafe, and freely entering with them on the fubject of their ftudies, their amufements, their difficulties, their hopes, and future profpects. In this way he ufually invited the whole of his numerous clafs, till he made himfelf acquainted with their abilities, their private character, and their objects of purfuit. Thofe among them whom he found moft affiduous, beft difpofed, or the moft friendlefs, he invited the moft frequently, till an intimacy was gradually formed, which proved highly beneficial to them. Their doubts, with regard to their objects of ftudy, he liftened to with attention, and folved with the moft obliging condefcenfion. His library, which confifted of an excellent affortment of the beft books, efpecially on medical fubjects, was at all times open for their accommodation; and his advice, in every cafe of difficulty to them, they always had it in their power moft readily to obtain. They feemed to be his family; and few perfons of diftinguifhed merit have left the univerfity of Edinburgh in his time, with whom he did not keep up a correfpondence till they were fairly eftablifhed in bufinefs. By thefe means he came to have a moft accurate knowledge of the ftate of every country, with refpect to practitioners in the medical line; the only ufe he made of which knowledge was, to direct ftudents in their choice of places, where they might have an opportunity of engaging in bufinefs with a reafonable profpect of fuccefs. Many, very many, able men has he thus put into a good line of bufinefs where they never could have thought of it themfelves; and they are now reaping the fruits of this beneficent forefight on his part.

Nor was it in this way only that he befriended the ftudents at the univerfity of Edinburgh. Poffeffing a benevolence of mind that made him ever think firft of the wants of others, and recollecting the difficulties that he himfelf had had to ftruggle with in his younger days, he was at all times fingularly attentive to their pecuniary concerns. From his general acquaintance among the ftudents, and the friendly habits he was on with many of them, he found no difficulty in difcovering thofe among them who were rather in hampered circumftances, without being obliged to hurt their delicacy in any degree. To fuch perfons, when their habits of ftudy admitted of it, he was peculiarly attentive. They were more frequently invited to his houfe than others; they were treated with more than ufual kindnefs and familiarity; they were conducted to his library, and encouraged by the moft delicate addrefs to borrow from it freely whatever books he thought they had occafion for: and as perfons in thefe circumftances were ufually more fhy in this refpect than others, books were fometimes preffed upon them as a fort of conftraint, by the Doctor infifting to have their opinion of fuch or fuch paffages they had not read, and defiring them to carry the book home for that purpofe. He, in fhort, behaved to them rather as if he courted their company, and ftood in need of their acquaintance than they of his. He thus raifed them in the opinion of their acquaintance to a much higher degree of eftimation than they could otherwife have obtained; which, to people whofe minds were depreffed by penury, and whofe fenfe of honour was fharpened by the confcioufnefs of an inferiority of a certain kind, was fingularly engaging. Thus they were infpired with a fecret fenfe of dignity, which elevated their minds, and excited an uncommon ardour of purfuit, inftead of that melancholy inactivity which is fo natural in fuch circumftances, and which too often leads to defpair. Nor was he lefs delicate in the manner of fupplying their wants, than attentive to difcover them. He often found out fome polite excufe for refufing to take payment for a firft courfe, and never was at a lofs for one to an after courfe. Before they could have an opportunity of applying for a ticket, he would fometimes lead the converfation to fome fubject that occurred in the courfe of his lectures; and as his lectures were never put in writing by himfelf, he would fometimes beg the favour to fee their notes, if he knew they had been taken with attention, under a pretext of affifting his memory. Sometimes he would exprefs a wifh to have their opinion of a particular part of his courfe, and prefented them with a ticket for that purpofe; and fometimes he refufed to take payment, under the pretext that they had not received his full courfe the preceding year, fome part of it having been neceffarily omitted for want of time, which he meant to include in this courfe. By fuch delicate addrefs, in which he greatly excelled, he took care to forerun their wants. Thus he not only gave them the benefit of his own lectures, but by refufing to take their money, he alfo enabled them to attend thofe of others that were neceffary to complete their courfe of ftudies. Thefe were particular devices he adopted to individuals to whom economy was neceffary; but it was a general rule with him, never to take money from any ftudent for more than two courfes of the fame fet of lectures, permitting him to attend thefe lectures as many years longer as he pleafed *gratis*.

He introduced another general rule into the univerfity, that was dictated by the fame principle of difinterefted beneficence, that ought not to be here paffed over in filence. Before he came to Edinburgh, it was the cuftom of medical profeffors to accept of fees for their medical affiftance, when wanted, even from medical ftudents themfelves, who were perhaps attending the profeffor's own lectures at the time. But Cullen never would take fees as a phyfician from any ftudent at the univerfity, though he attended them, when called in as a phyfician, with the fame affiduity and care as if they had been perfons of the firft rank, who paid him moft liberally. This gradually induced others to adopt a fimilar practice; fo that it is now become a general rule for medical profeffors to decline taking any fees when their affiftance is neceffary to a ftudent. For this ufeful reform, with many others, the ftudents of the univerfity of Edinburgh are folely indebted to the liberality of Dr Cullen.

The firft lectures which Cullen delivered in Edinburgh were on chemiftry; and for many years he alfo gave clinical lectures on the cafes which occurred in the Royal Infirmary. In the month of February 1763, Dr Alfton died, after having begun his ufual courfe of lectures on the materia medica; and the magiftrates of Edinburgh, as patrons of that profefforfhip in the univerfity, appointed Dr Cullen to that chair, requefting that he would finifh the courfe of lectures that had been begun for that feafon. This he agreed to do; and though he was under a neceffity of going on with the courfe in a few days after he was nominated, he did not once think of reading the lectures of his predeceffor, but refolved to deliver a new courfe entirely his own

The

Cullen.

The popularity of Cullen at this time may be gueffed at by the increafe of new ftudents who came to attend his courfe in addition to the eight or ten who had entered to Dr Alfton. The new ftudents exceeded 100. An imperfect copy of thefe lectures, thus fabricated in hafte, having been publifhed, the Doctor thought it neceffary to give a more correct edition of them in the latter part of his life. But his faculties being then much impaired, his friends looked in vain for thofe ftriking beauties that characterifed his literary exertions in the prime of life.

Some years afterwards, on the death of Dr White, the magiftrates once more appointed Dr Cullen to give lectures on the theory of phyfic in his ftead. And it was on that occafion Dr Cullen thought it expedient to refign the chemical chair in favour of Dr Black, his former pupil, whofe talents in that department of fcience were then well known, and who filled the chair till his death with great fatisfaction to the public*. Soon after, on the death of Dr Rutherford, who for many years had given lectures with applaufe on the practice of phyfic, Dr John Gregory (whofe name can never be mentioned by any one who had the pleafure of his acquaintance without the warmeft tribute of a grateful refpect) having become a candidate for this place along with Dr Cullen, a fort of compromife took place between them; by which they agreed each to give lectures alternately on the theory and on the practice of phyfic during their joint lives, the longeft furvivor being allowed to hold either of the claffes he fhould incline. In confequence of this agreement, Dr Cullen delivered the *firft* courfe of lectures on the practice of phyfic in winter 1766, and Dr Gregory fucceeded him in that branch the following year. Never perhaps did a literary arrangement take place that could have proved more beneficial to the ftudents than this. Both thefe men poffeffed great talents, though of a kind extremely diffimilar. Both of them had certain failings or defects, which the other was aware of, and counteracted. Each of them knew and refpected the talents of the other. They co-operated, therefore, in the happieft manner, to enlarge the underftanding, and to forward the purfuits of their pupils. Unfortunately this arrangement was foon deftroyed by the unexpected death of Dr Gregory, who was cut off in the flower of life by a fudden and unforefeen event. After this time, Cullen continued to give lectures on the practice of phyfic till a few months before his death, which happened on the 5th of February 1790, in the 77th year of his age.

* See *Black*, Suppl.

In drawing the character of Dr Cullen, Dr Anderfon, to whom we are indebted for this fketch, obferves, that in fcientific purfuits men may be arranged into two grand claffes, which, though greatly different from each other in their extremes, yet approximate at times fo near as to be blended indifcriminately together; thofe who poffefs a talent for detail, and thofe who are endowed with the faculty of arrangement. The firft may be faid to view objects individually as through a microfcope. The field of vifion is confined; but the objects included within that field, which muft ufually be confidered fingly and apart from all others, are feen with a wondrous degree of accuracy and diftinctnefs. The other takes a fweeping view of the univerfe at large, confiders every object he perceives not individually, but as a part of one harmonious whole: His mind is therefore not fo much employed in examining the feparate parts of this individual object, as in tracing its relations, connections, and dependencies, on thofe around it.—Such was the turn of Cullen's mind. The talent for arrangement was that which peculiarly diftinguifhed him from the ordinary clafs of mortals; and this talent he poffeffed perhaps in a more diftinguifhed degree than any other perfon of the age in which he lived. Many perfons exceeded him in the minute knowledge of particular departments, who, knowing this, naturally looked upon him as their inferior; but poffeffing not at the fame time that glorious faculty, which, "with an eye wide roaming, glances from the earth to heaven," or the charms which this talent can infufe into congenial minds, felt difguft at the pre-eminence he obtained, and aftonifhment at the means by which he obtained it. An Ariftotle and a Bacon have had their talents in like manner appretiated; and many are the perfons who can neither be exalted to fublime ideas with Homer, nor ravifhed with the natural touches of a Shakefpeare. Such things are wifely ordered, that every department in the univerfe may be properly filled by thofe who have talents exactly fuited to the tafk affigned them by heaven.

Had Cullen, however, poffeffed the talents for arrangement alone, fmall would have been his title to that high degree of applaufe he has attained. Without a knowledge of *facts*, a talent for arrangement produces nothing but chimeras; without materials to work upon, the ftructures which an over-heated imagination may rear up are merely "the bafelefs fabric of a vifion." No man was more fenfible of the juftnefs of this remark than Dr Cullen, and few were at greater pains to avoid it. His whole life, indeed, was employed, almoft without interruption, in collecting facts. Whether he was reading, or walking, or converfing, thefe were continually falling into his way. With the keen perception of an eagle, he marked them at the firft glance; and without ftopping at the time to examine them, they were ftored up in his memory, to be drawn forth as occafion required, to be confronted with other facts that had been obtained after the fame manner, and to have their truth afcertained, or their falfity proved, by the evidence which fhould appear when carefully examined at the impartial bar of juftice. Without a memory retentive in a fingular degree, this could not have been done; but fo very extraordinary was Dr Cullen's memory, that till towards the very decline of life, there was fcarcely a fact that had ever occurred to him which he could not readily recollect, with all its concomitant circumftances, whenever he had occafion to refer to it. It was this faculty which fo much abridged his labour in ftudy, and enabled him fo happily to avail himfelf of the labour of others in all his literary fpeculations. He often reaped more by the converfation of an hour than another man would have done in whole weeks of laborious ftudy.

In his prelections, Dr Cullen never attempted to read. His lectures were delivered *viva voce*, without having been previoufly put into writing, or thrown into any particular arrangement. The vigour of his mind was fuch, that nothing more was neceffary than a few fhort notes before him, merely to prevent him from varying from the general order he had been accuftomed to obferve. This gave to his difcourfes an eafe, a vivacity,

Cullen.

vacity, a variety, and a force, that are rarely to be met with in academical difcourfes. His lectures, by confequence, upon the fame fubject were never exactly the fame. Their general tenor indeed was not much varied; but the particular illuftrations were always new, well fuited to the circumftances that attracted the general attention of the day, and were delivered in the particular way that accorded with the caft of mind the prelector found himfelf in at the time. To thefe circumftances muft be afcribed that energetic artlefs elocution, which rendered his lectures fo generally captivating to his hearers. Even thofe who could not follow him in thofe extenfive views his penetrating mind glanced at, or who were not able to underftand thofe apt allufions to collateral objects which he could only rapidly point at as he went along, could not help being warmed in fome meafure by the vivacity of his manner. But to thofe who could follow him in his rapid career, the ideas he fuggefted were fo numerous, the views he laid open were fo extenfive, and the objects to be attained were fo important—that every active faculty of the mind was roufed; and fuch an ardour of enthufiafm was excited in the profecution of ftudy, as appeared to be perfectly inexplicable to thofe who were merely unconcerned fpectators. In confequence of this unfhackled freedom in the compofition and delivery of his lectures, every circumftance was in the niceft unifon with the tone of voice and expreffion of countenance, which the particular caft of mind he was in at the time infpired. Was he joyous, all the figures introduced for illuftration were fitted to excite hilarity and good humour: was he grave, the objects brought under view were of a nature more folemn and grand: and was he peevifh, there was a peculiarity of manner in thought, in word, and in action, which produced a moft ftriking and interefting effect. The languor of a nervelefs uniformity was never experienced, nor did an abortive attempt to excite emotions that the fpeaker himfelf could not at the time feel, ever produce thofe difcordant ideas which prove difgufting and unpleafing.

It would feem as if Dr Cullen had confidered the proper bufinefs of a preceptor to be that of putting his pupils into a proper train of ftudy, fo as to enable them to profecute thofe ftudies at a future period, and to carry them on much farther than the fhort time allowed for academical prelections would admit. He did not, therefore, fo much ftrive to make thofe who attended his lectures deeply verfed in the particular details of objects, as to give them a general view of the whole fubject; to fhew what had been already attained refpecting it; to point out what remained yet to be difcovered; and to put them into a train of ftudy that fhould enable them at a future period, to remove thofe difficulties that had hitherto obftructed our progrefs; and thus to advance of themfelves to farther and farther degrees of perfection. If thefe were his views, nothing could be more happily adapted to them than the mode he invariably purfued. He firft drew, with the ftriking touches of a mafter, a rapid and general outline of the fubject, by which the whole figure was feen at once to ftart boldly from the canvas, diftinct in all its parts, and unmixed with any other object. He then began anew to retrace the picture, to touch up the leffer parts, and to finifh the whole in as perfect a manner as the ftate of our knowledge at the time would permit. Where materials were wanting, the picture there continued to remain imperfect. The wants were thus rendered obvious; and the means of fupplying thefe were pointed out with the moft careful difcrimination. The ftudent, whenever he looked back to the fubject, perceived the defects; and his hopes being awakened, he felt an irrefiftible impulfe to explore that hitherto untrodden path which had been pointed out to him, and fill up the chafm which ftill remained. Thus were the active faculties of the mind moft powerfully excited; and inftead of labouring himfelf to fupply deficiencies that far exceeded the power of any one man to accomplifh, he fet thoufands at work to fulfil the tafk, and put them into a train of going on with it, when he himfelf fhould be gone to that country "from whofe dread bourne no traveller returns."

It was to thefe talents, and to this mode of applying them, that Dr Cullen owed his celebrity as a profeffor; and it was in this manner that he has perhaps done more towards the advancement of fcience than any other man of his time, though many individuals might perhaps be found who were more deeply verfed in the particular departments he taught than he himfelf was. Chemiftry, which was before his time a moft difgufting purfuit, was by him rendered a ftudy fo pleafing, fo eafy, and fo attractive, that it is now profecuted by numbers as an agreeable recreation, who but for the lights that were thrown upon it by Cullen and his pupils, would never have thought of engaging in it at all; though perhaps they never heard of Cullen's name, nor have at this time the moft diftant idea that they owe any obligations to him; and the fame may be faid of the other branches of fcience which he taught.

According to a man who knew him well, there are three things which eminently diftinguifhed Cullen as a profeffor. "The energy of his mind, by which he viewed every fubject with ardour, and combined it immediately with the whole of his knowledge.

"The fcientific arrangement which he gave to his fubject, by which there was a *lucidus ordo* to the dulleft fcholar. He was the firft perfon in this country who made chemiftry ceafe to be a chaos.

"A wonderful art of interefting the ftudents in every thing which he taught, and of raifing an emulative enthufiafm among them."

We are well aware that this character will by many be deemed an extravagant panegyric; but having no opportunity of judging for ourfelves, we would rather adopt from others an extravagant panegyric than an unmerited cenfure. Dr Anderfon himfelf admits that Cullen's character was far from perfect; and, in the opinion of moft other men with whom we have converfed on the fubject, and who were at the fame time qualified to form an eftimate of his mental powers, his imagination was not balanced by his judgment. Hence the common remark in the univerfity of Edinburgh, that Dr Cullen was more fuccefsful in demolifhing the theories of others than in giving ftability to thofe which were reared by himfelf.

Dr Cullen's external appearance, though ftriking and not unpleafing, was not elegant. His countenance was expreffive, and his eye in particular remarkably lively, and at times wonderfully penetrating. In his perfon he was tall and thin, ftooping very much about the fhoulders. When he walked, he had a contemplative look, and

and did not feem much to regard the objects around him.

CURFEU Bell (fee Curfew, *Encycl.*), called in the law Latin of the middle ages *ignitegium* or *pyritegium*, and in French, *cuvre-feu*—was a fignal for all perfons to extinguifh their fires at a certain hour. In thofe ages people made fires in their houfes in a hole or pit in the centre of the floor, under an opening formed in the roof; and when the fire was burnt out, or the family went to bed, the hole was fhut by a cover of wood or of earth. This practice ftill prevails among the cottagers in fome parts of Scotland, and we doubt not of other countries. In the dark ages, when all ranks of people were turbulent, a law was almoft everywhere eftablifhed, that the fire fhould be extinguifhed at a certain time in the evening; that the cover fhould be put over the fire-place; and that all the family fhould retire to reft, or at leaft keep within doors The time when this ought to be done was fignified by the ringing of a bell, called therefore the *curfeu-bell* or *ignitegium*. The law of William the Conqueror, which introduced this practice into England, as has been mentioned in the Encyclopædia, was abolifhed by Henry I. in 1100.

The ringing of the curfeu-bell gave rife to the prayer-bell, as it is called, which is ftill retained in fome Proteftant countries. Pope John XXIII. with a view to avert certain apprehended misfortunes, which rendered his life uncomfortable, gave orders, that every perfon, on hearing the *ignitegium*, fhould repeat the *Ave Maria* three times. When the appearance of a comet, and a dread of the Turks, afterwards alarmed all Chriftendom, Pope Calixtus III. increafed thefe periodical times of prayer, by ordering the prayer-bell to be rung alfo at noon. *Beckmann's Hiftory of Inventions.*

CURVE of Equable Approach. It was firft propofed by Leibnitz, namely, to find a curve, down which a body defcending by the force of gravity fhall make equal approaches to the horizon in equal portions of time. It has been found by Bernoulli and others, that the curve is the fecond cubical parabola, placed with its vertex uppermoft, and which the defcending body muft enter with a certain determinate velocity. Varignon rendered the queftion general for any law of gravity, by which a body may approach towards a given point by equal fpaces in equal times. And Maupertuis alfo refolved the problem in the cafe of a body defcending in a medium which refifts as the fquare of the velocity.

CUSSO, or Banksia Abyssinica, is a beautiful and ufeful tree, indigenous to the high country of Abyffinia. At leaft Mr Bruce, who has given of it the only defcription which we have feen, fays that he never faw it in any other part of Afia or Africa. It feldom grows above 20 feet high, very rarely ftraight, generally crooked or inclined. Its leaf, which is of a deep unvarnifhed green, having the fore part covered with foft hair or down, is about $2\frac{1}{4}$ inches long, divided by a ftrong rib into two unequal divifions, of which the upper is broader and larger than the lower. It is more indented than even the nettle leaf, which it in fome meafure refembles, only the leaf of the *Cuffo* is narrower and longer.

Thofe leaves grow two and two upon a branch, having between each two the rudiments of *two pair* of leaves, which probably are *deciduous*; but the branch is terminated with a fingle leaf or *ftipula* at the point. The end of this ftalk is broad and ftrong, like that of a palm branch. It is not folid like the gerid of the date tree, but opens in the part that is without leaves about an inch and a half from the bottom, and out of this aperture proceeds the flower. There is a round ftalk, bare for about an inch and a quarter, from which proceed crooked branches with fingle flowers attached to their ends; the ftalk that carries thefe proceeds out of every crook or geniculation. The whole clufter of flowers has very much the fhape of a clufter of grapes; the ftalks which fupport it refemble the ftalks of the grape; and a very few fmall leaves are fcattered through the clufter of flowers.

"The calyx or flower cup is of a *greenifh* colour, tinged with purple; when fully blown it is altogether of a deep *red* or purple; the corolla is *white*, and confifts of five petals; in the midft is a fhort piftil with a round head, furrounded by eight ftamina, of the fame form, loaded with yellow farina. The cup confifts of five petals, which much refemble another flower; they are rounded at the top, and nearly of an equal breadth every way. The feed is very fmall, fmaller than even the femen fantonicum; and being likewife very bitter it is ufed in Abyffinia as a vermifuge. From its fmallnefs, however, and its being very eafily fhed, no great quantity of it is ever gathered, and therefore the flower is often fubftituted in its ftead. The Abyffinians, fays our author, of both fexes, and at all ages, are troubled with the fort of worm called afcarides, of which every individual evacuates a large quantity once a-month. The method of promoting thefe evacuations is by infufing a handful of dry cuffo flowers in about two Englifh quarts of bouza, or the beer they make of teff (fee Teff, *Encycl.*), and after it has been fteeped all night, the next morning it is fit for ufe.

"The bark of the tree is fmooth, of a yellowifh white, interfperfed with brown ftreaks, which pafs through the whole body of the tree. It is not firm or hard, but rather ftringy and reedy. On the upper part, before the firft branch of leaves fet out, are rings round the trunk, of fmall filaments of the confiftence of horfe hair: thefe are generally fourteen or fixteen in number, and are a very remarkable characteriftic belonging to the tree."

From this defcription, which, it muft be confeffed, is not remarkable for perfpicuity, and from an infpection of the figure which Mr Bruce has given of the cuffo, we are inclined to rank it with the palms, as a new genus, neareft to the *caryota*.

CUVETTE, or Cunette, in fortification, is a kind of ditch within a ditch, being a pretty deep trench, about four fathoms broad, funk and running along the middle of the great dry ditch, to hold water; ferving both to keep off the enemy and prevent him from mining.

CYCLE of Indiction, is a feries of 15 years, returning conftantly around like the other cycles, and commenced from the third year before Chrift; whence it happens that if 3 be added to any given year of Chrift, and the fun be divided by 15, what remains is the year of the indiction.

CYCLOID (fee *Encycl.*) is a curve, which is thus generated: Suppofe a wheel or circle to roll along a ftraight line till it has completed juft one revolution; a nail or point in that part of the circumference of the circle, which at the beginning of the motion touches the ftraight line, will, at the end of the revolution, have defcribed on a vertical plane a cycloid.

DAGELET,

D.

Dagelet, Dairy.

DAGELET, the name given by *La Peroufe*, the celebrated though unfortunate navigator, to an ifland on the coaft of Corea (fee COREA, *Encycl.*), which he difcovered in the year 1787. It is little more than three leagues in circumference; and our author almoft made its circuit at the diftance of a mile without finding bottom. This fmall fpot is very fteep, but covered with the fineft trees from the fea-fhore to the fummit. A rampart of bare rock, like a wall, encircles the whole outline of it, with the exception of feven little fandy creeks, where it is poffible to land. In thefe creeks the Frenchmen faw upon the ftocks fome boats of a conftruction altogether Chinefe; but the fight of their fhips frightened the workmen, who fled from their dock-yard into the wood, which was not more than fifty paces diftant. As a few huts were feen, but neither villages nor cultivation, La Peroufe concluded that the ifland is without inhabitants, and that the men whom he faw at work were Corean carpenters, who during the fummer months go with provifion to Dagelet for the purpofe of building boats, which they fell upon the continent. He places the north-eaft point of this ifland in Lat. 37°. 25′. and E. Long. 129°. 2′. from Paris.

DAIRY is a word which fignifies fometimes the art of making various kinds of food from milk; fometimes the place where milk is manufactured; and fometimes the management of a milk-farm. On the *dairy*, in the firft and fecond of thefe fenfes, enough has been faid in the *Encyclopædia* under the titles BUTTER, CHEESE, and DAIRY; on the management of a milk farm that work contains nothing.

When a dairy is eftablifhed, the undertaker may fometimes think it his intereft to obtain the greateft poffible quantity of produce; fometimes it may be more beneficial for him to have it of the fineft quality; and at other times it may be neceffary to have both thefe objects in view, the one or the other in a greater or lefs proportion: it is therefore of importance that he fhould know how he may accomplifh the one or the other of thefe purpofes in the eafieft and moft direct manner.

To be able to convert his milk to the higheft poffible profit in every cafe, he ought to be fully acquainted with every circumftance refpecting the manufacture both of butter and of cheefe; as it may in fome cafes happen, that a certain portion of that milk may be more advantageoufly converted into butter than into cheefe, while another portion of it would return more profit if made into cheefe.

The firft thing to be adverted to, in an undertaking of this nature, is to choofe cows of a proper fort. Among this clafs of animals, it is found, by experience,

Dairy.

that fome kinds give milk of a much thicker confiftence and richer quality than others; nor is this richnefs of quality neceffarily connected with the fmallnefs of the quantity yielded by cows of nearly an equal fize; it therefore behoves the owner of a dairy to be peculiarly attentive to this circumftance. In judging of the value of a cow, it ought rather to be the quantity and the quality of the cream produced from the milk of the cow, in a given time, than the quantity of the milk itfelf: this is a circumftance that will be fhewn hereafter to be of more importance than is generally imagined. The fmall cows of the Alderney breed afford the richeft milk hitherto known; but individual cows in every country may be found, by a careful felection, that afford much thicker milk than others; thefe therefore ought to be fearched for with care, and their breed reared with attention, as being peculiarly valuable.

Few perfons who have had any experience at all in the dairy, can be ignorant, however, that in comparing the milk of two cows, to judge of their refpective qualities, particular attention muft be paid to the time that has elapfed fince their calving; for the milk of the fame cow is always thinner foon after calving than it is afterwards; as it gradually becomes thicker, though generally lefs in quantity, in proportion to the time fince the cow has calved. The colour of the milk, foon after calving, is richer than it is afterwards; but this, efpecially for the firft two weeks, is a faulty colour that ought not to be coveted.

To make the cows give abundance of milk, and of a good quality, they muft at all times have plenty of food. Grafs is the beft food yet known for this purpofe, and that kind of grafs which fprings up fpontaneoufly on rich dry foils is the beft of all. If the temperature of the climate be fuch as to permit the cows to graze at eafe throughout the day, they fhould be fuffered to range on fuch paftures at freedom; but if the cows are fo much incommoded by the heat as to be prevented from eating through the day, they ought in that cafe to be taken into cool fhades for protection; where, after allowing them a proper time to ruminate, they fhould be fupplied with abundance of green food, frefh-cut for the purpofe, and given to them by hand frequently, in fmall quantities, frefh and frefh, fo as to induce them to eat it with pleafure. When the heat of the day is over, and they can remain abroad with eafe, they may be again turned into the pafture, where they fhould be allowed to range with freedom all night, during the mild weather of fummer.

Cows, if abundantly fed, fhould be milked three times a-day, during the whole of the fummer feafon (A); in the

(A) If cows be milked only twice in the day (24 hours), while they have abundance of fucculent food, they will yield a much fmaller quantity of milk, in the fame time, than if they be milked three times. Some attentive obfervers think a cow, in thefe circumftances, will give nearly as much milk at each time, if milked three times, as if fhe were milked only twice. This fact, however, has not, that we know of, been afcertained by experiment. There can be no doubt but they give more, how much more is not afcertained; nor, whether it would be advantageous, in any cafe, to milk them four times, or oftener; nor, what effect frequent milking produces on the quality of the milk.

Dairy.

the morning early, at noon, and in the evening, juſt before night-fall. In the choice of perſons for milking the cows, great caution ſhould be employed; for if that operation be not carefully and properly performed, not only the quantity of the produce of the dairy will be greatly diminiſhed, but its quality alſo will be very much debaſed; for if all the milk be not thoroughly drawn from a cow when ſhe is milked, that portion of milk which is left in the udder ſeems to be gradually abſorbed into the ſyſtem, and Nature generates no more than to ſupply the waſte of what has been taken away. If this leſſened quantity be not again thoroughly drawn off, it occaſions a yet farther diminution of the quantity of milk generated; and thus it may be made to proceed, in perpetual progreſſion from little to leſs, till none at all is produced. In ſhort, this is the practice in all caſes followed, when it is meant to allow a cow's milk to dry up entirely, without doing her hurt. In this manner, therefore, the profits of a dairy might be wonderfully diminiſhed; ſo that it much behoves the owner of it to be extremely attentive to this circumſtance, if he wiſhes to avoid ruin. It ought to be a rule without an exception, never to allow this important department to be entruſted, without controul, to the management of hired ſervants (B). Its importance will be ſtill more manifeſt from what follows.

It is to Dr James Anderſon that we are indebted for theſe judicious obſervations, as well as for the following aphoriſms which, though they may be in part known to attentive houſewifes, he has reaſon to believe are not commonly adverted to as their importance deſerves.

Aphoriſm 1.

"Of the milk that is drawn from any cow at one time, that which comes off at the firſt is always thinner, and of a much worſe quality, than that which comes afterwards; and the richneſs goes on continually increaſing to the very laſt drop that can be drawn from the udder at that time."

Few perſons are ignorant that the milk which is laſt of all taken from the cow at milking (in this country called *ſtroakings*) is richer than the reſt of the milk; but fewer ſtill are aware of the greatneſs of the diſproportion between the quality of the firſt and the laſt drawn milk, from the ſame cow, at one milking. The following facts (ſays our author) reſpecting this circumſtance were aſcertained by me many years ago, and have been confirmed by many ſubſequent experiments and obſervations.

Having taken ſeveral large tea-cups, exactly of the ſame ſize and ſhape, one of theſe tea-cups was filled at the beginning of the milking, and the others at regular intervals, till the laſt, which was filled with the dregs of the ſtroakings. Theſe cups were then weighed, the weight of each having been ſettled, ſo as to aſcertain that the quantity of milk in each was preciſely the ſame; and from a great number of experiments, frequently repeated with many different cows, the reſult was in all caſes as follows:

The quantity of cream obtained from the firſt-drawn cup was, in every caſe, much ſmaller than from that which was laſt drawn; and thoſe between afforded leſs or more as they were nearer the beginning or the end. It is unneceſſary here to ſpecify theſe intermediate proportions; but it is proper the reader ſhould be informed, that the quantity of cream obtained from the laſt-drawn cup, from ſome cows, exceeded that from the firſt in the proportion of ſixteen to one. In other cows, however, and in particular circumſtances, the diſproportion was not quite ſo great; but in no caſe did it fall ſhort of the rate of eight to one. Probably, upon an average of a great many cows, it might be found to run as ten or twelve to one.

Secondly, The difference in the quality of the cream, however, obtained from theſe two cups, was much greater than the difference in the quantity. In the firſt cup, the cream was a thin tough film, thinner, and perhaps whiter, than writing paper; in the laſt, the cream was of a thick *butyrous* conſiſtence, and of a glowing richneſs of colour that no other kind of cream is ever found to poſſeſs.

Thirdly, The difference in the quality of the milk that remained, after the cream was ſeparated, was perhaps ſtill greater than either in reſpect to the quantity or the quality of the cream. The milk in the firſt cup was a thin bluiſh liquid, as if a very large proportion of water had been mixed with ordinary milk; that in the laſt cup was of a thick conſiſtence, and yellow colour, more reſembling cream than milk both in taſte and appearance.

From this important experiment, it appears that the perſon who, by bad milking of his cows, loſes but half a pint of his milk, loſes in fact about as much cream as would be afforded by ſix or eight pints at the beginning, and loſes, beſides, that part of the cream which alone can give richneſs and high flavour to his butter.

Aphoriſm 2.

"If milk be put into a diſh, and allowed to ſtand till it throws up cream, that portion of cream which riſes firſt to the ſurface is richer in quality, and greater in quantity, than what riſes in a ſecond equal ſpace of time; and the cream that riſes in the ſecond interval of time is greater in quantity, and richer in quality, than that which riſes in a third equal ſpace of time; that of the third than the fourth, and ſo on: the cream that riſes decreaſing in quantity, and declining in quality, continually, as long as any riſes to the ſurface."

Our ingenious author confeſſes, that his experiments not having been made with ſo much accuracy in this caſe as in the former, he was not enabled to aſcertain the difference in the proportion that takes place in equal portions of time; but they have been ſo often repeated as not to leave any room to doubt the fact, and it will be allowed to be a fact of no ſmall importance in the management of the dairy. It is not certain, however, but that a greater quantity of cream may, upon the whole, be obtained from the milk by taking it away

(B) Cows ſhould always be treated with great gentleneſs, and ſoothed by mild uſage, eſpecially when young and tickliſh, or when the paps are tender; in which laſt caſe, the udder ought to be fomented with warm water before milking, and touched with the greateſt gentleneſs, otherwiſe the cow will be in danger of contracting bad habits, becoming ſtubborn and unruly, and retaining her milk ever after. A cow never lets down her milk pleaſantly to the perſon ſhe dreads or diſlikes. The udder and paps ſhould always be waſhed with clean water before milking; but care ſhould be taken that none of that water be admitted into the milking-pail.

Dairy.

away at different times; but the process is so troublesome as not to be counterbalanced by the increased quantity obtained, if indeed an increased quantity be thus obtained, which is not as yet quite certain.

Aphorism 3. "Thick milk always throws up a smaller proportion of the cream it actually contains to the surface, than milk that is thinner; but that cream is of a richer quality. If water be added to that thick milk, it will afford a considerably greater quantity of cream than it would have done if allowed to remain pure, but its quality is, at the same time, greatly debased."

This is a fact that every person attentive to a dairy must have remarked; but I have never (says our author) heard of any experiment that could ascertain, either the precise amount of the increased quantity of cream that might thus be obtained, or of the ratio in the decrease of its quality. The effects of mixing water with the milk in a dairy are at least ascertained; and the knowledge of this fact will enable attentive persons to follow that practice which they think will best promote their own interest.

Aphorism 4. "Milk which is put into a bucket or other proper vessel, and carried in it to any considerable distance, so as to be much agitated, and in part cooled, before it be put into the milk-pans to settle for cream, never throws up so much, nor so rich cream, as if the same milk had been put into the milk-pans directly after it was milked."

In this case, it is believed the loss of cream will be nearly in proportion to the time that has elapsed, and the agitation the milk has sustained, after being drawn from the cow. But Dr Anderson says that he is not yet in possession of any experiments which sufficiently ascertain how much is to be ascribed to the time, and the agitation, taken separately. On every branch of agriculture we find experiments wanting, at each step we advance in our inquiries; and it is the duty of every enquirer to point out, as he goes along, where they are wanted, since the labours of no one man can possibly complete the whole.

From the above facts, the following corollaries seem to be clearly deducible:

First. It is of importance that the cows should be always milked as near the dairy as possible, to prevent the necessity of carrying and cooling the milk before it is put into the dishes; and as cows are much hurt by far driving, it must be a great advantage in a dairy-farm to have the principal grass fields as near the dairy or homestead as possible.

Secondly. The practice of putting the milk of all the cows of a large dairy into one vessel, as it is milked, there to remain till the whole milking is finished, before any part of it is put into the milk-pans—seems to be highly injudicious; not only on account of the loss that is sustained by agitation and cooling, but also, more especially, because it prevents the owner of the dairy from distinguishing the good from the bad cow's milk, so as to separate these from each other, where it is necessary. He may thus have the whole of his dairy product greatly debased by the milk of one bad cow, for years together, without being able to discover it. A better practice, therefore, would be, to have the milk drawn from each cow put separately into the creaming-pans as soon as it is milked, without being ever mixed with any other. Thus would the careful manager of the dairy be able on all occasions to observe the particular quality of each individual cow's milk, as well as its quantity, and to know with precision which of his cows it was his interest to dispose of, and which of them he ought to keep and breed from.

Dairy.

Thirdly. If it be intended to make butter of a very fine quality, it will be advisable in all cases to keep the milk that is first drawn separate from that which comes last; as it is obvious, that if this be not done, the quality of the butter will be greatly debased, without much augmenting its quantity. It is also obvious, that if this is done, the quality of the butter will be improved in proportion to the smallness of the quantity of the last-drawn milk that is retained; so that those who wish to be singularly nice in this respect, will do well to retain only a very small portion of the last-drawn milk.

To those owners of dairies who have profit only in view, it must ever be a matter of trial and calculation, how far it is expedient for them to carry the improving of the quality of their butter at the expence of diminishing its quantity. In different situations prudence will point out different kinds of practice as most eligible; and all persons must be left, after making accurate trials, to determine for themselves. It is likewise a consideration of no small importance, to determine in what way the inferior milk, that is thus to be set apart where fine butter is wanted, can be employed with the greatest profit. In the Highlands of Scotland they have adopted, without thinking of the improvement of their butter, a very simple and economical practice in this respect. As the rearing of calves is there a principal object with the farmer, every cow is allowed to suckle her own calf with a part of her milk, the remainder only being employed in the dairy. To give the calf its portion regularly, it is separated from the cow, and kept in an inclosure, with all the other calves belonging to the same farm. At regular times, the cows are driven to the door of the inclosure, where the young calves fail not to meet them. Each calf is then separately let out, and runs directly to its mother, where it sucks till the dairy-maid judges it has had enough; she then orders it to be driven away, having previously shackled the hinder legs of the mother, by a very simple contrivance, to oblige her to stand still. Boys drive away the calf with switches, and return it to the inclosure, while the dairy-maid milks off what was left by the calf: thus they proceed till the whole of the cows are milked. They obtain only a small quantity of milk, it is true, but that milk is of an exceeding rich quality; which in the hands of such of the inhabitants as know how to manage it, is manufactured into the richest marrowy butter that can be anywhere met with. This richness of the Highland butter is universally ascribed to the old grass the cows feed upon in their remote glens; but it is in fact chiefly to be attributed to the practice here described, which has long prevailed in those regions. Whether a similar practice could be economically adopted elsewhere, our author takes not upon him to say; but doubtless other secondary uses might be found for the milk of inferior quality. On some occasions, it might be converted into butter of an inferior quality; on other occasions, it might be sold sweet, where the situation of the farm was within reach of a market-town; and on others, it might be converted into cheeses, which, by being made of sweet milk, would

Dairy.

would be of a very fine quality if carefully made (c). Still other uſes might be deviſed for its application; of which the following is worthy of notice. Take common ſkimmed milk, when it has begun to turn ſour, put it into an upright ſtand-churn, or a barrel with one of its ends out, or any other convenient veſſel. Heat ſome water, and pour it into a tub that is large enough to contain with eaſe the veſſel in which the milk was put. Set the veſſel containing the milk into the hot water, and let it remain there for the ſpace of one night. In the morning it will be found that the milk has ſeparated into two parts; a thick cream-like ſubſtance, which occupies the upper part of the veſſel, and a thin watery part that remains at the bottom. Draw off the thin part (called in Scotland *wigg*), by opening a ſtop-cock, placed for that purpoſe cloſe above the bottom, and reſerve the cream for uſe. Not much leſs than half of the milk is thus converted into a ſort of cream, which, when well made, ſeems to be as rich and fat as real cream itſelf, and is only diſtinguiſhable from it by its ſourneſs. It is eaten with ſugar, and eſteemed a great delicacy, and uſually ſells at double the price of freſh unſkimmed milk. It requires practice, however, to be able to make this nicely; the degree of the heat of the water, and many other circumſtances, greatly affecting the operation.

Fourthly. If the quality of the butter be the chief object attended to, it will be neceſſary, not only to ſeparate the firſt from the laſt drawn milk, but alſo to take nothing but the cream that is firſt ſeparated from the beſt milk, as it is this firſt riſing cream alone that is of the prime quality. The remainder of the milk, which will be ſtill ſweet, may be either employed for the purpoſe of making ſweet milk cheeſes, or may be allowed to ſtand, to throw up cream for making butter of an inferior quality, as circumſtances may direct.

Fifthly. From the above facts, we are enabled to perceive, that butter of the very beſt poſſible quality can only be obtained from a dairy of conſiderable extent, judiciouſly managed; for when only a ſmall portion of each cow's milk can be ſet apart for throwing up cream, and when only a ſmall proportion of that cream can be reſerved, of the prime quality, it follows (the quantity of milk being upon the whole very inconſiderable), that the quantity of prime cream produced would be ſo ſmall as to be ſcarcely worth manufacturing ſeparately.

Sixthly. From theſe premiſes we are alſo led to draw another concluſion, extremely different from the opinion that is commonly entertained on this ſubject, viz. That it ſeems probable, that the very beſt butter could be made with economy in thoſe dairies only where the manufacture of cheeſe is the principal object. The reaſons are obvious: If only a ſmall portion of milk ſhould be ſet apart for butter, all the reſt may be made into cheeſe, while it is yet warm from the cow, and perfectly ſweet; and if only that portion of cream which riſes during the firſt three or four hours after milking is to be reſerved for butter, the rich milk which is left after that cream is ſeparated, being ſtill perfectly ſweet, may be converted into cheeſe with as great advantage nearly as the newly-milked milk itſelf.

But as it is not probable that many perſons could be found who would be willing to purchaſe the very fineſt butter, made in the manner above pointed out, at a price that would be ſufficient to indemnify the farmer for his trouble in making it, theſe hints are thrown out merely to ſhew the curious in what way butter poſſeſſing this ſuperior degree of excellence may be obtained, if they chooſe to be at the expence; but for an ordinary market, Dr Anderſon is ſatisfied, from experience and attentive obſervation, that if in general about the firſt drawn half of the milk be ſeparated at each milking, and the remainder only ſet up for producing cream, and if that milk be allowed to ſtand to throw up the whole of its cream (even till it begins ſenſibly to taſte ſouriſh), and that cream be afterwards carefully managed, the butter thus obtained will be of a quality greatly ſuperior to what can uſually be procured at market, and its quantity not conſiderably leſs than if the whole of

(c) The making of cheeſe has never yet been reduced to ſcientific principles, and conſequently the reaſoning relating to it is very inconcluſive. It is in general ſuppoſed, that the goodneſs of cheeſe depends almoſt entirely upon its richneſs, by which is meant the proportion of oily matter, whether natural or extraneous, it contains; nothing, however, is more certain, than that this opinion is erroneous. Sometimes a very lean cheeſe is much better taſted than one that is much fatter; and, which will appear to moſt perſons ſtill more extraordinary, it frequently happens that a cheeſe that taſtes ſoft and fat is much leaner than one that is hard, dry, and ſticky. The mode of manufacturing it occaſions this, and not the quantity of cream it contains. It is very poſſible by art to make poor ſkim milk cheeſe aſſume the ſoft buttery taſte and appearance even of cream cheeſe. This ſubject, therefore, deſerves to be more particularly elucidated than it has hitherto been.

Connected as they are with the object diſcuſſed in the text, we beg leave with our author to ſuggeſt the following particulars, as proper objects of examination and experiment, viz. Is the quantity of caſeous matter afforded by milk neceſſarily connected with the proportion of cream that milk contains, or does it depend upon ſome other principle not hitherto inveſtigated? Without pretending to decide this queſtion, Dr Anderſon feels himſelf ſtrongly inclined to believe it does not depend upon the quantity of cream. It is well known that cow's milk, which always throws up more cream, and that of a much richer quality, than ewe-milk, does in no caſe afford above one-half the proportion of cheeſe that ewe-milk does. Nor can this ſingular tendency of ewe-milk, to yield a great proportion of curd, be attributed to its ſuperior thickneſs; for cow-milk can be often had that is thicker and richer than ewe-milk, but it always affords a much ſmaller proportion of curd. From theſe conſiderations, it is not impoſſible but it might be found, upon a careful inveſtigation, that the refuſe milk, which ought to be ſeparated from the other in making the beſt butter, might be equally proper, or very nearly ſo, for making cheeſe, as if no ſuch ſeparation had been made. We therefore recommend this as a proper object of experimental enquiry.

of the milk had been treated alike. This, therefore, is the practice that our author thinks most likely to suit the frugal farmer, as his butter, though of a superior quality, could be afforded at a price that would always ensure it a rapid sale.

Dr Anderson throws out many other ingenious and useful observations on this important branch of rural economy. In particular, he points out, in the plainest manner, the requisites of a good milk-house, which, as he truly observes, should be cool in summer and warm in winter, so as to preserve a temperature nearly the same throughout the year. But we have treated of this part of the subject elsewhere, and must therefore refer such as are desirous to know the Doctor's sentiments on it, to *The Letters and Papers of the Bath and West-of-England Society* for the encouragement of agriculture, &c. or to the eighth volume of *The Repertory of Arts and Manufactures*.

DAHALAC, the largest island in the Red Sea, is thus described by Mr Bruce. It is low and even, the soil fixed gravel and white sand, mixed with shells and other marine productions. It is destitute of all sorts of herbage, at least in summer, unless a small quantity of bent grass, just sufficient to feed the few antelopes and goats that are on the island. There is a very beautiful species of this last animal found here, small, short-haired, with thin black sharp horns, having rings upon them, and they are very swift of foot.

This island is, in many places, covered with large plantations of acacia trees, which grow to no height, seldom above eight feet, but spread wide, and turn flat at top, probably by the influence of the wind from the sea. Though in the neighbourhood of Abyssinia, Dahalac does not partake of its seasons; no rain falls here from the end of March to the beginning of October; but in the intermediate months, especially December, January, and February, there are violent showers for 12 hours at a time, which deluge the island, and fill the cisterns so as to serve all next summer; for there are no hills nor mountains in Dahalac, and consequently no springs. These cisterns alone preserve the water, and of them there yet remain 370, all hewn out of the solid rock. They say these were the works of the Persians; it is more probable they were those of the first Ptolemies. But whoever were the constructors of these magnificent reservoirs, they were a very different people from those that now possess them, who have not industry enough to keep one of the 370 clear for the use of man. All of them are open to every sort of animal, and half full of the filth they leave there, after drinking and washing in them; yet one of these cisterns, cleaned and shut up with a door, might afford them wholesome sweet water all the year over.

After the rains fall, a prodigious quantity of grass immediately springs up; and the goats give the inhabitants milk, which in winter is the principal part of their subsistence, for they neither plow nor sow; all their employment is to work the vessels which trade to the different parts of the coast. One half of the inhabitants is constantly on the Arabian side, and by their labour is enabled to furnish with *dora* (millet or Indian corn) and other provisions the other half who stay at home; and when their time is expired, they are relieved by the other half, and supplied with necessaries in their turn. But the sustenance of the poorer sort is entirely shell and other fish. Their wives and daughters are very bold and expert fisherwomen. Several of them, entirely naked, swam off to the vessel before it came to an anchor, begging handfuls of wheat, rice, or dora. They are very importunate and sturdy beggars, and not easily put off with denials. These miserable people, who live in the villages not frequented by barks from Arabia, are sometimes a whole year without tasting bread. Yet such is the attachment to their place of nativity, they prefer living in this bare, barren, parched spot, almost in want of necessaries of every kind, especially of these essential ones, bread and water, to those pleasant and plentiful countries on both sides of them.

There are in Dahalac twelve villages or towns, of which each has a plantation of doomtrees round it, which furnish the only manufacture in the island. The leaves of this tree, when dried, are of a glossy white, which might very easily be mistaken for sattin: of these they make baskets of surprising beauty and neatness, staining part of the leaves with red or black, and working them into figures very artificially. Our author knew some of these, resembling straw-baskets, continue full of water for 24 hours, without one drop coming through. They sell these at Loheia and Jidda, the largest of them for four commesh, or sixpence. This is the employment, or rather amusement, of the men who stay at home; for they work but very moderately at it, and all of them indeed take special care not to prejudice their health by any kind of fatigue from industry.

People of the better sort, such as the Shekh and his relations, men privileged to be idle, and never exposed to the sun, are of a brown complexion. But the common sort employed in fishing, and those who go constantly to sea, are not indeed black but red, and little darker than the colour of new mahogany.

The inhabitants of Dahalac seemed to be a simple, fearful, and inoffensive people. It is the only part of Africa or Arabia (call it which you please) where you see no one carry arms of any kind: neither gun, knife, nor sword, is to be seen in the hands of any one. Whereas at Loheia, and on all the coast of Arabia, and more particularly at Yamboo, every person goes armed; even the porters, naked and groaning under the weight of their burden and heat of the day, have yet a leather belt, in which they carry a crooked knife, so monstrously long, that it needs a particular motion and address in walking not to lame the bearer. This was not always the case at Dahalac; several of the Portuguese, on their first arrival here, were murdered, and the island often treated ill, in revenge, by the armaments of that nation. The men seemed healthy. They told our author they had no diseases among them, unless sometimes in spring, when the boats of Yemen and Jidda bring the small-pox among them, and very few escape with life that are infected. He did not observe among them a man that seemed to be sixty years old; from which he inferred that they are not long livers, though the air should be healthy, as being near the channel, and as they have the north wind all summer, which moderates the heat.

Dahalac, like all the other islands in the Red Sea, depends upon Masuah. The revenue of its governor consists in a goat brought to him monthly by each of the twelve villages. Every vessel that puts in there for Masuah pays him also a pound of coffee, and every one from

Dahalac. from Arabia a dollar or pataka. No sort of small money is current at Dahalac, excepting Venetian glass-beads, old and new, of all sizes and colours, broken and whole.

Although this is the miserable state of Dahalac at present, matters were widely different in former times. The pearl fishery flourished greatly here under the Ptolemies; and even long after, in the time of the caliphs, it produced a great revenue, and till the sovereigns of Cairo, of the present miserable race of slaves, began to withdraw themselves from their dependency on the port, Dahalac was the principal island that furnished the pearl fishers or divers. It was, indeed, the chief port for the fishery on the southern part of the Red Sea, as Suakem was on the north; and the basha of Masuah passed part of every summer here, to avoid the heat at his place of residence on the continent.

The fishery extended from Dahalac and its islands nearly to lat. 20°. The inhabited islands furnished each a bark and so many divers, and they were paid in wheat, flour, &c. such a portion to each bark for their use, and so much to leave with their family for their subsistence; so that a few months employment furnished them with every thing necessary for the rest of the year. The fishery was rented in later times to the basha of Suakem; but there was a place between Suakem and the supposed river Frat, in lat. 21° 28′ north, called *Gungunnah*, which was reserved to the grand signior in particular, and a special officer was appointed to receive the pearls on the spot and send them to Constantinople. The pearls found there were of the largest size, and inferior to none in water or roundness. Tradition says, that this was exclusively the property of the Pharaohs; by which is meant, in Arabian manuscripts, the old kings of Egypt before Mahomet.

In the same extent between Dahalac and Suakem was another very valuable fishery, that of tortoises, from which the finest shells of that kind were produced, and a great trade was carried on with the East Indies (China especially) at little expence, and with very considerable profits. But the immense treasures in the bottom of the Red Sea have now been abondoned for near 200 years, though they never were richer in all probability than at present. No nation can now turn them to any profit but the English East India Company, more intent on multiplying the number of their enemies, and weakening themselves by spreading their inconsiderable force over new conquests, than creating additional profit by engaging in new articles of commerce. A settlement upon the river Frat, which never yet has belonged to any one but wandering Arabs, would open them a market both for coarse and fine goods from the southern frontiers of Morocco, to Congo and Angola, and set the commerce of pearls and tortoise shell on foot again. All this section of the gulf from Suez, as we are told, is in their charter, and twenty ships might be employed on the Red Sea without any violation of territorial claims. The myhrrh, the frankincense, some cinnamon, and variety of drugs, are all in the possession of the weak king of Adel; an usurper, tyrant, and Pagan, without protection, and willing to trade with any superior power that only would secure him a miserable livelihood.

There are neither horses, dogs, sheep, cows, nor any sort of quadruped but goats, asses, a few half-starved camels, and antelopes at Dahalac, which last are very numerous. The inhabitants have no knowledge of fire-arms, and there are no dogs nor beasts of prey in the island to kill them; they catch indeed some few of them in traps.

The language at Dahalac is that of the shepherds, though Arabic, too, is spoken by most of them. Our author states the latitude of Dahalac to lie between 15° 27′ 30″, and 15° 54′ 30″ north.

Dalrymple. DALRYMPLE (Sir David), was born in Edinburgh on the 28th of October (N. S.) 1726. His father was Sir James Dalrymple of Hailes, Bart. and his mother Lady Christian Hamilton, a daughter of the Earl of Hadinton. His grandfather Sir David Dalrymple was the youngest son of the first Lord Stair, and is said to have been the ablest of that family, so much distinguished for ability. He was Lord Advocate for Scotland in the reign of George I. and his son Sir James had the auditorship of the exchequer for life.

The subject of this memoir was educated at Eton school, where he was distinguished as a scholar, and long remembered as a virtuous and orderly youth. In that justly celebrated seminary he acquired a classical taste, which, though it was once prevalent in Scotland, has in that country been long on the decline; and formed, besides, friendships to persons and attachments to things, which accompanied him through life. Hence probably sprung his partiality to English manners and customs, which marked both his public conduct and private conversation, and was the source of much of his dignity, and some of his littlenesses.

From Eton he returned to Edinburgh, whence, after the usual course of a gentleman's studies in that university, he went to Utrecht to study the civil law; and remained there till after the rebellion in 1746. Upon his return to his native country, so promising were his parts, and such his industry and soberness of mind, that very sanguine expectations were entertained of his future eminence; and in some respects these expectations were not frustrated. To his intimate friends it was well known, that if left to follow the bent of his own inclinations, he would have devoted his time and his talents to the study of antiquities and the belles lettres; in both which departments of literature he was eminently qualified to excel. On the death of his father, however, he found his affairs so very much encumbered, that in order to retrieve them, and to provide for his brothers and sisters, he resolved to follow the law as a profession, in which some of his ancestors had made a distinguished figure.

He was called to the Scotch bar in 1748, where, notwithstanding the elegant propriety of the cases which he drew, it must be confessed that his success did not answer the expectations which had been formed of him. This was not owing either to want of science or to want of industry, but to certain peculiarities, which, if not inherent in his nature, were the result of early and deep-rooted habits. He possessed on all occasions a sovereign contempt, not only for verbal antithesis, but for well rounded periods, and every thing which had the semblance of declamation; and indeed he was wholly unfitted by an ill toned voice and ungraceful elocution, for shining as an orator. No wonder, then, that his pleadings, which were never addressed to the passions,

Dalrymple.

passions, did not rival those of some of his opponents, who, possessed of great rhetorical powers, did not, like him, employ strokes of irony too fine to be perceived by the bulk of any audience, but expressed themselves in full, clear, and harmonious periods. Even his memorials, though classically written, and often replete with valuable matter, did not on every occasion please the court; for they were always brief, and sometimes, as it was said, indicated more attention to the minutiæ of forms than to the merits of the cause. Yet on points which touched his own feelings, or the interests of truth and virtue, his language was animated, his arguments forcible, and his scrupulous regard to form thrown aside.

He was sometimes employed as a depute advocate, which gave him opportunities at the circuits of displaying that candour and tenderness of disposition which so well becomes the public prosecutor in a criminal court. Of this the following instance may be worth relating. On the first day of the court at Stirling, he was once accosted by another advocate in these words: "Sir David, why is there not a trial this forenoon? I would be getting on." "There are (replied he) some unhappy culprits to be tried for their *lives;* and therefore it is proper that they have time to confer with their men of law." "That is of little consequence (said the other). Last year I came to visit Lord Kames when he was here on the circuit, and he appointed me counsel for a man accused of a rape. Though I had very little time to prepare, yet I made a decent speech." "Pray, Sir, (said Sir David), was your client acquitted or condemned?" "O (replied the other), most unjustly condemned." "That, Sir, (said the depute advocate) is no good argument for hurrying on trials."

To return from this digression, if it be considered as such, it is surely to the honour of Sir David Dalrymple, that whatever men thought of his singularities, his detractors concurred with his admirers in believing him incapable of misleading the judge by a false statement of facts; or his clients, by holding out to them fallacious grounds of hope.

His high sense of honour, and his inflexible integrity, were indeed universally admitted; and it was with the warmest approbation of the public, that in 1766 he was appointed one of the judges of the court of session, the highest civil tribunal in Scotland. He took his seat on the bench, according to the usage of that court, by the title of Lord Hailes, the designation by which he is generally known among the learned of Europe; and the expectations entertained of him were again sanguine. His unwearied assiduity in sifting dark and intricate matters to the bottom was well known; his elegant and concise manner of expressing his sentiments was admirably suited to the character of a judge; and his legal opinions had been generally sound. Yet it must be confessed, that as a judge he was neither so useful nor so highly revered as he ought to have been from the extent of his knowledge, and his unquestioned integrity. The same minute attention to forms, which had in some degree obstructed his rise at the bar, accompanied him to the bench, and brought upon him the ridicule of the wits about the court (A): and we all know, that the character even of Socrates himself was not able to resist the torrent of ridicule. In extenuation of this foible, it may be observed, that by some of the judges of the court of session perhaps too little regard has been paid to form; and that forms, even apparently trifling, cannot in legal proceedings be wholly disregarded without involving in danger truth and justice. Be this as it may, such was the opinion which the other judges entertained of Lord Hailes's accuracy, diligence, and dignified manners, that, in the absence of the president, they generally voted him into the vacant chair.

In May 1776 he was appointed one of the lords commissioners of justiciary; and in that station he commanded the respect of all mankind. Fully impressed with a deep sense of the importance of his office, he seemed, in the criminal court, to lay aside his singularities. So far from throwing his whole weight into the scale of the crown, a charge which has been sometimes brought, we believe unjustly, against the Scotch judges, Lord Hailes, like the judges of England, was always counsel for the prisoner when the king's counsel appeared too strong for their opponents, or when there was any particular intricacy in the case. In administering the oath to the witnesses, he had none of that indecorum which we have elsewhere censured in some of his brethren (see OATH, *Encycl.*); but rising solemnly from his seat, he repeated the words in so serious a manner, as left no doubt in the most profligate mind but that he was himself impressed with a sense of the immediate presence of the Supreme Being, and with the firm belief of a future judgment. When the witness appeared to be young or ignorant, we have beheld, with the utmost love and veneration, the pious pains which his Lordship took to discover whether he was duly acquainted with the nature and obligation of an oath, before he admitted him to swear; and though it is perhaps impossible for human vigilance and sagacity to prevent perjury altogether in courts of justice, he must surely have been a villain uncommonly hardened and artful who could perjure himself in the presence of Lord Hailes. In doubtful cases his Lordship inclined always to the side of mercy; but when it became his duty to pass sentence of death upon convicted criminals, he addressed them in a strain of such piety and commiseration, as to draw tears from the eyes of every beholder, and was calculated to make a deep and proper impression on the unhappy person himself. In the discharge of this painful duty, we never saw him surpassed, and have seldom seen him equalled.

Had Lord Hailes been conspicuous only as a sound lawyer and an able and upright judge, we should not have thought his life intitled to a place in this Work; but he was no less eminent as a man of general erudition, and as a voluminous author. His skill in classical learning, the belles lettres, and historical antiquities, especially those of his own country, is universally admitted;

(A) In a satirical ballad on the court of session, Mr Boswell, alluding to Lord Hailes's fondness for verbal criticism, makes him address the president in the following words:

To judge of this matter I cannot pretend,
For justice, my Lord, wants an *e* at the end.

Dalrymple.

ted; but it cannot be denied, that the same fastidiousness, and the same microscopic attention to minutiæ, which characterised him as a barrister, prevented him from rising to that rank in the republic of letters to which his learning and genius would otherwise have infallibly carried him. But if he was not one of the most celebrated writers of the age, he was unquestionably one of the most virtuous; if his publications were not always edifying, they were at least innocent and ingenious; and some of them are in the highest degree valuable. In proof of this assertion, we need instance only his *Annals of Scotland*, and his *Inquiry into the Secondary Causes which Mr Gibbon has assigned for the Rapid Progress of Christianity*. Of the former of these works, though little calculated to please the common herd of readers, it may with truth be said, that in research and ingenuity it stands unrivalled among the writings of Scotch antiquaries; and of the latter, it is surely not too much to say, that it displays uncommon acumen, closeness of reasoning, and zeal for the cause of truth, without the usual rancour of theological controversy.

His taste for retirement, which the state of his affairs rendered for a while necessary, grew upon him as he advanced in years. His constitution, of which he was very careful, as well as his principles and habits, rendered him averse from dissipation of every kind. After he was made a judge, he considered abstraction from the gay and fashionable world as connected with the duty of one whose time was no longer his own; and when he chose to unbend his mind, it was in the society of a few easy friends, whom he selected as much for their worth and good humour as for their genius or their learning. He had indeed occasionally much conversation with that constellation of wits and men of science who flourished in Edinburgh at the same period with himself; but it was impossible for friendship or intimacy to subsist between men who thought so differently as he and they thought on the most important of all subjects. Though an old-fashioned whig, zealously attached to the constitution, he scorned to take any share in the civil or ecclesiastical broils in which some of his brother judges were warmly engaged for the first 20 years of the present reign; for he looked on these as either frivolous or mischievous.

Although his Lordship's constitution had been long in an enfeebled state, he prosecuted his studies, and attended his duty on the bench, till within three days of his death, which happened on the 29th of November 1792, in the 66th year of his age.

His Lordship was twice married; by his first wife Anne Brown, only daughter of Lord Coalston, one of the judges of the court of session, he left issue one daughter, who inherits the family estate. His second marriage (of which also their is issue one daughter) was to Helen Fergusson, youngest daughter of Lord Kilkerran, who has the affliction to survive him. Leaving no male issue, the title of Baronet descends to his nephew.

Though the church of Scotland does not much encourage funeral discourses, a very laudable endeavour was made to render the talents and virtues of Lord Hailes a theme of instruction to mankind, in a sermon preached soon after his death in the church of Inveresk, by his learned friend and venerable pastor Dr Carlyle; from which we shall transcribe a summary view of his character as a judge, a scholar, a Christian, and a citizen.

"His knowledge of the laws was accurate and profound, and he applied it in judgment with the most scrupulous integrity. In his proceedings in the criminal court, the satisfaction he gave to the public could not be surpassed. His abhorrence of crimes, his tenderness for the criminals, his respect for the laws, and his reverential awe of the Omniscient Judge, inspired him on some occasions with a commanding sublimity of thought, and a feeling solemnity of expression, that made condemnation seem just as the doom of Providence to the criminals themselves, and raised a salutary horror of crimes in the breast of the audience.

"Conscious of the dignity and importance of the high office he held, he never departed from the decorum that becomes that reverend character; which indeed it cost him no effort to support, because he acted from principle and sentiment, both public and private. Affectionate to his family and relations, simple and mild in his manners, pure and conscientious in his morals, enlightened and entertaining in his conversation; he left society only to regret, that, devoted as he was to more important employments, he had so little time to spare for intercourse with them.

"He was well known to be of high rank in the republic of letters, and his loss will be deeply felt through many of her departments. His labours, in illustration of the history of his country, and many other works of profound erudition, remain as monuments of his accurate and faithful research for materials, and his sound judgement in the selection of them. Of his unfeigned piety and devotion, you have very often been witnesses where we now are. I must add, however, that his attendance on religious ordinances was not merely out of respect to the laws and for the sake of example (motives which should never fail to have influence on persons of superior rank, for the most obvious reasons), but from principle and conviction, and the most conscientious regard to his duty; for he not only practised all the virtues and charities in proof of his faith, but he demonstrated the sincerity of his zeal by the uncommon pains he took to illustrate primitive Christianity, and by his elaborate and able defences of it against its enemies.

"His profound researches into history, and his thorough knowledge of the laws, made him perfectly acquainted with the progress of the constitution of Britain, from the first dawn of liberty in the common law of the land, and the trial by jury which precede all written records, and afterwards in the origin and establishment of parliaments, through all its vicissitudes and dangers, till at last, by the blessing of divine Providence, which brought many wonderful events to concur to the same end, it was renewed, strengthened, and finally confirmed by the Revolution.

"It was this goodly and venerable fabric of the British constitution which the deceased most respectable character contemplated with admiration and delight (of late, indeed, with a mixture of anxiety and fear), as the temple of piety, as the genuine source of greater happiness and freedom, to a larger portion of mankind than ever flowed from any government upon earth.

"Ill indeed can the times bear the loss of such an affectionate

Dalrymple.

affectionate patriot and able guardian of the laws of his country. But we must not murmur at the will of Providence, which in its mercy 'may have withdrawn the good man from the evil to come.' In mercy, I say, to him, whose righteous spirit was so deeply grieved when 'he saw the wicked rage, and the people imagine a vain thing.'"

Such is the memorial which, in the hour of recent sorrow, followed this excellent man to the grave; and we believe it will yet be allowed to be just by all who had the happiness of his Lordship's acquaintance, and are what he was, friends to the best interests of mankind.

This sketch of the life of Lord Hailes would be more imperfect than even it is, if we could not subjoin to it a catalogue of his publications, of which the greater part are exceedingly curious. We call them *publications*, because he employed almost as much of his time in republishing old and useful books as in preparing for the press his own valuable works.

Besides his essays in the papers called *The World* and *The Mirror*, which are well known and universally admired, his Lordship published the following works:

Sacred Poems, or a Collection of Translations and Paraphrases from the Holy Scriptures; by various authors, Edinburgh, 1751, 12mo. Dedicated to Charles Lord Hope, with a preface of ten pages.

The Wisdom of Solomon, Wisdom of Jesus the Son of Sirach, or Ecclesiasticus, 12mo, Edin. 1755.

Select Discourses (in number nine), by John Smith, late Fellow of Queen's College, Cambridge, 12mo, 291 pages. Edin. 1756; with a preface of five pages, "many quotations from the learned languages translated,—and notes added, containing allusions to ancient mythology, and to the erroneous philosophy which prevailed in the days of the author,—various inaccuracies of style have been corrected, and harsh expressions softened."

A discourse of the unnatural and vile Conspiracy attempted by John Earl of Gowry and his brother, against his Majesty's person, at St Johnstoun, upon the 5th of Aug. 1600. No date of the republication, but the edition and notes supposed by Lord Hailes, 12mo, 1757.

A Sermon, which might have been preached in East Lothian upon the 25th day of October 1761, on Acts xxviii. 1, 2. "The barbarous people shewed us no little kindness." Edin. 1761, pp. 25, 12mo. "Occasioned by the country people pillaging the wreck of two vessels, viz. the Betsy, Cunningham, and the Leith Packet, Pitcairn, from London to Leith, cast away on the shore between Dunbar and North Berwick. All the passengers on board the former, in number 17, perished; five on board the latter, October 16. 1761."—A most affecting discourse, admirably calculated to convince the offenders!

Memorials and Letters relating to the History of Britain, in the reign of James I. published from the originals, Glasgow, 1762.—Addressed to Philip Yorke, Viscount Royston, pp. 151. "From a collection in the advocate's library, by Balfour of Denmyln." The preface of four pages, signed Dav. Dalrymple.

The works of the ever memorable Mr John Hales of Eaton, now first collected together in 3 vols, Glasgow, 1765; preface of three pages. Dedicated to William (Warburton), Bishop of Gloucester. "The edition said to be undertaken with his approbation; obsolete words altered, with corrections in spelling and punctuation."

A specimen of a book entitled "Ane Compendious Booke of Godly and Spiritual Sangs, collectit out of sundrie parts of the Scripture, with sundrie of other Ballates changed out of prophaine Sanges, for avoyding of Sin and Harlotrie, with augmentation of sundry Gude and Godly Ballates, not contained in the first edition. Edinburgh, printed by Andro Hart." 12mo. Edin. 1765, pp. 42; with a Glossary of four pages.

Memorials and Letters relating to the History of Britain in the reign of Charles I. published from the originals, Glasgow, 1766, pp. 189. Preface of six pages, signed Dav. Dalrymple, chiefly collected by Mr Wodrow, author of the History of the Church of Scotland. Inscribed to Robert Dundas of Arniston, Lord President of the Court of Session.

An account of the preservation of Charles II. after the Battle of Worcester, drawn up by himself; to which are added, his Letters to several persons. Glasgow, 1766, pp. 190, from the MSS. of Mr Pepys, dictated to him by the king himself, and communicated by Dr Sandby, master of Magdalen College. The letters are collected from various books; some of them now first published, communicated by the tutors of the Duke of Hamilton, by the Earl of Dundonald, &c. The preface of four pages, signed Dav. Dalrymple, dedicated to Thomas Holles, Duke of Newcastle, chancellor of the university of Cambridge.

The Secret Correspondence between Sir Robert Cecil and James VI. 12mo, 1766.

A catalogue of the Lords of Session, from the Institution of the College of Justice in the year 1532, with Historical Notes. *Suum cuique—rependet posteritas.* Edin. 1767, 4to, pp. 26.

The Private Correspondence of Dr Francis Atterbury, Bishop of Rochester, and his friends, in 1725, never before published. Printed in 1768, 4to. Advertisement, pp. 2. Letters, pp. 10. A fac simile of the first from Bishop Atterbury to John Cameron of Lochiel, to prove their authenticity.

An examination of some of the Arguments for the High Antiquity of *Regiam Majestatem*; and an Inquiry into the authenticity of the *Leges Malcolmi*; by Sir David Dalrymple, 4to, pp. 52. Edin. 1769.

Historical Memoirs concerning the Provincial Councils of the Scottish Clergy, from the earliest Accounts to the Æra of the Reformation; by Sir David Dalrymple. Edinburgh, 1769, 4to, pp. 41.—*Nota*, Having no high opinion of the popularity of his writings, he prefixes to this work the following motto: "Si delectamur quum scribimus quis est tam invidus qui ab eo nos abducat? sin laboramus quis est qui alienæ modum statuat industriæ."—*Cicero.*

Canons of the church of Scotland, drawn up in the Provincial Councils held at Perth, A. D. 1242, and 1269. Edinburgh, 1769, 4to, pp. 48.

Ancient Scottish Poems, published from the MS. of George Bannatyne, 1568. Edin. 1770, 12mo. Preface six pages; Poems pp. 221; very curious notes pp. 92; glossary and lists of passages and words not understood, pp. 14.

The additional case of Elizabeth, claiming the title and dignity of Countess of Sutherland; by her Guardians.

Dalrymple.

dians. Wherein the facts and arguments in ſupport of her claim are more fully ſtated, and the errors in the additional caſes for the other claimants are detected, 4to.——This ſingularly learned and able caſe was ſubſcribed by Alexander Wedderburn (preſent Lord Chancellor), and Sir Adam Ferguſſon, but is the well-known work of Lord Hailes. It ought not to be regarded merely as a law-paper of great ability, but as a treatiſe of profound reſearch into the hiſtory and antiquity of many important and general points of ſucceſſion and family hiſtory. Introduction, pp. 21; the firſt four chapters pp. 70; the fifth and ſixth chapters pp. 177.

Remarks on the Hiſtory of Scotland, by Sir David Dalrymple.—"Utinam tam facile vera invenire poſſem quam falſa convincere." *Cicero.*—Edin. 1773, inſcribed to George Lord Lyttleton, in nine chapters, pp. 284. 12mo.

Huberti Langueti Epiſtolæ ad Philippum Sydneium Equitem Anglum, accurante D. Dalrymple de Hailes, Eq. Edinburgh, 1776, 8vo. Inſcribed to Lord Chief Baron Smythe.—Virorum Eruditorum Teſtimonia de Langueto, pp. 7. Epiſtolæ, pp. 289. Index Nominum, pp. 41.

Annals of Scotland, from the Acceſſion of Malcolm III. ſurnamed Canmore, to the Acceſſion of Robert I. by Sir David Dalrymple. Edin. 1776, pp. 311. Appendix, pp. 51.

Tables of the Succeſſion of the Kings of Scotland, from Malcolm III. to Robert I. their marriages, children, and time of their death; and alſo of the Kings of England and France, and of the Popes who were their contemporaries.

Chronological Abridgement of the Volume, pp. 30. The Appendix contains eight diſſertations: 1. Of the law of Evenus and Mercheta Mulierum, pp. 17. 2. A commentary on the 22d ſtatute of William the Lion, pp. 8. 3. Of the 18th ſtatute of Alexander III. pp. 5. 4. Bull of Pope Innocent IV. pp. 6. 5. Of Walter Stewart Earl of Menteeth, 1296, pp. 7. 6. Of M'Duff, ſlain at Falkirk in 1298, pp. 3. 7. Of the death of John Comyn, 10th February, 1305, pp. 4. 8. Of the origin of the houſe of Stuart, pp. 6.

Annals of Scotland, from the Acceſſion of Robert I. ſurnamed Bruce, to the Acceſſion of the Houſe of Stuart; by Sir David Dalrymple, Edin. 1779, 4to, pp. 277. Appendix, pp. 54, containing, 1. Of the manner of the death of Marjory, daughter of Robert I. pp. 7. 2. Journal of the campaign of Edward III. 1327, pp. 9. 3. Of the genealogy of the family of Seton in the 14th century. 4. Liſt of the Scottiſh commanders at the battle of Hallidon, 19th July 1383, pp. 11. 5. Whether Edward III. put to death the ſon of Sir Alexander Seton, pp. 8. 6. Liſt of the Scottiſh commanders killed or made priſoners at the battle of Durham, pp. 8. 7. Table of kings, p. 1. 8. Corrections and additions to volume i. pp. 16. Chronological abridgement of the volume, pp. 39.

Account of the Martyrs of Smyrna and Lyons, in the 2d century, 12mo, with explanatory notes, Edin. 1776. Dedicated to Biſhop Hurd, pp. 68. Notes and illuſtrations, pp. 142. This is a new and correct verſion of two moſt ancient epiſtles, the one from the church at Smyrna to the church at Philadelphia; the other from the Chriſtians at Vienna and Lyons to thoſe in Aſia and Phrygia—their antiquity and authenticity are undoubted. Great part of both is extracted from Euſebius's Eccleſiaſtical Hiſtory. The former was firſt completely edited by Archbiſhop Uſher. The author of the notes ſays of them, with his uſual and ſingular modeſty, "That they will afford little new or intereſting to men of erudition, though they may prove of ſome benefit to the unlearned reader." But the erudition he poſſeſſed in theſe branches is ſo rare, that this notice is unneceſſary. They diſplay much uſeful learning and ingenious criticiſm, and breathe the moſt ardent zeal, connected with an exemplary knowledge of Chriſtianity. N. B. This is the firſt volume of the remains of Chriſtian Antiquity.

Remains of Chriſtian Antiquity, with explanatory notes, vol. ii. Edin. 1778, 12mo. Dedicated to Dr Newton biſhop of Briſtol. Preface, pp. 7. This volume contains the trial of Juſtin Martyr and his companions, pp. 8. Epiſtle of Dionyſius biſhop of Alexandria, to Fabius biſhop of Antioch, pp. 16. The trial and execution of Cyprian biſhop of Carthage, pp. 8. The trial and execution of Fructuoſus biſhop of Tarracona in Spain, and of his two deacons, Augurius and Eulogius, pp. 8. The maiden of Antioch, pp. 2. Theſe are all newly tranſlated by Lord Hailes from Ruinart, Euſebius, Ambroſe, &c. The notes and illuſtrations of this volume extend from p. 47 to 165, and diſplay a moſt intimate acquaintance with antiquity, great critical acumen, both in elucidating the ſenſe and detecting interpolations; and above all, a fervent and enlightened zeal, in vindicating ſuch ſentiments and conduct as are conformable to the word of God, againſt the malicious ſarcaſms of Mr Gibbon. To this volume is added an Appendix of pp. 22, correcting and vindicating certain parts of vol. i.

Remains of Chriſtian Antiquity, vol. iii. Edin. 1780. Dedicated to Thomas Balguy, D. D. Preface, pp. 2. It contains the Hiſtory of the martyrs of Paleſtine in the third century, tranſlated from Euſebius, pp. 94. Notes and illuſtrations, pp. 135; in which Mr Gibbon again comes, and more frequently, under review.—The partiality and miſrepreſentations of this popular writer are here expoſed in the calmeſt and moſt ſatisfactory manner.

Pity it is that Lord Hailes ſhould have printed and publiſhed theſe valuable volumes, and indeed moſt of his other works, at his own expence; and diſperſed them ſo liberally to his friends, that they have been little circulated among any other.

Octavius, a Dialogue, by Marcus Minucius Felix. Edin. 1781, pp. 16. Preface.—The ſpeakers are, Cœcilius a Heathen, Octavius a Chriſtian; whoſe arguments prevail with his friend to renounce Paganiſm and become a Chriſtian proſelyte. Notes and illuſtrations, pp. 120.

Of the Manner in which the Perſecutors died; a Treatiſe, by L. C. F. Lactantius, Edin. 1782. Inſcribed to Dr Porteous biſhop of Cheſter (preſent biſhop of London). Preface, pp. 37, in which it is proved that Lactantius is the author. Text, pp. 125. Notes and illuſtrations, pp. 109.

L. C. F. Lactantii Divinarum Inſtitutionum Liber Quintus ſeu de Juſtitia, 1777.

Diſquiſitions concerning the Antiquity of the Chriſtian Church. Glaſgow, 1783. Inſcribed to Dr Halifax biſhop of Glouceſter, pp. 194.—This ſmall original

Dalrymple.

nal and most excellent work consists of six chapters. Chap 1. A commentary on the conduct and character of Gallio. Acts xviii. 5, 12, 17.—Chap. 2. Of the time at which the Christian religion became publicly known at Rome.—Chap. 3. Cause of the persecution of the Christians under Nero. In this the hypothesis of Mr Gibbon, vol. i. 4to, p. 641, is examined.—Chap. 4. Of the eminent Heathen writers who are said (by Gibbon) to have disregarded or contemned Christianity, viz. Seneca, Pliny sen. Tacitus, Pliny jun. Galen, Epictetus, Plutarch, Marcus Antoninus. To the admirers of Heathen philosophers, and to those especially who state between them and the Christian doctrine any consanguinity, this chapter is earnestly recommended.—Chap. 5. Illustration of a conjecture by Gibbon, respecting the silence of Dio Cassius concerning the Christians. In this chapter, with extreme impartiality, he amplifies and supports an idea of Mr Gibbon on this head. Chap. 6. Of the circumstances respecting Christianity that are to be found in the Augustan history.

It seems very probable that the close attention which Lord Hailes appears to have given to such subjects, was in some measure the effect of the mistakes and partiality of Gibbon. In no one work from 1776, the date of Mr Gibbon's first publication, has he omitted to trace this unfair and insinuating author; but in 1786 he came forth of set purpose with the most able and formidable reply which he has received, intitled, "An Inquiry into the Secondary Causes which Mr Gibbon has assigned for the rapid growth of Christianity; by Sir David Dalrymple." Edin. 1786; gratefully and affectionately inscribed to Richard (Hurd) Bishop of Worcester, 4to, pp. 213. In five chapters.

Sketch of the Life of John Barclay, 4to, 1786.

Sketch of the Life of John Hamilton, a Secular Priest, 4to (one of the most savage and bigotted adherents of Popery, who lived about A. D. 1600.)

Sketch of the Life of Sir James Ramsay, a general officer in the armies of Gustavus Adolphus king of Sweden, with a head.

Life of George Leslie (an eminent capuchin friar in the early part of the 17th century, 4to, pp. 24.

Sketch of the Life of Mark Alex. Boyd, 4to.

These lives were written and published as a specimen of the manner in which a *Biographia Scotica* might be executed; and it is likely that Lord Hailes selected purposely the least interesting.

The Opinions of Sarah Dutchess Dowager of Marlborough, published from her original MSS. 1788, 12mo, pp. 120. (with a few foot notes by Lord Hailes, in which he corrects the splenetic partiality of her Grace).

The Address of Q. Sept. Tertullian to Scapula Tertullus, Proconsul of Africa, translated by Sir David Dalrymple, 12mo. Edin. 1790, inscribed to Dr John Butler, bishop of Hereford; preface, pp. 4; translation, pp. 18; original, pp. 13; notes and illustrations, pp. 135.

This address contains many particulars relating to the church after the third century. The translator has rejected all words and phrases of French origin, and written entirely in the Anglo Saxon dialect. In the course of the notes many obscurities of the original, not adverted to by other commentators, are explained. Some strange inaccuracies of Mr Gibbon are also detected, not included in the misrepresentations of his two famous chapters.

Dalrymple, Darcy.

This was the last work of this truly learned, respectable, and useful man. Whether he left behind him any thing else finished for the press, is known only to his friends. We have repeatedly heard that he was engaged in examining the authenticity of the books of the New Testament, and that, with the exception of two or three, he found every verse contained in it in the writings of the first three centuries. This seems indeed to have been an object in all his works; for, at the end of each of his translations and editions of the primitive Christian writers, a table is given of passages quoted or mentioned by them. If his Lordship completed any work of this kind, it should not be withheld from the public. We may indeed be told that its utility is in a great measure superseded by the laborious collections of Lardner (B), and the more elegant work of Paley (C); but not to mention the prejudices generally entertained against Lardner on account of his evident bias to Unitarianism, it would surely be proper, in the present age of wild opinions, to shew the multitude, who are guided by authority, how important a subject the Christian religion was deemed by this learned and accomplished layman.

DARCY (Count), an ingenious philosopher and mathematician, was born in Ireland in the year 1725; but his friends being, like many other great and good families at that period, attached to the house of Stuart, he was at 14 years of age sent to France, where he spent the rest of his life. Giving early indications of a genius for science, he was put under the care of the celebrated Clairaut (see Clairaut, *Encycl*), under whose tuition he improved so rapidly in the mathematics, that at 17 years of age he gave a new solution of the problem concerning the curve of equal pressure in a resisting medium. This was followed the year after by a determination of the curve described by a heavy body, sliding by its own weight along a moveable plane, at the same time that the pressure of the body causes a horizontal motion in the plane.

Though Darcy served in the war of 1744, he found leisure, during the bustle of a military life, to send two memoirs to the academy: the first of these contained a general principle in mechanics, that of the preservation of the rotatory motion; a principle which he again brought forward in 1750, by the name of the principle of the preservation of action. He was taken prisoner in this war by the English; and such was either the respect paid to science, or the mercy of the cabinet of St James's, that he was treated, not as an Irish rebel, but as a French subject fighting for his king and his country.

In 1760, Darcy published An Essay on Artillery, containing some curious experiments on the charges of gunpowder, &c. &c. and improvements on those of the ingenious

(B) See his *Credibility of the Gospel History*, and other works, in 11 vols 8vo.
(C) See his *Evidences of the Christian Religion*, in 2 vols 8vo.

ingenious Robins; a kind of experiments which our author carried on occaſionally to the end of his life. In 1765, he gave to the public the moſt ingenious of all his works, his Memoir on the Duration of the Senſation of Sight; in which he endeavours to prove, and indeed completely proves, that a body may ſometimes paſs by our eyes without producing a ſenſation attended with conſciouſneſs or marking its preſence, otherwiſe than by weakening the brightneſs of the object which it may chance to cover in its paſſage. If in this work he ſhall be thought to have taken hints from Dr Hartley, it is not perhaps too much to ſay, that ſome of our moſt celebrated writers on viſion have ſince been beholden to Darcy. No man indeed has cauſe to be aſhamed of being indebted to him; for all his works diſplay in an eminent degree the union of genius and philoſophy; but as he meaſured every thing upon the largeſt ſcale, and required extreme accuracy in experiment, neither his time, fortune, nor avocations, allowed him to execute more than a very ſmall part of what he projected.

In his diſpoſition, Darcy was amiable, ſpirited, lively, and a lover of independence; a paſſion to which he nobly ſacrificed, even in the midſt of literary ſociety.—He died of a cholera morbus in 1779, at 54 years of age. He was admitted of the French academy in 1749, and was made penſioner-geometrician in 1770. His eſſays, printed in the Memoirs of the Academy of Sciences, are various and very ingenious, and are contained in the volumes for the years 1742, 1747, 1749, 1750, 1751, 1752, 1753, 1754, 1758, 1759, 1760, 1765, and in tom. I. of the Savans Etrangers.

DATA OF EUCLID, the firſt in order of the books that have been written by the ancient geometricians, to facilitate and promote the method of reſolution or analyſis. In general, a thing is ſaid to be given which is either actually exhibited or can be found out, that is, which is either known by hypotheſis, or that can be demonſtrated to be known: and the propoſitions in the book of Euclid's data ſhew what things can be found out or known, from thoſe that by hypotheſis are already known: ſo that in the analyſis or inveſtigation of a problem, from the things that are laid down as given or known, by the help of theſe propoſitions, it is demonſtrated that other things are given, and from theſe laſt that others again are given, and ſo on, till it is demonſtrated that that which was propoſed to be found out in the problem is given; and when this is done, the problem is ſolved, and its compoſition is made and derived from the compoſitions of the data which were employed in the analyſis. And thus the data of Euclid are of the moſt general and neceſſary uſe in the ſolution of problems of every kind.

Marinus, at the end of his preface to the data, is miſtaken in aſſerting that Euclid has not uſed the ſynthetical, but the analytical method in delivering them: for though in the analyſis of a theorem, the thing to be demonſtrated is aſſumed in the analyſis; yet in the demonſtrations of the data, the thing to be demonſtrated, which is, that ſomething is given, is never once aſſumed in the demonſtration; from which it is manifeſt, that every one of them is demonſtrated ſynthetically: though indeed if a propoſition of the data be turned into a problem, the demonſtration of the propoſition becomes the analyſis of the problem. *Simpſon's Preface to his Edition of the Data.*

CIRCULATING DECIMALS, called alſo *recurring* or *repeating decimals*, are thoſe in which a figure or ſeveral figures are continually repeated. They are diſtinguiſhed into *ſingle* and *multiple*, and theſe again into *pure* and *mixed*.

A *pure ſingle* circulate is that in which one figure only is repeated; as ·222, &c. and is marked thus $\cdot\dot{2}$.

A *pure multiple* circulate is that in which ſeveral figures are continually repeated; as ·232323, &c. marked $\cdot\dot{2}\dot{3}$; and ·524524, &c. marked $\cdot\dot{5}2\dot{4}$.

A *mixed ſingle* circulate is that which conſiſts of a terminate part, and a ſingle repeating figure; as 4·222, &c. or $4\cdot\dot{2}$. And

A *mixed multiple* circulate is that which contains a terminate part with ſeveral repeating figures; as $45\cdot\dot{5}2\dot{4}$.

That part of the circulate which repeats is called the *repetend;* and the whole repetend, ſuppoſed infinitely continued, is equal to a vulgar fraction, whoſe numerator is the repeating number or figures, and its denominator the ſame number of nines: ſo $.\dot{2}$ is $= \frac{2}{9}$; and $\cdot\dot{2}\dot{3}$ is $= \frac{23}{99}$; and $\cdot\dot{5}2\dot{4}$ is $= \frac{524}{999}$.

It ſeems it was Dr Wallis who firſt diſtinctly conſidered or treated of infinite circulating decimals, as he himſelf informs us in his Treatiſe of infinites. Since his time many other authors have treated on this part of arithmetic; the principal of theſe, however, to whom the art is moſtly indebted, are Meſſrs Brown, Cunn, Martin, Emerſon, Malcolm, Donn, and Henry Clarke; in whoſe writings the nature and practice of this art may be fully ſeen, eſpecially in the laſt mentioned ingenious author.

DEFERENS, or DEFERENT, in the ancient aſtronomy, an imaginary circle, which, as it were, carries about the body of a planet, and is the ſame with the eccentric; being invented to account for the eccentricity, perigee, and apogee of the planets.

DEFLECTION, the turning any thing aſide from its former courſe by ſome adventitious or external cauſe. The word is often applied to the tendency of a ſhip from her true courſe by reaſon of currents, &c. which turn her out of her right way. It is likewiſe applied by aſtronomers to the tendency of the planets from the line of their projection, or the tangent of their orbit. See ASTRONOMY in this Supplement.

DEJECTION, in aſtrology, is applied to the planets when in their detriment, as aſtrologers ſpeak, i. e. when they have loſt their force or influence, as is pretended, by reaſon of their being in oppoſition to ſome others which check and counteract them. Or it is uſed when a planet is in a ſign oppoſite to that in which it has its greateſt effect or influence, which is called its *exaltation*. Thus, the ſign Aries being the exaltation of the ſun, the oppoſite ſign Libra is its dejection.

DELIACAL PROBLEM, a celebrated problem among the ancients, concerning the duplication of the cube.

DEMI-BASTION, in fortification, a baſtion that has only one face and one flank.

DENDROMETER, in its uſual acceptation, is the name of an inſtrument for meaſuring trees, of which the reader will find a deſcription in the Encyclopædia Britannica. The ſame name has been lately given, by

William Pitt, Esq; of Pendeford near Wolverhampton, to an inſtrument propoſed by him for meaſuring diſtances by one obſervation.

The idea of ſuch an inſtrument is not new. It has been frequently diſcuſſed, both in converſation and upon paper; but has been generally treated by ſound mathematicians with contempt, on the ſuppoſition of its being founded on falſe principles. Of all this our author is fully aware; but he, notwithſtanding, ſtrongly recommends it to the attention of the ingenious mathematical inſtrument maker.

To determine diſtances by one obſervation, two methods may be propoſed, founded on different principles; the one on the ſuppoſition of the obſerver being in the centre, and the object in the circumference, of a circle; the other, on the contrary ſuppoſition, of the obſerver being in the circumference, and the object in the centre.

To determine the diſtance of any object on the firſt ſuppoſition, the bulk or dimenſions of ſuch object muſt be known, either by meaſure or eſtimation, and the angle formed by lines drawn to its extremities being taken by an accurate inſtrument, the diſtance is eaſily calculated; and ſuch calculations may be facilitated by tables or theorems adapted to that purpoſe. For this method our preſent inſtruments, with a nonius, and the whole very accurately divided, are ſufficient; the only improvement wanting ſeems to be the application of a micrometer to ſuch inſtruments, to enable the obſerver to read his angle with more minute accuracy, by aſcertaining, not only the degrees and parts of a degree, but alſo the minutes and parts of a minute.

As in this method the bulk of inacceſſible objects can only be eſtimated, the error in diſtance will be exactly in the proportion of the error in ſuch eſtimation; little dependence can therefore be placed on diſtances thus aſcertained. For the purpoſes of ſurveying, indeed, a ſtaff of known length may be held by an aſſiſtant; and the angle from the eye of the obſerver to its two ends being meaſured by an accurate inſtrument, with a micrometer fitted to aſcertain minutes and parts of a minute, diſtances may be thus determined with great accuracy; the application of a micrometer to the theodelite, if it could be depended upon, for thus determining the minute parts of a degree, in ſmall angles, is very much a deſideratum with the practical ſurveyor.

This method of meaſuring diſtances, though plain and ſimple enough, our author illuſtrates by an example: Suppoſe A, fig. 1. (ſee Plate XXI.) the place of the inſtrument; BC the aſſiſtant's ſtaff, with a perpendicular pin at D, to enable the aſſiſtant to hold it in its right poſition; now, if the angle BAC could, by the help of a micrometer, be aſcertained to parts of a minute, the diſtance from A to B, or to C, might be eaſily calculated by the rules of plane Trigonometry; for which ſee that article in the Encyclopædia.

But this method of aſcertaining diſtances cannot be applied to inacceſſible objects, and it is moreover ſubject to the inconvenience of an aſſiſtant being obliged to go to the object whoſe diſtance is required (an inconvenience almoſt equal to the trouble of actual admeaſurement); therefore the perfection of the ſecond method propoſed, if attainable, is principally to be deſired; namely, that of conceiving the obſervation made on the circumference of a circle, whoſe centre is in the object whoſe diſtance is to be aſcertained; and, none of our inſtruments now in uſe being adapted to this mode of obſervation, a new conſtruction of a mathematical inſtrument is therefore propoſed, the name intended for which is the *dendrometer*.

Our author admits, that this name is not now uſed for the firſt time, though he thinks that the principle has never been applied in practice, for the familiar purpoſe of aſcertaining terreſtrial diſtances, in ſurveying, or otherwiſe, though the ſame principle has been ſo generally and ſucceſsfully applied in determining the diſtance of the heavenly bodies by means of their parallax.

The following principles of conſtruction are propoſed, which may perhaps be otherwiſe varied and improved. O, fig. 2. the object of whoſe diſtance is required; ABCDE the inſtrument *in plano*; BC a teleſcope, placed exactly parallel to the ſide AE; CE an arch of a circle, whoſe centre is at A, accurately divided from E in degrees, &c.; AD an index, moveable on the centre A, with a nonius ſcale at the end D, graduated to apply to the diviſions of the arch; alſo with a teleſcope, to enable the obſerver to diſcriminate the object, or any particular part or ſide thereof, the more accurately. The whole ſhould be mounted on three legs, in the manner of a plain table or theodolite, and furniſhed with ſpirit-tubes to adjuſt it to an horizontal poſition. The inſtrument being placed in ſuch poſition, the teleſcope BC muſt be brought upon the object O, or rather upon ſome particular point or ſide thereof; when, being there faſtened, the index AD muſt be moved till its teleſcope exactly ſtrikes the ſame point of the object; then the diviſions on the arch ED mark out the angle DAE, which will be exactly equal to the angle BOA, as is demonſtrated in the XV. and XXIX. propoſitions of Euclid, Book I.; and the ſide BA, as well as the angles ABO, and BAO, being already known, the diſtance BO or AO may be eaſily determined.

As the perfection of this inſtrument depends altogether upon its accuracy in taking ſmall angles, ſo that accuracy muſt depend, not only upon the inſtrument's being properly fitted with a micrometer, but alſo in ſome meaſure upon the length of the line BA in the figure. That line, therefore, might be extended, by the inſtrument being conſtructed to fold or ſlide out to a greater length when in uſe; upon which principle, connected with the application of a micrometer, an accurate and uſeful inſtrument might certainly be conſtructed. To adjuſt ſuch inſtrument for uſe, let a ſtaff be held up at a diſtance, in the manner of fig. 1. exactly equal in length to the diſtance of the two teleſcopes, and the index AD being brought exactly upon the ſide AE, if the two teleſcopes accurately ſtrike either end of the ſtaff, the inſtrument is properly adjuſted.

The conſtruction of a ſimilar inſtrument, on the principles of Hadley's quadrant, for naval obſervations, would alſo doubtleſs be an acceptable object in navigation, by enabling the mariner to aſcertain the diſtances of ſhips, capes, and other objects, at a ſingle obſervation; and that, perhaps, with greater accuracy than can be done by any method now in uſe.

For this purpoſe, the following conſtruction is propoſed: ABCDE, fig. 3. the inſtrument *in plano*; O the object whoſe diſtance is required; at A, at C, at E, and at 3, are to be fixed ſpeculums, properly framed

med and fitted, that at 3 having only its lower part quickfilvered, the upper part being left tranfparent to view the object; the fpeculum at A being fixed obliquely, fo that a line A 1, drawn perpendicular to its furface, may bifect the angle BAC in equal parts; that at C being perpendicular to the line C 2; thofe at E and 3 being perpendicular to the index E 3, and that at E being furnifhed with a fight; the arch DC to be divided from D in the manner of Hadley's quadrant; the movement of the index to be meafured as before by a micrometer; and as the length of the line AE would tend to the perfection of the inftrument, it may be conftructed to fold up in the middle, on the line C 2, into lefs compafs when not in ufe. The inftrument may be adjufted for ufe by holding up a ftaff at a diftance, as before propofed, whofe length is exactly equal to the line AE.

To make an obfervation by this inftrument, it being previoufly properly adjufted, the eye is to be applied at the fight in the fpeculum E, and the face turned towards the object; when the object being received on the fpeculum A, is reflected into that at C, and again into that at E, and that at 3 on the index; the index being then moved till the reflected object in the fpeculum at 3 exactly coincides with the real object in the tranfparent part of the glafs, the divifions on the arch D 3, fubdivided by the micrometer, will determine the angle DE 3 = the angle AOE; from which the diftance O may be determined as before.

DENOMINATOR of a Ratio is the quotient arifing from the divifion of the antecedent by the confequent. Thus, 6 is the denominator of the ratio 30 to 5, becaufe 30 divided by 5 gives 6. It is otherwife called the *exponent* of the ratio.

DEPRESSION of a Star, or *of the Sun*, is its diftance below the horizon; and is meafured by an arc of a vertical circle, intercepted between the horizon and the place of the ftar.

Depression of the Vifible Horizon, or *Dip of the Horizon*, denotes its finking or dipping below the true horizontal plane, by the obferver's eye being raifed above the furface of the fea; in confequence of which, the obferved altitude of an odject is by fo much too great.

DEROOBUST, in Bengal, Entire; as an entire diftrict, oppofed to Kismut, which fee.

DESAULT (Peter Jofeph), furgeon in chief to the Hofpital of Humanity, formerly the *Hotel-Dieu* at Paris, was born on the 6th of February 1744 at Magny Vernois, a village in the neighbourhood of Lure, in the department of Haute Saone (formerly the province of *Franche Comté)*. His father and mother were in that fituation of life which is removed from want, and yet does not difpenfe with labour; he himfelf was the youngeft child of a numerous family.

At Lure, under the direction of a private inftructor, he was taught the firft rudiments of the Latin tongue; his parents afterwards confided him to the care of the Jefuits, then almoft exclufively entrufted with the education of youth in the public fchools. This celebrated fociety, prompt in difcovering, as expert at developing, and adroit in appropriating talents, foon diftinguifhed the young ftudent from the crowd; and he, in his turn, was not difpleafed with the life he led in one of their feminaries.

On the completion of his ftudies, his father, who had deftined him for the church, intimated a wifh that he fhould apply himfelf to theology; but his genius had taken a different direction, and he was averfe to the profeffion of an ecclefiaftic: in fhort, young Default declared that he was determined to betake himfelf to the ftudy of the healing art; and, after a long and ineffectual refiftance on the part of his family, he was fent to Béfort, in order to ferve an *apprenticefhip*, as it was then termed, in the military hofpital of that place. He accordingly fpent three years there; during which he acquired fome knowledge of anatomy, attended to the dreffing of the patients, and endeavoured to fupply, by his own obfervations, what was wanting in his inftruction.

Iu the midft of thefe profeffional labours, his mind frequently rambled towards another fcience but little connected with furgery: this was mathematics, the elements of which he had acquired among the Jefuits. His progrefs in this favourite ftudy was rapid; but he fell into one of the many errors fo common among the phyficians of that day; this confifted in a falfe application of the rules of geometry to the laws of the animal economy.

He not only perufed with avidity the treatife of Borelli *De Motu Animalium*, but actually tranflated the whole of it, and even added a commentary, ftill more abundant in calculation than that of the celebrated profeffor of Naples.

His fuccefs in a branch of phyfiology fo much cultivated at that time, attracted the attention of one of his fuperiors, a zealous partizan of the doctrine of the mechanicians, who wifhed to attach him to his perfon; but his defire of fame required a more extenfive theatre, and his love of ftudy made him folicitous of better means of inftruction. Paris prefented both thefe advantages; and he accordingly repaired thither in 1764, at the age of nineteen, in fearch of them.

Surgery at that period flourifhed in the capital under the aufpices of a Lafaye, a Morand, an Andouillet, and a Louis. The fight of fuch great mafters excited the genius of thofe who afpired to emulate them: young Default deemed himfelf worthy of equalling men whom other ftudents were content with only admiring. Animated by this fentiment, he entirely refigned himfelf to his ardour; anatomy became the fpecial object of his labours, and his diffections were not confined to the human body, for he inveftigated, by means of his knife, a prodigious number of animals of all kinds: at firft, from a difficulty of procuring human fubjects, and afterwards on account of the advantages which he experienced from this general method. In order to become intimately acquainted with our own organization, it is neceffary to compare it with whatever has a refemblance to it in other bodies.

He accordingly fpent the greater part of the day in the amphitheatres. The hours ftolen from his favourite labours were employed in attending the hofpitals; he was the firft at the bed of the patient where an operation was to be performed, and was fure to be prefent at the dreffings, on purpofe to examine the refult. The infirmities of mankind, fterile in refpect to the vulgar, ferved him as the beft treatife for curing them; and the great furgeons of all nations have formed their mode of practice by contemplating the fame book.

But

Default. But he reckoned too much on a robust and vigorous temperament; for, after two years close and assiduous application, he fell into a cachectical habit of body, which had nearly proved mortal, and which confined him for almost twelve months to his bed; but at length, owing partly to the vigour of his youth, and partly to the attention of his young friend Chopart, his inseparable companion in his operations, who attended him also during his last illness, and only survived him a few days, he was so fortunate as to recover.

Restored to life, he forgot that an excess of attention had conducted him to the very gates of death; a new career opened to his view, and required new efforts on his part. In the winter of 1766 he commenced a course of anatomy, and soon reckoned 300 pupils, most of them older than himself, who were attracted by the clearness of his demonstrations, the methodical arrangement of his descriptions, and, above all, by his indefatigable zeal in the science of instruction.

His success inspired the privileged professors, whose schools became deserted, with jealousy and revenge; they employed the authority of the corporation against him, and would have nipped his efforts in the bud, had it not been for the protection of Louis and Lamartiniere, who were zealous of protecting a youth of talents, whose sole reproach was, that he had not wealth enough to purchase certain franchises. After all, had it not been for the permission he obtained of borrowing the name of a celebrated physician, he must have actually desisted from his lectures.

Default's reputation now began to be buzzed about, and a multitude of patients claimed his assistance; but he constantly refused to practise until he should be placed at the head of some great establishment.

At length, at the repeated solicitations of his friends, he presented himself as a candidate to the corporation of surgeons; and they, much to their honour, admitted him in 1776, on condition of paying the usual fees when convenient. The following is the title of his thesis: "*De calculo vesicæ urinariæ, eoque extrahendo, præviâ sectione, ope instrumenti Haukensiani emendati.*"

His public lectures were accompanied with as much celebrity as his private ones. Brilliant discoveries were not the object of his anatomical labours, which were always connected with the art of healing: he was, however, the first man in France who taught surgical anatomy.

After becoming first a simple member, and then a counsellor, of the perpetual committee of the academy of surgery, he was appointed chief surgeon to the hospital of the college, and consulting surgeon to that of St Sulpice: neither of these added any thing to his fortune, but they gave him a clear insight into practice, and enabled him to judge of cases by the inductions arising from his own experience.

In 1779 he invented the bandage now in use for fractures; by means of which, the fragments being kept in a state of perpetual contact, become consolidated, without the least appearance of deformity, an almost inevitable consequence of the former mode.

On his appointment to the place of surgeon major to the hospital *de la Charité*, in 1782, he introduced a new method of treatment in oblique fractures of the thigh-bone; and he also healed, by means of a methodical compression, those various ulcers whose cure had hitherto been attended with great difficulty. In addition to this, he substituted new bandages in fractures of the humerus and clavicle, and adopted a new mode of treating the hare-lip, superior to that used by Louis. He never recurred to amputation but in extreme cases, when there was a certainty that dissolution would have followed a neglect of the operation.

When a premature death carried off Ferrand, chief surgeon of the *Hotel Dieu* in Paris, Default was considered as the most proper person to succeed him; and, on the demise of Moreau, the whole charge of the hospital devolved on him. After three years of solicitations and disputes, he at length in 1788 proceeded in his long projected scheme of establishing a clinical school; and a spacious amphitheatre was accordingly erected for that purpose. Scarcely had his first (A) course commenced, when the number of pupils who flocked around him was really astonishing. Foreigners repaired from all parts, and several of the neighbouring states sent students to Paris, expressly for the purpose of assisting at his demonstrations. More than 600 auditors constantly attended, in order to learn a new system, consisting of a simple mode of treatment, disengaged from ancient prejudices, and a complex incoherent practice.

A few of his improvements are here specified.

1. The method of ligature employed by the ancients in the cure of umbilical hernias of children, having been generally omitted in the practice of the moderns, he again introduced and perfected this mode, and demonstrated, by his success, its superiority over compressive bandages.

2. He was one of the first men in France to extract the loose cartilages *(cartilages flottans)* in joints.

3. He employed a new treatment, that of a methodical compression, in respect to schirrosities of the rectum; in order to which he introduced a candle or bougie, the size of whice he gradually augmented.

4. He simplified, and rendered more commodious, the reduction of luxations of the humerus.

5. Fatal experience having pointed out the danger of employing the trepan in wounds of the head, he substituted another method of treatment *(l'usage de l'émétique)* now adopted by many practitioners.

6. He made several very useful improvements on chirurgical instruments; such as those employed in the cases

(A) The business of the day was conducted in the following routine: 1. A public consultation concerning the indigent out-patients. 2. The young practitioners belonging to the hospital read a detailed account of all the interesting cases of such patients as were to be discharged that day. 3. The operations: each of these was preceded by a dissertation on the state of the patient, who was then carried to the amphitheatre, where Default, attended by his assistants, performed the operation in presence of all the pupils. 4. Argumentative details, by the professor, either on the dangerous maladies existing in the hospital, or on the situation of the patients on whom operations had been performed during the preceding day. 5. The dissection of subjects. And, 6. A lecture on some particular branch of pathology.

cases of polypus in the womb and nostrils *(la pince à gaîne et des porte-nœuds pour la ligature des polypes*, &c. ;) for cutting through obstructions in the different cavities (*le kiotome*) ; and for the *fistula in ano*. In cases of incision he introduced the use of the instrument (*le gorgeret*) invented by Marchetti, well known among foreigners, but almost totally neglected in France before this period.

He at the same time retrenched the use of a great number of superfluous ones, and banished all practices attended with greater pain than utility. Avoiding every thing that was complex, he proved that the art of healing, in imitation of nature, ought to be simple in its means, and fruitful in its resources.

In 1791 he published his *Journal de Chirurgerie*, which was edited by his pupils, and destined to describe the most interesting occurrences in his school, and also extracts from his lectures, which were then dedicated to the investigation of the maladies incident to the urinary passages. The treatment of these diseases, hitherto the reproach of practitioners, had been much improved by the assistance of the artist Bernard. The elastic probes (*les sandes élastiques*), on their first appearance, fixed the attention of all professional men ; but none knew better than Default how to appretiate their advantages. By means of them, he introduced a novel mode of cure in contractions of the urethra, which saved a great number of lives every year in the *Hotel-Dieu*. But he did not confine their use to the diseases of the urethra alone, for he employed them to remove the divers obstacles that impede deglutition or respiration.

In the midst of such a multiplicity of labours, and although he was obliged to attend 400 sick twice a-day, Default nevertheless employed more than four hours of his time in visiting private patients.

Few surgeons ever enjoyed such an exclusive share of public confidence ; few ever possessed similar means of enriching themselves ; and yet he neglected for a long time to take advantage of this. Had he been less ardent for glory, he would have been more favoured by fortune ; but he sacrificed all interested views to the noble ambition of advancing his art. His clinical and anatomical courses were gratuitously opened by him to the world after the year 1790 ; and while the public schools languished in the midst of troubles, inseparable perhaps from a mighty revolution, he was forming the greater part of those surgeons employed at this present moment in the numerous armies of the republic. Considered under this point of view alone, the services which he rendered to humanity are incalculable : too happy if persecution had not been his sole reward !

While out of mere attachment to the public weal, he added to his various functions that of a member of the council of health, conferred on him in 1792 by the minister Servan, he was denounced in the popular societies as an *egotist*, an *indifferent*, &c. and became one of the first victims of that proscription which, under Robespierre, extended to nearly every man of talents.

Chaumette accused him to the sections as having neglected the brave men wounded on the 10th of August, while they themselves were lavishing their blessings at the *Hotel-Dieu* on their faviour. Twice was he brought to the bar of a commune ; desirous of discovering a pretext for persecution, the clamours of the people were unremittingly excited against him. He was at length carried away from his amphitheatre, while in the very act of haranguing his pupils ; and, in consequence of a *mandat d'arr t* from the revolutionary committee, conducted by a body of armed men to the Luxembourg. From this horrid prison few ever departed but to meet their fate ; luckily, however, his name was not yet entered on that bloody list, in which those of Malesherbes and Lavoisier were inserted. On the contrary, at the end of three days he was liberated, and instantly resumed all his functions.

On the establishment of *L'Ecolede Santé*, Default was appointed clinical professor ; and for external maladies he soon after obtained from the government the conversion of the *Eveché* into an hospital for surgical operations.

In the midst of these plans, the troubles that occurred in the month of May unfortunately affected his mind, and made him dread lest the days of proscription should return. It was in vain that his friends attempted to soothe his sufferings ; for on the night of the 29th of May, a malignant fever made its appearance, and a nearly continual delirium ensued until his death, which occurred on the 1st of June 1795, on which day he breathed his last, in the arms of his pupils, at the age of 51.

The populace were persuaded that he was poisoned. This ridiculous opinion originated in consequence of the epoch of his death, which preceded but a short time that of the son of Louis XVI. whom he had visited during his illness in the prison of the Temple. It is pretended that he fell a victim to his constant refusal to yield to the criminal views entertained against the life of that child.

Default was of a middling stature. He was well proportioned, and possessed an open countenance. His temperament, naturally robust, had been fortified by his early education, and was never sapped by an excess of pleasures, for to them his heart was always indifferent. His ruling passion was the love of glory ; his favourite pursuit, the practice and advancement of his art. He was warm, nay sometimes violent ; and his scholars were not always inclined to praise the sweetness of his temper. On the other hand, his mind was noble, elevated, and great, even to excess.

The French republic, eager to pay homage to his memory, has presented his widow with a pension of 2000 livres *per annum*. A son, Alexis Mathias Default, was the sole fruit of his marriage ; and he has left but one work behind him, in which the name of his friend Chopart is joined with his own. It is entitled *Traité des Maladies Chirurgicales et des Operations qui leur conviennent*, 2 vols 8vo.

DETERMINATE PROBLEM, is that which has but one solution, or a certain limited number of solutions ; in contradistinction to an indeterminate problem, which admits of infinite solutions.

Determinate Section, the name of a tract or general problem, written by the ancient geometrician Apollonius. None of this work has come down to us, excepting some extracts and an account of it by Pappus, in the Preface to the 7th book of his Mathematical Collections. He there says that the general problem was, "To cut an infinite right line in one point so, that, of the segments contained between the point of section

section fought, and given points in the said line, either the square on one of them, or the rectangle contained by two of them, may have a given ratio, either to the rectangle contained by one of them and a given line, or to the rectangle contained by two of them."

DETONATION (see that word *Encycl.*). The astonishing violence with which the oxy-muriat of potass, when mixed with various substances, detonates, has been already noticed in this Supplement under the article CHEMISTRY, nº 722, where the theory of these explosions is likewise given. But as several chemists seem to think that this salt, which decrepitates by friction, and spontaneously takes fire when mixed with sulphur, contains in itself the elements and phenomena of thunder, it will not probably be unacceptable to our readers to find, in this place, a distinct account of the various mixtures which produce its detonations. The following are the principal which have been discovered by Fourcroy and Vauquelin.

1. Three parts of the oxy-muriat of potass, and one part of powdered sulphur, rubbed together in a metal mortar, produce numerous successive explosions, resembling the smacking of a whip, or even as loud as the report of a pistol or a musket, according to the rapidity of the motion, and the force of the pressure made use of. A few grains of the same mixture, by being struck smartly upon an anvil with a hammer, occasion a report equal to that of a musket; and torrents of purplish light are seen about the anvil. If this mixture be thrown into concentrated sulphuric acid, it instantly takes fire, and burns, without noise, with a flame of a dazzling whiteness.

2. A mixture of three parts of this salt, half a part of sulphur, and half a part of charcoal, causes stronger explosions than the preceding when rubbed in a mortar, and a louder noise when struck upon an anvil. Its flame also, when the mixture is made to explode, or when it is thrown into sulphuric acid, is more rapid, more lively, and of a redder colour, than that of the preceding.

3. A mixture of equal parts of oxy-muriat of potass and antimony in powder explodes with noise by percussion; but produces only reddish sparks when thrown into sulphuric acid. If zinc be substituted in the place of antimony, a similar explosion takes place, accompanied with a white flame. Sulphuric acid has no effect upon this last mixture.

4. With regulus of arsenic, this salt explodes very violently by the stroke of a hammer; it inflames, with singular rapidity and brilliancy, by the contact of sulphuric acid. In this last experiment there arises a smoke, which in the air takes the form of a crown, in the same manner as phosphorated hydrogenous gas does when it inflames spontaneously in a still atmosphere.

5. Sulphuret of iron or martial pyrites inflames rapidly, but without noise, when rubbed in a metal mortar with oxy-muriat of potass. This mixture, when struck upon an anvil, explodes violently, and with a red flame.

6. The red sulphuret of mercury or cinnabar, and the sulphurated calces of antimony, explode with the oxy-muriat of potass by percussion, but they do not inflame by sulphuric acid. The same thing happens when charcoal alone is mixed with this salt.

Any of the following substances, namely, sugar, gums, oils (both fixed and volatile), alcohol, ether, when mixed with oxy-muriat of potass, have the property of exploding very violently by the stroke of a hammer, and all of them send forth a brisk flame at the time of their explosion. The liquid combustible substances above mentioned are to be mixed with the salt in such a manner as to form a kind of paste. None of these mixtures explode or inflame by being rubbed in a mortar; but some of them inflame by being mixed with concentrated sulphuric acid, their combustion being slow and progressive.

8. All the substances above mentioned, which, being mixed with the oxy-muriat of potass, take fire and burn instantly, and with considerable noise, by the quick pressure of the strokes of a hammer, produce a much stronger explosion when they are so closely wrapped up in paper, two or three times doubled, as to be thereby compressed before they are struck.

9. An electric shock from a battery of large surface, charged by a strong electric machine, causes all the forementioned mixtures to explode in the same manner as percussion, and their explosion is also accompanied by a bright light.

To the above mentioned facts, the authors add, that it was already well known that gunpowder would explode by a violent blow, or very strong pressure; but they observe, that the stroke which is necessary for that purpose must be much stronger than that which suffices to produce an explosion in the above-mentioned mixtures of combustible substances with the oxy-muriat of potass; and that its explosion is by no means so remarkable as that which is produced by the help of this new salt.

DEWAN, under the Mogul government, the receiver general and civic governor of a province: in private life a steward.

DEWANNY, the revenue department of a province.

DIABETES MELLITUS (see MEDICINE, nº 318, &c. *Encycl.*), is so formidable a disease, though not very frequent, that it would be unpardonable in us not to mention every method of treating it successfully which has come to our knowledge. Since our article MEDICINE was published, Dr Rollo, surgeon general to the royal artillery, has suggested a method of treating this disease, which in various instances has been crowned with success.

The Doctor supposes, that in this complaint the vegetable matter taken into the stomach has not, from some defect in this organ, undergone a sufficient change to form proper chyle; that in consequence of this, much saccharine matter is evolved, which, when carried into the circulation, proves a general stimulus, producing head-aches and quickness of pulse, but that it acts more remarkably on the kidneys, occasioning a constant and copious secretion of sweet urine. From this hypothesis, he was naturally led to adopt a plan of cure, which has proved completely successful. The indications he lays down are: 1. To prevent the formation of saccharine matter in the stomach; and, 2. To remove the morbidly increased action of this organ, and restore it to a healthful condition. These indications are to be answered by a complete diet of animal food, and by the use of such medicines as shall diminish the action of the stomach, Diamond, Diderot. stomach, and at the same time counteract the formation of saccharine matter. The remedies employed for this purpose have been emetics, kali sulphuratum, lime-water, hepatized ammonia, and vegetable narcotics. But the principal dependence is to be placed on a total abstinence from all vegetable matter, which alone can supply the saccharine principle. By a regular perseverance in this plan, the first of two patients was completely cured in four weeks, although the disease had been of seven months continuance. The urine, which at the commencement of the treatment was sweet, and amounted to 24 pints daily, was at last reduced to $1\frac{1}{2}$ pint, being at the same time free from any saccharine impregnation. The second patient, from his age and other circumstances, although relieved from the diabetic affection, did not regain his wonted state of health; but even in this case, the effects produced by the treatment, when properly attended to, were most decidedly in confirmation of this plan of cure.

The Doctor has received several communications in consequence of the dispersion of the printed notes on the first case. The most important are the result of two cases treated in this way by Dr Cleghorn of Glasgow, and one by Drs Currie and Gerard at Liverpool; all of which afford the strongest corroboration of the efficacy of this mode of treatment.

DIAMOND, the most precious of all the gems; for the nature of which see CHEMISTRY, n° 33, &c. in this *Supplement*.

DIDEROT (Dionysius) of the academy of Berlin, the son of a cutler, was born at Langres in 1713. The Jesuits, with whom he went through a course of study, were desirous of having him in their order; and one of his uncles, designing him for a canonry which he had in his gift, prevailed upon him to take the tonsure.

His father seems to have known him better; for perceiving that he was not inclined to be a Jesuit, nor fit to be a canon, he sent him to Paris to prosecute the study of the law. To the law, however, he paid very little attention, but devoted his time to science and general literature; which so offended his father, that he stopped the remittance of his pecuniary allowance, and seemed for some time to have abandoned him.

The talents of young Diderot supplied him with a maintenance, and drew him from obscurity. According to his friends, his capacious mind embraced physics, geometry, metaphysics, ethics, and the belles lettres, from the time that he began to read with reflection; and it is certain that he aspired at being a master in all these departments of literature. His bold and elevated imagination seemed to give him likewise a turn for poetry; but he neglected it for the sciences. He settled at an early period at Paris, where the natural eloquence which animated his conversation procured him friends and patrons. What first drew the attention of the public to him as an author, and gave him a high reputation among a certain class of readers, was a small volume written against the Christian religion, and intitled *Pensées Philosophiques*; which was reprinted afterwards under the title of *Etrennes aux Esprits-forts*.

This book appeared in 1746, 12mo. The adepts of the new philosophy compared it, for perspicuity, elegance, and force of diction, to the *Pensées de Pascal*. But the aim of the two authors was widely different; Pascal employed his talents and his erudition, which was profound and various, to support and illustrate the great truths of our holy religion, which Diderot attacked by all the disingenuous arts of an unprincipled sophist. The *Pensées Philosophiques*, however, became popular. It contributed to promote the object of that conspiracy which had been for some time formed against every thing which ennobles human nature (See JACOBINS in this *Supplement*). It was therefore applauded by Voltaire and D'Alembert, and read, of course, by every man and woman of taste in Paris.

Diderot. Our author was more usefully employed in 1746, when, together with Messrs *Eidous* and *Toussant*, he published a general Dictionary of Medicine, in six volumes folio. This work, it must be confessed, has considerable merit; for though there are in it several articles superficial and erroneous, there are many others of such deep and accurate disquisition, as deservedly recommended it to men of science.

It was about this time that an intimacy was formed between Diderot and D'Alembert, and that, under the direction of Voltaire, they formed the idea of a *Dictionnaire Encyclopedique*. The great objects which they had in view when they entered upon this work are now universally known. D'Alembert was a profound mathematician, Diderot had considerable knowledge in the physical sciences, more especially mechanical philosophy, and Voltaire was a master of the belles lettres.

It is not to be supposed that such men would publish any thing very defective in these departments of science; but an *Encyclopædia* must treat of *religion*; and to every kind of religion they were all sworn enemies. They engaged, however, a very worthy, though not very acute, clergyman, to furnish the theological articles; and for other branches of knowledge, they were promised the assistance of several men of letters, and of a variety of artists.

Diderot took upon himself the description of arts and trades; one of the most important departments of the work, and the most acceptable to the public. To the particulars of the several processes of the workmen he sometimes added reflections, speculations, and principles, adapted to the elucidation. But besides his own department, he furnished articles on almost every other subject.

By those who knew not the great aim of the undertakers of this work, it has been regretted that Diderot was not less verbose, less of the dissertator, and less inclined to digressions. He has also been censured for employing needlessly a scientific language, and for having recourse to metaphysical doctrines, frequently unintelligible, which occasioned him to be called *the Lycophron of philosophy*; for having introduced a number of definitions incapable of enlightening the ignorant, and which the philosopher seems to have invented for no other purpose than to have it thought that he had great conceptions; while, in fact, he had not the art of expressing perspicuously and simply the ideas of others. But these complaints arise from mistaking entirely the purpose for which he wrote.

It has been completely proved, that one great object for which the philosophers, as they called themselves, undertook the compilation of the *Encyclopedie* was to sap the foundation of all religion. This was to be attempted, not directly and avowedly; for bare-faced atheism would not then have been suffered in France.

A

Diderot. A cloak, therefore, was to be worn, and the poiſoned dagger to be concealed under it. Whilſt the well-meaning divine was ſupporting, by the beſt arguments which he could deviſe, the religion of his country, Diderot and D'Alembert were overturning thoſe arguments under titles which properly allowed of no ſuch diſquiſitions. This neceſſarily produced digreſſions; for the greateſt genius on earth could not, when writing on the laws of motion, attack the myſteries of Chriſtianity without wandering from his ſubject; but that the object of theſe digreſſions might not paſs unnoticed by *any* claſs of readers, care was taken to refer to them from the articles where the queſtion was diſcuſſed by the divine. That when employed in this way, Diderot ſeems to write obſcurely, is indeed true; but the obſcurity is not his. His atheiſm was ſo plain, that for the moſt part D'Alembert, or ſome other leader of the gang, had to retouch his articles, and throw a miſt over them, to render their intention the leſs obvious.

Even with all this care and ſtudied obſcurity, the deſign of the *Encyclopedie* was too palpable not to be ſeen, and too wicked not to give offence. Certain wild poſitions on government and on religion occaſioned the impreſſion to be ſuſpended in 1752. At that time there were no more than two volumes of the dictionary publiſhed; and the prohibition of the ſucceeding ones was only taken off at the end of 1753. Five new volumes then ſucceſſively appeared. But in 1757 a new ſtorm aroſe, and the book was ſuppreſſed. The remainder did not appear till about ten years after; and was then for a while only privately diſtributed; ſome copies having been ſeized by government, and the printers ſhut up in the Baſtile. The merit, however, of ſome of the articles is confeſſedly great; and the firſt edition was quickly ſold off.

Thus was this great work in the preſs from 1751 to 1767; during which period, Diderot and D'Alembert were accuſtomed to frequent the coffee-houſes of Paris, and to enter with keenneſs into religious diſputes: the former attacking Chriſtianity; and the latter, under the maſk of piety, defending it; but always yielding to the arguments of his opponent. This practice was put a ſtop to by the police; and Diderot, when reproached by the lieutenant with preaching atheiſm, replied, "Cela eſt vrai, je ſuis athée, & m'en fais gloire."

Finding his impious converſations interrupted, and the publication of the *Encyclopedie* rendered tedious by the vigilance of government, he thought of propagating his notions by other vehicles. Alternately ſerious and ſportive, ſolid and frivolous, he publiſhed, at the very time he was working on the Dictionary of Sciences, ſeveral productions, which could ſcarcely have been expected from a man ſo completely employed. His *Bijoux Indiſcrets*, 2 vols 12mo, are of this number—a diſguſting work, even to thoſe young people who are unhappily too eager for following after licentious romances. Even here a certain philoſophical pedantry appears in the very paſſages where it is moſt miſplaced, and never is the author more aukward than where he intends to diſplay a graceful eaſe.

The *Fils Naturel*, and the *Pere de Famille*, two comedies in proſe, which appeared in 1757 and 1758, are not of the ſame kind with the *Bijoux Indiſcrets*. They are moral and affecting dramas, where we ſee at once a nervous ſtyle and pathetic ſentiments. The former piece is a picture of the trials of virtue, a conflict between interests and paſſions, wherein love and friendſhip play important parts. It has been ſaid that Diderot borrowed it from Goldoni: but if that be the caſe, the copy does honour to the original; and, with the exception of a ſmall number of ſcenes, where the author mixes his philoſophical jargon with the ſentiments of the heart, and ſome ſentences out of place, the ſtyle is affecting and natural enough. In the ſecond comedy, a tender, virtuous, and humane father appears, whoſe tranquillity is diſturbed by the parental ſolicitudes, inſpired by the lively and impetuous paſſions of his children. This philoſophical, moral, and almoſt tragical comedy, has produced conſiderable effects on ſeveral theatres of Europe. The dedication, to the princeſs of Naſſau Saarbuck, is a little moral tract of a ſingular turn, without deviating from nature. This piece, written with a true dignity of ſtyle, proves that the author poſſeſſed a great fund of moral ſentiments and philoſophical ideas. At the end of theſe two pieces, publiſhed together under the title of *Theatre de M. Diderot*, are dialogues, containing profound reflections and novel views of the dramatic art. In his plays he has endeavoured to unite the characters of Ariſtophanes and Plato; and in his reflections he ſometimes diſplays the genius of Ariſtotle.

This ſpirit of criticiſm is exhibited, but with too much licence, in two other works, which made a great noiſe. The former appeared in 1749, 12mo, intitled *Letters on the Blind for the Uſe of thoſe who See*. The free notions of the author in this work coſt him his liberty. He underwent a ſix months impriſonment at Viorcennes. Having naturally ſtrong paſſions and a haughty ſpirit, and finding himſelf on a ſudden deprived of liberty and of all intercourſe with human beings, he was threatened with the loſs of his reaſon. The danger was great; and to prevent it, they were obliged to allow him to leave his room, to take frequent walks, and to receive the viſits of a few literary men; among whom J. J. Rouſſeau, at that time his friend, went and adminiſtered conſolation to him, which he ought not to have forgotten.

The letter on the Blind was followed by another *On the Deaf and Dumb, for the Uſe of thoſe who can Hear and Speak*; 1751; 2 vols, 12mo. Under this title the author delivered reflections on metaphyſics, on poetry, on eloquence, on muſic, &c. In this eſſay there are ſome good things, among others abſurd and imperfect. Though he ſtrives to be perſpicuous, yet he is not always underſtood; and this is more his fault than that of his readers. Of what he has compoſed on abſtract ſubjects, it has been ſaid that it is a chaos on which the light ſhines only at intervals. The other productions of Diderot betray the ſame defect of clearneſs and preciſion, and the ſame uncouth emphaſis, for which he has always been blamed.

The principal of them are, 1. Principles of Moral Philoſophy, 1745, 12mo; of which the Abbé de Fontaine ſpeaks well, though it met with no great ſucceſs. It was our philoſopher's fate to write a great deal, and not to leave a good book, or at leaſt a book well compoſed. 2. Hiſtory of Greece, tranſlated from the Engliſh of Stanyan, 3 vols, 12mo; an indifferent tranſlation of an indifferent book 3. Pieces on ſeveral Mathematical Subjects, 1748, 8vo. 4. Reflections on the Inter-

Diderot. Interpretation of Nature, 1754, 12mo. This interpreter is very obfcure. 5. The Code of Nature, 1755, 12mo; which is certainly not the code of Chriftianity. 6. The Sixth Senfe, 1752, 12mo. 7. Of Public Education; one of that fwarm of publications produced by the appearance of Emelius, and the abolition of the Jefuits. Though all the ideas of this author could not be adopted, yet fome of them are very judicious, and would be highly ufeful in the execution. 8. Panegyric on Richardfon. Full of nerve and animation. 9. Life of Seneca. This is the laft work which he acknowledged; and it is one of thofe by Diderot that is perufed with moft pleafure, even in rectifying the judgments he paffes on Seneca and other celebrated men. The Abbé Barruel fays, that he was the anthor of *Syfteme de la Nature*, which is ufually given to Robinet; and it is certain, that if he was not the author, he furnifhed hints, and revifed the whole. Yet the junto of atheifts were themfelves afhamed of the firft edition of that work; and after all Diderot's care to improve it, the fubfequent editions are, notwithftanding his boafted knowledge of the laws of nature, contemptible in the eyes of a real mechanical philofopher.

When a new edition of the *Encyclopedie* was refolved on, Diderot, the editor of the former edition, thus addreffes the bookfellers who had undertaken to republifh it. "The imperfections (fays he) of this work originated in a great variety of caufes. We had not time to be very fcrupulous in the choice of our coadjutors. Among fome excellent perfons, there were others weak, indifferent, and altogether bad. Hence that motley appearance of the work, where we fee the rude attempt of the fchool-boy by the fide of a piece from the hand of a mafter; a piece of nonfenfe next neighbour to a fublime performance. Some working for no pay, foon loft their firft fervour; others, badly recompenfed, ferved us accordingly. The *Encyclopedie* was a gulf into which all kinds of fcribblers promifcuoufly threw their contributions; their pieces ill conceived, and worfe digefted, good, bad, contemptible, true, falfe, uncertain, and always incoherent and unequal; the reference that belonged to the very parts affigned to a perfon, never filled up by him. A refutation is often found where we fhould naturally expect a proof. There was no exact correfpondence between the text and the plates. To remedy this defect, recourfe was had to long explications. But how many unintelligible machines, for want of letters to denote the plates!" To this confeffion Diderot added particular details on various parts; fuch as proved that there were in the *Encyclopedie* fubjects to be not only retouched, but to be compofed afrefh: and this was what a new company of literati and artifts fet themfelves to work upon in the *Encyclopedie Methodique*.

This immenfe work is not yet completed; and therefore we cannot fpeak of it as a whole; but it is furely not lefs verbofe than the former edition, nor do the aims of its editors appear to be purer. That it contains much valuable information in chemiftry, and indeed in every department of phyfical fcience, no candid man will controvert: but its articles on abftract philofophy are prolix and obfcure; and it betrays the fame impiety, the fame eager defire to corrupt the principles of the rifing generation, and the fame contempt for every thing which can make mankind happy here or hereafter, with the former edition.

Notwithftanding his numerous publications, Diderot was never rich. Soon after the publication of the laft volumes of the *Encyclopedie*, upon which he had been employed for upwards of twenty years, his circumftances were fo ftraitened, that an expedient was to be devifed for their improvement. He had long correfponded with the late Emprefs of Ruffia, whom he perfuaded to confider him as the greateft, or *one* of the greateft economifts of France. In the courfe of the correfpondence he had mentioned his own library as one of the moft valuable in Europe; and when Catharine wanted to purchafe it and make him librarian, he faid that his conftitution could not fupport the cold climate of St Peterfburgh. She offered to let him keep it during his lifetime in Paris; and the library was fold for an immenfe price. When her ambaffador wanted to fee it, after a year or two's payments, and the vifitation could be no longer put off, Diderot was obliged to run in a hurry through all the bookfellers fhops in Germany to fill his empty fhelves with old volumes. He had the good fortune to fave appearances; but the trick took air, becaufe he had been niggardly in his attention to the ambaffador's fecretary. This, however, did not hinder him from vifiting his imperial pupil, to whom he told a poor ftory, in hopes of getting his daughter married with parade, and patronifed by her majefty; but it was feen through, and he was difappointed.

In the year 1784 Diderot's health began vifibly to decline; and one of his domeftics, perceiving that his death was at no great diftance, acquainted him with his apprehenfions, and addreffed him on the importance of preparing for another world. He heard the man with attention, thanked him kindly, acknowledged that his fituation required ferioufnefs, and promifed to weigh well what he had faid. Some time after this converfation he defired that a prieft might be brought; and the fame domeftic introduced to him M. de Farfac, Curé de St Sulpice. Diderot faw this ecclefiaftic feveral times, and was preparing to make a public recantation of his errors. Condorcet and the other adepts now crowded about him, perfuaded him that he was cheated, that his cafe was not fo dangerous as it was faid to be, and that he only wanted the country air to reftore him to health. For fome time he refifted their attempts to bring him back to atheifm, but was at laft prevailed upon to try the effect of the country air. His departure was kept fecret, and he was concealed in the country till the 2d of July, when he died. His dead body was fecretly brought back to Paris, and a report was fpread and believed that he died fuddenly on rifing from the table, without remorfe, and with his atheifm unfhaken.

To draw a formal character of this wretch is furely fuperfluous. His friends extol his franknefs, his difintereftednefs, and his integrity; but except his grofs avowal of atheifm, which may in France be called franknefs, this character is belied by every tranfaction of his life. He married, and had a daughter, as has been already mentioned. M. Bauzé, referred to by Abbé Barruel, coming one day into Diderot's houfe, found him explaining to this daughter a chapter of the gofpel. When he expreffed fome furprife at this conduct, Diderot faid: "J'entends ce que vous voulez dire; mais

Differential Method.

mais au fond, quelles meilleures leçons pourrois-je lui donner, ou trouverai-je mieux?" It was a common assertion of Diderot's, that between him and his dog "il n'y avoit de difference que habit." In uttering this sentiment, he resembled not Pope's Indian with untutored mind,

"Who thinks, admitted to that equal sky,
"His faithful dog shall bear him company."

The Indian hopes to carry his dog with him to heaven; but Diderot hoped to die like a dog, and to be as if he had never been.

DIFFERENTIAL METHOD, is the art of working with the differences of quantities. By this method any term of a series may be found from the several orders of differences being given; or *vice versa*, any difference may be found from having the terms of the series given: it likewise shews how to find the sum of such a series. And it gives rules to find by interpolation any intermediate term, which is not expressed in the series, by having its place or position given.

When any series of quantities is proposed, take the first term from the second, the second from the third, the third from the fourth, &c. then all these remainders make a new series, called the *first order of differences*. In this new series take the first term from the second, the second from the third, the third from the fourth, &c. as before; and these remainders make another series, called the *second order of differences*. In like manner, in this series, take the first term from the second, the second from the third, &c.; and these will make a series called the *third order of differences*; and after this manner you may proceed as far as you will. Thus in the following proposition A, b, c, d, e, &c. is the series; B, B^2, B^3, B^4, &c. the first order of differences; C, C^2, C^3, &c. the second order of differences; D, D^2, &c. the third order; E, &c. the fourth order, and so on. But the first terms of these several orders of differences, as B, C, D, E, &c. are those that are principally made use of in calculations by this method.

PROP. I. If there be any series, A, b, c, d, e, &c. and if there be taken the first differences B, B^2, B^3, &c. the second differences C, C^2, C^3, &c. the third differences D, D^2, D^3, &c. and so on.

Then if T stand for the first term of the nth differences, $\pm T = A - nb + n \times \frac{n-1}{2} c - n \times \frac{n-1}{2} \times \frac{n-2}{3} d + n \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4} e -$ &c. that is, $+T$, when n is even, and $-T$ when n is odd.

The several orders of differences being taken as before directed, will stand thus. Then,

A				
	B			
b		C		
	B^2		D	
		C^2		E
c	B^3		D^2	
		C^3		
d	B^4	&c.		
e				

series	A,	b,	c,	d,	e,	&c.
1st diff.	$b-A$,	$c-b$,	$d-c$,	$e-d$,	&c.	
2d diff.	$c-2b+A$,	$d-2c+b$,	$e-2d+c$,	&c.		
3d diff.	$d-3c+3b-A$,	$e-3d+3c-b$,	&c.			
4th diff.	$e-4d+6c-4b+A$,	&c.				

That is, $B = b - A$, $C = c - 2b + A$, $D = d - 3c + 3b - A$, $E = e - 4d + 6c - 4b + A$, &c. or $-B = A - b$, $+C = A - 2b + c$, $-D = A - 3b + 3c - d$, $+E = A - 4b + 6c - 4d + e$, &c. where, putting T successively equal to B, C, D, E, &c. and $n = 1, 2, 3, 4$, &c. the prop. will be evident.

Cor. Hence

$A = A$, the first term.
$B = -A + b$, the first difference.
$C = A - 2b + c$, the 2d difference.
$D = -A + 3b - 3c + d$, the 3d difference.
$E = A - 4b + 6c - 4d + e$, the 4th difference.
$F = -A + 5b - 10c + 10d - 5e + f$, the 5th difference, &c.

PROP. II. If A, b, c, d, e, &c. be any series, and there be taken B, C, D, E, &c. the first of the several orders of differences;

Then, the nth term of the series will be $= A + \frac{n-1}{1} B + \frac{n-1}{1} \times \frac{n-2}{2} C + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} D + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} \times \frac{n-4}{4} E +$, &c.

For from the equations in the last Prop. viz $B = b - A$, $C = c - 2b + A$, &c. we have, by transposing, $b = A + B$, $= -A + 2b + C = -A + 2A + 2B + C$ (expunging b); that is,
$c = A + 2B + C$, $d = A - 3b + 3c + D = A - 3A - 3B + 3A + 6B + 3C + D$ (expunging b and c); that is, $d = A + 3B + 3C + D$. Also $e = -A + 4b - 6c + 4d + E =$ (expunging b, c, d) $-A + 4A + 4B - 6A - 12B - 6C + 4A + 12B + 12C + 4D + E$; that is, $e = A + 4B + 6C + 4D + E$, &c.

Then putting A, b, c, d, &c. for the nth term, and n successively $= 1, 2, 3, 4$, &c. the series will be evident.

Cor. 1. If d', d'', d''', &c. be the first of the first, second, third order, &c. of differences; then

The nth term of the series A, b, c, d, &c. will be $= A + \frac{n-1}{1} d' + \frac{n-1}{1} \times \frac{n-2}{2} d'' + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} d''' + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} \times \frac{n-4}{4} d^{v\prime} +$ &c.

For $B = d'$, $C = d''$, $D = d'''$, &c. And the coefficients are the unciæ of the $n - 1$th power.

Cor. 2. Hence also it follows, that any term of a given series may be accurately determined, if the differences of any order happen at last to be equal.

Cor. 3. Hence

$A = A$, the first term.
$b = A + B$, the 2d term.
$c = A + 2B + C$, the 3d term.
$d = A + 3B + 3C + D$, the 4th term.
$e = A + 4B + 6C + 4D + E$, the 5th term.
$f = A + 5B + 10C + 10D + 5E + F$, the 6th term.
$g = A + 6B + 15C + 20D + 15E + 6F + G$, the 7th term, &c.

PROP. III. If a, b, c, d, e, &c. be any series, and d' d'', $d^{n\prime}$, &c. the first of the several orders of differences; then

The sum of n terms of the series is $= na + n \times \frac{n-1}{2} d' + n \times \frac{n-1}{2} \times \frac{n-2}{3} d'' + n \times \frac{n-1}{2} \times \frac{n-2}{3}$

×

$\times \frac{n-3}{4} d''' + n \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4} \times \frac{n-4}{5} d'''' +$, &c.

For in the ſeries of quantities,

	o ,	a ,	$a+b$,	$a+b+c$,	$a+b+c+d$,	&c.
1ſt diff. are		a ,	b ,	c ,	d ,	&c.
2d diff.			d' ,	$d'2$,	$d'3$,	&c.
3d diff.				d'' ,	$d''2$,	&c.
4th diff.					d''' ,	&c.

Therefore (by Cor. 1. Prop. II.) the $\overline{n+1}$th term of the ſeries, $o, a, a+b, a+b+c, a+b+c+d$, &c. or the $\bar{n}$th term of the ſeries, $a, a+b, a+b+c, a+b+c+d$, &c. is $= o + na + n \times \frac{n-1}{2} d' + n \times \frac{n-1}{2} \times \frac{n-2}{3} d'' +$ &c. But the nth term of the ſeries $a, a+b, a+b+c$, &c. is the ſum of n terms of the ſeries, a, b, c, d, &c. and therefore equal to $na + n \times \frac{n-1}{2} d' + n \times \frac{n-1}{2} \times \frac{n-2}{3} d'' +$ &c.

For a fuller account of this method, and its application to curves, we refer the reader to Emerſon's works, from which theſe three propoſitions are taken.

DIFFRACTION, a term firſt uſed by Grimaldi, to denote that property of the rays of light which others have called inflection; the diſcovery of which is attributed by ſome to Grimaldi, and by others to Dr Hook.

DIMINUTION, in muſic, is the abating ſomething of the full value or quantity of any note.

DIOPHANTUS, a celebrated mathematician of Alexandria, has been reputed to be the inventor of algebra; at leaſt his is the earlieſt work extant on that ſcience. It is not certain when Diophantus lived. Some have placed him before Chriſt, and ſome after, in the reigns of Nero and the Antonines; but all with equal uncertainty. It ſeems he is the ſame Diophantus who wrote the Canon Aſtronomicus, which Suidas ſays was commented on by the celebrated Hypatia, daughter of Theon of Alexandria. His reputation muſt have been very high among the ancients, ſince they ranked him with Pythagoras and Euclid in mathematical learning. Bachet, in his notes upon the 5th book De Arithmeticis, has collected, from Diophantus's epitaph in the Anthologia, the following circumſtances of his life; namely, that he was married when he was 33 years old, and had a ſon born five years after; that this ſon died when he was 42 years of age, and that his father did not ſurvive him above four years; from which it appears that Diophantus was 84 years old when he died.

DIOPTER, or DIOPTRA, the ſame with the index or alhidade of an aſtrolabe, or other ſuch inſtrument.

DIOPTRA was an inſtrument invented by Hipparchus, which ſerved for ſeveral uſes; as, to level water-courſes; to take the height of towers, or places at a diſtance; to determine the places, magnitudes, and diſtances of the planets, &c.

DIRECT, in arithmetic, is when the proportion of any terms, or quantities, is in the natural or direct order in which they ſtand; being the oppoſite to inverſe, which conſiders the proportion in the inverted order of the terms. So, 3 : 4 : : 6 : 8 directly; or 3 : 4 : : 8 : 6 inverſely.

DIRECTION, in aſtronomy, the motion and other phenomena of a planet when direct.

DIRECTION, in aſtrology, is a kind of calculus, by which they pretend to find the time in which any notable accident ſhall befal the perſon whoſe horoſcope is drawn.

DISCRETE QUANTITY, is ſuch as is not continued and joined together. Such, for inſtance, is any number.

DITTON (Humphry), an eminent mathematician, was born at Saliſbury, May 29. 1675. Being an only ſon, and his father obſerving in him an extraordinary good capacity, determined to cultivate it with a good education. For this purpoſe he placed him in a reputable private academy; upon quitting of which he, at the deſire of his father, though againſt his own inclination, engaged in the profeſſion of divinity, and began to exerciſe his function at Tunbridge in the county of Kent, where he continued to preach ſome years; during which time he married a lady of that place.

But a weak conſtitution, and the death of his father, induced Mr Ditton to quit that profeſſion. And at the perſuaſion of Dr Harris and Mr Whiſton, both eminent mathematicians, he engaged in the ſtudy of mathematics; a ſcience to which he had always a ſtrong inclination. In the proſecution of this ſcience he was much encouraged by the ſucceſs and applauſe he received: being greatly eſteemed by the chief profeſſors of it, and particularly by Sir Iſaac Newton, by whoſe intereſt and recommendation he was elected maſter of the new mathematical ſchool in Chriſt's Hoſpital; where he continued till his death, which happened in 1715, in the 40th year of his age, much regretted by the philoſophical world, who expected many uſeful and ingenious diſcoveries from his aſſiduity, learning, and penetrating genius.

Mr Ditton publiſhed ſeveral mathematical and other tracts, as below.—1. Of the Tangents of Curves, &c. Philoſ. Tranſ. vol. 23.

2. A Treatiſe on Spherical Catoptrics, publiſhed in the Philoſ. Tranſ. for 1705; from whence it was copied and reprinted in the Acta Eruditorem 1707, and alſo in the Memoirs of the Academy of Sciences at Paris.

3. General Laws of Nature and Motion, 8vo, 1705. Wolfius mentions this work, and ſays that it illuſtrates and renders eaſy the writings of Galileo, Huygens, and the Principia of Newton. It is alſo noticed by La Roche, in the Memoires de Literature, vol. viii. p. 46.

4. An Inſtitution of Fluxions, containing the firſt Principles, Operations, and Applications, of that admirable Method, as invented by Sir Iſaac Newton, 8vo, 1706. This work, with additions and alterations, was again publiſhed by Mr John Clarke, in the year 1728.

5. In 1709 he publiſhed the Synopſis Algebraica of John Alexander, with many additions and corrections.

6. His Treatiſe on Perſpective was publiſhed in 1712. In this work he explained the principles of that art mathematically; and beſides teaching the methods then generally practiſed, gave the firſt hints of the new method afterwards enlarged upon and improved by Dr Brook Taylor; and which was publiſhed in the year 1715.

7. In 1714, Mr Ditton publiſhed ſeveral pieces both theological and mathematical; particularly his Diſcourſe on the Reſurrection of Jeſus Chriſt; and The New Law of Fluids, or a Diſcourſe concerning the Aſcent of Liquids, in exact Geometrical Figures, between two nearly contiguous Surfaces. To this was annexed a tract, to demonſtrate the impoſſibility of thinking or perception being the reſult of any combination of the parts of matter and motion: a ſubject much agitated about that time. To this work alſo was added an advertiſement from him and Mr Whiſton, concerning a method for diſcovering the longitude, which it ſeems they had publiſhed about half a year before. This attempt probably coſt our author his life; for although it was approved and countenanced by Sir Iſaac Newton, before it was preſented to the Board of Longitude, and the method has been ſucceſsfully put in practice, in finding the longitude between Paris and Vienna; yet that board then determined againſt it: ſo that the diſappointment, together with ſome public ridicule (particularly in a poem written by Dean Swift), affected his health ſo that he died the enſuing year, 1715.

In an account of Mr Ditton, prefixed to the German tranſlation of his Diſcourſe on the Reſurrection, it is ſaid that he had publiſhed, in his own name only, another method for finding the longitude; but which Mr Whiſton denied. However, Raphael Levi, a learned Jew, who had ſtudied under Leibnitz, informed the German editor, that he well knew that Ditton and Leibnitz had correſponded upon the ſubject; and that Ditton had ſent to Leibnitz a delineation of a machine he had invented for that purpoſe; which was a piece of mechaniſm conſtructed with many wheels like a clock, and which Leibnitz highly approved of for land uſe; but doubted whether it would anſwer on ſhip-board, on account of the motion of the ſhip.

DIVING-BELL has been already deſcribed in the *Encyclopædia*; but in that work was given no account of its antiquity or its invention. In the works of Ariſtotle we read of a kind of kettle uſed by divers to enable them to remain for ſome time under water; but the manner in which thoſe kettles were employed is not clearly deſcribed. "The oldeſt information (ſays Profeſſor Beckmann) which we have of the uſe of the diving bell in Europe, is that of John Taiſnier, who was born at Hainault in 1509, had a place at court under Charles V. whom he attended on his voyage to Africa. He relates in what manner he ſaw at Toledo, in the preſence of the emperor and ſeveral thouſand ſpectators, two Greeks let themſelves down under water, in a large inverted kettle, with a burning light, and riſe up again without being wet. It appears that this art was then new to the emperor and the Spaniards, and that the Greeks were cauſed to make the experiment in order to prove the poſſibility of it."

When the Engliſh, in 1588, diſperſed the Spaniſh fleet, called the Invincible Armada, part of the ſhips went to the bottom, near the Iſle of Mull, on the weſtern coaſt of Scotland; and ſome of theſe, according to the account of the Spaniſh priſoners, contained great riches. This information excited, from time to time, the avarice of ſpeculators, and gave riſe to ſeveral attempts to procure part of the loſt treaſure. In the year 1665, a perſon was ſo fortunate as to bring up ſome cannon, which, however, were not ſufficient to defray the expences. Of theſe attempts, and the kind of diving bell uſed in them, the reader will find an account in a work printed at Rotterdam in 1669, and entitled *G. Sinclari Ars nova et magna gravitatis et levitatis*. In the year 1680, William Phipps, a native of America, formed a project for ſearching and unloading a rich Spaniſh ſhip ſunk on the coaſt of Hiſpaniola; and repreſented his plan in ſuch a plauſible manner, that King Charles II. gave him a ſhip, and furniſhed him with every thing neceſſary for the undertaking. He ſet ſail in the year 1683; but being unſucceſsful, returned again in great poverty, though with a firm conviction of the poſſibility of his ſcheme. By a ſubſcription promoted chiefly by the Duke of Albemarle, the ſon of the celebrated Monk, Phipps was enabled, in 1687, to try his fortune once more, having previouſly engaged to divide the profit according to the twenty ſhares of which the ſubſcription conſiſted. At firſt all his labour proved fruitleſs; but at laſt, when his patience was almoſt entirely exhauſted, he was ſo lucky as to bring up, from the depth of ſix or ſeven fathoms, ſo much treaſure that he returned to England with the value of two hundred thouſand pounds ſterling. Of this ſum he himſelf got about ſixteen, others ſay twenty thouſand, and the duke ninety thouſand pounds. After he came back, ſome perſons endeavoured to perſuade the king to ſeize both the ſhip and the cargo, under a pretence that Phipps, when he ſolicited for his majeſty's permiſſion, had not given accurate information reſpecting the buſineſs. But the king anſwered, with much greatneſs of mind, that he knew Phipps to be an honeſt man, and that he and his friends ſhould ſhare the whole among them had he returned with double the value. His majeſty even conferred upon him the honour of knighthood, to ſhew how much he was ſatisfied with his conduct. We know not the conſtruction of Phipps's apparatus: but of the old figures of a diving-machine, that which approaches neareſt to the diving-bell is in a book on fortification by Lorini; who deſcribes a ſquare box bound round with iron, which is furniſhed with windows, and has a ſtool affixed to it for the diver. This ingenious contrivance appears, however, to be older than that Italian; at leaſt he does not pretend to be the inventor of it.

In the year 1617, Francis Keſsler gave a deſcription of his water-armour, intended alſo for diving, but which cannot really be uſed for that purpoſe. In the year 1671, Witſen taught, in a better manner than any of his predeceſſors, the conſtruction and uſe of the diving-bell; but he is much miſtaken when he ſays that it was invented at Amſterdam. In 1679 appeared, for the firſt time, Borelli's well known work *de motu animalium*; in which he not only deſcribed the diving-bell, but alſo propoſed another, the impracticability of which was ſhewn by James Bernoulli. When Sturm publiſhed his *Collegium curioſum* in 1678, he propoſed ſome hints for the improvement of this machine, on which remarks were made in the *Journal des ſçavans*. To him ſucceeded Dr Halley, whoſe bell is well known.

DODECATEMORY, the 12 houſes or parts of the zodiac of the primum mobile. Alſo the 12 ſigns of the zodiac are ſometimes ſo called, becauſe they contain each the 12th part of the zodiac.

DOME. See ARCH in this Supplement.

DOMINGO, or St Domingo. See Hispaniola, both in *Encycl.* and in this Supplement.

DON Martin de Mayorga, the name given by the Spaniards to a cluster of islands in the South Sea, discovered on the 27th of February 1781 by Don F. A. Maurelle, a celebrated pilot of that nation.

Those islands are described by him as abounding with tropical fruits and roots, as highly cultivated, and as inhabited by a people considerably polished. The fertility of the land, says he, is such, that its cultivation cannot fail to promise a favourable harvest. Every where are seen an endless number of cocoa-nut trees, beautiful banana trees ranged in lines with the greatest order, and numerous plantations of potatoes, of which he describes some as fifteen feet in length, and of the thickness of a man's thigh. He admired the order with which every thing was disposed. No weeds were suffered to grow between the plants; and their roads were kept in repair with a diligence deserving imitation by the most civilized nations.

Their government appears from his account to be despotic. The sovereign, who is called the *Tubou*, is held in the highest veneration by his subjects, whose lives and properties are at his disposal. Under him there is an order of nobles called *Equis*, who, though they shrink into insignificance in the presence of the *Tubou*, have great authority over the people. These people are said by Maurelle to be of great muscular strength and large stature, the ordinary height of the men being six feet or six feet four inches, while many of them are much taller. It would appear, too, that they delight in gymnastic exercises; for when the *Tubou*, by whom he had been treated with great hospitality, wished to amuse him and his ship's company, he exhibited to them feats of wrestling and boxing, and that as well by the women as by the men.

Though these people put the greatest confidence in the Spaniards, and frequently staid whole nights on board the frigate, they had yet the common inclination of savages to steal. "Every time they came on board (says our author), clothes, iron-work, whatever fell in their way, they considered as lawful prize. They drew out through the port-holes, or the windows, whatever was within their reach. They thieved even to the very chain of the rudder. I made my complaints to the king; he gave me permission to kill whomsoever I should detect in the act; and I was assured he had himself discovered and punished with death the authors of the complained of theft. Our vigilance was necessarily called into action; we surprised the islanders striving to tear away the new rudder chains; we fired a pistol at them, one of them fell dead on the occasion, and this was an awful lesson for those who were either on board or alongside of the frigate; they said to themselves, or to one another, *chito* (robber) *fama* (death)."

They make of the bark of trees a kind of cloth not unlike that which has been brought from other islands in the South Sea; and our author describes the women as being peculiarly neat both in their dress and in their persons. They had their mantles or loose garments adjusted in neat plaits and folds, and becomingly attached by a knot over the left shoulder. They wore garlands or wreaths on the head, and chaplets of large glass beads round their necks; the hair was pleasingly disposed in tresses, and the whole person perfumed with an oil of an agreeable odour; above all, the skin was so exquisitely clean, that they would not have suffered the smallest particle of dust to remain upon it a moment.

In this archipelago Don Maurelle found a safe harbour, to which he gave the name of El Refugio; and which he places in South Lat. 18°. 36′. and W. Lon. 177°. 47′. 45″. of Greenwich.

DRACŒNA Draco (see Dracoena, *Encycl.*), is a native of Madeira, though it is there becoming scarce. The following account of it is by La Martiniere, naturalist in the last voyage of discovery by La Perouse. "The idea of the dracœna draco (says he) given by the shabby specimens cultivated in our hot-houses, is far inferior to that we entertain of it when we have an opportunity of seeing it in its native soil. I met with three in particular, of which the trunk was six or seven feet high, and four and a half, or five in diameter. The principal branches, 12 or 15 in number, and as thick as a man's body, shoot out a little obliquely, dividing themselves generally into two, and now and then into three, to the height of 40 or 50 feet, including the seven feet of the trunk. The leaves are all at the extremity of the branches, where they are placed in alternate order, and form a cluster. This tree presents the most perfect regularity to the eye, and tempts the spectator to think that the most skilful gardener makes it the object of his daily care."

DRAINS. Under this word in the Encyclopædia we published Mr Bayley of Hope's method of draining land; and by a letter from the author, we have since learned, that experience, the best guide, has fully proved the usefulness and durability of his *drains*. With a candour, however, worthy of a man who writes not for fame, but for the good of the public, he informs us of a mistake into which he had led us; and requests us to correct it in this Supplement.

"I wish (says he) that, in the Supplement to the Encyclopædia, due notice may be taken of a very great error into which I was led in my scheme of making the *main drains*. I conjectured, that where the bottom of the trench was of a hard or solid body, as *clay* or *marl*, it might not be necessary to lay it with bricks or stones; but in this I was quite wrong. By the runs of water, the alternate changes from wet to dry, and the access of air, these hard bottoms have been rendered friable; they have crumbled away, and let in all my drains which were not supported by a bottom laid with brick or stone." For this information we request the author to accept of our thanks, and we are persuaded we may add the thanks of the public.

As the draining of land is a matter of great importance in agriculture, and as the subject has been again brought before us, we imagine that our agricultural readers will be glad to find here the substance of a paper on this subject, for which the author received the silver medal of the *Society* instituted for the encouragement of Arts, Manufactures, and Commerce. That author is Mr John Wedge of Bickenhill, near Coventry, who is not only a great farmer himself, but had likewise been employed by the Earl of Alesford in the management of several estates. Encouraged by his lordship's liberality, Mr Wedge informs the society, that he had been employed for some years in draining large portions of land, of which part was in the Earl's occupation, and part in his own, as tenant to his lordship.

The

The principles upon which he proceeded, as well as his mode of procedure, he ſtates in the following terms:

In every country there are large portions of land that, in wet ſeaſons, have always what may be called a *dry ſurface*, and other portions of land that have always a *moiſt* or *wet ſurface*; the former of theſe admitting all the water which falls upon them to ſink freely through their pores to various depths, till falling on clay, or ſome other unctuous earth, whoſe pores will not permit it to paſs through, it is there held up to a height proportioned to the quantity of water which comes upon it, and the facility with which that water is diſcharged. Thus, held up to various heights, it ſerves as a fountain to diſtribute its water (either by veins of ſand, pebbles, or rock), according to the formation of the different under ſtrata on the neighbouring lands, and there forms bogs and other varieties of wet ſurface, on a baſis that will be always found to conſiſt of marl, or clay, or ſome mixture thereof. The effect of water thus diſtributed may be divided into two claſſes. The firſt claſs, where the water is thrown out by a body of marl or clay, &c. upon the ſurface of deſcending ground, and in the valley (there held up by clay alſo) forms bogs or ſwamps. The ſecond claſs, where the water is held up by marl or clay, as before, having above that marl or clay a ſtratum of ſand, or pebbles, through which the water paſſes; and above thoſe ſands or pebbles another ſtratum of marl or clay, through the weakeſt parts of which the water, by a continual preſſure from its fountain, forces a paſſage upwards; and thus, through the weakeſt parts of the marl or clay, furniſhes a continual ſupply of water on the ſurface, for the formation or growth of bogs, &c. in proportion as this water is more or leſs abundantly ſupplied by its fountain or head, namely, the higher lands, into which rain-water freely paſſes, as before deſcribed. There are alſo different ſoils, under different circumſtances, which may form a third claſs of land for draining; ſuch as, ſtrong deep ſoils, or open light ſoils, having near the ſurface a body of marl or clay. In either of theſe caſes, the water which falls on the ſurface muſt, for reaſons which are ſelf-evident, keep ſuch lands, in rainy ſeaſons, conſtantly wet and cold; and it ſhould be obſerved, that a mixture of all the three before-deſcribed claſſes of wet land ſometimes occur in one field, by ſudden alterations of the under ſtrata, and thereby perplex the operator, by requiring all the different modes of draining in the ſame field.

If it be admitted that bogs are thus formed and fed, their cure may be effected with certainty. The firſt claſs, by cutting through the ſtratum (be it ſand, pebbles, or rock,) that conveys the water to the bog, and carrying off that water by a cloſe drain to ſome proper place, where the level admits of its diſcharge. The ſecond claſs, by ſinking a drain to any convenient depth in the upper clay; and then digging or boring with a large auger, at a ſmall diſtance on one ſide of this drain, through the remaining part, be it (the upper clay) ever ſo deep, into the under ſtratum of ſand, pebbles, or rock, through which the water paſſes; which will then ruſh up into the drain ſo made, with a velocity proportioned to the height of the land or fountain whence it is ſupplied. As this drain advances through the land, holes muſt be dug or bored, as before, every ſeven yards, or at ſuch diſtance as the ſtrength of the ſprings may require; and the whole of the water thus brought up by tapping the ſprings, is carried off by the drain made in the upper clay, which muſt be a cloſe one, to its proper level, and there diſcharged.

By both theſe methods of draining, large tracts of land, under favourable circumſtances, may be cured with one drain. The beſt place for fixing theſe drains is where the ſtratum that conveys the water comes neareſt to the ſurface; and the beſt method of aſcertaining that, is to bore or dig in different parts through the different under ſtrata.

The third claſs may be eaſily cured by cloſe drains, at ſuch diſtances and depths as will beſt carry off the ſurface-water. It may not be improper to obſerve, that where the different ſtrata or meaſures crop out, that is, become gradually more and more ſhallow in ſome certain direction (as is often the caſe, till, one after the other, they all preſent themſelves in ſucceſſion on the ſurface of the earth), draining may often be much more eaſily and better effected by croſſing with the drain the different ſtrata or meaſures where the levels and other circumſtances will admit.

Some of the land drained was part of a common, in the pariſh of Church Bickenhill, in the county of Warwick; part of it was covered with moſs and ling, had a peaty ſurface about ſix inches deep, and produced little or no graſs: in all wet ſeaſons it was filled quite to the ſurface, and often overflowed, with water. Some of the land was much more unſound, deeper of peat, and covered with moſs, in moſt parts nine inches long; another part was an abſolute bog in all ſeaſons.

Having dug or bored with a large auger into ſeveral parts of the land, Mr Wedge found peat, gravel, and ſand mixed, and a quick-ſand almoſt uniformly. The quick-ſand in every part, after getting an inch or two into it, ſeemed almoſt as fluid as water. Judging from this, that no materials for a drain could be laid in the quick-ſand, but what it would immediately bury, he dug a trench almoſt to the quick-ſand, leaving gravel, &c. of ſufficient ſtrength to bear up the materials for a hollow drain; theſe materials were two ſides and a coverer of ſtone, with a peat-turf on the top to keep out the ſoil. At every ſeven yards forward, by the ſide of this drain, he dug a hole in the quick-ſand as deep as it would permit. From theſe holes the water roſe freely into the hollow drain, and was by it diſcharged at a proper level. It may be proper to remark, that the ſtone made uſe of for this drain, and all others here mentioned, was a red ſand and rag-ſtone, which eaſily ſplit into proper ſizes for the purpoſe, and is very durable; it coſt about ſixpence per ton getting, excluſive of carriage. The drain thus formed ran on the whole rather freely, and made the land dry for a few yards on each ſide thereof, but was far from having the effect he improperly expected; for it evidently appears that the drain could only take a very ſmall portion of the water from ſo large a quick-ſand, which it did not penetrate more than two inches; and that it could drain only to its own depth, or, at moſt, to that depth in the fountain which ſupplied the quick-ſand. His purpoſe was then defeated; and his motive for mentioning this error cannot, he hopes, be miſtaken.

He now did what he ſays he ought to have done before, that is, examined the different ſtrata to a greater depth, particularly on the bog, and at the upper edges thereof

thereof, and found the bog to be what has been defcribed under the firft clafs. He therefore determined to attempt the cure in the manner before prefcribed for that clafs, namely, to cut through the whole of the ftratum (in this inftance, of quick-fand), through which he found the water pafs. This he effected as follows: The fummer being dry, and favourable for the purpofe, and having previoufly made his main open drain, he began his main clofe drain the firft week in June 1791, three feet wide, on the declivity near the edge of the great bog. In the firft operation he dug through the peat, the hard fand, and gravel, and one fpade's graft (about nine inches deep, and feven inches wide) into the quick-fand the whole length of this drain, which was 73 perches, of eight yards to the perch, in length. The drain thus dug ran copioufly, not lefs than 60 gallons per minute. In this ftate he left it about nine days: the effect of it was rapid, both above the drain and on the bog below. Upon examination, he now found about three inches on the top of the fpade's graft, which had been made into the quick-fand perfectly dry. He then dug out thefe three inches of dry fand, to nearly the whole width of the drain, three feet; and at the fame time dug out, as before, another fpade's graft from the top of the quick-fand, as near the middle of the drain as poffible. This was left to run a few days, as before, and had the fame effect, namely, three or four inches more of the top of the quick-fand became dry and hard. The fame operation was repeated again and again with the fame effect, till the purpofe of getting through this quick-fand was completed, fo far at leaft as the level of the main open drain would permit. The ftream of water continued increafing during the whole operation; the bog below the drain was quite dry, and the land above perfectly fo. The drain which was firft made, and continued running for fome time during the progrefs of the main clofe drain, became gradually dry; and has not, fince that drain was finifhed, difcharged one fingle drop of water. Great care was neceffary, in making the main clofe drain, to keep the ftream of water in the middle of it, otherwife the current would have undermined the fides, as it fometimes had done, and caufed them to fall in. For this reafon it was neceffary, when the dry fand was taken from the top of the quick-fand, immediately to take out a fpade's graft from the middle thereof, in order to divert the current from the fides.

The main clofe drain thus made was three feet wide at top, about nine feet deep on the average, and, bevelling a little from the top, it was about one foot ten inches wide at the bottom. The ftone and other materials were put into this drain in the following manner:

Where the drain went through the quick-fand into the ftratum of clay below it, as in moft places it did, the bottom, and in fome inftances the fides, wanted no particular fecurity (A); but where it did not go quite through the quick-fand, which the level of his main open drain in fome places would not admit, the bottom of the drain was covered half an inch thick with ling; then peat-turfs, one foot wide and three or four inches thick, were cut in convenient lengths, and placed on their edges on each fide of the bottom of the drain, forming two fides of a trough of peat; then fide ftones about eight inches high, and a ftone coverer, were put in upon the ling between the peat-turfs; a large peat-turf, near two feet wide and four inches thick, was then cut and firmly placed over the whole: this left in the bottom of the drain an open fpace, of more than fix inches fquare, for the water to pafs. The whole was then completed by filling in the upper part of the drain.

In this way the author drained, for about L. 80, thirty acres of land, which, from being of no value whatever, became worth at leaft 14 fhillings per acre of yearly rent. He likewife hollow-drained nine acres by the method prefcribed for the third clafs of wet land. Thefe drains were made a few yards below that part of each field where the dry and wet land feparate, about 22 inches deep, with fides and a coverer of ftone, and ling on the top of it, to keep the earth from running in. The length of thefe drains was 880 yards, and the expence of labour and materials three halfpence per yard. The drains, in wet weather, difcharge a large quantity of water; and will, he has no doubt, anfwer the intended purpofe. Thus far relates to land in his own occupation.

Nine acres of the land in the earl of Aylesford's occupation was almoft an entire pulp. This bog was of the fecond clafs, namely, water paffing through a quick-fand, and confined by a ftratum of clay below, and another ftratum of clay above it. The water thus confined, being preffed by its fountain, and forced up thro' the weakeft parts of the clay, had formed a bog of irregular thicknefs on the furface, in fome places fix feet deep, in others not more than two. As there is a confiderable fall in this land from eaft to weft, he thought it expedient to put two drains into it; and this appears to him to have been neceffary, from a confideration that both thefe drains continue to run in the fame proportions as when firft opened. The manner in which thefe drains were executed was, by digging through the different upper ftrata, and as deep into the clay as the main open drain would admit; then digging or boring through the remaining part of that clay into the quick-fand, at the diftance of about fix yards in a progreffive manner.

The water rifing rapidly through thefe holes into the clofe drains, has effected a complete cure of this land, every part of which will now bear a horfe to gallop upon it. Thefe drains difcharge 3660 gallons an hour; which is much lefs than they did at firft, as muft be the cafe in all bogs. This land will be worth twenty fhillings per acre. The draining coft twenty-five pounds; and the length of the under-ground drains is eight hundred and fourteen yards.

Mr Wedge had juft finifhed (January 1792) draining another piece of land, about forty-three acres. As this was intended to anfwer two purpofes, one, to drain the land, the other, to give an additional fupply of water to a mill-pool, and as a circumftance arofe in the execution of the work which frequently happens in draining land, namely, a fudden alteration in the pofition

(A) He will probably find in time that he was under the fame miftake with Mr Bayley, and we hope that with Mr Bayley's candour he will acknowledge it.

sition of the under strata—a description thereof will not, we hope, be thought tedious. This draining was begun at the level of a mill-pool, and continued, without any great difficulty, to the distance of about thirty-two chains, in the manner before described as a cure for the second class of boggy land: but at or near that place the under strata altered their position; the quick-sand which conveyed the water now became of twice its former thickness; and the clay, which had hitherto been above that quick sand, for some distance disappeared. From the quick-sand thus becoming so much deeper, he could not, with the level of the mill-pool, cut through it; nor indeed, from the wetness of the season, would such an operation have been proper. He therefore continued a shallow drain to some distance, making side-holes into the quick-sand, which ran freely; but as this could not cure the whole of the bog below, he branched out another drain (which was made by the method described for curing the second class of wet or boggy land), by sinking a close drain through the upper strata into the upper clay, and then, at a small distance on one side of this close drain, boring a hole with an auger through the remaining part of that clay into the quick-sand; and at every eight yards, as this close drain advanced, still boring other holes, in the manner before described: through many of these holes the water rushed with great rapidity. The water discharged by these drains into the mill-pool is 168 gallons per minute, or 3780 hogsheads in a day; which is after the rate of 1,379,700 hogsheads in a year.

About six acres of this land were always found; about twelve acres on the north side were an absolute pulp, and the remaining twenty six acres very unsound. The whole is now sound, and will, when cultivated, be worth sixteen shillings per acre. This land would have been drained at a much less expence into the main open drain; but then the water, which was much wanted for the mill, would have been lost. These close drains are in length 1452 yards, and cost L. 100, of which about L. 30 ought to be charged to the mill.

Important as this subject is, we must not enlarge this article, or we should make large extracts from Dr Anderson's *Practical Treatise on Draining Bogs and Swampy Grounds*, lately published. It is proper, however, to inform the public, that the author puts in his claim for being the first discoverer of that mode of draining for which Mr Elkington has obtained from Parliament a premium of L. 1000; and the reader who shall turn to the article Drains in the Encyclopædia, will perceive that his claim is well-founded.

DROSSERA Anglicana, or the Sundew (see Drossera, *Encycl.*), is a very minute villous plant, usually growing entangled with moss on peat bogs; the leaves are curiously fringed with numerous strong reddish hairs, terminated by small pellucid globules of viscous liquor, which occasion, by the reflection of the sun, that peculiar lustre from which its name is derived. It is in these hairs that these essential properties of the plant reside; for if a small insect should fix itself on one of the leaves, these hairs immediately begin to close, one by one, till the insect is wholly environed by them, and then the leaf in which it is imprisoned gradually bends inwards, so as to reach the base: in this state the insect is killed by the operation of the acrimonious juice exuding from the ends of the hairs. Rothius (as quoted by Withering, in his Arrangement of British Plants,) mentions the effects of this singular plant, occasioned by the irritation of an ant, which he placed on the centre of one of the leaves with a pair of pincers. The ant, in endeavouring to escape, was held fast by the viscous juice of the smaller hairs till the large ones, together with the edges of the leaf, closed in and imprisoned it. The ant died in fifteen minutes; but he observes, that the effects followed sooner or later, in different experiments, according to the state of the weather. Dr Whithering has published a similar account of the sensitive properties of the sundew, which was communicated to him by two of his botanical friends, and which he has made very entertaining and interesting. The same thing is confirmed by a writer in the Monthly Magazine for August 1797; who says, that whenever he made experiments on the drossera with ants and other diminutive insects, he commonly found them perish in a shorter time than fifteen minutes. His experiments were made on the drossera rotundifolia. Rothius, however, observes, that the longifolia produces the same effects, but with greater rapidity. In concluding his account, Dr Withering suggests this enquiry, "Whether this destruction of insects be not necessary to the welfare of the plant?" And it is surely worth some botanist's while to take some pains to answer the question.

DRUGS (see *Encycl.*) are so commonly counterfeited, or at least adulterated, that, in London, the royal college of physicians, it is well known, has long ago appointed a court of examiners to investigate the goodness of drugs and medicines in the different chemists and apothecaries shops. The counterfeit, however, is made up with such dexterity, that not only the merchant and drug-broker, but even the man of skill, is sometimes deceived; and indeed nothing can detect this imposition but a practical knowledge of chemistry. We therefore recommend it to every father of a family to study our Supplementary article Chemistry with this view, if with no other; for whatever be the faults of that atricle, we have lost much labour if it be not sufficiently perspicuous to enable every man, not an absolute stranger to physical science in all its branches, to detect the common impostures of drug-sellers.

DUFTER, in Bengal, an office or department.

Dufter Cana, the place where the office is kept.

DWARFING of vegetables, an art invented by the Chinese, to which the attention of Sir George Staunton was attracted on the following occasion:

When the embassy was at Chusan (See Chusan in this Supplement), the gentlemen who went on shore were introduced to the governor in his hall of audience, where on several tables were placed, in frames filled with earth, dwarf pines, oaks, and orange trees, bearing fruit. None of them exceeded in height two feet. Some of those dwarfs bore all the marks of decay from age: and upon the surface of the soil were interspersed small heaps of stones, which, in proportion to the adjoining dwarfs, might be termed rocks. These were honey-combed and moss-grown, as if untouched for ages, which served to maintain the illusion, and to give an antique appearance to the whole. This kind of stunted vegetation seemed to be much relished by the curious in China; and specimens of it were to be found in every considerable dwelling. To produce them formed a part of the gardener's skill, and was an art invented

 in

Dwarfing. in that country. Beſide the mere merit of overcoming a difficulty, it had that of introducing vegetables into common apartments, from which their natural ſize muſt otherwiſe have excluded them.

The general method of obtaining vegetable dwarfs is ſaid to be the following: A quantity of clay or mould is applied to the upper part of the trunk of a tree, from which a dwarf is intended to be taken, and cloſe to its diviſion into branches. The mould is to be confined to the ſpot by coarſe hempen or cotton cloth, and to be carefully kept moiſt by water. In conſequence of this application, continued ſometimes above a twelvemonth, ſmall tender fibres ſhoot down like roots from the wood into the mould. The part of the trunk emitting thoſe new fibres, together with the branch riſing immediately above it, is then to be carefully ſeparated from the reſt of the tree, and planted in new earth, in which the fibres become new roots, while the former branch is now the ſtem of the vegetable thus transformed in ſome meaſure. This operation does not deſtroy or alter the productive faculty which thoſe parts enjoyed before their ſeparation from their parent root. That which, while a branch of the original tree, bore flowers and fruit, continues to produce the ſame, though no longer ſupported upon any ſtock. The terminal buds of ſuch branches of trees as are meant to become dwarfs are torn off; which circumſtance prevents the further elongation of thoſe branches, and forces other buds and branchlets from the ſides. Theſe branchlets are bent by wires to whatever form the operator wiſhes: and when the appearance of age and decay is meant to be given to a dwarf tree, it is repeatedly ſmeared with treacle or molaſſes, which attracts multitudes of ants, who, in purſuit of thoſe ſweet juices, attack the bark, and, by a gradual corroſion of it, produce the deſired effect. Theſe different proceſſes are ſometimes attempted to be kept ſecret by the gardeners, and they vary deſignedly in the mode of carrying them on; but the principle on which they are founded is ſufficiently apparent from what is related here; and the contrivance argues ingenuity and perſeverance, rather than the practice does true taſte, which conſiſts in aſſiſting Nature in its moſt favourite works—not in counteracting its operations or diſtorting its productions.

Dyeing. DYEING is an art into which, ſince the article in the Encyclopædia was publiſhed, improvements have been introduced of ſuch importance, that it would be unpardonable not to notice them in this Supplement. They ought to be noticed under the preſent title; but, for reaſons aſſigned at the time, we were under the neceſſity of poſtponing them, in the firſt edition, to the title *Vegetable*, *Animal*, and *Dyeing* SUBSTANCES. We might now reſtore the article DYEING to its proper place; but though we confidently announce this as an improved edition, we doubt whether we can, in juſtice to the purchaſers of the firſt edition, alter its arrangement. We therefore ſtill refer the reader to the article *Dyeing* SUBSTANCES.

DYNAMICS.

1 Definition. THIS name marks that department of phyſico-mathematical ſcience which contains the abſtract doctrine of MOVING FORCES; that is, whatever neceſſarily reſults from the relations of our ideas of motion, and of the immediate cauſes of its production and changes.

2 Object of dynamics is change of that condition of a thing which we call its *motion*. All *changes* of motion are conſidered by us as the indications, the characteriſtics, and the meaſures of changing cauſes. This is a phyſical law of human thought, and therefore a principle to which we may refer, and from which we muſt derive all our knowledge of thoſe cauſes. When we appeal to our own thoughts or feelings, we do not find in ourſelves any diſpoſition to refer mere exiſtence to any cauſe, although the beginning of exiſtence certainly produces this reference in an inſtant. Had we always obſerved the univerſe in motion, it does not appear that we ſhould have aſcribed it to a cauſe, till the obſervation of relative reſt, or ſomething leading to it, had enabled us to ſeparate, by abſtraction, the notion of matter from that of motion. We might then perceive, that reſt is not incompatible with matter; and we might even obſerve, by means of relative motions, that abſolute reſt might be produced by the concourſe of equal and oppoſite motions. But all this requires reflection and reaſoning; whereas we are now ſpeaking of the firſt ſuggeſtions of our minds.

3. We cannot have any notion of motion *in abſtracto*, without conſidering it as a ſtate or condition of exiſtence, which would remain, if not changed by ſome cauſe. It is from changes alone, therefore, that we infer any agency in nature; and it is in theſe that we are to find all that we know of their cauſes.

4 Mechanical relation, what. When we look around us, we cannot but obſerve that the motions of bodies have, in moſt caſes, if not always, ſome relation to the ſituation, the diſtance, and the diſcriminating qualities of other bodies. The motions of the moon have a palpable relation to the earth; the motions of the tides have as evident a relation to the moon; the motions of a piece of iron have a palpable dependence on a magnet. The vicinity of the one ſeems to be the occaſion, at leaſt, of the motions of the other. The cauſes of theſe motions have an evident connection with or dependence on the other body. We are even diſpoſed to imagine, that they are inherent in that body, and that it poſſeſſes certain qualities which are the cauſes of thoſe modifications of motion in other bodies. Theſe ſerve to diſtinguiſh ſome bodies from others, and may therefore be called PROPERTIES; and, ſince the condition of other bodies ſo evidently depends on them, theſe properties expreſs very intereſting relations of bodies, and are chiefly attended to in the enumeration of the circumſtances which aſcertain what we call the *nature* of any thing. We do not mean to ſay that theſe inferences are always juſt; nay, we know that many of them are ill-founded: but they are real, and they ſerve abundantly for informing us what we may expect from any propoſed ſituation of things. It is enough for us to know, that when a piece of iron is ſo and ſo ſituated in relation to a magnet, it will move in a certain manner.

This mutual relation of bodies is differently conſidered, according to the intereſt that we chance to take in the phenomenon. The cauſe of the approach of the iron to a magnet is generally aſcribed to the magnet, which

which is ſaid to attract the iron, becauſe we commonly employ the magnet in order that theſe motions may take place. The ſimilar approach of a ſtone to the earth is aſcribed to the ſtone, and we ſay that it tends to the earth. In all probability, the procedure of nature is the ſame in both; for they are obſerved, in every inſtance, to be mutual between the related bodies. As iron approaches a magnet, ſo the magnet approaches the iron. The ſame thing is obſerved in the motions of electrified bodies; alſo in the caſe of the ſtone and the earth. Therefore the cauſe of the motions may be conceived as inherent in either, or in both.

Force and *Action* are figurative terms when uſed in mechaniſm;

The qualities thus inherent in bodies, conſtituting their mechanical relations, have been called the MECHANICAL AFFECTIONS OF MATTER. But they are more commonly named POWERS or FORCES; and the event which indicates their preſence, is conſidered as the effect and mark of their agency. The magnet is ſaid to ACT on the iron, the earth is ſaid to ACT on the ſtone, and the iron and the ſtone are ſaid to ACT on the magnet and on the earth.

All this is figurative or metaphorical language. All languages have begun with ſocial union, and have improved along with it. The firſt collections of words expreſſed the moſt familiar and the moſt intereſting notions. In the proceſs of ſocial improvement, the number of words did not increaſe in the ſame proportion with the notions that became intereſting and familiar in their turn: for it often happened that relations of certain ideas ſo much reſembled the relations of certain other ideas, that the word expreſſing one of them ſerved very well for expreſſing the other; becauſe the diſſimilar circumſtances of the two caſes prevented all chance of miſtake. Thus we are ſaid to *ſurmount* a difficulty without attaching to the word the notion of *getting over* a ſteep hill. Languages are thus filled with figurative expreſſions.

5
But the analogy is not in the force, but in the effect.

POWER, FORCE, and ACTION, are words which muſt have appeared in the language of the moſt ſimple people; becauſe the notions of perſonal ability, ſtrength, and exertion, are at once the moſt familiar and the moſt intereſting that can have a place in the human mind. Theſe terms, when uſed in their pure, primitive ſenſe, expreſs the notions of the power, force, and action of a ſentient, active, being. Such a being only is an agent. The exertion of his power or force is (excluſively) action: But the relation of cauſe and effect ſo much reſembles in its reſults the relation between this force and the work performed, that the ſame term may be very intelligibly employed for both. Perhaps the only caſe of pure unfigurative action is that of the mind on the body. But as this is always with the deſign of producing ſome change on external bodies, we think only of them; the inſtrument or tool is overlooked, and we ſay that we act on the external body. Our *real* action therefore is but the firſt movement in a long train of ſucceſſive events, and is but the remote cauſe of the intereſting event. The reſemblance to ſuch actions is very ſtrong indeed in many caſes of mechanical phenomena. A man throws a ball by the motion of his arm. A ſpring impels a ball in the ſame manner by unbending. Theſe two events reſemble each other in every circumſtance but the action of the mind on the corporeal organ—the reſt of it is a train of pure mechaniſm. In general, becauſe the ultimate reſults of the mutual influence of bodies on each other greatly reſemble the ultimate reſults of our actions on bodies, we have not invented appropriated terms, but have contented ourſelves with thoſe already employed for expreſſing our own actions, the exertions of our own powers or forces. The relation of phyſical cauſe and effect is expreſſed metaphorically in the words which belong properly to the relation of agent and action. This has been attended by the uſual conſequences of poverty of language, namely, ambiguity, and ſometimes miſtake, both in our reflections (which are generally carried on by mental diſcourſe), our reaſonings, and our concluſions. It is neceſſary to be on our guard againſt ſuch miſtakes; for they frequently amount to the confounding of things totally different. Many philoſophers of great reputation, on no better foundation than this metaphorical language, have confounded the relations of activity and of cauſation, and even denied that there is any difference; and they have affirmed, that there is the ſame invariable relation between the determinations of the will and the inducements that prompt them, as there is between any phyſical power and its effect. Others have maintained, that the firſt mover in the mechanical operations, and indeed through the whole train of any complicated event, is a percipient and intending principle in the ſame manner as in our actions. According to theſe philoſophers, a particle of gravitating matter perceives its relation to every other particle in the univerſe, and determines its own motion according to fixed laws, in exact conformity to its ſituation. But the language, and even the actions of all men, ſhew that they have a notion of the relation of an agent to the action, eaſily diſtinguiſhable (becauſe all diſtinguiſh it) from the relation between the phyſical cauſe and its effect. The proofs of this fact have been adduced in other parts of the Encyclopædia Britannica, as, for example, in the article PHILOSOPHY, nº 42. and in this Supplement in the article ACTION.

These remarks are not made in this place for any philological purpoſe, ſuch as the mere improvement of language; but becauſe this metaphorical language has affected the doctrines of mechanical philoſophy, and has produced a diſpute about ſome of its firſt principles; and becauſe we find that the only way to decide this diſpute is to avoid, moſt ſcrupulouſly, all metaphorical language, though at the expence of much circumlocution.

6
Directions for the ſafe employment of this analogy.

When we ſpeak of powers or forces as reſiding in a body, and the effect as produced by their exertion, the body, conſidered as poſſeſſing the power, is ſaid to ACT on the other. A magnet is ſaid to act on a piece of iron; a billiard ball in motion is ſaid to act on one that is hit by it: but if we attempt to fix our attention on this action, as diſtinct both from the agent and the thing acted on, we find no object of contemplation—the exertion or procedure of nature in producing the effect does not come under our view. When we *ſpeak* of the action as diſtinct from the agent, we find that it is not the action, properly ſpeaking, but the act, that we ſpeak of. In like manner, the action of a mechanical power can be conceived only in the effect produced.

7
Action implies change; and mere motion is not action.

A man is not ſaid to act unleſs he produces ſome effect. Thought is the act of the thinking principle; motion of the limb is the act of the mind on it. In mechanics, alſo, there is action only in ſo far as there is mechanical effect produced. I muſt act violently in order

order to begin motion on a ſlide: I muſt exert force, and this force exerted produces motion. I conceive the production of motion, in all caſes, as the exertion of force; but it requires no exertion to continue the motion along the ſlide; I am conſcious of none, therefore I ought to infer that no force is neceſſary for the continuation of any motion. The continuation of motion is not the production of any new effect, but the permanency of an effect already produced. We indeed conſider motion as the effect of an action; but there would be no effect if the body were not moving. Motion is not the action, but the effect of the action.

8 *Preſſion, impulſion.*

Mechanical actions have been uſually claſſed under two heads: they are either PRESSURES or IMPULSIONS. They are generally conſidered as of different kinds; the exertions of different powers. PRESSURE is ſuppoſed to differ eſſentially from IMPULSE.

Inſtead of attempting to define, or deſcribe, theſe two kinds of forces and actions, we ſhall juſt mention ſome inſtances. This will give us all the knowledge of their diſtinctions that we can acquire.

Examples of preſſion.

When a ball lies on a table, and I preſs it gently on one ſide, it moves toward the other ſide of the table. If I follow it with my finger, continuing my preſſure, it accelerates continually in its motion. In like manner, when I preſs on the handle of a common kitchen jack, the fly *begins* to move. If I continue to urge or preſs round the handle, the fly accelerates continually, and may be brought into a ſtate of very rapid motion. Theſe motions are the effects of genuine preſſure. The ball would be urged along the table in the ſame manner, and with a motion continually accelerated, by the unbending of a ſpring. Alſo, a ſpring coiled up round the axis of the handle of the jack would, by uncoiling itſelf, urge round the fly with a motion accelerating in the ſame way. The more I reflect on the preſſure of my finger on the ball, and compare it with the effect of the ſpring on it, the more clearly do I ſee the perfect ſimilarity; and I call theſe influences, exertions, or actions, by one name, PRESSURE, taken from the moſt familiar inſtance of them.

Again, the very ſame motion may be produced in the ball or fly, by pulling the ball or the machine by means of a thread, to which a weight is ſuſpended. As both are motions accelerated in the ſame manner, I call the influence or action of the thread on the ball or machine by the ſame name PRESSURE, and WEIGHT is conſidered as a preſſing power. Indeed I feel the ſame compreſſion from the real preſſure of a man on my ſhoulders that I would feel from a load laid on them. But the weight in our example is acting by the intervention of the thread. By its preſſure, it is pulling at that part of the thread to which it is faſtened; this part is pulling at the next by means of the force of coheſion; and this pulls at a third, and ſo on, till the moſt remote pulls at the ball or the machine. Thus may elaſticity, weight, coheſion, and other forces, perform the office of a genuine power; and ſince their reſult is always a motion beginning from nothing, and accelerating by perceptible degrees to any velocity, this reſemblance makes us call them by one familiar name.

But farther, I ſee that if the thread be cut, the weight will fall with an accelerated motion, which I will increaſe to any degree, if the fall be great enough. I aſcribe this alſo to a preſſing power acting on the weight. Nay, after a very little refinement, I conſider this power as the cauſe of the body's weight; which word is but a diſtinguiſhing name for this particular inſtance of preſſing power. Gravitation is therefore added to the liſt of preſſures; and, for ſimilar reaſons, the attractions and repulſions of magnets or electric bodies may be added to the liſt; for they produce actual compreſſions of bodies placed between them, and they produce motions gradually accelerated, preciſely as gravitation does. Therefore all theſe powers may be diſtinguiſhed by this deſcriptive name *preſſures*, which, in ſtrict language, belongs to one of them only.

Gravity, attractions, and repulſions, are conſidered as preſſions.

Several writers, however, ſubdivide this great claſs into preſſions and ſolicitations. Gravity is a ſolicitation *ab extra*, by which a body is urged downward. In like manner, the forces of magnetiſm and electricity, and a vaſt variety of other attractions and repulſions, are called *ſolicitations*. We ſee little uſe for this diſtinction, and the term is too like an affection of mind.

9 **Examples of impulſion.**

IMPULSION is exhibited when a ball in motion puts another ball into motion by hitting, or (to ſpeak metaphorically) by ſtriking it. The appearances here are very different. The body that is ſtruck acquires, in the inſtant of impulſe, a ſenſible quantity of motion, and ſometimes a very rapid motion. This motion is neither accelerated nor retarded after the ſtroke, unleſs it be affected by ſome other force. It is alſo remarked, that the rapidity of the motion depends, *inter alia*, on the previous velocity of the ſtriking body. For inſtance, if a clay ball, moving with any velocity, ſtrike another equal ball which is at reſt, the ſtruck ball moves with half the velocity of the other. And it is farther remarkable, that the ſtriking body always loſes as much motion as the ſtruck body gains. This univerſal and remarkable fact ſeems to have given riſe to a confuſed or indiſtinct notion of a ſort of transference of motion from one body to another. The phraſeology in general uſe on this ſubject expreſſes this in the moſt preciſe terms. The one ball is not ſaid to cauſe or produce motion in the other, but to *communicate* motion to it; and the whole phenomenon is called the *communication of motion*. We call this an *indiſtinct* notion; for ſurely no one will ſay that he has any clear conception of it. We can form the moſt diſtinct notion of the communication of heat, or of the cauſe of heat; of the communication of ſaltneſs, ſweetneſs, and a thouſand other *things*; but we cannot conceive how part of that identical motion which was formerly in A, is now infuſed into B, being given up by A. It is in our attempt to form this notion that we find that motion is not a *thing*, not a ſubſtance which can exiſt independently, and is ſuſceptible of actual transference. It appears in this caſe to be a ſtate, or condition, or mode of exiſtence, of which bodies are ſuſceptible, which is producible, or (to ſpeak without metaphor) cauſable, in bodies, and which is the effect and *characteriſtic* of *certain* natural qualities, properties, or powers. We are anxious to have our readers impreſſed with clear and preciſe notions on this ſubject, being confident that ſuch, and only ſuch, will carry them through ſome intricate paths of mechanical and philoſophical reſearch.

Communication of motion, not a good expreſſion.

10 *Inherent force* **is the diſtinctive character of impulſion,**

The remarkable circumſtance in this phenomenon is, that a rapid motion, which requires for the effecting it the action of a preſſing power, continued for a ſenſible, and frequently a long time, ſeems to be effected in an inſtant by impulſion. This has tended much to ſupport the notion of the actual transference of ſomething formerly

formerly poſſeſſed excluſively by the ſtriking body, inhering in it, but ſeparable, and now transfuſed, into the body ſtriken. And now room is found for the employment of metaphor, both in thought and language. The *ſtriking* body affects the body which it thus impels: It therefore poſſeſſes the *power* of impulſion, that is, of *communicating* motion. It poſſeſſes it only while it is in motion. This *power*, therefore, is the efficient diſtinguiſhing cauſe of its motion, and its only office muſt be the continuation of this motion. It is therefore called the INHERENT FORCE, the force inherent in a moving body, VIS INSITA *corpori moto*. This force is transfuſed into the body impelled; and *therefore* the transference is inſtantaneous, and the impelled body continues its motion till it is changed by ſome other action. All this is at firſt ſight very plauſible; but a ſcrupulous attention to thoſe feelings which have given riſe to this metaphorical conception, ſhould have produced very different notions. I am conſcious of exertion in order to begin motion on a ſlide; but if the ice be very ſmooth, I am conſcious of no exertion in order to ſlide along. My power is felt only while I am conſcious of exerting it: Therefore I have no primitive feeling or notion of power while I am ſliding along. I am certain that no exertion of power is neceſſary here. Nay, I find that I cannot think of my moving forward without effort otherwiſe than as a certain mode of my exiſtence. Yet we imagine that the partiſans of this opinion did really deduce it in ſome ſhape from their feelings. We muſt continue the *exertion* of walking in order to walk on; our power of walking muſt be continually exerted, otherwiſe we ſhall ſtop. But this is a very imperfect, incomplete, and careleſs obſervation. Walking is much more than mere continuance in progreſſive motion. It is a continually repeated lifting our body up a ſmall height, and allowing it to come down again. This renewed aſcent requires repeated exertion.

11
And ſaid to be infinitely greater than preſſion.

We have other obſervations of importance yet to make on this force of moving bodies, but this is not the moſt proper occaſion. Mean while we muſt remark, that the inſtantaneous production of rapid motion by impulſe has induced the firſt mechanicians of Europe to maintain, that the power or force of impulſe is unſuſceptible of any compariſon with a preſſing power. They have aſſerted, that impulſe is infinitely great when compared with preſſure; not recollecting that they held them to be things totally diſparate, that have no proportion more than weight and ſweetneſs. But theſe gentlemen are perpetually enticed away from their creed by the ſimilarity of the ultimate reſults of preſſure and impulſe. No perſon can find any difference between the motion of two balls moving equally ſwift, in the ſame direction, one of which is deſcending by gravity and the other has derived its motion from a blow. This ſtruggle of the mind to maintain its faith, and yet accommodate its doctrines to what we ſee, has occaſioned ſome other curious forms of expreſſion. Preſſure is conſidered as an *effort* to produce motion. When a ball lies on a table, its weight, which they call a *power*, continually and repeated *endeavours* (mark the metaphorical word and thought) to move the ball downward. But theſe efforts are ineffectual. They ſay that this ineffectual power is *dead*, and call it a VIS MORTUA; but the force of impulſion is called a VIS VIVA, a living force. But this is very whimſical and very inaccurate. If the impelling ball falls perpendicularly on the other lying on the table, it will produce no motion any more than gravity will; and if the table be annihilated, gravity becomes a *vis viva*.

Arguments indiſtinct and inconcluſive.

We muſt now add, that in order to prove that impulſe is infinitely greater than preſſure, theſe mechanicians turn our attention to many familiar facts which plead ſtrongly in their favour. A carpenter will drive a nail into a board with a very moderate blow of his hammer. This will require a preſſure which ſeems many hundred times greater than the impelling effort of the carpenter. A very moderate blow will ſhiver into pieces a diamond which would carry the weight of a mountain. Seeing this prodigious ſuperiority in the impulſe, how ſhall they account for the production of motion by means of preſſure? for this motion of the hammer might have been acquired by its falling from a height; nay, it is actually acquired by means of the continued preſſure of the carpenter's arm. They conſider it as the aggregate of an infinity of ſucceeding preſſures in *every* inſtant of its continuance; ſo that the inſignificant ſmallneſs of each effort is compenſated by their inconceivable number.

No difference between preſſion and impulſion.

On the whole, we do not think that there is clear evidence that there are two kinds of mechanical force eſſentially different in their nature. It is virtually given up by thoſe who ſay that impulſe is infinitely greater than preſſure. Nor is there any conſiderable advantage to be obtained by arranging the phenomenon under thoſe two heads. We may perhaps find ſome method of explaining ſatisfactorily the remarkable difference that is really obſerved in the two modes of producing motion; namely, the gradual production of motion by acknowledged preſſure, and the inſtantaneous production of it by impulſe. Indeed, we ſhould not have taken up ſo much of our reader's attention with this ſubject, had it not been for ſome inferences that have been made from theſe premiſes, which meet us in our very entry on the conſideration of firſt principles, and that are of extenſive influence on the whole ſcience of mechanical philoſophy, and, indeed, on the whole ſtudy of nature.

12
Is impulſion the ſole cauſe of motion?

Mechanicians are greatly divided in their opinion about the nature of the ſole moving force in Nature. Thoſe whom we are now ſpeaking of, ſeem to think that all motion is produced by preſſure: For when they conſider impulſe as equivalent to the aggregate of an infinity of repeated preſſures, they undoubtedly ſuppoſe any preſſure, however inſignificant, as a moving force. But there is a party, both numerous and reſpectable, who maintain that impulſion is the ſole cauſe of motion. We ſee bodies in motion, ſay they, and we ſee them impel others; and we ſee that this production of motion is regulated by ſuch laws, that there is but one abſolute quantity of motion in the univerſe which remains unalterably the ſame. It muſt therefore be transfuſed in the acts of colliſion. We alſo ſee, with clear evidence, in ſome caſes, that motion can produce preſſure. Euler adduces ſome very whimſical and complicated caſes, in which an action, preciſely ſimilar to preſſure, may be produced by motion. Thus, two balls connected by a thread, may be ſo ſtruck that they ſhall move forward, and at the ſame time wheel round. In this caſe the connecting thread will be ſtretched between them. Now, ſay the philoſophers, ſince we ſee motion, and ſee that preſſure may be produced by motion, it is prepoſterous to imagine that it is any thing elſe than

a

a refult of certain motions; and it is the bufinefs of a philofopher to inquire and difcover what motions produce the preffures that we obferve.

They then proceed to account for thofe preffing powers, or folicitations to motion, which we obferve in the acceleration of falling bodies, the attractions of magnetifm and electricity, and many other phenomena of this kind, where bodies are put in motion by the vicinity of other bodies, or (in the popular language) by the action of other bodies at a diftance. To fay that a magnet cannot act on a piece of remote iron, is to fay that it can act *where* it is not; which is as abfurd as to fay, that it can act *when* it is not. *Nihil movetur*, fays Euler, *nifi a contiguo et moto.*

How does it produce preffure? The bulk of thefe philofophers are not very anxious about the way in which thefe motions are produced, nor do they fall upon fuch ingenious methods of producing preffure as the one already mentioned, which was adduced by Euler. The piece of iron, fay they, is put in motion when brought into the neighbourhood of a magnet, becaufe there is a ftream of fluid iffuing from one pole of the magnet, which circles round the magnet, and enters at the other pole: This ftream impels the iron, and arranges it in certain determined pofitions, juft as a ftream of water would arrange the flote grafs. In the fame manner, there is a ftream of fluid continually moving towards the centre of the earth, which impels all bodies in lines perpendicular to the furface; and fo on with regard to other like phenomena. Thefe motions are thus reduced to very fimple cafes by impulfion.

Incompatible with the rules of philofophifing. It is unneceffary to refute this doctrine at prefent; it is enough that it is contrary to all the dictates of common fenfe. To *fuppofe* an agent that we do not fee, and for whofe exiftence we have not the fmalleft argument; with equal propriety we might fuppofe miniftering fpirits, or any thing that we pleafe.

13 Others maintain that preffure is the fole moving force. Other philofophers are fo diffatisfied with this notion of the production of preffure, that they, on the other hand, affirm that preffure is the only moving force in nature; not according to the popular notion of preffure, by the mutual contact of folid bodies, but that kind of preffure which has been called *folicitation;* fuch as the power of gravity. They affirm, that there is no fuch thing as contact on inftantaneous communication of motion by real collifion. They fay (and they prove it by very convincing facts (fee Optics, n° 63—68. *Encycl.*), that the particles of folid bodies exert very ftrong repulfions to a fmall diftance; and therefore, when they are brought by motion fufficiently near to another body, they repel it, and are equally repelled by it. Thus is motion produced in the other body, and their own motion is diminifhed. And they then fhew, by a fcrupulous confideration of the ftate of the bodies while the one is advancing and the other retiring, in what manner the two bodies attain a common velocity, fo that the quantity of motion before collifion remains unchanged, the one body gaining as much as the other lofes. They alfo fhew cafes of fuch mutual action between bodies, where it is evident that they have never come into contact; and yet the refult has been precifely fimilar to thofe cafes where the motion appeared to be changed in an inftant. Therefore they conclude, that there is no fuch thing as inftantaneous *communication*, or transfufion of motion, by contact in collifion or impulfe. The reafon why previous motion of the impelling body is neceffary, is not that it may have a *vis infita corpori moto*, a force inherent in it *by its being in motion*, but that it may continue to follow the impelled and retiring body, and exert on it a force inherent in itfelf, whether in motion or at reft.—According to thefe philofophers, therefore, all moving forces are of that kind which has been named *folicitation;* fuch as gravity. We fhall know it afterwards by the more familiar and defcriptive name of Accelerating or Retarding force.

14 *Action, Refiftance, Reaction.* The exertions of mechanical forces are differently termed, according to the reference that we make to the refult. If, in boxing or wreftling, I ftrike, or endeavour to throw my antagonift, I am faid to act; but if I only parry his blows, or prevent him from throwing me, I am faid to resist. This diftinction is applied to the exertions of mechanical powers. When one body A changes the motion of another B, we may confider the change in the motion of B either as the indication and meafure of A's power of producing motion, or as the indication and meafure of A's refiftance to the being brought to reft, or having its motion any how changed. The diftinction is not in the thing itfelf, but only in the reference that we are difpofed, by other confiderations, to make of its effect. They may be diftinguifhed in the following manner: If a change of motion follow when one of the powers ceafes to be exerted, that power is conceived as having refifted. The whole language on this fubject is metaphorical. Refiftance, effort, endeavour, &c. are words which cannot be employed in mechanical difcuffions without figure, becaufe they all exprefs notions which relate to fentient beings; and the unguarded indulgence of this figurative language has fo much affected the imagination of philofophers, that many have almoft animated all matter. Perhaps the word Reaction, introduced (we think) by Newton, is the beft term for expreffing that mutual force which is perceived in all the operations of nature that we have inveftigated with fuccefs. As the magnet attracts iron, and in fo doing is faid to *act* on it; fo the iron attracts the magnet, and may be faid to *react* on it.

15 We need not fuppofe action at a diftance. *Tendency.* With refpect to the difficulty that has been objected to the opinion of thofe who maintain that all the mechanical phenomena are produced by the agency of attracting or repelling forces; namely, that this fuppofes the bodies to act on each other at a diftance, however fmall thofe diftances may be, which is thought to be abfurd, we may obferve, that we may afcribe the mutual approaches or receffes to tendencies to or from each other. What we call *the attraction of the magnet* may be confidered as a tendency of the iron to the magnet, fomewhat fimilar to the gravitation of a ftone toward the earth. We furely (at leaft the unlearned) can and do conceive the iron to be affected by the magnet, *without thinking* of any intermedium. The thing is not therefore inconceivable; which is all that we know about abfurdity: and we do not know any thing about the nature or effence of matter which renders this tendency to the magnet impoffible. That we do not fee intuitively any reafon why the iron fhould approach the magnet, muft be granted; but this is not enough to entitle us to fay, that fuch a thing is impoffible or inconfiftent with the nature of matter. It appears, therefore, to be very hafty and unwarrantable, to fuppofe the impulfe of an invifible fluid, of which we know nothing, and of the exiftence of which we have no proof. Nay, if

if it be true that bodies do not come into contact, even when one ball hits another, and drives it before it, this invisible fluid will not solve the difficulty; because the same difficulty occurs in the action of any particle of the fluid on the body. We are obliged to say, that the production of motion without any *observed* contact, is a much more familiar phenomenon than the production of motion by impulsion. More motion has been produced in this way by the gravitation of a small stream of water, running ever since the creation, than by all the impulses in the world twice told. We do not mean by this to say, that the giving to this observed mutual relation between iron and a loadstone the name tendency makes it less absurd, than when we say that the loadstone attracts the iron; it only makes it more conceivable: It suggests a very familiar analogy; but both are equally figurative expressions; at least as the word tendency is used at present. In the language of ancient Rome, there was no metaphor when Virgil's hero said, *Tendimus in Latium. Tendere versus solem* means, in plain Latin, to *approach the sun*. The safe way of conceiving the whole is to say, that the condition of the iron depends on the vicinity of the magnet.

16 *Attraction, Repulsion,* are figurative terms

When the exertions of a mechanical power are observed to be always directed toward a body, that body is said to attract; but when the other body always moves off from it, it is said to repel. These also are metaphorical expressions. I attract a boat when I pull it toward me by a rope; this is purely ATTRACTION: and it is pure, unfigurative REPULSION, when I push any body from me. The same words are applied to the mechanical phenomena, merely because they resemble the results of real attraction or repulsion. We must be much on our guard to avoid metaphor in our conceptions, and never allow these words to suggest to our mind any opinion about the *manner* in which the mechanical forces produce their effects. It is plain, that if the opinion of those who maintain the existence and action of the above-mentioned invisible fluid be just, there is nothing like attraction or repulsion in the universe. We must always recur to the simple phenomenon, the motion to or from the attraction or repelling body; for this is all we see, and generally all that we know.

17 Forces are conceived as measurable quantities.

We conceive one man to have twice the strength of another man, when we see that he can withstand the united effort of two others. Thus animal force is conceived as a quantity, made up of, and measured by, its own parts. But we doubt exceedingly whether this be an accurate conception. We have not a distinct notion of one strain added to another; though we have of their being joined or combined. We want words to express the difference of these two notions in our own minds; but we imagine that others perceive the same difference. We conceive clearly the addition of two lines or of two minutes; we can conceive them apart, and perceive their boundaries, common to both, where one ends and the other begins. We cannot conceive thus of two forces combined; yet we cannot say, that two equal forces are *not* double of one of them. We measure them by the effects which they are known to produce. Yet there are not wanting many cases where the action of two men, equally strong, does not produce a double motion.

How measured.

In like manner, we conceive all mechanical forces as measurable by their effects; and thus they are made the subjects of mathematical discussion. We talk of the proportions of gravity, magnetism, electricity, &c.; nay, we talk of the proportion of gravity to magnetism:—Yet these, considered in themselves, are disparate, and do not admit of any proportion; but they produce effects, some of which are measurable, and whose assumed measures are susceptible of comparison, being quantities of the same kind. Thus, one of the effects of gravity is the acceleration of motion in a falling body: magnetism will also accelerate the motion of a piece of iron; these two accelerations are comparable. But we cannot compare magnetism with heat; because we do not know any measurable effects of magnetism that are of the same kind with any effects of heat.

When we say, that the gravitation of the moon is the 3600th part of the gravitation at the sea-shore, we mean that the fall of a stone in a second is 3600 times greater than the fall of the moon in the same time. By their effects.
But we also mean (and this expresses the proportion of the *tendency* of gravitation more purely), that if a stone, when hung on a spring steelyard, draw out the rod of the steelyard to the mark 3600, the same stone, taken up to the distance of the moon, will draw it out no further than the mark 1. We also mean, that if the stone at the sea-shore draw out the rod to any mark, it will require 3600 such stones to draw it out to that mark, when the trial is made at the distance of the moon. It is not, therefore, in consequence of any immediate perception of the proportion of the gravitation at the moon to that at the surface of the earth that we make such an assertion; but these motions, which we consider as its effects in these situations, being magnitudes of the same kind, are susceptible of comparison, and have a proportion which can be ascertained by observation. It is these proportions that we contemplate; although we speak of the proportions of the unseen causes, the forces, or endeavours to descend. It will be of material service to the reader to peruse the judicious and acute dissertation on *quantity* in the 45th volume of the Philosophical Transactions; or he may study the article QUANTITY in the *Encyclopædia*, where, we trust, he will see clearly how force, velocity, density, and many other magnitudes of very frequent occurrence in mechanical philosophy, may be made the subjects of mathematical discussion, by means of some of those proper quantities, measurable by their own parts, which are to be assumed as their measures. Pressures are measurable only by pressures. When we consider them as moving powers, we should be able to measure them by *any* moving powers, otherwise we cannot compare them; therefore it is not as pressures that we then measure them. This observation is momentous.

One circumstance must be carefully attended to. That those assumed measures may be accurate, they must be invariably connected with the magnitudes which they are employed to measure, and so connected, that the degrees of the one must change in the same manner with the degrees of the other. This is evident, and is granted by all. But we must also *know* this of the measure we employ; we must see this constant and precise relation. How can we know this? We do not perceive force as a separate existence, so as to see its proportions, and to see that these are the same with the proportions of the measures, in the same manner that Euclid sees the proportions of triangles and those of their

their baſes, and that theſe proportions are the ſame, when the triangles are of equal altitudes. How do we diſcover that to every magnitude which we call *force* is invariably attached a correſponding magnitude of acceleration or deflection?—Clearly. In fact, the very exiſtence of the force is an inference that we make from the obſerved acceleration; and the degree of the force is, in like manner, an inference from the obſerved magnitude of the acceleration. Our meaſures are therefore neceſſarily connected with the magnitudes which they meaſure, and their proportions are the ſame; becauſe the one is always an inference from the other, both in ſpecies and in degree.

18 Dynamics is a demonſtrative ſcience.

It is now evident, that theſe diſquiſitions are ſuſceptible of mathematical accuracy. Having ſelected our meaſures, and obſerved certain mathematical relations of thoſe meaſures, every inference that we can draw from the mathematical relations of the proportions of thoſe repreſentations is true of the proportions of the motions; and therefore of the proportions of the forces. And thus dynamics becomes a demonſtrative ſcience, one of the *diſciplinæ accuratæ*.

19. But moving forces are conſidered as differing alſo in kind; that is, in direction. We aſſign to the force the direction of the obſerved change of motion; which is not only the indication, but alſo the characteriſtic, of the changing force. We call it an *accelerating*, *retarding*, *deflecting*, *force*, according as we obſerve the motion to be accelerated, retarded, or deflected.

Theſe denominations ſhew us inconteſtably that we have no knowledge of the forces different from our knowledge of the effects. The denominations are all either deſcriptive of the effects, as when we call them accelerating, penetrating, protruſive, attractive, or repulſive forces; or they are names of reference to the ſubſtances in which the accelerating, protruſive, &c. forces, are ſuppoſed to be inherent, as when we call them *magnetiſm*, *electricity*, *corpuſcular*, &c.

20 Forces are diſcovered by their oppoſition to other forces.

When I ſtruggle with another, and feel, that in order to prevent being thrown, I muſt exert force, I learn that my antagoniſt is exerting force. This notion is transferred to matter; and when a moving power which is *known* to operate, produces no motion, we conceive it to be oppoſed by another equal force; the exiſtence, agency, and intenſity of which is detected and meaſured by theſe means. The quieſcent ſtate of the body is conſidered as a change on the ſtate of things that would have been exhibited in conſequence of the known action of one power, had this other power not acted; and this change is conſidered as the indication, characteriſtic, and meaſure of another power, detected in this way. Thus forces are recogniſed not only by the changes of motion which they produce, but alſo by the changes of motion which they prevent. The coheſion of matter in a ſtring is inferred not only by its giving motion to a ball which I pull toward me by its intervention, but alſo by its ſuſpending that ball, and hindering it from falling. I know that gravity is acting on the ball, which, however, does not fall. The ſolidity of a board is equally inferred from its ſtopping the ball which ſtrikes it, and from the motion of the ball which it drives before it. In this way we learn that the particles of tangible matter cohere by means of moving forces, and that they reſiſt compreſſion with force; and in making this inference, we find that this corpuſcular force exerted between the particles is mutual, oppoſite, and equal: for we muſt apply force equally to *a* or to *b*, in order to produce a ſeparation or a compreſſion. We learn their equality, by obſerving that no motion enſues while theſe mutual forces are known to act on the particles; that is, each is oppoſed by another force, which is neither inferior nor ſuperior to it.

First Law of Motion

Of the Laws of Motion.

Such, then, being our notions of mechanical forces, the cauſes of the ſenſible changes of motion, there will reſult certain conſequences from them, which may be called axioms or laws of motion. Some of theſe may be intuitive, offering themſelves to the mind as ſoon as the notions which they involve are preſented to it. Others may be as neceſſary reſults from the relations of theſe notions, but may not readily offer themſelves without the mediation of axioms of the firſt claſs. We ſhall ſelect thoſe which are intuitive, and may be taken for the firſt principles of all diſcuſſions in mechanical philoſophy.

First Law of Motion.

Every body continues in a ſtate of reſt, or of uniform rectilineal motion, unleſs affected by ſome mechanical force.

This is a propoſition, on the truth of which the whole ſcience of mechanical philoſophy ultimately depends. It is therefore to be eſtabliſhed on the firmeſt foundation; and a ſolicitude on this head is the more juſtifiable, becauſe the opinions of philoſophers have been, and ſtill are, extremely different, both with reſpect to the truth of this law, and with reſpect to the foundation on which it is built. Theſe opinions are, in general, very obſcure and unſatisfactory; and, as is natural, they influence the diſcuſſions of thoſe by whom they are held through the whole ſcience. Although of contradictory opinions one only can be juſt, and it may appear ſufficient that this one be eſtabliſhed and uniformly applied; yet a ſhort expoſition, at leaſt, of the reſt is neceſſary, that the greateſt part of the writings of the philoſophers may be intelligible, and that we may avail ourſelves of much valuable information contained in them, by being able to perceive the truth in the midſt of their imperfect or erroneous conceptions of it. 21.

It is not only the popular opinion that reſt is the natural ſtate of body, and that motion is ſomething foreign to it, but it has been ſeriouſly maintained by the greateſt part of thoſe who are eſteemed philoſophers. They readily grant that matter will continue at reſt, unleſs ſome moving force act upon it. Nothing ſeems neceſſary for matter's remaining where it is, but its continuing to exiſt. But it is far otherwiſe, ſay they, with reſpect to matter in motion. Here the body is continually changing its relations to other things; therefore the continual agency of a changing cauſe is neceſſary (by the fundamental principle of all philoſophical diſcuſſion), for there is here the continual production of an effect. They ſay that this metaphyſical argument receives complete confirmation (if confirmation of an intuitive truth be neceſſary) from the moſt familiar obſervation. We ſee that all motions, however violent, terminate in reſt, and that the continual exertion of ſome force is neceſſary for their continuance. 22 Does continued motion indicate continued action?

Theſe philoſophers therefore aſſert, that the continual action of the moving cauſe is *eſſentially* neceſſary 23 Whimſical notion element for minds.

for the continuance of the motion: but they differ among themſelves in their notions and opinions about this cauſe. Some maintain, that all the motions in the univerſe are produced and continued by the immediate agency of Deity; others affirm, that in every particle of matter there is inherent a ſort of mind, the φυσις and ὑπερψυχη of Ariſtole, which they call an ELEMENTAL MIND, which is the cauſe of *all* its motions and changes. An overweaning reverence for Greek learning has had a great influence in reviving this doctrine of Ariſtotle. The Greek and Roman languages are affirmed to be more accurate expreſſions of human thought than the modern languages are. In thoſe ancient languages, the verbs which expreſs motion are employed both in the active and paſſive voice; whereas we have only the active verb *to move*, for expreſſing both the ſtate of motion and the act of putting in motion. "The ſtone *moves* down the ſlope, and *moves* all the pebbles which lie in its way;" but in the ancient languages the mere ſtate of motion is always expreſſed by the paſſive or middle voice. The accurate conception of the ſpeakers is therefore extolled. The ſtate of motion is expreſſed as it ought to be, as the reſult of a continual action." Κινειται, *movetur*, is equivalent to "it is moved." According to theſe philoſophers, every thing which *moves* is mind, and every thing that *is moved* is body.

The argument is futile, and it is falſe; for the modern languages are, in general, equally accurate in this inſtance: "*ſe mouvoir*," in French; "*ſich bewegen*," in German; "*dvigatſu*," in Sclavonic; are all paſſive or reflected. And the ancients ſaid, that "rain falls, water runs, ſmoke riſes," juſt as we do. The ingenious author of *Ancient Metaphyſics* has taken much pains to gives us, at length, the procedures of thoſe elementary minds in producing the oſtenſible phenomena of local motion; but it ſeems to be merely an abuſe of language, and a very frivolous abuſe. This elemental mind is known and characteriſed only by the effect which we aſcribe to its action; that is, by the motions or changes of motions. Uniform and unexcepted experience ſhews us that theſe are regulated by laws as preciſe as thoſe of mathematical truth. We conſider nothing as more fixed and determined than the common laws of mechaniſm. There is nothing here that indicates any thing like ſpontaneity, intention, purpoſe; none of thoſe marks by which mind was firſt brought into view: but they are very like the effects which we produce by the exertions of our corporeal forces; and we have accordingly given the name *force* to the cauſes of motion. It is ſurely much more appoſite than the name mind, and conveys with much more readineſs and perſpicuity the very notions that we wiſh to convey.

24 Action not neceſſary for the continuance of motion.

We now wiſh to know what reaſon we have to think that the continual action of ſome cauſe is neceſſary for continuing matter in motion, or for thinking that reſt is its natural ſtate. If we pretend to draw any argument from the nature of matter, that matter muſt be known, as far as is neceſſary for being the foundation of argument. Its very exiſtence is known only from obſervation; all our knowledge of it muſt therefore be derived from the ſame ſource.

If we take this way to come at the origin of this opinion, we ſhall find that experience gives us no authority for ſaying that reſt is the natural condition of matter. We cannot ſay that we have ever ſeen a body at reſt; this is evident to every perſon who allows the validity of the Newtonian philoſophy, and the truth of the Copernican ſyſtem of the ſun and planets; all the parts of this ſyſtem are in motion. Nay, it appears from many obſervations, that the ſun, with his attending planets, is carried in a certain direction, with a velocity which is very great. We have no unqueſtionable authority for ſaying that any one of the ſtars is abſolutely fixed: but we are *certain* that many of them are in motion. Reſt is therefore ſo rare a condition of body, that we cannot ſay, from any experience, that it is its natural ſtate.

It is eaſy, however, to ſee, that it is from obſervation that this opinion has been derived; but the obſervation has been limited and careleſs. Our experiments in this ſublunary world do indeed always require continued action of ſome moving force to continue the motion; and if this be not employed, we ſee the motions ſlacken every minute, and terminate in reſt after no long period. Our firſt notions of ſublunary bodies are indicated by their operation in caſes where we have ſome intereſt. Perpetually ſeeing our own exertions neceſſary, we are led to conſider matter as ſomething not only naturally quieſcent and inert, but ſluggiſh, averſe from motion, and prone to reſt (we muſt be pardoned this metaphorical language, becauſe we can find no other term). What is expreſſed by it, on this occaſion, is preciſely one of the erroneous or inadequate conceptions that are ſuggeſted to our thoughts by reaſon of the poverty of language. We animate matter in order to give it motion, and then we endow it with a ſort of moral character in order to explain the appearance of thoſe motions. 25.

But more extended obſervation has made men gradually deſert their firſt opinions, and at laſt allow that matter has no peculiar aptitude to reſt. All the retardations that we *obſerve* have been diſcovered, one after another, to have a diſtinct reference to ſome external circumſtances. The diminution of motion is always obſerved to be accompanied by the removal of obſtacles, as when a ball moves through ſand, or water, or air; or it is owing to oppoſite motions which are deſtroyed; or it is owing to roughneſs of the path, or to friction, &c. We find that the more we can keep thoſe things out of the way, the leſs are the motions diminiſhed. A pendulum will vibrate but a ſhort while in water; much longer in air; and in the exhauſted receiver, it will vibrate a whole day. We know that we cannot remove *all* obſtacles; but we are led by ſuch obſervations to conclude that, if they *could be completely removed*, our motions would continue for ever. And this concluſion is almoſt demonſtrated by the motions of the heavenly bodies, to which we know of no obſtacles, and which we really obſerve to retain their motions for many thouſand years without the ſmalleſt ſenſible diminution. 26.

Another ſet of philoſophers maintain an opinion directly oppoſite to that of the inactivity of matter, and aſſert, that it is eſſentially active, and continually changing its ſtate. Faint traces of this are to be found in the writings of Plato, Ariſtotle, and their commentators. Mr Leibnitz is the perſon who has treated this queſtion moſt ſyſtematically and fully. He ſuppoſes every particle of matter to have a principle of individuality, which he therefore calls a MONAD. This monad 27 Inactivity of matter denied by Leibnitz. *Monads*, what.

First Law of Motion.

nad has a ſort of *perception* of its ſituation in the univerſe, and of its relation to every other part of this univerſe. Laſtly, he ſays that the monad acts on the material particle, much in the ſame way that the ſoul of man acts on his body. It modifies the motion of the material atom (in conformity, however, to unalterable laws), producing all thoſe modifications of motion that we obſerve. Matter therefore, or at leaſt particles of matter, are continually active, and continually changing their ſituation.

This opinion ill founded.

It is quite unneceſſary to enter on a formal confutation of Mr Leibnitz's ſyſtem of monads, which differs very little from the ſyſtem of elemental minds, and is equally whimſical and frivolous; becauſe it only makes the unlearned reader ſtare, without giving him any information. Should it even be granted, it would not, any more than the action of animals, invalidate the general propoſition which we are endeavouring to eſtabliſh as the fundamental law of motion. Thoſe powers of the monads, or of the elemental minds, are the cauſes of all the changes of motion; but the mere material particle is ſubject to the law, and requires the exertion of the monad in order to exhibit a change of motion.

28 Some philoſophers deduce this law of motion from the want of a *determining* cauſe.

A third ſect of philoſophers, at the head of which we may place Sir Iſaac Newton, maintain the doctrine enounced in the propoſition. But they differ much in reſpect of the foundation on which it is built.

Some aſſert that its truth flows from the nature of the thing. If a body be at reſt, and you aſſert that it will not remain at reſt, it muſt move in ſome one direction. If it be in motion in any direction, and with any velocity, and do not continue its equable, rectilineal, motion, it muſt either be accelerated or retarded; it muſt turn either to one ſide, or to ſome other ſide. The event, whatever it be, is individual and determinate; but no cauſe which can determine it is ſuppoſed: therefore the determination cannot take place, and no change will happen in the condition of the body with reſpect to motion. It will continue at reſt, or perſevere in its rectilineal and equable motion.

But conſiderable objections may be made to this argument, of *ſufficient reaſon*, as it is called. In the immenſity and perfect uniformity of ſpace and time, there is no determining cauſe why the viſible univerſe ſhould exiſt in the place in which we ſee it rather than in another, or at this time rather than at another. Nay, the argument ſeems to beg the queſtion. A cauſe of determination is required as eſſentially neceſſary—a determination may be without a cauſe, as well as a motion without a cauſe.

29 Others deduce it from experience.

Other philoſophers, who maintain this doctrine, conſider it merely as an experimental truth; and proofs of its univerſality are innumerable.

When a ſtone is thrown from the hand, we preſs it forward while in the hand, and let it go when the hand has acquired the greateſt rapidity of motion that we can give it. The ſtone continues in that ſtate of motion which it acquired gradually along with the hand. We can throw a ſtone much farther by means of a ſling; becauſe, by a very moderate motion of the hand, we can whirl the ſtone round till it acquire a very great velocity, and then we let go one of the ſtrings, and the ſtone eſcapes, *by continuing* its rapid motion. We ſee it ſtill more diſtinctly in ſhooting an arrow from a bow. The ſtring preſſes hard on the notch of the arrow, and it yields to this preſſure and goes forward. The ſtring alone would go faſter forward. It therefore *continues* to preſs the arrow forward, and accelerates its motion. This goes on till the bow is as much unbent as the ſtring will allow. But the ſtring is now a ſtraight line. It came into this poſition with an accelerated motion, and it therefore goes a little beyond this poſition, but with a retarded motion, being checked by the bow. But there is nothing to check the arrow; therefore the arrow quits the ſtring, and flies away.

Theſe are ſimple caſes of perſeverance in a ſtate of motion, where the procedure of nature is ſo eaſily traced that we perceive it almoſt intuitively. It is no leſs clear in other phenomena which are more complicated; but it requires a little reflection to trace the proceſs. We have often ſeen an equeſtrian ſhowman ride a horſe at a gallop, ſtanding on the ſaddle, and ſtepping from it to the back of another horſe that gallops alongſide at the ſame rate; and he does this ſeemingly with as much eaſe as if the horſes were ſtanding ſtill. The man has the ſame velocity with the horſe that gallops under him, and keeps this velocity while he ſteps to the back of the other. If that other were ſtanding ſtill, the man would fly over his head. And if a man ſhould ſtep from the back of a horſe that is ſtanding ſtill to the back of another that gallops paſt him, he would be left behind. In the ſame manner, a ſlack wire-dancer toſſes oranges from hand to hand while the wire is in full ſwing. The orange, ſwinging along with the hand, retains the velocity; and when in the air follows the hand, and falls into it when it is in the oppoſite extremity of its ſwing. A ball, dropped from the maſt-head of a ſhip that is ſailing briſkly forward, falls at the foot of the maſt. It retains the motion which it had while in the hand of the perſon who dropped it, and follows the maſt during the whole of its fall.

We alſo have familiar inſtances of the perſeverance of a body in a ſtate of reſt. When a veſſel filled with water is drawn ſuddenly along the floor, the water daſhes over the poſterior ſide of the veſſel. It is left behind. In the ſame manner, when a coach or boat is dragged forward, the perſons in it find themſelves ſtrike againſt the hinder part of the carriage or boat. Properly ſpeaking, it is the carriage that ſtrikes on them. In like manner, if we lay a card on the tip of the finger, and a piece of money on the card, we may nick away the card, by hitting it neatly on its edge; but the piece of money will be left behind, lying on the tip of the finger. A ball will go through a wall and fly onward; but the wall is left behind. Buildings are thrown down by earthquakes; ſometimes by being toſſed from their foundations, but more generally by the ground on which they ſtand being haſtily drawn ſidewiſe from under them, &c.

But common experience ſeems inſufficient for eſtabliſhing this fundamental propoſition of mechanical philoſophy. We muſt, on the faith of the Copernican ſyſtem, grant that we never ſaw a body at reſt, or in uniform rectilineal motion; yet this ſeems abſolutely neceſſary before we can ſay that we have eſtabliſhed this propoſition experimentally. 30 Common experience inſufficient.

What we imagine, in our experiments, to be putting a body, formerly at reſt, into motion, is, in fact, only changing a moſt rapid motion, not leſs, and probably much greater, than 90,000 feet per ſecond. Suppoſe a cannon pointed eaſt, and the bullet diſcharged at noon day

First Law of Motion.

day with 60 times greater velocity than we have ever been able to give it. It would appear to set out with this unmeasurable velocity to the eastward; to be gradually retarded by the resistance of the air, and at last brought to rest by hitting the ground. But, by reason of the earth's motion round the sun, the fact is quite the reverse. Immediately before the discharge, the ball was moving to the westward with the velocity of 90,000 feet per second nearly. By the explosion of the powder, and its pressure on the ball, some of this motion is destroyed, and at the muzzle of the gun, the ball is moving slower, and the cannon is hurried away from it to the westward. The air, which is also moving to the westward 90,000 feet in a second, gradually communicates motion to the ball, in the same manner as a hurricane would do. At last (the ball dropping all the while) some part of the ground hits the ball, and carries it along with it.

Other observations must therefore be resorted to, in order to obtain an experimental proof of this proposition. And such are to be found. Although we cannot measure the absolute motions of bodies, we can observe and measure accurately their relative motions, which are the differences of their absolute motions. Now, if we can shew experimentally, that bodies shew equal tendencies to resist the augmentation and the diminution of their relative motions, they, *ipso facto*, shew equal tendencies to resist the augmentation or diminution of their absolute motions. Therefore let two bodies, A and B, be put into such a situation, that they cannot (by reason of their impenetrability, or the actions of their mutual powers) persevere in their relative motions. The change produced on A is the effect and the measure of B's tendency to persevere in its former state; and therefore the proportion of these changes will shew the proportion of their tendencies to maintain their former states. Therefore let the following experiment be made at noon.

Experiments proper for the purpose.

Let A, apparently moving westward three feet per second, hit the equal body B apparently at rest. Suppose, *1st*, That A impels B forward, without any diminution of its own velocity. This result would shew that B manifests no tendency to maintain its motion unchanged, but that A retains its motion undiminished.

2dly, Suppose that A stops, and that B remains at rest. This would shew that A does not resist a diminution of motion, but that B retains its motion unaugmented.

3dly, Suppose that both move westward with the velocity of one foot per second. The change on A is a diminution of velocity, amounting to two feet per second. This is the effect and the measure of B's tendency to maintain its velocity unaugmented. The change on B is an augmentation of one foot per second made on its velocity; and this is the measure of A's tendency to maintain its velocity undiminished. This tendency is but half of the former; and this result would shew, that the resistance to a diminution of velocity is but half of the resistance to augmentation. It is perhaps but one quarter; for the change on B has produced a double change on A.

4thly, Suppose that both move westward at the rate of $1\frac{1}{2}$ feet per second. It is evident that their tendencies to maintain their states unchanged are now equal.

5thly, Suppose A = 2 B, and that both move, after the collision, two feet per second, B has received an addition of two feet per second to its former velocity. This is the effect and the measure of A's whole tendency to retain its motion undiminished. Half of this change on B measures the persevering tendency of the half of A; but A, which formerly moved with the apparent or relative velocity three, now moves (by the supposition) with the velocity two, having lost a velocity of one foot per second. Each half of A therefore has lost this velocity, and the whole loss of motion is two. Now this is the measure of B's tendency to maintain its former state unaugmented; and this is the same with the measure of A's tendency to maintain its own former state undiminished. The conclusion from such a result would therefore be, that bodies have equal tendencies to maintain their former states of motion without augmentation and without diminution.

What is supposed in the *4th* and *5th* cases is really the result of all the experiments which have been tried; and this law regulates all the changes of motion which are produced by the mutual actions of bodies in impulsions. This assertion is true without exception or qualification. Therefore it appears that bodies have no preferable tendency to rest, and that no fact can be adduced which should make us suppose that a motion once begun should suffer any diminution without the action of a changing cause.

But experience is not the proper foundation of an axiom.

But we must now observe, that this way of establishing the first law of motion is very imperfect, and altogether unfit for rendering it the fundamental principle of a whole and extensive science. It is subject to all the inaccuracy that is to be found in our best experiments; and it cannot be applied to cases where scrupulous accuracy is wanted, and where no experiment can be made.

Let us therefore examine the proposition by means of the general principles adopted in the article PHILOSOPHY, *Encycl.* which contain the foundation of all our knowledge of active nature. These principles will, we imagine, give a decision of this question that is speedy and accurate, shewing the proposition to be an axiom or intuitive consequence of the relations of those ideas which we have of motion, and of the causes of its production and changes.

31 Logical proof.

It has been fully demonstrated that the powers or forces, of which we speak so much, are never the immediate objects of our perception. Their very existence, their kind, and their degree, are instinctive inferences from the motions which we observe and class. It evidently follows from this experimental and universal truth, *1st*, That where no change of motion is observed, no such inference is made; that is, no power is *supposed* to act. But whenever any change of motion is observed, the inference is made; that is, a power or force is supposed to have acted.

In the same form of logical conclusion, we must say that, *2dly*, When no change of motion is *supposed* or thought of, no force is *supposed*; and that whenever we *suppose* a change of motion, we, in fact, though not in terms, suppose a changing force. And, on the other hand, whenever we suppose the action of a changing force, we suppose the change of motion; for the action of this force, and the change of motion, is one and the same thing. We cannot think of the action without thinking of the indication of that action; that is, the change of motion.—In the same manner, when we do not think of a changing force, or suppose that there is

no

First Law of Motion.

no action of a changing force, we, in fact, though not in terms, suppose that there is no indication of this changing force; that is, that there is no change.

It is a law of human thought,

Whenever, therefore, we suppose that no mechanical force is acting on a body, we, in fact, suppose that the body continues in its former condition with respect to motion. If we suppose that nothing accelerates, or retards, or deflects the motion, we suppose that it is not accelerated, nor retarded, nor deflected. Hence follows the proposition in express terms—*We suppose that the body continues in its former state of rest or motion, unless we suppose that it is changed by some mechanical force.*

Thus it appears, that this proposition is not a matter of experience or contingency, depending on the properties which it has pleased the Author of Nature to bestow on body: it is, to us, a necessary truth. The proposition does not so much express any thing with regard to body, as it does the operations of our mind when contemplating body. It may perhaps be essential to body to move in some particular direction. It may be essential to body to stop as soon as the moving cause has ceased to act; or it may be essential to body to diminish its motion gradually, and finally come to rest. But this will not invalidate the truth of this proposition. These circumstances in the nature of body, which render those modifications of motion essentially necessary, are the causes of those modifications; and, in our study of nature, they will be considered by us as changing forces, and will be known and called by that name. And if we should ever see a particle of matter in such a situation that it is affected by those essential properties alone, we shall, from observation of its motion, discover what those essential properties are.

And almost an identical proposition.

This law turns out at last to be little more than a tautological proposition: But mechanical philosophy, as we have defined it, requires no other sense of it: for, even if we should suppose that body, of its own nature, is capable of changing its state, this change must be performed according to some law which characterises the nature of body; and the knowledge of the law can be had in no other way than by observing the deviations from uniform rectilineal motion. It is therefore indifferent whether those changes are derived from the nature of the thing, or from external causes: for in order to consider the various motions of bodies, we must first consider this nature of matter as a mechanical affection of matter, operating in every instance; and thus we are brought back to the law enounced in this proposition. This becomes more certain when we reflect that the external causes (such as gravity or magnetism), which are acknowledged to operate changes of motion, are equally unknown to us with this essential original property of matter, and are, like it, nothing but inferences from the phenomena.

The above very diffuse discussions may appear superfluous to many readers, and even cumbersome; but we trust that the philosophical reader will excuse our anxiety on this head, when he reflects on the complicated, indistinct, and inaccurate notions commonly had of the subject; and more especially when he observes, that of those who maintain the truth of this fundamental proposition, as we have enounced it, many (and they too of the first eminence), reject it in fact, by combining it with other opinions which are inconsistent with it, nay, which contradict it in express terms. We may even include Sir Isaac Newton in the number of those who have at least introduced modes of expression which mislead the minds of incautious persons, and suggest inadequate notions, incompatible with the pure doctrine of the proposition. Although, in words, they disclaim the doctrine that rest is the natural state of body, and that force is necessary for the continuation of its motion, yet in words they (and most of them in thought) likewise abet that doctrine: for they say, that there resides in a moving body a *power* or *force*, by which it perseveres in its motion. They call it the VIS INSITA, the INHERENT FORCE OF A MOVING BODY. This is surely giving up the question: for if the motion is supposed to be continued in consequence of a force, that force is *supposed* to be exerted; and it is supposed, that if it were not exerted, the motion would cease; and therefore the proposition must be false. Indeed it is sometimes expressed so as seemingly to ward off this objection. It is said that the body continues in uniform rectilineal motion, unless affected by some *external cause*. But this way of speaking obliges us, at first setting out in natural philosophy, to assert that gravity, magnetism, electricity, and a thousand other mechanical powers, are external to the matter which they put in motion. This is quite improper: It is the business of philosophy to discover whether they be external or not; and if we assert that they are, we have no principles of argumentation with those who deny it. It is this one thing that has filled the study of nature with all the jargon of æthers and other invisible intangible fluids, which has disgraced philosophy, and greatly retarded its progress. 32

Vis insita, inherent force, are improper terms in their usual acceptation.

We must observe, that the terms *vis insita*, inherent *force*, are very improper. There is no dispute among philosophers in calling every thing a force that produces a change of motion, and in inferring the action of such a force whenever we observe a change of motion. It is surely incongruous to give the same name to what has not this quality of producing a change, or to infer (or rather to suppose) the energy of a force when no change of motion is observed. This is one among many instances of the danger of mistake when we indulge in analogical discussions. All our language, at least, on this subject is analogous. I feel, that in order to oppose animal force, I must exert force. But I must exert force in order to oppose a body in motion: Therefore I imagine that the moving body possesses force. A bent spring will drive a body forward by unbending: Therefore I say that the spring exerts force. A moving body impels the body which it hits: Therefore I say, that the impelling body possesses and exerts force. I imagine farther, that it possesses force only by being in motion, or because it is in motion; because I do not find that a quiescent body will put another into motion by touching it. But we shall soon find this to be false in many, if not in all cases, and that the communication of motion depends on the mere vicinity, and not on the motion of the impelling body; yet we ascribe the exertion of the *vis insita* to the circumstance of the continued motion. We therefore conceive the force as arising from, or as consisting in, the impelling body's being in motion; and, with a very obscure and indistinct conception of the whole matter, we call it *the force by which the body preserves itself in motion*. Thus, taking it for granted that a force resides in the body, and being obliged to give it some office, this is the only one that we can think of.

But

First Law of Motion.

But philosophers imagine that they perceive the necessity of the exertion of a force in order to the continuation of a motion. Motion (say they) is a continued action; the body is every instant in a new situation; there is the continual production of an effect, therefore the continual action of a cause.

But this is a very inaccurate way of thinking. We have a distinct conception of motion; and we conceive that there is such a thing as a moving cause, which we distinguish from all other causes by the name *force*. It

33 Motion is not the continual production of an effect.

produces motion. If it does this, it produces the character of motion, which is a continual change of place. Motion is not action, but the effect of an action; and this action is as incomplete in the instant immediately succeeding the beginning of the motion as it is a minute after. The subsequent change of place is the continuation of an effect already produced. The *immediate* effect of the moving force is a DETERMINATION, by which, if not hindered, the body would go on for ever from place to place. It is in this determination only that the state or condition of the body can differ from a state of rest; for in any instant, the body does not describe any space, but has a determination, by which it will describe a certain space uniformly in a certain time. Motion is a condition, a state, or mode of existence, and no more requires the continued agency of the moving cause than yellowness or roundness does. It requires some chemical agency to change the yellowness to greenness; and it requires a mechanical cause or a force to change this motion into rest. When we see a moving body stop short in an instant, or be gradually, but quickly, brought to rest, we never fail to speculate about a cause of this cessation or retardation. The case is no way different in itself although the retardation should be extremely slow. We should always attribute it to a cause. It requires a cause to put a body out of motion as much as to put it into motion. This cause, if not external, must be found in the body itself; and it must have a self-determining power, and may as well be able to put itself into motion as out of it.

If this reasoning be not admitted, we do not see how any effect can be produced by any cause. Every effect supposes something *done*; and any thing done implies that the thing done may remain till it be *undone* by some other cause. Without this, it would have no existence. If a moving cause did not produce continued motion by its instantaneous action, it could not produce it by any continuance of that action; because in no instant of that action does it produce continued motion.

We must therefore give up the opinion, that there resides in a moving body a force by *which it is kept in motion*; and we must find some other way of explaining that remarkable difference between a moving body and a body at rest, by which the first causes other bodies to move by hitting them, while the other does not do this by merely touching them. We shall see, with the clearest evidence, that motion is necessary in the impelling body, in order that it may permit the forces inherent in one or both bodies to continue this pressure long enough for producing a sensible or considerable motion. But these moving forces are inherent in bodies, whether they are in motion or at rest.

The foregoing observations shew us the impropriety of the phrase *communication of motion*. By thus reflecting on the notions that are involved in the general conception of one body being made to move by the impulse of another, we perceive that there is nothing individual transferred from the one body to the other. The determination to motion, indeed, existed only in the impelling body before collision; whereas, afterwards, both bodies are so conditioned or determined. But we can form no notion of the thing transferred. With the same metaphysical impropriety, we speak of the communication of joy, of fever.

34 Communication of motion is an improper phrase,

Kepler introduced a term INERTIA, VIS INERTIÆ, into mechanical philosophy; and it is now in constant use. But writers are very careless and vague in the notions which they affix to these terms. Kepler and Newton seem generally to employ it for expressing the fact, the perseverance of the body in its present state of motion or rest: but they also frequently express by it something like an indifference to motion or rest, *manifested by its requiring the same quantity of force to make an augmentation of its motion as to make an equal diminution of it*. The popular notion is like that which we have of actual resistance; and it always implies the notion of force *exerted* by the resisting body. We suppose this to be the exertion of the *vis insita*, or the *inherent force* of a body in motion. But we have the same notion of resistance from a body at rest which we set in motion. Now surely it is in direct contradiction to the common use of the word *force*, when we suppose resistance from a body at rest; yet *vis inertiæ* is a very common expression. Nor is it more absurd (and it is very absurd) to say, that a body maintains its state of rest by the exertion of a *vis inertiæ*, than to say, that it maintains its state of motion by the exertion of an *inherent force*. We should avoid all such metaphorical expressions as *resistance*, *indifference*, *sluggishness*, or *proneness to rest* (which some express by *inertia*), because they seldom fail to make us indulge in metaphorical notions, and thus lead us to misconceive the *modus operandi*, or procedure of nature.

35 So is *vis inertiæ*.

There is *no resistance whatever observed* in these phenomena; for the force employed always produces its *complete* effect. When I throw down a man, and find that I have employed no more force than was sufficient to throw down a similar and equal mass of dead matter, I know by this that he *has not* resisted; but I conclude that he *has* resisted, if I have been obliged to employ much more force. There is therefore no resistance, properly so called, when the exerted force is observed to produce its full effect. To say that there *is* resistance, is therefore a real misconception of the way in which mechanical forces have operated in the collision of bodies. There is no more resistance in these cases than in any other natural changes of condition. We are guilty, however, of the same impropriety of language in other cases, where the cause of it is more evident. We say that colours in grain *resist* the action of soap and of the sun, but that Prussian blue does not. We all perceive, that in this expression the word resistance is entirely figurative: and we should say that Prussian blue *resists* soap, if we are right in saying that a body resists any force employed to change its state of motion; for soap must be employed to discharge or change the colour; and *it does change it*. Force must be employed to change a motion; *and it does change it*. The impropriety, both of thought and language, is *plain* in the one case, and it is no less *real* in the other. Both

of

of the terms, *inherent force* and *inertia*, may be used with safety for abbreviating language, if we be careful to employ them only for expressing, *either the simple fact of persevering in the former state*, or *the necessity of employing a certain determinate force, in order to change that state, and if we avoid all thought of resistance.*

36 Deviations from uniform rectilineal motion are the only indications of force.

From the whole of this discussion, we learn, that the deviations from uniform motions are the indications of the existence and agency of mechanical forces, and that they are the only indications. The indication is very simple, mere change of place; it can therefore indicate nothing but what is very simple, the something competent to the production of the very motion that we observe. And when two changes of motion are precisely similar, they indicate the same thing. Suppose a mariner's compass on the table, and that by a small tap with my finger I cause the needle to turn off from its quiescent position 10 degrees. I can do the same thing by bringing a magnet near it; or by bringing an electrified body near it; or by the unbending of a fine spring pressing it aside; or by a puff of wind; or by several other methods. In all these cases, the indication is the same; therefore the thing indicated is the same, namely, a certain intensity and direction of a moving power. How it operates, or in what manner it exists and exerts itself in these instances, outwardly so different, is not under consideration at present Impulsiveness, intensity, and direction, are all the circumstances of resemblance by which the affections of matter are to be characterised; and it is to the discovery and determination of these alone that our attention is now to be directed. We are directed in this research by the

Second Law of Motion.

Every change of motion is proportional to the force impressed, and is made in the direction of that force.

37. This law also may almost be considered as an identical proposition; for it is equivalent to saying, that the changing force is to be measured by the change which it produces, and that the direction of this force is the direction of the change. Of this there can be no doubt, when we consider the force in no other sense than that of the cause of motion, paying no attention to the form or manner of its exertion. Thus, when a pellet of tow is shot from a pop-gun by the expansion of the air compressed by the rammer, or where it is shot from a toy pistol by the unbending of the coiled wire, or when it is nicked away by the thumb like a marble—if, in all these cases, it moves off in the same direction, and with the same velocity, we cannot consider or think of the force, or at least of its exertion, as any how different. Nay, when it is driven forward by the instantaneous percussion of a smart stroke, although the manner of producing this effect (if possible) is essentially different from what is conceived in the other cases, we must still think that the propelling force, considered as a propelling force, is one and the same. In short, this law of motion, as thus expressed by Sir Isaac Newton, is equivalent to saying, "That we take the changes of motion as the measures of the changing forces, and the direction of the change for the indication of the direction of the forces:" For no reflecting person can pretend to say, that it is a deduction from the acknowledged principle, that effects are proportional to their causes. We do not affirm this law, from having observed the proportion of the forces and the proportion of the changes, and that these proportions are the same; and from having observed that this has obtained through the whole extent of our study of nature. This would indeed establish it as a physical law, an universal fact; and it is, in fact, so established. But this does not establish it as a law of motion, according to our definition of that term; as a law of human thought, the result of the relations of our ideas, as an intuitive truth. The injudicious attempts of philosophers to prove it as a matter of observation, have occasioned the only dispute that has arisen in mechanical philosophy. It is well known that a bullet, moving with double velocity, penetrates four times as far. Many other similar facts corroborate this: and the philosophers observe, that four times the force has been expended to generate this double velocity in the bullet; it requires four times as much powder. In all the examples of this kind, it would seem that the ratio of the forces employed has been very accurately ascertained; yet this is the invariable result. Philosophers, therefore, have concluded, that moving forces are not proportional to the velocities which they produce, but to the squares of those velocities. It is a strong confirmation, to see that the bodies in motion seem to possess forces in this very proportion, and produce effects in this proportion; penetrating four times as deep when the velocity is only twice as great, &c.

But if this be a just estimation, we cannot reconcile it to the concession of the same philosophers, who grant that the velocity is proportional to the force impressed, in the cases where we have no previous observation of the ratio of the forces, and of its equality to the ratio of the velocities. This is the case with gravity, which these philosophers always measure by its accelerating power, or of the velocity which it generates in a given time. And this cannot be refused by them; for cases occur, where the force can be measured, in the most natural manner, by the actual pressure which it exerts. Gravity is thus measured by the pressure which a stone exerts on its supports. A weight which at Quito will pull out the rod of a spring steelyard to the mark 312, will pull it to 313 at Spitzbergen. And it is a fact, that a body will fall 313 inches at Spitzbergen in the same time that it falls 312 at Quito. Gravitation is the cause both of the pressure and the fall; and it is a matter of unexcepted observation, that they have always the same ratio. The philosophers who have so strenuously maintained the other measure of forces, are among the most eminent of those who have examined the motions produced by gravity, magnetism, electricity, &c.; and they never think of measuring those forces any other way than by the velocity. It is in this way that the whole of the celestial phenomena are explained in perfect uniformity with observation, and that the Newtonian philosophy is considered as a demonstrative science.

There must, therefore, be some defect in the principle on which the other measurement of forces is built, or in the method of applying it. Pressure is undoubtedly the immediate and natural measure of force; yet we know that four springs, or a bow four times as strong, give only a double velocity to an arrow.

The truth of our law rests on this only, that we assume the changes of motion as the measure of the changing forces; or, at least, as the measures of their exertions in producing motion. In fact, they are the measures only of

Second Law of Motion

of a certain circumſtance, in which the actions of very different natural powers may reſemble each other; namely, the competency to produce motion. They do not, perhaps, meaſure their competency to produce heat, or even to bend ſprings. We can ſurely conſider this apart from all other circumſtances; and it is worthy of ſeparate conſideration. Let us ſee what can be, and what ought to be, deduced from this way of treating the ſubject.

38 Change of motion is, itſelf, a motion.

The motion of a body may certainly remain unchanged. If the direction and velocity remain the ſame, we perceive no circumſtance in which its condition, with reſpect to motion, differs. Its change of place or ſituation can make no difference; for this is implied in the very circumſtance of the body's being in motion.

But if either the velocity or direction change, then ſurely is its mechanical condition no longer the ſame; a force has acted on it, either intrinſic or from without, either accelerating, or retarding, or deflecting it. Suppoſing the direction to remain the ſame, its difference of condition can conſiſt in nothing but its difference of velocity. This is the only circumſtance in which its condition can differ, as it paſſes through two different points of its rectilineal path. It is this determination by which the body will deſcribe a certain determinate ſpace uniformly in a given time, which defines its condition as a moving body: the changes of this determination are the meaſures of their own cauſes;—and to thoſe cauſes we have given the name *force*. Thoſe cauſes may reſide in other bodies, which may have other properties, characteriſed and meaſured by other effects. Preſſure may be one of thoſe properties, and may have its own meaſures; theſe may, or may not, have the ſame proportion with that property which is the cauſe of a change of velocity: and therefore changes of velocity may not be a meaſure of preſſure. This is a queſtion of fact, and requires obſervation and experience; but, in the mean time, velocity, and the change of velocity, is the meaſure of moving force and of changing force. When therefore the change of velocity is the ſame, whatever the previous velocity may be, the changing force muſt be conſidered as the ſame: therefore, finally, if the previous velocity is nothing, and conſequently the change on that body is the very velocity or motion that it acquires, we muſt ſay, that the force which produces a certain change in the velocity of a moving body, is the ſame with the force which would impart to a body at reſt a velocity equal to this change or difference of velocity produced on the body already in motion.

39. This manner of eſtimating force is in perfect conformity to our moſt familiar notions on theſe ſubjects. We conceive the weight or downward preſſure of a body as the cauſe of its motion downwards; and we conceive it as belonging to the body at all times, and in all places, whether falling, or riſing upwards, or deſcribing a parabola, or lying on a table; and, accordingly, we obſerve, that in every ſtate of motion it receives equal changes of velocity in the ſame, or an equal time, and all in the direction of its preſſure.

40. All that we have now ſaid of a change of velocity might be repeated of a change of direction. It is ſurely poſſible that the ſame change of direction may be made on any two motions. Let one of the motions be conſidered as growing continually ſlower, and terminating in reſt. In every inſtant of this motion it is poſſible to make one and the ſame change on it. The ſame change may therefore be made at the very inſtant that the motion is at an end. In this caſe, the change is the very motion which the body acquires from the changing force. Therefore, in this caſe alſo, we muſt ſay, that a change of motion is itſelf a motion, and that it is the motion which the force would produce in a body that was previouſly at reſt.

41 How aſcertained and meaſured.

The reſult of theſe obſervations is evidently this, that we muſt aſcertain, in every inſtance, what is the change of motion, and mark it by characters that are conſpicuous and diſtinguiſhing; and this mark and meaſure of change muſt be a motion: Then we muſt ſay, that the changing force is that which would produce this motion in a body previouſly at reſt. We muſt ſee how this is manifeſt, as a motion, in the difference between the former motion and the new motion; and, on the other hand, we muſt ſee how the motion produceable in a quieſcent body may be ſo combined with a motion already exiſting, as to exhibit a new motion, in which the agency of the changing force may appear.

Suppoſe a ſhip at anchor in a ſtream; while one man walks forward on the quarter-deck at the rate of two miles per hour, another walks from ſtem to ſtern at the ſame rate, a third walks athwart ſhip, and a fourth ſtands ſtill. Let the ſhip be ſuppoſed to cut or part her cable, and float down the ſtream at the rate of three miles per hour. We cannot conceive any difference in the change made on each man's motion in abſolute ſpace; but their motions are now exceedingly different from what they were: the firſt man, whom we may ſuppoſe to have been walking weſtward, is now moving eaſtward one mile per hour; the ſecond is moving eaſtward four miles per hour; and the third is moving in an oblique direction, about three points north or ſouth of due eaſt. All have ſuffered the ſame change of condition with the man who had been ſtanding ſtill. He has now got a motion eaſtward three miles per hour. In this inſtance, we ſee very well the circumſtance of ſameneſs that obtains in the change of theſe four conditions. It is the motion of the ſhip, which is blended with the other motions. But this circumſtance is equally preſent whenever the ſame previous motions are changed into the ſame new motions. We muſt learn to expiſcate this; which we ſhall do, by conſidering the manner in which the motion of the ſhip is blended with each of the mens motions.

42 Compoſition of motion.

This kind of combination has been called the Composition of motion; becauſe, in every point of the motion really purſued, the two motions are to be found.

The fundamental theorem on this ſubject is this:—Two uniform motions in the ſides of a parallelogram compoſe an uniform motion in the diagonal.

Plate XXI.

Suppoſe that a point A (fig. 1.) deſcribes AB uniformly in ſome given time, while the line AB is carried uniformly along AC in the ſame time, keeping always parallel to its firſt poſition AB. The point A, by the combination of theſe motions, will deſcribe AD, the diagonal of the parallelogram ABDC, uniformly in the ſame time.

For it is plain, that the velocities in AB and AC are proportional to AB and AC, becauſe they are uniformly deſcribed in the ſame time. When the point has got to E, the middle of AB, the line AB has got into the ſituation GH, half way between AB and CD,

and

Second Law of Motion.

and the point E is in the place *e*, the middle of GH. Draw E*e*L parallel to AC. It is plain that the parallelograms ABDC and AE*e*G are ſimilar; becauſe AE and AG are the halves of AB and AC, and the angle at A is common to both. Therefore, by a propoſition in the Elements, they are about the ſame diagonal, and the point *e* is in the diagonal of AD. In like manner, it may be ſhewn, that when A has deſcribed AF, $\frac{3}{4}$ths of AB, the line AB will be in the ſituation IK, ſo that AI is $\frac{3}{4}$ths of AC, and the point *f*, in which A is now found, is in the diagonal AD. It will be the ſame in whatever point of AB the deſcribing point A be ſuppoſed to be found. The line AB will be on a ſimilar point of AC; and the deſcribing point will be in the diagonal AD.

Moreover, the motion in AD is uniform: for A*e* is deſcribed in the time of deſcribing AE; that is, in half the time of deſcribing AB, or in half the time of deſcribing AD. In like manner, A*f* is deſcribed in $\frac{3}{4}$ths of the time of deſcribing AD, &c. &c.

Laſtly, the velocity in the diagonal AD is to the velocity in either of the ſides as AD is to that ſide. This is evident, becauſe they are uniformly deſcribed in the ſame time.

This is juſtly called *a compoſition of the motions* AB *and* AC, as will appear by conſidering it in the following manner: Let the lines AB, AC be conceived as two material lines like wires. Let AB move uniformly from the ſituation AB into the ſituation CD, while AC moves uniformly into the ſituation BD. It is plain that their interſection will always be found on AD. The point *e*, for example, is a point common to both lines. Conſidered as a point of EL, it is then moving in the direction *e*H or AB; and, conſidered as a point of GH, it is moving in the direction *e*L. Both of theſe motions are therefore blended in the motion of the interſection along AD. We can conceive a ſmall ring at *e*, embracing looſely both of the wires. This material ring will move in the diagonal, and *will really partake* of both motions.

Thus we ſee how the motion of the ſhip is actually blended with the motions of the three men; and the circumſtance of ſameneſs which is to be found in the four changes of motion is this motion of the ſhip, or of the man who was ſtanding ſtill. By compoſition with each of the three former motions, it produces each of the three new motions. Now, when each of two primitive motions is the ſame, and each of the new motions is the ſame, the change is ſurely the ſame. If one of the changes has been brought about by the actual compoſition of motions, we know preciſely what that change is; and this informs us what the other is, in whatever way it was produced. Hence we infer, that,

43 Its mark and meaſure.

When a motion is any how changed, the change is that motion which, when compounded with the former motion, will produce the new motion. Now, becauſe we aſſume the change as the meaſure and characteriſtic of the changing force, we muſt do ſo in the preſent inſtance; and we muſt ſay,

44 Changing force.

That *the changing force is that which will produce in a quieſcent body the motion which, by compoſition with the former motion of a body, will produce the new motion.*

And, on the other hand,

Its effect.

When the motion of a body is changed by the action of any force, the new motion is that which is compounded of the former motion, and of the motion which the force would produce in a quieſcent body.

Deflecting force.

When a force changes the direction of a motion, we ſee that its direction is tranſverſe in ſome angle BAC; becauſe a diagonal AD always ſuppoſes two ſides. As we have diſtinguiſhed any change of direction by the term DEFLECTION, we may call the tranſverſe force a DEFLECTING FORCE.

In this way of eſtimating a change of motion, all the characters of both motions are preſerved, and it expreſſes every circumſtance of the change; the mere change of direction, or the angle BAD, is not enough, becauſe the ſame force will make different angles of deflection, according to the velocity of the former motion, or according to its direction: but in this eſtimation, the full effect of the deflecting force is ſeen; it is ſeen *as a motion;* for when half of the time is elapſed, the body is at *e* inſtead of E; when three-fourths are elapſed, it is at *f* inſtead of F; and at the end of the time it is at D inſtead of B. In ſhort, the body has moved uniformly away from the points at which it would have arrived independent of the change; and this motion has been in the ſame direction, and at the ſame rate, as if it had moved from A to C by the changing force alone. Each force has produced its full effect; for when the body is at D, it is as far from AC as if the force AC had not acted on it; and it is as far from AB as it would have been by the action of AC alone.

For all theſe reaſons, therefore, it is evident, that if we are to abide by our meaſure and character of force as a mere producer of motion, we have ſelected the proper characteriſtic and meaſure of a changing force: and our deſcriptions, in conformity to this ſelection, muſt be agreeable to the phenomena of nature, and retain the accuracy of geometrical procedure; becauſe, on the other hand, the reſults which we deduce from the ſuppoſed influence of thoſe forces are formed in the ſame mould. It is not even requiſite that the real exertions of the natural forces, ſuch as preſſure of various kinds, &c. ſhall follow theſe rules; for their deviations will be conſidered as new forces, although they are only indications of the differences of the real forces from our hypotheſis. We have obtained the precious advantage of mathematical inveſtigation, by which we can examine the law of exertion which characteriſes every force in nature.

On theſe principles we eſtabliſh the following fundamental elementary propoſition, of continual and indiſpenſable uſe in all mechanical inquiries.

45 Fundamental theorem.

If a body or material particle be ſubjected at the ſame time to the action of two moving forces, each of which would ſeparately cauſe it to deſcribe the ſide of a parallelogram uniformly in a given time, the body will deſcribe the diagonal uniformly in the ſame time.

For the body, whoſe motion AB was changed into AD, had gotten its motion by the action of ſome force. It was moving along NAB; and, when it reached the point A, the force AC acted on it. The primitive motion is the ſame, or the body is in the ſame condition in every inſtant of the primitive motion. It may have acquired this motion when it was in N, or when at O, or any other point of NA. In all theſe caſes, if AC act on it when it is in A, it will always deſcribe AD; therefore it will deſcribe AD when it acquires the primitive motion alſo in A; that is, if the two forces

Second Law of Motion

ces act on it at one and the same instant. The demonstration may be neatly expressed thus: The change induced by each force on the motion produced by the other, is the motion which it would produce in the body if previously at rest. Therefore the motion resulting from joint action is the motion which is compounded of these two motions; or it is a motion in the diagonal of the parallelogram, of which these motions are the sides.

Composition of forces.

This is called the COMPOSITION OF FORCES. The forces which produce the motions along the sides of the parallelogram are called the SIMPLE FORCES, or the CONSTITUENT FORCES; and the force which would alone produce the motion along the diagonal is called the COMPOUND FORCE, the RESULTING FORCE, the EQUIVALENT FORCE.

46. On the other hand, the force which produces a motion along any line whatever, may be conceived as resulting from the combined action of two or more forces. We may *know* or *observe* it to be so; as when we see a lighter dragged along a canal by two horses, one on each side. Each pulls the boat directly toward himself in the direction of the track-rope; the boat cannot go both ways, and its real motion, whatever it is, results from this combined action. This might be produced by a single force; for example, if the lighter be dragged along the canal by a rope from another lighter which precedes it, being dragged by one horse, aided by the helm of the foremost lighter. Here the real force is not the resulting, or the compound, but the equivalent force.

Resolution of forces.

This view of a motion, mechanically produced, is called the RESOLUTION OF FORCES. The force in the diagonal is said to be *resolved* into the two forces, having the directions and velocities represented by the sides. This practice is of the most extensive and multifareous use in all mechanical disquisitions. It may frequently be exceedingly difficult to manage the complication of the many real forces which concur in producing a phenomenon; and by substituting others, whose combined effects are equivalent, our investigation may be much expedited. But more of this afterwards.

We must carefully remember, that when the motion AD is once begun, all composition is at an end, and the motion is a simple motion. The two determinations, by one of which the body would describe AB, and by the other of which it would describe AC, no longer *co-exist* in the body. This was the case only *in the instant*, in the very act of changing the motion AB into the motion BD; yet is the motion AD equivalent to a motion which is produced by the *actual composition* of two motions AB and AC; in which case the two motions co-exist in every point of AD.

47
Usual demonstration inconclusive.

Accordingly this is the way in which the composition of forces is usually illustrated, and thought to be demonstrated. A man is supposed (for instance) to walk uniformly from A to C on a sheet of ice, while the ice is carried uniformly along AB by the stream. The man's real motion is undoubtedly along AD; but this is by no means a demonstration that the instantaneous or short-lived action of two forces would produce that motion; the man must continue to exert force in order to walk, and the ice is dragged along by the stream. Some indeed express this proof in another way, saying, let a body describe AB, while the space in which this motion is performed is carried along AC. The ice may be carried along, and may, by friction, or otherwise, drag the man along with it; but a space cannot be removed from one place to another, nor, if it could, would it take the man with it. Should a ship start suddenly forward while a man is walking across the deck, he would be left behind, and fall toward the stern. We must *suppose* a transverse force, and we must *suppose* the composition of this force without proof. This is no demonstration.

We apprehend that the demonstration given above of this fundamental proposition is unexceptionable, when the terms force and deflection are used in the abstract sense which we have affixed to them; and we hope, by these means, to maintain the rigour of mathematical discussion in all our future disquisitions on these subjects. The only circumstance in it which can be the subject of discussion is, whether we have selected the proper measure and characteristic of a change of motion—We never met with any objection to it.

48
Objections to the demonstration of n° 45. It will not apply to pressures.

But some have still maintained, that it does not evidently appear, from these principles, that the motion which results from the joint action of two natural powers, whose known and measurable intensities have the same proportions with AB and BC, and which also exert themselves in those directions, will produce a motion, having the direction and proportion of AD. They will not, if the velocities produced by these forces are not in the proportion of those intensities, but in the subduplicate ratio of them. Nay, they say, that it is not so. If a body be impelled along AC by one spring, and along AB by two springs equally strong, it will not describe the diagonal of a parallelogram, of which the side AB is double the side AC. Nay, they add, that an indefinite number of examples can be given where a body *does not* describe the diagonal of the parallelogram by the joint action of two forces, which, separately, would cause it to describe the sides. And, lastly, they say that, at any rate, it does not appear evident to the mind, that two *incitements* to motion, having the directions and the same proportion of intensity with that of the sides of a parallelogram, actually generate a third, which is the immediate cause of the motion in the diagonal. An equivalent force is not the same with a resulting force.

Yet we see numberless cases of the composition of incitements to motion, and they seem as determinate, and as susceptible of being combined by composition, as the things called moving forces, which are measured by the velocities: we see them actually so combined in a thousand instances, as in the example already given of a lighter dragged by two horses pulling in different directions. Nay, experiment shews, that this composition follows precisely the same rule as the composition of the forces which are measured by the velocities; for if the point A (fig. 1.) be pulled by a thread, or pressed by a spring, in the direction AB, and by another in the direction AC, and if the pressures are proportional to AB and AC, then it will be withheld from moving, if it be pulled or pressed by a third force, acting in the direction A *d*, opposite to AD, the pressure being also proportional to AD. This force, acting in the direction A *d*, would certainly withstand an equal force acting in the direction AD; therefore we must conclude, that the two pressures AB and AC really generate a force AD. This uniform agreement shews 49.

that

that the compoſition is deducible from fixed principles; but it does not appear that it can be held as demonſtrated by the arguments employed in the caſe of motions. A demonſtration of the compoſition of preſſures is ſtill wanted, in order to render mechanics a demonſtrative ſcience.

This compoſition is of more difficult inveſtigation.

Accordingly, philoſophers of the firſt eminence have turned their attention to this problem. It is by no means eaſy; being ſo nearly allied to firſt principles, that it muſt be difficult to find axioms of greater ſimplicity by which it may be proved.

Mechanicians generally contented themſelves with the ſolution given by Ariſtotle; but this is merely a compoſition of motions: indeed he does not give it for any thing elſe, and calls it "συνθεσις των φυ αν." The firſt writer who appears to have conſidered it as different from the mere compoſition of motions, was the celebrated Dutch engineer Stevinus in his work *on Sluices*; but his ſolution is obſcure. It was ſufficient, however, to convince Daniel Bernoulli of the neceſſity and the difficulty of the problem. He has given the firſt complete demonſtration of it in the firſt volume of the Commentaries of the Imperial Academy of Sciences at St Peterſburgh. It is extremely ingenious; but it is tedious and intricate, requiring a ſeries of 15 propoſitions to demonſtrate that two preſſures, having the directions and magnitudes of the ſides of any parallelogram, compoſe a third, which has the direction and magnitude of its diagonal. His firſt propoſition is, that *two equal preſſures, acting at right angles, compoſe a third, in the direction of the diagonal of a ſquare, and having to either of the other two the proportion of the diagonal of a ſquare to its ſides.*

Mr D'Alembert has greatly ſimplified and improved this demonſtration, by beginning with a caſe that is ſelf-evident; namely, *If three equal forces are inclined to each other in equal angles of* 120 *degrees, any one of them will balance the combined action of the other two.* Surely; for neither of them can prevail. Therefore *two* equal forces, inclined in an angle of 120 degrees, produce a third, which has the direction and proportion of the diagonal of the rhombus; for this is equal and oppoſite to one of the three above mentioned. He then demonſtrates the ſame thing of two equal forces inclined in *any* angle; and by a ſeries of eight propoſitions more, demonſtrates the general theorem. This diſſertation is in the Memoirs of the Academy at Paris for 1769. He improves it ſtill farther in a ſubſequent memoir.

Mr Riccati and Mr Fonſenex, in the Commentaries of the Academy of Turin, have given analytical demonſtrations, which are alſo very ingenious and conciſe, but require acquaintance with the higher mathematics.—There is another very ingenious demonſtration in the *Journal des Sçavans* for June 1764, but too obſcure for an elementary propoſition. It is ſomewhat ſimplified by Belidor in his *Ingenieur François*. Friſius, in his *Coſmographia*, has given one, which is perhaps the beſt of all thoſe that are eaſily comprehended without acquaintance with the higher mathematics: but we imagine that, although no one can doubt of the concluſion, it has not that intuitive evidence for every ſtep of the proceſs that ſeems neceſſary.

50 *Compoſition of preſſures.*

We here offer another, compoſed by blending together the methods of Bernoulli and D'Alembert; and we imagine that no objection can be made to any ſtep of it. We limit it entirely to preſſures, and do not at all conſider nor employ the motions which they may be ſuppoſed to produce.

(A) If two equal and oppoſite preſſures or incitements to motion act at once on a material particle, it ſuffers no change of motion; for if it yields in either direction by their joint action, one of the preſſures prevails, and they are not equal.

Equal and oppoſite preſſures are ſaid TO BALANCE each other; and ſuch as balance muſt be eſteemed equal and oppoſite.

(B) If a and b are two magnitudes of the ſame kind, proportional to the intenſities of two preſſures which act in the ſame direction, then the magnitude $a+b$ will meaſure the intenſity of the preſſure, which is equivalent, and may be called equal, to the combined effort of the other two; for when we try to form a notion of preſſure as a meaſurable magnitude, diſtinct from motion or any other effect of it, we find nothing that we can meaſure it by but another preſſure. Nor have we any notion of a double or triple preſſure different from a preſſure that is equivalent to the joint effort of two or three equal preſſures. A preſſure a is accounted triple of a preſſure b, if it balances three preſſures, each equal to b, acting together. Therefore, in all proportions which can be expreſſed by numbers, we muſt acknowledge the legitimacy of this meaſurement; and it would ſurely be affectation to omit thoſe which the mathematicians call *incommenſurable.*

In like manner, the magnitude $a-b$ muſt be acknowledged to meaſure that preſſure which ariſes from the joint action of two preſſures a and b acting in oppoſite directions, of which a is the greateſt.

(C) Let ABCD and AbCd (fig. A) be two rhombuſes, which have the common diagonal AC. Let the angles BAb, DAd, be biſected by the ſtraight lines AE and AF.

If there be drawn from the points E and F the lines EG, EH, Fg, Fh, making equal angles on each ſide of EA and FA, and if Gg, Hh be drawn, cutting the diagonal AC in I and L: then AI + AL will be greater or leſs than AQ, the half of AC, according as the angles GEH, gFh, are greater or leſs than GAH, gAh.

Draw GH, gh, cutting AE, AF, in O and o, and draw Oo, cutting AC in K.

Becauſe the angles AEG and EAG are reſpectively equal to AEH and EAH, and AE is common to both triangles, the ſides AG, GE are reſpectively equal to AH, HE, and GH is perpendicular to AE, and is biſected in O; for the ſame reaſons, gh is biſected in o. Therefore the lines Gg, Oo, Hh, are parallel, and IL is biſected in K. Therefore AI + AL is equal to twice AK. Moreover, if the angle GEH be greater than GAH, AO is greater than EO, and AK is greater than KQ. Therefore AI + AL is greater than AQ; and if the angle GEH be leſs than GAH, AI + AL is leſs than AQ.

(D) Two equal preſſures, acting in the directions AB and AC (fig. 2.), at right angles to each other, compoſe a preſſure in the direction AD, which biſects the right angle; and its intenſity is to the intenſity of each of the conſtituent preſſures as the diagonal of a ſquare to one of the ſides. It is evident that the direction of the preſſure, generated by their joint action, will

Second Law of Motion.

will bisect the angle formed by their directions; because no reason can be assigned for the direction inclining more to one side than to the other.

In the next place, since a force in the direction AD does, in fact, arise from the joint action of the equal pressures AB and AC, the pressure AB may be conceived as arising from the joint action of two equal forces similarly inclined and proportioned to it. Draw EAF perpendicular to AD. One of these forces must be directed along AD, and the other along AE. In like manner, the pressure AC may arise from the joint action of a pressure in the direction AD, and an equal pressure in the direction AF. It is also plain, that the pressures in the directions AE and AF, and the two pressures in the direction AD, must be all equal. And also, any one of them must have the same proportion to AB or to AC, that AB or AC has to the force in the direction AD, arising from their joint action.

Therefore, if it be said that AD does not measure the pressure arising from the joint action of AB and AC, let A *d*, greater than AD, be its just measure, and make A *d* : AB = AB : A *g* = AB : A *e*. Then A *g* and A *e* have the same inclination and proportion to AB that AB and AC have to A *d*. We determine, in like manner, two forces A *f* and A *g* as constituents of AC.

Now A *d* is equivalent to AB and AC, and AB is equivalent to A *e* and A *g*; and AC is equivalent to A *f* and A *g*. Therefore A *d* is equivalent to A *e*, A *f*, A *g*, and A *g*. But (A) A *e* and A *f* balance each other, or annihilate each other's effect; and there remain only the two forces or pressures A *g*, A *g*. Therefore (B) their measure is a magnitude equal to twice A *g*. But if A *d* be greater than the diagonal AD of the square, whose sides are AB and AC; then A *g* must be less than AI, the side of the square whose diagonal is AB. But twice A *g* is less than AD, and much less than A *d*. Therefore the measure of the equivalent of AB and AC cannot be a line A *d* greater than AD. In like manner, it cannot be a line A *δ* that is less than AD. Therefore it must be equal to AD, and the proposition is demonstrated.

(E) *Cor.* Two equal forces AB, AC, acting at right angles, will be balanced by a force AO, equal and opposite to AD, the diagonal of the square whose sides are AB and AC; for AO would balance AD, which is the equivalent of AB and AC.

(F) Let AECF (fig. 3.) be a rhombus, the acute angle of which EAF is half of a right angle. Two equal pressures, which have the directions and measures AE, AF, compose a pressure, having the direction and measure AC, which is the diagonal of the rhombus.

It is evident, in the first place, that the compound force has the direction AC, which bisects the angle EAF. If AC be not its just measure, let it be AP less than AC. Let ABCD be a square described on the same diagonal, and make AP : AQ = AE : AO, = AF : A *o*. Draw KOG, K *o g* perpendicular to AE, AF; draw GI *g*, OH *o*, EG, EK, F *g*, FK, PF, and PE.

The angles CAB and FAE are equal, each being half of a right angle. Also the figures AEPF and AGEK are similar, because AP : AQ = AE : AO. Therefore FA : AP = KA : AE, and EA : AP = GA : AE. Therefore, in the same manner that the forces AE, AF are affirmed to compose AP, the forces AG and AK may compose the force AE, and the forces A *g* and AK may compose the force AF. Therefore (B) the force AP is equivalent to the four forces AG, AK, A *g*, AK. But (D) AG and A *g* are the sides of a square, whose diagonal is equal to twice AI: and the two forces AK, AK are equal to, or are measured by, twice AK. Therefore the four forces AG, AK, A *g*, AK, are equivalent to 2 AI + 2 AK, = 4 AH.

But because AP was supposed less than AC, the angle FPE is greater than FAE, and GEK is greater than GAK, AO is greater than OE, and AH is greater than HQ, and 2 AH is greater than AQ; and therefore 4 AH is greater than AC, and much greater than AP. Therefore AP is not the just measure of the force composed of AE and AF.

In like manner, it is shewn, that AE and AF do not compose a force whose measure is greater than AC. It is therefore equal to AC; and the proposition is demonstrated.

(G) By the same process it may be demonstrated, that if BAD be half a right angle, and EAF be the fourth of a right angle, two forces AE, AF will compose a force measured by AC. And the process may be repeated for a rhombus whose acute angle is $\frac{1}{8}$th, $\frac{1}{16}$th, &c. of a right angle; that is, any portion of a right angle that is produced by continual bisection. Two forces, forming the sides of such a rhombus, compose a force measured by the diagonal.

(H) Let ABCD, A *b c d* (fig. 4.) be two rhombuses formed by two consecutive bisections of a right angle. Let AECF be another rhombus, whose sides AE and AF bisect the angles BA *b* and DA *d*.

The two forces AE, AF, compose a force AC.

Bisect AE and AF in O and *o*. Draw the perpendiculars GOH, *g o h*, and the lines GI *g*, OK *o*, HL *h*, and the lines EG, EH, F *g*, F *h*.

It is evident, that AGEH and A *g* F *h* are rhombuses; because AO = OE, and A *o* = *o* F. It is also plain, that since *b* A *d* is half of BAD, the angle GAH is half of *b* A *d*. It is therefore formed by a continual bisection of a right angle. Therefore (G) the forces AG, AH, compose a force AE; and A *g*, A *h*, compose the force AF. Therefore the forces AG, AH, A *g*, A *h*, acting together, are equivalent to the forces AE, AF acting together. But AG, A *g* compose a force = 2 AI; and the forces AH, A *h* compose a force = 2 AL. Therefore the four forces acting together are equivalent to 2 AI + 2 AL, or to 4 AK. But because AO is $\frac{1}{2}$ AE, and the lines G *g*, O *o*, H *h*, are evidently parallel, 4 AK is equal to 2 AQ, or to AC; and the proposition is demonstrated.

(I) *Cor.* Let us now suppose, that by continual bisection of a right angle we have obtained a very small angle *a* of a rhombus; and let us name the rhombus by the multiple of *a* which forms its acute angle.

The proposition (G) is true of *a*, 2 *a*, 4 *a*, &c. The proposition (H) is true of 3 *a*. In like manner, because (G) is true of 4 *a* and 8 *a*, proposition (H) is true of 6 *a*; and because it is true of 4 *a*, 6 *a*, and 8 *a*, it is true of 5 *a* and 7 *a*. And so on continually till we have demonstrated it of every multiple of *a* that is less than a right angle.

(K) Let RAS (fig. 5.) be perpendicular to AC, and

Second Law of Motion.

and let ABCD be a rhombus, whose acute angle BAD is some multiple of 2 *a* that is less than a right angle. Let A *b c d* be another rhombus, whose sides A *b*, A *d* bisect the angles RAB, SAD. Then the forces A *b*, A *d* compose a force AC.

Draw *b* R, *d*S parallel to BA, DA. It is evident, that AR *b* B and AS *d* D are rhombuses, whose acute angles are multiples of *a* that are each less than a right angle. Therefore (I) the forces AR and AB compose the force A *b*, and AS, AD compose A *d*; but AR and AS annihilate each other's effect, and there remains only the forces AB, AD. Therefore A *b* and A *d* are equivalent to AB and AD, which compose the force AC; and the proposition is demonstrated.

(L) *Cor.* Thus is the corrollary of last proposition extended to every rhombus, whose angle at A is some multiple of *a* less than two right angles. And since *a* may be taken less than any angle that can be named, the proposition may be considered as demonstrated of every rhombus: and we may say,

(M) *Two equal forces, inclined to each other in any angle, compose a force which is measured by the diagonal of the rhombus, whose sides are the measures of the constituent forces.*

(N) Two forces AB, AC (fig. 6.), having the direction and proportion of the sides of a rectangle, compose a force AD, having the direction and proportion of the diagonal.

Draw the other diagonal CB, and draw EAF parallel to it; draw BE, CF parallel to DA.

AEBG is a rhombus; and therefore the forces AE and AG compose the force AB. AFCG is also a rhombus, and the force AC is equivalent to AF and AG. Therefore the forces AB and AC, acting together, are equivalent to the forces AE, AF, AG, and AG acting together, or to AE, AF, and AD acting together: But AE and AF annihilate each other's action, being opposite and equal (for each is equal to the half of BC). Therefore AB and AC acting together, are equivalent to AD, or compose the force AD.

(O) Two forces, which have the direction and proportions of AB, AC (fig. 7.) the sides of any parallelogram, compose a force, having the direction and proportion of the diagonal AD.

Draw AF perpendicular to BD, and BG and DE perpendicular to AC.

Then AFBG is a rectangle, as is also AFDE; and AG is equal to CE. Therefore (N) AB is equivalent to AF and AG. Therefore AB and AC acting together, are equivalent to AF, AG, and AC acting together; that is, to AF and AE acting together; that is (N) to AD; or the forces AB and AC compose the force AD.

Hence arises the most general proposition,

51 Composition of all incitements to motion.

If a material particle be urged at once by two pressures or incitements to motion, whose intensities are proportional to the sides of any parallelogram, and which act in the directions of those sides, it is affected in the same manner as if it were acted on by a single force, whose intensity is measured by the diagonal of the parallelogram, and which acts in its direction: Or, two pressures, having the direction and proportion of the sides of a parallelogram, generate a pressure, having the direction and proportion of the diagonal.

Thus have we endeavoured to demonstrate from abstract principles the perfect similarity of the composition of pressures, and the composition of forces measured by the motions which they produce. We cannot help being of the opinion, that a separate demonstration is indispensably necessary. What may be fairly deduced from the one case, cannot always be applied to the other. No composition of pressures can explain the change produced by a deflecting force on a motion already existing; for the changing pressure is the only one that exists, and there is none to be compounded with it. And, on the other hand, our notions and observations of the composition of motions will not explain the composition of pressures, unless we take it for granted that the pressures are proportional to the velocities; but this is perhaps a gratuitous assumption. At any rate, it is not an intuitive proposition; and we have mentioned some facts where it seems that they do not follow the same proportion. The pressure of four equal springs produces only a double velocity. It would appear, therefore, that there are circumstances which oblige us to say, that the *exertion* of pressure, as a cause of motion, is not (always at least) proportional to the real measurable pressure. We are therefore anxious to discover in what the difference consists; and in the mean time must allow, that the pressure exerted on a body at rest is different from its exertion in producing motion. We cannot indeed state any immediate comparison between pressure and motion, nor have we any clear conception of the connection between them. It is only by our sensations of touch that we have any notion of pressure, and it is experience that teaches us that it always accompanies every cause of motion. We can, however, observe the proportions of pressures, and compare them with the proportions of motion. We very often observe them different; and therefore it was indispensably necessary to investigate the laws of combined pressure as we did the laws of combined motion in consequence of pressure. Yet we should err, if we hastily asserted that pressures are not proportional to the motions which they produce; all that we are intitled to call in doubt is, whether the pressures in their exertion, while they actually produce motion, or changes of motion, continue to be the same as when they do not produce motion, being withstood or balanced by opposite pressures. Considered as causes of motion, we ought to think that they do not vary while they produce motion, and that the actual pressure, while it produces a double motion, is really double, although it may be quadruple when the body exerting it is made to act on a body that it cannot move. We are confirmed in this opinion by observing, that other facts shew us, that even while producing motion, the pressure which we call quadruple, because we have measured it by four equal pressures balancing it, is really quadruple, considered as the cause of motion, and produces a quadruple motion. A bow which requires four times the force to draw it to any given extent, will communicate the same velocity to a bundle of four arrows that a bow four times easier drawn communicates to one arrow, and will therefore produce a quadruple motion. Yet it will only produce a double velocity in the arrow that acquired a simple velocity from a bow having one fourth of the strength.

52 Seeming difference of the compositions of motion and of pressure disappear when carefully examined.

These discrepancies should excite the endeavours of mechanicians to investigate the laws observed in the action of pressures in producing motion. Had this been done with care and with candour, we should not have had

Second Law of Motion.

had the great difference of opinion, which ſtill divides philoſophers, about the meaſures of moving forces. But a ſpirit of party, which had ariſen from other cauſes, gave importance to what was at firſt only a difference of expreſſion, and made the partiſans of Mr Leibnitz avail themſelves of the figurative language which has done ſo much harm in all the departments of philoſophy. Notwithſtanding all our caution, it is hardly poſſible to avoid metaphorical conceptions when we employ the language of metaphor. The abettors of the Leibnitzian meaſure of moving forces, or perhaps, to ſpeak more properly, the abettors of the Leibnitzian meaſure of that force which is ſuppoſed to preſerve bodies in their condition of motion—inſiſt, that the force which is exerted in producing any change of motion is greater in proportion as the motion changed is greater: and they give a very ſpecious argument for their aſſertion. They appeal to the exertions which we ourſelves make. Here we are conſcious of the fact. Then they give ſimilar examples of the action of bodies. A clay ball, moving ſix feet per ſecond, will make the addition of one foot to the velocity of an equal clay ball that is already moving four feet per ſecond in the ſame direction. But if this laſt ball be already moving ten feet per ſecond, we muſt follow it with a velocity of twelve feet in order to increaſe its velocity one foot. But, without inſiſting on the numberleſs paralogiſms and inconſiſtencies which this way of conceiving the matter would lead us into, it ſuffices to obſerve, that the phenomena give us abundant aſſurance that there has been the ſame exertion in both theſe caſes. This acceleration is always accompanied by a compreſſion of the balls, and the compreſſion is the ſame in both. This compreſſion is a very good meaſure of the force employed to produce it; and in the preſent caſe, we need not even trouble ourſelves with any rule for its meaſurement: for ſurely when the compreſſion is not different, but the ſame, the force exerted is the ſame. This is farther confirmed by obſerving, that it requires the ſame force to make the ſame pit, or to give the ſame motion, to a piece of clay lying on the table of a ſhip's cabin, whether the ſhip be ſailing two miles or ten miles per hour.

Thus we ſee that there are ſtrong reaſons for believing, that the exertions of preſſure in producing motion, or that the preſſures *actually exerted*, are proportional to the changes of motion obſerved, and that they coincide in this reſpect with our abſtract conceptions of moving forces.

But we have ſtill better arguments. None of the Leibnitzians think of denying the equal exertions of gravity, or of any of thoſe powers which they call *ſolicitations* or *accelerating forces*. They all admit, that gravity, or any conſtant accelerating force, produces equal increments of velocity in equal times, and that a double gravity will produce a double increment in an equal time, and an equal increment in half of the time; and that a quadruple gravity will produce a double velocity in half the time. All theſe things are granted by them, and their writings are full of reaſonings from this principle. Now from the fact, acknowledged by the Leibnitzians, that the quadruple force of a bow gives a double velocity to the arrow, in every inſtant of its action, it indiſputably follows, that it has acted on it only for half the time of the action of the four times weaker bow, which gives the arrow only half the velocity; and thus has the diſcrepancy between the effects of preſſures and of our abſtract moving forces entirely diſappeared. For this circumſtance of the difference in the time of acting will be found, on ſtrict examination, in all the caſes of the change of motion by preſſures which we meaſure by their effects on a body at reſt. When this and the appreciable changes of actual preſſure, during the time of producing the motion, are taken into conſideration, all difference vaniſhes, and the compoſition of preſſures is in perfect harmony with the compoſition of motions, or of abſtract moving forces. DYNAMICS is thus made a demonſtrative ſcience, and affords the opportunity of inveſtigating, by obſervation and experiment, the nature of thoſe mechanical powers which reſide in bodies, and which appear to us under the form of preſſure, inducing us to conſider preſſure as a cauſe of motion.

In this, however, we are rather inaccurate. Preſſure is one of the ſenſible effects of that property which is alſo the cauſe of motion. It is not the preſſure of a piece of lead, but its heavineſs, that is the reaſon that it gives motion to a kitchen jack. Preſſure is merely a generic name, borrowed from a familiar inſtance, and given to moving forces, which have the ſame nature, but different names that ſerve to mark their connection with certain ſubſtances, in which they may be ſuppoſed to reſide. Natural philoſophy is almoſt entirely employed in examining the nature of theſe various preſſures or accelerative forces; and the general doctrines of dynamics, by aſcertaining what is common to them all, enable us to mark with preciſion what is characteriſtic of each.

53 General corollaries.

We have now advanced very far in this inveſtigation; for we have obtained the criterion by which we learn the direction and the magnitude of every changing force: and, on the other hand, we ſee how to ſtate what will be the effect of the exertion of any force that is known or ſuſpected to act. All this we learn by the compoſition of forces; and the greateſt part of mechanical diſquiſition conſiſts in the application of this doctrine. For ſuch reaſons it merits minute conſideration; and therefore we muſt point out ſome general concluſions from the properties of figure, which will greatly facilitate the uſe of the parallelogram of forces.

1. The conſtituent and the reſulting forces, or the ſimple and compound forces, act in the ſame plane; for the ſides and diagonal of a parallelogram are in one plane. 54.

2. The ſimple and the compound forces are proportional to the ſides of any triangle which are parallel to their directions. For if any three lines, *ab*, *bd*, *ad*, be drawn parallel to AB, AC, and AD (fig. 7, n° 2.), they will form a triangle ſimilar to the triangle ABD. For the ſame reaſons they are proportional to the ſides of a triangle *a'b'd*, which are reſpectively perpendicular to their directions. 55.

3. Therefore each is proportional to the ſine of the oppoſite angle of this triangle; for the ſides of any triangle are proportional to the ſines of the oppoſite angles. 56.

4. Each is proportional to the ſine of the angle contained by the directions of the other two; for AD is to AB as the ſine of the angle ABD to the ſine of the angle ADB. Now the ſine of ABD is the ſame 57.

with

Second Law of Motion.

with the sine of BAC contained between the directions AB and AC, and the sine of ADB is the same with the sine of CAD; also AB is to AC, or BD, as the sine of ADB (or CAD) to the sine of BAD.

58 Some special uses of the parallelogram of forces.

We now proceed to the application of this fundamental proposition. And we observe, in the first place, that since AD may be the diagonal of an indefinite number of parallelograms, the motion or the pressure AD may result from the joint action of many pairs of forces. It may be produced by forces which would separately produce the motions AF and AG. This generally gives us the means of discovering the forces which concur in its production. If one of them, AB, is known in direction and intensity, the direction AC, parallel to BD, and the intensity, are discovered. Sometimes we know the directions of both. Then, by drawing the parallelogram or triangle, we learn their proportions. The force which deflects any motion AB into a motion AD, is had by simply drawing a line from the point B (to which the body would have moved from A in the time of really moving from A to D) to the point D. The deflecting force is such as would have caused the body move from B to D in the same time. And, in the same manner, we get the compound motion AD, which arises from any two simple motions AB and AC, by supposing both of the motions to be accomplished in succession. The final place of the body is the same, whether it moves along AD or along AB and BD in succession.

59 Equivalent of many forces.

This theorem is not limited to the composition of two motions or two forces only; for since the combined action of two forces puts the body into the same state as if their equivalent alone had acted on it, we may suppose this to have been the case, and then the action of a third force will produce a change on this equivalent motion. The resulting motion will be the same as if only this third force and the equivalent of the other two had acted on the body. Thus, in

Plate XXII. fig. 8. the three forces AB, AC, AE, may act at once on a particle of matter. Complete the parallelogram ABDC; the diagonal AD is the force which is generated by AB and AC. Complete the parallelogram AEFD; the diagonal AF is the force resulting from the combined action of the forces AB, AC, and AE. In like manner, completing the parallelogram AGHF, the diagonal AH is the force resulting from the combined action of AB, AC, AE, and AG, and so on of any number of forces.

This resulting force and the resulting motion may be much more expeditiously determined, in any degree of composition, by drawing lines in the proportion and direction of the forces in succession, each from the end of the preceding. Thus, draw AB, BD, DF, FH, and join AH; AH is the resulting force. The demonstration is evident.

60.

It is to be noticed here, that in the composition of more than two forces, we are not limited to one plane. The force AD is in the same plane with AB and AC; but AE may be elevated above this plane, and AG may lead below it. AF is in the plane of AD and AE, and AH is in the plane of AF and AG.

Complete the parallelograms ABLE, ACKE, ELFK. It is evident that ABLFKCD is a parallelopiped, and that AF is one of its diagonals. Hence we derive a more general theorem of great use.

Three forces having the proportion and direction of the three sides of a parallelopiped, compose a force having the proportion and direction of the diagonal.

61 One force may balance many acting together.

Any number of forces acting together on one particle of matter are balanced by a force that is equal and opposite to their resulting force; for this force would balance their resulting force which is equivalent to them in action. When this is duly considered, we perceive that each force is then in equilibrio with the equivalent of all the others; for a force can balance only what is equal and opposite to it. It appears very readily by the geometrical construction. If, instead of the circuit A, B, D, F, H, we take B, D, F, H, A, we have BA for the equivalent of the forces AC, AE, AG; but AB is equal and opposite to BA. Therefore the force AB is in equilibrio with the equivalent of all the others.

62.

When any number of forces act on one particle of matter, and are in equilibrio, if they be considered as acting in parcels, the equivalents of these parcels are in equilibrio; for let the forces AB, AC, AE, AG, A*h*, be in equilibrio, and let them be considered in the two parcels AB, AC, and AE, AG, A*h*; then AD is the equivalent of AB, BD (or AC), and DA is the equivalent of DF, FH, HA (or A*h*): now AD and DA balance each other. This corollary enables us to simplify many intricate complications of force; it also enables us to draw accurate conclusions from very imperfect observations. In most of our practical discussions we know, or at least we attend to, a part only of the forces which are acting on a material particle; and in such cases we reason as if we saw the whole: yet is our mathematical reasoning good with respect to the equivalent of all the parcels which we are contemplating, and the equivalents of the smaller parcels of which it consists; and the neglected force, or parcel of forces, induces no error on our conclusions.

63. Expeditious methods for obtaining the resulting motion in complicated cases.

In the spontaneous phenomena of nature, the investigation and discovery of our ultimate object of search is frequently very difficult, on account of the multiplicity of directions and intensities of the operating forces or motions. We may generally facilitate the process, by substituting equivalent forces or motions acting in convenient directions. It is in this way that the navigator computes the ship's place with very little trouble, by substituting equivalent motions in the meridional and equatoreal directions for the real oblique courses of the ship. Instead of setting down ten miles on a course, S. 36. 52. W. he supposes that the ship has sailed eight miles due south, and six miles due west, which brings her near to the same place. Then, instead of fourteen miles south-west, he sets down ten miles south and ten miles west; and he proceeds in the same way for every other course and distance. He does this expeditiously by means of a traverse table, in which are ready calculated the meridional and equatoreal sides of right angled triangles, corresponding to every course and distance. Having done this for the course of a whole day, he adds all the southings into one sum and all the westings into another: he considers these as forming the sides of a right angled triangle; he looks for them, paired together, in his traverse table, and then notices what angle and what distance corresponds to this pair. This gives him the position and magnitude of the straight line joining the beginning and end of his day's work.

The

Second Law of Motion.

The miner proceeds in the same way when he takes the plan of subterraneous workings, measuring, as he goes along, and noticing the bearing of each line by the compass, and setting down, from his traverse table, the northing or southing, and the easting or westing, for each oblique line: but there is another circumstance which he must attend to, namely, the slope of the various drifts, galleries, and other workings. This he does by noting the rise or the dip of each sloping line. He adds all these into two sums; and taking the risings from the dips, he obtains the whole dip. Thus he learns how far the workings proceed to the north, how far to the east, and how far to the dip.

The reflecting reader will perceive that the line joining the two extremities of this progression will form the diagonal of a rectangular parallelopiped; one of whose sides lies north and south, the other lies east and west, and the third is right up and down.

The mechanician proceeds in the very same way in the investigation of the very complicated phenomena which frequently engage his attention. He considers every motion as compounded of three motions in some convenient directions, at right angles to each other. He also considers every force as resulting from the joint action of three forces, at right angles to each other, and takes the sum or difference of these in the same or opposite directions. From this process he obtains the three sides of a parallelopiped, and from these computes the position and magnitude of the diagonal. This is the motion or force resulting from the composition of all the partial ones.

Forces may be estimated by, or reduced to, 64 A given direction,

This procedure is called the ESTIMATION or REDUCTION of motions and forces.

A motion or force AB (fig. 9.) is said to be *estimated* in the direction EF, or to be *reduced* to this direction when it is conceived as compounded of the motions or forces AC, AD, one of which AC is parallel to EF, and the other AD is perpendicular to it. This expression is abundantly significant; for it is plain that the motion AD neither promotes nor hinders the progress along EF, and that AC expresses the whole progress in this direction.

65 Or a given plane.

In like manner, a force AB (fig. 10.) is said to be *estimated in*, or *reduced to*, a given plane EFGH, when it is conceived as resulting from the joint action of two forces AC, AD, one of which is parallel to a line *a b* drawn in that plane, and the other AD is perpendicular to it. The position of the line *a b* is determined by letting fall B *b* perpendicular to the plane, and drawing *b* P to the point P, in which BA meets the plane; then A *a* being drawn parallel to B *b*, will cut off *b a*, which is the reduction of the motion AB to the plane. Drawing AC parallel to *a b*, and completing the parallelogram ACBD, it is evident that the motion AB is equivalent to AD and AC, which is parallel to *a b*, and the three forces AB, AC, AD, are, as they should be, in one plane perpendicular to the plane EG.

66 Equilibrium of forces so estimated or reduced.

If three forces AB, AC, AD (fig. 11.), are in equilibrio, and are reduced to any one direction *d* A *l*, or to one plane EFGH, the reduced forces are also in equilibrio.

First, Let them be reduced to one direction *d l* by drawing the perpendiculars B *b*, C *c*, D *d*; make AL equal to AD, and join BL, CL, and draw the perpendiculars L *l*, C *c*; then, because the forces AB, AC, AD, are in equilibrio, ABLC must be a parallelogram, and AL is the force equivalent to AB and AC combined; then, because the lines D *d*, B *b*, C *c*, L *l*, are parallel, *d* A is equal to A *l*, and A *b* to C *o*, or to *c l*; therefore A *l* is equal to the sum of A *b* and A *c*, which are the reductions of AB and AC; therefore *d* A is equal to the same sum, and in equilibrio with them.

Secondly, Let them be reduced to one plane EFGH, and let $\alpha\beta$, $\alpha\kappa$, $\alpha\delta$, be the reduced forces. The lines D δ, A α, B β C κ, L λ, are all parallel, being perpendicular to the plane; therefore the planes AB $\beta\alpha$ and CL $\lambda\kappa$ are parallel, and $\alpha\beta$, $\kappa\lambda$, are parallel. For similar reasons $\beta\lambda$, $\alpha\kappa$, are parallel; therefore $\alpha\beta\lambda\kappa$ is a parallelogram. Also, because the lines D δ, A α, L λ, are parallel, and DA is equal to AL; therefore $\delta\alpha$ is equal to $\alpha\lambda$. But because $\alpha\beta\lambda\kappa$ is a parallelogram, the forces $\alpha\beta$, $\alpha\kappa$, are equivalent to $\alpha\lambda$; and $\alpha\delta$ is equal and opposite to $\alpha\lambda$, and will balance it; and therefore will balance $\alpha\beta$ and $\alpha\kappa$, which are the reductions of AB and AC to the plane EFGH, while $\alpha\delta$ is the reduction of AD; therefore the proposition is demonstrated.

The most useful mode of reduction to their co-ordinates.

The most usual and the most useful mode of reduction is to estimate all forces in the directions of three lines drawn from one point, at right angles to each other, like the three plane angles of a rectangular chest, forming the length, the breadth, and the depth of the chest. These are commonly called the three co-ordinates. The resulting force will be the diagonal of this parallelopiped. This process occurs in all disquisitions in which the mutual action of solids and fluids is considered, and when the oscillation or rotation of detached free bodies is the subject of discussion.

67 Relative motions of bodies not affected by any extraneous equal and parallel force.

The only other general theorem that remains to be deduced from this law of motion is, that if a number of bodies are moving in any manner whatever, and an equal force act on every particle of matter in the same or parallel directions, their relative motions will suffer no change; for the motion of any body A (fig. 12.), relative to another body B, which is also in motion, is compounded of the real motion of A, and the opposite to the real motion of B; for let A move uniformly from A to C, while B describes BD uniformly, draw AB, also draw AE equal and parallel to BD, join EC, DC, ED. The motion of A, relative to B, consists in its change of position and distance. Had A described AE, while B described BD, there would have been no change of relative place or distance; but A is now at C, and DC is its new direction and distance. The relative or apparent motion of A therefore is EC. Complete the parallelogram ACFE; it is plain that the motion EC is compounded of EF, which is equal and parallel to AC, the real motion of A, and of EA, the equal and opposite to BD, the real motion of B.

Now let the motions of A and B sustain the same change; let the equal and parallel motions AG, BH, be compounded with the motions AC and BD; or let forces act at once on A and B, in the parallel directions AG, BH, and with equal intensities; in either supposition, the resulting motions will be A *c*, B *d*, the diagonals of the parallelograms A G *c* C, and B H *d* D. Construct the figure as before, and we see that the relative motion is now *e c*, and that it is the same with EC both in respect of magnitude and position.

Here we still see the constant analogy between the composition of motions and the composition of forces.

In

Second Law of Motion.

In the firſt caſe, the relative motions of things are not changed, whatever common motion be compounded with them all; or, as it is uſually, but inaccurately, expreſſed, although the ſpace in which they move be carried along with any motion whatever. In the ſecond caſe, the relative motions and actions are not changed by any external force, however great, when equally exerted on every particle in parallel directions.

Thus it is that the evolutions of a fleet in a uniform current are the ſame, and produced by the ſame means, as in ſtill water. Thus it is that we walk about on the ſurface of this globe in the ſame manner as if it neither revolved round the ſun, nor turned round its axis. Thus it is that the ſame ſtrength of a bow will communicate a certain velocity to an arrow, whether it is ſhot eaſt, or weſt, or north, or ſouth. Thus it is that the mutual actions of ſublunary bodies are the ſame, in whatever directions they are exerted, and notwithſtanding the very great changes in their velocities by reaſon of the earth's rotation and orbital revolution. The real velocity of a body on the earth's equator is about 3000 feet per ſecond greater at midnight than at midday. For at midnight the motion of rotation nearly conſpires with the orbital motion, and at midday it nearly oppoſes it. The difference between the velocities at the beginning of January and the beginning of July is vaſtly greater. And at other times of the day, and other ſeaſons of the year, both motions of the earth are tranſverſely compounded with the eaſterly or weſterly motion of an arrow or cannon bullet. Yet we can obſerve no change in the effects of the mutual actions of bodies.

68 This affords a demonſtration of the proportionality of moving forces to the motions produced by them,

This is an important obſervation; becauſe it proves that forces are to be meaſured by no other ſcale than by the motions which they produce. We have had repeated occaſions to mention the very different eſtimation of moving forces by Mr Leibnitz; and have ſhewn how, by a very partial conſideration of the action of thoſe natural powers called *preſſures*, he has attempted to prove that moving forces are proportional to the ſquares of the velocities; and we ſhewed briefly, in what manner a right conſideration of what paſſes when motion is produced by meaſurable preſſures, proves that the forces really exerted are as the velocities produced. But the moſt copious proof is had from the preſent obſervation, that, in fact, the mutual actions of bodies depend on their relative motions alone.

69 And is incompatible with their proportionality to the ſquares of thoſe motions.

The Leibnitzian meaſure of moving force is altogether incompatible with the univerſal fact now mentioned, *viz.* that the relative motions of bodies, reſulting from their mutual actions, are not affected by any common motion, or the action of any equal and parallel force on both bodies: for this univerſal fact imports, that when two bodies are moving with equal velocities in the ſame direction, a force applied to one of them, ſo as to increaſe its velocity, gives it the ſame motion relative to the other, as if both bodies had been at reſt. Here it is plain that the ſpace deſcribed by the body in conſequence of the primitive force, and of the force now added, is the ſum of the ſpaces which each of them would generate in a body at reſt. Therefore the forces are proportional to the velocities or changes of motion which they produce, and not to the ſquares of thoſe velocities. This meaſure of forces, or the poſition that a force makes the ſame change on any velocity whatever, and the dependence of the relative motions on any motion that is the ſame on all the bodies of a ſyſtem, are counterparts of each other. Since this independence is a matter of obſervation in all terreſtrial bodies, we are intitled to ſay, that the powers which the Author of Nature has imparted to natural bodies are no way different from what are competent to matter once called into exiſtence. And it alſo follows from this, that we muſt always remain ignorant of the abſolute motions of bodies. The fact, that it has required the unremitted ſtudy of ages to diſcover even the relative motions of our ſolar ſyſtem, is an argument to prove that the influence of this mechanical principle extends far beyond the limits of this ſublunary world; nor has any phenomenon yet been exhibited which ſhould lead us to imagine that it is not univerſal.

So Bernoulli's defence of this laſt opinion is without force.

When we have made uſe of theſe arguments with ſome zealous partizans of Mr Leibnitz's doctrine, they have anſwered, that if indeed this independence of the relative motions of terreſtrial bodies were obſerved to obtain exactly, it would be a concluſive argument. But the motion with which all is carried along is ſo great in compariſon with the motions which we can produce in our experiments, that the ſmall additions or diminutions that we can make to the velocity of this common motion muſt obſerve very nearly the proportions of the additions or diminutions of their ſquares. The differences of the ſquares of 2, 3, and 4, are very unequal; but the differences of the ſquares of 9, 10, 11, are much nearer to the ratio of equality; and the differences of the ſquares of 1000001, 1000002, 1000003, do not ſenſibly deviate from this ratio. But it is not fact that we cannot produce motions which have a very ſenſible proportion to the common motion. The motion of a cannon ball, diſcharged with one-third of its weight of powder, is nearly equal to that of the rotation of the earth's equator. When, therefore, we diſcharge the ball eaſtward, we double its motion; when to the weſtward, we deſtroy it. Therefore, according to Leibnitz, the action in the firſt caſe is three times the action in the ſecond. In the firſt caſe it changes the ſquare of the velocity (which we may call 1) from 1 to 4; and, in the ſecond, it changes it from 1 to 0. But ſay the Leibnitzians, the velocity of rotation is but $\frac{1}{61}$ of the orbital velocity of the earth, and our obſervations of the velocities of cannon bullets are not ſufficiently exact to enſure us againſt an error of $\frac{1}{31\frac{1}{2}}$. But the later obſervations on the peculiar motions of the fixed ſtars concur in ſhewing, that the ſun, with his attending planets, are carried along with a very great motion, which, in all probability, has a ſenſible ratio to the orbital motion of the earth. This muſt make a prodigious change on the earth's abſolute motion, according as her orbital motion conſpires with, oppoſes, or croſſes, this other motion: the earth may even be at abſolute reſt in ſome points of its orbit. Thus will the compoſition with the motions produced in our experiments be ſo varied, that caſes *muſt* occur when the difference of the reſults of the two meaſures of force will be very ſenſible.

But, farther, they have not attended to the agreement of our experiments, when the diſcharges of cannon are made in a direction tranſverſe to that of the common motion. Here the immenſity of the common motion, and the minuteneſs of our experimental velocities, can have no effect in diminiſhing the difference of the reſults of the two doctrines. This will appear diſtinctly

Second Law of Motion.

tinctly to every reader who is much converfant in difquifitions of this kind; and it is in thefe more moderate motions that the complete independence of the relative motions on the common motions moft accurately appears. Pendulum clocks and watches have been often executed which do not deviate from perfect equability of motion one part in 86400. This could not be obtained in all directions of the ofcillations, if the forces deviated from the ratio of the velocities one part in 86400.

Perfect agreement of the abftract notion of force with all our accurate obfervations of the exertions of natural powers.

On the whole, we may confider it as eftablifhed on the fureft foundation, that the action of thofe powers of natural bodies which we call *preffure*, fuch as the force of fprings, the exertions of animals, the cohefion of bodies, as well as the action of thofe other incitements to motion which we call *attractions* and *repulfions*, fuch as gravitation, magnetifm, and electricity—is proportional to the change of velocity produced by it. And we muft obferve here, that this is not a mere mode of conception, the refult of the laws of human thought, which cannot conceive a natural power as the caufe of motion otherwife than by its producing motion, and which cannot conceive any degree of *moving* power different from the degree of the motion. This is the abftract doctrine, and is true whether the preffures are proportional to the velocities or to the fquares of the velocities. But we fee farther, that whatever is the preffure of a fpring (for example) on a quiefcent body, yet the preffure actually exerted in producing a double velocity is only double, and not quadruple, as our firft imperfect obfervations make us imagine.

70
Newton's third law of motion is founded on experience alone, and is not a neceffary truth.

Sir Ifaac Newton has added another propofition to the number of laws of motion; namely, that *every action is accompanied by an equal and contrary reaction.* But in affirming this to be a law of nature, he only means that it is an univerfal fact: And he makes this affirmation on the authority of what he conceives to be a law of human thought; namely, that thofe qualities which we find in all bodies on which we can make experiments and obfervations, are to be confidered as univerfal qualities of body. But we have limited the term *law of motion* to thofe confequences that neceffarily flow from our notions of motion, of the caufes of its production and changes. Now this third Newtonian propofition is not fuch a refult. A magnet is faid to act on a piece of iron when, and only when, the vicinity of the magnet is obferved to be accompanied by certain motions of the iron. But it by no means follows from this obfervation, that the prefence of the iron fhall be accompanied by any motion, or any change of ftate whatever of the magnet, or any appearance that can fuggeft the notion that the iron acts on the magnet. When this was obferved, it was accounted a difcovery. Newton *difcovered* that the fun acts on the planets, and that the earth acts on the moon; and Kepler *difcovered* that the moon reacts on the earth. Newton had obferved that the iron reacts on the magnet; that the actions of electrified bodies were mutual; and that every action of fublunary bodies was, in fact, accompanied by an equal and contrary reaction. On the authority of his rule of philofophizing, he affirmed that the planets react on the fun, and that the fun is not at reft, but is continually agitated by a fmall motion round the general centre of gravitation. He pointed out feveral confequences of this reaction. Aftronomers examined the celeftial motions more narrowly, and found that thofe confequences do really obtain, and difturb all the planetary motions. It is now found that this reciprocity of action obtains throughout the folar fyftem with the utmoft precifion, and that the third Newtonian propofition is really a law of nature, although it is not a law of human thought. It is a difcovery. The contrary involves no abfurdity or contradiction. It would indeed be contrary to experience; but things might have been otherwife. It is conceivable, and poffible, that a ball A fhall ftrike another equal ball B, and carry it along with it, without any diminution of its velocity. The fact, that the velocity of A is reduced to one-half, is the indication of a force refiding in B, which force changes the motion of A; and the intenfity of this force is learned from the change which it produces. This *is found* to be equal to the change produced by A on B. And thus the reaction of B is *difcovered* to be equal to the action of A.

It is highly probable, that this univerfality and equality of reaction to action is the confequence of fome general principle, which we may in time difcover; meanwhile we are intitled to fuppofe it univerfal, and to reafon from this topic in our difquifitions about the actions of bodies on each other.

Maupertuis, Leibnitz, and other philofophers, have entertained very inadequate opinions concerning the foundation of the laws of motion.

Although the celebrated philofophers of Europe have at laft agreed in the reception of the two propofitions fo largely difcuffed by us as the laws of motion, they have differed exceedingly in their opinion about their origin and validity: Some afferted that they are entirely matters of experience; while others affirmed them to be neceffary truths. The royal academy of Berlin made this queftion the fubject of their prize differtation in the year 1744. Mr Maupertuis, prefident of the academy, publifhed a differtation; in which he endeavoured to prove that they are neceffary truths, only becaufe *they are fuch as make the quantity of action the leaft poffible* an economy which is worthy of infinite wifdom; and therefore certainly directs the choice of the Author of Nature. On this account alone are they neceffary truths.

But this is not the way to confider a queftion of this kind. We know too little about infinite wifdom to be able to fay with Meffrs Leibnitz and Maupertuis, that the Deity fhould or fhould not imprefs on bodies laws different from thofe which are effential to matter; and we are not to inquire whether God could or could not do this. We know from our own experience, that matter, when fubjected to the action of intelligence, may be moved in a way extremely different from what it would follow if left to itfelf, and that its motions may either be regulated by fixed, but contingent, laws, or may be without any conftancy whatever, and vary in every inftance. When we fuppofe the exiftence of matter and motion, a variety of truths are involved in the fuppofition, in the fame manner as all the theorems in the third book of Euclid's Elements are involved in the conception of a circle and a ftraight line. Our firft employment fhould be to evolve thofe truths. We can do this in no way but by firft noticing the relations of the ideas that we have of the different objects of contemplation, and then following the laws of human thought in our judgments concerning thofe relations. This procefs of the mind is expreffed in the train of a geometrical demonftration. The different parts or argu-

 mentations

Second Law of Motion.

mentations of this train are not the caufes of our conclufions, but the means by which we form our judgement; not the reafons of the truth of our ultimate conclufion, but the fteps by which we arrive at the knowledge of it. The young geometer generally thinks otherwife: But that this is the matter of fact is plain from this, that more than one demonftration, and often very different, can be given of the fame theorem. We muft proceed in the fame manner in the prefent queftion; and the firft general truths which we find involved in the notions of matter, motion, and force, muft be received as *neceffary* truths. The fteps by which we arrive at the difcovery are the laws of human thought; and the expreffion of the difcovery, involving both the truth itfelf and the manner of conceiving it, is a neceffary law of motion. There may be other facts, perhaps as general as any of thofe neceffary laws, but which do not neceffarily refult from the relations of our notions of motion and of force. Thefe are difcovered by obfervation only; and they ferve to characterife the forces which nature prefents to our view. Thefe facts are *contingent* laws of motion.

We apprehend that this method has been followed in treating this article. The firft propofition, termed *a law of motion*, is only a more convenient way of expreffing our contemplation of motion in body as an effect of the general caufe which we term *force*. The fecond propofition does nothing but exprefs more diftinctly the relation between this caufe and its effect; it expreffes what we mean by the magnitude and the kind of the caufe. The propofition, ftating the compofition of forces, is but another form of the fame law, better fuited to the ordinary procedure in geometrical difquifitions.

These propofitions might have completed the doctrines of dynamics; but it appears that, in order to the production of a material univerfe which fhould accomplifh the purpofes of the Creator, it was neceffary that there be certain characteriftic differences between the forces inherent in the various collections of matter which compofe this univerfe. The facts or phyfical laws (for the above-mentioned laws are metaphyfical) of motion may be different from thofe which would have been obferved had matter been left entirely to itfelf. This difference may have introduced other laws of motion as neceffarily refulting from the nature of the forces. We have occafionally mentioned fome inftances where this appears to obtain, but gave good reafons for affirming, that a due examination of all circumftances which may be obferved in the production or variation of motion by thofe forces, has demonftrated that there are no fuch deviations from the two laws of motion already determined, but that all the mechanical powers of bodies, when confidered merely as caufes of motion, act agreeably to the fame laws. Careful examination was, however, faid to be neceffary.

This examination muft confift in diftinctly noticing the circumftances that occur in the production of motion by any force whatever. It is by no means enough to ftate fimply the intenfity of the force and the direction of its exertion. If a force continue to act, it continues to vary the motion already produced. Should the force change its intenfity or direction while it is acting, thefe circumftances muft induce ftill farther changes in the motion; and it is not till all action has ceafed that the motion is brought to its oftenfible ftate, in which it is the object of our attention and our future difcuffions. Inftances of the effects of fuch continued and fuch varied actions are to be feen in moft of the phenomena of nature or art. The communication of motion by impulfe is perhaps the only inftance (very frequent indeed) that can be produced where this is not neceffary: Nay, we fhall perhaps find reafon to conclude, that this inftance is not an exception, and that even the communication of motion from one billiard ball to another is brought about by an action continued for fome time, and greatly varied during that time. Much preparation is therefore neceffary before we can apply the general laws of motion to the folution of moft of the queftions which come before us in the courfe even of our elementary difquifitions. We muft lay down fome general propofitions which determine the refults of the continued, and perhaps varied, actions of moving forces; and we muft mark the different effects of the fimple continuation of action, and alfo thofe of the variations in this continued action, both in refpect of intenfity and direction. The effect of a mere continuance of action muft be an acceleration of the motion; or a retardation of it, if the force continue to act in the oppofite direction. The effect of the continued action of a tranfverfe force muft be a continual deflection, that is, a curvelineal motion. Thefe muft therefore now occupy our attention in their order.

Of Accelerated and Retarded Motions.

Of Accelerated and Retarded Motions.

71 Circumftantial expofition of our conception of the condition of a body in refpect to motion.

All men can perceive, that a ftone dropped from the hand, or fliding down an uniform flope, has its motion continually accelerated, and that the motion of an arrow rifing perpendicularly through the air is continually retarded; and they feel no difficulty in conceiving thefe changes of motion as the effects of the continual operation of their weight or heavinefs. The falling ftone is in a different condition in refpect of motion in the beginning and the end of its fall. In what refpect do thefe ftates of the body differ? Only in refpect to what we call its *velocity*. This is an affection of motion; it is an expreffion of the relation between the two notions or ideas which concur to form the idea of motion; namely, the fpace and the time. Thefe are all the circumftances that we obferve in a motion. Time elapfes, and during its currency a fpace is defcribed. The term *velocity* expreffes the magnitude of the fpace which correfponds to fome unit of time. Thus, the rate of a fhip's motion is determined, when we fay that it is nine miles in an hour, or nine miles per hour. We fometimes fay (but aukwardly) "The motion is at the rate, or with the velocity, of a mile in three days." It is moft conveniently expreffed by a number of fome given units of length, which completely make up the line defcribed during this unit of time. But the mechanicians exprefs it in a way more general by a fraction, of which the numerator is a number of inches, feet, yards, fathoms, or miles, and the denominator is the number of feconds, minutes, or hours, employed in moving along this line. This is a very proper expreffion; for when we fpeak of any velocity, and continue to reafon from it, we conceive ourfelves to fpeak of fomething that remains the fame, in the different occafions of ufing the term. Now if the velocity be conftant, it is indifferent how

how long the line may be; because the time of its description will be lengthened in the same proportion. Thus if 48 feet be described in 12 seconds, 36 feet will be described in 9 seconds, 16 feet will be described in 4 seconds, &c. Now $\frac{48}{12}$, $\frac{36}{9}$, and $\frac{16}{4}$, are fractions of equal value, being equal to $\frac{4}{1}$, or 4, that is, to the velocity of 4 feet per second. The value of this fraction, or the quotient of the number of the units of length, divided by the number of units of time, is the number of those units of length described uniformly in one unit of time.

Magnitude of a velocity of which we have no actual measure.

But how shall we determine the velocity of any instant or in any point of a motion that is continually changing? Suppose that a body has fallen 144 feet, and that we would ascertain its velocity in that point of its fall, or the velocity which it has in passing through that point? In the next second the body falls 112 feet farther. This cannot be the measure of the velocity at the beginning of the fourth or the end of the third second. It is too great. The fall during the preceding second was 80 feet. This is too small. The mean of these two, or $\frac{80+112}{2}, = \frac{192}{2}, = 96$, is probably more exact. Due attention to the nature of this motion shews us, that 96 is the proper measure, or that the motion at that instant is at the rate of 96 feet per second. But it is peculiar to this kind of motion that the half sum of the spaces described in two succeeding equal moments is the measure of the velocity in the middle instant. Therefore this method will not generally give an accurate measure. Yet it is indispensably necessary to obtain some accurate measure; for it is in this particular alone that the state of the body differs from its similar state in another instant. The difference of place makes no distinction; for if a body continue its motion unchanged, its condition in every different instant of time, or point of space, is unchanged or the same. The change of place is not a change of motion, but is involved in the very conception of the continuation of the motion. The change of condition consists, therefore, in the change of velocity. Therefore the change of velocity is the only indication, and the only measure of the action (perhaps accumulated) of the changing force. It is therefore the chief object of our search; and accurate measures of velocity are absolutely necessary.

When the velocity changes continually, there can be no *actual* measure of it. In what then does the magnitude of a velocity consist, when there is no actual measure of it? It is a certain undescribable DETERMINATION; by which, if not changed, a certain space *would* be uniformly described in a given unit of time. Thus we know, that if, when a stone has fallen 16 feet, its motion be directed along a horizontal plane, without diminution, it will move on for ever at the rate of 32 feet per second. The space which would be thus described is not the velocity, but the measure of the velocity. But the proportions of those spaces, being the proportions of those measures, are the proportions of the velocities themselves. We may discover these proportions in the following manner:

72

Momentary proportion of velocities that are continually changing. Fundamental requisite in all mechanical disquisitions.

Let ACG (fig. 13.) be a line described by a body with a motion anyhow continually, but gradually, varied; and let it be required to determine the proportion of the velocity in any point C to the velocity in any other point F.

AXIOM.—If A be to B in a ratio that is greater than any ratio less than that of C to D, but less than any ratio greater than that of C to D, then A is to B as C to D.

Take the straight line *a c g* to represent the time of the body's motion along ACG, so that the points *a*, *c*, *f*, *g*, may represent the instants of time in which the body passes through the points A, C, F, G; and the portions *a c*, *c f*, *f g*, of the line *a g*, may represent the times employed in describing the portions AC, CF, FG; and therefore *a c* is to *a f* as the time of describing AC to the time of describing AF.

Moreover, let *h k n o* be a line so related to the straight line *a c f g*, by the perpendicular ordinates *a h*, *c k*, *f n*, *g o*, and the areas *a c k h*, *a f n h*, *a g o h*, may be proportional to the portions AC, AF, AG, of the line described by the moving body; and let this relation be true with respect to every point B, D, E, &c. and the corresponding points *b*, *d*, *e*, &c.

Then it is affirmed, that *the velocity in the point* C *is to the velocity in the point* F *as c k is to f n*.

Let the equal lines *b c*, *c d*, *e f*, *f g*, represent equal moments of time, and let B, D, E, G, be the points through which the body is passing at the instants *b*, *d*, *e g*. Then the areas *b i k c*, *c k l d*, *e m n f*, *f n o g*, will represent, and be proportional to, the spaces BC, CD, EF, FG, which are described during the moments *b c*, *c d*, *e f*, *f g*.

Draw *t p* parallel to *a g*, so as to make the rectangle *b t p c* equal to the trapezium *b i k c*; and draw the lines *q v*, *u r*, *s x*, in the same manner, so that each rectangle may be equal to its corresponding trapezium.

If the motions had been uniform during the moments *b c* and *f g*, that is, if the spaces BC and FG had been uniformly described, then the velocity in the point C would have been to the velocity in the point F as *c p* to *f s*: For since the rectangles *b t p c* and *f s x g* are respectively equal to the trapeziums *b i k c* and *f n o g*; and since *b i k c* is to *f n o g* as BC is to FG, the rectangle *b t p c* is to the rectangle *f s x g* as BC to FG. But because these two rectangles have equal altitudes *b c* and *f g*, they are to each other in the proportion of their bases *c p* and *g x*, or *c p* and *f s*. Therefore BC is to FG as *c p* to *f s*. But if BC and FG are uniformly described in equal times, they are proportional to the velocities of those uniform motions. Therefore *c p* is to *f s* as the velocity with which BC is uniformly decribed to the velocity with which FG is uniformly described in an equal time.

But the motion expressed by the figure is not uniform, because the line *h l o* recedes from the axis *a g*, and the areas, cut off by the parallel ordinates, increase in a greater proportion than the corresponding parts of the axis; that is, the spaces increase faster than the times: for the moments *b c*, *c d*, *e f*, *f g*, being all equal, it is evident that the corresponding slips of the area continually augment. The motion is swifter at the instant *c* than at the instant *b*, and the velocity at the instant *c* is *greater* than that with which the space BC would be uniformly described in the same time. For the same reason, the velocity at the instant *f* is *less* than that with which the space FG would be uniformly described in the same time. Therefore the velocity at the instant *c* is to the velocity at the instant *f* in a greater ratio than that of *c p* to *f s*. In the very same manner, it will appear by comparing the motion during the moment *c d* with the motion during the moment *e f*, that the velocity at the instant *c* is to the velocity at the instant *f* in a less ratio than that of *c q* to *f r*.

Therefore the velocity in the point C is to the velocity in the point F in a greater ratio than that of *c p* to *f s*, but in a less ratio than that of *c q* to *f r*.

But by continually diminishing the equal moments *b c*, *c d*, *e f*, *f g*, it is evident that *c p* and *c q* continually approach to equality with *c k*; and *f r* and *f s*, continually approach to equality with *f n*, that when *c p* is less than *c k*, *f s* is greater than *f n*, and when *c q* is greater than *c h*, *f r* is less than *f n*.

Therefore the velocity in the point C is to the velocity in the point F in a ratio that is greater than the ratio of *any* line less than *c k* to *any* line greater than *f n*, but which is less than the ratio of any line greater than *c k* to any line less than *f n*. Therefore the ratio of the velocity in C to the velocity in F is greater than any ratio that is less than that of *c k* to *f n*; but it is less than any ratio that is greater than that of *c k* to *f n*. Therefore the velocity in the point C is to the velocity in the point F as *c k* to *f n*.

This important theorem may be expressed in more general terms as follows:

If the abscissa a g *of a line* h k o *represent the time of any motion, and if the areas bounded by parallel ordinates be proportional to the spaces described, the ordinates are proportional to the velocities.*

Remark. The propriety or aptitude of expressing the time by the portions of the axis *a c g*, will, perhaps, appear more clearly in the following manner.

Let *a c g* be any straight line, and let *h k v* be another line, straight or curved. Let the straight line *a h z*, perpendicular to *a g*, be carried uniformly down along this line, keeping always perpendicular to it, and therefore always parallel to its first position *a h z*. In its various situations *c k z*, *e m z*, &c. it will cut off areas *a c k h*, *a e m h*, &c. bounded by the axis by the ordinates *a h* and *c k*, or by the ordinates *a h* and *c m*, &c. and by the line *h k g*. By this motion the moveable ordinate is said, in the language of modern geometry, to *generate* the areas *a c k h*, *a e m h*, &c. At the same time, let a point A move along the line ACG, setting out from A at the instant when the line *a z* sets out from *a*; and let the motion of the point A be so regulated, that the spaces AB, AC, AD, &c. generated by this motion, may increase at the same rate with the areas, *a b*, *i h*, *a c k h*, *a d l h*, &c. or such that we shall have AB to AC as *a b i h*, to *a c k h*, &c. It is plain, that the motion along AG is the same with that described in the enunciation of the proposition: for because the motion of the ordinate *a z*, along the axis *a g*, is supposed to be uniform, the spaces *a b*, *a c*, *a d*, &c. are proportional to the times in which they are described, and may therefore be taken to measure or to represent those times.

73. Cor. 1. *In a motion continually varied, the velocities in the different points of the path are to each other in the limiting or ultimate ratio of the spaces described in equal times*, those times being supposed to diminish continually: for it is evident, that if the equal moments *b c*, *c d*, *e f*, *f g*, are supposed to diminish continually, till the instants *b* and *d* coalesce with *c*, and the instants *e* and *g* coalesce with *f*; then the ratio of *c k* to *f n* is the limit of the continually increasing ratio of *c p* to *f s*, or of the continually diminishing ratio of *c q* to *f r*. Sir Isaac Newton calls this the ultimate ratio of *c p* to *f s*, or of *c q* to *f r*. Now the ratio of *c p* to *f s* is, by construction, the same with the ratio of the rectangle *b t p c* to the rectangle *f s x g*, and the ratio of *c q* to *f r* is the same with the ratio of the rectangle *c q v d* to the rectangle *e u r f*. But the ratio of the rectangle *b t p c* to the rectangle *f s x g* is the same with the ratio of the space *b i k c* to the space *f n o g*; that is (by hypothesis), the same with the ratio of the space BC to the space FG; and the ratio of the rectangles *c q v d* and *e u r f* is the same with that of the spaces CD and EF. Therefore the ratio of the velocity at C to the velocity at F is the same with the ultimate ratio of the small increments BC, FG, or CD, EF of the spaces generated in very small and equal times.

It is also evident, that because the ratio of *c k* to *f n* is the limit both of the ratio of *c p* to *f s* and of the ratio of *c q* to *f r*, these ultimate ratios are the same, and that we may say that the velocity in C is to the velocity in F in the ultimate ratio of BC to EF, or in the ultimate ratio of CD to FG.

We also can easily perceive, that the ratio of the area *b i k c* to the area *e m n f* approaches more near to the ratio of *c k* to *f n* as we take the moments *b c* and *e f* smaller. Therefore, in many cases of practice, where it may be easy to measure the spaces described in the different small moments of the motion, but difficult to ascertain their ultimate ratio, so as to obtain accurate measures of the proportions of the velocities, we may reduce the errors of measurement to something very insignificant, by taking these moments extremely small; and we shall diminish the error still more, by taking the proportion of the half sum of BC and CD to the half sum of EF and FG for the proportion of the velocities in C and F.

It often happens that we have it not in our power to compare the spaces described in small moments which are precisely equal. Still we can find the exact proportion of the velocities, if we can ascertain the ultimate ratio of the increments of the spaces, and the ultimate ratio of the moments of time in which these increments are described: for it is plain, by considering the gradual approach of the points *p* and *r* to the points *k* and *n*, that the ratio of *c k* to *f n* is still the ultimate ratio of the bases of rectangles equal to the mixtilineal areas, whether the altitudes (representing the moments) are equal or not. Now the bases of two rectangles are in the proportion of the rectangles directly, and of their altitudes inversely. But the ultimate ratio of the altitudes is the ultimate ratio of the moments, and the ultimate ratio of the rectangles is the ultimate ratio of the spaces described in those unequal moments. Therefore, in such cases, we have,

Cor. 2. *The velocities are in the ratio compounded of the direct ultimate ratio of the momentary increments of the spaces, and the inverse ultimate ratio of the increments (or moments) of the times in which these increments of the spaces are made.* 74.

If *s*, *v*, and *t*, are taken to represent the magnitudes of the spaces, velocities, and times, and if *s*, *v*, and *t*, are taken always in the limiting or ultimate ratio of their momentary increments, we shall have *v* always in the

the proportion of $\dot{s}$ directly, and of $\dot{t}$ inversely. We express this by the proportional equation $v \doteq \frac{\dot{s}}{\dot{t}}$, which is equivalent to the analogy $V : v = \frac{\dot{S}}{\dot{T}} : \frac{\dot{s}}{\dot{t}}$, or $V : v = \dot{S}\dot{t} : \dot{s}\dot{T}$.

75. *N. B.* Here observe, that this is not the only way of stating the relation of space and time—the abscissa may be made the time, and the ordinate the space; then the velocity $= \frac{\dot{y}}{\dot{x}}$.

The converse of this proposition may be thus expressed.

76 Converse theorem.

If the axis a g *of the line* h k o *represent the time of a varied motion along the line* AG, *and if the ordinates* a h, b i, c k, *&c. be as the velocities in the instants* a, b, c, *or in the points* A, B, C; *then the areas* a b i h, a c k h, a l l h, *&c. are proportional to the spaces* AB, AC, AD, *&c.*

This may be demonstrated in the same way with the former; but the indirect demonstration is more brief, and equally strict.

If the spaces AC, AF, &c. are not proportional to the areas $a c k h$, $a f n h$, &c. they are proportional to some other areas $a c k h'$, $a f n' h'$, &c. which are bounded by the same ordinates, and by another line $h' k n'$. But because the areas $a c k h'$, $a f n' h'$, &c. are always proportional to the spaces AC, AF, &c. described on the line AG, the velocity in the point C is to the velocity in the point F as the ordinate $c k$ is to the ordinate $f n'$. But, by hypothesis, the velocity in C is to the velocity in F as $c k$ to $f n$, and $f n'$ is equal to $f n$; which is absurd. Therefore the spaces AC, AF, are not proportional to any other areas, &c.

77. Cor. *The ultimate ratio of the momentary increments of the spaces is compounded of the ratio of the velocities, and the ultimate ratio of the increments of the times:* for when the moments $b c$, $e f$, are equal, it is evident that the ultimate ratio of the rectangles $b c p t$, $e f r u$ is the same with the ultimate ratio of the increments of the spaces. But the ultimate ratio of these rectangles is the same with their bases $c p$ and $f r$; that is, the ratio of $c k$ to $f n$, that is, the ratio of the velocities. And when the moments are unequal, the ratio of the rectangles is compounded of the ratio of their bases and the ratio of their altitudes; that is, compounded of the ratio of the velocities and the ultimate ratio of the moments of time.

We have, therefore, $\dot{S} : \dot{s} = VT : vt$, and $\dot{s} \doteq v\,\dot{t}$.

It most commonly happens, that we can only observe the accumulated results of varied motions; and in them we only observe a space passed over, and a certain portion of time that has elapsed during the motion. But being able to distinguish the portions of the whole space which are described in known portions of the whole time, and having made such observations in several parts of the motion, we discover the general law that the motion affects, and we affirm this law to hold universally, even though we have not observed it in *every* point. We do this with a degree of probability and confidence proportioned to the frequency of our observation. It is not till we have done this that we can make use of the first of these two propositions, which enables us to ascertain the velocity of the motion in its different moments. Thus if we observe, that a stone in falling descends one foot in the quarter of a second, 16 feet in a second, 64 feet in two seconds, and 144 feet in three seconds; the general law immediately observed is, "that the spaces described are as the squares of the times;" for 1 is to 16 as the square of $\frac{1}{4}$th to the square of 1. Again, 16 is to 64 as 1^2 to 2^2; and 16 is to 144 as 1^2 to 3^2. Hence we infer, with great probability, that the stone would fall 36 feet in a second and a half; for 16 is to 36 as 1^2 to $1\frac{1}{2}^2$; and we conclude in the same way for all other parts of the motion.

78 A good example of the geometrical method.

This immediate observation of the analogy between the spaces and the squares of the times suggests an easy determination of the velocity in this particular kind of motion; and it merits particular notice, being very often referred to. We can take $a g$ to represent the time; and then, because the areas which are to represent the spaces described must be proportioned to the squares of the portions of $a g$, we perceive that the line which comes in place of $h k o$ must be a straight line drawn from a. For example, the straight line $a \delta \gamma$. For this is the only boundary which will give areas $a b \beta$, $a c \kappa$, $a d \delta$, &c. proportional to $a b^2$, $a c^2$, $a d^2$, &c. And we perceive that *any* straight line drawn from a will have this property.

Having thus got our representations of the times and the spaces, we say, on the authority of our theorem, that the velocity at the instant b is to the velocity at the instant d as $b \beta$ to $d \delta$, &c. And now we begin to make inferences, purely geometrical, and express our discovery of the velocities in a very general and simple manner. We remark, that $b \beta$ is to $d \delta$ as $a b$ is to $a d$; and we make the same affirmation concerning the magnitudes represented by these lines. We say that the velocity at the instant b is to the velocity at the instant d as the time $a b$ is to the time $a d$. We say, in terms still more general, that the velocities are proportional to the times from the beginning of the motion. We moreover perceive, that the spaces are also proportional to the squares of the acquired velocities; or the velocities are as the square roots of the spaces.

We can farther infer, from the properties of the triangle, that the momentary increments of the spaces are proportional to the momentary increments of the squares of the times, or of the squares of the velocities.

We also observe, that not only the whole acquired velocities are proportional to the whole elapsed times, but that the increments of the velocities are proportional to the times in which they are acquired; for $\pi \kappa$ is to $\rho \phi$ as $b c$ to $d f$, &c. Equal increments of velocity are therefore acquired in equal times. Therefore such a motion may, in great propriety of language, be denominated a UNIFORMLY ACCELERATED MOTION; that is, *a motion in which we observe the spaces proportioned to the squares of the times, is a motion uniformly accelerated;* and spaces in the duplicate ratio of the times form the ostensible characteristic of an uniformly accelerated motion.

Lastly, if we draw $\varepsilon \lambda$ parallel to the axis $a b$, we perceive that the rectangle $a e \varepsilon \lambda$ is double of the triangle $a e \varepsilon$. Now because $a e$ represents the time of the motion, and $e \varepsilon$ represents the acquired velocity, the rectangle $a e \varepsilon \lambda$ will represent the space which would be uniformly described with the velocity $e \varepsilon$ during the time 79.

$a e$.

Of Accelerating and Retarding Forces.

ae. But the triangle *ae* represents the space really described with the uniformly accelerated motion during the same time. Hence we infer, that the space that is described in any time, with a motion increasing uniformly from nothing, is one-half of the space which would be uniformly described during the same time with the final velocity.

These are but a part of the inferences which we may draw from the geometrical properties of those representations which we had selected of the different measureable affections of motion. We may affirm, with respect to the motions themselves, all the inferences which relate to magnitude and proportion, and thus improve our knowledge of the motions.

We took the opportunity of this very simple and perspicuous axample, to give our young readers a just conception of the *mathematical method* of prosecuting mechanical knowledge, and to make them sensible of the unquestionable authority for every theorem deduced in this manner.

One of the most important is, to discover the accumulated result of a motion of which we only observe the momentary increments. This is to be done by finding the area, or portions of the area, of the mixtilineal space *a g o h*; and it is evidently analogous to the inverse method of fluxions, or the integral calculus.

In most cases, we must avail ourselves of the corollary $\dot{s} = v\,\dot{t}$, and we obtain the solution of our question only in the cases where our knowledge of the quantities s, t, and v (considered as geometrical magnitudes, that is, as lines and surfaces), enables us to discover s and t.

Of Accelerating and Retarding Forces.

80. Having thus discovered the proportions of the velocities in motions varying in any manner whatever, we can observe the variations which happen in them. These variations are the effects, and the only marks and measures, of the changing forces. They are the characteristics of their kinds (considered merely as moving forces); that is, the indications of the directions in which they act; for this is the only difference *in kind* of which they are susceptible in this general point of view. If they increase the velocity, their direction must be conceived as the same with that of the previous motion; because the result of the action of a force is equivalent to the composition of the motion which that force would produce in a quiescent body with the motion already existing: and an increase of velocity is equivalent to the composition of a motion in the same direction.

Having no other mark of the force but the acceleration, we have no other name for it in the abstract doctrines of dynamics, and we call it an ACCELERATING FORCE. Had it retarded the motion, we should have called it a RETARDING FORCE.

In like manner, we have no measure of the *magnitude* or *intensity* of an accelerating force, but the acceleration which it produces. In order therefore to investigate the powers which produce all the changes of motion, we must endeavour to obtain measures of the acceleration.

A continual increase of velocity is the effect of the continued action of accelerating forces. If equal increments of velocity are produced in every succeeding equal moment of time, we cannot conceive that there is any change in the accelerating force. Therefore a uniformly accelerated motion is the mark of the unvaried action of an accelerating force, that is, of the continued action of a constant force; of a force whose intensity is always the same. When therefore we observe a body describe spaces proportional to the squares of the times, we must infer that it is urged forward by a force whose intensity does not change; and, on the other hand, a constant force must produce a uniformly accelerated motion by its continued action. And if any previous circumstances assure us of this continued action of an invaried force, we may make all the inferences which were mentioned under the article of uniformly accelerated motion.

81 Measure of an accelerating force.

That force must surely be accounted double which produces a double increment of velocity in the same time by its uniform action, we can form no other estimation of its magnitude. And, in general, *accelerating forces must be accounted proportional to the increments of velocity which they produce, by acting uniformly during the same or equal times.*

Supposing them to act on a body at rest. Then the velocity produced is itself the increment; and we must say, that accelerating forces are proportional to the velocities which they generate in a body in equal times. And because we found (n° 79.), that the space described with a uniformly accelerated motion is half the space which would be uniformly described in the same time with the final velocity, which space is the direct measure of this velocity, and because halves have the same proportion with the wholes—we may say that *accelerating forces are proportional to the spaces through which they impel a body from rest in equal times by their uniform action.* (Another measure.)

This is an important remark; because it gives us an easy measure of the force, without the trouble of first computing the velocities. It also gives us the only distinct notion that we have of the measurement of forces by the motions which they produce. When speaking of the composition of forces we distinguished or denominated them by the sides and diagonal of a parallelogram These lines must be conceived as proportional to the spaces through which the forces urge the body *uniformly* during the small and insensible time of their action, which time is supposed to be the same for both forces; for the sides of the parallelogram are supposed to be separately described in equal times, and therefore to be proportional to the velocities generated by the constituent forces. If indeed the forces do not act uniformly, nor similarly, nor during equal times, we cannot say (without farther investigation) what is the proportion of the intensity of the forces, nor can we infer the composition of their action. We must at least suppose, that in every instant of this very small time of their joint action, their direction remains unchanged, and that their intensities are in the same ratio. We shall see by and bye, that with these conditions the sides of the parallelogram are still proportional to the velocities generated. In the mean time, we may take the spaces through which a body is uniformly impelled from rest (that is, with a uniformly accelerated motion) as the measures of the forces; yet these spaces are but the halves of the measures of the velocities. Then, if a body be moving with the velocity of 32 feet per second, and an accelerating force acts on it during a second, and

Of Accelerating and Retarding Forces.

and if this force be ſuch that it would impel the body (from a ſtate of reſt) 16 feet, it will add to the body a velocity of 32 feet per ſecond. Accordingly, this is the effect of gravity—the weight of a pound of lead may be conſidered as a force which does not vary in its intenſity. We know that it will cauſe the lead to fall 16 feet in a ſecond; but if the body has already fallen 16 feet, we know that it is then moving with the velocity of 32 feet per ſecond. And the fact is, that it will fall 48 feet farther in the next ſecond, and will have acquired the velocity of 64 feet per ſecond. It has therefore received an augmentation of 32 feet of velocity by the action of gravity during the 2d ſecond; and gravity is in fact a conſtant force, cauſing equal increments of velocity in equal times, however great the velocities may be. It does not act like a ſtream of fluid, whoſe impulſe or action diminiſhes as the ſolid body withdraws from it by yielding.

But ſuppoſing that we have not compared the increments of velocity uniformly acquired during equal times, in what manner ſhall we meaſure the accelerating forces? In ſuch a caſe, that force muſt be accounted double which generates the ſame velocity, by acting uniformly during half the time; for when the force is ſuppoſed invariable, the changes of velocity which it produces are proportional to the times of its action; therefore if it produces an equal velocity in half the time, it will produce a double velocity in an equal time, and is therefore a double force. The ſame may be ſaid of every proportion of time in which an equal change of velocity is produced by the uniform action of an accelerating force. The force muſt be accounted greater in the ſame proportion that the time required for the production of a given velocity in a body is leſs. Hence we infer, that *accelerating forces are inverſely proportional to the times in which a given change of velocity is produced by their uniform action.*

By combining theſe two propoſitions we eſtabliſh this
82 general theorem:

Meaſure of accelerating force,

Accelerating forces are proportional to the changes of velocity which they produce in a body by their uniform action directly, and to the times in which theſe changes are produced inverſely.

If, therefore, A and a are the forces, V′ and v' the changes of velocity, and T′ and t' the portions of time in which they are uniformly produced, we have

$$A : a = V't' : v'T', = \frac{V'}{T'} : \frac{v'}{t'}$$

$$\text{And } a \doteq \frac{v'}{t'}.$$

The formula $a \doteq \frac{v'}{t'}$ is not reſtricted to any particular magnitude of v' and t'. It is true, therefore, when the portion of time is diminiſhed without end; for ſince the action is ſuppoſed uniform, the increment of velocity is leſſened in the ſame proportion, and the value of the fraction $\frac{v'}{t'}$ remains the ſame. The characters or ſymbols v' and t' are commonly uſed to expreſs *finite* portions of v and t. The ſymbols $\dot{v}$ and $\dot{t}$ are uſed by Newton to expreſs the ſame things taken in the ultimate or limiting ratio. They are uſually conſidered as *indefinitely ſmall* portions of v and t. We ſhall abide by the formula $a \doteq \frac{\dot{v}}{\dot{t}}$.

It muſt always be kept in mind, that v and t are abſtract numbers; and that v refers to ſome unit of ſpace, ſuch as a foot, an inch, a yard; and that t refers to ſome unit of time, ſuch as an hour, a minute, a ſecond; and eſpecially that a is the number of the ſame units of ſpace, which will be uniformly deſcribed in *one* unit of the time with the velocity generated, by the force acting uniformly during *that* unit. It is twice the ſpace actually deſcribed by the body during that unit when impelled from reſt by the accelerating force. It is neceſſary to keep hold of theſe clear ideas of the quantities expreſſed by the ſymbols.

83 Is an abſtract number.

Meaſure of a change of velocity.

On the other hand, when the meaſure of the accelerating force is previouſly known, we employ the theorem $a\,t' = v'$; that is, the addition made to the velocity during the whole, or any part, of the time of the action of the force is obtained by multiplying the acceleration of one unit of time by the number of ſuch units contained in t'.

Theſe meaſures expreſs the greateſt part of our knowledge of mechanical nature.

Theſe are evidently leading theorems in dynamics; becauſe all the mechanical powers of nature come under the predicament of accelerating or retarding forces. It is the collection of theſe in any ſubject, and the manner in which they accompany, or are inherent in it, which determine the mechanical character of that ſubject; and therefore the phenomena by which they are brought into view are the the characteriſtic phenomena. Nay, it may even be queſtioned, whether the phenomena bring any thing more into view. This force, of which we ſpeak ſo familiarly, is no object of diſtinct contemplation; it is merely a ſomething that is proportional to $\frac{\dot{v}}{\dot{t}}$. And when we obſerve, that the $\frac{\dot{V}}{\dot{T}}$, found in the motions that reſult from the vicinity of a body A, is double of the $\frac{\dot{v}}{\dot{t}}$, which reſults from the vicinity of another body B; we ſay that a force reſides in A, and that it is double of the force reſiding in B. The accelerations are the things immediately and truly expreſſed by theſe ſymbols. And the whole ſcience of dynamics may be completely taught without once employing the word *force*, or the conception which we imagine that we form of it. It is of no uſe till we come to ſtudy the mechanical hiſtory of bodies. Then, indeed, we muſt have ſome way of expreſſing the fact, that an acceleration $= \frac{32\text{ feet}}{1''}$ is obſerved in every thing on the ſurface of this globe; and that an acceleration $= \frac{418\text{ feet}}{1''}$ is obſerved over all the ſurface of the ſun. Theſe facts are characteriſtic of this earth and of the ſun; and we expreſs them ſhortly by ſaying, that ſuch and ſuch forces reſide in the earth and in the ſun. It will preſerve us from many miſtakes and puzzling doubts, if we reſolutely adhere to this meaning of the term *force*; and this will carry mathematical evidence through the whole of our inveſtigations.

84 Another meaſure of accelerating force.

As velocity is not an immediate object of contemplation, and all that we obſerve of motion is a ſpace and a time, it may be proper to give an expreſſion of this meaſure of accelerating force which involves no other idea. Suppoſing the body to have been previouſly at reſt, we have $a \doteq \frac{\dot{v}}{\dot{t}}$. Multiply both parts

Of Accelerating and Retarding Forces.

of the fraction by t, which does not change its value, and we have $a \doteq \frac{v\,t}{t^2}$. But $v\,t = s$; and therefore $a \doteq \frac{s}{t^2}$.

The formula $a = \frac{s}{t^2}$ is equivalent to the proportion $t^2 : 1 = s : a$; and a would then be the space through which the accelerating force would impel the body in one unit of the time t. But this is only half of the measure of the velocity which the accelerating force generates during that unit of time. For this reason we did not express the accelerating force by an ordinary equation, but used the symbol $\doteq$. In this case, therefore, of uniform action, we may express the accelerating force by $a = \frac{2\,s}{t^2}$.

The following theorem is of still more extensive use in all dynamical disquisitions.

85 Most general measure of accelerating force.

Accelerating forces are proportional to the momentary increments of the squares of the velocities directly, and as the spaces along which they are uniformly acquired inversely.

Let A'B, A'C, and AD (fig. 14.), be three lines, described in the same or equal times by the uniform action of accelerating forces; the motions along these lines will be uniformly accelerated, and the lines themselves will be proportional to the forces, and may be employed as their measures. On the greatest of them AD, describe the semicircle ABCD, and apply the other two lines A'B, A'C as chords AB, AC. Draw EB, FC perpendicular to AD. Take any small portions B b, C c of AB and AC, and draw $b\,e$, $c\,f$ perpendicular to AD, and E h and F k parallel to AB and AC.

Then, because the triangles DAB and BAE are similar, we have $AD : AE = AD^2 : AB^2$. And because AD is to AB as the velocity generated at D is to the velocity generated at B (the times being equal), we have AD to AE as the square of the velocity at D to the square of the velocity at B; which we may express thus:

$$AD : AE = V^2, D : V^2, B.$$

For the same reasons we have also

$$AD : AF = V^2, D : V^2, C. \quad \text{Therefore}$$
$$AE : AF = V^2, B : V^2, C.$$

But because in any uniformly accelerated motion, the spaces are as the squares of the acquired velocities, we have also

$$AE : A\,e = V^2, B : V^2\,b, \text{ and}$$
$$AF : A\,f = V^2, C : V^2\,c.$$

Therefore E e is to F f as the increment of the square of the velocity acquired in the motion along B b to the increment of the square of the velocity acquired along C c.

But, by similarity of the triangles ABD and E e h, we have

$$AB : AD = E\,e : E\,h; \text{ and, in like manner,}$$
$$AD : AC = F\,k : F\,f. \quad \text{Therefore}$$
$$AB : AC = E\,e \times F\,k : F\,f \times E\,h.$$

Now AB and AC are proportional to the forces which accelerate the body along the lines A'B and A'C; E e and F f are proportional to the increments of the squares of the velocities acquired in the motions along the portions B b and C c; and E h and F k are equal to those portions respectively. The ratio of AB to AC is compounded of the direct ratio of E e to F f; and the inverse ratio of E h to F k. The proposition is therefore demonstrated.

The proportion may be expressed thus:

$AB : AC = \frac{E\,e}{E\,h} : \frac{F\,f}{F\,k}$, and may be expressed by the proportional equation $AB \doteq \frac{E\,e}{E\,h}$ or, symbolically, $a \doteq \frac{(\dot{v^2})}{\dot{s}}$.

$\dot{v}\,\dot{v}$ is but one-half of the increment of v^2.

Remark. Because the motion along any of these three lines is uniformly accelerated, the relation between spaces, times, and velocities, may be represented by means of the triangle ABC (fig. 15.); where AB represents the time, BC the velocity, and ABC the space. If BC be taken equal to AB, the triangle is half of the square ABCF of the velocity BC; and the triangle ADE is half of the square ADEG of the velocity DE. Let D d and B b be two moments of time, equal or unequal. Then D d e E and B b c C are half the increments of the squares of the velocities DE and BC, acquired during the moments D d and B b. It was demonstrated, that the ratio of the area D d e E to the area B b c C is compounded of the ratio of DE to BC, and the ultimate ratio of D d to B b. But D d and B b are respectively equal to $\epsilon\,e$ and $\kappa\,c$. Therefore D d e E is to B b c C, in the ratio compounded of the ratio of DE to BC, and the ultimate ratio of $\epsilon\,e$ to $\kappa\,c$. If we represent DE and BC by V and v, then $\epsilon\,e$ and $\kappa\,c$ must be represented by V' and v', the increments of V and v; and then the compounded ratio will be the ratio of VV' to $v\,v'$; and if we take the ultimate ratio of the moments, and consequently the ultimate ratio of the increments of the velocities, we have the ratio of $V\dot{V}$ to $v\,\dot{v}$. If, therefore, V^2 and v^2 represent the squares of the velocities, $V\dot{V}$ and $v\,\dot{v}$ will represent not the increments of those squares, but half the increments of them.

We may now represent this proposition concerning accelerating forces by the proportional equation $a \doteq \frac{v\dot{v}}{\dot{s}}$; and we must consider this as equivalent with $a = \frac{V^2 - v^2}{2\,(S - s)}$; keeping always in mind, that a, V, and v, relate to the same units of time and space, and that a is that number of units of the scale on which S and s are measured, which is run over in *one* unit of time.

Measure of gravity considered as an accelerating force.

This will be more clearly conceived by taking an example. Let us ascertain the accelerative power of gravity, supposing it to act uniformly on a body. Let the spaces be measured in feet and the time in seconds. It is a matter of observation, that when a body has fallen 64 feet, it has acquired a velocity of 64 feet per second: and that when it has fallen 144 feet, it has acquired the velocity of 96 feet per second. We want to determine what velocity gravity communicated to it by acting on it during one second. We have $V^2 = 9216$, and $v^2 = 4096$; and therefore $V^2 - v^2 = 5120$. $S = 144$, and $s = 64$, and $S - s = 80$, and $2\,(S - s) = 160$. Now $a = \frac{5120}{160}, = 32$. Therefore gravi-

ty

Of Accelerating and Retarding Forces.

ty has generated the velocity 32 feet per ſecond by acting uniformly during one ſecond.

86. *The augmentation of the ſquare of the velocity is proportional to the force and to the ſpace jointly.* For, becauſe $a = \frac{\dot{v}\, v}{\dot{s}}$, we have $a\,\dot{s} = v\,\dot{v}$.

Thus we learn, that a given force acting uniformly on a body along a given ſpace, produces the ſame increment of the ſquare of the velocity, whatever the previous velocity may have been. Alſo, in the ſame manner as we formerly found that the augmentation of the velocity was proportioned to the time during which the force has acted, ſo the augmentation of the ſquare of the velocity is proportional to the ſpace along which it has acted.

Theorems reſpecting retarding forces.

It is pretty plain, that all that we have ſaid of the uniform action of an *accelerating* force may be affirmed of a *retarding force*, taking a diminution or decrement of velocity in place of an increment. A uniformly retarded motion is that in which the decrements of velocity in equal times are equal, and the whole decrements are proportional to the whole times of action. Such a motion is the indication of a conſtant or invariable force acting in a direction oppoſite to that of the motion. We conceive this to be the caſe when an arrow is ſhot perpendicularly upwards; its weight is conceived as a force continually preſſing it perpendicularly downwards.

In ſuch motions, however great the initial velocity may be, the body will come to reſt; becauſe a certain determined velocity will be taken from the body in each equal ſucceſſive moment, and ſome multiple of this will exceed the initial velocity. Therefore the velocity will be extinguiſhed before the end of a time that is the ſame multiple of the time in which the velocity was diminiſhed by the quantity above mentioned. It is no leſs evident, that the time in which any velocity will be extinguiſhed by an oppoſing or retarding force, is equal to the time in which the ſame force would generate this velocity in the body previouſly at reſt. Therefore,

87. 1. The times in which different initial velocities will be extinguiſhed by the ſame oppoſing force are proportional to the initial velocities.

88. 2. The diſtances to which the body will go till the extinction of its velocity are as the ſquares of the initial velocities.

3. They are alſo as the ſquares of the times elapſed.

89. 4. The diſtance to which a body, projected with any velocity, will go till its motion be extinguiſhed by the uniform action of a retarding force, is one half of the ſpace which it would deſcribe uniformly during the ſame time with the initial velocity.

Forces generally variable in their intenſity.

It very rarely happens, that the force which accelerates the body acts uniformly, or with an unvaried intenſity. The attraction of a magnet, for example, increaſes as the iron approaches it. The preſſure of a ſpring diminiſhes as it unbends. The impulſe of a ſtream of water or wind diminiſhes as the impelled ſurface retires from it by yielding. Therefore the effects of accelerating forces are very imperfectly explained, till we have ſhewn what motions reſult from any given variation of force, and how to diſcover the variation of force from the obſerved motion. This laſt queſtion is perhaps the moſt important in the ſtudy of mechanical nature. It is only thus that we learn what is uſually called *the nature of a mechanical force.* This chiefly conſiſts in the relation ſubſiſting between the intenſity of the force and the diſtance of the ſubſtance in which it reſides. Thus the nature of that power which produces all the planetary motions, is conſidered as aſcertained when we have demonſtrated that its preſſure or intenſity is inverſely as the ſquare of the diſtance from the body in which it is ſuppoſed to reſide.

Acceleration expreſſes ſome relation of the velocity and time. This relation may be geometrically expreſſed in a variety of ways. In figure 13. the uniform acceleration or the unvaried relation between the velocity and the time is very aptly expreſſed by the conſtant ratio of the ordinates and abſciſſes of the triangle $a\,g\,v$. The ratio of $d\,\delta$ to $a\,d$ is the ſame with that of $e\,\varepsilon$ to $a\,e$, or that of $f\,\varphi$ to $a\,f$, &c.; or the ratio of the increment of velocity $\varpi\,\kappa$ to the increment of the time $\beta\,\varpi$ or $b\,c$, or that of $i\,\varphi$ to $\varepsilon\,i$, &c. This ratio $\varpi\,\kappa : \beta\,\varpi$ is equivalent to the ſymbol $\frac{\dot{v}}{\dot{t}}$

But when the ſpaces deſcribed in a varied motion are repreſented by the areas bounded by a curve line $h\,k\,o$, we no longer have that conſtant ratio of the increments of the ordinates and abſciſſes.

Therefore in order to obtain meaſures of the accelerating forces, or at leaſt of their proportions, let the abſciſſa $a\,e\,g$ (fig. 13.) of the line $h\,k\,o$ again repreſent the time of a motion. But let the areas bounded by parallel ordinates now repreſent the velocities, that is, let the whole area increaſe during the time $a\,g$ at the ſame rate with the velocities of the motion along the line AG. In this caſe the ordinates $b\,i$, $c\,k$, $d\,l$, &c. will be as the accelerations at the inſtants b, c, d, &c. or in the points B, C, D, &c. 90

Their meaſures in ſuch caſes how obtained? Theorems of moſt extenſive uſe.

This is demonſtrated in the ſame way as the former propoſition (n° 72.). If the accelerating force be ſuppoſed conſtant during any two equal moments $b\,c$ and $f\,g$, the rectangles $b\,c\,p\,t$ and $f\,g\,x\,s$ would expreſs the increments of velocity uniformly acquired in equal times, and their baſes $c\,p$ and $f\,s$ would have the ratio of the accelerations, or of the accelerating forces. But as the velocities expreſſed by the figure increaſe faſter than the times during every moment, the force at the inſtant c is to the force at the inſtant f in a greater ratio than that of $c\,p$ to $f\,s$; but, for ſimilar reaſons, it is in a leſs ratio than that of $c\,q$ to $f\,r$; and therefore (as in the other propoſition) the force at the inſtant c is to the force at the inſtant f as $c\,k$ to $f\,n$.

Cor. Becauſe $c\,p$ is to $f\,s$ in the ratio compounded of the direct ratio of the rectangle $c\,p\,t\,b$ to the rectangle $f\,s\,x\,g$, and the inverſe ratio of the altitude $b\,c$ to the altitude $f\,g$; and becauſe theſe rectangles are proportional to the increments of velocity, and the ultimate ratio of the altitudes is the ultimate ratio of the moments or increments of the time—we muſt ſay, that *the accelerating forces (that is, their intenſities or preſſures producing acceleration) are directly as the increments of velocity, and inverſely as the increments of the times:* Which propoſition may be expreſſed, in regard to two accelerations A and a, by this analogy: 91.

$$A : a = \frac{\dot{V}}{\dot{T}} : \frac{\dot{v}}{\dot{t}}.$$

Or by the proportional equation $a \doteq \frac{\dot{v}}{\dot{t}}$. Also $a \dot{t} \doteq \dot{v}$, and $\int a \dot{t} = v'$. And thus do these theorems extend even to the cases where there cannot be observed an immediate measure, either of velocity or of acceleration; because neither the space nor the velocity increases uniformly.

See Barrow's Lect. Geometr. passim.

The theorem $a \doteq \frac{\dot{v}}{\dot{t}}$ is employed when we would discover the variation in the intensity of some natural power. We observe the motion and represent it by a figure analogous to fig. 13. where the abscissa represents the times, and the area is made to increase at the same rate with the spaces described. Then the ordinates will represent the velocities, or have the proportion of the velocities. Then we may draw a second curve on the other side of the same abscissa, such that the areas of this last curve shall be proportioned to the ordinates of the first. The ordinates of this last curve are proportional to the accelerating forces.

92. On the other hand, when we know from other circumstances that a force, varying according to some known law, acts on a body, we can determine its motion. The intensity of the force in every instant being known, we can draw a line so related to another line representing the time that the ordinates shall be proportional to the forces: The areas will be proportional to the velocities. We can draw another curve to the same abscis, such that the ordinates of this shall be proportional to the areas of the other, that is, to the velocities of the motion. The areas of this second curve will be proportional to the spaces described.

93

All these theorems relate to *changes* of velocity; by which means they indicate *immediately* the operation of natural powers.

We must now observe, that all that has been said concerning the effects of accelerating forces continually varying, relates to *changes* of motion, independent of what the absolute motions may be. The areas of the line whose ordinates represent the velocities do not necessarily represent the spaces described, but the change made on the spaces described in the same time, not the motions, but the changes of motion. If, indeed, the body be supposed to be at rest when the forces begin to act, these areas represent the very spaces that are passed over, and the ordinates are the very velocities. In every case, however, the accelerations are the real increments of the velocities.

This circumstance gives a great extension to our theorems, and enables us to ascertain the disturbances of any species of regular motion, apart from the motions themselves, and thus avoid a complication which would frequently be inextricable in any other way. And this process, which is merely mathematical, is perfectly conformable to mechanical principles. It is in fact an application of the doctrine of the composition of motion; a doctrine rigidly demonstrated when we measure a mechanical force by the *change* of motion which it produces. Acceleration is the continual composition of a new motion with the motion already produced.

No finite change of velocity can be produced in an instant by any accelerating force.

We may learn from this investigation of the value of an accelerating force, that no finite change of velocity is effected in an instant by the action of an accelerating force. When the fig. 13. is used for the scale of accelerations, and they are represented by the ordinates of the line $h\,k\,o$, the increment of velocity is represented by an area, that is, by a slip of the whole area; which slip must have some altitude, or must occupy some portion of the abscissa which represents time. Some portion of time, however small it may be, must elapse before any measurable addition can be made to the velocity. The velocity must change *continually*. As no motion can be conceived as instantaneous, because this would be to conceive, that in one instant the moving particle is in every point of its momentary path; so no velocity can change, by a finite quantity, in one instant; because this would be to conceive, that in that instant the particle had all the intervening velocities. The instant of change is at once the last instant of the preceding velocity, and the first of the succeeding, and therefore must belong to both. This cannot be conceived, or is absurd. As a body, in passing from one part of space to another, must pass in succession through all the intermediate places; so, in passing from one velocity to another, it must in succession have all the intermediate velocities. It must be *continually* accelerated; we must not say *gradually*, however small the steps.

But to return from this digression:

94

More convenient manner of considering the action of forces, and more frequently coming into view.

The most frequent cases which come under examination do not shew us the relation between the forces and times, but the relation between the forces and spaces. Thus, when a piece of iron is in the neighbourhood of a magnet, or a planet is considered in the neighbourhood of the sun, a force is acting on it in every point of its path, and we have discovered that the intensity of this force varies in a certain proportion. Thus, a spring varies in its pressure as it unbends; gunpowder presses less violently as it expands, &c. &c.

Our knowledge is generally confined to some such effect as this. We know, that while a body is moving along a line ADE (fig. 16.), it is urged forward by a force, of which the intensity varies in the proportion of the ordinates BF, CG, DH, EI, &c. of the line FGHI.

To investigate the motion or change of motion produced by the action of this force, let CD be supposed a very small portion of the space s, which we may express by s'. Draw GK perpendicular to DH. Then, if we suppose that the force acts with the unvaried intensity CG through the whole space CD, the rectangle CDKG will express half of the increment of the square of the velocity (n° 85.). We may suppose that the force acts uniformly along the adjoining small space Dr with the intensity DH. The rectangle DH $o\,r$ will in like manner express another half increment of the square of the velocity. And in like manner we may obtain a succession of such increments. The aggregate or sum of them all will be half the difference between the square of the velocity at B and the square of the velocity at E.

If we employ f to express the indetermined or variable intensity of the accelerating force, and v to express the variable velocity, and v its increment *uniformly* acquired; then the rectangle CDKG will be expressed by $f\,s'$. We have seen that this is equal to $v\,v'$. Therefore, in every case where we can tell the aggregate of all the quantities $f\,s$, it is plain that we will obtain half the difference between the squares of the velocities in B and E, on the supposition that the intensity of the force was constant along each little space, and

varied

Of Accelerating and Retarding Forces.

varied by ſtarts. Then, by increaſing the number, and diminiſhing the magnitude, of thoſe little portions of the ſpace without end, it is evident that we terminate in the expreſſion of the real ſtate of the caſe, *i. e.* of a force varying continually; and that in this caſe the aggregate of theſe rectangles occupies the whole area AEIF, and is equivalent to the fluent of $f\dot{s}$, or to the ſymbol $\int fs$, uſed by the foreign mathematicians to expreſs this fluent, which they indeed conceive as an aggregate of ſmall rectangles fs'. And we ſee that this area expreſſes half of the augmentation of the ſquare of the velocity. Therefore,

95 Moſt important theorem (*Newton's Principia*, I. 39.)

If the abſciſſa AE (fig. 16.) *of a line* FGI *is the path along which a body is urged by any accelerating force, and if the ordinates* BF, CG, DH, *&c. are proportional to the forces acting on the points* B, C, D, *&c. the intercepted areas* BCGF, BEIF, *&c. are proportional to the augmentations of the ſquare of the velocity.*

Obſerve that the areas BCGF and DEIH are alſo proportional to the augmentations made on the ſquares of the velocities in B and D.

Obſerve alſo, that it is indifferent what may have been the original velocity. The action of the forces repreſented by the ordinates make always the ſame addition to its ſquare; and this addition is half the ſquare of the velocity which thoſe forces would generate in the body by impelling it from reſt in the point A.

96. Laſtly, on this head, obſerve, that we can ſtate what conſtant or variable force will make the ſame augmentation of the ſquare of the velocity by impelling the body uniformly along the ſame ſpace BE; or along what ſpace a given force muſt impel the body, in order to produce the ſame increaſe of the ſquare of its velocity. In the firſt caſe, we have only to make a rectangle BENφ, equal to the area BEIF, and then Bφ is the intenſity of the conſtant force wanted. In the ſecond caſe, in which the force EO is given, we muſt make the rectangle AαOE equal to the area BEIF, and AE is the ſpace required.

97 Converſe.

The converſe of this propoſition, *viz. If the areas are as the increments of the ſquare of the velocity, the ordinates are, as the forces*, is eaſily demonſtrated in the ſame way; for if the elementary areas CDKG and EIMe repreſent increments of the ſquares of the velocity, the accelerating forces are in the ratio compounded of the direct ratio of theſe rectangles and the inverſe ratio of their altitudes, becauſe theſe altitudes are the increments of the ſpace (nº 85.). Now the baſe CG of the rectangle CDKG, is to the baſe EI of the rectangle EIMe in the ſame compounded ratio; therefore the force in C is to the force in E as CG to EI.

98 *Scales* of force, velocity, acceleration, time, &c.

The line hko (fig. 13.) was called by Dr Barrow (who firſt introduced this extenſive employment of motion into geometry), the SCALE *of velocities*; and the line FHL (fig. 16.) was named by him the *ſcale of accelerations*. Hermann, in his *Phoronomia*, calls it the *ſcale of forces*. We ſhall retain this name, and we may call hko of fig. 13. the *ſcale of* accelerations, when the areas repreſent the velocities. Sir Iſaac Newton added another ſcale of very great uſe, viz. a ſcale of times. It is conſtructed as follows.

99. Let ABE (fig. 16.) be the line along which a body is accelerated, and let FHI be the ſcale of forces, that is, having its ordinates FB, HD, IE, &c. proportional to the forces acting at B, D, E, F, &c.; let fhi be another line ſo related to ABE, that Cg is to Ei in the inverſe ſubduplicate ratio of the area BFGC to the area BFIE; or, to expreſs it more generally, let the ſquares of the ordinates to the line fgi be inverſely, as the areas of the line FHI intercepted between theſe ordinates and the firſt ordinate drawn through B; then the times of the bodies moving from a ſtate of reſt in B are as the intercepted areas of the curve fgi.

For let CD and Ee be two very ſmall portions of the ſpace deſcribed in equal times. They will be ultimately as the velocities in C and E. The area FBCG is to the area FBEI as the ſquare of Ei to the ſquare of Cg (by conſtruction); but the area FBCG is to FBEI as the ſquare of the velocity at C is to the ſquare of the velocity at E (by the propoſition); therefore the ſquare of the velocity at C is to the ſquare of the velocity at E as the ſquare of Ei to the ſquare of Cg; therefore Ei is to Cg as the velocity at C to the velocity at E, that is, as CD to Ee: but ſince Ei : Cg = CD : Ee, we have Ei × Ee = Cg × CD, and the elementary rectangles CgkD and Eime are equal, and may repreſent the equal moments of time in which CD and Ee were deſcribed. Thus the areas of the line fgl will repreſent or expreſs the times of deſcribing the correſponding portions of the abſciſſa.

We may expreſs the nature of this ſcale more briefly thus. Let BE be the ſpace deſcribed with any varied motion, and fgl a curve, ſuch that its ordinates are inverſely as the velocities in the different points of the abſciſſa, then the area will be as the times of deſcribing the correſponding portions of the abſciſſa.

100 Examples of the application of nº 95.

In all the caſes where our mathematical knowledge enables us to aſſign the values of the ordinates of the figure 16, we can obtain the law of action of the forces, or the nature of the force; and where we can aſſign the value of the areas from our knowledge of the proportions of the ordinates or forces, we can aſcertain the velocities of the motion. We ſhall give an example or two, which will ſhew the way in which we avail ourſelves of the geometrical properties of figure, in order to aſcertain the effects of mechanical forces.

1. Let the accelerating force which impels the body along the line AB be conſtant, and let the body be previouſly at reſt in B; the line which bounds the ordinates that repreſent the forces muſt be ſome line φHN parallel to AB. The area BDHφ is to the area BENφ as the ſquare of the velocity at D to the ſquare of the velocity at E. Theſe areas, having equal baſes DH and EN, are as their altitudes BD and BE; that is, the ſpaces deſcribed are as the ſquares of the acquired velocities. And we ſee that this characteriſtic mark of uniformly accelerated motion is included in this general propoſition.

101 Example ſecond of peculiar importance.

2. Let us ſuppoſe that the body is impelled from A (fig. 17.) towards the point C, by a force proportional to its diſtance from that point. This force may be repreſented by the ordinates DA, EB, eb, &c. to the ſtraight line DC. We may take any magnitude of theſe ordinates; that is, the line DC may make any angle with AC. It will ſimplify the inveſtigation if we make the firſt force AD = AC. About C deſcribe the circle AHa, cutting the ordinate EB in F; let eb be another ordinate, cutting the circle in f very near

to F; draw CH perpendicular to AC, and make the arch H h = f F, and draw h c parallel to HC; join FC and DH, and draw F g perpendicular to f b. Let IML be another ordinate.

The area DABE is to the area DAKL as the ſquare of the velocity at B to the ſquare of the velocity at K. But DABE is the exceſs of the triangle ADC above the triangle EBC, or it is half of the exceſs of the ſquare of CA or CF above the ſquare of CB, that is, half the ſquare of BF. In like manner, the area DAKL is equal to half the ſquare of KM; but halves have the ſame ratio as the integers; therefore the ſquare of BF is to the ſquare of KM as the ſquare of the velocity at B to the ſquare of the velocity at K; therefore the velocity at B is to the velocity at K as BF is to KM. The velocities are proportional to the ſines of the arches of the quadrant AFH deſcribed on AC.

Cor. 1. The final velocity with which the body arrives at C, is to the velocity in any other point B as radius to the ſine of the arch AF.

Cor. 2. The final velocity is to the velocity which the body would acquire by the uniform action of the initial force at A as 1 to $\sqrt{2}$; for the rectangle DA CH expreſſes the ſquare of the velocity acquired by the uniform action of the force DA; and this is double of the triangle DAC; therefore the ſquares of theſe velocities are as 1 and 2, and the velocities are as $\sqrt{1}$ and $\sqrt{2}$, or as 1 to $\sqrt{2}$.

Cor. 3. The time of deſcribing AB is to the time of deſcribing AC as the arch AF to the quadrant AFH.

102. For when the arch F f is diminiſhed continually, it is plain that the triangle f i F is ultimately ſimilar to CFB, by reaſon of the equal angles C i b (or CFB) and f i F, and the right angles CBF and f F i; therefore the triangles f g F and CBF are alſo ſimilar. Moreover, B b is equal to F g, F f is equal to h H, which is ultimately equal to c C; therefore ſince the triangles f g F and CFB are ſimilar, we have F g : F f = FB : FC, = FB : HC; therefore B b is to c C as FB to HC, that is, as the velocity at B to the velocity at C; therefore B b and c C are deſcribed in equal moments when indefinitely ſmall; therefore equal portions F f, h H, of the quadrant correſpond to equal moments of the accelerated motion, along the radius AC; and the arches AF, FM, MH, &c. are proportional to the times of deſcribing AB, BK, KC, &c.

Cor. 4. The time of deſcribing AC with the unequally accelerated motion, is to the time of deſcribing it uniformly with the final velocity as the quadrantal arch is to the radius of a circle; for if a point move in the quadrantal arch ſo as to be in F, f, M, H, &c. when the body is in B, b, K, C, it will be moving uniformly, becauſe the arches are proportional to the times of deſcribing thoſe portions of AC; and it will be moving with the velocity with which the body arrives at C, becauſe the arch h H is ultimately = C c. Now if two bodies move uniformly with this velocity, one in the arch AFH, and the other in the radius AC, the times will be proportional to the ſpaces uniformly deſcribed; but the time of deſcribing AFH is equal to the time of the accelerated motion along AC; therefore the propoſition is manifeſt.

103. *Cor.* 5. If the body proceed in the line C a, and be retarded in the ſame manner that it was accelerated along AC, the time of deſcribing AC uniformly with the velocity which it acquires in C is to the time of deſcribing AC a with the varied motion, as the diameter of a circle to the circumference; for becauſe the momentary retardations at K′, B′, &c. are equal to the accelerations at K and B, &c. the time of deſcribing AC a is the ſame with that of deſcribing AH a uniformly with the greateſt velocity. That is, to the time of deſcribing AC uniformly as AH a to AC, or as the circumference of a circle to the diameter. Therefore, &c. *N. B.* In this caſe of retarding forces it is convenient to repreſent them by ordinates K′L, B′E, a D′, lying on the other ſide of the axis AC a; and to conſider the areas bounded by theſe ordinates as ſubtractive from the others. Thus the ſquare of the velocity at K′ is expreſſed by the whole area DACK′L′D, the part C′K′L being negative in reſpect of the point DAC. This obſervation is general (See alſo OPTICS, nº 125, *Encycl.*)

Cor. 6. The time of moving along KC, the half of AC, by the uniform action of the force at A, is to that of deſcribing AC a by the varied action of the force directed to C, and proportional to the diſtance from it, as the diameter of a circle to the circumference; for when the body is uniformly impelled along KC by the conſtant force IK, the ſquare of the velocity acquired at C is repreſented by half the rectangle IKCH, and therefore it is equal to the velocity which the variable force generates by impelling it along AC (by the way, an important obſervation). The body will deſcribe AC uniformly with this velocity in the ſame time that it is uniformly accelerated along KC. Therefore by *Cor.* 5. the propoſition is manifeſt.

Cor. 7. If two bodies deſcribe AC and KC by the action of forces which are every where proportional to the diſtances from C, their final velocities will be proportional to the diſtances run over, and the times will be equal.

For the ſquares of the final velocities are proportional to the triangles ADC, LKC, that is, to AC^2, KC^2, and therefore the velocities are as AC, KC. The times of deſcribing AC and KC uniformly, with velocities proportional to AC and KC, muſt be equal; and theſe times are in the ſame ratio (*viz.* that of radius to $\frac{1}{4}$th of the circumference) to the times of deſcribing AC and KC with the accelerated motion. Therefore, &c.

Thus, by availing ourſelves of the properties of the circle, we have diſcovered all the properties or characters of a motion produced by a force always directed to a fixed point, and proportional to the diſtance from it.

Some of theſe are remarkable, ſuch as the laſt corollary; and they are all important; for there are innumerable caſes where this law of action obtains in Nature. It is nearly the law of action of a bow ſtring, and of all elaſtic bodies, when their change of figure during their mutual action is moderate; and it has been by the help of this propoſition, firſt demonſtrated in a particular caſe by Lord Brouncker and Mr Huyghens, that we have been able to obtain preciſe meaſures of time, and conſequently of actual motions, and conſequently of any of the mechanical powers of Nature. It is for this reaſon, as well as for the eaſy and perſpicuous employment of the mathematical method of proceeding, that we have ſelected it.

Inſtead of giving any more particular caſes, we may obſerve

Of Accelerating and Retarding Forces.

observe in general, that if the intensity of the force be proportional to any power whose index is $n - 1$ of the distance, and if a be the distance from the fixed point at which the body begins to be accelerated, and x its distance from that point in any part of the motion, the velocity will be $\doteq \sqrt{a^n - x^n}$. This is very plain, because the increment CGHD of the area of fig. 16. which is also the increment of the square of the velocity, is $\doteq x^{n-1}\dot{x}$, and the area is $\doteq x^n$; and the whole area, corresponding to the distance a, is a^n. Therefore the portion of the area lying beyond the distance x is $a^n - x^n$. This is as the square of the velocity, and therefore the velocity is as the square root $\sqrt{a^n - x^n}$ of this quantity.

This proposition, $f\dot{s} \doteq v\dot{v}$, or $f \doteq \frac{v\dot{v}}{\dot{s}}$, is the 39th of the first book of Newton's *Principia*, and is perhaps the most important in the whole doctrine of dynamics, whether employed for the investigation of forces or for the explanation of motions. It furnishes the most immediate data for both purposes, but more especially for the last. By its help Sir Isaac Newton was able to point out the numerous disturbances of the planetary motions, and to separate them from each other; thus unravelling, as it were, that most intricate motion in which all are blended together. He has given a most wonderful specimen of its application in his Lunar Theory.

We now are able to explain all the puzzling facts which were adduced by Leibnitz and his partisans in support of their measure of the forces of bodies in motion. We see why four springs, equally bent, communicate but a double velocity, and nine springs but a triple velocity; why a bullet moving twice as fast will penetrate an earthen rampart to a quadruple depth, &c. &c.

Conservatio virium vivarum.

This theorem also gives a most perspicuous explanation of the famous doctrine called *conservatio virium vivarum*. When perfectly elastic bodies act on each other, it is found that the sum of the masses multiplied by the squares of the velocities is always the same. This has been substituted, with great encomiums, by the German philosophers in place of Des Cartes's principle, that the quantity of motion in the universe, estimated in one direction, remains always the same. They are obliged, however, to acknowledge, that in the actions of perfectly hard bodies, there is always a loss of *vis viva*, and therefore have denied the existence of such bodies. But there is the same loss in the mutual actions of all soft or ductile, or even imperfectly elastic, bodies; and they are miserably puzzled how to explain the fact; but both the *conservatio* and the *amissio* are necessary consequences of this theorem.

In the collision of elastic bodies, the whole change of motion is produced during the short time that the bodies are compressed, and while they regain their figure. When this is completed, the bodies are at the same distance from each other as when the mutual action began. Therefore the preceding body has been accelerated, and the following body has been retarded, along equal spaces; and in every point of this space the accelerating and the retarding force has been equal. Consequently the same area of fig. 17. expresses the change made on the square of the velocity of both bodies. Therefore, if V and U are the velocities before collision, and v and u the velocities after collision, of the two bodies A and B, we must have $A \times \overline{V^2 - v^2} = B \times \overline{u^2 - V^2}$, and therefore $A \times V^2 + B \times U^2 = A \times v^2 + B \times u^2$.

But in the other class of bodies, which do not completely regain their figure, but remain compressed, they are nearer to each other when their mutual action is ended than when it began. The foremost body has been accelerated along a shorter space than that along which the other has been retarded. The mutual forces have, in every instant, been equal and opposite. Therefore the area which expresses the diminution of the square of the velocity, must exceed the area expressing the augmentation by a quantity that is always the same when the permanent compression is the same; that is, when the relative motion is the same. $A \times \overline{V^2 - v^2}$ must exceed $B \times \overline{u^2 - U^2}$, and $A \times V^2 + B \times U^2$ must exceed $A \times v^2 + B \times u^2$.

This same theorem is of the most extensive use in all practical questions in mechanic arts; and without it mechanics can go no farther than the mere statement of equilibrium.

History of nº 95. is curious.

Hermann, professor of mathematics at Pavia, one of the ornaments of the mathematical class of philosophers, has given a pretty demonstration of this valuable proposition in the *Acta Eruditorum Lipsiæ* for 1709; and says, that having searched the writings of the mathematicians with great care, he found himself warranted to say, that Newton was the undoubted author, and boasts of his own as the first synthetical demonstration. The purpose of this assertion was not very apparent at the time; but long after, in 1746, when Hermann's papers, preserved in the town-house of Pavia, were examined, in order to determine a dispute between Maupertuis and Koenig about the claim to the discovery of *the principle of least action*, letters of Leibnitz's were found, requesting Hermann to search for any traces of this proposition in the writings of the mathematicians of Europe. Leibnitz was by this time the envious detractor from Newton's reputation; and could not but perceive, that all his contorted arguments for his doctrine received a clear explanation by means of this proposition, in perfect conformity to the usual measure of moving forces. Newton had discovered this theorem long before the publication of the *Principia*, and even before the discovery of the chief proposition of that book in 1666; for in his Optical Lectures, the materials of which were in his possession in 1664, he makes frequent use of a proposition founded on this (see nº 42.) We may here remark, that Hermann's demonstration is, in every step, the same with Dr Barrow's demonstration of it as a theorem merely geometrical, without speaking of moving forces (see *Lect. Geometr.* xi. p. 85. edit. 16.), but giving it as an instance of the transformation of curves, which he calls SCALES of velocity, of time, of acceleration, &c. It is very true that Barrow, in these mathematical lectures, approached very near to both of Newton's discoveries, the fluxionary geometry, and the principles of dynamics; and the junto on the continent, who were his continual detractors, charge him with impudent plagiarism from Dr Barrow, and even say that he has added nothing to the discoveries of his teacher. But surely Dr Barrow was the best judge of this matter;

ter; and ſo far from reſenting the uſe which Newton has made of what he had taught him, he was charmed with the genius of the *juvenis ſpectatiſſimus* his ſcholar, and of his own accord gave him his profeſſorial chair, and ever after lived in the utmoſt harmony and friendſhip with him. Nay, it would even appear, from ſome expreſſions in thoſe very lectures, that Dr Barrow owed to young Newton the firſt thought of making ſuch extenſive uſe of motion in geometry. We recommend this work of Barrow's to the ſerious peruſal of our readers, who wiſh to acquire clear notions of the ſcience of motion, and an elegant taſte in their mechanical diſquiſitions. After all the cultivation of this ſcience by the commentators and followers of Newton, after the *Phoronomia* of Hermann, the *Mechanica* of Euler, the *Dynamique* of D'Alembert, and the *Mechanique Analytique* of De la Grange, which are undoubtedly works of tranſcendent merit and utility, the *Principia* of Newton will ſtill remain the moſt pleaſing, perſpicuous, and elegant ſpecimen of the application of mathematics to the ſcience of *univerſal mechanics*, or what we call DYNAMICS.

The two fundamental theorems $f\,\dot{t} = \dot{v}$, and $f\,\dot{s} = v\,\dot{v}$, enable us to ſolve every queſtion of motion accelerated or retarded by the action of the mechanical powers of nature. But the employment of them may be greatly expedited and ſimplified by noticing two or three general caſes which occur very frequently.

104 Similar inſtants and points, what?

Theſe may be called ſimilar inſtants of time, and ſimilar points of ſpace which divide given portions of time, and of ſpace in the ſame ratio. Thus the middle is a ſimilar inſtant of an hour or of a day, and is the ſimilarly ſituated point of a foot or of a yard. The beginning of the 21ſt minute, and of the 9th hour, are ſimilar inſtants of an hour and of a day. The beginning of the 5th inch, and of the 2d foot, are ſimilar points of a foot and of a yard.

105 Similar actions, what?

Forces may be ſaid to act ſimilarly when their intenſities in ſimilar inſtants of time, or in ſimilar points of ſpace, are in a conſtant ratio. Thus in fig. 17. when one body is impelled towards C from A, and another from K, each with a force proportional to the diſtance of every point of its motion from C, theſe forces may be ſaid to act ſimilarly along the ſpaces AC and KC, or during the times repreſented by the quadrantal arches AFH, KNO The following propoſitions on ſimilar actions will be found very uſeful on many occaſions; but we muſt premiſe a geometrical lemma.

106. If there be two lines EFGH (fig. 18.), $e\,f\,g\,h$, ſo related to their abſciſſes AD, $a\,d$, that the ordinates IK, $i\,k$, drawn from ſimilar points I and i of the abſciſſes, are in the conſtant ratio of AE to $a\,e$; then the area ADHE is to the area $a\,d\,h\,e$ as the rectangle of AD $\times$ AE to the rectangle $a\,d \times a\,e$.

For let each abſciſſa be divided into the ſame number of equal and very ſmall parts, of which let CD and $c\,d$ be one in each. Inſcribe the rectangles CGID, $c\,g\,i\,d$. Then becauſe the number of parts in each axis is the ſame, the lengths of the portions CD and $c\,d$ will be proportional to the whole abſciſſes AD and $a\,d$. And becauſe C and c are ſimilar points, CG is to $c\,g$ as AE is to $a\,e$. Therefore $\text{CD} \times \text{CG} : c\,d \times c\,g = \text{AD}$ $\text{AE} : a\,d \times a\,e$. This is true of each pair of correſponding rectangles; and therefore it is true of their ſums. But when the number of theſe rectangles is increaſed, and their breadth diminiſhed without end, it is evident that the ultimate ratio of the ſum of all the rectangles, ſuch as CDHG to the ſum of all the rectangles $c\,d\,h\,g$, is the ſame with that of the area ADHE to the area $a\,d\,h\,e$, and the propoſition is manifeſt.

If two particles of matter are ſimilarly impelled during given times, the changes of velocity are as the times and as the forces jointly. 107.

Let the times be repreſented by the ſtraight lines ABC (fig. 19.) and $a\,b\,c$, and the forces by the ordinates AD, BE, CF, and $a\,d$, $b\,e$, $c\,f$. Then if B and b are ſimilar inſtants (ſuppoſe the middles) of the whole times, we have $\text{BE} : b\,e = \text{AD} : a\,d$. Therefore, by the lemma, the area ACDF is to $a\,c\,f\,d$ as $\text{AC} \times \text{AD}$ to $a\,c \times a\,d$. But theſe areas are proportional to the velocities (n° 72), and the propoſition is demonſtrated. For the ſame reaſon the change of velocity during the time AB is to the change during $a\,b$ as $\text{AB} \times \text{AD}$ to $a\,b \times a\,d$.

Cor. 1. If the times and forces are reciprocally proportional, the changes of velocity are equal; and if the forces are inverſely as the times, the changes of velocity are equal.

If two particles be ſimilarly urged along given ſpaces, the changes made on the ſquares of the velocities are as the forces and ſpaces jointly. 108.

For if AC (fig. 19.) and $a\,c$ are the ſpaces along which the particles are impelled, and the forces are as the ordinates AD and $a\,d$, the areas ACFD and $a\,c\,f\,d$ are as the changes on the ſquares of the velocities. But theſe areas are as $\text{AC} \times \text{AD}$, and $a\,c \times a\,d$. Therefore, &c.

Cor. 2. If the ſpaces are inverſely as the forces, the changes of the ſquares of the velocities are equal; and if theſe are equal, the ſpaces are inverſely as the forces.

Cor. 3. If the ſpaces, along which the particles have been impelled from a previous ſtate of reſt, are directly as the forces, the velocities are alſo as the forces. For, becauſe the changes of the ſquares of the velocities are as the ſpaces and forces jointly, they are in this caſe as the ſquares of the forces or of the ſpaces; but the changes of the ſquares of the velocities are in this caſe the whole ſquares of the velocities; therefore the ſquares of the velocities are as the ſquares of the forces, and the velocities are as the forces. *N. B.* This includes the motions repreſented in fig. 17.

If two particles be ſimilarly impelled along given ſpaces, from a ſtate of reſt, the ſquares of the times are proportional to the ſpaces directly, and to the forces inverſely. 109.

Let ABC (fig. 19.) $a\,b\,c$ be the ſpaces deſcribed, and AD, $a\,d$, the accelerating forces at A and a Let V, B expreſs the velocity at B, and v, b the velocity at b.

Let GHK and $g\,h\,k$ be curves whoſe ordinates are inverſely as the velocities at the correſponding points of the abſciſſa. Theſe curves are therefore exponents of the times (n° 99) Then, becauſe the forces act ſimilarly, we have, by the laſt theorem, $\text{AC} \times \text{AD} : a\,c \times a\,d = \text{V}^2, \text{B} : v^2, b, = h\,b^2 : \text{HB}^2$. Therefore $\text{HB} : h\,b = \sqrt{\overline{a\,c \times a\,d}} : \sqrt{\overline{\text{AC} \times \text{AD}}}$, and therefore in a conſtant ratio. Call this the ratio of m to n. But, ſince the ordinates of the lines GHK, $g\,h\,k$ are inverſely as the velocities, the areas are as the times (n° 99); and

Of Accelerating and Retarding Forces.

and since these ordinates are in the constant ratio of m to n, the areas are in the ratio of $AC \times m$ to $ac \times n$. Therefore (calling the times of the motions T and t), we have

$$T : t = m AC : n ac \text{; and therefore}$$
$$T^2 : t^2 = m^2 \times AC^2 : n^2 \times ac^2. \text{ But}$$
$$m^2 : n^2 = ac \times ad : AC \times AD. \text{ Therefore}$$
$$T^2 : t^2 = ac \times ad \times AC^2 : AC \times AD \times ac^2,$$
$$\text{Or } T^2 : t^2 = ad \times AC : AD \times ac.$$
$$\text{Or } T^2 : t^2 = \frac{AC}{AD} : \frac{ac}{ad}.$$

The attentive reader will observe that these three propositions give a great extension to the theorems which were formerly deduced from the nature of uniformly accelerated motion, or of uniform action of the forces, and were afterwards demonstrated to obtain in the momentary action of forces any how variable.

The first of the three propositions, $V : v = F \times T : f \times t$, is the extension of the theorem $f \times \dot{t} = \dot{v}$. The second, $V^2 : v^2 = F \times S : f \times s$, is the extension of the theorem $f \times \dot{s} = v \dot{v}$. And the third, $T^2 : t^2 = \frac{S}{F} : \frac{s}{f}$, is the extension of $f = \frac{\dot{s}}{(\dot{t^2})}$, or of $f \times (\dot{t^2}) = \dot{s}$. These theorems hold true of all *similar* actions; and only for this reason, are true of uniformly accelerated motions, or uniform actions.

Aggregate of many equal accelerating forces.

There remains one thing more to be said concerning the action of accelerating forces. Their magnitude is ascertained by their effect. Therefore that is to be considered as a double force which produces a double quantity of motion. Therefore when a body A contains twice the number of equal atoms of matter, and acquires the same velocity from the action of the force F that another body a, containing half the number of atoms, acquires from the action of a force f, we conceive F to be double of f. That this is a legitimate inference appears clearly from this, that we conceive the sensible weight of a body, or that pressure which it exerts on its supports, as the aggregate of the equal pressure, of every atom, accumulated perhaps on one point; as when the body hangs by a thread, and, by its intervention, pulls at some machine. Without inquiring in what manner, or by what intervention, this accumulation of pressure is brought about, we see clearly that it results from the equal accelerating force of gravity acting immediatly on each atom. When this weight is thus employed to move another body by the intervention of the thread, which is attached to one point perhaps of that body, it puts the whole into motion, generating a certain velocity v in every atom, by acting uniformly during the time t. We conceive each atom to have sustained the action of an equal accelerating force; whose measure is $\frac{v}{t}$. Without considering how this force is exerted on each atom, or by what it is immediately exerted, or how it is diffused through the body from the point to which the weight of the other body is applied by means of the thread; we still consider it as the aggregate of the action of gravity on each atom of that other body. Moreover, attending only to the motion produced by it, and perhaps not knowing the weight of the impelling body, we measure it, as a moving force, by considering it as the aggregate of the forces propagated to each atom of the impelled body, and measured by $\frac{v}{t}$. If we know that the impelled body contains the number m of atoms, the aggregate of forces is $m\frac{v}{t}$, or $\frac{mv}{t}$.

But since we measure forces by the quantity of motion which they produce, we must conceive, that when the same force is applied to a body which consists of n particles, and produces the velocity u, by acting uniformly during the same time t, the force $n\frac{u}{t}$ is equal to the force $m\frac{v}{t}$.

110 Moving force, motive force, vis motrix, as distinguished from accelerating force.

Sir Isaac Newton found it absolutely necessary, in the disquisitions of natural philosophy, to keep this circumstance of acceleration clear of all notions of quantity of matter, or other considerations, and to contemplate the affections of motion only. He therefore considered $\frac{v}{t}$ as the true original measure of accelerating force, and $m\frac{v}{t}$ as an aggregate. He therefore calls the aggregate a *vis motrix*, a *moving force*, measured by the *quantity of motion* that it generates. And he confines the term *accelerating force* to the quantity $\frac{v}{t}$, measured by the *acceleration* or *velocity* only. It would be convenient, therefore, also to confine the symbol f to $m\frac{v}{t}$, and to retain the symbol a for expressing the accelerating force $\frac{v}{t}$.

This appellation of *motive force* is perfectly just and simple; for we may conceive it as the same with the accelerating force which produces the velocity m times v in one particle, by acting on it uniformly during the time t. This motion of one particle having the velocity mv, is the same with that of m particles having each the velocity v.

If therefore a motive force f acts on a body consisting of m particles, the accelerating force a is $= \frac{f}{m}\frac{v}{t}$.

Therefore the three last propositions concerning the similar, the uniform, or the momentary actions of moving forces, when expressed in the most general terms, are,

$$v = \frac{f}{mt},$$
$$vv = \frac{fs}{m}, \text{ or } v\dot{v} = \frac{f\dot{s}}{m}$$
$$t^2 = \frac{ms}{f}.$$

Of Deflecting Forces.

111 Deflecting forces.

When we observe the direction of a body to change, we unavoidably infer the agency of a force which acts in a direction that does not coincide with that of the body's motion; and we may distinguish this circumstance by calling it a DEFLECTING FORCE. We have already shewn how to estimate and measure this deflecting force, by considering it as competent to the pro-

Of Deflecting Forces.

production of that motion which, when compounded with the former motion, will produce the new motion (n° 44.) Now, as all changes of motion are really compositions of motions or forces, it is evident that we shall explain the action of deflecting forces when we shew this composition.

Alteration of deflections are continual, and produce curvilineal motions.

We may almost venture to say *à priori*, that all deflections must be continual, or exhibit curvilineal motions: for as no finite velocity, or change of velocity, can be produced in an instant by the action of an accelerating force, no polygonal or angular deflection can be produced; because this is the composition of a finite velocity produced in an instant. Deflective motions are all produced by the composition of the former motion, having a finite velocity, with a transverse motion continually accelerated from a state of rest. Of this we can form a very distinct notion, by taking the simplest case of such accelerated motion, namely, an uniformly accelerated motion.

112 Example Determination of the path,

Let a body be moving in the direction AC (fig. 20.) with any constant velocity, and when it comes to A, let it be exposed to the action of an accelerating force, acting uniformly in any other direction AE. This alone would cause the body to describe AE with a uniformly accelerated motion, so that the spaces AD, AE would be as the squares of the times in which they are described. Therefore, if AB be the space which it would have described uniformly in the time that it describes AD by the action of the accelerating force, and AC the space which it would have described uniformly while it describes AE by the action of the accelerating force—nothing more is wanted for ascertaining the real motion of the body but to compound the uniform motion in the direction AC with the uniformly accelerated motion in the direction AE. AD is to AE as the square of the time of describing AD to the square of the time of describing AE; that is, as the square of the time of describing AB to the square of the time of describing AC; that is, as AB^2 to AC^2 (by reason of the uniform motion in AC). This composition is performed by taking the simultaneous points B, D, and the simultaneous points C, E, and completing the parallelograms ABFD, ACGE. The body will be found in the points F and G in the instants in which it would have been found at B and C by the uniform motion, or in D and E by the accelerated motion. In the same manner may be found as many points of the real path as we please. It is plain that these points will be in a line AFG, so related to AE that $AD : AE = DF^2 : EG^2$; or so related to the original motion AC, that $AB^2 : AC^2 = BF : CG$, &c. This line is therefore a parabola, of which AE is a diameter, DF and EG are ordinates, and which touches AC in A.

And of the motion in this path.

Having thus ascertained the path of the body, we can also ascertain the motion in that path; that is, the velocity in any point of it. We know that the velocity in the point G is to the velocity of the uniform motion in the direction AC as the tangent TG is to the ordinate EG; because this is the ultimate ratio of the momentary increment of the arch AFG to the momentary increment of the ordinate EG. Thus is the velocity in every point of the curve determined. We have taken it for granted, that the line of projection touches the path, and that the direction in every point is that of the tangent. To suppose that the curve, in any portion of it, coincides with the tangent, is to suppose that the body is not deflected; that is, is not acted on by a transverse accelerating force: And to suppose that the tangent makes a finite angle with any part of the path, is to suppose that the deflection is not continual, but by starts—both of which are contrary to the conditions of the case. No straight line can be drawn between the direction of the body and the succeeding portion of the path, otherwise we must again suppose that the deflection is subsultory, and the motion angular.

113. But while the investigation is so easy when the direction and intensity of the deflecting force in every point of the curve are known, the investigation of the deflecting force from the observed motion is by no means easy. The observed curvilineal motion always arises from a composition of a uniform motion in the tangent with some transverse motion. But the same curvilineal motion may be produced by compounding the uniform motion in the tangent with an infinity of transverse motions; and the law of action will be different in these transverse motions according as their directions differ. We must learn, not only the intensity of the deflecting force, and the law of its variation, but also its direction in every point of the curve. It is not easy to find general rules for discovering the direction of the transverse force; most commonly this is indicated by extrinsic circumstances. The deflecting force is frequently observed to reside in, or to accompany, some other body. It may be presumed, therefore, that it acts in the direction of the line drawn to or from that body; yet even this is uncertain. The most general rule for this investigation is to observe the place of the body at several intervals of time before and after its passing through the point of the curve, where we are interested to find its precise direction. We then draw lines, joining those places with the places of the tangent where the body would have been by the uniform motion only. We shall perhaps observe these lines of junction keep in parallel positions: we may be assured that the direction of the transverse force is the same with that of any of these lines. This is the case in the example just now given of a parabolic motion. But when these lines change position, they will change it gradually; and their position in the point of contact is that to which their positions on both sides of it gradually approximate.

But all this is destitute of the precision requisite in philosophical discussion. We are indebted to Sir Isaac Newton for a theorem which ascertains the direction of the transverse force with all exactness, in the cases in which we most of all wish to attain mathematical accuracy, and which not only opened the access to those discoveries which have immortalised his name, but also pointed out to him the path he was to follow, and even marked his first steps. It therefore merits a very particular treatment.

114 Newton's fundamental theorem for the direction of a deflecting force.

If a body describes a curve line ABC, DEF (fig. 21.) lying in one plane; and if there be a point S so situated in this plane that the line joining it with the body describes areas ASB, ASC, ASD, &c. proportional to the times in which the body describes the arches AB, AC, AD, &c. the force which deflects the body from rectilineal motion is continually directed to the fixed point S.

Let

Of Deflecting Forces.

Let us first suppose that the body describes the polygon ABCDEF, &c. formed of the chords AB, BC, CD, DE, EF, &c. of this curve: and (for greater simplicity of argument) let us consider areas described in equal successive times; that is, let us suppose that the triangles ASB, BSC, CSD, &c. are equal, and described in equal times. Make $Bc = AB$, and draw cS.

Areas ∸ to the times indicate central forces.

Had the motion AB suffered no change in the point B, the body would have described Bc in the equal moment succeeding the first: but it describes BC. The body has therefore been deflected by an external force; and BC is the diagonal of a parallelogram (n° 45, 46.), of which Bc is one side, and cC is another. The deflecting force will be discovered, both in respect of direction and intensity, by completing the parallelogram $BcCb$. Bb is the space which the deflecting force would have caused the body to describe in the time that it describes Bc or BC. Because Bc is equal to BA, the triangles BSc, BSA are equal. But (by the nature of the motion) BSA is equal to BSC. Therefore the triangles BSC and BSc are equal. They are also on the same base BS; therefore they lie between the same parallels, and Cc is parallel to SB. But cC is parallel to Bb. Therefore Bb coincides with BS, and the deflecting force at B is directed toward S. By the same argument, the deflecting force at the angles D, E, F, &c. is directed to S.

Now, let the sides of the polygon be diminished, and their number increased without end. The demonstration remains the same; and continues, when the polygon finally coalesces with the curve, and the deflection is continual.

When areas are described proportional to the times, equal areas are described in equal times; and therefore the deflection is always directed to S. Q. E. D.

Centre of deflection. Centre of forces. Central forces.

The point S may, with great propriety of language, be called the CENTRE OF DEFLECTION, or THE CENTRE OF FORCES; and forces which are thus continually directed to one fixed point, may be distinguished from other deflecting forces by the name CENTRAL FORCES.

The line joining the centre of forces with the body, and which may be conceived as a stiff line, carrying the body round, is usually named the RADIUS VECTOR.

Radius vector.

115 Central forces produce areas proportional to the times.

The converse of this proposition, viz. that if the deflecting forces be always directed to S, the motion is performed in one plane, in which S is situated, and areas are described proportional to the times—is easily demonstrated by reversing the steps of this demonstration. The motion will be in the plane of the lines SB and Bc; because the diagonal BC of the parallelogram of forces is in the plane of the sides. Areas are described proportional to the times; for Cc being parallel to SB, the triangles SCB and ScB are equal; and therefore SCB and SAB are equal, &c. &c.

116 Velocity is inversely as the perpendicular from the centre.

Cor. 1. When a body describes areas round S proportional to the times, or when it is continually deflected toward S, or acted on by a transverse force directed to S, the velocities in the different points A and E of the curve are inversely proportional to the perpendiculars Sr and St, drawn from the centre of forces to the tangents in those points; that is, to the perpendiculars from the centre on the momentary directions of the motion: For since the triangles ASB, ESF are equal, their bases AB, EF are inversely as their altitudes Sr, St. But these bases, being described in equal times, are as the velocities; and they ultimately coincide with the tangents at A and E.

Cor. 2. If $B\alpha$ and $F\epsilon$ be drawn perpendicular to SA and SE, we have $SA \times B\alpha = SE \times F\epsilon$, and $SA : SE = F\epsilon : B\alpha$: For $SA \times B\alpha$ is double of the triangle BSA, and $SE \times F\epsilon$ is double of the equal triangle SFE. 117.

118 Angular velocity is inversely as the square of the distance from the centre of forces.

Cor. 3. The angular velocity round S, that is, the magnitude of the angle described in equal times by the radius vector, is inversely proportional to the square of the distance from S. For when the arches AB, EF are diminished continually, the perpendiculars $B\alpha$ and $F\epsilon$ will ultimately coincide with arches described round S with the radii SB and SF. Now the magnitude of an angle is proportional to the length of the arch which measures it directly, and to the radius of the arch inversely. In any circle, an arch of two inches long measures twice as many degrees as an arch one inch long; and an arch an inch long contains twice as many degrees of a circle whose radius is twice as short. Therefore, ultimately, the angle ASB is to the angle ESF as $B\alpha$ to $F\epsilon$, and as SF to SB jointly: that is, as $B\alpha \times SF$ to $F\epsilon \times SB$. But $B\alpha : F\epsilon = SE : SA$ (*Cor.* 2.) Therefore $ASB : ESF = SE \times SF : SB \times SA$, = ultimately $SE^2 : SB^2$.

This corollary gives us an ostensible mark, in many very important cases, of the action of a deflecting force being always directed to a fixed point. We are often able to measure the angular motion when we cannot measure the real velocities.

Intimate connection of dynamics and the higher geometry.

Having thus discovered the chief circumstances which enable us to ascertain the direction of the deflecting force, we proceed to investigate the quantity of this deflective determination in the different points of a curvilineal motion. This is a more difficult task. The momentary effect of the deflecting force is a small deviation from the tangent; and this deviation is made with an accelerated motion. The law of this acceleration regulates the curvature of the path, and is to be determined by it. We may be allowed to observe by the way, that it appears clearly from the form in which Newton has presented all his dynamical theorems, that we are indebted to these problems for the immense improvement which he has made in geometry by his invention of fluxions. The purposes he had in view suggested to his penetrating mind the means for attaining them; and the connection between dynamics and geometry is so intimate, that the same theorems are in a manner common to both. This is particularly the case in all that relates to curvature. Or shall we say that the geometry of Dr Barrow suggested the dynamical theorems to Newton? We have seen how the curvature of a parabola is produced by a force acting uniformly. The *momentary* action of all finite forces may be considered as uniform; and therefore the curvature will be that of some portion of some parabola; but it will be difficult to determine the precise degree without some farther help. We are best acquainted with the properties of the circle, and will have the clearest notions of the curvature of other curves by comparing them with circles.

Measure of curvature.

The curvature of a circular arch of given length is so much greater as its radius is shorter; for it will contain so many more degrees in the same length; and therefore

therefore the change of direction of its extremities is ſo much greater. Curvatures may always be meaſured by the length of the arch directly and the radius inverſely.

119 Evolution and involution of curves.

Suppoſe a thread made faſt at one end of a material curve ABCD (fig. 22), and applied to it in its whole length. Taking hold of its extremity D, unfold it gradually from the curve DCBA; the extremity D will deſcribe another curve D*cba*. This geometrical operation is called the EVOLUTION of curves, and D*cba* is called the EVOLUTE of DCBA, which is called the INVOLUTE of D*cba*. Perhaps this denomination has been given from the geneſis of the area or ſurface contained by the two lines, which is folded up and unfolded ſomewhat like a fan. When the deſcribing point is in *b*, the thread *b*B is, undoubtedly, the momentary radius of a circle *ebf*, whoſe centre is B, the point of the involute which it is juſt going to quit. The momentary motion of *b* is the ſame, whether it is deſcribing an arch of the evolute paſſing through *b*, or an arch of a circle round the centre B. The ſame line *bt*, perpendicular to the thread *b*B, touches the circle *ebf* and the curve D*ba* in the point *b*. This circle *ebf* muſt lie within the curve D*ba* on the ſide of *b*B toward *a*; becauſe on this ſide the momentary radius is continually increaſing. For ſimilar reaſons, the circle *ebf* lies without the curve on the other ſide of *b*B. Therefore the circle *ebf* both touches and cuts the curve D*ba* in the point *b*. Moreover, becauſe every portion of the curve between *b* and D is deſcribed with radii that are ſhorter than *b*B, it muſt be more incurvated than any portion of the circle *ebf*. For ſimilar reaſons, every portion of the curve between *b* and *a* muſt be leſs incurvated than this circle; therefore the circle has that preciſe degree of curvature that belongs to the curve in the point *b*; it is therefore called the

Circle of curvature. Equicurve circle.

EQUICURVE CIRCLE, or the CIRCLE OF CURVATURE, and B is called the centre, and B*b* the RADIUS OF CURVATURE. It is eaſy to perceive that no circle can be deſcribed which ſhall touch the curve in *b*, and come between it and the circle *ebf*; for its centre muſt be in ſome point *i* of the radius *b*B. If *ib* be leſs than B*b*, it muſt fall within the curve on both ſides of *b*, and if *ib* is greater than B*b*, the circle muſt fall without the curve on both ſides of B*b*. The circle *ebf* lies cloſer to the curve, has cloſer contact with it than any other, and has therefore got the whimſical name of OSCULATING CIRCLE; and this ſort of contact was called OSCULATION.

This view of the geneſis of curve lines is of particular uſe in dynamical diſcuſſions. It exhibits to the eye the perfect ſameneſs of the momentary motion, and therefore of the momentary deflection, in the curve and in the equicurve circle, and leaves the mind without a doubt but that the forces which produce the one will produce the other. A great variety of curves may be deſcribed in this way. If perpendiculars be drawn to the curve D*ba* in every point, they will interſect each other, each its immediate neighbour, in the circumference of the curve DBA: and geometry teaches us how to find the curve DBA which ſhall produce the curve D*ba* by evolution. See EVOLUTION and INVOLUTION, *Supplement*.

It is a matter worthy of remark, that the path of a body that is deflected from rectilineal motion by a *finite* force, varying according to any law whatever, may always be deſcribed by evolution. This includes almoſt every caſe of the action of deflecting forces; none being excepted but when, by the oppoſite action of different forces, the body is in equilibrio in one ſingle point of its path.

Our taſk is now brought within a very narrow compaſs, namely, to meaſure the deflection in the arch of a circle.

Had the motion repreſented in fig. 21. been polygonal, it is plain that the deflecting force in the point B is to that in the point E as the diagonal B*b* of the parallelogram ABC*b* to the diagonal E*i* of the parallelogram DEF*i*; therefore let ABCZY be a circle paſſing through the points A, B, and C, and let the radius vector BS cut the circumference in Z; draw AZ, CZ, and the diagonal AC, which neceſſarily biſects and is biſected by the diagonal B*b*. The triangles *b*BC and CBZ are ſimilar; for the angle C*b*B is equal to the alternate angle AB*b* or ABZ, which is equal to the ACZ, ſtanding on the ſame chord AZ. And the angle CB*b*, or CBZ, is equal to CAZ, ſtanding on the ſame chord CZ; therefore the remaining angle *b*CB is equal to the remaining angle AZC; therefore ZA is to AC as BC to B*b*, and B*b* $=\frac{AC \times BC}{AZ}$. In like manner E*i* $=\frac{DF \times EF}{Dz}$.

Now let the points A and C continually approach, and ultimately coaleſce with B; it is evident that the circle ABCZY is ulimately the equicurve or coinciding circle at the point B, and that AS ultimately coaleſces with, and is equal to, BS, and that AC × BC is ultimately $2BC^2$; therefore ultimately B*b* : E*i* = $\frac{2BC^2}{BZ} : \frac{2EF^2}{Ez}$, or $= \frac{BC^2}{\frac{1}{2}BZ} : \frac{EF^2}{\frac{1}{2}Ez}$.

Measure of deflecting forces.

Now BC and EF being deſcribed in equal times, are as the velocities: B*b* and E*i* are the meaſures of the velocities which the deflective forces at B and E would generate in the time that the body deſcribes BC or EF, and are therefore the meaſures of thoſe forces. *They are as the ſquares of the velocities directly, and inverſely as thoſe chords of the equicurve circles which have the directions of the deflection.*

Obſerve, that B*b* or E*i* is the third proportional to half of the chord and the arch deſcribed; for B*b* : BC $= BC : \frac{BZ}{2}$.

It is evident that as the arches AB, BC, continually diminiſh, AC is ultimately parallel to the tangent B*r*, and BO is equal to the actual deflection from the tangent. The triangles BOC and AOZ are ſimilar, and BO $=\frac{OC^2}{OZ}$, or ultimately $=\frac{BC^2}{BZ}$. We may meaſure the forces by the actual deflections, becauſe they are the halves of the meaſures of the generated velocities; and we may ſay that

120 Measure of deflection.

The actual momentary deflection from the tangent is a third proportional to the deflective chord of the equicurve circle and the arch deſcribed during the moment.

Caution.

Either of theſe meaſures may be taken, but we muſt take care not to confound them. The firſt is the moſt proper, becauſe the change produced on the body (which is the *immediate* effect and meaſure of the force) is the determination, left inherent in it, to move with

a

a certain velocity. This is the meaſure alſo which we obtain by means of the differential or fluxionary calculus; but the other meaſure muſt be obtained when our immediate object is to mark the actual path of the body. What is now delivered coincides with what was more briefly ſtated in ASTRONOMY, *Suppl.* nº 16. and is repeated in this place, becauſe the ſteps of this demonſtration, which is Newton's, ſo naturally terminate in the equicurve circle, and give at once the immediate meaſure of the deflecting force: at the ſame time the reader muſt perceive that this meaſure does not depend on the force being always directed to one centre; it is enough that the two ſides of the polygon, in immediate ſucceſſion, are deſcribed in equal times. This is neceſſary in order that ABC *b* may be a parallelogram, and that the diagonals AC and B *b* may mutually biſect each other.

Thus have we obtained a meaſure of deflecting force, and, in the moſt important caſes, a method of diſcovering its direction. It only remains to point out the relation between the intenſity of the force, the curvature of the path, and the velocity of the motion. Theſe three circumſtances have a neceſſary connection; for we ſee that the intenſity is expreſſed by certain values of the other two in the formula $f \doteq \frac{\text{Arch}^2}{\frac{1}{4}\text{Chord}}$, or $f = \frac{2\,BC}{BZ}$. The deflective velocity B *b* is acquired in the time that the body deſcribes BC; therefore the deflective velocity is to the velocity in the curve as B *b* to BC. The velocity B *b* is acquired by an accelerated motion along BO; for while, by progreſſive motion, the body deſcribes BC, it deflects from the tangent through a ſpace equal to the half of B *b*, becauſe the momentary action of the deflecting force may be conſidered as uniform. The progreſſive velocity BC may be generated by the ſame force, uniformly acting through a ſpace greater than BC; call this ſpace *x*. The ſpaces along which a body muſt be uniformly impelled in order to acquire different velocities, are as the ſquares of thoſe velocities; therefore $Bb^2 : BC^2 = Bo : x$; but $Bb : BC = BC : \frac{1}{4}BZ$; therefore $Bb^2 : BC^2 = Bb : \frac{1}{4}BZ$, and $Bb : \frac{1}{4}BZ = Bo : x$, and $Bb : Bo = \frac{1}{4}BZ : x$; but B *o* is $\frac{1}{2}$ of B *b*; therefore *x* is $\frac{1}{2}$ of BZ; that is,

121. *The velocity in any point of a curvilineal path, is that which the deflecting forces in that point would generate in the body by impelling it uniformly along one fourth part of the deflective chord of the equicurve circle.* If the velocity increaſe, the chord of the equicurve circle muſt increaſe; that is, the path becomes leſs incurvated. If the force be increaſed, the curvature will alſo increaſe, for the chord of curvature will be leſs.

There is another general obſervation to be made on the velocity of a curvilineal motion, which greatly aſſiſts us in our inveſtigations.

122 Compariſon of orbital motion with direct approach to the centre.

If a body deſcribes a curve by the action of a force always directed to a fixed point, and varying according to any proportion whatever of the diſtances from that point, and if another body, acted on by the ſame centripetal force, move toward the centre in a ſtraight line, and if in any one caſe of equal diſtances from the centre of force the two bodies have equal velocities, they will have equal velocities in every other caſe of equal diſtances from the centre.

Let one body be impelled from A (fig. 23.) toward C along the ſtraight line AVDEC, and let another be deflected along the curve line VIK *k*. About the centre C deſcribe concentric arches ID, KE, very near to each other, and cutting the curve in I and K, and the line AC in D and E: draw IC, cutting KE in N, and draw NT perpendicular to the arch IK of the curve, and complete the parallelogram ITNO. Let the bodies be ſuppoſed to have equal velocities at I and at D.

Then, becauſe the centripetal forces are ſuppoſed to be the ſame for both bodies when they are at equal diſtances, the accelerating forces at D and I may be repreſented by the equal lines DE and IN; but the force IN is not wholly employed in accelerating the body along the arch IK, but, acting tranſverſely, it is partly employed in incurvating the path. It is equivalent to the two forces IO and IT, of which only IT accelerates the body. Now IKN is a right-angled triangle, as is alſo the triangle INT; and they are ſimilar; therefore IN : IT = IK : IN, or DE : IT = IK : DE; that is, the force which accelerates the body along DE is to the force which accelerates the body along IK as the ſpace IK is to the ſpace DE; therefore (nº 86.) the increment of the ſquare of the velocity acquired along DE is equal to the increment of the ſquare of the velocity acquired along IK. But the velocities at D and I were equal, and conſequently their ſquares were equal; and theſe having received equal increments, therefore the ſquares of the velocities at E and K are equal, and the velocities themſelves are equal. And ſince this is the caſe in all the correſponding points of the line AC and the curve VIK, the velocities at all equal diſtances from C will be equal.

It it evident that the concluſion will be the ſame, if the bodies, inſtead of being accelerated by approaching the centre in the ſtraight line AC, and in the curve VIK, are moving in the oppoſite directions from E to A, or from I to V, and are therefore retarded by the centripetal force.

Cor. Hence it follows, that if a body be projected from any point, ſuch as V, of the curve, in a line tending ſtraight from the centre, with the velocity which it had in that point of the curve, it would go to a diſtance VA, ſuch, that if it were impelled along AV by the centripetal force, it would acquire its former velocity in the point V; alſo in any point between V and A it will have the ſame velocity in its receſs from the centre that it has there in its approach to the centre. 123 Retarded curvilineal motion always accompanied by receſs from the centre.

The line BLFG, whoſe ordinates are as the intenſities of the centripetal force in A, V, D, E, or in A, V, I, K, may be called the SCALE or EXPONENT of force; the areas bounded by the ordinates AB, VL, DF, EG, &c. drawn from any two points of the axis, are as the ſquares of the velocity acquired by acceleration along the intercepted part of the axis, or in any curvilineal path, while the body approaches the centre, or which are loſt while the body retires from it. When we can compute theſe areas we obtain the velocities (ſee nº 102.).

We are now in a condition to ſolve the chief problem in the ſcience of dynamics, to which the whole of it is, in a great meaſure, ſubſervient. The problem is this,

Let a body be projected with a known velocity from

a

Of Deflecting Forces.

124 Inverse problem of centripetal forces.

a given point and in a given direction, and let it be under the influence of a mechanical force, whose direction, intensity, and variation, are all known : it is required to determine its path, and its motion in this path, for any given time?

This problem is susceptible of three distinct classes of conditions, which require different investigation.

1. The force may act in one constant direction ; that is, in parallel lines.

2. The force may be always directed to a fixed point.

3. It may be directed to a point which is continually changing its place.

1. When the force acts in parallel lines, the problem is solved by compounding the rectilineal accelerated motion which the force would produce in its own direction with the uniform motion which the projection alone would have produced. The motion must be curvilineal, when the accelerating force is transverse, in any degree whatever, to the projectile motion ; and the curvilineal path must be concave on that side to which the deflecting force tends ; for the force is supposed to act incessantly. The place of the body will be had for any time, by finding where the body would have been at the end of that time by each force acting alone, and by completing the parallelogram. Thus, suppose a body projected along AB (fig. 20.) while it is continually acted on by a force whose direction is AD. Let D and B be the places where the body would be at the end of a given time. Then the body will at the end of that time be in F, the opposite angle of the parallelogram ABFD. But it has not described the diagonal AF ; because its motion has been curvilineal, as we shall find by determining its place at other instants of this time.

The velocity in any point F is found by first determining the velocity at D, and making DT to DF as the velocity at D to the velocity at B (that is, the velocity of projection, because the motion along AB is uniform). Then draw TF. Then AB is to TF as the constant velocity of projection to the velocity at F. We have seen already (n° 112—119.) that TF is a tangent to the curve in F. Hence we may determine the velocity at F in another way. Having determined the form of the path in the way already described, by finding its different points, draw the tangent F *d*, cutting the line DA in *d*. Then the velocity at A is to that at F as AB to *d* F. Hence also we see, that the velocities in every point of the curve are proportional to the portion of the tangents at those points which are intercepted between *any* two lines parallel to AD.

Either of these methods for ascertaining the velocity, in this case of parallel deflections, will in general be easier than the general method in n° 121. by the equicurve circle.

It was thus that Galileo discovered the parabolic motion of heavy bodies.

Inverse problem of centripetal forces.

2 We must consider the motions of bodies affected by centripetal or centrifugal forces, always tending to one fixed point. This is the celebrated *inverse problem of centripetal forces*, and is the 42d proposition of the first book of Newton's *Principia*. We shall give the solution after the manner of its illustrious author ; because it is elementary, in the purest sense of the word, keeping in view the two leading circumstances, and these only, namely, the motion of approach and recess from the centre, and the motion of revolution. By this judicious process, it becomes a pattern by which more refined, and, in some respects, better solutions should be modelled. At the same time we shall supply some steps of the investigation which his elegant conciseness has made him omit.

Let a body, which tends to C (fig. 24) with a force proportional to the ordinates of the exponent BLFG, having the axis CA, be projected from V in the direction VQ , with the velocity which the centripetal force would generate in it by accelerating it along AV It is required to determine the path or orbit VIKI of the body, and its place I in this orbit, at the end of the assigned time T ? 125.

Suppose the thing done, and that I is the place of the body. About the centre C, with the distances CV and CI, describe the circles YV and ID. Draw CIX to the circumference, and draw the ordinate DF of the exponent of forces, producing it toward *x*, and produce the ordinate VL toward *a*. Let V *t* be the distance to which the body would go along the tangent VQ in the time T, and join *t* C. Let this be supposed done for every point of the curve. Let *a i k* and *a x y* be two curves so related to the curve VIK, that the ordinate DF cuts off an area V *a i* D equal to the orbital sector VCI, and an area V *a x* D equal to the circular sector VCX.

Then, because the velocity of projection is given, the distance V *t* is known, and the area of the triangle VC *t*. But this is equal to the area VCI, by the laws of central forces (n° 115.). Therefore the area V *a i* D is given. Also, because the area VCI increases in the proportion of the time, the area V *a i* D increases at the same rate. Therefore having these subsidiary curves *a i k*, *a x y*, the problem is solved as follows :

Draw an ordinate D *i*, cutting off an area V *a i* D proportional to the time, and describe a circle DIR. Then draw a line CX, cutting off a sector VCX, equal to the area V *a x* D cut off by the ordinate D *i x*. This line will cut the circle DR in the point I, which is the point of the orbit that was demanded.

But the chief difficulty of the problem consists in the description of the two subsidiary curves *a i k* and *a x y*, into which the lines VIK and VXY are transformed. We attain this construction by resolving the motion in the arch of the orbit into two motions, one of which is in the direction of the transverse force, or of the radius vector, and the other is in the direction of revolution, or perpendicular to the radius.

Let V *k* and IK be two very small arches described in equal moments, and therefore ultimately in the ratio of the velocities in V and I (n° 73.). Describe the circle KE, cutting IC in N. Draw KC and *k* C, and *k n* perpendicular to VC.

The element ICK of the orbit is $= \frac{IC \times KN}{2}$, or to $\frac{1}{2}$ IC × KN. This is equal to the element D *i k* E of the area V *a i* D, or to D *i* × DE, or to D *i* × IN. Therefore IN : KN = $\frac{1}{2}$ IC : D *i*, or 2 IN : KN = IC : D *i*, and D *i* = $\frac{IC \times KN}{2\ IN}$.

Now let A *l f g h* be the exponent of the velocities, that

that is (n° 86.), let $V l^2$ be to $D f^2$ as ABLV to ABFD, or $V l : D f = \sqrt{ABLV} : \sqrt{ABFD}$. Make $V v$ and $I i$ in the tangents respectively equal to $V l$ and $D f$. Draw $v u$ and $i o$ perpendicular to VC and IC, and $v m$ perpendicular to LV produced. Let $m r z$ be an equilateral hyperbola, having VC, ZC, for its assymptotes, and cutting FD produced in r. Then the ordinates $V m$, $D r$, are inversely proportional to CV, CD, or $V m : D r = CD : CV, = CI : CV$. But because the momentary sectors VCk and ICK are equal, $k n : KN = CI : CV$. Therefore,

$$V m : D r = k n : KN$$

but $\quad V v : V m = V k : k n$

and $\quad I i \text{ (or } D f) : V v = IK : V k$

therefore $\quad I i : D r = IK : KN$

but $\quad I i : i o = IK : KN$, by sim. triang.

Therefore $D r = i o$, and $i o : V m = VC : CI$.

Also, by similarity of triangles, $I o : i o = IN : KN$, and $2 I o : i o = 2 IN : KN$.

Now it was shewn, that in order that the space $D i k E$ may be equal to the space ICK, we must have

$$2 IN : KN = IC : D i$$

or $\quad 2 I o : i o = IC : D i$

but $\quad i o : V m = VC : IC$

therefore $\quad 2 I o : V m = VC : D i$

and $D i = \frac{VC \times V m}{2 I o}$.

Having obtained $D i$, we easily get $D x$; for the ultimate ratio of ICK to XCY is that of IC^2 to VC^2. Therefore make

$$IC^2 : VC^2 = D i : D x.$$

Thus are the points of the two subsidiary curves $a i k$, $a x y$, determined.

The rectangle $VC \times V m$ is a constant magnitude; and is given, because VC is given, and $V m$ is the given velocity $V l$, diminished in the ratio of radius to the sine of the given angle CVQ.

But the line $2 I o$ is of variable magnitude, but it is also given, by means of known quantities. $I o^2$ is $= I i^2 - i o^2 = D f^2 - D r^2$, and $I o = \sqrt{D f^2 - D r^2}$. Moreover, $D f^2 = ABFD$, and $D r^2 = \frac{VC^2 \times V m^2}{IC^2}$.

Therefore $2 I o = 2 \sqrt{ABFD - \frac{VC^2 \times V m^2}{IC^2}}$, expressed in known quantities, because ABFD is known from the nature of the centripetel force.

Let the indeterminate distance CI or CD be $= x$, and let the ordinate DF, expressing the force, be y. Let VC be a, and $V m$ be c, and let $a b$ be a rectangle equal to the whole area of the exponent of force lying between the ordinate AB and the ordinate CZ, so that $a b - \int y \dot{x}$ may represent the indeterminate area ABFD.

We have $D i = \frac{a c}{2 \sqrt{a b - \int y \dot{x} - \frac{a^2 c^2}{x^2}}}$

and $D x = \frac{a^3 c}{2 x^2 \sqrt{a b - \int y \dot{x} - \frac{a^2 c^2}{x^2}}}$

Remark. We have hitherto supposed that the velocity of projection is acquired by acceleration along AV. But this was merely for greater simplicity of argument, and that the final values of $D i$ and $D x$ might be easier conceived. In whatever way the velocity is acquired, it will still be true, that when in any point V we make $V l$ to $V m$ as the momentary increment $V k$ of the arch is to the perpendicular $k n$ on the radius vector, we shall have in every other point, such as I, the line $D f$ to the line $D r$ as the increment IK of the arch to KN. And in the final equation $D f$ will still be expressed by $\sqrt{a b - \int y \dot{x}}$.

126. *Cor.* 1. The angle which the path of the projectile makes with the radius vector is determined by this solution; for $I i$ is to $i o$ as radius to the sine of this angle; which sine is therefore $= \frac{a c}{x \sqrt{a b - \int y x}}$.

127. Apsides determined; *Cor.* 2. When the magnitude $\frac{a c}{x}$ is equal to $\sqrt{a b - \int y x}$, the path is perpendicular to the radius vector, and the body is a tone of the apsides of its orbit, and begins to recede from the centre after having approached to it, or begins to approach after having receded.

128. And curvature. *Cor.* 3. The curvature of the orbit VIK is also determined in every point; for the curvature of any line is inversely as the radius of the equicurve circle, and this is to the chord which passes through C as radius to the sine of the angle CI i. Because the velocity in any point I is $= \sqrt{ABFD}$, and is equal to what the centripetal force at I would produce, by impelling the body along $\frac{1}{4}$th of the deflective chord of the equicurve circle, we have this chord $= 4 \frac{ABFD}{DF}$. Or we obtain it by taking a third proportional to the momentary deflection and the momentary arch of the curve, or by other processes of the higher geometry, all proceeding on the quantities furnished in this investigation.

129. Newton the inventor. Such is the solution of this celebrated problem given by Sir Isaac Newton, who may justly be called the inventor of the science of which it is the chief result, as well as of the geometry, by help of which it is prosecuted. For we cannot give this glory to Galileo; for his simple problem of the motion of bodies affected by uniform and parallel gravity, however just and elegant his solution may be, was peculiar; and the same must be said of Mr Huyghens's doctrine of centrifugal forces. Besides, these theorems had been investigated by Newton several years before, *sua mathesi facem preferente*, as corollaries which he could not pass unnoticed, from his general method. This is proved by letters from Huyghens. Newton's investigation is extremely, but elegantly, concise, and is one of the best exertions of his sagacious mind.

130. History of this problem. Whether we consider this problem as a piece of mere mathematical speculation, or attend to its consequences, which include the whole of the celestial motions in all their extent and complication, we must allow it to be highly interesting, and likely to engage much attention in the period of ardent inquiry which closed the last century. Accordingly, it was no sooner known, by the publication of the *Mathematical Principles of Natural Philosophy* in 1686, than it occupied the talents of the most eminent mathematicians; and many solutions were published, some of which differ considerably from Newton's; some are more expeditious, and better fitted for computation. Of these, the most remarkable for

Of Deflecting Forces.

for originality and ingenuity are those of de Moivre, Hermann, Keill, and Stewart. The last differs most from the methods pursued by others. M'Laurin's propositions on this subject, and in that part of his fluxions which treats of curvature, are highly valuable, classing the chief affections of curvilineal motions geometrically, as they are suggested by the fluxionary method; and then shewing, in a very instructive manner, the connection between these mathematical affections of motion and the powers of nature which produce them. This part of his excellent work is a fine example of the real nature of all inquiries in dynamics; shewing that it differs from geometry little more than in the language, in which the word *force* is substituted for *acceleration*, *retardation*, or *deflection*. We recommend the careful perusal of these propositions to all who wish to have clear conceptions of the subject. Dr John Keill and Dr Horseley (bishop of Rochester) have given particular treatises on the motions of bodies deflected by centripetal forces inversely proportional to the cubes of the distances; induced by the singular motions which result from this law of action, and the multitude of beautiful propositions which they suggest to the mathematician. Newton, indeed, first perceived both of these peculiarities, and has begun this branch of the general problem. He first demonstrated the description of the logarithmic and hyperbolic spirals, and indicated a variety of curious recurring elliptical spirals, which would be described by means of this force, and shewing that they are all susceptible of accurate quadrature. Several of those authors affect to consider their solutions as more perfect than Newton's, and as more immediately indicating the remarkable properties of such motions; and also affect to have deduced them from different and original principles. But we cannot help saying, that their claims to superiority are very ill founded; there is not a principle made use of in their solutions which was not pointed out by Newton, and employed by him. The appearance of originality arises from their having taken a more particular concern in some general property of curvilineal motions; such as the curvature, the centrifugal force, &c. and the making that the leading step of their process. But Newton's is still the best; because it is strictly elementary, aiming at the two leading circumstances, the motion to or from the centre, and the motion of revolution round that centre. To these two purposes he adapted his two subsidiary curves. This procedure became Newton, *pater, et rerum inventor*, who was teaching the world, and who might say,

> *Avia Pieridum peragro loca, nullius ante*
> *Trita pede* ——

Singular boast of John Bernoulli.

Is it not surprising, that 25 years after the publication of Newton's *Principia*, a mathematician on the continent should publish a solution in the Memoirs of the French academy, and boast that he had given the first demonstration of it? Yet John Bernoulli did this in 1710. Is it not more remarkable that this should be precisely the solution given by Newton, beginning from the same theorem, the 40th I. Prin. following Newton in every step, and using the same subsidiary lines? Yet so it is. Bernoulli actually reduces the whole to two functions; namely, $\frac{ac}{\sqrt{ab - \int \varphi \dot{x} - \frac{a^2c^2}{x^2}}}$ and $\frac{a^2c}{\sqrt{abx^4 - \int \varphi x^4 - a^2c^2x^2}}$; which last is plainly the same with Newton's $\frac{Q \times CX^2}{A^2\sqrt{ABDF - Z^2}}$; because Newton's $\frac{Q}{A}$ is the same with $\frac{a\varphi}{x}$, and Newton's $A^2\sqrt{ABFD - Z^2}$ is the same with $x^2\sqrt{ab - \int \varphi \dot{x} - \frac{a^2c^2}{x^2}}$, which Bernoulli has changed (apparently to hide the borrowing) into $\sqrt{abx^4 - \int \varphi x^4 \dot{x} - a^2c^2x^2}$. This publication of Bernoulli is perhaps the most impudent piece of literary *robbery*, for theft is too mild a term, that has ever appeared; and is the more deserving of severe reprehension, because it is full of reflections on the simple and supremely elegant method of Newton. It is hardly conceivable that a person of Bernoulli's consummate mathematical knowlege was so much blinded by the mechanical procedure of the symbolical calculus (which indeed is rarely accompanied by any ideas of the subject in hand) as not to perceive the perfect sameness of his solution. No; he shews, from time to time, that the physical ideas of motion and force were present to his mind; for he affects to shew, that all Newton's brightest discoveries, such as the proportionality of the areas and times, &c. flow as corollaries from his procedure.

Bernoulli's chief boast in this dissertation is, that *now* philosophers may be assured that the planets will always describe conic sections; a truth of which they had not as yet received any proof: because, says he, Newton's argument for it in the corollary of the 13th proposition is inconclusive, and because he had not been able to accommodate his demonstration of the 41st and 42d proposition to the particular case of the planetary gravitation. Two assertions that border on insolence. Newton's demonstration in the corollary of the 13th proposition is just, founded on the principle on which the very demonstration of the 42d, adopted by Bernoulli, proceeds, and without which that demonstration is of no force; namely, that a body in given circumstances of situation, velocity, direction, and centripetal force, can describe no other figure than what it really describes. Newton did not accommodate the demonstration of the 42d proposition to the planetary motions, because he had already demonstrated the nature of their orbits; but mentions the case of a force proportional to the reciprocal of the cubes of the distance; not as a deduction from the 42d, but because it *was not* a deduction from it, and admitted a very singular and beautiful investigation by methods totally and essentially different.

Bernoulli also says, that Newton's solution does not give us the notion of a continuous path, as his own does, but only informs us how to ascertain points of this path. This is the boldest of all his assertions. Bernoulli uses the differential calculus. It is the *essential* character of this calculus that it exhibits, and *can* exhibit, nothing but detached points. This is undeniable. And this has been objected to Newton's first proposition. But Newton's fluxionary *geometry*, of which the calculus exhibits only elements (being the same with the differential), supposes

ſuppoſes the continuity of all magnitudes; and when applied to dynamics, is no ſubſtitution whatever, but the *ipſa corpora*. This geometry offered itſelf to the mind of Newton, the accompliſhed and darling ſcholar of Barrow, whoſe geometry flaſhed on Newton's mind as the torch which was to ſhew him the ſteps of this yet untrodden path.

We truſt that our readers will not be diſpleaſed with our repeated endeavours to defend our great philoſopher from the injurious attacks that have been made on him. During his own illuſtrious life, while he was diffuſing light and knowledge around him, and never contended for fame, happy in being the inſtructor of mankind, he was injured by thoſe who envied his reputation, while they derived their chief honours from being his beſt commentators. Now, ſince he has left this world, he has been more groſsly injured by thoſe who avail themſelves of that very reputation: and who, by crude and contemptible inferences from his doctrine of elaſtic undulations, and groſs miſrepreſentations of his notions of an etherial fluid, have pretended to ſupport a ſyſtem of materialiſm; and thus have ſet Newton at the head of the atheiſtical ſect, which he held in abhorrence. For our part, we always think with pleaſure on the wonderful energy of that great mind; becauſe it gives us a foretaſte of thoſe pleaſures that await the wiſe and good, when the ſorrows flowing from the infirmities, the vices, and the arrogant vanity of man, are paſt;

Utque in hoc infelici campo,
Ubi luctus regnat, et pavor,
Mortalibus prorſus non abſit ſolatium.
Hujus enim ſcripta evolvas,
Mentemque tantarum rerum capacem
Corpori caduco ſuperſtitem credas.

132 Concluſion. It cannot be expected that, in the narrow limits preſcribed to a work like ours, we can proceed to conſider the various departments of this celebrated problem. We are only giving the outlines of the general doctrines of dynamics; and we have beſtowed more time on thoſe which are purely elementary than ſome readers may think they deſerve. We were anxious to give juſt conceptions of the fundamental principles of dynamics; becauſe we know that nothing elſe can intitle it to the name of a demonſtrative ſcience, and becauſe we ſee much indiſtinctneſs and uncertainty, and a general vagueneſs or want of preciſion, in ſeveral elementary works which are put into the hands of perſons entering on the ſtudy. This leads to errors of more conſequence than a perſon is apt to think; becauſe they affect our leading thoughts of mechaniſm itſelf, and our notions of the intimate nature of the viſible univerſe.

133 Reaſons for omiſſions. But we muſt conclude the article with this great problem. Many very general doctrines of dynamics remain untouched; all, namely, that relate to the rotative motion of rigid bodies, and all that relate to the mutual action of bodies on each other in the way of impulſe.

The rotative motions, with the doctrine of mechanic momenta, have been conſidered at large in the article Rotation of the *Encycl. Britan.*; and we propoſe to offer ſome important conſiderations on the ſame ſubject in our ſupplement to the articles Machine and Mechanics. In the article Impulsion will be conſidered ſuch doctrines as are truly general, and independent of the ſpecific differences of the bodies. Dynamics profeſſes to involve no notions but thoſe of force, and its marks and meaſures.

Notwithſtanding theſe great omiſſions, we muſt obſerve that no new principle remains to be conſidered. We have given all that are neceſſary; and there is no queſtion that occurs in the caſes omitted, which cannot be completely anſwered by means of the propoſitions already eſtabliſhed. We have taught how to diſcover the exiſtence and agency of a mechanical force, to meaſure and characteriſe it, and then to ſtate what will be its various effects, according to the circumſtances of the caſe.

134 Univerſal reaction is a law of the material world. Proceeding by theſe principles, men have diſcovered an univerſal fact, that every action of one body on another is accompanied by an equal reaction of that other on the firſt, in the oppoſite direction; that is, to expreſs it in the language of dynamics, "all the phenomena which make us infer that the body A poſſeſſes a force by which it changes the motion of the body B, ſhew, at the ſame time, that B poſſeſſes a force by which it makes an equal and oppoſite alteration in the motion of A." This, however, is not a doctrine of abſtract dynamics: it does not flow from our idea of force; therefore it was not included in our liſt of the Laws of Motion. It is a part of the mechanical hiſtory of nature, juſt as the law of univerſal gravitation is; and it might be called the law of Universal Reaction. Sir Iſaac Newton has, in our humble apprehenſion, deviated from his accuſtomed logical accuracy, when he admits, as a third *axiom* or law of motion, that reaction is always equal and contrary to action. It is a phyſical law, in as far as it is *obſerved* to obtain through the whole extent of the ſolar ſyſtem. But Newton himſelf did not, in the ſubſequent part of his noble work, treat it as a logical axiom; that is, as a law of human thought with reſpect to motion: for he labours with much ſolicitude, and with equal ſagacity, to prove, by *fact and obſervation*, that it really obtains through the whole extent of the ſolar ſyſtem; and it is in this diſcovery that his chief claim to unequalled penetration and diſcernment appears.

135 Impulſion explained by it; Availing ourſelves of this fact, we, with very little trouble, ſtate all the laws of impulſion. The body A, for example, moving to the weſtward at the rate of eight feet per minute, overtakes the double body B, moving at the rate of four feet per minute. What muſt be the conſequence of their mutual impenetrability, and of the equality and contrariety of action and reaction? Their motions muſt be ſuch that both ſuſtain equal and oppoſite changes. They muſt give, in ſome way or other, *this* indication of poſſeſſing equal and oppoſite forces. This will be the caſe if, when the changes are completed, A and B move on in contact at the rate of four feet per minute: for here A has produced in each half of B a change of motion two; and therefore a totality of change equal to four. This is the effect, the mark, the meaſure, of the *impulſive* force of A; for it is the whole *impulſion*. B has produced in A a change of motion four, equal to the former, and in the oppoſite direction. This is the effect, mark, and meaſure, of the *repulſive* force of A; for it is the whole *repulſion*. And this is all that we obſerve in the colliſion of two lumps of clay; and the obſervation is one of the facts on which the reality of the phyſical law of equal action and reaction is founded: and we can make no farther inference from *this* fact.

Conclusion. But the event might have been very different. A and B may be two magnets floating on corks on water, with their north poles fronting each other. We know, by other means, that they really possess forces by which they equally repel each other. The dynamical principles already established tell us also what must happen in this case. That both conditions of equal reaction and sensible repulsion may be fulfilled, A must come to rest, and B must move forward at the rate of four feet per minute. The same thing must happen in the meeting of perfectly elastic bodies, such as billiard balls. If elasticities are known to be imperfect in any degree, our dynamical principles will still state the effect of their collision, in conformity to the law of equal reaction.

136 And rotation. In like manner, all the motions of rotation are explained or predicted by means of the same principles of dynamics applied to the force of cohesion. This is considered as a moving force, because, when the attraction of a magnet acts on a bit of iron attached to one end of a long lath floating on water, the whole lath is moved, although the magnet does not act on it at all: some other force acts on it; it is its cohesion; which is therefore a moving force, and the subject of dynamical discussion.

137. And thus it appears that these subjects do not come necessarily, nor, perhaps, with scientific propriety, under the category of dynamics, but are parts of the mechanical history of nature. Yet, did a work like ours give room in this place, the study of mechanical nature might be considerably improved by giving a system of such *general* doctrines as involve no other notions but those of force and its measures, and the hypothesis of equal reaction. Some very general, nay universal, consequences of this combination might be established, which would greatly assist the mechanician in the solution of difficult and complicated problems. Such is the proposition, that *the mutual actions of bodies depend on their relative motions only, and require no knowledge of their real motions.* This principle simplifies in a wonderful manner the most difficult and the most frequent cases of action which nature presents to our view; but at the same time gives a severe blow to human vanity, by forcing us to acknowledge that we know nothing of the real motion of any thing in the universe, and never shall know any thing of it till our intellectual constitution, or our opportunities of observation, are completely changed.

138. Mr D'Alembert has made this principle still more serviceable for extricating ourselves from the immense complication of actions that occurs in all the spontaneous phenomena of nature, by presenting it to us in a different form, which more distinctly expresses what may be called the *elements* of the actions of bodies on each other. His proposition is as follows (*see his Dynamique*, page 73.):

D'Alembert's general principle of dynamics. "In whatever manner a number of bodies change their motions, if we suppose that the motion which each body would have in the following moment, if it were perfectly free, is decomposed into two others, one of which is the motion which it really takes in consequence of their mutual actions, the other will be such, that if each body were impressed by this force alone (that is, by the force which would produce this motion) the whole system of bodies would be in equilibrio."

This is almost self-evident; for if these second constituent forces be not such as would put the system in equilibrio, the other constituent motions could not be those which the bodies really take by the mutual action, but would be changed by the first.

For example, let there be three bodies P, Q, R, and let the forces A, B, C, act on them, such as would give them the velocities p, q, r, in any directions whatever, producing the momenta, or quantities of motion, $P\times p$, $Q\times q$, $R\times r$, which we may call A, B, C, because they are the proper measures of the moving force. Let us moreover suppose, that, by striking each other, or by being any how connected with each other, they cannot take these motions A, B, and C, but really take the motions a, b, and c. It is plain that we may conceive the motion A impressed on the body P, to be composed of the motion a, which it really takes, and of another motion α. In like manner, B may be resolved into b, which it takes, and another β; and C into c and κ. The motions will be the same, whether we act on P with the force A, or with the two forces a and α; whether we act on Q with the force B, or with b and β; and on R with the force C, or with c and κ. Now by the supposition, the bodies actually take the motions a, b, and c; therefore the motions α, β, and κ, must be such as will not derange the motions a, b, and c; that is to say, that if the bodies had only the motions α, β, and κ, impressed on them, they would destroy each other, and the system would remain at rest.

Mr D'Alembert has applied this proposition with great address and success to the very difficult questions that occur in the motions and actions of fluids, and many other most difficult problems, such as the precession of the equinoxes, &c. The cause of its utility is, that in most cases it is not difficult to find what forces will put a system in equilibrio; and, combining these with the known extraneous forces whose effects we are interested to discover, we obtain the motions which really follow the mutual action of the bodies.

This is not, properly speaking, a principle: it is a form in which a general fact may be conceived. In the same way the celebrated mathematician De la Grange observed, that a system of bodies acting on each other in any way, is in equilibrio, if there be impressed on its parts forces in the inverse proportion of the velocities which each body takes in consequence of their action or connection; and he expresses this universal fact by a very simple formula; and calling this also a principle, he solves every question with ease and neatness, by reducing it to the investigation of those velocities. In this way he has written a complete system of dynamics, to which he gives the title of *Mechanique Analytique*, full of the most ingenious and elegant solutions of very interesting and difficult problems; and all this without drawing a line or figure, but accomplishing the whole by algebraic operations.

But this is not teaching mechanical philosophy; it is 139. merely employing the reader in algebraic operations, each of which he perfectly understands in its quality of an algebraic or arithmetical operation, and where he may have the fullest conviction of the justness of his procedure. But all this may be (and, in the hands of an expert algebraist, it generally is), without any notions, distinct or indistinct, of the things, or the processes of reasoning that are represented by the symbols made use of. It is precisely like the occupation of a banker's clerk when he carries his eye up and down the columns of pounds shillings and pence, calculates the compound interest, reversionary values, &c.

Conclusion.

Disadvantages of the symbolical method.

It were well if this were all, although it greatly diminishes the pleasure which an accomplished mathematician might receive; but this total absence of ideas exposes even the most eminent analyst to frequent risks of paralogism and physical absurdity. Euler, who was perhaps the most expert algebraist of the last century, making use of the Newtonian theorem for ascertaining the motion of a body impelled along a straight line AC (fig. 24) by a centripetal force, by comparing it with the motion in an ellipse, of which the shorter axis was diminished till it vanished altogether, expresses his surprise at finding, that when he computes the place of the body for a time subsequent to that of its arrival at C, the body is back again, and in some place between C and A; in short, that the body comes back again to A, and plays backward and forward. He says that this is somewhat wonderful, and seems inconsistent with sound reason: "*sed analysi magis fidendum.*" It must be so. And he goes on to another problem.

In like manner Mr Maupertuis, an accomplished man and good philosopher and geometer, finding the symbol MVS, or the quantity of matter, multiplied by the velocity and by the distance run over during the action, always present itself to him as a mathematical *minimum* in the actions of bodies on each other; he was amused by the observation, and presumed that there was some reason for it in the nature of things. Finding that it gave him very neat solutions of many elementary problems in dynamics, he thought of trying whether it would assist him in accounting for the constant ratio of the sines of incidence and refraction; he found that it gave an immediate and very neat solution. This problem had, before his time, occupied the minds of Des Cartes and Fermat. Each of these gentlemen solved the problem by saying, that the light did not take the *shortest* way from a point in the air to a point under water, but the *easiest* way, in conformity with the acknowledged economy of nature and consummate wisdom of its adorable Author. But how was this the easiest way, the course that economised the labour of nature? One of these gentlemen proved it to be so, if light move faster in air than in water; the other proved it to be so, if light move faster in water than in air. Both could not be right. Maupertuis was convinced that he had discovered what it was that nature was so chary of, and grudged to waste—it was MVS! Therefore MVS can mean nothing but labour; nothing but natural exertion, mechanical action; therefore MVS is the proper measure of action. He kept this great discovery a profound secret; and, being President of the Royal Academy of Berlin, he proposed for the annual prize question, "Are the laws of motion necessary or contingent truths?" He could not compete for the prize, by the laws of the Academy; but before the time of decision, he published at Paris his *Dissertation on the Principle of the least Action;* in which he pointed out the singular fact of MVS being always a minimum; and therefore, in fact, the object of nature's economical care. He solved a number of problems by making the minimum state of $\frac{f v s}{m}$ a condition of the problems; and, to crown the whole, shewed that the laws of motion which obtain in the universe could not be but what they are, because this economy was worthy of infinite wisdom; and *therefore* any other laws were impossible. The reputation of Maupertuis was already established as a good mathematician and a worthy and amiable man, and he was a favourite of Frederic. The principle of least action became a mode; and it drew attention for some time, till it went out of fashion. It is no mechanical principle, but a necessary mathematical truth, as any person must see who recollects that v is the same with $\dot{s}$, and that f is the same with $m\dot{v}$.

Great advantages of the geometrical method.

To avoid such paralogisms and such whims, we are convinced that it is prudent to deviate as little as possible in our discussions from the *geometrical* method. This has surely the advantage of keeping the real subject of discussion close in view; for motion includes the notion of lines, with all their qualities of magnitude and position. It is needless to take a representative when the original itself is in our hands, and affords a much more comprehensible object than one of its abstract qualities, mere magnitude. Let any person candidly compare the lunar theory by Mayer or Euler with that by its illustrious inventor Sir Isaac Newton, and say which of the two is most luminous and most pleasing to the mind. No person will deny that these later performances are incomparably more adapted to all practical purposes, and lead to corrections which it would be extremely difficult and tedious to investigate geometrically; but it must be acknowledged, at the same time, that *till this be done*, we have no idea whatever of the deviation of the track which this correction ascertains from the path which the moon would follow, independent of the disturbance expressed by the correction. In like manner, Dan. Bernoulli, by mixing as much as possible the linear method with the algebraic, in his dissertations on musical chords, made the beautiful discovery of the secondary trochoids, and demonstrated the co-existence of the harmonic sounds in a full musical note. Let the accomplished mathematician push forward our knowledge of dynamics by the employment of the symbolical analysis; but let him be followed as close as possible by the geometer, that we may not be robbed of ideas, and that the student may have light to direct his steps. But,—*manum e tabulâ.*

 DYN

Dynanometer.

DYNANOMETER, an instrument for ascertaining the relative muscular strength of men and other animals. That it would be desirable to know our relative strengths at the different periods of life, and in different states of health, will hardly be denied; and there can be no doubt but that it would be highly useful to have a portable instrument by which we could ascertain the relative strength of horses or oxen intended for the plough or the waggon. Such an instrument was invented, many years ago, by Graham, and improved by Desaguliers; but being constructed of wooden work it was too bulky to be portable, and therefore it was limited in its use.

M. Leroy of the Academy of Sciences at Paris constructed a much more convenient Dynanometer than Graham's, consisting of a metal tube, 10 or 12 inches

Dynanometer. in length, placed vertically on a foot like that of a candleſtick, and containing in the inſide a ſpiral ſpring, having above it a graduated ſhank terminating in a globe. This ſhank, together with the ſpring, ſunk into the tube in proportion to the weight acting upon it, and thus pointed in degrees the ſtrength of the perſon who preſſed on the ball with his hand.

This was a very ſimple conſtruction, and, we think, a good one; but it did not ſatisfy Buffon and Gueneau. Theſe two philoſophers wiſhed not merely to aſcertain the muſcular force of a finger or a hand, but to eſtimate that of each limb ſeparately, and of all the parts of the body. They therefore employed M. Regnier to contrive a new *dynanometer;* and the account which he gives * of his attempts to fulfil their wiſhes is calculated to enhance the difficulty of the enterprize. The inſtrument, however, which he conſtructed, is not ſuch as appears to us to have required any uncommon ſkill in mechanics, or any very great ſtretch of thought. It conſiſts chiefly of an elliptical ſpring, 12 inches in length, rather narrow, and covered with leather that it may not hurt the fingers when compreſſed by the hands. This ſpring is compoſed of the beſt ſteel well welded and tempered, and afterwards ſubjected to a ſtronger effort than is likely to be ever applied to it either by men or animals, that it may not loſe any of its elaſticity by uſe.

* *Journal de l'Ecole Polytechnique*, v. 2.

The effects of this machine are eaſily explained. If a perſon compreſſes the ſpring with his hands, or draws it out lengthwiſe by pulling the two extremities in contrary directions, the ſides of the ſpring approach towards each other; and it has an apparatus (we do not think a very ſimple one) appended to it, conſiſting of an index and ſemicircular plate, by which the degree of approach, and conſequently of effort, employed, is aſcertained with great accuracy. The author gives a tedious deſcription of other appendages, by means of which horſes or oxen may be employed to compreſs the ſpring. But as any mechanic may deviſe means for this purpoſe, we do not think it worth while to tranſcribe that deſcription. The Engliſh reader will find a full account of the whole apparatus in the 4th number of the very valuable miſcellany intitled *The Philoſophical Magazine.* The principle of the contrivance conſiſts in the elliptical ſpring, of which we confeſs ourſelves unable to perceive the ſuperiority to the ſpiral ſpring of M. Leroy, though the author ſees it very clearly.

Dyſentery. DYSENTERY. See MEDICINE-*Index*, Encycl.—For the cure of this diſeaſe we have the following ſimple preſcription by Dr Perkins and Dr B. Lynde Oliver, of the State of Maſſachuſetts in North America.

Saturate any quantity of the beſt vinegar with common marine ſalt; to one large table-ſpoonful of this ſolution add four times the quantity of boiling water; let the patient take of this preparation, as hot as it can be ſwallowed, one ſpoonful once in half a minute until the whole is drank: this for an adult. The quantity may be varied according to the age, ſize, and conſtitution of the patient. If neceſſary, repeat the doſe once in ſix or eight hours. Conſiderable evacuations I conceive (ſays Dr Parkins) to be not only unneceſſary, but injurious, as they ſerve to debilitate and prolong the diſeaſe. A tea of plantain, or ſome other cooling ſimple drink, may be uſeful; and if a thirſt for cyder be diſcovered, it may be gratified. Carefully avoid keeping this preparation in veſſels partaking of the qualities of lead or copper, as the poiſon produced by that means may prove dangerous.

The ſucceſs of the remedy depends much on preparing and giving the doſe as above directed.—The ſimplicity of this treatment renders it the more valuable, as all perſons have it in their power to avail themſelves of its uſe.

Dr Perkins ſays, that he has found it uſeful in agues, diarrhœas, and the yellow fever.

E.

Earth. EARTH, in chemiſtry. See CHEMISTRY-*Index* in this Supplement.

EARTH, in aſtronomy and geography. See *Encyclopædia.*

EARTH, in ancient philoſophy, one of the elements, the ſubſtance of which this globe is compoſed. To aſcertain the denſity of that ſubſtance, many experiments have been made; but perhaps none more ingenious than thoſe of Mr Cavendiſh, which are detailed at full length in Part II. of the Tranſactions of the Royal Society of London for 1798. They were projected by the late Rev. John Michell, F. R. S. but he did not live to carry them into effect. After his death, the apparatus came to the Rev. F. J. H. Wollaſton, Jackſonian Profeſſor at Cambridge, who transferred them to Mr Cavendiſh. The apparatus contrived for making ſenſible the attraction of ſmall quantities of matter, and which has been improved by Mr Cavendiſh, is very ſimple: it conſiſts of a wooden arm 6 feet long, ſuſpended by the middle in an horizontal poſition by a ſlender wire 40 inches long; to each extremity is hung a leaden ball about two inches in diameter; and the whole is incloſed in a wooden caſe to defend it from the wind.

As no more force is required to turn this balance on its centre than is neceſſary to twiſt the ſlender ſuſpending wire, the ſmalleſt degree of attraction of a leaden weight or weights, a few (eight) inches in diameter, brought near to the ſmall ſuſpended ball or balls of the balance, will be ſufficient to move it ſenſibly aſide.

To determine from hence the denſity of the earth, all that is neceſſary is, to aſcertain what force is required to draw the arm aſide through a given ſpace, and then to have recourſe to calculation.

To prevent any diſturbance from currents that might be produced within the box that contained the balance, by even the difference of temperature that might be occaſioned

casioned by heat being communicated by the bodies of the experimenters to one side of it more than another, it was supported in the middle of a close room; the operators, from adjoining apartments, viewed the operation through holes in the wall by means of telescopes; and the apparatus had a strong light thrown upon its two ends (an opening being left at each end of the box for the purpose) by means of two lamps, also in the adjoining apartments, the rays from which were likewise made to pass through the holes formed in the wall.

The two large balls were suspended from a beam near the cieling, which could be moved in an horizontal direction, by means of a string and pulley, so as to be brought near to the small balls of the balance, or made to recede again, without requiring any person to be in the room.

From this description it will be easily seen, that on the two large balls being brought near to the two small ones, but on opposite sides of each, that their forces may not counteract each other—the small suspending wire of the balance must be twisted by the movements of the arms, occasioned by attraction, which carries the small towards the large balls; and that the wire, endeavouring to untwist itself, will again in its turn carry the small balls away from the large ones. Vibrations are thus occasioned, which would continue a long time before the small balls would settle between the first point of rest and the large balls: but it is not necessary to wait for this; an ivory scale at each end of the balance enables the experimenters, by means of their telescopes, to see the two extreme divisions to which the small balls move in their vibrations, and thus to determine the middle point. The time necessary for each vibration is also noticed.

A full account of these experiments, and of the calculations founded on them, would be little interesting to the great majority of our readers. We shall therefore only mention the result. By a mean of the experiments the density of the earth comes out 5·48 times greater than that of water.

By the experiments made by Dr Maskelyne on the attraction of the hill Schehallien, the density of the earth was computed to be only $4\frac{1}{2}$ times that of water. The difference of result, therefore, is almost one-fifth, which no doubt must lessen our confidence in either set of experiments, or in the principle on which they were devised.

Earth Worm (see Lumbricus, *Encycl.*), is an animal which occasions such destruction in gardens, by gnawing the tender roots of shrubs and plants, that various methods have been proposed for remedying this evil. One of the latest, and that which promises to prove the most successful, is given by M. Socoloff in the fifth volume of the New Transactions of the Imperial Academy of Sciences at Petersburgh. As the destructive power of quick lime, heightened by a fixed alkali, which corrodes or dissolves all the tender parts of animals, has been long known, it occurred to our author that this mixture would be the best means for accomplishing the object which he had in view. He therefore took three parts of quicklime, newly made, and two parts of a saturated solution of fixed alkali in water, and thence obtained a somewhat milky liquor sufficiently caustic, highly hostile and poisonous to earth-worms and other small animals; for as soon as it touched any part of their bodies, it occasioned in them violent symptoms of great uneasiness. If this liquor be poured into those holes in which the earth-worms reside under ground, they immediately throw themselves out as if driven by some force; and, after various contortions, either languish or die. If the leaves of plants or fruit trees frequented by the voracious caterpillars, which are so destructive to them, be sprinkled over with this liquor, these insects suddenly contract their bodies and drop to the ground. For though Nature has defended them tolerably well by their hairy skins from any thing that might injure their delicate bodies, yet as soon as they touch with their feet or mouths leaves which have been moistened by this liquor, they become as if it were stupified, instantly contract themselves, and fall down.

Earth, Eau de luce.

With regard to plants or corn, these sustain no injury from the liquor, because it has no power over the productions of the vegetable kingdom, as our author has fully learned from experience; or if any hurt is to be suspected, all the danger will be removed by the first shower that falls. This liquor may be procured in abundance in every place where lime is burnt. If the lime be fresh, one part of it infused into about seventy parts of common water will produce real lime-water. The want of the fixed alkali may be supplied by boiling wood-ashes in water, and thickening the ley by evaporation.

This liquor might be employed also to kill bugs and other domestic insects; but on account of its strong lixivious smell, M. Socoloff thinks it could not be used with safety in houses that are inhabited. Nothing, however, more speedily or more effectually destroys bugs, as our author says he has repeatedly experienced, than the oily pickle that remains in casks in which salted herrings have been packed.

EAU de Luce, a fragrant alkaline liquor which was some years ago in great repute, especially among the fair sex, and of which the leading perfection is, that it shall possess and retain a milky opacity.

Mr Nicholson, in the second number of his valuable journal, tells us, that being informed by a philosophical friend, that the usual recipes for making this compound (see Chemistry, *Encycl.* n° 1037.) do not succeed, and that the use of mastic in it has hitherto been kept a secret, he made the following trials to procure a good eau de luce.

One dram of the rectified oil of amber was dissolved in four ounces of the strongest ardent spirit of the shops; its specific gravity being .840 at 60 degrees of Fahrenheit. A portion of the clear spirit was poured upon a larger quantity of fine powdered mastic than it was judged could be taken up. This was occasionally agitated without heat; by which means the gum resin was for the most part gradually dissolved. One part of the oily solution was poured into a phial, and to this was added one part of the solution of mastic. No opacity or other change appeared. Four parts of strong caustic volatile alkali were then poured in, and immediately shaken. The fluid was of a dense opake white colour, affording a slight ruddy tinge when the light was seen through a thin portion of it. In a second mixture, four parts of the alkali were added to one of the solution of mastic; it appeared of a less dense and more yellowish white than the former mixture. More of the gum resinous solution was then poured in; but it still appeared less opaque than that mixture. It was

ruddy

Eau de luce || Ecliptic.

ruddy by tranſmitted light. The laſt experiment was repeated with the oily ſolution inſtead of that of maſtic. The white was much leſs denſe than either of the foregoing compounds, and the requiſite opacity was not given by augmenting the doſe of the oily ſolution. No ruddineſs nor other remarkable appearance was ſeen by tranſmitted light. Theſe mixtures were left at repoſe for two days; no ſeparation appeared in either of the compounds containing maſtic; the compound conſiſting of the oily ſolution and alkali became paler by the ſeparation of a cream at the top.

It appears, therefore, that the firſt of theſe three mixtures, ſubject to variation of the quantity of its ingredients, and the odorant additions which may be made, is a good eau de luce.

In a ſubſequent number of the ſame Journal, we have the following recipe by one of the author's correſpondents, who had often proved its value by experience. "Digeſt ten or twelve grains of the whiteſt pieces of maſtic, ſelected for this purpoſe and powdered, in two ounces of alcohol; and, when nearly diſſolved, add twenty grains of elemi (See Amyris, *Encycl.*). When both the reſins are diſſolved, add ten or fifteen drops of rectified oil of amber, and fifteen or twenty of eſſence of bergamot: ſhake the whole well together, and let the fæces ſubſide. The ſolution will be of a pale amber colour. It is to be added in very ſmall portions to the beſt aqua ammoniæ puræ, until it aſſumes a milky whiteneſs, ſhaking the phial well after each addition, as directed by Macquer. The ſtrength and cauſticity of the ammoniac are of moſt eſſential conſequence. If, upon the addition of the firſt drop or two of the tincture, a denſe opaque coagulated precipitate is formed, not much unlike that which appears on dropping a ſolution of ſilver into water ſlightly impregnated with common ſalt, it is too ſtrong, and muſt be diluted with alcohol. A conſiderable proportion of the tincture, perhaps one to four, ought to be requiſite to give the liquor the proper degree of opacity."

EAVES Board, or Eaves-Lath, a thick featheredged board, uſually nailed round the eaves of a houſe for the lowermoſt tiles, ſlate, or ſhingles, to reſt upon.

ECLIPSAREON, an inſtrument invented by Mr Ferguſon for ſhewing the phenomena of eclipſes; as their time, quantity, duration, progreſs, &c.

ECLIPTIC. See *Encycl.* both under Ecliptic and in Astronomy-*Index*. It was obſerved in Astronomy, *Encycl.* n° 407. that the obliquity of the ecliptic has been found gradually to decreaſe. This was obſerved, among others, by *La Lande*, who, in the third edition of his aſtronomy, reckoned the ſecular diminution of this obliquity at 50 ſeconds. From a new examination, however, of ancient obſervations, he has ſince found reaſon to eſtimate it at only 36 ſeconds; but whether this be perfectly accurate, is very doubtful. The mean obliquity was determined for the 1ſt of January 1793, with circular inſtruments, by *Mechain* at Barcelona, and *Piazzi* at Palermo, to be $23° 27' 53''.3$. Yet the obſervation of the ſummer ſolſtice of 1796, by *Mechain* and *Le Français*, gave 11 ſeconds more; which was juſtly conſidered as a perplexing circumſtance. But, as one of the ableſt of our literary journaliſts obſerves, might not this difference ariſe from the uncertainty of our tables of refraction, as affected by the hygroſcopic variations of the atmoſphere?

Ecliptic Bounds, or *Limits*, are the greateſt diſtances from the nodes at which the ſun or moon can be eclipſed, namely, near 18 degrees for the ſun, and 12 degrees for the moon.

Ecliptic, Edyſtone.

EDYSTONE Rocks, ſo remarkable for the lighthouſe built on them, obtained their name from the great variety of contrary ſets of the tide or current in their vicinity. They are ſituated nearly S. S. W. from the middle of Plymouth Sound, according to the true meridian. The diſtance from the port of Plymouth is nearly 14 miles, and from the promontory called *Ramhead* about 10 miles. They are almoſt in the line, but ſomewhat within it, which joins the Start and the Lizard points; and as they lie nearly in the direction of veſſels coaſting up and down the channel, they were neceſſarily, before the eſtabliſhment of a light houſe, very dangerous, and often fatal to ſhips under ſuch circumſtances. Their ſituation, likewiſe, with regard to the Bay of Biſcay and Atlantic ocean, is ſuch, that they lie open to the ſwells of the Bay and ocean from all the ſouth-weſtern points of the compaſs: which ſwells are generally allowed by mariners to be very great and heavy in thoſe ſeas, and particularly in the Bay of Biſcay. It is to be obſerved, that the ſoundings of the ſea from the ſouth-weſtward toward the Edyſtone are from 80 fathoms to 40, and everywhere till you come near the Edyſtone the ſea is full 30 fathoms in depth; ſo that all the heavy ſeas from the ſouthweſt come uncontrouled upon the Edyſtone rocks, and break on them with the utmoſt fury.

Smeaton's Account of the Edyſtone Light-houſe.

The force and height of theſe ſeas is increaſed by the circumſtance of the rocks ſtretching acroſs the Channel, in a north and ſouth direction, to the length of above 100 fathoms, and by their lying in a ſloping manner toward the ſouth-weſt quarter. This *ſloping* of the rock, as it is technically called, does not ceaſe at low water, but ſtill goes on progreſſively; ſo that, at 50 fathoms weſtward, there are 12 fathoms water; nor do they terminate altogether at the diſtance of a mile. From this configuration it happens, that the ſeas are ſwelled to ſuch a degree in ſtorms and hard gales of wind, as to break on the rocks with the utmoſt violence.

The effect of this ſlope is likewiſe ſenſibly felt in moderate, and even in calm weather; for the libration of the water, cauſed in the Bay of Biſcay in hard gales at ſouth-weſt, continues in thoſe deep waters for many days, though ſucceeded by a calm; inſomuch, that when the ſea is to all appearance ſmooth and even, and its ſurface unruffled by the ſlighteſt breeze, yet thoſe librations ſtill continuing, which are called the *groundſwell*, and meeting the ſlope of the rocks, the ſea breaks upon them in a frightful manner, ſo as not only to obſtruct any work being done on the rock, but even the landing upon it, when, figuratively ſpeaking, you might go to ſea in a walnut ſhell. A circumſtance which ſtill farther increaſes the difficulty of working on the rock is, there being a ſudden drop of the ſurface of the rock, forming a ſtep of about four and a half, or five feet high; ſo that the ſeas, which in moderate weather come ſwelling to this part, meet ſo ſudden a check that they frequently fly to the height of 30 or 40 feet.

Notwithſtanding theſe difficulties, it is not ſurpriſing that the dangers to which navigators were expoſed by the Edyſtone rocks ſhould make a commercial nation deſirous of having a light-houſe on them. The wonder is, that any one ſhould be found hardy enough to undertake the building. Such a man was firſt found in in the perſon of *Henry Winſtanley* of Littlebury in Eſſex, Gent. who, in the year 1696, was furniſhed by the maſter, wardens, and aſſiſtants, of the Trinity-houſe of Deptford-ſtrond with the neceſſary powers to carry the deſign into execution.

Mr Winſtanley had diſtinguiſhed himſelf in a certain branch of mechanics, the tendency of which is to raiſe wonder and ſurpriſe. He had at his houſe at Littlebury a ſet of contrivances, ſuch as the following: Being taken into one particular room of his houſe, and there obſerving an old ſlipper careleſsly lying on the floor; if, as was natural, you gave it a kick with your foot, up ſtarted a *ghoſt* before you. If you ſat down in a certain chair, a couple of arms would immediately claſp you in, ſo as to render it impoſſible to diſentangle yourſelf till your attendant ſet you at liberty. And if you ſat down in a certain arbour by the ſide of a canal, you were forthwith ſent out *afloat* to the middle of the canal, from whence it was impoſſible for you to eſcape till the manager returned you to your former place.—Whether thoſe things were ſhewn to ſtrangers at his houſe for money, or were done by way of amuſement to thoſe that came to viſit the place, is uncertain, as Mr Winſtanley is ſaid to have been a man of ſome property; but it is at leaſt certain, that he eſtabliſhed a place of public exhibition at Hyde Park-corner, called *Winſtanley's water-works*, which were ſhewn at ſtated times at one ſhilling each perſon. The particulars of thoſe water works are not now known; but, according to the taſte of the times, we muſt naturally ſuppoſe a great variety of *jets d'eau*, &c.

Theſe particulars are at preſent of no other importance than that they ſerve to give a ſketch of the talents and turn of mind of the original undertaker, and to account for the whimſical kind of buildings which he erected on the Edyſtone; from the deſign of which, it ſeems as if it were not ſufficient for his enterpriſing genius to erect a building on the ſpot, where, of all others, it was leaſt likely to ſtand unhurt; but that he would alſo give it an elevation, in appearance the moſt liable to ſubject it to damage from the violence of the wind and waves.

This ingenious man entered upon his great undertaking in 1696, and completed it in ſomething more than four years. The firſt ſummer was occupied with making 12 holes in the rock, and in faſtening 12 great irons, which were to hold the work that was afterward to be done. The next ſummer was ſpent in making a ſolid body, or round pillar, 12 feet high and 14 feet in diameter. In the third year, the aforeſaid pillar or work was made good at the foundation, from the rock, to 16 feet in diameter; and all the work was raiſed, which, to the vane, was 80 feet high. Being all finiſhed, with the lantern, and all the rooms that were in it, we "ventured (ſays Mr Winſtanley) to lodge there ſoon after midſummer, for the greater diſpatch of this work: but the firſt night the weather came bad, and ſo continued, that it was eleven days before any boats could come near us again; and not being acquainted with the height of the ſeas riſing, we were almoſt all the time drowned with wet, and our proviſions in as bad a condition, though we worked night and day, as much as poſſible, to make ſhelter for ourſelves."

Mr Winſtanley, however, ſucceeded in ſetting up the light on the 14th of November in that year (1698); but he was detained till within three days of Chriſtmas before he could return to ſhore, being almoſt at the laſt extremity for want of proviſions.

In the fourth year, obſerving the effects that the ſea produced on the houſe, burying the lantern at times, although more than 60 feet high, Mr Winſtanley encompaſſed the aforeſaid building early in the ſpring with a new work of four feet thickneſs from the foundation, making all ſolid for near 20 feet high; and taking down the upper part of the firſt building, and enlarging every part in its proportion, he raiſed it 40 feet higher than it was at firſt: Yet, he obſerves, "the ſea, in times of ſtorms, flies in appearance *one hundred feet above the vane*, and at times doth cover half the ſide of the houſe and the lantern as if it were under water."

No material occurrences concerning this building happened till November 1703, when the fabric, needing ſome repairs, Mr Winſtanley went down to Plymouth to ſuperintend the work. And "we muſt not wonder (ſays Mr Smeaton), if, from the preceding accounts of the violence of the ſeas, and the ſtructure of the light-houſe, the common ſenſe of the public led them to ſuppoſe this building would not be of long duration. The following is an anecdote which I received to the ſame effect from ſo many perſons that I can have no doubt of the truth of it: Mr Winſtanley being among his friends previous to his going off with his workmen on account of thoſe reparations, the danger being intimated to him, and that one day or other the light-houſe would certainly be overſet; he replied, "He was ſo very well aſſured of the ſtrength of his building, he ſhould only wiſh to be there in the greateſt ſtorm that ever blew under the face of the heavens, that he might ſee what effect it would have on the ſtructure."—It happened that Mr Winſtanley was but too amply gratified in this wiſh; for while he was there with his workmen and light-keepers, that dreadful ſtorm began which raged moſt violently on the 26th of November 1703, in the night; and of all the accounts of the kind which hiſtory furniſhes us with, we have none that has exceeded this in Great Britain, or was more injurious or extenſive in its devaſtation. The next morning, November 27th, when the violence of the ſtorm was ſo much abated that it could be ſeen whether the light-houſe had ſuffered by it, nothing appeared ſtanding, but, upon a nearer inſpection, ſome of the large irons by which the work was fixed upon the rock; nor were any of the people, or any of the materials of the building, ever found afterwards, ſave only part of an iron chain, which had got ſo faſt jambed into a chink of the rock, that it could never afterwards be diſengaged till it was cut out in the year 1756."

Thus periſhed Mr Winſtanley, together with his building: but ſo great was the utility of that building while it ſtood, that the public could not fail to be deſirous of having another in its place. Accordingly, in 1706, an act of parliament of the 4th of Queen Anne was paſſed, for the better enabling the maſter, &c. of the Trinity-houſe of Deptford-ſtrond to rebuild the ſame. By this act, the duties payable by ſhipping paſſing the light-houſe were veſted in the corporation of the Trinity-houſe, who were empowered to grant a leaſe to ſuch undertaker or undertakers as they ſhould approve. In conſequence, they agreed with a Captain *Lovel* or *Lovet* for a term of 99 years, commencing from the day on which a light ſhould be exhibited, and continuing ſo long as that exhibition ſhould laſt during the

Edystone. the said term. On this foundation Captain Lovet engaged Mr John Rudyerd to be his engineer or architect and surveyor.

It does not appear that Mr Rudyerd was bred to any mechanical business or scientific profession, being at that time a silk mercer on Ludgate-hill; nor is it known that, in any other instance, he had distinguished himself by any mechanical performance before or after. His want of personal experience, however, was in a degree assisted by Mr Smith and Mr Norcutt, both shipwrights in the King's yard at Woolwich.

It is not, as Mr Smeaton observes, very material in what way this gentleman became qualified for the execution of his work; it is sufficient that he directed the performance in a masterly manner, and so as perfectly to answer the end for which it was intended. He saw the errors in the former building, and avoided them; instead of a polygon he chose a circle for the outline of his building, and carried up the elevation in that form. His principal aim appears to have been *use* and *simplicity*; and indeed, in a building so situated, the former could hardly be acquired in its full extent without the latter. He seems to have adopted ideas the very reverse of his predecessor; for all the unwieldy ornaments at top, the open gallery, the projecting cranes, and other contrivances, more for ornament and pleasure than use, Mr Rudyerd laid totally aside. He saw, that how beautiful soever ornaments might be in themselves, yet when they are improperly applied and out of place, by affecting to shew a taste, they betray ignorance of its first principle, *judgment*; for whatever deviates from propriety is erroneous, and at best insipid.

It is impossible for us to give an accurate account of the construction of Mr Rudyerd's light-house. We can only say, in general terms, that it was altogether built of wood; for the courses of moorstone, which Mr Rudyerd, adverting to the maxim, that *weight* is best resisted by *weight*, introduced into the solid part of his building, must be considered as being of the nature of ballast; the weight of these amounted to above 270 tons. The main column of the building consisted of one simple figure, being an elegant frustum of a cone, unbroken by any projecting ornament, or any thing on which the violence of the storms could lay hold; measuring, exclusively of its sloping foundation, 22 feet and eight inches on its largest circular base; 61 feet high above that circular base; and 14 feet and three inches in diameter at the top: so that the circular base was somewhat greater than one-third of the total height, and the diameter at the top was less than two-thirds of the base at the greatest circle. On the flat roof of this main column, as a platform, Mr Rudyerd fixed his lantern, which was an octagon of ten feet and six inches diameter externally. The mean height of the window-frames of the lantern above the balcony floor was nearly nine feet; so that the elevation of the centre of the light above the highest side of the base was 70 feet; that is, lower than the centre of Mr Winstanley's second lantern by seven feet, but higher than that of his first by 24 feet. The width of Mr Rudyerd's lantern was, however, nearly the same as that of Mr Winstanley's second: but instead of the towering ornaments of iron-work, and a vane that rose above the top of the cupola no less than 21 feet, Mr Rudyerd judiciously contented himself with finishing his building with a round ball of two feet and three inches diameter, which terminated at three feet above the top of his cupola. The whole height of Mr Rudyerd's light-house, from the lowest side to the top of the ball, was 92 feet, on a base of 23 feet and four inches, taken at a medium between the highest and lowest part of the rock that it covered. The whole building was completed in the year 1709, three years from its commencement.

This great work, after having braved the elements for forty-six years, was burnt to the ground in 1755. On the 2d of December of that year, when the light-keeper, then on the watch, went, about two o'clock in the morning, into the lantern, to snuff the candles according to custom, he found it in a smoke; and in spite of all that he and his companions could do, the whole edifice was on fire in the compass of little more than eight hours, and in a few days was burnt to its foundation. The three light-men were with much difficulty got on shore, when one of them immediately ran off, and has never since been heard of. Another, who had been dreadfully burned by melted lead, of which, according to his own account, he had swallowed a quantity, lingered in agony for twelve days, and then expired. His stomach being opened, there was found in it a solid piece of lead of a flat oval form, which weighed seven ounces and five drachms; and thus was verified an assertion which, to the surgeon and others who attended him, appeared altogether incredible, *viz.* that any human being could live after receiving melted lead into the stomach.

On the destruction of Mr Rudyerd's light-house, Mr Smeaton (see SMEATON in this Supplement) was recommended by Lord Macclesfield, then president of the Royal Society, as the fittest person in England to build another. It was with some difficulty that he was able to persuade the proprietors that a stone building, properly constructed, would in all respects be preferable to one of wood; but having at last convinced them, he turned his thoughts to the shape which was most suitable to a building so critically situated. Reflecting on the structure of the former buildings, it seemed a material improvement to procure, if possible, an enlargement of the base, without increasing the size of the *waist*, or that part of the building which is between the top of the rock and the top of the solid work. Hence he thought a greater degree of strength and stiffness would be gained, accompanied with less resistance to the acting power. On this occasion, the natural figure of the waist or bole of a large spreading oak occurred to Mr Smeaton.

"Let us (says he) consider its particular figure.—Connected with its roots, which lie hid below ground, it rises from the surface with a large swelling base, which at the height of one diameter is generally reduced by an elegant curve, concave to the eye, to a diameter less by at least one third, and sometimes to half its original base. From thence, its taper diminishing more slowly, its sides by degrees come into a perpendicular, and for some height form a cylinder. After that, a preparation of more circumference becomes necessary, for the strong insertion and establishment of the principal boughs, which produces a swelling of its diameter.—Now we can hardly doubt but that every section of the tree is nearly of an equal strength in proportion to what it has to resist; and were we to lop off its principal boughs, and expose it in that state to a rapid current of water, we should find it as capable of

resisting

Edyſtone resisting the action of the heavier fluid, when divested of the greater part of its clothing, as it was that of the lighter, when all its spreading ornaments were exposed to the fury of the wind: and hence we may derive an idea of what the proper shape of a column of the greatest stability ought to be, to resist the action of external violence, when the quantity of matter is given of which it is to be composed."

The next thing to be considered was, how the blocks of stone could be bonded to the rock, and to one another, in so firm a manner as that not only the whole together, but every individual piece, when connected with what preceded, should be proof against the greatest violence of the sea. For this purpose, cramping was the first idea, but was rejected on account of the great quantity of iron which was necessary, and from the trouble and loss of time which would attend that operation. In its place was substituted the method of dovetailing. From some specimens which Mr Smeaton had seen in Belidor's description of the stone floor of the great sluice at Cherburgh, (where the tails of the upright headers are cut into dovetails for their insertion into the mass of rough masonry below,) he was led to think, that if the blocks themselves were, both inside and outside, formed into large dovetails, they might be managed so as to lock one another together, being primarily engrafted into the rock; and in the round or entire courses above the top of the rock, they might all proceed from, and be locked to, one large centre stone. These particulars being digested in his own mind, he explained his design by the help of drawings; with which, after mature deliberation, the proprietors were perfectly satisfied; and declared, that the scheme was not only in itself practicable, but, as appeared to them, the only means of doing the business effectually.

During this time Mr Smeaton had never visited the rock on which he was to be employed: he therefore resolved to go to Plymouth early in the spring of 1756, that he might lose no opportunity of viewing it. At Plymouth he met Mr Josias Jessop, to whom he was referred for information and assistance, and who afterwards proved of great service: he was not only an approved workman in his branch as a shipwright, but a competent draughtsman and an excellent modeller; 'in which last (says the author) he was accurate to a great degree: he therefore appeared to be a very fit person to overlook the exact execution of a design given.' Mr Jessop, like others, expressed his doubts that a stone building could stand on the Edystone: but they were removed by the proposed mode of its construction.—As Mr Smeaton was impatient to go to the rock, he seized the first opportunity that seemed to promise any chance of landing on it. On the 2d of April he got within a stone's throw of it, but could not land: on the 5th he was more fortunate; he now landed, and staid on the rock for two hours and a half. This time was employed in taking a general view of the whole. No remains of the house could be perceived either on the rock, or about it, except the greatest part of the iron branches that had been fixed by Mr Rudyerd; and some of the moorstones were discerned lying in the bottom of the gut. Such traces were also observed of the situation of the irons fixed by Mr Winstanley, as to render it no very difficult task to make out his plan, and the position of the edifice; whence it appeared very probable, that Mr Winstanley's building was overset altogether, and that it had torn up a portion of the rock itself, as far as the irons had been fastened in it. With regard to the steps, which were said to have been cut in the rock by Mr Rudyerd, the traces of only five were remaining; these were faintly cut, and without much regularity. It was next tried in what degree the rock was workable; and Mr Smeaton had the satisfaction of finding every thing succeed to his wishes. Edyſtone.

Having thus determined that there was no impracticability in fixing a stone building, it became of the greatest importance to secure a more safe and certain landing on the rock; as it would frequently happen, while the vessels were lying off the rock, waiting for a favourable time to enter the gut, that tides might change, ground swells come on, winds shift, and storms arise, which would of course make it desirable to return to Plymouth, if possible, though the purpose of the voyage was unperformed. In addition to this, when vessels had got with some facility into the gut, they frequently could not get out again without extreme danger: for as the larger sort had not room to turn in it, they were in reality obliged to go out stern forward; the Sugar-loaf rock being so critically placed, with shallow water on both sides of it, that it prohibits a thorough passage. It was true, indeed, that by the skill and expertness of those seamen who had frequently attended the service of the Edystone, not only row boats, but the attendant vessels, after having delivered their cargoes, had been carried quite through, at the top of an high tide, with a fair wind and smooth water: but this was not an experiment to be commonly repeated. The two voyages which Mr Smeaton had made were in a small sailing vessel of about ten or twelve tons burden, which was built for the service, and called the Edystone Boat. It occurred to him, that while the light house was standing, if the boat had been staved on the rocks while lying in the gut, there was a possibility of the men being saved by getting into the house, as the light-keepers would have been ready to throw out a rope to their assistance: but that if any accident of the kind were to happen now that the house was down, and no protection nor shelter to be had, there was little chance of their escape;—and these considerations being likely to cast a damp on every exertion to land, he determined to go out no more without another sailing boat to attend.

The weather being unfavourable for visiting the rock, all exertions were used to forward the work on shore; and, first, a work-yard was chosen in a field adjacent to Mill Bay, about a mile west from Plymouth. The next object was to procure moor stone, or granite; and with this view the author visited Hingstone Downs, and observed the manner of working the stone, which is curious. He next went to Lanlivery, near Fowey harbour, from which place the stone-work for the late light-house had been furnished.

During this time he had made five voyages to the rock with little success: the event of the last had strongly pointed out, that the much greater tonnage of the stone which must be necessary to be carried out and fixed, in case of a stone building, than was requisite in the compositions of his predecessors, would make the uncertainty and delay which they had described as being attendant on their voyages, in order to fix their work, bear far heavier on the scheme; and would thus occasion

Edyſtone. occaſion the whole time of the performance to be lengthened. It appeared, therefore, that had a veſſel been fixed within a quarter of a mile, or ſome ſuch competent diſtance from the rocks, and which ſhould be capable of lodging the workmen, all their tools and looſe materials, the ſeveral pieces of wrought ſtone only excepted, that then the workmen might, by means of ſmall row boats or yawls, have effected a landing both of themſelves and of their materials, and have been at work on the rock during the greateſt part of thoſe days which otherwiſe, as voyagers, they would have loſt in fruitleſs endeavours to get to the place of action. Agreeably to this opinion, it was propoſed to build a ſtrong and very well found ſloop of about fifty tons, with iron chains for mooring her on the rocky ground near the Edyſtone. A veſſel was in fact afterward moored in this ſituation: but it was one not built for the ſervice, but originally intended to have been ſtationed as a temporary floating light during the rebuilding of the light-houſe.

Mr Smeaton now made a ſixth voyage to the rock, on which he employed himſelf for nineteen hours in taking ſuch dimenſions as would enable him to make an accurate model of its ſurface. He likewiſe attempted a ſeventh voyage: but being unable to reach the Edyſtone, he bore away for Falmouth, in order to examine the moor-ſtone works at Conſtantine in that neighbourhood. From the difficulties which occurred here, as well as at other places, he was convinced that a ſufficient quantity of moor-ſtone could not be readily and expeditiouſly procured, in order to complete the whole building; and that he muſt therefore confine the moor-ſtone to the outſide, as being more durable, and content himſelf with the uſe of Portland, or ſome other free-working ſtone, for the inſide work. In conſequence, after making three more voyages to the rock, and completing all the obſervations which he was deſirous of taking there, he viſited the iſle of Portland in his return to London, and made the neceſſary agreements for carrying on his work.

On his arrival in London, Mr Smeaton again met the proprietors, from whom he experienced the greateſt liberality and confidence: they declared, that as he was now apprized of what was to be done, they left both the time and the means of its accompliſhment to him.

'On this occaſion (he obſerves), I found myſelf totally unfettered; and perhaps no reſolution of the proprietors ever more conduced to the ultimate ſucceſs of the work than this, which ſet me ſo much at liberty. Had they been of the ſame temper and diſpoſition of by far the greateſt part of thoſe who have employed me, both before and ſince, their language would have been, Get on, Get on, for God's ſake get on! the public is in expectation; get us ſomething ſpeedily to ſhew, by which we may gain credit with the public!—This, however, was not their tone, which I looked upon as a happy earneſt from the proprietors in the outſet.'

During his ſtay in London, he reſolved, as an abſolutely neceſſary preliminary ſtep, to form models of the rock, both in its preſent ſtate and as cut to the intended ſhape for receiving the building. Connected with the laſt was a model of the building itſelf, ſhewing diſtinctly how the work was to be adapted to each ſeparate ſtep in the aſcent of the rock, and particularly exhibiting the conſtruction of the firſt entire courſe after riſing to the level of the upper ſurface of the rock: to this a ſolid being fitted, the model ſhewed the external form of the whole building, including the lantern; while, by a ſection on paper, the whole inſide work was repreſented. Theſe models, as well, indeed, as moſt of the material parts of the buſineſs, were the entire work of Mr Smeaton's own hands. After exhibiting theſe to the Lords of the Admiralty, who expreſſed their warmeſt approbation, he returned to Plymouth on the 23d of July 1756.

On his arrival at Plymouth, he found that Mr Jeſſop had completely fitted up, for preſent ſervice, the ſloop, which had before been uſed as an attendant; as well as the Edyſtone boat, and a large yawl, with ſails and oars. Another ſeaman was now taken into the ſervice, which made the number of the crew ſix. The Neptune Buſs, which had been built for the purpoſe of exhibiting a temporary light, but which was afterward moored near to the rock, was arrived: but as her deſtination was not known, all orders for mooring-chains were ſuſpended, and Mr Smeaton was obliged to content himſelf with preparing cables in the beſt manner that he could for mooring the ſloop in that ſituation. As the weather was unfavourable, he had but one opportunity of viſiting the rock; he therefore applied vigorouſly to prepare every thing on ſhore. The firſt buſineſs was to eſtabliſh the working companies, which were to conſiſt of two complete ſets of hands, to relieve each other by turns; ſo that, whenever winds and tides would permit, the work might be purſued by day and night. In his diſtribution and management of theſe people he appears to have acted with great judgment. He made choice of, and agreed with, Mr Thomas Richardſon, a maſter maſon of Plymouth, to act as foreman of one of the companies; and alſo with William Hill, who had been ſome time foreman to another maſter maſon of the ſame place, to act as the other foreman. He likewiſe entered three maſons, and nine tinners (Corniſh miners), as a company, to go out with Mr Richardſon to take the firſt turn, or week, commencing from Saturday the 31ſt of July. Mr Jeſſop was appointed general aſſiſtant. The wages of the foremen, while at ſea, were to be 5 s. per day certain; and for every hour ſpent on the rock, the farther premium of 1 s.—but when employed in the work-yard or otherwiſe on ſhore, their wages were to be 3 s. 6 d. per day. The wages of the maſons were to be 2 s. 6 d. per day certain at ſea, with a premium of 9 d. per hour; and the tinners were to have 2 s. per day certain at ſea, and 8 d. per hour. In the work-yard, or at ſhore, the maſons were to have 20d. and the tinners 18d. per day, and to be paid for over-time when required to work;—and that the ſeamen might not want inducement to do their utmoſt in landing the workmen at the Edyſtone as early as poſſible at every opportunity, and in ſupplying them with what was neceſſary for keeping them at work, over and above their weekly wages, which were ſettled at 8 s. per week, they were all to receive a premium for every landing on the rock; the maſter ſeamen having 2s. 6 d. and the ordinary men 2s. to make their advantage equivalent to that of the other workmen, in whatever ſervice the ſeamen, who were conſtantly on duty, were employed. Mr Jeſſop, as general aſſiſtant, was to have 10s. 6 d. per day at ſea, and 5 s. per day on land; and every one was to ſupply himſelf with victuals.—Mr Smeaton likewiſe agreed for half an acre of ground on the weſt ſide of Mill-bay for

Edyſtone.

a work-yard, as before mentioned, which he marked out, and ordered to be fenced with boards. At this time arrived Mr John Harriſon, who was to act as clerk to the Edyſtone works, with whom a plan was digeſted for keeping the accounts and correſpondence; and for the diſtinct noting of ſo great a variety of articles, it was found expedient to open fourteen different books.

Matters being thus ſettled on ſhore, and the weather having become more promiſing, Mr Richardſon and his company embarked in the ſloop, with her ground tackle on board, attended by the author and Mr Jeſſop, and having the yawl alſo properly manned. Having landed on the rock, Mr Smeaton proceeded to fix the centre, and to lay down the lines of the intended work on its ſurface; and being followed by Mr Richardſon, he, with ſharp picks, left indelible traces of thoſe lines, ſo as that the workmen might proceed on them when ever they ſhould be able to land. The roughneſs of the ſea, however, ſoon rendered it adviſable to return to the ſloop; and from the ſame cauſe it was thought unſafe to attempt to moor her that evening. On the next day, the wind continued to blow very freſh; but on the following they were able to moor the ſloop: and every one being anxious to make a beginning, the whole company landed on the rock, and immediately began the work, which was purſued for about four hours, when they were driven off by the ſea. On the following day, all hands landed before ſun-riſe, and worked, during that tide, for ſix hours; and in the afternoon's tide they again landed, and continued the work, by the help of links, till ten o'clock at night. They purſued this courſe for ſome time with very little interruption, working, at an average, for about five hours in each tide.

The weather had now been fair from Auguſt 27th to the 14th of September; and in this ſpace they had worked for 177 hours on the rock. During this interval, alſo, Mr Jeſſop had prevented a weſt Indiaman homeward bound, and a man of war's tender, from driving on the rocks, to which they were approaching, though they themſelves were not aware of it. On the 16th, the work on the rock was in the following ſituation: The loweſt new ſtep (the moſt difficult to work, becauſe the loweſt), with its dovetails, was quite completed.—The ſecond ſtep was rough bedded, and all its dovetails ſcapelled out.—The third ſtep (being the loweſt in Mr Rudyerd's work) was ſmooth bedded, and all the dovetails roughed out.—The fourth was in the like ſtate.—The fifth was rough bedded, and its dovetails were ſcapelled out; and the ſixth was ſmooth bedded, and all the dovetails roughed out.—Laſtly, the top of the rock, the greateſt part of the bulk whereof had been previouſly taken down as low as it could be done with propriety, was now to be reduced to a level with the upper ſurface of the ſixth ſtep; the top of that ſtep being neceſſarily to form a part of the bed for the ſeventh or firſt regular courſe: ſo that what now remained, was to bring the top of the rock to a regular floor by picks; and from what now appeared (as all the upper parts that had been damaged by the fire were cut off) the new building was likely to reſt on a baſis even more ſolid than the former lighthouſes had done.

The equinoctial winds that were now reigning, afforded little proſpect of doing much more work on the rock for this ſeaſon: for though a more moderate interval of weather might be expected, yet that muſt be employed in weighing the Buſs's moorings. To prevent the neceſſity of this, however, it was an object of conſideration, whether they could not diſpenſe with that operation, and thereby have a little more time for work on the rock. Mr Smeaton's contrivance for this purpoſe was admirable; but it was rendered vain by the bad ſailing of the buſs. After overcoming many difficulties, the buſs with Mr Smeaton on board was driven at a great rate towards the bay of Biſcay, in danger every hour of being ſwallowed up by the waves or daſhed in pieces on the rocks of Scilly. At laſt, on Friday morning the 26th of November, they reached Plymouth Sound, and relinquiſhed all thoughts of returning to their work on the rock that ſeaſon.

The winter therefore of 1756, and the following ſpring, were employed in preparing materials for the outwork: the maſonry particularly required great attention. It was a deſirable object to uſe large and heavy pieces of ſtone in the building; yet their ſize muſt neceſſarily be limited by the practicability of landing them with ſafety. Now ſmall veſſels only could deliver their cargoes alongſide of this hazardous rock; and theſe could not deliver very large ſtones, becauſe the ſudden riſing and falling of the veſſels in the gut amounted frequently to the difference of three or four feet, even in moderate weather; ſo that in caſe after a ſtone was raiſed from the floor of the veſſel, her gunwale ſhould take a ſwing, ſo as to hitch under the ſtone, one of a very large magnitude muſt, on the veſſel's riſing, infallibly ſink her. From this conſideration, it was determined that ſuch ſtones ſhould be uſed as did not much exceed a ton weight; though occaſionally particular pieces might amount to two tons. That they might attain a certainty in putting the work together on the rock, the ſtones of each courſe were tried together in their real ſituation with reſpect to each other; and they were ſo exactly marked, that every ſtone, after the courſe was taken aſunder, could be replaced in the identical poſition in which it lay on the platform, within the fortieth part of an inch:—nor was this judged ſufficient; for every courſe was not only tried ſingly together on the platform and marked, but the courſe above it was put on it, and marked in the ſame way; ſo that every two contiguous courſes might fit each other on the outſide, and prevent an irregularity in the outline. This degree of accuracy might ſeem ſuperfluous: but as the nature of the building required the workmen to be in a condition to reſiſt a ſtorm at every ſtep, it became neceſſary to fix the centre ſtone firſt, as being leaſt expoſed to the ſtroke of the ſea; and in order to have ſure means of attaching all the reſt to this, and to one another, it was indiſpenſable that the whole of the two courſes ſhould be tried together; in order that, if any defect appeared at the outſide, by an accumulation of errors from the centre, it might be rectified on the platform.

Another circumſtance, to which Mr Smeaton was particularly attentive, and concerning which his remarks are very valuable, was to aſcertain the moſt proper compoſition for water cements. In making mortar for buildings expoſed to water, *tarras* had been moſt eſteemed: but ſtill there were objections to its uſe. Mr Smeaton was therefore induced to try the *terra puzzolana*, found in Italy, as a ſubſtitute for *tarras*. Fortunately there was a quantity of it in the hands of a merchant at Plymouth, which had been imported as a venture

Edyſtone. ture from Civita Vecchia, when Weſtminſter-bridge was building; and which he expected to have ſold for that work to a good advantage, but failed in his ſpeculation: for having found that *tarras* anſwered their purpoſe, neither commiſſioners, engineers, nor contractors, would trouble themſelves to make a trial of the other material. This was found in every reſpect equal to *tarras*, as far as concerned the hardening of water-mortar, if not preferable to it; and if made into a mortar with lime produced from a ſtone found at Aberthaw, on the coaſt of Glamorganſhire, it exceeded, in hardneſs, any of the compoſitions commonly uſed in dry work; and in wet and dry, or wholly wet, was far ſuperior to any which Mr Smeaton had ſeen, inſomuch that he did not doubt its making a cement that would equal the beſt merchantable Portland ſtone in ſolidity and durability.

Theſe preliminary arrangements being ſettled, they proceeded, on the 3d of June 1757, to carry out the Neptune buſs, and to begin the work. After getting up the moorings (a work of no ſmall difficulty and ſome danger), and after fixing the fender-piles, the ſhears, windlaſs, &c. the firſt ſtone was landed, got to its place, and fixed, on Sunday the 12th of June; and on the next day the firſt courſe was completed. On the 14th, the ſecond courſe was begun: but, in conſequence of a freſh gale, the workmen were obliged to quit the rock, after ſecuring every thing as well as poſſible. Such was the violence of the gale, that it was impracticable for the boats to get out of the gut, otherwiſe than by paſſing the Sugar-loaf rock, in which they providentially ſucceeded. On the 18th, they were again as ſuddenly driven from their work, and ſeveral pieces of ſtone were waſhed away by the violence of the ſea. In the night of the 6th of July, the watch on the deck of the buſs eſpied a ſail on the rocks, and one of the yawls was ſent to her relief, which brought back the whole crew, ſeveral of whom were in their ſhirts, and in great diſtreſs. It was a ſnow of about 130 tons burthen, which was returning in ballaſt from Dartmouth; but not knowing exactly where they were, they had miſtaken the rocks for ſo many fiſhing-boats, till it was too late to clear them; and on the veſſel's ſtriking, ſhe filled ſo quickly, that the boat floated on deck before they could get into it.

During this time the building went on, though its progreſs was retarded by various interruptions and accidents; till, at the latter end of Auguſt, when the ſeventh courſe was nearly finiſhed, a violent ſtorm aroſe, which carried away the ſhears and triangles, together with two of the largeſt ſtones which had been left chained on the rock! yet notwithſtanding theſe and various other difficulties, the ninth courſe was completed by the end of September.

"Being now arrived at the eve of October (ſays Mr Smeaton), I maturely conſidered our ſituation; and finding that we had been 18 days in completing the laſt courſe, whereas the former one was begun and finiſhed in five, though the weather, both on ſhore and above head, had remained to all appearance much the ſame; I from thence concluded it to be very probable, we might not get another courſe completed in the compaſs of the month of October: So that when I reflected on the many diſaſters that we had ſuffered laſt year by continuing out to the month of November, and how little work we in reality did after this time, it appeared to me very problematical whether we might be able, with every poſſible exertion, to get another courſe finiſhed this ſeaſon; and conſidering how very ineligible it was to have a courſe lie open during the winter in this ſtage of the work, and that we had now got three complete courſes eſtabliſhed above the top of the rock, the ſum of whoſe height was four feet ſix inches; and that we could not leave the work in a more defenſible ſtate, whether as relative to the natural violence of the ſea, or the poſſibility of external injuries—from theſe conſiderations, it appeared to me highly proper to put a period to the outwork of the preſent ſeaſon."

At the commencement of the following year, 1758, the weather proved very tempeſtuous till March; and on viſiting the rock, they diſcovered that the great buoy on the moorings had been carried away; nor were the mooring chains, though ſought with the greateſt perſeverance, recovered till the middle of May. In conſequence of this delay, and from other accidents, the tenth courſe of the building was not completed till the 5th of July. From this time, the progreſs was without any very material interruption; ſo that on the 26th of September the 25th courſe, being the firſt of the ſuperſtructure, was finiſhed. The work was now ſo far advanced, that Mr Smeaton made a propoſal to the Trinity Board and to the proprietors, of exhibiting a light during the enſuing winter; and for this purpoſe he continued his operations longer than he otherwiſe would have done, in order to complete the firſt room, and make it habitable; but foul weather coming on, he was obliged to quit the rock, and returned to Plymouth. A ſtorm enſued; and, on the next morning, looking out with his teleſcope, he could diſcern the houſe with the ſea breaking over it, but nothing of the buſs. On the following day, the air being more clear, he had a diſtinct view of the building; but the buſs was really gone. This was a day of double regret, as it likewiſe brought a negative on his propoſal for exhibiting a light from the houſe during the winter. The buſs had run into Dartmouth harbour; ſhe was brought home; and the work on the rock being ſecured againſt the winter, the operations of the third ſeaſon were cloſed.

During the early part of 1759, Mr Smeaton was employed in London in forming and making out the neceſſary deſigns for the iron rails of the balcony, the caſt iron, the wrought iron, and the copper works for the lantern, together with the plate glaſs work. It was not till the 22d of June that he arrived at Plymouth. As the moorings had been again loſt, new chains were provided, and the buſs was once more fixed in her ſituation. On the 5th of July he landed on the rock, and found every thing perfectly ſound and firm, without the leaſt perceptible alteration, excepting that the cement, uſed in the firſt year, now in appearance approached the hardneſs of the moorſtone; and that uſed in the laſt year had the full hardneſs of Portland; but on hauling up the ſtones for the next circle from the ſtore-room, where they had been depoſited, he had the mortification to find only ſeven inſtead of eight. It was imagined that a body of falling water, making its way through the open ribs of the centre, had waſhed this ſtone out of the ſtore-room door, though it weighed between four and five hundred weight.

The progreſs of the work, however, was now ſuch, that

Edyſtone. that a whole room, with its vaulted cover, was built complete in ſeven days.

On the 17th of Auguſt the main column was completed.

On the 27th Mr Richardſon and his company left the Edyſtone, and gave an account that they had lived in it ſince the 23d, having found it much more warm than the buſs's hold and cabin.

They had now finiſhed every thing belonging to the maſonry. The work of the cupola was going on briſkly in the yard at Mill-bay, though it was retarded by the ſucceſſive illneſſes of the two principal copperſmiths. However, by the exertions of Mr Smeaton, who was himſelf ready to work at every buſineſs, all matters were put in ſuch forwardneſs, that by the 8th of September there was nothing to prevent the frame of the lantern from being fixed in its place but bad weather. It was not till the 15th that the weather permitted the boats to deliver their cargoes. The 16th was remarkably fine; ſo that by the evening the whole frame of the lantern was ſcrewed together, and fixed in its place. On the 17th, which was alſo exceedingly fine, the cupola was brought out, and the ſhears and tackle were ſet up for hoiſting it.

"This (ſays Mr Smeaton) perhaps may be accounted one of the moſt difficult and hazardous operations of the whole undertaking; not ſo much on account of its weight, being only about 11 cwt. as on account of the great height to which it was to be hoiſted clear of the building, and ſo as, if poſſible, to avoid ſuch blows as might bruiſe it. It was alſo required to be hoiſted a conſiderable height above the balcony floor; which, though the largeſt baſe that we had for the ſhears to ſtand on, was yet but 14 feet within the rails, and therefore narrow in proportion to their height. About noon the whole of our tackle was in readineſs; and in the afternoon the Weſton (boat) was brought into the gut, and in leſs than half an hour her troubleſome cargo was placed on the top of the lantern without the leaſt damage. During the whole of this operation it pleaſed God that not a breath of wind diſcompoſed the ſurface of the water, and there was the leaſt ſwell about the rocks I had obſerved during the ſeaſon.

"Tueſday, September 18th, in the morning, I had the ſatisfaction to perceive the Edyſtone boat, on board of which I expected the ball to be; and which being double gilt, I had ordered the carriage of it to be carefully attended to. The wind and tide were both unfavourable to the veſſel's getting ſoon near us; therefore, being deſirous to get the ball ſcrewed on before the ſhears and tackle were taken down, one of the yawls was diſpatched to bring it away. This being done, and the ball fixed, the ſhears and tackle were taken down, which took up nearly as much time as was employed in ſetting them up; that is, near 12 hours each, in the whole, to do the work of an hour.—I muſt obſerve, that by choice I ſcrewed on the ball with mine own hands, that in caſe any of the ſcrews had not held quite tight and firm, the circumſtance might not have been ſlipped over without my knowledge; being well aware, that even this part would at times come to a conſiderable ſtreſs of wind and ſea, and which could not be replaced without ſome difficulty in caſe any thing ſhould fail.—It may not be amiſs to intimate to thoſe who may in future have to perform the ſame operation, that the ſcaffold on which this was done conſiſted of four boards only, well nailed together, at ſuch diſtances as to permit it to be lifted over the ball when done with. It reſted on the cupola, encompaſſing its neck; and Roger Cornthwaite, one of the maſons, placed himſelf on the oppoſite ſide upon it, to balance me while I moved round to fix the ſcrews."

Reſpecting the diſpoſition of the internal part of the edifice, Mr Smeaton fixed the beds in the uppermoſt room, and the fire-place, which conſtituted the kitchen, in the room below it; whereas, in the late houſe, the upper room was the kitchen, and the beds were placed in one of the rooms below: the conſequence of which was, that the beds and bedding were generally in a very damp and diſagreeable ſtate. The preſent diſpoſition has perfectly anſwered the end propoſed, as nothing can be more completely dry than the two habitable rooms.

On the 1ſt of October, every thing being finiſhed, and the chandeliers hung, there was nothing to hinder a trial by lighting the candles in the day-time. Accordingly 24 candles were put into their proper places, and were continued burning for three hours, during which time it blew a hard gale; and a fire being kept at the ſame time in the kitchen, they both operated without any interference; not any degree of ſmoke appearing in the lantern nor in any of the rooms: and by opening the vent-holes, which had been made in the bottom of the lantern for occaſional uſe, it could be kept quite cool; whereas, in the late light-houſe, it uſed to be ſo hot, eſpecially in the ſummer, as to give much trouble by the running of the candles.

All being thus in readineſs, and a conductor, in caſe of lightning, being adapted to the building, notice was given to the Trinity-houſe that the light would be exhibited on the 16th of October 1759. The ſeaſon of the year being now advanced to that which was always very precarious, the Neptune buſs was unmoored, and on the 9th of October ſhe came to an anchor in Plymouth harbour.—"And thus (ſays Mr Smeaton), after innumerable difficulties and dangers, was a happy period put to this undertaking, without the loſs of life or limb to any one concerned in it, or accident, by which the work could be ſaid to be materially retarded."

With regard to ſubſequent occurrences, it is truly obſerved, that the beſt account is, that after a trial of 40 years, which have elapſed ſince the finiſhing of the building, it ſtill remains in its original good condition. A few particulars are however intereſting. On the 19th of October Mr Smeaton, with Mr Jeſſop, &c. viſited the houſe, and, landing, found all well. Henry Edwards, one of the light-keepers, gave an account that they lighted the houſe as they were directed, and found the lights to burn ſteadily, notwithſtanding it blew very hard; that they had the greateſt ſeas on the days immediately preceding the lighting; and that then the waves broke up ſo high, that had they not been thrown off by the cove courſe, they would have endangered breaking the glaſs in the lantern; that when the ſeas broke the higheſt, they had experienced a ſenſible motion; but that, as it was barely perceptible, it had occaſioned them neither fear nor ſurpriſe.

During his ſtay at Plymouth, in the times of ſtormy weather, Mr Smeaton took ſeveral opportunities of viewing the light-houſe with his teleſcope from the Hoa, and alſo from the garriſon; both which places were ſufficiently elevated to ſee the baſe of the building, and the whole of the rock at low water in clear weather;

ther; and though he had many occaſions of viewing the unfiniſhed building when buried in the waves in a ſtorm at ſouth-weſt, yet having never before had a view of it under this circumſtance in its finiſhed ſtate, he was aſtoniſhed to find that the account given by Mr Winſtanley did not appear to be at all exaggerated. At intervals of a minute, and ſometimes of two or three, when a combination happened to produce one overgrown wave, it would ſtrike the rock and the building conjointly, and fly up in a white column, enwrapping it like a ſheet, riſing at leaſt to double the height of the houſe, and totally intercepting it from the ſight; and this appearance being momentary, both as to its riſing and falling, he was enabled to judge of the comparative height very nearly by the comparative ſpaces, alternately occupied by the houſe and by the column of water in the field of the teleſcope.

The year 1759 concluded with ſome very ſtormy weather; and in January 1760, Mr Jeſſop viſited the houſe, but could not land. He got a letter, however, from Henry Edwards, acquainting him that there had been ſuch very bad weather that the ſea frequently ran over the houſe; ſo that for 12 days together they could not open the door of the lantern nor any other. He ſaid, "the houſe did ſhake as if a man had been up in a great tree. The old men were almoſt frighted out of their lives, wiſhing they had never ſeen the place, and curſing thoſe that firſt perſuaded them to go there. The fear ſeized them in the back; but rubbing them with oil of turpentine gave them relief." He farther mentioned, that on the 5th of December, at night, they had a very great ſtorm; ſo that the ladder, which was laſhed below the entry door, broke looſe, and was waſhed away. Alſo, on the 13th, there was ſo violent a ſtorm of wind that he thought the houſe would overſet; and at midnight the ſea broke one pane of glaſs in the lantern. They had a very melancholy time of it, having alſo had a great deal of thunder and lightning.—"The ſtorms (obſerves Mr Smeaton) which the building has now ſuſtained without material damage, convince us, and every one, of the ſtability of the ſtone light-houſe, except thoſe (who are not a few) who had taken a notion that nothing but *wood* could reſiſt the ſea upon the Edyſtone rocks; who ſaid, that though they allowed it was built very ſtrong, yet if ſuch a ſtorm as had deſtroyed Winſtanley's light-houſe was again to happen, they doubted not but it muſt ſhare the ſame fate. The year 1762 was uſhered in with ſtormy weather, and indeed produced a tempeſt of the firſt magnitude; the rage of which was ſo great, that one of thoſe who had been uſed to predict its downfal was heard to ſay, If the Edyſtone light-houſe is ſtanding now, it will ſtand till the day of judgment. And, in reality, from this time, its exiſtence has been ſo entirely laid out of mens minds, that whatever ſtorms have happened ſince, no inquiry has ever been made concerning it."

For the length of this detail we cannot bring ourſelves to make any apology. If there be a few of our readers to whom it may appear tedious, we are perſuaded that there are many more to whom it will be in a high degree intereſting; while ſuch of them as are engineers will derive inſtruction even from this very abridged hiſtory of the Edyſtone light-houſe.

EFFECTION, denotes the geometrical conſtruction of a propoſition. The term is alſo uſed in reference to problems and practices, which, when they are deducible from, or founded upon, ſome general propoſitions, are called the *geometrical effection* of them.

ELASTICITY. In addition to the article in the *Encyclopædia*, ſee, in this *Supplement*, the view of Boscovich's theory of natural philoſophy, n° 26.

ELECTIONS, or Choice, ſignify the ſeveral different ways of taking any number of things propoſed, either ſeparately, or as combined in pairs, in threes, in fours, &c.; not as to the order, but only as to the number and variety of them. Thus, of the things a, b, c, d, e, &c. the elections of
one thing are (a,) $1 = 2^1 - 1$,
two things are (a, b, ab,) $3 = 2^2 - 1$,
three things are (a, b, c, ab, ac, bc, abc,) $7 = 2^3 - 1$,
&c.; and of any number n, all the elections are $2^n - 1$; that is, one leſs than the power of 2 whoſe exponent is n, the number of ſingle things to be choſen, either ſeparately or in combination.

ELECTRICITY.

WE cannot but be ſomewhat ſurpriſed that, among the many attempts which have been made by the philoſophers of Britain to explain the wonderful phenomena which are claſſed under this name, no author of eminence, beſides the Hon. Mr Cavendiſh and Lord Mahon, have availed themſelves of their ſuſceptibility of mathematical diſcuſſion; and our wonder is the greater, becauſe it was by a mathematical view of the ſubject, in the phenomena of attraction and repulſion, that the celebrated philoſopher Franklin was led to the only knowledge of electricity that deſerves the name of ſcience; for we had ſcarcely any leading facts, by which we could claſs the phenomena, till he publiſhed his theory of *poſitive* and *negative*, or *plus* and *minus*, electricity. This is founded entirely on the phenomena of attraction and repulſion. Theſe furniſh us with all the indications of the preſence of the mighty agent, and the marks of its kind, and the meaſures of its force. Mechanical force accompanies every other appearance; and this accompaniment is regulated in a determinate manner. Many of the effects of electricity are ſtrictly mechanical, producing local motion in the ſame manner as magnetiſm or gravitation produce it. One ſhould have expected that the countrymen of Newton, prompted by his ſucceſs and his fame, would take to this mode of examination, and would have endeavoured to deduce, from the laws obſerved in the action of this motive force, an explanation of other wonderful phenomena, which are inſeparably connected with thoſe of attraction and repulſion.

But this has not been the caſe, if we except the labours of the two philoſophers above mentioned, and a few very obvious poſitions, which muſt occur to all the inventors and improvers of electrometers, batteries, and other things of meaſurable nature.

This view has, however, been taken of the ſubject by a philoſopher of unqueſtioned merit, Mr Æpinus of the Imperial Academy of St Peterſburgh. This gentleman,

gentleman, ſtruck with the reſemblance of the electrical properties of the tourmalin to the properties of a magnet, which have always been conſidered as the ſubject of mathematical diſcuſſion, fortunately remarked a wonderful ſimilarity in the whole ſeries of electrical and magnetical attractions and repulſions, and ſet himſelf ſeriouſly to the claſſification of them. Having done this with great ſucceſs, and having maturely reflected on Dr Franklin's happy thought of plus and minus electricity, and his conſequent theory of the Leyden phial, he at laſt hit on a mode of conceiving the whole ſubject of magnetiſm and electricity, that bids fair for leading us to a full explanation of all the phenomena; in as far, at leaſt, as it enables us to claſs them with preciſion, and to predict what will be the reſult of any propoſed treatment. He candidly gives it the modeſt name of a hypotheſis.

This was publiſhed at St Peterſburg in 1759, under the title of *Theoria Electritatis et Magnetiſmi*, and is unqueſtionably one of the moſt ingenious and brilliant performances of the eighteenth century. It is indeed moſt ſurpriſing that it is ſo little known in this country. This, we imagine, has been chiefly owing to the very ſlight and almoſt unintelligible account which Dr Prieſtley has given of it in his hiſtory of electricity; a work which profeſſes to comprehend every thing that has been done by the philoſophers of Europe and America for the advancement of this part of natural ſcience, and which indeed contains a great deal of inſtructive information, and, at the ſame time, ſo many looſe conjectures and inſignificant obſervations, that the reader (eſpecially if acquainted with the Doctor's character as an unwearied bookmaker) reaſonably believes that he has let nothing ſlip that was worthy of notice. We do not pretend to account for the manner in which Dr Prieſtley has mentioned this work, ſo much, and ſo deſervedly celebrated on the continent. We cannot think that he has read it ſo as to comprehend it; and imagine, that ſeeing ſo much algebraic notation in every page, and being at that time a novice in mathematical learning, he contented himſelf with a few ſcattered paragraphs which were free of thoſe embaraſſments; and thus could only get a very imperfect notion of the ſyſtem. The Hon. Mr Cavendiſh has done it more juſtice in the 61ſt volume of the Philoſophical Tranſactions, and conſiders his own moſt excellent diſſertation only as an extenſion and more accurate application of Æpinus's theory. That we have not an account of this expoſition of the Franklinian theory of electricity in our language, is a material want in Britiſh literature; and we truſt, therefore, that our readers will be highly pleaſed with having the ingenious diſcoveries of the great American philoſopher put into a form ſo nearly approaching to a ſyſtem of demonſtrative ſcience.

We propoſe, therefore, in this place, to give ſuch a brief account of Æpinus's theory of electricity, as will enable the reader to reduce to a very ſimple and eaſily remembered law all the phenomena of electricity which have any cloſe dependence on the mechanical effects of this powerful agent of Nature; referring for a demonſtration of what is purely mathematical to Sir Iſaac Newton's Principia, and the Diſſertation by Mr Cavendiſh already mentioned, except in ſuch important articles as we think ourſelves able to preſent in a new, and, we hope, a more familiar form. We do not mean, in this place, to give a ſyſtem of philoſophical electricity, nor even to narrate and explain the more remarkable phenomena. Of theſe we have already given a vaſt collection in the article Electricity, *Encycl.* We confine ourſelves to the phenomena which may be called *mechanical*, producing meaſurable motion as their *immediate* effect; and thus giving us a principle for the mathematical examination of the cauſe of electrical phenomena. We ſhall conſider the reader as acquainted with the other phyſical effects of electricity, and ſhall frequently refer to them for proofs.

Moreover, as our intention is merely to give a ſynoptical view of this elaborate and copious performance of Mr Æpinus, hoping that it will excite our countrymen to a careful peruſal of ſo valuable a work, we ſhall omit moſt of the algebraic inveſtigations contained in it, and preſent the concluſions in a more familiar, and not leſs convincing form. At the ſame time we will inſert the valuable additions made by Mr Cavendiſh, and many important particulars not noticed by either of thoſe gentlemen.

Hypothesis of Æpinus.

The phenomena of electricity are produced by a fluid of peculiar nature, and therefore called the electric fluid, having the following properties: 1 Hypotheſis.

1. Its particles repel each other, with a force decreaſing as the diſtances increaſe. 2.

2. Its particles attract the particles of ſome ingredient in all other bodies, with a force decreaſing, according to the ſame law, with an increaſe of diſtance; and this attraction is mutual. 3.

3. The electric fluid is diſperſed in the pores of other bodies; and moves, with various degrees of facility, through the pores of different kinds of matter. In thoſe bodies which we call *non-electrics*, ſuch as water or metals, it moves without any perceivable obſtruction; but in glaſs, roſins, and all bodies called *electrics*, it moves with very great difficulty, or is altogether immoveable. 4.

4. The phenomena of electricity are of two kinds; 1. Such as ariſe from the actual motion of the fluid from a body containing more into one containing leſs of it. 2. Such as do not immediately ariſe from this transference, but are inſtances of its attraction and repulſion. 5.

Theſe things being ſuppoſed, certain conſequences neceſſarily reſult from them, which ought to be analogous to the obſerved phenomena of electricity, if this hypotheſis be complete, or ſome farther modification of the aſſumed properties is neceſſary, in order to make the analogy perfect.

Suppoſe the body A (fig. 1.) to contain a certain quantity of fluid. Its particles adjoining to the ſurface, ſuch as P, are attracted by the particles of common matter in the body, but repelled by the other particles of the fluid. The totality of the attractive forces acting on P may be equal to the totality of the repulſive forces, or may be unequal. If theſe two ſums are equal, P is in equilibrio, and has no tendency to change its place. But there may be ſuch a quantity of fluid in the body, that the repulſions of the fluid exceed the attractions of the common matter. In this caſe, P has a tendency to quit the body, or there is an expulſive force acting on it, and it *will* quit the body if it be moveable. 6. Plate XXIV.

moveable. Becauſe the ſame muſt be admitted in reſpect of every other particle of moveable fluid, it is plain that there will be an efflux, till the attraction of the common matter for the particles of fluid is equal to the repulſion of the remaining fluid. On the other hand, if the primitive repulſion of the fluid acting on the particle P be leſs than the attractions of the common matter, there will be the ſame, or at leaſt a ſimilar, ſuperiority of attraction acting on the fluid reſiding in the circumambient bodies; and there will be an influx from all hands, till an equilibrium be reſtored.

7 Natural quantity, why ſo called.

Hence it follows, that there may always be aſſigned to any body ſuch a quantity of fluid that there ſhall be no tendency either to efflux or influx. But if the quantity be increaſed, and nothing prevent the motion, the redundant fluid will flow out; and if the proper quantity be diminiſhed, there will be an influx of the ſurrounding fluid, if not prevented by ſome external force. This may be called the body's NATURAL QUANTITY; becauſe the body, when left to itſelf, will always be reduced to this ſtate.

8. If two bodies A and B, contain each its natural quantity, they will not exert any ſenſible action on each other; for, becauſe the fluid contained in B is united by attraction to the common matter, and is alſo repelled by the fluid in A, it neceſſarily follows that the whole body B is repelled by the fluid in A. But, on the other hand, the matter in A attracts the fluid in B, and conſequently attracts the whole body B: Similar action is exerted by B on A. Theſe contrary forces are either equal, and deſtroy each other, or unequal, and one of them prevails. This equality or inequality evidently depends on the quantity of fluid contained in one or both of the bodies (n° 7.) Now it is known that bodies left entirely to themſelves neither attract nor repel; and it follows from the hypothetical properties of the fluid, that if there be either a redundancy or deficiency of fluid, there will be an efflux or influx, till the attractions and repulſions balance each other. Therefore the internal ſtate of two bodies which neither attract nor repel each other, is that where each contains its natural quantity of electric fluid.

9. In order, therefore, to conceive diſtinctly the ſtate of a body containing its natural quantity, and to have a diſtinct notion of this natural quantity, we muſt ſuppoſe that the quantity of fluid competent to a particle of matter in A repels the fluid competent to a particle of matter in B, juſt as much as it attracts that particle of matter; and alſo, that the fluid belonging to a particle of matter in A, repels the fluid belonging to a particle of matter in B, juſt as much as the particle of matter in A attracts it. Thus the whole fluid in the one repels the whole fluid in the other as much as it attracts the whole matter.

Since this muſt be conceived of every particle of common matter in a body, we muſt admit, that when a body is in its natural ſtate, the quantity of electric fluid in it is proportional to the quantity of matter, every particle being united with an equal quantity of fluid. This, however, does not neceſſarily require that different kinds of matter, in their natural or ſaturated ſtate, ſhall contain the ſame proportion of fluid. It is ſufficient that each contains ſuch a quantity, uniformly diſtributed among its particles, that its repulſion for the fluid in another body is equal to its attraction for the common matter in it. It is, however, more probable, for reaſons to be given afterwards, that the quantity of electric fluid attached, or competent, to a particle of all kinds of matter is the ſame.

We ſhall now conſider more particularly the immediate reſults of this hypotheſis, in the moſt ſimple caſes, from which we may derive ſome elementary propoſitions.

10 Electric phenomena ariſe from redundancy or deficiency in fluid, total or partial.

Since our hypotheſis is accommodated to the fact, that bodies in their natural ſtate, having their natural quantity of electric fluid, are altogether inactive on each other, by making this natural quantity ſuch, that its mutual repulſion exactly balances its attraction for the common matter—it follows, that we muſt deduce all the electric phenomena from a redundancy or deficiency of electric fluid. This accordingly is the Franklinian doctrine. The redundant ſtate of a body is called by Dr Franklin POSITIVE OR PLUS ELECTRICITY, and the deficient ſtate is called NEGATIVE OR MINUS ELECTRICITY.

A body may contain more than its natural quantity, or leſs, in every part, or it may be redundant in one place and deficient in another. Theſe different conditions will exhibit different appearances, which muſt be conſidered firſt of all.

11 Action of the redundant fluid or matter, how computed.

Let the body (fig. 1.) be ſuppoſed in its natural ſtate throughout, which we ſhall generally expreſs by ſaying that it is SATURATED; and let us expreſs the quantity of fluid required for its ſaturation by the ſymbol Q. Let P be a ſuperficial particle of the fluid. It is attracted by the common matter of the body (which we ſhall in future call ſimply the *matter*), and it is repelled equally by the fluid. Let us call the attraction a, and the repulſion r. Then the force with which the ſuperficial particle is attracted by the body, muſt be $= a - r$, and $a - r$ muſt be $= 0$, becauſe $a = r$. Let the quantity f of fluid be added to the body, and uniformly diſtributed through its ſubſtance. Then, becauſe we muſt admit that the action is in proportion to the quantity of acting fluid, and this is now $Q + f$, we have $Q : Q + f = r : \frac{\overline{Q+f} \times r}{Q}$; and therefore P is repelled by the whole fluid with the force $\frac{\overline{Q+f} \times r}{Q}$, or $\frac{Qr}{Q} + \frac{fr}{Q}$, or $r + \frac{fr}{Q}$. But it is attracted by the common matter in the ſame manner as before, that is, with a force $= a$. Therefore the whole action on P is $= a - r - \frac{fr}{Q}$. But $a - r = 0$. Therefore the whole action on P is $= -\frac{fr}{Q}$; that is, P is repelled with the force $\frac{fr}{Q}$.

This will perhaps be as diſtinctly conceived by recollecting, that as much of the fluid as was neceſſary for ſaturation, that is, the quantity Q, puts the particle P in equilibrio; and therefore we need only conſider the action of the redundant fluid f. To find the repulſive force of this, ſay $Q : f = r : \frac{fr}{Q}$, and prefix the ſign $-$; becauſe we are to conſider attractions as poſitive, and repulſions as negative, quantities.

Unleſs, therefore, the particle P be withheld by ſome other

12 States of a body causing efflux or influx.

ther force, it will quit the body, being expelled by a force $\frac{fr}{Q}$. And as every superficial particle is in a similar situation, we see that there will be an efflux from an overcharged body, till all the redundant fluid has quitted it. This efflux will indeed gradually diminish as the expelling force $\frac{fr}{Q}$ diminishes; that is, as f diminishes, but will never cease till f be reduced to nothing. But if there be either an external force acting on the superficial fluid in the opposite direction, or some internal obstruction to its motion, the efflux will stop when the remaining expelling force is just in equilibrio with this external force, or this obstruction.

13. On the other hand, if the body contains less than its natural quantity of fluid, there will be an influx from without; for if there be a deficiency of fluid $= f$, the particle P will be repelled with the force $\frac{\overline{Q-f}\times r}{Q}$ $= r - \frac{fr}{Q}$. It is attracted with the force a; and therefore the whole action is $= a - r + \frac{fr}{Q}, = + \frac{fr}{Q}$ (because $a - r = 0$); that is, P is attracted with the force $\frac{fr}{Q}$. Fluid will therefore enter from all quarters, as long as there is any deficiency of the quantity necessary for saturation, unless it be opposed by some external force, or hindered by some internal obstruction.

When there is a deficiency of fluid, there is a redundancy of matter, such that its attraction for external fluid is equal to the repulsion of a quantity f of fluid. This confirms the assumption in n° 10, that *the action of a body on the electric fluid depends entirely on the redundant fluid, or the redundant matter of the body.*

14 How bodies are ideo-electrics or non-electrics.

The efflux or influx may be prevented, either by surrounding the body with substances, through the pores of which the fluid cannot move at all, or by the body itself being of this constitution. And thus we see, that the very circumstance of being impervious to the fluid, or completely permeable, renders the body capable or incapable of permanently exhibiting electrical phenomena, if surrounded by permeable bodies. This circumstance alone, therefore, is sufficient to constitute the difference between *electrics per se*, and *non-electrics*.—Here, then, is a numerous class of phenomena, which receive an explanation by this hypothetical constitution of the electric fluid. All electrics *per se* are bodies fit for confining electricity in bodies which are rendered capable (by whatever means) of producing electrical phenomena; and no conductor, or substance which allows the electricity to pass through it, can be made electric by any of the means which produce that effect in *insulators*. And it is well known that the electricity of electrics is vastly more durable than that of non-electrics in similar situations. It is true, indeed, that an electric, which has been excited so as to exhibit electric phenomena with great vivacity, loses this power very quickly if plunged into water, or any other conducting body. But this is owing to the redundancy or deficiency being quite superficial, so that the parts which are disposed to give out or to take in the fluid are in immediate contact with the conducting matter. That the redundancy or deficiency is superficial, follows from this hypothesis; for when the surface is overcharged by the means employed for exciting, the impermeability of the electric *per se* prevents this redundant fluid from penetrating to any depth; and when the surface has been rendered deficient in fluid, the same impermeability prevents the fluid from expanding from the interior parts, so as to contribute to the replenishing the superficial stratum with fluid. If, indeed, we could fall on any way of overcharging the interior parts of a glass ball, or of abstracting the natural quantity from them, it is highly probable, that it would continue to attract or repel even after it had been plunged in water. Although the surrounding water would instantly take off the fluid redundant contained in the very surface, the repulsion of the fluid in the internal parts would still be sensible; nay, if a very small permeability be supposed, the body would again become overcharged at the surface; just as we see, that when we plunge a red-hot ball of iron into water, and take it out again immediately, it is black on the surface, and may be touched with the finger; but in half a minute after, it again becomes red hot. Perhaps this may be accomplished with a globe of sealing wax, which is permeable while liquid, by electrifying it in a particular way while in that state, and allowing it to freeze. But the reader is not far enough advanced in the hypothesis to understand the process which must be followed. He cannot but recollect, however, many examples in coated glass, &c. where the electricity is most pertinaciously retained by a surface in very close contact with conductors.

15 Consequences of unequable distribution of fluid. 1. Action on external fluid.

Let us now suppose a body NS (fig. 2.) containing in the half NA a quantity f of redundant fluid, and in the half AS let there be a deficiency g of fluid; that is, let there be a quantity of matter unsaturated, and such as will attract fluid as much as the quantity g of fluid would repel it. Let the fluid necessary for the saturation of each half of NS be Q, as before. Let the attraction of the whole matter of NA for a particle of fluid at N be a; and let r be the repulsion exerted on the same particle N by the whole uniformly distributed fluid in NA, and let r' be the repulsion exerted by the *same quantity* of fluid in the remote part SA. Then the force with which the particle N or S is attracted by the merely saturated body NS must be $= a - r - r'$. This is evidently nothing, if the body be in its natural state. But as NA contains the redundant fluid f, and SA is deficient by the quantity g, the whole action must be $a - \frac{\overline{Q+f}\times r}{Q}$ $- \frac{\overline{Q-g}\times r'}{Q}$. But because $a - r - r' = 0$, the action becomes $= \frac{gr' - fr}{Q}$, or because r is greater than r', the particle N is repelled with the force $\frac{fr - gr'}{Q}$. In like manner the particle S is attracted with the force $\frac{gr - fr'}{Q}$.

16 2. Action on the contained fluid.

In the mean time, a particle C, situated at the middle, must be in equilibrio, if the body be in its natural state, being equally attracted, and also equally repelled, on both sides. But as we suppose that NA is overchar-

ged

ged with the quantity f, C must be repelled in the direction CS with the force $\frac{fr}{Q}$. And if we also suppose that AS is deficient by the quantity g, C is attracted in the direction CS with a force $\frac{gr}{Q}$. Therefore, on the whole, it is urged in the direction CS with the force $\frac{fr+gr}{Q}$, or $\frac{\overline{f+g}\times r}{Q}$.

17 It will be uniformly diffused, unless obstructed.

Hence we learn, that as long as there is any redundancy in AN, and deficiency in AS, there is a tendency of the redundant fluid to move from N toward S; and, if the body be altogether permeable by the electric fluid, we cannot have a permanent state till the fluid is similarly distributed, and equally divided, between the two halves of NS. Therefore a state like that assumed in this example cannot be permanent in a conducting body, unless an external force act on it; but it may subsist in a non-conductor, and in a lesser degree, in all imperfect conductors.

18 Nature of the obstruction.

It is necessary, in this place, to consider a little the nature of that resistance which must be assigned to the motion of the electric fluid through the pores of the body. If it resemble the resistance opposed by a perfect fluid, arising solely from the inertia of its particles, then there is no inequality of force so minute but that it will operate a uniform distribution of the fluid, or at least a distribution which will make the excess of the mutual attractions and repulsions precisely equal and opposite to the external force which keeps it in any state of unequal distribution. But it may resemble the resistance to the descent of a parcel of small shot disseminated among a quantity of grain, or the resistance to motion through the pores of a plastic or ductile body, such as clay or lead. Here, in order that a particle may change its place, it must overcome the tenacity of the adjoining particles of the body. Therefore, when an unequal distribution has been produced by an external force, the removal or alteration of that force will not be followed by an equable distribution of the fluid. In every part there will remain such an inequality of distribution, that the want of equilibrium between the electric attractions or repulsions is balanced by the tenacity of the parts.

19. We learn farther from the foregoing propositions, that a particle at N is less repelled than if the part AS were overcharged as AN is: for in that case, it would be expelled by a force $\frac{f\times\overline{r+r'}}{Q}$, which is much greater than $\frac{fr-gr'}{Q}$. And, in like manner, the particle S is attracted with less force than it would be if NA were equally undercharged with SA.

20. The condition of the body now described may be changed by different methods. The redundant fluid in AN may flow into AS, where it is deficient, till the whole be uniformly distributed; or fluid may escape from AN, and fluid may enter into AS, till the body be in its natural state. The first method will be so much the slower as the body is less permeable, or more remarkably *electric per se*; and the second method will be slower than if the whole body were overcharged or undercharged.

21. What we have been now saying of a body NS that is overcharged at one end, and undercharged at the other, and capable of retaining this state, is applicable, in every particular, to two conducting bodies NA and SA′, having a non-conducting body Z interposed between them, as in fig. 3. All the formulas, or expressions of the forces which tend to expel or to draw in fluid, are the same as before. Perhaps this is the best way of forming to ourselves a distinct notion of the body that is redundant in fluid at one end, and deficient at the other. And we perceive, that the state of the two bodies, separated by the electric Z, will be more permanent when one is overcharged, and the other undercharged, than if both are either over or undercharged.

22 A body may be inactive, or neutral, where it is redundant or deficient.

It must be remarked, that the quantities f and g were taken at random. They may be so taken, that the force with which the fluid tends to escape at N, or to enter at S, may be nothing, or may even be changed to their opposite. Thus, in order that there may be no tendency to escape from N, we have only to suppose $gr'-fr=0$, or $g:f=r:r'$, and $g=\frac{fr}{r'}$. In this case, the particle at N is as much attracted by the redundant matter in SA as it is repelled by the redundant fluid in NA.

23 Conditions necessary for this.

When the extremity N is rendered inactive in this manner, the condition of the other extremity S is considerably changed. To discover this condition, put $\frac{fr}{r'}$ in place of g in the formula $\frac{gr-fr'}{Q}$, which expresses the attraction for a particle at S, and we obtain $\frac{f\times\overline{r^2-r'^2}}{Qr'}$.

On the other hand, we may have the redundancy and deficiency so balanced, that there shall be no tendency to influx at S. For this purpose, we must make $g=\frac{fr'}{r}$. When this obtains at S, the action at N will be had by putting $\frac{fr'}{r}$ in place of g in the formula $\frac{fr-gr'}{Q}$, and this will give us $\frac{f\times\overline{r'^2-r^2}}{Qr}$ for the force repelling a particle at N. 24.

When the tendency to efflux or influx is induced in this manner, by a due proportion of the redundancy and deficiency of electric fluid, the part of the body where this obtains is by no means in its natural state, and may contain either more or less than its natural quantity. But it neither acts like an overcharged nor like an undercharged body, and may therefore be called NEUTRAL. The reader, who is conversant with electrical experiments, will recollect numberless instances of this, and will also recollect that they are important ones. Such, for example, is the case with the plates and covers of the electrophorus. These circumstances, therefore, claim particular attention. 25.

As the quantities f and g may be so chosen, that the appartus shall be *neutral*, either at S or at N; they may likewise be so, that either end shall exhibit either the appearance of *redundancy* or *deficiency*. Thus, instead of neutrality at N, we may have repulsion, as at the first, by making g less in any degree than $\frac{fr}{r'}$. If, on the contrary, g be greater than $\frac{fr}{r'}$, the extremity N, tho' overcharged, will attract fluid. In like manner, if g be 26.

be less than $\frac{fr'}{r}$, the extremity S, although undercharged, will repel fluid.—We may make the following general remarks.

27 Both ends cannot be neutral at once.

1. Both extremities N and S cannot be neutral at the same time: for since the neutrality arises from the increased quantity of redundancy or deficiency at the other extremity, so as to compensate for its greater distance, the activity of that extremity must be proportionably greater on the fluid adjoining to its surface, whether externally or internally. When an overcharged extremity is rendered neutral, the other extremity attracts fluid more strongly; and when a deficient extremity is rendered neutral, the other repels fluid more strongly. All these elementary corollaries will be fully verified afterwards, and give clear explanations of the most curious phenomena.

2. We have been supposing that the redundant fluid is uniformly spread, and that the body is divided into equal portions; but this was merely to simplify the procedure and the formulæ. The reader must see that the general conclusions are not affected by this, and that similar formulæ will be obtained, whatever is the disposition of the fluid. We cannot tell in what manner the redundant fluid is disposed, even in a body of the simplest form, till we know what is the variation of its attraction and repulsion by a change of distance; and even when this has been discovered, we find it difficult in most cases, and impossible in many, to ascertain the mode of distribution. We shall learn it in some important cases, by means of various phenomena judiciously selected.

28. A body may be considered in many divisions, in some of which the fluid is redundant, and in others deficient. We may express the repulsion of the whole of this body in the same way as we express that of a body considered in two divisions, using the letters f, g, h, &c. to express the quantities of redundant or deficient fluid in each portion, while Q expresses the quantity necessary for saturating each of them; and the repulsion at different distances may be expressed by r, r', r'', r''', &c. as they are more and more remote; and we may express their action as attractive or repulsive by prefixing the sign + or —. Thus the attraction may be $\frac{(fr - gr' + hr'' - ir''')}{Q}$, &c.

29 Sensible actions of electrical bodies.

Having obtained the expressions of the invisible actions of electrified bodies on the fluid within them, or surrounding them, let us now consider their sensible actions on other bodies, producing motion, or tendencies to motion.

Here it is obvious that the mechanical phenomena exhibited are what may be called *remote* EFFECTS of the acting forces. The immediate effects, or the mutual actions of the particles, are not observed, but hypothetically inferred. The tangible matter of the body is put in motion, in consequence of its connection with the fluid residing in the body, which fluid is the only subject of the action of the other body.

In considering these phenomena, we shall content ourselves with a more general view of the actions which take place between the fluid or tangible matter of the one body, and the fluid or matter of the other, so as to gain our purpose by more simple formulæ than those hitherto employed. They were premised, however, because we *must* have recourse to them on many very important particular occasions.

Let there be two bodies, A and B, in their natural state. Let the tangible matter in A be called M, and let the fluid necessary for its saturation be called F, and let m and f be the tangible matter and the fluid in B. Let the mutual action between a single particle of fluid and the matter necessary for its saturation be expressed by the indeterminate symbol z, because it varies by a change of distance. 30.

The actions are mutual and equal. Therefore when the motion of B by the action of A is determined, the motion of A is also ascertained. We shall therefore only consider how A is affected. 1. Every particle of fluid in A tends toward every particle of matter in B with the force z. The whole tendency of A toward B may therefore be expressed by z, multiplied by the product of F and m. 2. Every particle of fluid in A is repelled by every particle of fluid in B, with the same force z. 3. Every particle of matter in A is attracted by every particle of fluid in B, with the same force. We may express this more purely and briefly thus:

1. F tends *toward m* with the force $+ Fmz$
2. F tends *from f* with the force $— Ffz$
3. M tends *toward f* with the force $+ Mfz$

Therefore the sensible tendency of A to or from B will be $= z \times \overline{Fm + Mf - Ff}$. But, by the hypothesis, the attraction of a particle of the fluid in A for a particle of the matter in B, is equal to its repulsion for the particle or parcel of the fluid attached or competent to that particle of matter. Therefore the attraction Fmz is balanced by the repulsion Ffz. Therefore there remains the attraction of the matter in A for the fluid in B unbalanced, and the body A will tend toward the body B with the force Mfz, or B attracts A with the force Mfz. A must therefore move toward B. And, by the 3d law of motion, B must move toward A with equal force.

31 Completion of the hypothesis of Æpinus.

But the fact is, that no tendency of any kind is observed between bodies in their natural state. The hypothesis, therefore, is not complete. If we abide by it, as far as it is already expressed, we must farther suppose, that there is some repulsive force exerted between the bodies to balance the attraction of M for f. Mr Æpinus, therefore, supposes, that every particle of tangible matter repels another particle as much as it attracts the fluid necessary for its saturation. The whole action of B on A will now be $= z \times \overline{Fm - Ff - Mm + Mf}$. Fmz is balanced by Ffz, and Mmz by Mfz, and no excess remains on either side.

32 Objections answered.

Æpinus acknowledges that this circumstance appeared to himself to be hardly admissible; it seeming inconceivable that a particle in A shall repel a particle in B, or tend from it, electrically, while it attracts it, or tends toward it, by planetary gravitation. We cannot conceive this; but more attentive consideration shewed him, that there is nothing in it contrary to the observed analogy of natural operations. We must acknowledge, that we see innumerable instances of inherent forces of attraction and repulsion; and nothing hinders us from referring this lately discovered power to the class of primitive and fundamental powers of nature. Nor is there any difficulty in reconciling this repulsion with universal gravitation; for while bodies are in their natural state,

ſtate, the electric attractions and repulſions preciſely balance each other, and there is nothing to diſturb the phenomena of planetary gravitation; and when bodies are not in their natural electrical ſtate, it is a fact that their gravitation is diſturbed. Although we cannot conceive a body to have a tendency to another body, and at the ſame time a tendency from it, when we derive our notion of theſe tendencies entirely from our own conſciouſneſs of effort, endeavour, *conatus, niſus accedendi ſeu recedendi*, nothing is more certain than that bodies exhibit at once the appearances which we endeavour to expreſs by theſe words. We can bring the north poles of two magnets near each other, in which caſe they recede from each other; and if this be prevented by ſome obſtacle, they preſs on this obſtacle, and ſeem to endeavour to ſeparate. If, while they are in this ſtate, we electrify one of them, we find that they will now approach each other; and we have a diſtinct proof that both tendencies are in actual exertion by varying their diſtances, ſo that one or other force may prevail; or by placing a third body, which ſhall be affected by the one but not by the other, &c. We do not underſtand, nor can conceive in the leaſt, how either force, or how gravity, reſides in a body; but the effects are paſt contradiction. It muſt be granted, therefore, that this additional circumſtance of Æpinus's hypotheſis has nothing in it that is repugnant to the obſerved phenomena of Nature.

N. B. It is not neceſſary to ſuppoſe (although Mr Æpinus does ſuppoſe it), that every atom of tangible matter repels every other atom. It will equally explain all the phenomena, if we ſuppoſe that every particle contains an atom or ingredient having this property, and that it is this atom alone which attracts the particles of electrical fluid. The material atoms having this property, and their correſponding atoms of fluid, may be very few in compariſon with the number of atoms which compoſe the tangible matter. Their mutual ſpecific action being very great in compariſon with the attraction of gravitation (as we certainly obſerve in the action of light), all the phenomena of electricity will be produced without any ſenſible effect on the phenomena of gravitation, even although neither the electric fluid nor its ally, this ingredient of tangible matter, ſhould not gravitate. But this ſuppoſition is by no means neceſſary.

Since we call that the natural electrical ſtate of bodies in which they do not affect each other, and the hypothetical powers of the fluid are accommodated to this condition, we may conſider any body that has more than its natural quantity as conſiſting of a quantity of matter ſaturated with fluid, and a quantity of redundant fluid ſuperadded; and an undercharged body may be conſidered as conſiſting of a quantity of matter ſuperadded. The ſaturated matter of theſe two bodies will be totally inactive on another body in its natural ſtate, and will neither attract nor repel it, nor be attracted nor repelled by it; therefore the action of the overcharged body will depend entirely on the redundant fluid; and that of the undercharged body will depend entirely on the redundant matter; therefore we need only conſider them as conſiſting of this redundant fluid or matter, agreeably to what was ſaid in more vague terms in nº 10. and 13. This will free us from the complicated formulæ which would otherwiſe be neceſſary for expreſſing all the actions of the fluid and tangible matter of two bodies on each other. The reſults will be ſufficiently particular for diſtinguiſhing the ſenſible action of bodies in the chief general caſes: but in ſome particular and important caſes, it is abſolutely neceſſary to employ every term.

1. Suppoſe two bodies A and B, containing the quantities F' and f' of redundant fluid, it is plain that their mutual action is expreſſed by $F' \times f' + z$, and that it is a repulſion; for ſince every particle of redundant fluid in A repels every particle of redundant fluid in B with the force z; and ſince F' and f' are the numbers of ſuch particles in each, the whole repulſion muſt be expreſſed by the product of theſe numbers. 33 General expreſſion (ſymbolical) of the mutual action.

2. In like manner, two bodies A and B, containing the redundant matter M' and m', will repel each other with the force $M'\,m'\,z$. 34.

3. And two bodies A and B, one of which A contains the redundant fluid F', and the other B contains the redundant matter m', will attract each other with the force $F\,m'\,z$. 35.

4. It follows from theſe premiſes, that if either of the bodies be in its natural ſtate, they will neither attract nor repel each other; for, in ſuch a caſe, one of the factors F', or f', or M', or m', which is neceſſary for making a product, is wanting. This may be perceived independent of the mathematical formula; for if A contain redundant fluid, and B be in its natural ſtate, every particle of the redundant fluid in A is as much repelled by the natural fluid in B as it is attracted by the tangible matter. 36.

The three firſt propoſitions agree perfectly with the known phenomena of electricity; for bodies repel each other, whether both are poſitively or both are negatively electrified, and bodies always attract each other when the one is poſitively and the other negatively electrified. But the fourth caſe ſeems very inconſiſtent with the moſt familiar phenomena. Dr Franklin and all his followers aſſert, on the contrary, that electrified bodies, whether poſitive or negative, always attract, and are attracted, by all bodies which are in their natural ſtate of electricity. But it will be clearly ſhewn preſently, that they are miſtaken, and that Franklin's theory neceſſarily ſuppoſes the truth of the fourth propoſition, otherwiſe two bodies in their natural ſtate could not be neutral or inactive, as any one may perceive on a very ſlight examination by the Franklinian principles. It will preſently appear, with the fulleſt evidence; and, in the mean time, we proceed to explain the action of bodies which are overcharged in ſome part, and undercharged in another. 37 Seeming paradox.

Let the body B (fig. 4.) be overcharged in the part B *n*, and undercharged in the part B *s*, and let f' and m' be the redundant fluid and common matter in thoſe parts; let A be overcharged, and contain the redundant fluid F; let z and z' expreſs the intenſity of action correſponding with the diſtances of A from the overcharged and undercharged parts of B; the part B *n* repels A with the force $F'\,f'\,z$, while the part B *s* attracts it with the force $F'\,m'\,z$: A will therefore be attracted or repelled by B, according as $F'\,m'\,z'$ is greater or leſs than $F'\,f'\,z'$; that is, according as $m'\,z'$ is greater or leſs than $f'\,z$. This, again, depends on the proportion of f' to m', and on the proportion of z to z'. The firſt depends on many external circumſtances, which may occaſion a greater or leſs redundancy or deficiency of electrical fluid; the ſecond depends 38 Action of a body having the fluid unequably diſpoſed.

pends entirely on the law of electric attraction and repulſion, or the change produced in its intenſity by a change of diſtance. As we are, at preſent, only aiming at very general notions, it is enough to recollect, that all the electric phenomena, and indeed the general analogy of nature, concur in ſhewing that the intenſity of both forces (attraction and repulſion) decreaſes by an increaſe of diſtance; and to combine this with that circumſtance of the hypotheſis which ſtates the repulſion to be equal to the attraction at the ſame diſtance; therefore both forces vary by the ſame law, and we have z always greater than z. The viſible action of B on A (which, by the 3d law of motion, is accompanied by a ſimilar action of A on B) may be various, even with one poſition of B, and will be changed by changing this poſition.

Caſes of ſenſible repulſion.

1. We may ſuppoſe that B contains, on the whole, its natural quantity, but that part of it is abſtracted from B *s*, and is crowded into B *n*. This is a very common caſe, as we ſhall ſee preſently, and it will be expreſſed in our formula by making $f' = m'$. In this caſe, therefore, we have $F f' z$ greater than $F m' z$, becauſe z is greater than z'. A will therefore be repelled by B, and will repel it; and the repulſion will be $F' f' \times \overline{z - z'}$.

Of attraction.

It is evident that if A be placed on the other ſide of B, the appearances will be reverſed, and the bodies will attract each other with the force $F' f' \times \overline{z - z'}$.

It is alſo plain, that if A be as much undercharged as we have ſuppoſed it overcharged, all the appearances will be reverſed; if on the undercharged ſide of B, it will be repelled; and if on the overcharged ſide of B, it will be attracted.

39 Of neutrality.

2. If the redundancy and deficiency in the two portions of B be inverſely proportional to the forces, ſo that $F' : m' = z' : z$, we ſhall have $f' z = m' z'$, and $m' = \frac{f' z}{z'}$. In this caſe theſe two actions balance each other, and A is neither attracted nor repelled when at this preciſe diſtance from the overcharged ſide of B. B may be ſaid to be NEUTRAL with reſpect to A, although A and the adjoining ſide of B are both overcharged.

40 Bodies neutral at one end are more active at the other.

But if A be placed at the ſame diſtance on the other ſide of B, the effect will be very different: For becauſe $m' = \frac{f' z}{z'}$, and $m' z'$ is now changed into $m' z$, and $f' z$ into $f z'$, we have the action on $A = F' \times \left(\frac{f' z}{z'} - f' z'\right), = F' f' \times \frac{z^2 - z'^2}{z'}$; that is, A is ſtrongly attracted.

In like manner, f' and m' may be ſo proportioned, that when A, containing redundant fluid, is placed near the undercharged end of *s* B, it ſhall neither be attracted nor repelled, B becoming neutral with regard to A at that preciſe diſtance. For this purpoſe m' muſt be $= \frac{f z'}{z}$. And if A be now placed at the ſame diſtance on the other ſide of B, it will be repelled with the force $F' f' \times \frac{z^2 - z'^2}{z}$.

Thus, when the overcharged end is rendered neutral to an overcharged body, the other end ſtrongly attracts it; and when the undercharged end is rendered neutral to the ſame body, the overcharged end ſtrongly repels it.

Similar appearances are exhibited when A is undercharged.

Theſe caſes are of frequent occurrence, and are important, as will appear afterwards.

It is eaſy now to ſee what changes will be made on the action of B on A, by changing the proportion of 41.
f' and m'. If m' be made greater than $\frac{f' z}{z'}$, A will be attracted in the ſituation where it was formerly neutral; and if m' be made leſs, A will be repelled, &c. &c.

Therefore, when we obſerve B to be neutral, or attractive, or repulſive, we muſt conclude that m' is equal to $\frac{f z}{z'}$, or greater or leſs than it, &c.

We have been thus minute, that the reader may perceive the agreement between this action on a body containing redundant fluid, and the action on the ſuperficial fluid formerly conſidered in n° 21, 22, 23, 24. When theſe things are attended to, we ſhall explain, with great eaſe, all the curious phenomena of the electrophorus.

42 Neutrality generally limited to a preciſe diſtance. Important information obtained from this.

There is another circumſtance to be attended to here, which will alſo explain ſome electrical appearances that ſeem very puzzling. We limited the inactivity of B to a certain preciſe diſtance of the body A. This inactivity required that m' ſhould be $= \frac{f z}{z'}$. If A be brought nearer, both z and z' are increaſed. If they are both increaſed in the ſame proportion, the value of $\frac{z}{z'}$ will be the ſame as before, and the body A will neither be attracted nor repelled at this new diſtance. But if z increaſe faſter than z', we ſhall have $f' z$ greater than $m' z'$, and A will be repelled; and if z increaſes more ſlowly than z', A will be attracted by bringing it nearer. The contrary effects will be obſerved if A be removed farther from the overcharged end of B. This explains many curious phenomena; and thoſe phenomena become inſtructive, becauſe they enable us to diſcover the law of electric action, by ſhewing us the manner in which it diminiſhes by a change of diſtance. Electricians cannot but recollect many inſtances, in which the motion of the electrometer appeared very capricious. The general fact is, that when an overcharged pith ball is ſo ſituated near the overcharged ſide of the electrophorus as to be neutral, it is repelled when brought nearer, but attracted when removed to a greater diſtance. This ſhews that z increaſes faſter than z' when A is brought nearer to B. Now, ſince the bodies may be again rendered neutral at a greater diſtance than before, and the ſame appearances are ſtill obſerved, it follows, that the law of action is ſuch, that *every* diminution of diſtance cauſes z to increaſe faſter than z'. We ſhall find this to be valuable information.

43 Action when the fluid is unequably diſpoſed in both bodies.

Let us, in the laſt place, inquire into the ſenſible effect on A when it alſo is partly overcharged and partly undercharged. This is a much more complicated caſe, and is ſuſceptible of great variety of external appearances, according to the degrees of redundancy and deficiency, and according to the kind of electricity (poſitive or negative) of the ends which front each other.

Firſt,

First, then, let the overcharged end of A (fig. 5.) fron the undercharged end of B, they being overcharged in N and *n*, but undercharged in S and *s*. Let F and *f* be the quantity of fluid natural to each; and let F′ and *f*′ be the redundancy in N and *n*, and M′ and *m*′ the deficiency in S and *s*. Moreover, let Z and Z′ represent the intensity of actions of a particle in N on a particle in *n* and *s*; and let *z* and *z*′, represent the actions of a particle in S on a particle in *n* and in *s*; or, in other words, let Z, Z′, *z*, *z*′, represent the intensity of action between particle and particle, corresponding to the distances N *s*, N *n*, S *s*, S *n*.

Proceeding in the same manner as in the former examples, we easily see, that the action of B on A is $= \frac{F' m' Z - F' f' Z' - M' m' z + M' f' z'}{F f}$; the attractions are considered as positive quantities, having the sign + prefixed to them, and the repulsions are negative, having the sign —.

This action will be either attractive or repulsive, according as the sum of the first and last terms of the numerator exceeds or falls short of the sum of the second and third: And the value of each term will be greater or less, according to the quantity of redundant fluid and matter, and also according to the intensity of the electric action. It would require several pages to state all those possible varieties. We shall therefore content ourselves at present with stating the simplest case; because a clear conception of this will enable the reader to form a pretty distinct notion of the other possible cases; and also, because this case is very frequent, and is the most useful for the explanation of phenomena.

We shall suppose, that the redundant part of each body is just as much overcharged as the deficient part is undercharged; so that $F = M'$, and $f' = m'$. In this case, the formula becomes $\frac{F' f' (Z - Z' - z + z'}{F f}$.

Useful representation of the mutual forces by ordinates to a curve.

Here we see that the sensible or external effect on A depends entirely on the law of electric action, or the variation of its intensity by a change of distance. If the sum of Z and *z*′ exceed the sum of Z′ and *z*, A will be attracted; but if $Z + z'$ be less than $Z' + z$, A will be repelled. This circumstance suggests to us a very perspicuous method of expressing these actions between particle and particle, so that the imagination shall have a ready conception of the circumstance which determines the external complicated effect of this internal action. This will be obtained by measuring off from a fixed point of a straight line portions respectively equal to the distances N *s*, N *n*, S *s*, and S *n*, between the points of the two bodies A and B, where we suppose the forces of the redundant fluid and redundant matter to be concentrated, and erect ordinates having the proportion of those forces. If the law of action be known, even though very imperfectly, we shall see, with one glance, of which kind the movements or tendencies of the bodies will be. Thus, in fig. 5. drawing the line C *z*, take C *p* = N *s*, C *q* = N *n*, C *r* = S *s*, and C *t* = S *n*, and erect the ordinates P*p*, Q*q*, R *r*, and T *t*. If the electric action be like all the other attractions and repulsions which we are familiarly acquainted with, decreasing with an increase of distance, and decreasing more slowly as the distances are greater, these ordinates will be bounded by a curve PQRTZ, which has its convexity turned toward the axis. We shall presently get full proof that this is the case here; but we premise this general view of the subject, that we may avoid the more tedious, but more philosophical, process of deducing the nature of the curve from the phenomena now under consideration.

45 General character of the scale of electric force.

This construction evidently makes the pair of ordinates P *p*, Q *q*, equidistant with the pair R *r*, T *t*. Also, P *p*, R *r*, and Q *q*, T *t*, are equidistant pairs. It is no less clear, that the sum of P *p* and T *t* exceeds the sum of Q *q* and R *r*. For if C *z* be bisected in V, and V *v* be drawn perpendicular to it, cutting the straight lines PT and QR in *x* and *y*, then *x v* is the half sum of P *p* and T *t*, and *y v* is the half sum of Q *q* and R *r*. Moreover, if Q *m* and T *n* are drawn parallel to the base, we see that P *m* exceeds R *r*; and, in general, that if any pair of equistant ordinates are brought nearer to C, their difference increases, and *vice versa*. Also, if two pairs of equidistant ordinates be brought nearer to C, each pair by the same quantity, the difference of the nearest pair will increase more than the difference of the more remote pair. And this will hold true, although the first of the remote pair should stand between the two ordinates of the first pair. If the reader will take the trouble of considering these simple consequences with a little attention, he will have a notion of all the effects that are to be expected in the mutual actions of the two bodies, sufficiently precise for our present purpose. We shall give a much more accurate account of these mathematical truths in treating the article MAGNETISM, where precision is absolutely necessary, and where it will be attended with the greatest success in the explanation of phenomena.

Now let us apply this to our present purpose. *First*, then, When the overcharged end of A is turned toward the undercharged end of B, A must be attracted; for $P p + T t$ is greater than $Q q + R r$. 46.

Secondly, This attraction must increase by bringing the bodies nearer; for this will increase the difference between P *m* and R *n*. 47.

Thirdly, The attraction will increase by increasing the length either of A or of B (the distance N *s* remaining the same); for by increasing the length of A, which is represented by *pr* or *q t*, R *r* is more diminished than T *t* is. In like manner, by increasing B, whose length is represented by *p q* or *r t*, we diminish Q *q* more than T *t*. 48.

49 Use of this picture of the forces.

On the other hand, if the overcharged end of B front the overcharged end of A, their mutual action will be $\frac{F' f' (-P p + Q q + R r - T t),}{F f}$ and A will be repelled, and the repulsion will increase or diminish, by change of distance or magnitude, precisely in the same manner that the attractions did. It is hardly necessary to observe, that all these consequences will result equally from bringing an apparatus similar to that represented in fig. 3. near to another of the same kind; and that they will be various according to the position and the redundancy or deficiency of the two parts of each apparatus.

50 Curious phenomena which should result from the hypothesis resembling magnetism.

If the body B of fig. 5. is not at liberty to approach toward A, nor to recede from it, and can only turn round its centre B, it will arrange itself in a certain determinate position with respect to that of A. For example, if the centre B (fig. 7.) be placed in the line passing

paſſing through S and N of the body A, B will arrange itſelf in the ſame ſtraight line: for if we forcibly give it another poſition, ſuch as s B n, N will attract s and repel n, and theſe actions will concur in putting B into the poſition s' B n'. S, however, will repel s and attract n; and theſe forces tend to give the contrary poſition. But S being more remote than N, the former forces will prevail, and B will take the poſition s' B n'.

If the centre B be placed ſomewhere on the line AD, drawn through a certain point of the body NAS (which will be determined afterwards), at right angles to NAS, the body B will aſſume the poſition n' B s', parallel to NAS, but ſubcontrary. For if we forcibly give it any other poſition n B s, it is plain that N repels n and attracts s, while S attracts n and repels s. Theſe four forces evidently combine to turn the body round its centre, and cannot balance each other till B aſſume the poſition n' B s', where n' is next to S, and s' is next to N.

Form of the electric meridian.

If the centre of B have any other ſituation, ſuch as B′, the body will arrange itſelf in ſome ſuch poſition as n' B′ s'. It may be demonſtrated, that if B be infinitely ſmall, ſo that the action of the end of A on each of its extremities may be conſidered as equal, B will arrange itſelf in the tangent BT of a curve NB′S, ſuch that if we draw NB, SB, and from any point T of the tangent draw TE parallel to BN, and TF parallel to B′S, we ſhall have BE to BF, as the force of S to the force of N. This arrangement of B will be ſtill more remarkable and diſtinct if N be an overcharged ſphere, and S an undercharged one, and both be inſulated. We muſt leave it to the reader's reflection to ſee the changes which will ariſe from the inequality of the redundancy and deficiency in A or B, or both, and proceed to conſider the conſequences of the mobility of the electric fluid. Theſe will remove all the difficulty and paradox that appears in ſome of the foregoing propoſitions.

51 Conſequence (fundamental) of the mobility of the fluid in the pores of bodies.

Let the body A (fig. 4.) contain redundant fluid, and let B be in its natural ſtate, but let the fluid in A be fixed, and that in B perfectly moveable; it is evident that the redundant fluid in A will repel the moveable fluid in B, toward its remote extremity n, and leave it undercharged in s. The fluid will be rarefied in s, and conſtipated in n. We need only conſider the mutual actions of the redundant fluid and redundant matter. It is plain that things are now in the ſituation deſcribed in n° 15.: A muſt be attracted by B, becauſe $f' = m'$, and z is greater than z'. The attractive force is $F' f i \times (z - z')$.

Bodies containing the natural quantity, in the natural ſtate, attract and are attracted by electrified bodies.

Thus we ſee that the hypotheſis is accommodated to the phenomena in the caſe in which it appeared to differ ſo widely from it. Had the fluid been immoveable, the mutual actions would have ſo balanced each other that no external effects would have appeared. But now the greater vicinity of the redundant matter prevails, A is attracted by B, and, the actions being all mutual, B is attracted by A, and approaches it.

52 And change the ſtate of thoſe bodies, which increaſes attraction.

We have ſuppoſed that the fluid in A is immoveable; but this was for the ſake of greater ſimplicity. Suppoſe it moveable. Then, as ſoon as the uniform diſtribution of the fluid in B is changed, and B becomes undercharged at s, and overcharged at n, there are forces acting on the fluid in A, and tending to change its ſtate of diſtribution. The redundant matter in S attracts the redundant fluid in A more than the more remote redundant fluid in n repels it, becauſe z' is leſs than z. This tends to conſtipate the redundant fluid of A in the nearer parts, and render N more redundant, and S leſs redundant in fluid than before. It is plain that this muſt increaſe their mutual action, without changing its nature. It can be ſtrictly demonſtrated, that however ſmall the redundancy in A may be, it can never be rendered deficient in its remote extremity by the action of the unequally diſpoſed fluid in B, if the fluid in B be no more nor leſs than its natural quantity. It is alſo plain that this change in the diſpoſition of the fluid in A muſt increaſe the ſimilar change in B. It will be ſtill more rarefied in s, and condenſed in n; and this will go on in both till all is in equilibrio. When things are in this ſtate, a particle of fluid in B is in equilibrio by the combined action of ſeveral forces. The particle B is propelled toward n by the action of the redundant fluid in A. But it is urged toward S by the repulſion of the redundant fluid on the ſide of n, and alſo by the attraction of the redundant matter on the ſide of s; and the repulſion of the redundant fluid in A muſt be conceived as balancing the united action of thoſe two forces reſiding in B.

Hence we may conclude, that the denſity of the fluid in B will increaſe gradually from s to n. It will be extremely difficult to obtain any more preciſe idea of its denſity in the different parts of B, even although we knew the law of action between ſingle particles. 53

53 General notion of the forced diſpoſition of electric fluid in a body.

This muſt depend very much on the form and dimenſions of B; for any individual particle ſuſtains the ſenſible action of all the redundant fluid and redundant matter in it, ſince we ſuppoſe it affected by the more remote fluid in A. All that we can ſay of it in general is, that the denſity in the vicinity of s is leſs than the natural denſity; but in the vicinity of n it is greater; and therefore there muſt be ſome point between s and n where the fluid will have its natural denſity. This point may be called a NEUTRAL point. We do not mean by this that a particle of ſuperficial fluid will neither be attracted nor repelled in this place. This will not always be the caſe (although it will never be *greatly* otherwiſe); nor will the variation of the denſity in the different parts of B be proportional to the force of A on thoſe parts. Some eminent naturaliſts have been of this opinion; and, having made experiments in which it appeared to be otherwiſe, they have rejected the whole theory. But a little reflection will convince the mathematician, that the ſum of the internal forces which tend to urge a particle of fluid from its place, and which are balanced by the action of A, are *not* proportional to the variations of denſity, although they increaſe and decreaſe together. We ſhall take the proper opportunity of explaining thoſe experiments; and will alſo conſider ſome ſimple, but important caſes, where we think the law of diſtribution of the fluid aſcertained with tolerable preciſion.

Neutral point.

If we ſuppoſe, on the other hand, that A is undercharged, the redundant matter in A will attract the moveable fluid in B, and will abſtract it from the remote extremity, and crowd it into the adjacent extremity. Moreover, the fluid now becoming redundant in the nearer extremity of B, will act more ſtrongly on the moveable fluid in A than the more remote redundant matter of B; and thus fluid will be propelled toward the remote ſide of A, which will become now under-

charged

charged in its nearer fide, and lefs undercharged in its remote fide than if B were taken away. This muft increafe the inequability of diftribution of the fluid in B, and both will be put farther from their natural ftate; but A will never become overcharged in its remote extremity.

Things being in this ftate, it is plain that A and B will mutually attract each other in the fame manner, and with the fame force, as when A was as much overcharged as it is now undercharged.

54 Electric atmofphere is not adequate to the explanation of the phenomena.

Thus, then, we fee how the attraction obtains, whether A be over or undercharged. A fact which Dr Franklin could never explain to his own fatisfaction; nor will it ever be explained confiftently with the acknowledged principles and obferved laws of mechanics by any perfon who employs elaftic atmofpheres for this purpofe. It is indeed a fufficient objection to the employment of fuch electric or other atmofpheres, that the fame extent of attraction and repulfion between the particles of the atmofphere is neceffary, as is employed here between the particles of the fluid refiding in the body; and therefore they ceafe to give any explanation, even although their fuppofed actions were legitimately deduced from their conftitution. This is by no means the cafe. Let any perfon examine ferioufly the *modus operandi* of the electric atmofpheres employed by Lord Mahon (the only perfon who has written mathematically on the fubject), and he will fee that the whole is nothing but figurative language, without any diftinct perception of what is meant by thefe atmofpheres, as diftinct from the fluid moveable in the conducting bodies, or any perception how the unequal denfity of thefe atmofpheres protrudes the fluid along the conductor. Befides, it is well known that a conducting wire becomes pofitive at one end, and negative at the other, by the mere vicinity of an overcharged or undercharged body, and this in an inftant, although it be furrounded with fealing-wax, or other non-conductors, to any thicknefs: in this cafe there can be no atmofpheres to operate on the included fluid. To this we may add Dr Franklin's judicious experiment of whirling an electrified ball many times round his head, with great rapidity, by means of a filk line, without any fenfible diminution of its electricity. It is not conceivable that an electric atmofphere could remain attached to the ball; nor could it be inftantaneoufly formed round the ball, in every point of its motion, fo as to be operative the moment he ftopped it and tried it; for this would have exhaufted or greatly diminifhed the electricity of the ball); whereas that fagacious philofopher affirms (and any perfon will find it true), that when the air is dry, he did not obferve the electricity more diminifhed than that of another ball which remained all the while in the fame place.

55 Induced electricity.

Let the overcharged body A (fig. 6.) be brought near the ends of two oblong conductors B and C in their natural ftate, and lying parallel to each other; the fluid will be propelled toward their remote ends N, *n*, where it will be condenfed, while it will be rarefied in the ends S and *s*, adjacent to A. Both will be attracted by A, and will attract it. But the redundant fluid in NB will repel the redundant fluid in *n* C; and the redundant matter in SB will repel the redundant matter in *s* C. For this reafon the bodies B and C will repel each other, and will feparate; but SB attracts *n* C, and NB attracts *s* C; and on this account the bodies fhould approach: but the diftances of the attracting parts being greater than thofe of the repelling parts, the repulfions muft prevail, and the bodies muft really feparate.

It is equally clear that the very fame *fenfible* appearance will refult from bringing an undercharged body near the ends of B and C, although the internal motions are juft the oppofite to the former.

If another body D, electrified in the fame way with A, be brought near the oppofite ends of B and C, it will prevent or diminifh the internal motions, and it fhould therefore prevent or diminifh the external effects.

If another conducting body be brought near to the end *s* of C that fronts A, it will be affected as C is, and the end *f* will repel *s*; but if it be brought near the remote end, as is the cafe with the body F, it will attract this remote end. As the body A, containing more or lefs than its natural fhare of electric fluid, affects every other body, while they do not (when out of its neighbourhood) affect each other, it is ufually faid to be the electrified body, and the others are faid to be electrified by it; and fince thefe bodies, when perfect conductors, cannot retain their power of exhibiting electrical appearances (fee n° 17.), it will be convenient to diftinguifh this laft electrical ftate by a particular name. We fhall call it ELECTRICITY BY POSITION, or INDUCED ELECTRICITY. It is induced by pofition with regard to the permanently electrical body.

We have fuppofed, in thefe laft propofitions, that the fluid was perfectly moveable in B, and, at laft, alfo, in A: but let us examine the confequences of fome obftruction to this motion. 56 Confequences of obftructions. Without entering into a minute enquiry on this head, we may ftate the obftruction as uniform, and fuch that a certain fmall force is neceffary for caufing a particle of fluid to get through between two particles of the common matter, juft as we conceive to happen in tenacious bodies of uniform texture (fee n° 18.).

It is evident, that when an overcharged body A (fig. 4. or 5.) is brought near fuch an imperfect conductor B, the fluid cannot be fo copioufly propelled to the remote extremity *n*. We may conceive the ftate of diftribution by taking a conftant quantity from the intenfities of the force of A at every point of B. This circumftance alone fhews us that there will not be fo unequable a diftribution of the fluid, and therefore *there will not be fuch a ftrong attraction between imperfect as between perfect conductors.* But befides this, we fee that an incomparably longer time muft elapfe before things come to a ftate of equilibrium. Each particle of fluid employs time to overcome the obftacle to its motion, and it cannot advance till after the fucceeding ones, each efcaping in its turn, have again come up with the foremoft. An important confequence refults from this. The neutral point, where the fluid is of the natural denfity, will not be fo far from the other body as it would have been without thefe obftructions; and this point will be a confiderable while of advancing along the imperfect conductor. At the firft approach of the overcharged electric, the near extremity of the imperfect conductor becomes a little undercharged, and the neutral point advances from the very extremity a fmall way, the difplaced fluid being crowded a little before it, and giving way by degrees as as its foremoſt particles get paſt the obſtructions. The motion forward takes place over a conſiderable extent at the very firſt; namely, in that part of the conductor where the propelling power of the neighbouring electric is juſt able to puſh a particle over the obſtruction. As the propulſion goes on, the neutral point muſt gradually advance, and at laſt reach a certain diſtance, determined by the degree of the obſtruction. It is plain, that the final accumulation at the remote end of the imperfect conductor will be leſs than in a perfect conductor, and the neutral point will be nearer to the other end.

57 Irregular diſtribution.

There is another remarkable conſequence of the obſtruction. It muſt always happen that, at the beginning of the action, the greateſt conſtipation will not be towards the remote extremity, but in a place much nearer to the diſturbing cauſe. Beyond this, the conſtipation will diminiſh. As time elapſes during this operation, this conſtipated fluid acts on the fluid beyond it by repulſion, and may do this with ſufficient force to diſplace ſome of it, and render a part of the imperfect conductor deficient, with a ſmall conſtipation beyond it. This may, in like manner, produce a rarefaction farther on, followed by another condenſation; and this may be frequently repeated when the obſtruction is very great, and the repulſion of the overcharged body very great alſo. This can be ſtrictly demonſtrated in ſome very ſimple caſes, but the demonſtration is very tedious: As the reſult, however, is of the firſt importance in the theory of electricity, and ſerves to explain ſome of the moſt abſtruſe phenomena, we wiſh the reader to have ſome ſtronger ground of confidence than the above bare aſſertion. He may obſerve ſimilar effects of cauſes preciſely ſimilar. If we dip the end of a flat ruler into water, and if, after allowing the water to become perfectly ſtill, we move the ruler gently along in a direction perpendicular to the face, we ſhall obſerve a ſingle wave heap up before the ruler, and keep before it, all the reſt of the water before it remaining ſtill: but if we do the ſame thing in a veſſel of clammy fluid, eſpecially if the clammy part is ſwimming on the ſurface of a more perfect fluid, like a cream, we ſhall obſerve a ſeries of ſuch waves to curl up before the ruler, and form before it in ſucceſſion; and if we have previouſly ſpotted the ſurface of the cream, we ſhall ſee that it is not the ſame individual waves that are puſhed before the ruler, but that they are ſucceſſively formed out of different parts of the ſurface, and that the particles which, at one time, form the ſummit of a wave, are, immediately after, at the bottom, &c. In like manner, when a cannon is fired in clear air, at no great diſtance, we hear a ſingle ſnap; but, in a thick fog, we hear the ſnap both preceded and followed by a quivering noiſe, reſembling the ruſhing of a fluttering wind, which laſts perhaps half a ſecond. A ſlight reflection on theſe facts will ſhew that they are neceſſary reſults of the mechanical laws of ſuch obſtruction.

Several neutral points.

The conſequence of this mode of action muſt be, that an imperfect conductor may have more than one neutral point, and more than one overcharged and undercharged portion, ſo that its action on diſtant bodies may be extremely various. The formula of n° 28. was accommodated to this caſe, and will be found to have very curious reſults. Another body may be placed in the direction of the axis, and will be attracted at one diſtance, repelled when this diſtance is increaſed, and again attracted when at a ſtill greater diſtance, &c. &c.

Suppoſe the obſtruction not to be conſiderable: The immediate operation of the neighbouring overcharged body will be the production of an undercharged part in the adjoining extremity, an overcharged part beyond this, an undercharged portion farther on, &c. In a little while theſe will ſhift along the conductor; one after another will diſappear at the farther end, and the body will have at laſt but one neutral point. A greater obſtruction will leave the body, finally, with more than one neutral point, and their ultimate number will be greater in proportion as the obſtruction to the fluid's motion is ſuppoſed greater.

58 Induced electricity, rendered permanent.

Now, let the overcharged body, the cauſe of this unequal diſtribution, be removed. We have ſeen, n° 17. that when a body contains its natural quantity of fluid, but unequally diſtributed, there is a force acting on every particle, and tending to reſtore the original equable diſtribution; and that ſuch a force remains as long as there is any inequality in this reſpect. If, therefore, there be no obſtruction, the uniform diſtribution will take place immediately; for it is well known, that the ſpeed with which electricity is propagated is immenſe. The elaſticity, or the attractive and repulſive forces, muſt be very great indeed when compared with any that we know, except, perhaps, the force which impels the particles of light. The electricity, therefore, of a perfect conductor, that is, its power of acting on other bodies in the ſame way that an original electric acts on them, muſt be quite momentary, and ceaſe as ſoon as the inducing cauſe is removed. The conductor is electrical merely in conſequence of its poſition. Hence the propriety of our denominations. Nothing material is ſuppoſed in this theory to be communicated from the overcharged body: Nay, this theory teaches, that the ſenſible electricity of the overcharged body is augmented in ſome reſpects; for it becomes more overcharged in the part neareſt to the conductor. Indeed it becomes leſs overcharged on the other end, and will act leſs forcibly on that ſide than if the conductor were away. It may be remarked here (it ſhould have been mentioned in n° 5.) that when F is preſented in the manner ſhewn in fig. 6. the body B becomes more ſtrongly overcharged at the end remote from A, and more ſtrongly undercharged at the end next to A, than when F is away. The contrary *may* happen, by preſenting a body in the manner of E. We wiſh theſe particulars to be kept in mind. In the mean time, all theſe circumſtances are neceſſary conſequences of the ſuppoſition, that nothing is communicated from A to B or C. The electricity induced on perfect conductors is momentary, requiring the continual preſence of a body that is electrified in ſome way or other.

But the caſe is quite otherwiſe in imperfect conductors. When the overcharged, or otherwiſe electrical body A is removed, the forces which tend to reſtore the uniform diſtribution of the fluid immediately operate, and muſt reſtore it in part. They cannot, however, do it completely: For when the force which urges any particle from an overcharged to an undercharged part, is juſt in equilibrio with the obſtruction, it will remain, juſt as a number of grains of ſmall ſhot may lie, uniformly mixed with a maſs of clammy fluid, or, as ſuch fluids retain heavy mud, in a ſtate of equable or inequable diffuſion. If the reſiſtance ariſe merely from the inertia of the tangible matter, there is no force ſo ſmall but it will in time reſtore the uniform diſtribution. But this cannot be the caſe in ſolid bodies. Their particles exert lateral forces, by which they maintain themſelves in particular ſituations: theſe muſt be overcome by *ſuperior* forces.

We ſhould therefore expect, that imperfect conductors will retain part of their inequable conſtitution; and, *in conſequence of this*, their power of affecting other bodies like electrics; that is, their Electricity. For we muſt obſerve (having neglected to do it in the beginning), that the term *electricity* is as often uſed to expreſs this power of producing electrical phenomena as it is uſed for expreſſing a ſubſtance ſuppoſed to be the original cauſe of all theſe appearances. It is neceſſary to keep this diſtinction in mind; becauſe there are many phenomena which clearly indicate the transference of this cauſe, and they muſt not be confounded with others, where the exhibition of electric phenomena is evidently propagated to a diſtance. We muſt not always ſuppoſe, that when the electric appearances are exhibited in an inſtant at the far end of a wire $4\frac{1}{2}$ miles long, the ſame numerical particles of the electric fluid have moved over this ſpace. We muſt diſtinguiſh thoſe caſes where this muſt be granted from thoſe in which it certainly has not happened. Of theſe there are innumerable inſtances.

59 Imperfect conductors are neceſſarily idio-electrics.

We have now to obſerve, that by this theory the ſingle circumſtance of perfect and imperfect conducting power is ſufficient for eſtabliſhing the whole difference between idio-electrics and non-electrics. The idio-electrics are ſuſceptible of excitation in various ways, and retain their electricity; and this may be done in any part of them without affecting the reſt in any remarkable degree. This cannot be done in perfect conductors, plainly *becauſe they are perfect conductors.* Any inequality of diſtribution of the electric fluid, which is all that is neceſſary for rendering them electric, is immediately deſtroyed by its uniform diffuſion. We can have no direct proof of their incapability of excitation; but if they can be excited, they cannot ſhew it. We doubt, however, their excitability; becauſe the appearances in the excitation of electrics ſeem to indicate, that oppoſite ſtates of two bodies are neceſſary previous to the appearance of electricity. This is impoſſible in perfect conductors. By this theory, therefore, perfect conductors are neceſſarily non-electrics; and non-conductors are neceſſarily (if excitable) idio-electrics.

With reſpect to the particular phenomena which may be expected on the removal of the original electric; it may juſt be remarked, that the electric appearances of the imperfect conductor will go off in the contrary order to that of their indication. The accumulation and deficiency will diminiſh gradually, and the neutral point or points will gradually approach the end which had fronted the original electric. The imperfect conductor will be finally left with one or more neutral points, according to the magnitude of the obſtructions, and the force which had been employed in its electrification: And their final ſtate will be ſo much the more inequable, and conſequently they will retain ſo much the greater electric powers, as they are leſs perfect conductors.

The laſt obſervation which we ſhall make on this head at preſent is, that whether electrified by induction, or by friction, or moſt other modes of excitation, the electrification will be nearly ſuperficial in bodies which conduct very imperfectly; and bodies which are altogether impervious (if there be any ſuch) muſt have the accumulation or deficiency altogether at their ſurface. If a glaſs globe be ſuch a body, it will hardly be poſſible to electrify it to any depth; and all that we can expect is alternate ſtrata of overcharged and undercharged glaſs. If theſe ſtrata are once formed, they tend greatly to make the body retain its ſuperficial electricity. A ſuperficial ſtratum of redundant fluid, tending, by the mutual repulſion of its particles, to eſcape, is retained by the ſtratum of redundant matter immediately below it: And the almoſt inſuperable obſtruction prevents the fluid of the ſtratum beyond this from coming up to ſupply the vacancy. If we can fall on any contrivance to produce ſuch deficient ſtrata within the glaſs, we ſhall make it much more retentive and capable of holding faſt a much greater quantity. We have already mentioned ſomething of this in n° 14. and we recommend the caſe to the attentive conſideration of the reader. 60 Electrics are only ſuperficially ſo.

61 Compariſon of the theory with experiment.

Thus have we given a ſketch of the leading doctrines of this elegant theory of Mr Æpinus, all legitimately deduced from the circumſtances aſſumed in the hypotheſis concerning the *mechanical* properties of that ſubſtance which he calls *the electric fluid.* Let us now ſee with what ſucceſs this hypotheſis may be applied to account for the phenomena. It would have been more philoſophical to have arranged the phenomena, and from the compariſon to have deduced the hypotheſis. But this would have required much more room than can be afforded in a Work like ours.

We preſume, that many of our readers, namely, all ſuch as are already converſant with electrical phenomena and with electric experiments, have ſeen, as we went along, the perfect agreement of the hypotheſis with the various phenomena of attraction and repulſion, and all thoſe which are uſually claſſed under the name of electric atmoſpheres: and we are confident, that when they compare the conſequences that ſhould neceſſarily reſult from ſuch a fluid with the legitimate conſequences of the mechanical action of elaſtic atmoſpheres, they will acknowledge the great ſuperiority of this hypotheſis in point of ſimplicity, perſpicuity, and analogy with other general operations of nature. To ſuch readers it would not be neceſſary to ſtate any farther compariſon; but there are many who have not yet formed any diſtinct *ſyſtematic* view of the appearances called *electrical.* We do not know any way of giving ſuch a view of them as by means of this hypotheſis; and we may venture to ſay, that it will enable the ſtudent of Nature to claſs them all, with hardly a ſingle exception. After which, the hypotheſis may be thrown aſide by the faſtidious philoſopher; and the uſeful claſſification, and general laws of the electric phenomena, will remain ready foundations for a more perfect theory. For the ſake of ſuch readers, therefore, we ſhall take a ſhort review of thoſe general appearances which are accompanied by attractions and repulſions, and compare them with this Æpinian theory.

We ſhall not at preſent conſider the various modes of excitation, although this theory alſo affords much inſtruction

ſtruction on the ſubject, but confine ourſelves entirely to the facts which are moſt immediately dependent on it, and ſhould be employed to ſupport or overturn it; and we ſhall ſuppoſe the reader acquainted with moſt parts of the common apparatus; ſuch as electrometers, inſulation, &c. We alſo preſume that he knows, that when a ſmall pith-ball has been electrified by touching a piece of glaſs which has been excited by rubbing with dry flannel, it will repel another body ſo electrified; and that balls, which have received their electricity in this manner from ſealing-wax excited by the ſame rubber, alſo repel each other; but that balls, thus electrified by glaſs, attract thoſe which are electrified by ſealing-wax.

The following ſimple apparatus will ſerve for all the experiments which are neceſſary for eſtabliſhing the theory:

62
Apparatus neceſſary for this compariſon.

1. Two ſlender glaſs rods A (fig. 8.), having a braſs ball B at the end, about a quarter of an inch in diameter, ſuſpending a very ſmall and delicate pith-ball electrometer C.

2. Some electrometers (fig. 9.), conſiſting of two pieces of ruſh pith, about four inches long, nicely ſuſpended, and hanging parallel, and almoſt in contact with each other. It is proper to have them as ſmooth as poſſible, and neatly rounded at the ends, to prevent unneceſſary diſſipation.

3. Some pith-ball electrometers (fig. 10.), whoſe threads are of ſilk, about four inches long, and ſome with flaxen threads moiſtened with a ſolution of ſome deliqueſcent ſalt, that they may be always in a good conducting ſtate.

4. Several braſs conductors (fig. 11.), each ſupported on an inſulating ſtalk and foot. They ſhould be about an inch and half or two inches long, and about three-fourths of an inch in diameter, with round ends, and well poliſhed, to prevent all diſſipation. The foot muſt be ſo narrow as to allow them to touch each other at the ends.

5. Two balls (fig. 12.), one of glaſs, and the other of glaſs coated with ſealing-wax, each furniſhed with an inſulating handle, the other end of which may be occaſionally ſtuck into a foot, or into the ſide of a block of wood, which can be ſlid up or down on a wooden pillar, and fixed at any height. Theſe balls ſhould be about three inches in diameter. They muſt be excited by rubbing with dry warm flannel.

6. Some little pieces of gilt card (fig. 13.), about two inches long, half an inch broad, and rounded at the ends, and made as ſmooth as poſſible. Each muſt have a dimple ſtruck in the middle with a poliſhed blunt point, ſo that it will traverſe freely like a mariner's needle when ſet on a glaſs point, rounded in the flame of a lamp. More artificial needles may be made of ſome light wood, having ſmall cork balls at the ends, all gilt and poliſhed, and turning, in like manner, on glaſs ſtalks: alſo ſome ſimilar needles made of ſealing-wax, one end of each being black, and the other red.

The mechanical phenomena of electricity may be expreſſed in a few ſimple propoſitions. The moſt general fact that we know, and from which all the reſt may be deduced, is the following:

If any body A is electrified, by any means whatever, and if another body B is brought into its neighbourhood, the laſt becomes electrical by poſition.

Set the braſs conductors in a row, touching each other, as repreſented in fig. 11. by A, B, C; and let a pith-ball electrometer, having ſilk threads, be ſet near one end of the conductors. Excite one of the globes, by rubbing it with dry flannel. When this is brought near the end of the conductor, the pith-ball will approach the other end. But the globe muſt not be brought ſo near as to cauſe the pith-ball to ſtrike againſt the other end. On removing the globe, the pith-ball will move off and hang perpendicularly. The ſame effect is produced by both globes. 63

63
A neutral body attracted, becauſe rendered electrical by induction.

Thus the mere vicinity of the electric renders the conductor electric, and the electricity ceaſes on removing the globe. This is perfectly conformable to the theory, whether we ſuppoſe the fluid to be made redundant or deficient at the remote end of the conductor. If one ſhould aſcribe the approach of the pith-ball to the immediate action of the globe, it is ſufficient to obſerve, that if the ball be ſuſpended near the *ſide* of the conductor, it will approach the conductor, ſhewing that it is affected by the conductor, and not by the globe.

State of diſtribution aſcertained experimentally.

Let the globe be held in the poſition D (fig. 12.), about ſix inches from the conductor, and a little above the line of its axis. Take the glaſs rod (fig. 8.), and bring its knob into contact with the under ſide of the remote end *c* of the conductor. The balls of the electrometer will ſeparate, ſhewing that they are electrified in the ſame manner, and repel each other. Slide the braſs knob along the under ſide of the conductors, quite to the end *a*. The balls will gradually collapſe as the knob approaches a point near the middle of the conductors, where they will hang parallel. Paſſing this point, they will again ſeparate, and moſt of all when the knob is at *a*. In this ſituation they will deviate toward the globe, and will be directed ſtraight toward it, if it be held too near, or in the direction of the axis. This would diſturb the experiment, and muſt be avoided. Theſe phenomena are conformable to the account given of the diſpoſition of the fluid in the conductor. The electrometer may be conſidered as making a part of the conductor; and when its threads hang parallel, it is in its natural ſtate, having its fluid of its natural denſity. This, however, cannot be ſtrictly true, according to the theory; becauſe the balls of the electrometer muſt be conſidered as more remote from the electric, and their electrical ſtate muſt correſpond to a point of the conductor more remote than that where the knob of the electrometer touches it. This will be more remarkably the caſe as the threads are longer. Accordingly, an electrometer with very long threads will never collapſe. The place of the neutral point cannot be accurately aſcertained in this way. Lord Mahon imagined that its ſituation B was determined (in his experiments with a long conductor) to be ſuch, that D *c* was harmonically divided in B and *a*; and he finds this to be agreeable to the reſult of an electric atmoſphere whoſe denſity is inverſely proportional to the ſquare of the diſtance. But we cannot deduce this from his narration of the experiment. He gives no reaſon for his ſelection of the point D, nor tells us the form and dimenſions of the electric employed, nor takes into account the action of the fluid in the long conductor. It is evident that no computation can be inſtituted, even on his Lordſhip's principles, till all this be done. We have always

Lord Mahon's determination of the neutral point not warranted by his explanation.

always found that the neutral point was farther from the electric, in proportion as the conductor was ſmaller, and when the electricity was ſtronger; and that the differences in this reſpect were ſo very conſiderable, that no dependence could be had on this experiment for determining the law of action. It ſhould be ſo, both according to Lord Mahon's and Mr Æpinus's theory. But to proceed with our examination:

Having touched the end *c* of the conductor with the knob of the electrometer, bring it away. The balls will continue to repel each other, and they are attracted by any body that is in its natural ſtate. Touch the ſame end with the knob of the other electrometer, and bring it alſo away; the balls of the two electrometers will be found to repel each other: but if one has touched the conductor at *c*, and the other has touched it at *a*, the electrometers will ſtrongly attract each other. All this is quite conformable to the theory. If the fluid has been compreſſed at *c*, and therefore the balls of that electrometer are overcharged, they muſt repel each other, and repel any other body electrified in the ſame way. They muſt attract and be attracted by any natural body. But the balls of the other electrometer having touched the conductor at *a*, muſt be undercharged, and the redundant fluid of the one muſt attract the redundant matter of the other.

If the conductor has been electrified by the vicinity of excited glaſs, the electrometer which touched it in the remote end *c*, will be repelled by a piece of excited glaſs, but attracted by excited ſealing-wax. The electrometer which touched the conductor in *a* will be attracted by excited glaſs, and repelled by excited ſealing-wax. The contrary will be obſerved if the conductor has had its electricity induced on it by the vicinity of the globe covered with ſealing-wax. This is a complete proof that Mr Dufuy's doctrine of *vitreous* and *reſinous* electricity is unfounded. Both kinds of electricity are produced in a conducting body, without any material communication, by mere juxta-poſition to a body poſſeſſed of either the vitreous or the reſinous electricity.

64 Conſtant diſtinctions of redundancy and deficiency.

We have not yet mentioned any reaſons which indicate which end of the conductor is electrical by the redundancy of electric fluid, nor is the reader prepared for ſeeing their force. It is generally believed that the remote end of a conductor which is electrified by glaſs, excited by rubbing it with flannel or amalgamated leather, is electrical by redundancy. No difference has been obſerved in the attractions and repulſions. But there are other marks of diſtinction which are conſtant, and undoubtedly ariſe from a difference in the mode of action of thoſe of mechanical forces. If, while the excited glaſs globe remains at D, a glaſs mirror, foiled as uſual with tin-leaf, be made to touch the remote end of the conductor, and ſlowly drawn tranſverſely, ſo that the conductor draws a line as it were acroſs it—this mirror being laid down with the foiled ſide undermoſt, the duſt, which ſettles on it in the courſe of a day or two, will be chiefly collected along this line, ſomewhat in the form of the fibres of a feather. But if the conductor was rendered electrical by the globe covered with ſealing-wax, the duſt will be collected along this line in little ſpots like a row of beads. The appearances will be reverſed if the mirror has been paſſed acroſs the end of the conductor which is neareſt to the excited electric. In ſhort, in whatever way the drawing point has been electrified, if it repel a ball which has touched excited glaſs, the line will be feathered; but if it attract ſuch a ball, the line will be ſpotted. There are many ways of making this appearance much more remarkable (ſee Electricity, *Encycl.* Sect. viii. n° 48.) than this; but we have mentioned it on this occaſion, becauſe the circumſtances which occaſion the difference, whatever it is, are the moſt ſimple poſſible. Nothing is communicated; and therefore the effect muſt ariſe from the unnatural ſtate of a ſubſtance or power reſiding in the body. If it be a ſubſtance *ſui generis*, the electric action muſt ariſe from a different diſtribution of this ſubſtance; from a redundancy and deficiency of it in the different portions of the conductor. Without pretending as yet to ſay which is redundant, we ſhall ſuppoſe, with Dr Franklin, that the electricity of excited glaſs is ſo; and we ſhall uſe the words *redundant* and *poſitive* to diſtinguiſh this electricity from the other. This is merely that we may, on many occaſions, conſiderably abbreviate language.

The different electrical ſtates of the different portions of the conductor may be ſeen in another way, which is perhaps more ſimple and unexceptionable than that already narrated. While the globe remains at D, take the two extreme pieces A and C aſide; or, if only two pieces have been uſed, draw the remote piece farther away. Now remove the excited globe. When we examine A ſeparately, we ſhall find it wholly negative, or undercharged, ſtrongly repelling a ball electrified by ſealing-wax, and attracting a ball electrified by glaſs. The other piece C exhibits poſitive electricity, attracting and repelling what A repelled and attracted. If only three pieces of the conductor have been employed, the middle piece B is generally poſitive; but this in a very faint degree.

If all the pieces be again joined, they are void of electricity. If, inſtead of ſuch conductors, a row of metal balls, ſuſpended by ſilk lines, are employed, one of them may generally be found without any ſenſible electricity, when ſeparated from the reſt, having been the neutral part of the row while united.

Theſe very ſimple facts ſhew, as completely as can be wiſhed, that if the electric phenomena depend on a fluid moveable in the pores of the body, the conſtitution given it by Mr Æpinus is adequate to the explanation. We may now venture to aſſert, that every other phenomenon of attraction and repulſion will be found in exact conformity with the legitimate conſequences of this conſtitution of the electric fluid.

65 In the induction of electricity nothing is communicated. Inherent powers are excited.

That nothing is communicated from the electric will appear ſtill more forcibly by the following experiment: Let a conductor be rendered electrical in the way now deſcribed, and touch either extremity of it with the little electrometer, and obſerve attentively the divergency of its threads. Now approach its remote extremity with another conducting body, ſuch as a ſingle piece of thoſe conductors, it will be rendered electrical; as may be diſcovered by a delicate electrometer. Obſerve carefully whether the electrometer in contact with the firſt conductor be affected:—it will generally be found to ſpread its threads wider. It will *certainly* be thus affected if the other conductor be very long and bulky, or touched by the hand; or if, inſtead of this ſecond conductor, we approach the firſt with the extended palm

palm of the hand. As the second conductor was rendered electrical, so, undoubtedly, is the hand also: and its electrification has not deprived the first conductor of any of its electric power, but, on the contrary, has increased it. And this augmentation of its power is equally sensible at both ends: For an electrometer at the other end will also diverge more when the hand is brought near the remote end. This theory explains this in the most satisfactory manner. The first conductor renders the second electric, by propelling its fluid to a greater distance. The second conductor now acts on the fluid that is moveable in the first, and causes a greater accumulation in its end which is farthest from the electric; that is, renders it more electric.

66 The forced disposition of fluid is affected by other electrified bodies.

Suppose that, instead of employing an excited globe of glass, we had made use of a conducting body, slightly overcharged. Thus if we employ the conductor A, overcharged, to induce electricity on C; this will produce the same general effect on our set of conductors. But if we have previously examined the force of the redundant body, by suspending a pith-ball near it, and observing its deviation from the perpendicular, we may sometimes be led to think that it has imparted something to the other body. For if the other body and the pith-ball be on opposite sides of the redundant body, the pith-ball will fall a little; indicating a diminution of electric force. But this *should happen* according to the theory; for it was shewn, in n° 52. that the constipation in the remote end of the overcharged body will be diminished, and along with this, its action on the pith ball. We should find the electricity of the other end, next the conductor, increased, could we find an easy way of examining it; but an electrometer applied there will be too much affected by the conductor.

The same conclusions may be drawn from the following facts: Hang up a rush-pith electrometer. Approach it below with a body slightly electrified. The legs of the electrometer immediately diverge, though attracted by the electrified body. Hold the hand above the electrometer, and they will diverge still more; touch the top of it, and they spread yet farther. Hold the electrified body (very weakly electrified) above the electrometer, so that its legs may diverge a little. Hold the hand above the electrified body; the legs of the electrometer will come nearer each other.

These appearances are observed whether the electric be positive or negative. We need not take up time in explaining this by the theory, its agreement is so obvious.

Electric needles polarity and verticity.

Lastly, on this head, if, in place of a fixed conductor, we use one of the needles of gilt card, set on its pivot, and if we then approach it with another conducting body, in the manner represented by E and C of fig. 6. we shall observe that end of the needle to avoid the other body; but if we bring them together, in the manner represented by F and B, they will attract each other. The attraction will be greater when the body F is long; and most of all when it communicates with the ground. These phenomena are therefore in perfect conformity with the theory; but it may sometimes happen that E will attract the end of C that is nearest to A, and E will be electrified positively if A be positive. This seems inconsistent with the theory; and, accordingly, it has been adduced by Volta against Lord Mahon's account of the electrical state of a conductor in a situation similar to that of C. But the theory of Æpinus shews the possibility of this case. When E is very long, or when it is held in the hand, it is rendered *much more* undercharged than the adjacent part of C; and the fluid in the remoter, but not much remoter, part of C is strongly attracted by the copious redundant matter in the near end of E, and is brought back again, and passes over into E, in the way to be described immediately. The case is rare, and it will not happen at any considerable distance from the neutral point of C. If, indeed, E touch the near end of C before A is brought near, the approach of A will cause fluid to pass into E immediately, and C will be left undercharged on the whole.

The reader, who is at all conversant with electrical experiments, will be sensible, that these experiments are delicate, requiring the greatest dryness of air, and every attention to prevent the dissipation of electricity during the performance. This, by changing the state of the conductors and electrometers, will frequently occasion irregularities. The electrometers are most apt to change in this respect, it being scarcely possible to make them perfectly smooth and free from sharp angles. It may therefore happen, that when the conductors have affected them *for some time*, by the action of the disturbing electric, the removal of this electric will not cause the electrometers to hang perpendicular; they will often be attracted by the conductors, and often repelled; but the intelligent experimenter, aware of these circumstances, will know what allowances to make. 67

Phenomena of imperfect conductors greatly corroborate the theory.

The theory obtains a still more complete support from a comparison with similar experiments made with imperfect conductors. If, in place of the series A, B, C, of metalline conductors, we employ cylinders of glass or sealing wax, or even dry wood or marble, and electrometers with silk threads in place of the rush-pith electrometers, we shall find all the appearances to be such as the theory enables us to predict. If, for example, we use a single cylinder A of glass, we shall find that the neighbourhood of the electric D scarcely induces any electricity on A. The electrometer will hardly exhibit the smallest attraction, and its motions will be almost entirely such as arise from the immediate influence of the electric body D. A cylinder of very dry wood will be more affected by the electric D; and a circumstance of theoretical importance is very distinctly observed, namely, the gradual shifting of the neutral point. It will be found to advance along the cylinder for a very long while, when every circumstance is very favourable, the air very dry, and the wood almost a nonconductor; and its final situation will be found much nearer to the electric than in the brass conductor. Several instructive experiments of this kind may be found in a treatise published in 1783 by Dr Thomas Milner at Maidstone in Kent, entitled, "Experiments and Observations on Electricity." The author does not profess to advance any new doctrines, but only to exhibit experiments scientifically arranged for forming a system. He supports the Franklinian system as it was generally understood at that time; but is much embarrassed for the explanation of the repulsion of negative electrics. The Æpinian correction of this theory did not offer itself to his mind.

Irregularities. 68

We need not go over the same ground again with imperfect conductors. It is well known that such bodies

dies are more weakly attracted and repelled; that the balls of an electrometer with linen threads diverge vastly more when an electrified body is held below it, than if the threads are silken: that such electrometers frequently exhibit very capricious appearances from the slow but real progress of the electricity along the threads. These anomalies will be better understood when we explain the dissipation of electricity along imperfect conductors.

69 Induced electricity of imperfect conductors is really permanent.

A very essential deduction from the theory is, that the electricity induced on an imperfect conductor must have some permanency. This is fully confirmed by experiment. But the remarkable instances of this particular cannot be produced till we be better acquainted with the methods of producing great accumulations of fluid. It is enough to observe at present, that a permanent electricity may always be observed at the junction of the conductors with their insulating stalks. The brass conductor A ceases to be electric as soon as the excited globe is removed; but the very top of the glass stalk on which it is supported will sensibly affect a delicate electrometer for a long while after. The following pretty experiment shews this permanency very distinctly. Set one of the sealing wax needles on its pivot, and place it between two insulated metal spheres of considerable size, at such a distance from both as not to receive a spark. Electrify these balls moderately, one of them positively, and the other negatively, and keep them thus electrified for some hours by renewing their electrification. The needle quickly arranges itself in the line adjoining the two spheres, just as a magnetic needle will do when placed between two magnets whose dissimilar poles front each other. Any gentle force will derange the needle; but it will vibrate like a magnetic needle, and finally settle in its former position. When this has been continued some time, that end of the needle which pointed to the positive globe will be found negative, and the other will be found positive, if examined with an electroscope. And now, if the two globes be removed, this little needle will remain electrical for entire days in dry frosty weather, and its ends will approach any body that is brought near it (taking care not to come too close); and the end which pointed to the positive globe will avoid a piece of rubbed sealing wax, but will approach a piece of rubbed glass; but the other end will be affected in the opposite way. In short, it proves an electric needle with a positive and negative pole.

If two small insulated balls are moderately electrified, and placed about six inches asunder, this needle, when carried round them, will arrange itself exactly as a magnetic needle does when carried round a magnet of the same length. If the same trial be made with the needle of gilt card, it will arrange itself in the same manner that a soft iron needle arranges itself near a magnet, but either end will turn indifferently to either globe.

Electrical meridians.

If a thin glass plate, coated with red sealing wax, be set on the positive and negative globes, and we sprinkle (from a considerable height) a fine powder of black sealing wax, and then pat the plate gently with a glass rod so as to agitate it a little, the particles of wax powder will gradually arrange themselves into curve lines, diverging from the point over one of the globes, and converging to the point over the other, precisely like the curves formed by iron-filings sprinkled on a paper held over a magnet. Each little rag of wax becomes electrical by position, acquires two poles, and the positive pole of one attracts the negative pole of another; and they adhere in a certain determinate position, nearly a tangent to the curve, which was mentioned in n° 50, and indicates the law of magnetic action. When in this state, if a hot brick be held over the plate till the wax soften a little, the particles of black wax will adhere to the red coating, and give us a permanent specimen of the action.

70 It is well known that liquid sealing wax is a conductor. The writer of this article filled a glass tube with powdered sealing wax, and melted it, and then exposed it, in its melted state, to the influence of a positive and a negative globe, hoping to make a powerful and permanent electric needle, which should have two poles, and exhibit a set of phenomena resembling those of magnetism. Accordingly he, in some measure, succeeded, by keeping the globes continually electrified for several hours, till the wax was quite cold. It had two distinct poles, and preserved this property, *even though plunged in water, and while immersed in the water;* but he was greatly disappointed as to the degree of its electricity. It just affected a sensible electrometer at the distance of six inches from either pole. It was considerably stronger than if it had not been melted during the impregnation, but by no means in the degree that he expected. It retained some electricity for about six weeks, although lying neglected among conducting bodies. After its power seemed quite extinct, he was melting it again in order to renew it. Some light fibrous things chanced to be near it. While it was softening, it became very sensibly electrical, causing these fibres to bend towards it, and even to cling to the tube. We shall see by and bye, that he was mistaken in expecting more remarkable appearances, and that the theory, when properly applied, does not promise them. Having thus established (as we think) this theory on sufficient foundations for making it a very perspicuous way of explaining the phenomena of induced electricity, we proceed to compare it with the second general fact in electricity.

71 Electricity by communication

Prop. II. When an insulated body B is brought very near an electrified body A, a spark is observed to pass between them, accompanied with a noise (which we shall call the electric Snap), and B is now electrified permanently, and the electricity of A is diminished.

Although this be one of the most familiar facts in electricity, it will be proper to consider its attending circumstances in a way that connects it with what we have now learned concerning electricity by position.

Let the insulated body A (fig. 14.) be furnished with a cork-ball, hanging by a silk thread from a glass stalk connected with A; let B be fitted up in the same manner; let A be electrified weakly, and its degree of electricity be estimated by the inclination of the ball *towards* A: since B is not electrified, its electrometer will hang perpendicular; but when it approaches A (keeping the electrometers on the remote sides of both), its electrometer will approach it, and the electrometer of A will gradually approach the perpendicular. When the bodies are brought very near, a spark is seen between them; and, at that instant, the electrometer of B comes

B comes much nearer to it, and that of A drops farther from it. If they be now ſeparated, their electrometers will retain their new poſitions with very little change, and B will now manifeſt the ſame kind of electricity with A.

Such is the appearance when A has been but weakly electrified. Bringing B near A, the fluid in B is drawn to the remote ſide, if A be overcharged, or drawn to the ſide neareſt to A, if A has been undercharged. B acts on its electrometer in conſequence of the change made in the diſpoſition of its fluid. The electrometer is attracted. In the mean time, the change made in the diſpoſition of the fluid in B affects the moveable fluid in A. If A was overcharged, the adjacent ſide of B becomes undercharged, and its redundant matter, attracting the fluid in A, condenſes it in the adjacent ſide, abſtracting part of the redundant fluid from that ſide which is next to the pith-ball. Then the joint action of the whole redundant fluid in A on the pith-ball is diminiſhed.

Muſt happen abruptly.

As there is now an attraction in the redundant fluid in A for the redundant matter on the adjacent ſide of B, it is reaſonable to ſuppoſe that when this attraction, joined to the repulſion of the redundant fluid behind it, is able to overcome the attraction which connects it with the ſuperficial particles of the matter, it will then eſcape and fly into B: but this will not happen gradually, but at once, as ſoon as the expelling force has ariſen to a very conſiderable intenſity. We cannot ſay what is the preciſe augmentation that is neceſſary; but we can clearly ſee, that however great the attraction for the adjoining particles may be, while the particle is ſurrounded by them on *all* ſides, it will yield to the ſmalleſt inequality of force, becauſe the particles before it attract as much as thoſe behind it; but when it is juſt about to quit the laſt or ſuperficial particles of A, a much greater force is now neceſſary. It can be ſtrictly demonſtrated, that when the mutual tendency is inverſely as the ſquare of the diſtance, the action of a particle placed immediately without a ſphere of ſuch matter is double of its action when ſituated in the very ſurface *. A *ſaltus* of this kind muſt obtain whatever be the law of electric attraction. We ſhall ſee other cauſes alſo which ſhould prevent the eſcape of redundant fluid, and alſo its admiſſion, till the impelling force is encreaſed in a certain abrupt degree.

* *Opuſcles de d'Alembert*, t. I. 257.

72. Theſe obſervations muſt ſuffice at preſent to explain the deſultory nature of this tranference, if there be really a transference. That this has happened, may be confidently inferred from the ſudden diminution of the electricity of A, indicated by the ſudden fall of its electrometer; but it is more expreſsly eſtabliſhed, that there has been a transference by the change produced on B. It is now permanently electrified, and its electricity is of the ſame kind with that of A, poſitive or negative according as A is poſitive or negative. And now we are enabled to explain the third general fact in electricity.

73 Imparted electricity produces mutual repulſion.

Prop. III. When a body has imparted electricity to another, it conſtantly repels it, unleſs that other has afterwards imparted all its electricity to other bodies. This fact, from which there is no exception, is an immediate conſequence of the theory. Before the transference ſuppoſed by it, B was in its natural ſtate; after the transference, both bodies contain redundant fluid, or redundant matter; therefore they muſt mutually repel.

We may now take another form of the experiment, which will be much more convincing and inſtructive. Let A be electrified poſitively, or by redundancy, and let its electrometer be attached to it by a conducting ſtalk, and have a flaxen thread; let this be the caſe alſo with the electrometer of B; then the appearances ſhould happen in the following order: When A is made to approach B, the electrometer of B muſt gradually riſe, diverging *from* B; becauſe the fluid condenſed on the ſide remote from A, and in the electrometer, will act more ſtrongly on it than the deſerted matter on the other ſide of B; and when the ſudden transference is made, and B is wholly overcharged, its electrometer will immediately riſe much higher, and muſt remain at that height, nearly, when A is removed. On the other hand, the electrometer attached to the remote ſide of A muſt deſcend, by reaſon of the change made in the diſpoſition of the fluid in A by the induced electrical ſtate of B: and when a conſiderable portion of the redundant fluid in A paſſes into B, the electrometer of A muſt ſudenly ſink much lower, and remain in that ſtate when B is removed.

Many circumſtances of this phenomenon corroborate our belief of a real transference of matter. The cauſe of electric action reſided formerly in A alone; it now reſides alſo in B. The larger that B is, the greater is the diminution of A's electric power, and the ſmaller is the power acquired by B. It perfectly reſembles, in this reſpect, the communication of ſaltneſs, ſweetneſs, &c. by mixing a ſolution of ſalt or ſugar with different quantities of water; and the evidence of a transference of a ſubſtance, the cauſe of electric attractions and repulſions, is at leaſt as cogent as the evidence of the transference of heat, when we mix hot water with a quantity of cold, or when a hot ſolid body is applied to the ſide of a cold one. We alſo ſee ſo many chemical and other changes produced by this communication of electricity, that we can hardly refuſe admitting that *ſome material ſubſtance* paſſes from one body to another, and, in its new ſituation, exerts its attractions and repulſions, and produces all their effects. Transference of a peculiar ſubſtance highly probable.

We may deduce the following corollaries; all of which are exactly conformable to the phenomena, ſerving ſtill more to confirm the juſtneſs of the theory.

74 Degrees of vivacity proportioned to the quantity imparted.

1. A certain quantity of what poſſeſſes theſe powers of attraction and repulſion is neceſſary for giving a determined vivacity to the appearances. Another ſpark muſt paſs between the bodies, *only if they be brought ſtill nearer*, and their electrometers muſt riſe and fall ſtill farther. For by the firſt transference of electric fluid into B, the expelling power of A is diminiſhed, and the ſuperior attraction of the redundant matter in the adjacent ſide of B is alſo counteracted by the repulſion of the fluid which has entered into it; therefore no more will follow unleſs theſe forces be encreaſed, at leaſt to their former degree. When this addition has been made to B, and this abſtraction from A, their reſpective electrometers muſt be affected. All this is in perfect conformity to experience.

75 Communication moſt remarkable in conductors.

2. All the phenomena of communicated electricity muſt be more remarkable in proportion to the conducting power of the bodies. A very imperfect conductor,

ductor, such as glass or sealing wax, will impart or receive fluid only between the very nearest parts; whereas a metalline body is instantly affected through its whole extent. This deduction is perfectly agreeable to the whole train of electric experiments. The finger receives a strong spark from a large metalline electrified body, which discharges *every part of it* of a portion of its electricity. But an excited globe, which shews, by its action on a distant body, as great a degree of electricity, will give only a very small spark; and it is found not to be affected at any considerable distance from the point of its surface from which the transference was made. The whole electricity of a perfect conductor is discharged by touching it; but a non-conductor will successively give sparks, if touched in many different parts; and it may be seen by a nice electrometer, that each contact takes away the electricity only from a very small space round it: and it is further highly deserving of notice, that some time after a spark has been obtained from a particular spot of the electric, a second spark may be obtained from it, the electricity of the neighbouring parts having been gradually diffused through it.

76 Insulation necessary for electric appearances.

3. If an electrified conducting body touch any thing communicating with the ground by perfect conductors, all its electricity must disappear, and none can appear in the body touched by it; for the mass of the earth bears such an unmeasurable proportion to that of the greatest body that we can electrify, that when the redundancy or deficiency is divided between them, it must be imperceptible in both.

77. Hence the necessity of *insulation*, as it is called, or the surrounding by non-conductors every body which we would have exhibit electric appearances. We must refer the reader to the article ELECTRICITY in the *Encycl.* for all the observations on this head, and the reasons of preference given to certain substances to be employed for insulating supports. But we must consider, in its proper place, the manner in which the electric fluid is dissipated by imperfectly insulating substances; a subject intimately connected with the theory.

78 An electrified body attracts and then repels any unelectrified body.

4. Any unelectrified body will be first attracted by an electrified body, will touch it, and will then be repelled. The neutral body is rendered electrical by induction. It is, *in consequence of this*, attracted, comes near enough to receive a spark, or even touches it, and is then electrified by communication; and, *in consequence of this*, it is repelled. This is confirmed by an endless train of experiments. It was first taken notice of (we think) by Sir Isaac Newton. Otho Guericke, a gentleman of Magdeburgh, to whom we owe the air pump, mentions many instances of the repulsion, but did not observe that it was an universal law. Newton was so struck with it as to engage in a considerable train of experiments in the early part of his life, while meditating on the power of gravity; but even his sagacious mind did not observe the whole process of nature in his experiments. He observed, that the light bodies which rose and adhered to the rubbed plate of glass were soon after repelled by it; but did not observe that the same piece would again rise to the glass after it had touched the table. This fact is now the foundation of many experiments, which the itinerant electricians vie with each other in rendering very amusing. We may render them instructive. Take away the middle conductor B (fig. 11.), and hang in its place a cork ball by a long silk thread. As soon as the electric body D is brought near to A, the ball is attracted by its remote end, comes into contact, is repelled by it, and attracted by the adjacent end of C, touches it, is faintly repelled by it, and again attracted by A; and the operation is repeated several times. When all has ceased, remove C, and also the electric D. C is found to have the same electricity with D, and A has the opposite electricity. The process is too obvious to need any detailed application of the theory. The cork ball was the carrier of fluid from A to C if D was electric by redundancy, or from C to A if D was undercharged. If instead of removing C when the vibrations of the ball have ceased, we bring D a little nearer, they will be renewed, and after some time will again cease. The reason is plain. The carrier ball had brought the conductor A into a state of equilibrium with the action of D. But this action is now increased, and the effects are renewed. If we now remove D, the ball will vibrate between A and C with great rapidity for a considerable time before the vibrations come to an end; and we shall find their number to be the same as before. The cause of this is also obvious from the theory. We may suppose A to be negative, and C positive. One of them will attract the ball into contact, and will repel it, having put it into an electric state opposite to that of the other conductor. It now becomes a carrier of fluid from the positive to the negative conductor, till it nearly restore both to their primitive state of neutrality.

There is frequently a seeming capriciousness in those attractions and repulsions. A pith ball, or a down feather, hung by silk, will cling to the conductor, or otherwise electrified body, and will not fly off again, at least for a long while. This only happens when those bodies are so dry as to be almost non-conductors. They acquire a positive and negative pole, like an iron nail adhering to a magnet, and are not repelled till they become almost wholly positive or negative. It never happens with conducting light bodies. 79 Irregularities frequent—Why.

5. It should follow from the theory, that the electric attractions and repulsions will not be prevented by the intervention of non-conducting substances in their neutral state. Accordingly, it is a fact, that the interposition of a thin pane of glass, let it be ever so extensive, does not hinder the electrometer from being affected. Also, if an insulated electric be covered with a glass bell, an electrometer on the outside will be affected. Nay, a metal ball, covered to any thickness with sealing wax, when electrified, will affect an electrometer in the same way as when naked. We cannot see how these facts can be explained by the action of electric atmospheres. It is indeed said, that the atmosphere on one side of the glass produces an atmosphere on the other; but we have no explanation of this production. If the interposed plate be a non-conductor, how does the one atmosphere produce the other? It must produce this effect by acting at a distance on the particles which are to form this atmosphere. Of what use, then, is the atmosphere, even if those atmospheres could effect the observed motions of the electrometer in consistency with the laws of mechanics? The atmospheres only substitute millions of attractions or repulsions in place of one. We must observe, however, that the motions 80 Electric action, like gravitation, is not hindered by the interposition of non-conductors.

of

of the electrometer are modified, and ſometimes greatly changed, by the interpoſed non-conducting plate; but this is owing to the electricity induced on the plate. If the electric is poſitive, the adjacent ſurface of the plate becomes faintly negative, and the ſide next the electrometer ſlightly poſitive. This affects the electrometer even more than the more remote electric does. That this is the cauſe of the difference between the ſtate of the electrometer when the plate is there and when it is removed, will appear plainly by breathing gently on the glaſs plate to damp it, and give it a ſmall conducting power. This will make ſome change in the poſition of the electrometer. Continue this more and more, till the plate will no longer inſulate. The changes produced on the electrometer's poſition will form a regular ſeries, till it is ſeen to aſſume the very poſition which it would have taken had the plate been braſs. Then, conſidering thoſe changes in a contrary order, and ſuppoſing the ſeries continued a little farther, we ſhall always find that it leads to the poſition which it would have taken when no plate whatever is interpoſed. We conſider this as an important fact, ſhewing that the electric action is ſimilar to gravitation, and that there is no more occaſion for the intervention of an atmoſphere for explaining the phenomena of electricity than for explaining thoſe of gravitation.

81 Strong electricity may be excited without appearing.

6. Since non-electrics are conductors, and ſince electrics may be excited by friction with a non-electric, it follows, that if this non-electric be inſulated, and ſeparated from the electric, it will exhibit ſigns of electricity; but when they are together, there muſt not appear any marks of it, however ſtrong the excitation may be. We do not pretend to comprehend diſtinctly the manner in which friction, or the other modes of excitation, operate in changing the connection between the particles of the fluid and thoſe of the tangible matter; nor is this explained in any electric theory that we know: but if we are ſatisfied with the evidences which we have for the exiſtence of a ſubſtance, whoſe preſence or abſence is the cauſe of the electric phenomena, we muſt grant that its uſual connection with the tangible matter of bodies is changed in the act of excitation, by friction, or by any other means. In the caſe of friction producing poſitive electricity on the ſurface of the electric, we muſt ſuppoſe that the act of friction cauſes one body to emit or abſorb the fluid more copiouſly than the other, or perhaps the one to emit and the other to abſorb. Whichever is the caſe, the adjoining ſurfaces muſt be in oppoſite ſtates, and the one muſt be as much overcharged as the other is undercharged. When the bodies (which we may ſuppoſe to have the form of plates) are joined, and the one exactly covers the other, the aſſemblage muſt be inactive; for a particle of moveable fluid, ſituated anywhere on the ſide of the overcharged plate, will be as much attracted by the undercharged ſurface of the remote plate as it is repelled by the overcharged ſurface of the near plate. The ſurfaces are equal, and equally electric, and act on either ſide with equal intenſity; and they are coincident. Therefore their actions balance. The action is expreſſed by the formula of n° 43; namely, $F' m' \times \overline{z - z'}$; and $z - z'$ is $= 0$, by reaſon of the equal diſtances of theſe ſurfaces from the particle of exterior fluid.

But let the plates be ſeparated. Part, and probably the greateſt part, of the redundant fluid on one of the rubbed ſurfaces will fly back to the other, being urged both by the attraction of the redundant matter and the repulſion of its own particles. But the electric, being electric becauſe, and only becauſe, it is a non-conductor, muſt retain ſome, or will remain deprived of ſome, in a ſtratum a little within the ſurface. The two plates muſt therefore be left in oppoſite ſtates, and the conducting, or non-electric plate, if inſulated before ſeparation, muſt now exhibit electric action.

All this is exactly agreeable to fact. We alſo know that electrics may be excited by rubbing on each other; and if of equal extent, and equally rubbed, they exhibit no electric powers while joined together; but when parted, they are always in oppoſite ſtates. The ſame thing happens when ſulphur is melted in a metal diſh, or when Newton's metal is melted in a glaſs diſh. While joined, they are moſt perfectly neutral; but manifeſt very ſtrong oppoſite electricities when they are ſeparated. This completely diſappears when they are joined again, and reappears on their ſeparation, even after being kept for months or years in favourable circumſtances. We have obſerved the plates of talc, and other laminated foſſils, exhibit very vivid electricity when ſplit aſunder.

82 Principles of the conſtruction of electric machines.

Attention to theſe particulars enables us to conſtruct machines for quickly exciting vivid electricity on the ſurface of bodies, and for afterwards exhibiting it with continued diſpatch. The whirling globe, cylinder, or plate, firſt employed by Mr Hauksbee, for the ſolitary purpoſe of examining the electricity of the globe, was moſt ingeniouſly converted by Hauſen, a German profeſſor, into a rapid collector and diſpenſer of electricity to other bodies, by placing an inſulated prime conductor cloſe to that part of the ſurface of the globe which had been excited by friction. Did our limits give us room, we ſhould gladly enlarge on this ſubject, which is full of moſt curious particulars, highly meriting the attention of the philoſopher: But it might eaſily occupy a whole volume; and we have ſtill before us the moſt intereſting parts of the mechanical department of electricity, and ſhall hardly find room for what is eſſentially requiſite for a clear and uſeful comprehenſion of it. We muſt therefore requeſt our readers to have recourſe to the original authors, who have conſidered the excitation by friction minutely. And we particularly recommend the very careful peruſal of Beccaria's Diſſertations on it, comparing the phenomena, in every ſtep, with this theory of Æpinus. Much valuable information is alſo obtained from Mr Nicholſon's Obſervations, of which an abſtract is given in the article Electricity in the *Encyclopædia Britannica*. The Æpinian theory will be found to connect many things, which, to an ordinary reader, muſt appear ſolitary and accidental.

83 Evidences of the materiality of the electric fluid.

Seeing that this very ſimple hypotheſis of Æpinus ſo perfectly coincides in its legitimate conſequences with all the general phenomena of attraction and repulſion, and not only with thoſe that are ſimple, but even ſuch as are compounded of many others—we may liſten, without the imputation of levity, to the other evidences which may be offered for the materiality and mobility of the cauſe of thoſe mechanical phenomena. Such evidences are very numerous, and very perſuaſive. We have ſaid that the transference of electricity is deſultory, and that the change made in the electric ſtate of the com-

communicating bodies is always confiderable. It appears to keep fome fettled ratio to the whole electric power of the body. When the form of the parts where the communication takes place, and other circumftances, remain the fame, the transference increafes with the fize of the bodies; and all the phenomena are more vivid in proportion. When the conductor is very large, the fpark is very bright, and the fnap very loud.

Snap,

1. This fnap alone indicates fome material agent. It is occafioned by a fonorous undulation of the air, or of fome elaftic fluid, which fuddenly expands, and as fuddenly collapfes again. But fuch is the rapidity of the undulation, that when it is made in clofe veffels it does not exift long enough, in a very expanded ftate, to affect the column of water, fupported in a tube by the elafticity of the air, for the purpofe of a delicate thermometer or barometer; juft as a mufket ball will pafs through a loofe hanging fheet of paper without caufing any fenfible agitation.

Spark, and heat.

2. The fpark is accompanied by intenfe heat, which will kindle inflammable bodies, will melt, explode, and calcine metals.

Chemical effects.

3. The fpark produces fome very remarkable chemical effects. It calcines metals even under water or oil; it renders Bolognan phofphorus luminous: It decompofes water, and makes new compofitions and decompofitions of many gaziform fluids; it affects vegetable colours; it blackens the calces of bifmuth, lead, tin, luna cornea; it communicates a very peculiar fmell to the air of a room, which is diftinct from all others; and in the calcination of metals, it changes remarkably the fmells with which this operation is ufually accompanied: it affects the tongue with an acidulous tafte; it agitates the nervous fyftem.—When we compare thefe appearances with fimilar chemical and phyfiological phenomena, which naturalifts never hefitate in afcribing to the action of material fubftances, transferable from one body, or one ftate of combination, to another, we can fee no greater reafon for hefitating in afcribing the electric phenomena to the action of a material fubftance; which we may call *a fluid*, on account of its connected mobility, and *the electric fluid*, on account of its diftinguifhing effects. We are well aware, that thefe evidences do not amount to demonftration; and that it is poffible that the electric phenomena, as well as many chemical changes, may refult from the mere difference of arrangement, or pofition, of the ultimate particles of bodies, and may be confidered as the refult of a change of modes, and not of things. But in the inftances we have mentioned, this is extremely improbable.

This is therefore affumed.

We therefore venture to affume the exiftence of this fubftance, which philofophers have called *the electric fluid*, as a propofition abundantly demonftrated; and to affirm, on the authority of all the above-mentioned facts, that its mechanical character is fuch as is expreffed in Mr Æpinus's hypothefis.

We proceed, therefore, to explain the moft interefting phenomena of electricity from thefe principles.

84
Diftribution of it depends on its law of action.

We have feen that, in a perfect conductor, in its natural ftate, the electric fluid is uniformly diftributed, and cannot remain in any other condition. We are particularly interefted to know how it is diftributed in an overcharged or undercharged body, and how this is affected by the circumambient non-conducting air. It is evident that much depends on this. The tendency to efcape, and particularly the tendency to transference from one body to another, muft be greateft where the fluid is moft conftipated. We know that it tends remarkably to diffipate from all protuberances, edges, and long bodies, and that it is impoffible to confine it in a body having very acute far-projecting points; and, what is more paradoxical, it is hardly poffible to prevent its entering into a body furnifhed with a fharp point. The fmalleft reflection muft fuggeft to our imagination, that a perfectly moveable fluid, whofe particles mutually repel, even at confiderable diftances, and which is confined in a veffel from which it cannot efcape, muft be compreffed againft the fides of the veffel, and be denfer there than in the middle of the veffel. But in what proportion its denfity will diminifh as we recede from the walls of the veffel, muft depend on the change of electric repulfion by an increafe of diftance. The intenfity varies in the proportion of fome function of the diftance, and may be expreffed by the ordinates of a curve, on whofe axis the diftances are meafured. But we are ignorant of this function. We muft therefore endeavour to difcover it, by obferving a proper folution of phenomena. Having made fome approximation to this difcovery, fuch as fhall give rife to a *probable conjecture* concerning the function which expreffes the intenfity of electric repulfion, mathematics will then enable us to fay how the fluid muft be diftributed (at leaft in fome fimple and inftructive cafes) in a perfectly conducting body furrounded by the air, and what will be its action on another body. Thus we fhall obtain oftenfible refults, which we can compare with experiments. The writer of this article made many experiments with this view above 30 years ago, and flatters himfelf that he has not been unfuccefsful in his attempts. Thefe were conducted in the moft obvious and fimple manner, fuggefted by the reafonings of Mr Æpinus; and it was with fingular pleafure that, fome years after, he perufed the excellent differtation of Mr Cavendifh in the Philofophical Tranfactions, vol. 61. where he obtained a much fuller conviction of the truth of the conclufion which he had drawn, in a ruder way, from more familiar appearances. Mr Cavendifh has, with fingular fagacity and addrefs, employed his mathematical knowledge in a way that opened the road to a much farther and more fcientific profecution of the difcovery, if it can be called by that name. After this, Mr Coulomb, a diftinguifhed member of the French Academy of Sciences, engaged in the fame refearch in a way ftill more refined; and fupported his conclufions by fome of the moft valuable experiments that have been offered to the public. We fhall now give a very brief account of this argument: and have premifed thefe hiftorical remarks; becaufe the writer, although he had eftablifhed the general conclufion, and had read an account of his inveftigation in a public fociety in 1769, in which it was applied to the moft remarkable facts then known in electricity, has no claim to the more elaborate proofs of the fame doctrine, which is given in fome of the following paragraphs. Thefe are but an application of Mr Cavendifh's more cautious and general mathematical procedure, to the function which the writer apprehends to be fufficiently eftablifhed by obfervation.

Procefs for difcovering this law.

The moft unexceptionable experiments with which we can begin, feem to be the repulfions obfervable between

tween two *small* fpheres. Whatever be the law of diftribution of the particles in a fphere, the general action of its particles on the particles of another fphere will follow a law which will not differ much from the law of action between two particles, if the diameters of the fpheres be fmall in proportion to their diftance from each other. The inveftigation was therefore begun with them. But the fubject required an electrometer fufceptible of comparifon with others, and that could exhibit abfolute meafures. The one employed was made in the following manner; and we give it to the public as a valuable philofophical inftrument.

85 Comparable electrometer.

Fig 15. reprefents the electrometer in front. A is a polifhed brafs ball, ¼th of an inch in diameter. It is fixed on the point of a needle three inches long, as flender as can be had of that length. The other end of the needle paffes through a ball of amber or glafs, or other firm non-conducting fubftance, about half or three-fourths of an inch in diameter; but the end muft not reach quite to the furface, although the ball is completely perforated. From this ball rifes a flender glafs rod FEL, three inches long from F to E, where it bends at right angles, and is continued on to L, immediately over the centre of the ball A. At L is fixed a piece of amber C, formed into two parallel cheeks, between which hangs the ftalk DCB of the electrometer. This is formed by dipping a ftrong and dry filk thread, or fine cord in melted fealing-wax, and holding it perpendicular till it remain covered with a thin coating, and be fully penetrated by it. It muft be kept extended, that it may be very ftraight; and it muft be rendered fmooth, by holding it before a clear fire. This ftalk is faftened into a fmall cube of amber, perforated on purpofe, and having fine holes drilled in two of its oppofite fides. The cheeks of the piece C are wide enough to allow this cube to move freely between them, round two fine pins, which are thruft thro' the holes in the cheeks, and reach about half way to the ftalk. The lower part of the ftalk is about three inches long, and terminates in a gilt and burnifhed cork-ball (or made of thin metal), a quarter of an inch in diameter. The upper part CD is of the fame length, and paffes through (with fome friction) a fmall cork-ball. This part of the inftrument is fo proportioned, that when FE is perpendicular to the horizon, and DCB hangs freely, the balls B and A juft touch each other. Fig. 16. gives a fide perfpective view of the inftrument. The ball F is fixed on the end of the glafs rod FI, which paffes perpendicularly through the centre of a graduated circle GHO, and has a knob handle of boxwood on the farther end I. This glafs rod turns ftiffly, but fmoothly, in the head of the pillar HK, &c. and has an index NH, which turns round it. This index is fet parallel to the line LA, drawn through the centre of the fixed ball of the electrometer. The circle is divided into 360 degrees, and 0 is placed uppermoft, and 90 on the right hand. Thus the index will point out the angle which LA makes with the vertical. It will be convenient to have another index, turning ftiffly on the fame axis, and extending a good way beyond the circle.

This inftrument is ufed in the following manner: A connection is made with the body whofe electricity is to be examined, by fticking the point of the connecting wire into the hole at F, till it touch the end of the needle; or, if we would merely electrify the balls A and B, and then leave them infulated, we have only to touch one of them with an electrified body. Now, take hold of the handle I, and turn it to the right till the index reach 90. In this pofition, the line LA is horizontal, and fo is CB; and the moveable ball B is refting on A, and is carried by it. Now electrify the balls, and gently turn the handle backwards, bringing the index back toward 0, &c. noticing carefully the two balls. It will happen that, in fome particular pofition of the index, they will be obferved to feparate. Bring them together again, and again caufe them to feparate, till the exact pofition at feparation is afcertained. This will fhew their repulfive force in contact, or at the diftance of their centres, equal to the fum of their radii. Having determined this point, turn the inftrument ftill more toward the vertical pofition. The balls will now feparate more and more. Let an affiftant turn the long index fo as to make it parallel to the ftalk of the electrometer, by making the one hide the other from his view. The mathematical reader will fee that this electrometer has the properties afcribed to it. It will give abfolute meafures: for by poizing the ftalk, by laying fome grains weight on the cork-ball D, till it becomes horizontal and perfectly balanced, and computing for the proportional lengths of BC and DC, we know exactly the number of grains with which the balls muft repel each other (when the ftalk is in a horizontal pofition), in order *merely to feparate*. Then a very fimple computation will tell us the grains of repulfion when they feparate in any oblique pofition of the ftalk; and another computation, by the refolution of forces, will fhew us the repulfion exerted between them when AL is oblique, and BC makes any given angle with it. All this is too obvious to need any farther explanation. The reafon for giving the connection between A and C fuch a circuitous form, was to avoid all action between the fixed and the moveable part of the electrometer, except what is exerted between the two balls A and B. The needle AF, indeed, may act a little, and might have been avoided, by making the horizontal axis FI to join with A: but as it was wanted to make the inftrument of more general ufe, and frequently to connect it with an electrical machine, a battery, or a large body, no mode of connection offered itfelf which would not have been more faulty in this refpect. The neateft and moft compendious form would have been to attach the axis FI to C, and to make CA and CB ftiff metalline wires, in the fame manner as Mr Brookes's electrometer is made. But as the whole of their lengths would have acted, this conftruction would have been very improper in the inveftigation of the law of electric repulfion. As it now ftands, we imagine that it has confiderable advantages over Mr Brookes's conftruction; and alfo over Mr De Luc's comparable electrometer, defcribed in his Effays on Meteorology. It has even advantages over Mr Coulomb's incomparably more delicate electrometer, which is fenfible, and *can meafure* repulfions which do not exceed the 50,000 of a grain; for the inftrument which we have defcribed will meafure the *attractions* of the oppofitely electrified bodies; a thing which Mr Coulomb could not do without a great circuit of experiments. For inftead of making the ball B *above* A, by inclining the inftrument to the right hand, we may incline it to the

the left; and then, by electrifying one of the balls poſitively, and the other negatively, when at a great diſtance from each other, their mutual attraction will cauſe them to approach; CB will deviate from the vertical toward A; and we can compute the force by means of this deviation.

We muſt remind the perſon who would make obſervations with this inſtrument, that every part of it muſt be ſecured againſt diſſipation as much as poſſible, by varniſhing all its parts, by having all angles, points, and roughneſſes removed, and by chooſing a dry ſtate of the air, and a warm room; and, becauſe it is impoſſible to prevent diſſipation altogether, we muſt make a previous courſe of experiments, in a variety of circumſtances, in order to determine the diminution per minute correſponding to the circumſtances of the experiments that are to be made with further views.

We truſt that the reader will accept of this particular account of an inſtrument which promiſes to be of conſiderable ſervice to the curious naturaliſt; and we now proceed with an account of the concluſions which have been drawn from obſervations made with it.

Here we could give a particular narration of ſome of the experiments, and the computations made from them; but we omit this, becauſe it is really unneceſſary. It ſuffices to ſay, that the writer has made many hundreds, with different inſtruments, of different ſizes, ſome of them with balls of an inch diameter, and radii of 18 inches. Their coincidence with each other was far beyond his expectation; and he has not one in his notes which deviate from the medium $\frac{1}{8}$th of the whole force, and but few that have deviated $\frac{1}{12}$th. The deviations were as frequently in exceſs as in defect. His cuſtom was to meaſure all the forces by a linear ſcale, and expreſs them by ſtraight lines erected as ordinates to a baſe, on which he ſet off the diſtances from a fixed point; he then drew the moſt regular curve that he could through the ſummits of theſe ordinates. This method ſhews, in the moſt palpable manner, the coincidence or irregularity of the experiments.

86 Spheres, when electrified, repel with a force proportional to $\frac{1}{x^2}$;

The reſult of the whole was, that the mutual repulſion of two ſpheres, electrified poſitively or negatively, was very nearly in the inverſe proportion of the ſquares of the diſtances of their centres, or rather in a proportion ſomewhat greater, approaching to $\frac{1}{x^{2,06}}$. No difference was obſerved, although one of the ſpheres was much larger than the other; and this circumſtance enables us to make a conſiderable improvement on the electrometer. Let the ball A be made an inch in diameter, while B is but $\frac{1}{4}$th of an inch. This greatly diminiſhes the proportion of the irregular actions of the reſt of the apparatus of the whole force, and alſo diminiſhes the diſſipation when the general intenſity is the ſame.

87 And attract according to the ſame law.

When the experiments were repeated with balls having oppoſite electricities, and which therefore attracted each other, the reſults were not altogether ſo regular, and a few irregularities amounted to $\frac{1}{6}$th of the whole; but theſe anomalies were as often on one ſide of the medium as on the other. This ſeries of experiments gave a reſult which deviated as little as the former (or rather leſs) from the inverſe duplicate ratio of the diſtances; but the deviation was in defect as the other was in exceſs.

We therefore think that it may be concluded, that the action between two ſpheres is exactly in the inverſe duplicate ratio of the diſtance of their centres, and that this difference between the obſerved attractions and repulſions is owing to ſome unperceived cauſe in the form of the experiment.

88 Attractions and repulſions are equal at equal diſtances.

It muſt be obſerved alſo, that the attractions and repulſions, with the ſame denſity and the ſame diſtances, were, to all ſenſe, equal, except in the forementioned anomalous experiments. The mathematical reader will ſee that the above-mentioned irregularities are imperfections of experiment, and that the gradations of this function of the diſtances are too great to be much affected by ſuch ſmall anomalies. The indication of the law is preciſe enough to make it worth while to adopt it, in the mean time, *as a hypotheſis*, and then to ſelect, with judgment, ſome legitimate conſequences which will admit of an exact compariſon with experiment, on ſo large a ſcale, that the unavoidable errors of obſervation ſhall bear but an inſignificant proportion to the whole quantity. We ſhall attempt this: and it is peculiarly fortunate that this obſerved law of action between two ſpheres gives the moſt eaſy acceſs to the law of action between the particles which compoſe them; for Sir Iſaac Newton has demonſtrated (and it is one of his moſt precious theorems), that if the particles of matter act on each other with a force which varies in the inverſe duplicate ratio of the diſtances, then ſpheres, conſiſting of ſuch particles, and of equal denſity at equal diſtances from the centre, alſo act on each other with forces varying in the ſame proportion of the diſtances of their centres. He demonſtrates the ſame thing of hollow ſpherical ſhells. He demonſtrates that they act on each other with the ſame force as if all their matter were collected in their centres. And, laſtly, he demonſtrates, that if the law of action between the particles be different from this, the ſenſible action of ſpheres, or of hollow ſpherical ſhells, will alſo be different (ſee *Principia*, I. Prop. 74, &c. alſo ASTRONOMY, *Encycl.* 307.)

89 Electric action is inverſely as the ſquare of the diſtance.

Therefore we may conclude, that the law of electric attraction and repulſion is ſimilar to that of gravitation, and that each of thoſe forces diminiſhes in the ſame proportion that the ſquare of the diſtance between the particles increaſe. We have obtained much uſeful information from this diſcovery. We have now full confirmation of the propoſitions concerning the mutual action of two bodies, each overcharged at one end and undercharged at the other. Their evidence before given amounted only to a reaſonable probability; but we now ſee that the curve line, whoſe ordinates repreſent the forces, is really convex to the abſciſſa, and that $Z + z'$ is always greater than $Z' + z$; from which circumſtance all the reſt follows of courſe.

90 Diſpoſition of ſuch fluid when redundant or deficient.

Let us now enquire into the manner in which the redundant fluid, or redundant matter, is diſtributed in bodies; the proportion in which it ſubſiſts in bodies communicating with each other; the tendencies to eſcape; the forces which produce a transference, &c. &c.

In the courſe of this enquiry, a continual reference will be made to the following elementary propoſition:

91 Lemma.

Let ABD (fig. 17.) be the baſe of a cone or pyramid, whoſe vertex is P, and axis PC; and let *abd* be another ſection of it by a plane parallel to the baſe; let theſe two circles, or ſimilar polygons, conſiſt of matter or fluid of equal and uniform denſity; and let P be a particle of fluid or matter; the attraction or repulſion of this particle for the whole matter or fluid in the figure ABD is equal to its attraction or repulſion for the

the whole matter or fluid in $a\,b\,d$. For the attraction for a particle in ABD is to the attraction for a particle similarly placed in $a\,b\,d$ as $P\,c^2$ to PC^2; and the number of particles in ABD is to that of those in $a\,b\,d$ as PC^2 to $P\,c^2$; therefore the whole attraction for ABD is to that for $a\,b\,d$ as $P\,c^2 \times PC^2$ to $PC^2 \times P\,c^2$, or in the ratio of equality.

Cor. 1. The same will be true of the action of plates of equal thickness and equal density; or, in general, having such thickness and density as to contain quantities of matter or fluid proportional to their areas.

2. The action of all such sections made by parallel planes, or by planes equally inclined to their axis, are equal.

3. The tendency of a particle P to a plane, or plate of uniform thickness and density, and infinitely extended, or to a portion of it bounded by the same pyramid, is the same, at whatever distance it be placed from the plate, and it is always perpendicular to it.

4. This tendency is proportional to the density and thickness of the plate or plates jointly.

It is only in two or three simple cases that we can propose to state with precision what will be the disposition and action of the electric fluid in bodies; but we shall select those that are most instructive, and connected with the most remarkable and important phenomena.

92 Disposition in parallel plates,

Let A $a\,d$ D (fig. 18.) and E $e\,h$ H represent the sections of a part of two infinitely extended parallel plates (which we shall call A and E), consisting of solid conducting matter, in which the electric fluid can move without any obstruction, but from which it cannot escape.

When both are overcharged,

First, Let them be both overcharged, A containing the quantity r of redundant fluid, and E containing the quantity s, and let r be greater than s.

The fluid will be disposed in the following manner:

1. There will be two strata, A $a\,b$ B and G $g\,h$ H, adjoining to the remote surfaces, in each of which the quantity $\frac{r+s}{2}$ will be crowded together as close as possible.

2. Adjoining to the interior surface (that is, the surface nearest to E) of the plate A, there will be a stratum C $c\,d$ D, containing the quantity $\frac{r-s}{2}$ crowded together.

3. The adjacent side of E will have a stratum E $e\,f$ F, just sufficient for containing the quantity $\frac{r-s}{2}$ at its natural density. This stratum will be entirely exhausted of fluid.

4. The spaces B $b\,c$ C and F $f\,g$ G will be in their natural state.

For a particle of fluid in the space B $b\,c$ C is urged in the direction $a\,d$ by the force $\frac{r+s}{2}$ (n° 91, 3.), and in the direction $d\,a$ by the force $\frac{r-s}{2}$, therefore it is, on the whole, urged in the direction $a\,d$ with the force s, which will balance the repulsion of the redundant fluid in the other plate. A particle of fluid in the space F $f\,g$ G is repelled in the direction $h\,e$ by a force $\frac{r+s}{2}$ by the fluid in G $g\,h$ H, and it is attracted in the same direction by the redundant matter in E $e\,f$ F, with the force $\frac{r-s}{2}$. These make a force r which balances the repulsion r of the other plate. No other disposition will be permanent; for if a particle be taken out from either stratum A $a\,b$ B or C $c\,d$ D into the space between them, the repulsion from that stratum which it quitted is lessened, and the repulsion of the opposite stratum, joined to that of the other plate, will drive it back again. The same thing holds with respect to the fluid in the other plate.

Cor. 1. If the two plates be equally overcharged, all the redundant fluid will be crowded on the remote surfaces, and the adjacent surfaces will be in the natural state. 93.

94 When they are undercharged,

In the *second* place, let the plates be undercharged, and let r be the fluid wanting in A, and s the fluid wanting in E, and let s be greater than r; then,

1. The strata adjoining to A a and H h will be completely exhausted of fluid, and the redundant matter in each will be such as would be saturated by $\frac{r+s}{2}$.

2. The stratum C $c\,d$ D will contain redundant fluid $\frac{s-r}{2}$, crowded close.

3. The stratum E $e\,f$ F will be deprived of fluid, and the quantity abstracted is $\frac{s-r}{2}$.

4. The spaces B $b\,c$ C and F $f\,g$ G are in the natural state.

The demonstration is the same as in the former case.

95 When they are in opposite states,

Thirdly, Let A be overcharged, and E undercharged, A containing the redundant fluid r, and E wanting the fluid s; and let r be greater than s. Then,

1. The strata A $a\,b$ B and G $g\,h$ H contain the redundant fluid $\frac{r-s}{2}$, crowded close.

2. The stratum C $c\,d$ D contains the quantity $\frac{r+s}{2}$, crowded close.

3. The stratum E $e\,f$ F is exhausted, and wants the quantity $\frac{r+s}{2}$.

4. The rest is in the natural state.

Cor. 2. If the redundant fluid in A be just sufficient to saturate the redundant matter in E, the two remote surfaces will be in their natural state, all the redundant fluid in A being crowded into the stratum C $c\,d$ D, and all the redundant matter being in E $e\,f$ F. 96.

This disposition will be the same, whatever is the distance or thickness of the plates, unless the redundant fluid in A be more than can be contained in the whole of E when crowded close.

97 Pressure and tendency to escape.

When the two plates are overcharged, the fluid presses their remote surfaces with the force $\frac{\overline{r+s}^2}{4}$, and would escape with that force if a passage were opened. It would enter the remote surfaces of two undercharged plates with the same force; and, in either case, it would run from the inner surface of one to the adjacent surface of the other, with the force $\frac{\overline{r-s}^2}{4}$.

If one be overcharged and the other undercharged, fluid would escape from the remote surface with the force

force $\frac{\overline{r-s}^2}{4}$, and would run through a canal between them with the force $\frac{\overline{r+s}^2}{4}$.

Mutual actions. They repel or attract each other with the force $\overline{r+s}^2$ according as they are both over or undercharged, or as one is overcharged and the other undercharged.

This example of parallel plates, infinitely extended, is the ſimpleſt that can be ſuppoſed. But it cannot obtain under our obſervation; and in all caſes which we can obſerve, the fluid cannot be uniformly ſpread in any ſtratum, but muſt be denſer near the edges, or near the centre, as they are overcharged or undercharged.

98 Diſpoſition in a ſphere. Let ABD (fig. 19.) repreſent a ſphere of perfectly conducting matter, overcharged with electric fluid, which is perfectly moveable in its pores, but cannot eſcape from the ſphere. Let it be ſurrounded by conducting matter ſaturated with moveable fluid. It is required to determine the diſpoſition of the fluid within and without this ſphere.

Sir Iſaac Newton has demonſtrated (*Princ.* I. 70.) that a particle *p*, placed anywhere within this ſphere, is not affected by any matter that is without the concentric ſpherical ſurface *p q r* in which itſelf is ſituated, therefore not affected by what is between the ſurfaces ABD and *p q r*. He alſo demonſtrates, that the matter within the ſurface *p q r* acts on the particle *p* in the ſame manner as if the whole of it were collected in the centre C.

Hence it follows, that the redundant fluid will be all conſtipated as cloſe as poſſible within the external ſurface of the ſphere, forming a ſhell of a certain minute thickneſs, between the ſpherical ſurfaces ABD and *abd*; and all that is within this (that is, nearer the centre C) will be in its natural ſtate.

With reſpect to the diſtribution of the fluid in the ſurrounding matter, which we ſuppoſe to be infinitely extended, we muſt recollect that this ſhell of conſtipated redundant fluid repels any external particle of fluid in the ſame manner as if all were collected at C. Hence it is evident, that the fluid in the ſurrounding matter will be repelled, and, being moveable, it will recede from this centre; and there will be a ſpace all round the ſphere ABD which is undercharged, forming a ſhell between the concentric ſurfaces ABD and $\alpha\beta\delta$. This ſhell will contain ſuch a quantity of redundant matter, that its attraction for a particle of fluid is equal to the repulſion of the ſhell of fluid crowded internally on the ſurface ABD. All beyond this ſurface $\alpha\beta\delta$ will be in its natural ſtate; for this redundant matter acts on a particle of fluid, ſituated farther from the centre, in the ſame manner as if all this redundant matter were collected in the centre C. So does the redundant fluid in the conſtipated ſhell. Therefore their actions balance each other, and there is no force exerted on any particle of fluid beyond this deficient ſhell. This deficient ſhell will not affect the fluid in the ſphere *a b d* by Newton's demonſtration. No other diſpoſition will be permanent. But farther: This undercharged ſhell muſt be completely exhauſted: for a particle of fluid placed between ABD and $\alpha\beta\delta$ will be more repelled by the fluid in the crowded ſhell within the ſurface ABD, than it is attracted by the redundant matter of its own ſhell that is leſs remote from the centre; and it is not affected by what is more remote from the centre. Therefore the fluid without the ſphere ABD cannot be in equilibrio, unleſs the ſhell between ABD and $\alpha\beta\delta$ be not only rarefied, but altogether exhauſted of fluid.

If the ſphere be undercharged, the ſpace between ABD and *a b d* will be entirely exhauſted of fluid, and there will be a ſhell $\alpha\beta\delta$ of redundant matter ſurrounding the ſphere. All within *a b d*, and all without $\alpha\beta\delta$, will be in its natural ſtate. It is unneceſſary to repeat the ſteps of the ſame demonſtration.

This valuable propoſition is by the Hon. Mr Cavendiſh.

This would be the diſpoſition in and about a glaſs globe filled and ſurrounded with an ocean of water, and having redundant fluid within it, on the ſuppoſition that glaſs is impervious to the electric fluid. But it would not affect an electrometer, even ſuppoſing that the movements of the electrometer could be effected under water. Suppoſe the globe of water to be ſurrounded with air, and that the fluid is diſpoſed in both in the manner here deſcribed; it will be perfectly neutral in its action on any electrometer ſituated in the air. But, by reaſon of the almoſt total immobility of the fluid in pure dry air, this ſtate cannot ſoon obtain; and, till it obtain, the conſtipated ſhell within the glaſs muſt repel the fluid in an electrometer more than the partially rarefied ſhell of air, which ſurrounds the glaſs, attracts it. By the gradual retiring of the fluid in the ſurrounding air from the globe, the attraction of the deſerted matter will come nearer to equality with the repulſion of the conſtipated ſhell within the glaſs, and the globe will appear to have loſt fluid. Yet it may retain all the redundant fluid which it had at the firſt. Therefore we are not to imagine that a body ſimilar to this globe has no redundant electric fluid, or only a ſmall quantity, becauſe we obſerve it inactive, or nearly ſo. 99 Conſequences of this diſpoſition.

Thus we ſee, as we proceed, that the Æpinian theory is adequate to the explanation of the phenomena. But we ſee it much more remarkably in a very familiar and amuſing experiment, uſually called the ELECTRIC WELL. See ELECTRICITY, *Encycl.* Sect. x. 4. 100 Verified by the phenomena. Electric Well explained.

To ſee it in perfection, make a glaſs veſſel of globular ſhape, with a narrow mouth, ſufficiently wide, however, to admit an electrometer ſuſpended to the end of a glaſs rod of a crooked form, ſo that the electrometer can be preſented to any part of the inſide. Smear the outſide of the globe with ſome tranſparent clammy fluid, ſuch as ſyrup. Set it on an inſulating ſtand (a wine glaſs), and electrify it poſitively. Hold the electrometer near it, anywhere without, and it will be ſtrongly affected. Its deviations from the perpendicular (if the ball of the electrometer has alſo been electrified) will indicate a force inverſely as the ſquare of the diſtance from the centre of the globe, pretty exactly, if the thread of the electrometer is of ſilk. Now let down the electrometer into the inſide of the globe. It will not be affected in any ſenſible degree, nor approach or avoid any body that is lying within the globe. The electrometer may be held in all parts of the globe, and when brought out again, is perfectly inactive and neutral. But if the balls of the electrometer be touched with a wire, while hanging free within the globe, they will, on withdrawing the wire, repel each other; and when taken out, they will be found negatively electri-

fied.

fied. The experiment fucceeds as well with a metal globe; nay, even although the mouth be pretty wide; in which cafe, there is not a perfect balance of action in every direction. The electrometer may be made to touch the bottom of the globe, or anywhere not too near the mouth, without acquiring any fenfible electricity; but if we touch the outfide with the electrometer, it will inftantly be electrified and ftrongly repelled. Deep cylinders, and all round veffels with narrow mouths, exhibit the fame faintnefs of electricity within, except near the brims, although ftrongly electric without; and even open metal cups have the interior electricity much diminifhed.

101 Electric bodies are only fuperficially fo.

Reflecting on this valuable propofition of Mr Cavendifh, we fee clearly why an overcharged electric is only fuperficially fo; and that this will be the cafe even although we attempt to accumulate a great quantity of electricity in it, by melting it in a thin glafs globe, and electrifying it while liquid, and keeping up the accumulating force till it becomes quite cold. The prefent writer, not having confidered the fubject with that judicious accuracy that Mr Cavendifh exerted, had hopes of producing a powerful and permanent electric in this way, and was mortified and puzzled by the difappointment, till he faw his miftake on reading Mr Cavendifh's differtation.

Cautions in certain experiments.

Thefe obfervations alfo point out a thing which fhould be attended to in our experiments for difcovering the electricity excited in the fpontaneous operations of nature, as in chemical compofition and decompofition, congelation, fufion, evaporation, &c. It has been ufual to put the fubftances into glafs, or other nonconducting veffels, or into veffels which conduct very imperfectly. In this laft cafe efpecially, the very faint electricity which is produced, inftantly forms a compenfation to itfelf in the fubftance of the veffel, and the apparatus becomes almoft neutral, although there may have been a great deal of electricity excited. It will be proper to confider, whether the nature of the experiment will admit of metalline veffels. In the experiments on metalline folutions, the beft method feems to be, to make the veffel itfelf the fubftance that is to be diffolved.

102 Electricity more nearly proportional to the furface than to the quantity of matter.

For fimilar reafons we may collect, without a more minute examination, that bodies of all fhapes, when overcharged, will have the redundant fluid much denfer near the furface than in the interior parts; and denfer in all elevations, bumps, projections, angles, and near the ends of oblong bodies; and that, in general, the quantity of redundant fluid, or redundant matter, will be much more nearly proportional to the furfaces of bodies than to their quantities of matter. All this is fully proved by experience. The experiment of the electrified chain is a very beautiful one. Lay a long metal chain in an infulated metal difh furnifhed with an electrometer. Let one end be held an inch or two above the coil by a filk thread. Electrify the whole, and obferve the divergency of the electrometer; then, gradually drawing up the chain from the coil, the electrometer will gradually fall lower, and lowering the chain again will gradually raife it.

103. We now fee with how little reafon Lord Mahon concluded that the point of his conductor, obferved to be neutral, correfponded with his theory; namely, one of the media of a harmonic divifion. We fee no reafon for beginning the computation at the extremity of the prime conductor. It certainly fhould not have been from the extremity. Had the prime conductor been a fingle globe, it fhould have begun from the centre of this globe. If it was of the ufual form, with an outftanding wire, terminated by a large ball, the action of the body of the conductor fhould certainly have been taken into the account. In fhort, almoft any point of the long conductor might have been accommodated to his Lordfhip's theory.

We might now proceed to inveftigate the diftribution 104.
of the electric fluid in bodies expofed to the action of others, and particularly in the oblong conductors made ufe of in our preparatory propofitions. The problem is determinate, when the length and diameter of cylindric conductors are given; but even when the electric employed for inducing the electricity is in the form of a globe, we muft employ functions of the diftances that are pretty complex, and oblige us to have recourfe to fecond fluxions. The mutual actions of two oblong conductors, of confiderable diameters, give a problem that will occupy the firft mathematicians; but which is quite improper for this fcanty abftract. Nor is a minute knowledge of the difpofition of the fluid of very important fervice. We may therefore content ourfelves with a general reprefentation of the ftate of the fluid in the following manner, which will give us a pretty diftinct notion how it will act in moft cafes:

General reprefentation of the difpofition of the fluid.

Let A (fig. 20.) be an overcharged fphere, and BC a conducting cylindric or prifmatic body; draw $b\,c$ parallel to BC, and erect perpendiculars B b, C c, P p, &c. to reprefent the equable denfity of the fluid, when the conductor is in its natural ftate; but let B d, C r, P s, &c. reprefent the unequal denfities in its different points, while in the vicinity of the overcharged fphere. Thefe ordinates muft be bounded by a line $d\,n\,r$, which will cut the line $b\,c$ in the point n of the perpendicular, drawn from the neutral point N of the conductor. The whole quantity of fluid in the conductor is reprefented by the parallelogram BC $c\,b$; which muft therefore be equal to the fpace BC $r\,n\,d$: the redundant fluid in any portion CP or PN is reprefented by the fpaces $c\,r\,t\,p$, or $t\,p\,n$; and the redundant matter, or deficient fluid, in any portion BQ, is reprefented by $b\,d\,v\,q$. The action of this body on any body placed near it, depends entirely on the area contained between this curve line and its axis $b\,c$. The only circumftance that we can afcertain with refpect to this curve is, that *the variations of curvature* in every point are proportional to the forces exerted by the fphere A; and are therefore inverfely as the fquares of the diftances from A. This property will be demonftrated by and bye. The place of n, and the magnitude of the ordinates, will vary as the diameter of the conductor varies. We fhall confider this a little more particularly in fome cafes which will occur afterwards. We may confider the fimpleft cafe that can occur; namely, when the conductor is, like a wire, of no fenfible diameter, nay, as containing only one row of particles.

In a very flender canal the fluid muft be almoft equally diftributed.

Let AE (fig. 21.) be fuch a flender conducting canal; and let B b, C c, E e, &c. reprefent the denfity of the fluid which occupies it, being kept in this ftate of inequable denfity by the repulfion for fome overcharged body. A particle in C is impelled in the direction CE by all the fluid on the fide of A, and in the direction

direction CA by all the fluid on the side of E. The moving force, therefore, arises from the difference of these repulsions. When the diameter of the canal is constant, this arises only from the difference of density. The force of the element adjacent to E may therefore be expressed by the excess of D d above C c, and the action at the distance CD jointly. Therefore, drawing $\beta c \varepsilon$ parallel to AE, this force of the element E will be expressed by $\frac{d\delta}{c\delta^2}\dot{x}$, repelling the particle in the direction CA. If CF be taken equal to CD, the force of the element at F will be expressed by $\frac{f\varphi}{c\varphi^2}\dot{x}$, or $\frac{f\varphi}{c\delta^2}\dot{x}$, also impelling the particle in the direction CA. The joint action of these two elements therefore is $\frac{d\delta + f\varphi}{c\delta^2}\dot{x}$. If $b c e$ were a straight line, we should have $d\delta + f\varphi$ always proportional to $c\delta$; and it might be expressed by $m \times c\delta$; m being a number expressing what part of $c\delta$ the sum of $d\delta$ and $f\varphi$ amounts to (perhaps $\frac{1}{10}$th, or $\frac{1}{20}$th, or $\frac{1}{30}$th, &c.). But in the case expressed in the figure, $d\delta$ does not increase so fast as $c\delta$, and $f\varphi$ increases faster than $c\delta$. However, in the immediate neighbourhood of any point C, we may express the accelerating force tending towards A by $\frac{mc\delta}{c\delta^2}\dot{x}$, without any sensible error; that is, by $m\frac{\dot{x}}{x}$; that is, by the fluxion of the area of a hyberbola HD′G, having CC′ and CK for its assymptotes; and the whole action of the fluid between F and D, on the particle C, will be expressed by the area C′GDD′H. Hence it follows, that the action of the smallest conceivable portion of the canal immediately adjoining to C on both sides, or the difference of the actions of the two adjoining elements, is equal to the action of all beyond it. This shews, that the state of compression is hardly affected by any thing that is at a sensible distance from C; and that the density of the fluid, in an indefinitely slender canal, is, to all sense, uniform. The geometer will also see, that the second fluxion of D d is proportional to the force of the distant body. We learn, therefore, so much of the nature of the curve $b c e$.—(*Coulomb*).

We are now in a condition to examine the communication of electricity by means of conducting canals (which is one of the most important articles of the study,) having found that the fluid, in a very slender canal, is very nearly of uniform density throughout.

106
Communication and transference by canals.

There can be no doubt but that, if a body B (fig. 22.) be overcharged or undercharged, any other body C, which communicates with it by a conducting canal, will also be overcharged or undercharged. It is as evident, that if a body, in any state of electricity, be in the neighbourhood of an overcharged or undercharged body A, while it communicates with C by a canal leading from the side most remote from A, fluid will be driven from B into C, or abstracted from C into B.

107
By crooked canals.

It is not, however, so clear, that when the canal leads from the side nearest to A (as in fig. 23.), fluid will be driven from B into C. We conceive the fluid to be moveable in the body and in this canal, but not to escape from it. Its motion, therefore, in this case, should, in the opinion of Mr Cavendish, resemble the running of water in a syphon by the pressure of the air. While the repulsion of the redundant fluid in A allows the bend of the syphon nearest to A to retain fluid, a current should take place from B along the short leg, in consequence of the superior action on the fluid in the long leg. But if the repulsion of A can drive the fluid out of the bend between B and F, Mr Cavendish thinks, that it does not appear that fluid will come up from B in opposition to the repulsion of A, and then run along to D. But fluid does not move, in either of these cases, on the principle of a syphon; because there is nothing to hinder the fluid from expanding in the part EDF. And we are rather disposed to think, that it will always move from B, over the bend, to C; For even if the fluid can be completely driven out of the bend EF, it must be done by degrees, and the fluid in the long leg will, from the very beginning of the action of A, be more moved from its place than that in the short leg; and therefore will yield to the compression, which acts transversely, and, by thus yielding more toward F than toward E, the fluid will rush through the contracted part, and go into C. We do not say this with full confidence; but are thus particular, on account of an important use that may be made of the experiment. For if the body A be undercharged, fluid will certainly be attracted from C, and pass over the bend into B, however great the action of A may be. Perhaps this may be so contrived, therefore, as to decide the long agitated question, *Whether the electricity of excited glass be plus or minus?* If it be found that this apparatus, being presented to the rubber of an electrical machine, diminishes the positive electricity of C, and increases that of B; but that, presenting the same apparatus to the prime conductor, makes little change—we may conclude, that the electricity of the prime conductor is positive. We have tried the experiment, paying attention to every circumstance that seemed likely to insure success; but we have always found hitherto, that the apparatus was equally affected by both electricities.

Proposal for discovering redundancy of fluid.

We must now consider the action of electrified bodies on the canals of communication; because this will give us the easiest method of ascertaining the proportion in which the expelling fluid is distributed between them. For when two bodies communicate by a canal, and have attained a permanent state, we must conceive that their opposite actions on the fluid moveable along this canal are in equilibrio, or are equal. This will generally be a much easier problem than their action on each other, since we have seen a little ago, that the fluid in a slender canal is of uniform density very nearly. A very few examples of the most important of the simple cases must suffice.

108
Action of a plate on a rectilineal canal.

Therefore let AC a (fig. 24.) represent the edge of a thin conducting circular plate, to which the slender canal CP is perpendicular in the centre. It is required to determine the action of the matter or fluid, uniformly spread over this plate, on the fluid moveable in the canal PC?

1. Required the action of a particle in A on the fluid in the whole canal? Join AP; and call CP x, 109
AP y, and AC r; and let f express the intensity of action at the distance 1, or the unit of the scale on which the lines are measured.

The action of A on P, in the direction AP, is $\frac{f}{y^2}$. This,

This, when estimated in the direction CD, is reduced to $\frac{f}{y^2} \times \frac{x}{y}$; and is therefore $= f\frac{x}{y^3}$. Therefore the fluxion of the action, in the direction CP, on the whole canal, is $f\frac{x}{y^3}\dot{x} = f\frac{y\dot{y}}{y^3}$ (because $x : y = \dot{y} : \dot{x}$) $= f \times \frac{\dot{y}}{y^2}$. The variable part of the fluent is $= f\frac{-1}{y}$, and the complete fluent is $= f\left(C - \frac{1}{y}\right)$, where C is a constant quantity, accommodated to the nature of the case. Now, the action must vanish when the canal vanishes, or when $x = 0$, and $y = r$. Therefore $C - \frac{1}{r} = 0$, and $C = \frac{1}{r}$; and the general expression of the action is $f\left(\frac{1}{r} - \frac{1}{y}\right), = f\frac{y-r}{ry}$, expressing the action of a particle in the circumference of the plate on the fluid in the whole canal CP.

110 2. Required the action of the plate, whose diameter is A a, on the particle P?

1. On a single particle in the canal.

Let a represent the area of a circle, whose diameter is $= 1$. Then ar^2 is the area of the plate, and $2ar\dot{r}$ is the fluxion of this area: because $r : y = \dot{y} : \dot{r}$, $2ar\dot{r}$ is $= 2ay\dot{y}$. Therefore the fluxion of the action of the plate on the particle P is $f \times 2ay\dot{y} \times \frac{x}{y^3} = 2fa\,x \times \frac{\dot{y}}{y^2}$. The fluent of this has for its variable part $2fax \times \frac{-1}{y}$ (for when the particle P is given, x does not vary). This is $= 2fa \times \frac{-x}{y}$. To complete this fluent, we must add a constant quantity, which shall make the fluent $= 0$ when the particle P is at an infinite distance; and therefore when $x = y$. Therefore $\frac{y}{y} - \frac{x}{y} = 0$, or $1 - \frac{x}{y} = 0$, or $C = 1$; and the complete fluent for the whole plate is $2fa\left(1 - \frac{x}{y}\right)$.

111. The meaning of this expression may not occur to the reader: For $1 - \frac{x}{y}$ is evidently an abstract number; so is a. Therefore the expression appears to have no reference to the size of the plate. But this agrees with the observation in n° 91. where it was shewn that, provided the angle of the cone or pyramid remained the same, the magnitude of the base made no change in its attraction or repulsion for a particle in the vertex.

It will appear by and bye, that $1 - \frac{x}{y}$ is a measure or function of a certain angle of a cone.

Cor. If PC be very small in proportion to AC, the action is nearly the same as if the plate were infinite: For when the plate is infinite, $\frac{x}{y}$ is $= 0$, and the action is $= 1$, whatever is the distance (see n° 91—93.) Therefore, when x is very small in comparison of r, and consequently of y, $1 - \frac{x}{y}$ is very nearly $= 1$.

3. To find the action of the plate on the whole column? 112

2. On the whole canal.

The fluxion of this must be $= 2fa \times \left(1 - \frac{x}{y}\right)\dot{x}$, or $2fa\left(\dot{x} - \frac{x\dot{x}}{y}\right)$, or $2fa \times (\dot{x} - \dot{y})$; because $\dot{y} = \frac{x\dot{x}}{y}$. The fluent of this has for its variable part $2fa \times (x - y)$. A constant quantity must be added, which shall make it $= 0$ when the column $= 0$; that is, when $y = r$, and $x = 0$; that is, $C - r = 0$, and $C = r$. Therefore the complete fluent is $= 2fa\,(x + r - y$.

Thus we have arrived at a most simple expression of the attraction or repulsion of a plate for such a column, or for portions of such a column. And it is most easily constructed geometrically, so as to give us a sensible image of this action of easy conception and remembrance. It is as follows: Produce PC till CK = CA, and about the centre P describe the arch AI, cutting CK in I. Then $2fa \times$ IK is evidently the geometrical expression of the attraction or repulsion. This is plainly a cylinder, whose radius is a unit of the scale, and whose height is twice IK. 113

Geometrical expression of these actions.

In like manner, by describing the arch Ai round the centre p, we have $2fa \times i$K for the action of the plate on the small column Cp; and $2fa \times$ Ii is the action of the plate on the portion Pp.

The general meaning of the expression $2fa \times$ IK is, that the action of the whole plate on the column PC is the same as if all the fluid in the cylinder $a \times 2$IK, were placed at the distance 1 from the acting particle.

From this proposition may be easily deduced some very useful corollaries by the help of the geometrical construction.

1. If PC be very great in comparison with AC, the action is nearly the same as if the column were infinitely extended; for in this case IK is very nearly = CK, the difference being to the whole nearly as AC to twice AP. 114.

2. If, in addition to this last condition, another column pC be very small in comparison of AC, then the action on PC is to that on pC very nearly as pC to AC. For it will appear that iK : IK = pC : AC very nearly. It is exactly so when CP : CA = CA : Cp; and it will always be in a greater proportion than that of pC to IK. 115

Important corollary.

This will be found to be a very important observation.

The redundant fluid has hitherto been supposed to be uniformly spread over the plate: but this cannot be; because its mutual repulsion will cause it to be denser near the circumference. We have not determined, by a formula of easy application, what will be the variation of density. Therefore let us consider the result of the extreme case, and suppose the whole redundant fluid to be crowded into the circumference of the plate, as we saw that it must be on the surface of a globe.

In this case, the action on the fluid in the canal will be $fa\left(r - \frac{r^2}{y}\right)$. For the area of the plate is ar^2, and the 116

Action of a circumference on a canal.

the action of a particle in the circumference on the whole canal was ſhewn (n°109.) to be $f\left(\frac{y-r}{ry}\right)$. Therefore the action of the whole fluid crowded into the circumference is $f\,a\,r^2 \times \frac{y-r}{ry}$, $= f\,a\,r\frac{y-r}{y}$. It may be repreſented as follows: Deſcribe the quadrant CbBE, cutting AP and Ap in B and b. Draw BD and bd parallel to PC. Then PB $= y - r$, and DC $= r\,\frac{y-r}{y}$. Therefore the action is repreſented by f multiplying a cylinder, whoſe radius is 1 and height is DC. In like manner, dC is the height of the cylinder correſponding to the column pC, and Dd the height correſponding to Pp.

117. *Cor.* 1. When CP is very great in compariſon with CA, the point D is very near to A, and I is very near to C, and CD is to IK nearly in the ratio of equality. In this caſe the action of the fluid, uniformly ſpread over the plate, is nearly double of the action of the ſame fluid crowded round the circumference; for they are as cylinders, having the ſame baſes and heights in the ratio of 2 IK to DC, which is nearly the ratio of 2 to 1.

118. 2. On the other hand, when the column pC is very ſhort, the action of the fluid ſpread uniformly over the plate is to its action, when crowded round the circumference, nearly in the ratio of 4 AC to pC. For theſe actions are in the ratio of $2fa \times i$K to $1fa \times d$C, or as 2 iK to dC, or nearly as 2 pC to dC, or more nearly as 2 bd to dC. But Cd : bd = bd : bA + Ad, or nearly = bd : 2 CA. Therefore Cd : 2 bd = pC : 4 CA nearly.

119. Hence we ſee that the action on ſhort columns is much more diminiſhed by the receſs of the redundant fluid toward the circumference than that on long columns. Therefore, any external electric force which tends to ſend fluid along this canal, and from thence to ſpread it over the plate, will ſend into the plate a greater quantity of fluid than if the fluid remained ultimately in a ſtate of uniform diſtribution over its ſurface; and that the odds will be greater when the canal is ſhort.

120 Equivalent centre of action.

Laſtly, on this ſubject. If KL be taken equal to AP, or PL be equal to KI, the repulſion which all the fluid in the plate, collected in K, would exert on the fluid in the canal CL, is equal to the repulſion which the ſame fluid, conſtipated in the circumference, would exert on the column CP. For we have ſeen that the action of a particle in A, on the whole column PC, when eſtimated in the direction PC, is $\frac{y-r}{yr}$; and it is well known that the action of a particle in K for the column CL is $\frac{1}{\text{KC}} - \frac{1}{\text{KL}}$, or $\frac{1}{r} - \frac{1}{y}, = \frac{y-r}{yr}$. Therefore the action of the whole fluid, collected in the circumference, on the column CP, is equal to that of the ſame fluid, collected in K, on the columns CL.

121. *Cor.* 1. If the column CP is very long in proportion to AC or KC, the actions of the fluids in theſe two different ſituations are very nearly the ſame. The action of the fluid collected in K exceeds its action when collected in A only by its action on the ſmall and remote column LP. The action of all the fluid collected at K on the column CP, is eaſily had by taking Cl = KP. It is equal to the action of the ſame fluid placed in A on the column Cl.

Cor. 2. The action of all the fluid uniformly ſpread, exerted on the column CP, is to the action of the ſame fluid collected in K, exerted on the column CL, as 2 IK to CD. 122.

If the column CP is very great in proportion to AC, the half breadth of the plate, the action in the firſt caſe is very nearly double of the action in the other caſe, and is exactly in this proportion if CP is of infinite extent. 123.

124 Action of a ſpherical ſurface, or ſhell, or ſolid, on the ſame canal.

Cor. 3. If CNO be a ſpherical ſurface or ſhell of the ſame thickneſs and diameter as the plate Aa, and containing redundant fluid of the ſame uniform denſity, the action of this fluid on the column CL is double of the action of the fluid uniformly ſpread over the plate on the column CP, and quadruple of the action of the fluid collected in the circumference: for the action is the ſame as if all were collected in the centre K, and the ſurface of the ſphere is four times that of the plate, and therefore they are as IK to 2 CD.

Let us now conſider the comparative actions of different plates or ſpheres on the canals.

125 Action of two plates, or two ſpheres, are as their diameters, when the canals are infinitely long.

If two circular plates, DE, de (fig. 25.), or two ſpherical ſhells, ABO, abo, of equal diameters and thickneſs with the plates, and containing redundant fluid of equal denſity, communicate with infinitely extended ſtraight canals OP, op, paſſing through their centres perpendicular to their ſurfaces, alſo containing fluid uniformly diſtributed and of equal denſity—the repulſions will be as the diameters. For the repulſion of the ſpherical ſurfaces is the ſame as if all the fluid were collected at their centres; and the repulſion of the fluid uniformly ſpread over the ſurfaces of the plates is double of its repulſion if collected at the centres of theſe ſpheres; it follows, that the repulſions of the plates are proportional to thoſe of the ſpheres. But becauſe the repulſion of a plate whoſe radius is r was ſhewn to be $= 2a \times \overline{r + x - y}$, and when the column is infinitely extended, x is equal to y, and $\overline{r + x - y} = r$, it follows, that the repulſions of the plates are as $2a \times$ R and $2a \times r$, or proportional to their diameters. Therefore the repulſions of the ſpheres are in the ſame proportion.

Cor. 1. If the canals are very long in proportion to the diameters of the plates or ſpheres, the repulſions are nearly in the ſame proportion. 126.

127 The proportion of the greateſt action is diminiſhed if the canals are ſhort.

Cor. 2. But as the lengths of the canals diminiſh, the repulſions approach to equality; for it was ſhewn, that when the canal was very ſmall, the repulſion was to that for an infinite column as the length of the canal to the radius of the plate. Therefore if the radius of the greater plate be (for example) double of that of the ſmaller, and the little column be $\frac{1}{10}$th of the radius, it will be $\frac{1}{10}$th of the radius of the ſmaller plate. Now $\frac{1}{10}$th of half the repulſion is equal to $\frac{1}{10}$th of the double repulſion. Alſo, in the caſe of the ſpheres, the repulſion of a particle at the ſurface is as the quantity of fluid directly, and as the ſquare of the radius inverſely; but when the denſity is the ſame in both ſhells, the quantity is as the ſurface, or as the ſquare of the radius. Therefore the repulſions are equal.

Cor. 3. If the denſity of the fluid in two ſpherical ſhells be inverſely as the diameters, the repulſions for an infinitely

128 infinitely extended column of fluid are equal; for each repels as if all the fluid was collected in the centre. Therefore, if the density, and consequently the quantity, be varied in any proportion, the repulsion will vary in the same proportion. The repulsions will now be as $CO \times \frac{1}{CO}$ to $co \times \frac{1}{co}$, or in the ratio of equality.

Actions of two spheres are equal if the density be inversely as the diameters;

129 *Cor.* 4. When the quantities of redundant fluid in two spheres are proportional to their diameters, their repulsions for an infinitely extended canal are equal: for if this redundant fluid is constipated in the surfaces of the spheres, as it always will be when they consist of conducting matter, the densities are as the diameters inversely, because the surfaces are as the squares of the diameters. Therefore, by the last corollary. their actions on an infinitely extended canal are equal. But in spheres of nonconducting matter it may be differently disposed, in concentric shells of uniform density. This makes no change in the action on the fluid that is without the sphere, because each shell acts on it as if it were all collected in the centre. Therefore the repulsions are still equal.

Or if the quantity of redundant fluid be as the diameters.

130 *Cor.* 5. Two overcharged spheres, or spherical shells, OAB, *oab* (fig. 26.), communicating by an infinitely extended canal of conducting matter, contain quantities of redundant fluid proportional to their diameters; for their actions on the fluid in the interjacent canal must be in equilibrio, and therefore equal. This will be the case only when the quantities of fluid are in the proportion of their diameters.

Two spheres overcharged in this proportion are in equilibrio if communicating by a very long canal.

When the canals are very long in proportion to the diameters of the spheres, the proportion of the quantities of redundant fluid will not greatly differ from that of the diameters.

131. *Cor.* 6. When the spheres of conducting matter are thus in equilibrio, the pressures of the fluid on their surfaces are inversely as their diameters; for the repulsion of a particle at the surface is the same with the tendency of that particle from the centre of the sphere, the actions being mutual. Now this is proportional to the quantity of redundant fluid directly, and to the square of the distance from the centre inversely, that is, to the diameter directly, and to the square of the diameter inversely, that is, to the diameter inversely.

Tendency of the fluid to escape is inversely as the diameter.

Hence it follows, that the tendency to escape from the spheres is inversely as the diameter, all other circumstances being the same: for in as far as the escape proceeds from mere electric repulsion, it must follow this proportion. But there are evident proofs of the co-operation of other physical causes. We observe chemical compositions and decompositions accompanying the escape of electric fluid, and its influx into bodies: we are ignorant how far, and in what manner, these operations are affected by distance. Boscovich shews most convincingly, that the action of a particle (of whatever order of composition), on external atoms and particles, is surprisingly changed by a change in the distance and arrangement of its component atoms. A constipation, therefore, to a certain determined degree and lineal magnitude, may be necessary for giving occasion to some of those chemical operations that accompany, and perhaps occasion, the escape of the electric fluid. If this be the case (and it is *demonstrable* to be possible, if the operations of Nature be owing to attractions and repulsions), the escape *must* be desultory. It is actually so; and this confirms the opinion.

The public is indebted to Mr Cavendish for the preceding theorems on the action of spheres and circular plates. He has given them in a more abstract and general form, applicable to any law of electric action which experience may warrant. We have accommodated them to the inverse duplicate ratio of the distances, as a point sufficiently established; and we hope that we have rendered them more simple and perspicuous. We have availed ourselves of Mr Coulomb's demonstration of the uniform density in the canal, without which the theorems could not have been demonstrated. The minute quantity of the fluid in the canal can have no sensible effect on the disposition or proportion of the fluid in the plates or spheres.

It may be thought that the last corollary, respecting the equilibrium of two spheres, is not agreeable to hydrostatical principles, which require the equality of the two forces which balance each other at the orifices of the slender cylindric canal; whereas, in that corollary, the forces at the extremities of the canal are inversely as the diameters of the spheres or plates. This would be a valid objection, if the compressing forces acted only on the extremities of the canals; but they act on every particle through their whole length. It is not, therefore, the pressure at one end of the canal that is in equilibrio with the pressure at the other end, by the interposition of the fluid. It is the pressure at one end, together with the sum of all the intermediate pressures in that direction, that is in equilibrio with all the pressure in the opposite direction. The pressures at the ends are only parts of the whole opposite pressures; they are the first in each account. In this manner a slender pipe, having a ball at each end, may be kept filled with mercury, while lying horizontal, if the air in each ball is of equal density. But if it be raised perpendicular to the horizon, it cannot remain filled from end to end, unless the air of the ball below be made so elastic by condensation, that its pressure on the lower orifice of the pipe exceed the pressure of the air in the upper ball on the other orifice by a force equal to the weight of the mercury, that is, to the aggregate of the action of gravity on each particle of mercury in the pipe. Therefore the repulsions of the spheres that we are speaking of are in equilibrio by the intervention of the fluid in the canal, in perfect consistency with the laws of hydrostatical pressure.

This proposition agrees with hydrostatical laws.

Mr Cavendish has pursued this subject much farther, and has considered the mutual action of more than two bodies, communicating with each other by canals of moveable fluid uniformly dense. But as we have not room for the whole of his valuable propositions, we selected those which were elementary and leading theorems, or such as will enable us to explain the most important phenomena. They are also such, as that the attentive reader will find no difficulty in the investigation of those which we have omitted.

Mr Cavendish's most general proposition is as follows: 132

General proposition with respect to the state of communicating bodies.

When an overcharged body communicates, by a canal of *very great* length, straight or crooked, with two or more similar bodies, also at a very great distance from each other, and all are in electric equilibrium, and consequently

consequently each body overcharged in a certain determined proportion, depending on its magnitude, if any two of these bodies are made to communicate in the same manner, their degrees of electricity are such, that no fluid will pass from one to the other, their mutual actions on the fluid in this canal being also in equilibrio. He brings out this by induction and combination of the single cases, each of which he demonstrates by means of the following theorem:

133 It is indifferent whether the canal be straight or crooked.

The action of an overcharged sphere ACB (fig. 25.) on the fluid in the whole of a canal *d f* P that is oblique, tending to impel the fluids in the direction of that canal, is equal to its action on the fluid in the whole of the rectilineal canal CP. Let *h i* be a minute portion of the straight canal, and *f d* the portion of the crooked canal which is equidistant from the centre C of the sphere; draw the radii C*f*, C*d*, and the concentric arches *h f*, *i d*, cutting *f* C in *g*; and draw *g e* perpendicular to *f d*; the force acting on *i h*, impelling it toward P, may be represented by *h i*. The same force acting on *d f*, in the direction *c f*, must therefore be expressed by *g f*. This, when estimated in the direction of the canal *d f*, is reduced to *e f*; but it is exerted on each particle of *d f*. Now $df : gf = gf : ef$, and $df \times ef = gf^2, = gf \times hi$; therefore the whole force on *d f*, in the direction *d f*, is equal to the force on *i h*, in the direction *i h*. Hence the truth of the proposition is manifest.

We beg the curious reader to apply this to the case in hand, and he will find that the most complicated cases may all be reduced to the simple ones which we have demonstrated to be strictly true when the bodies are spheres or plates, and the canals infinitely long, and which are very nearly true when the canals are *very long*, and the bodies similar: And we now proceed to one compound case more, which includes all the most remarkable phenomena of electricity.

134 Curious and very important case of four plates.

Let HK, AB, DF, and LM (fig. 27.), be four parallel and equal circular plates, two of which, HK and AB, communicate by a canal GC of indefinite extent, joining their centres, and perpendicular to their planes; let DF and LM be connected in the same manner, and let the two canals be in one straight line; let the plate HK be overcharged, and the plate LM just saturated. It is required to determine the disposition and proportion of the electric fluid in the plates which will make this condition of HK and LM possible and permanent, every thing being in equilibrio?

The plate HK being overcharged, and communicating with AB, AB must be overcharged in the same manner; and being also equal to HK, it must be overcharged in the same degree, containing an equal quantity of redundant fluid disposed in the same manner. To simplify the investigation, we shall first suppose that the redundant fluid is uniformly spread over the surfaces of both.

When the plates HK and AB are in this state, let the plates DF and LM be brought near them, as is represented in the figure, CE being the distance of the centres of AB and DF. It is evident that the redundant fluid in AB will act on the natural moveable fluid in DF, and drive some of it along the canal EN, and render LM overcharged. Take off this redundant fluid in LM. This will diminish or annihilate the repulsion which it was beginning to exert on the canal EN; therefore more fluid will come out of DF, and again render LM overcharged. The redundant fluid in LM may again be taken off, in less quantity than before, as is plain. Do this repeatedly till no more can be taken off. But this will undoubtedly render DF undercharged, and it will now contain redundant matter. This will act on the fluid in the canal GC, and abstract it from G; therefore fluid will come out of HK into AB. HK will be less overcharged than before, and AB will be more overcharged. But the now increased quantity of redundant fluid in AB will act more strongly on the moveable fluid in DF, and drive more out of it. This will leave more redundant matter in it than before, and this will act as before on the fluid in the canal GC. This will go on, by repeatedly touching LM, till at last all is in equilibrio. Or this ultimate state may be produced at once by allowing LM to communicate with the ground. And now, in this permanent state of things, HK contains a certain quantity of redundant fluid; AB contains a greater quantity; DF contains redundant matter; and LM contains its natural quantity. The demand of the problem therefore is to determine the proportion of the redundant fluid in HK to that in AB, and the proportion of the redundant fluid in AB to the deficiency of fluid in DF. The dynamical considerations which determine these proportions are, 1*st*, The repulsion of the redundant fluid in AB, for the fluid in the canal EN, must be precisely equal to the attraction of the redundant matter in DF for the same fluid in the canal; for LM, being saturated, is neutral. 2*d*, The repulsion of the redundant fluid in HK, for the whole fluid in the canal GC, must balance the excess of the repulsion of the redundant fluid in AB above the attraction of the redundant matter in DF for the same.

Let the redundant fluid in AB be $= f$.
the redundant matter in DF $= m$.
the redundant fluid in HK $= F$.

Because HK and AB are equal, there can be no doubt but that the fluid in those plates would be similarly disposed; and it is highly probable, that if AB be very near DF, the redundant fluid in AB, and the redundant matter in DF, will also be disposed nearly in the same manner. This will appear plainly when we consider with attention the forces acting between a very small portion of AB and the corresponding portion of DF. The probability that this is the case is so evident, that we apprehend it unnecessary to detail the proofs. We shall afterwards consider some circumstances which shew that the disposition in the three plates will (though nearly similar) be nearer to a state of uniform distribution than if only AB and HK had been in action. Assuming therefore this similarity of distribution, it follows, that their actions on the fluid in the canals will be similar, and nearly proportional to their quantities.

Therefore let 1 be to *n* as the repulsion of the fluid in AB, for the fluid that would occupy CE, is to its repulsion for the fluid in EN or CG.

Then the action of AB on EN is $f \times \overline{n-1}$, and the action of DF on EN is mn; therefore, because the plate LM is inactive, the actions of AB and DF on EN must balance each other, and $f \times \overline{n-1} = mn$, and $m = f \times \frac{n-1}{n}$.

The

The repulsion of f for the fluid in CG is fn. The attraction of m for it is $m \times \overline{n-1}$; and because $m = f \times \frac{n-1}{n}$, the attraction of m for the fluid in CG is $f \times \frac{\overline{n-1}}{n} \times \overline{n-1}$. Therefore the repulsion of f is to the attraction of m as fn to $f \times \frac{\overline{n-1}^2}{n}$, or as fn^2 to $f \times \overline{n-1}^2$, or as n^2 to $\overline{n-1}^2$. Call the repulsion of f r, and the attraction of m a.

We have $r : a = n^2 : \overline{n-1}^2$

and $r : r - a = n^2 : n^2 - (n-1)^2 = n^2 : 2n - 1$.

Therefore, because the repulsion of F is equal to this excess of r above a, we have $n^2 : 2n - 1 = f : \text{F}$, and $\text{F} = f \frac{2n-1}{n^2}$, or $f = \text{F} \frac{n^2}{2n-1}$. Therefore, if n^2 is much greater than $2n - 1$, the quantity of redundant fluid in AB will be much greater than the quantity in HK.

135 Prodigious accumulation of redundant fluid; Now, when the electric action is inversely as the square of the distance, and EC is very small in comparison with AC, we have seen (n° 115.) that $1 : n$ nearly $=$ CE : CA, or that n is nearly $\frac{\text{AC}}{\text{EC}}$. When this is the case, and consequently n is a considerable number, we may take the number $\frac{n^2}{2n}$ or $\frac{n^2}{2n-1}$ without any great error. In this case f is equal to $\text{F} \times \frac{n}{2}$ very nearly. Suppose CA to be six inches, and CE to be $\frac{1}{20}$th of an inch; this will give $n = 120$, and $f = 60$ F; or, more exactly, $\text{F} = \frac{n^2}{2n-1} = \frac{14{,}400}{239}$; $= 60\frac{1}{4}$. If, instead of the plate HK, we employ a globe of the same diameter, f will be but half of this quantity, or $f = \text{F} \times \frac{n}{4}$ (n° 123, 124.)

136 And evacuation: It also appears, that when the plates AB and DF are very near to each other, and consequently n a large number, the deficiency in DF is very nearly equal to the redundancy in AB. In the example now given, m is $\frac{59}{60}$ of f, being $= f \times \overline{n-1}$.

137 Yet no very sensible appearance. Yet this great deficiency in DF does not make it electrical on the side toward LM. It is just so much evacuated that a particle of fluid at its surface has no tendency to enter or to quit it.

Lastly, this great quantity of fluid collected in AB does not render it more electrical than HK.

In general, things are in the condition treated of in n° 22, 23, &c.

The attentive reader will readily see, that this account of the apparatus of four plates is only an approximation to the condition that readily obtains under our observation. Our canals are not of indefinite length, nor occupied by fluid that is distributed with perfect uniformity; nor is the fluid uniformly spread over the surface of the plates. He will also see, that the real state of things, as they occur in our experiments, tends to diminish the great disproportion which this imaginary statement determines. But when the canals are very long in comparison with the diameters of the plates, and AB is very near to DF, the difference from this determination is inconsiderable. We shall note these differences when we consider the remarkable phenomena that are explained by them.

In the mean time, we shall just mention some simple consequences of the present combination of plates.

138 Method of destroying this great accumulation: 1. By degrees; Suppose AB touched by a body. Electric fluid will be communicated; but by no means all the redundant fluid contained in AB: only as much will quit it as will reduce it to a neutral state, if the body which touches it communicates with the ground; that is, till the attraction in the redundant matter in DF attracts fluid on the remote side of AB as much as the redundant fluid left in AB repels it. When this has been done, DF is no longer neutral; for the repulsion of AB for the fluid in EN is now diminished, and therefore the attraction of DF will prevail. If we now touch DF, it may again become neutral with respect to EN; but AB will now repel again the fluid in CG, and again be electric on that side by redundancy. Touching AB a second time takes more fluid from it, and DF again becomes electric by deficiency, and attracts fluid on that side.—And thus, by repeatedly touching AB and DF alternately, the great accumulation of fluid in AB may be exhausted, and the nearly equal deficiency in DF may be made up.

139 2. All at once. But this may be done in a much more expeditious way. Suppose a slender conducting canal $a\,b\,d$ brought very near to the outsides of the plates, the end a being near to A, and the end d to D. The vicinity of a to A causes the fluid in ab to recede a little from a by the repulsion of the redundant fluid in AB. This will leave redundant matter in a, which will strongly attract the redundant fluid from A, and a may receive a spark. But the consequence, even of a nearer approach of the fluid to the outward surface of A, will render the corresponding part of DF more attractive, and the retiring of fluid from a along $a\,b$ will push some of its natural fluid toward d; and thus A becomes more disposed to give out, and a to take it in, while d is disposed to emit, and D to attract. Thus every circumstance favours the passage of the whole, or almost the whole, redundant fluid to quit AB at A, to go along $a\,b\,d$, and to enter into DF at D.

140 The plates strongly attract each other. It is plain that there must be a strong tendency in the fluid in AB to go into DF, and that the plates must strongly attract each other. A particle of fluid situated between them tends toward DF with a force, which is to the sole repulsion of AB nearly as twice the redundant fluid in it to what it would contain if electrified to the same degree while standing alone.

With this particular and remarkable case of induced electricity, we shall conclude our explanation of Mr Æpinus's Theory of Electric Attraction and Repulsion. The reader will recollect, that we began the consideration of the disposition of the electric fluid in bodies, in order to deduce such legitimate consequences of the hypothetical law of action as we could compare with the phenomena.

141 Method of examining the validity of this theory. These comparisons are abundantly supplied by the preceding paragraphs, particularly by n° 74, 75, 76; by n° 130, and by n° 134.

Let a smooth metal sphere be electrified positively in any manner whatever, and then touch it with a small one

one in its natural ſtate. The redundant fluid is divided between them in a proportion which the theory determines with accuracy. By the theory alſo the redundant fluid in both acts as if collected in the centre. Therefore the proportion of the repulſions is determined. Theſe can be examined by our electrometer. But as this menſuration may be ſaid to depend on the truth of the theory, we may examine this independent of it. Let the balls be equal. Then the redundant fluid is divided equally between the bodies, whatever be the law of action. Therefore obſerve the electrometer, as it is affected by the electrified body, both before and after the communication. This will give the poſitions of the electrometer which correſpond to the quantities 2 and 1.

142 Graduation of electrometer. Take off the electricity of one of the balls by touching it, and then touch the other ball with it. This will reduce to $\frac{1}{2}$ the original quantity $\frac{1}{2}$, and therefore to $\frac{1}{4}$th of the original quantity. This will determine the value of another poſition of the electrometer. In like manner, we obtain $\frac{1}{8}$th, $\frac{1}{16}$th, &c. &c. Then, by touching a ball containing 1 with a ball containing $\frac{1}{2}$, we get a poſition for $\frac{3}{2}$, $\frac{3}{4}$, $\frac{3}{8}$, &c. Proceeding in this way, we graduate our electrometer independently of all theory, and can now examine the electricity of bodies with confidence. The writer of this article took this method of examining his electrometer, not having then ſeen Mr Cavendiſh's diſſertation, which gives another mode of meaſurement. He had the ſatisfaction of obſerving, in the firſt place, that the poſitions of the inſtrument, which unqueſtionably indicated 1, $\frac{1}{2}$, $\frac{1}{4}$, &c. were preciſely thoſe which ſhould indicate them if electric repulſion be inverſely as the ſquares of the diſtances. Having thus examined the electrometer, it was eaſy to give to balls any propoſed degree of electricity, and then make a communication between balls of very different diameters. The electrometer informed us when the repeated abſtractions by a ſmall ball reduced the electricity of a large ball to $\frac{1}{2}$, $\frac{1}{4}$, &c. This ſhewed the proportion of electricity contained in balls of different diameters. This was alſo found to be ſuch as reſulted from an action in the inverſe duplicate ratio of the diſtances.

143. Long after this, Mr Cavendiſh's inveſtigation pointed out the proportion of the redundant electric fluid in balls of different ſizes joined by long wires; in n° 130, &c. theſe were examined—and found to be ſuch as were ſo indicated by the electrometer.

144. And, laſtly, the mode of accumulating great quantities of fluid by means of parallel plates, gave a third way of confronting the hypothetical law with experiment. The argument was no leſs ſatisfactory in this caſe; but the examination required attention to particulars not yet mentioned, which made the proportions between the fluid in HK and AB (fig. 27.) widely different from thoſe mentioned in the preceding paragraphs. Theſe circumſtances are among the moſt curious and important in the whole ſtudy, and will be conſidered in their place.

145 The law of electric action is well determined. We reſt therefore with confidence on the truth of the law of electric action, aſſumed by us as a principle of explanation and inveſtigation. It is quite needleſs and unprofitable to give any detail of the numerous experiments in which we confronted it with the phenomena. The ſcrupulous reader will get ample ſatisfaction from the excellent experiments of Mr Coulomb with his delicate electrometer. He will find them in the Memoirs of the Academy of Sciences of Paris for 1784, 1785, 1786, and 1787. Some of them are of the ſame kind with thoſe employed by the writer of this article; others are of a different kind; and many are directed to another object, extremely curious and important in this ſtudy, namely, to diſcover how the electric fluid is diſpoſed in bodies; and a third ſet are directed to an examination of the manner in which the electric fluid is diſſipated along imperfect conductors.

But we have already drawn this article to a great length, and muſt bring it to an end, by explaining ſome very remarkable phenomena, namely, the operation of the Leyden phial, the operation of the electrophorus, and the diſſipation of electricity by ſharp points and by imperfect conductors.

The obſervations of Mr Watſon on the neceſſity of connecting the rubber of an electrical machine with the ground, might have ſuggeſted to philoſophers the doctrine of *plus* and *minus* electricity, eſpecially after the valuable diſcoveries of Mr Symmer and Cigna. A ſerious conſideration of theſe general facts would have led to the theory of coated glaſs almoſt at its firſt appearance. But the hiſtorical fact was otherwiſe; and a conſiderable time elapſed betwen the firſt experiments with charged glaſs by Kleiſt, and the clear and ſatisfactory account given by Dr Franklin, of all the eſſential parts of the apparatus, and the probable procedure of nature in the phenomenon. The impermeability of glaſs by the electric fluid, and the conſequent abſtraction of it from the one ſide while it was accumulated on the other, ſuggeſted to his acute mind the leading principle of electrical philoſophy; namely, that all the phenomena ariſe from the redundancy or deficiency of electric fluid, and that a certain quantity of it reſides naturally in all bodies in a ſtate of uniform diſtribution, and, in this ſtate, produces no ſenſible effect. This was, in his hands, the inlet to the whole ſcience; and the greateſt part of what has been ſince added is a more diſtinct explanation how the redundancy or deficiency of electric fluid produces the obſerved phenomena. Dr Franklin deduced this leading principle from obſerving, that as faſt as one ſide of a glaſs plate was electrified poſitively, the other ſide appeared negative, and that, unleſs the electricity of that ſide was communicated to other bodies, the other ſide could be no farther electrified. Having formed this opinion, the old obſervations of Watſon, Symmer, and Cigna, were explained at once, and the explanation of the Leyden phial would have come in courſe. It is for theſe reaſons, as much as for the important diſcovery of the ſameneſs of electricity and of thunder, that Dr Franklin ſtands ſo high in the rank of philoſophers, and is juſtly conſidered as the author of this department of natural ſcience. Whatever credit may be due to the chemical ſpeculations of De Luc, Wilcke, Winkler, and many others, who have attempted to aſſociate electricity with other operations of nature, by reſolving the electric fluid into its conſtituent parts, all their explanations preſuppoſe a mathematical and mechanical doctrine concerning the mode of action of the ingredients, which will either account for the total inactivity of the compound, or which will explain, in the very ſame manner, the action of the compound itſelf: yet all ſeem to

146 Of the Leyden phial.

to content themſelves with a vague and indiſtinct notion of this preliminary ſtep, and have allowed themſelves to ſpeak of electrical atmoſpheres, and ſpheres of activity, and ſuch other creatures of the mind, without once taking the trouble of conſidering whether thoſe aſſumptions afforded any real explanation. How different was Newton's conduct. When he diſcovered that the planets attracted each other in the inverſe duplicate ratio of the diſtances, and that terreſtrial gravity was an inſtance of the ſame force, and that *therefore* the deflection of the earth was the effect of the accumulated weight of all its parts; he did not raſhly affirm this of the planets, till he examined what would be the effect of the accumulated attraction in the abovementioned proportion.

147. Mr Æpinus has the honour of firſt treading in the ſteps of our illuſtrious countryman; and he has done it with ſingular ſucceſs in the explanation of the phenomena of attraction and repulſion, as we have already ſeen. In no part of the ſtudy has his ſucceſs been ſo conſpicuous as in the explanation of the curious and important phenomena of the Leyden phial. It only remained for him to account for the accumulation of ſuch a prodigious quantity of this agent as was competent to the production of effects which ſeemed to exceed the ſimilar effects in other caſes, out of all proportion. Indeed, the diſproportion is ſo great, as to make them appear to be of a different and incomparable nature. Dr Wilſon's experiments in the pantheon are therefore precious, by ſhewing that nothing was wanted for the production of all the effects of the Leyden phial but a ſurface ſufficiently extenſive for containing a vaſt quantity of fluid, and ſo perfectly conducting as to admit of its ſimultaneous and rapid transference. Therefore we aſſert that one of the chief merits of Mr Æpinus's theory is the ſatisfactory explanation of the accumulation of this vaſt quantity of fluid in a ſmall ſpace. We truſt, therefore, that our readers will peruſe it with pleaſure. But we muſt here obſerve, that Mr Æpinus has not expreſsly done this in his work which we have already made ſo much uſe of, nor in any other that we know of. He has gone no farther than to point out to the mathematicians, that his hypotheſis is adequate to the accounting for any degree of accumulation whatever. This he does in that part of his work which contains the formulæ of n° 38, 39, 40, 41, &c. And he afterwards ſhews, that all the phenomena of attraction and repulſion which are obſerved in the charged jar are preciſely ſuch as are neceſſary conſequences of his theory.

148 Theory of charged glaſs completed by Mr Cavendiſh.

It is to the Hon. Mr Cavendiſh that we are indebted for the ſatisfactory, the complete (and we may call it *the popular*), explanation of all the phenomena. Forming to himſelf the ſame notion of the mechanical properties of the electric fluid with Mr Æpinus, he examined, with the patience, and much of the addreſs, of a Newton, the action of ſuch a fluid on the fluid around it, and the ſenſible effects on the bodies in which it reſided; the diſpoſition of it in a conſiderable variety of caſes; and particularly its action on the fluid contained in ſlender canals and in parallel plates;—till he arrived at a ſituation of things ſimilar to the Leyden phial. And he then pointed out the preciſe degree of accumulation that was attainable, on different ſuppoſitions concerning the law of electric action in general. We have given an abſtract of this inveſtigation accommodated to the inverſe duplicate ratio of the diſtances.

From this it appears (n° 135), that whatever quantity of electric fluid we can put into a circular plate 12 inches in diameter, by ſimple communication with the prime conductor of an electrical machine, we can accumulate 60 times as much in it by bringing the plate within $\frac{1}{20}$th of an inch of another equal plate which communicates with the ground; and it appears in n° 139, that all this accumulated fluid may be transferred in an inſtant to the other plate (which is ſhewn to be almoſt equally deprived of fluid), by connecting the two plates by a ſmall wire. 149.

But as it was alſo ſhewn in that paragraph, that the force with which the accumulated fluid was attracted by the redundant matter in the other plate was exceedingly great, and conſequently its tendency to eſcape was proportionably increaſed; this accumulation cannot be obtained unleſs we can prevent this ſpontaneous transference.

150 Inexplicable by material atmoſpheres.

Here the non-conducting power of idio-electrics, without any diminution, the action of the electric fluid on fluid or matter on the other ſide of them, comes to our aid, and we at once think of interpoſing a plate of glaſs, or wax, or roſin, or any other electric, between our conducting plates. Such is the immediate ſuggeſtion of a perſon's mind who entertains the Æpinian notion of the electric fluid; and ſuch, we are convinced, is the thought of all who imagine that they underſtand the phenomena of the Leyden phial. But thoſe who attempt to explain electric action by means of what they call electric atmoſphere of variable denſity or intenſity, are not intitled to make any ſuch inference, nor to expect any ſuch phenomena as the Leyden phial exhibits. Electricity, they ſay, acts by the intervention of atmoſpheres: Therefore, whatever allows the propagation of this action (conceive it in any manner whatever), allows the propagation of theſe agents; and whatever does not conduct electric action, does not conduct the agents. Interpoſed glaſs ſhould therefore prevent all action on the other plate. This is true, even although it were poſſible (which we think it is not) to form a clear notion of the free paſſage of this material atmoſphere in an inſtant, and this without any diminution of its quantity, and conſequently of its action, by the diſplacement of ſo much of it by the ſolid matter of the body which it penetrates. Yet without this undiminiſhed action of the electrified plate on the fluid, and on the matter, beyond the glaſs, and on the canal by which its fluid may be driven off into the general maſs—no ſuch accumulation can take place; and if the phenomena of the Leyden phial are agreeable to the reſults of the Æpinian hypotheſis, all explanation by atmoſpheres muſt be abandoned. Indeed when the partiſans of the atmoſpheres attempt to explain their conceptions of them, they do not appear to differ from what are called *ſpheres of activity* (a phraſe firſt uſed by Dr Gilbert of Colcheſter, in his celebrated work *De Magnete et Corporibus Magneticis*): and ſpheres of activity will be found nothing more than a figurative expreſſion of ſome indiſtinct conception of *action in every direction*. When we uſe the words *attraction* and *repulſion*, we do not ſpeak a whit more figuratively than when we uſe the general word *action*. Theſe terms are all figurative, only *attraction* and *repulſion* have the advantage

vantage of ſpecifying the *direction* in which we conceive the *action* to be exerted.

It therefore becomes ſtill more intereſting to the philoſopher to compare the phenomena of CHARGED GLASS with the Æpinian theory. They afford an *experimentum crucis* in the queſtion about electric atmoſpheres.

151 Phenomena of charged glaſs explained.

Let G (fig. 28.) repreſent the end of a prime conductor, furniſhed with Henley's electrometer. Let AB repreſent a round plate of tinfoil, paſted on a pane of glaſs which exceeds the tinfoil about two inches all round. The pane is fixed in a wooden foot, that it may ſtand upright, and be ſhifted to any diſtance from the conductor DF repreſents another plate of the ſame dimenſions as AB, in the centre of which is a wire EN, having a ſmall ball on the end N, to which is attached a Canton's electrometer. This wire paſſes through the wooden ball O, faſtened to the inſulating ſtand P. The glaſs pane muſt be very clean, dry, and warm. Connect the conductor G with AB by a wire reaching to the centre C. Turn the cylinder of the electrical machine ſlowly, till the electrometer riſe to 30° or 40°, and note the number of turns. Take off the electricity; and having taken away the connecting wire GC, turn the machine again till the electrometer riſe to the ſame height. The difference in the number of turns will give ſome notion of the expenditure of fluid neceſſary for electrifying the plate of tinfoil alone. This will be found to be very trifling when the electricity is in ſo moderate a degree. It is proper, however, to keep to this moderate degree of electrification, becauſe when it is much higher, the diſſipation from the edges of the plate is very great. Replace the wire, and again raiſe the electrometer to 30°. Now bring forward the plate DF, keeping it duly oppoſite and parallel to AB, and taking care not to touch it. It will produce no ſenſible change on the poſition of the electrometer till it come within four or three inches of the glaſs pane; and even when we bring it much nearer (if a ſpark do not fly from the glaſs pane to DF), the electrometer HG will ſink but two or three degrees, and the electrometer at N will be little affected. Now remove the plate DF again to the diſtance of two or three feet, and attach to its ball N a bit of chain, or ſilver or gold thread, which will trail on the table. Again, raiſe the electrometer to 30°, and bring DF gradually forward to AB. The electrometer HG will gradually fall down, but will riſe to its former height, if DF be withdrawn to its firſt ſituation. It is ſcarcely neceſſary to ſhew the conformity of this to the theory contained in n° 134, 135, &c. As the plate DF approaches, the redundant fluid in AB acts on the fluid in DF, and drives it to the remote end of the wire EN, as was ſhewn by the divergency of the balls at N; and then an accumulation begins in AB, and the electrometer HG falls in the ſame manner as if part of the fluid in the prime conductor were communicated to AB. When DF communicates with the ground, the electrometer at N cannot ſhew any electricity, but much more fluid is now driven out of DF, in proportion as it is brought nearer to AB. Inſtead of connecting AB immediately with the prime conductor, let the wire GC have a plate at the end G, of the ſame dimenſions as AB, having an electrometer attached to the ſide next to AB. Let this apparatus of two plates be electrified anyhow, and note the divergency of the electrometer at H, before DF, communicating with the ground, is brought near it, and then attend to the changes. We ſhall find the divergency of this electrometer correſpond with the diſtance of DF very nearly as the theory requires.

152 State of the coatings.

While the plates AB and DF are near each other, eſpecially when DF communicates with the ground, if we hang a pith-ball between them by a ſilk thread, it will be ſtrongly attracted by the plate which is neareſt to it, whether DF or AB; and having touched it, it will be briſkly repelled, and attracted by the glaſs pane, which will repel it after contact, to be again attracted and repelled by DF; and thus bandied between the plates till all electricity diſappear in both, the electrometer attached to H deſcending gradually all the while.

As all theſe phenomena are more remarkable in proportion as the plates are brought nearer, they are moſt of all when DF is applied cloſe to the glaſs pane. And if, in this ſituation, we take any accurate method for meaſuring the intenſity of the electricity in the plate HG, before the approach of DF, we ſhall find the diminution, occaſioned by its coming into full contact with the pane, conſiderably greater than what is pointed out in n° 135. When we employed plates of 12 inches diameter, paſted on a pane one fortieth of an inch in thickneſs, we found the diminution not leſs than 199 parts of 200; and we found that it required at leaſt 200 times the revolution of the cylinder to raiſe the electrometer to the ſame height as before. This compariſon is not ſuſceptible of great accuracy, by reaſon of many circumſtances, which will occur to an electrician. But in all the trials we have made, we are certain that the accumulation greatly exceeded that pointed out by the Æpinian theory as improved by Mr Cavendiſh. And we muſt here obſerve, that we found this ſuperiority more remarkable in ſome kinds of glaſs than others, and more remarkable in ſome other idioelectrics. We think that, in general, it was moſt remarkable in the coarſe kinds of glaſs, provided they were uniformly tranſparent. We found it moſt remarkable in ſome common glaſs which had exfoliated greatly by the weather; but we alſo found that ſuch glaſſes were very apt to be burſt by the charge. The hardeſt and beſt London crown-glaſs ſeemed to accumulate leſs than any other; and a coloured glaſs, which when viewed by reflection ſeemed quite opake, but appeared brown by tranſmitted light, admitted an accumulation *greatly* exceeding all that we have tried; but it could not be charged much higher without the certainty of being burſt. This diverſity in the accumulation, which may be made in different kinds of glaſs, hinders us from comparing the *abſolute* accumulations aſſigned by the theory with thoſe which experiment gives us. But though we cannot make this compariſon, we can make others which are equally ſatisfactory. We can diſcover what proportion there is between the accumulation in glaſs of the ſame kind, as it may differ in thickneſs and in extent of ſurface. Uſing mirror glaſs, which is of uniform and meaſurable thickneſs, and very flat plates, which come into accurate or equable contact—we found that the accumulation is inverſely as the thickneſs of the plates; but with this exception, that when two plates were uſed inſtead of a plate of double thickneſs, the diminution by the increaſe of thickneſs was not nearly in the proportion of this increaſe. Inſtead

ſtead of being reduced to one half, it was more than two-thirds; and in the kind called Dutch plate, the diminution was inconſiderable.

154 Strong attraction between them.

The experiments with the Dutch and other double plates, ſuggeſted another inſtructive and pretty experiment. Obſerving theſe plates to cohere with conſiderable force, it was thought worth while to meaſure it; which was attempted in this manner: Two very flat braſs plates AB, DF (fig. 29.) furniſhed with wires and balls, were ſuſpended, about three inches aſunder, by ſilk threads, as repreſented in the figure. At G was attached a very fine ſilver wire, which hung very looſe between it and the prime conductor, without coming near the table. Another was attached to N, which touched the table. A plate of mirror glaſs was ſet between them, as ſhewn by QR. When this apparatus was electriſied, the threads of ſuſpenſion immediately began to deviate from the perpendicular, and the plates to approach the glaſs pane and each other. The pane was carefully ſhifted, ſo as to be kept in the exact middle between them. This reſult ſhewed very plainly the preſſure of the fluid on one of the plates, and the mutual attraction of the redundant matter and redundant fluid. This increaſed as the accumulation increaſed; and it was attempted to compare the attraction with the accumulation, by comparing the deviation of the ſuſpending threads with that of the electrometer attached to the prime conductor; but we could not reconcile the ſeries (which, however, was extremely regular) with the law of electric action. This harmony was probably diſturbed by the force employed in raiſing the ſilver wires. When more flexible ſilver threads were uſed, much was loſt by diſſipation from the roughneſs of the thread. We did not think of employing a fine flaxen thread moiſtened: but, indeed, an agreement was hardly to be expected; becauſe theory teaches us, that the diſtribution of the redundant fluid in AB will be extremely different from the diſtribution of the redundant matter in DF, till the plates come very near each other. The accumulation in AB depends greatly on the law of diſtribution, being leſs (with any degree of redundancy) when the fluid is denſer near the centre of the plate. Other circumſtances concurred to diſturb this trial; but the theory was abundantly confirmed by the experiment, which ſhewed the ſtrong attraction ariſing from the accumulation. This was ſo great, that although the plates were only three inches in diameter, and the glaſs pane was $\frac{1}{12}$ of an inch thick, and the threads deviated about 18 degrees from the perpendicular—it required above an ounce weight, hung on the wire EN, to ſeparate the plates from the glaſs.

155 Diſcharge; how it is effected.

The experienced electrician need not be told, that by bringing the two ends of a bent wire in contact with the two plates (firſt touching DF with it) diſcharges the apparatus, and cauſes the plates to drop off from the pane. But he may farther obſerve, that if there be attached to each end of the diſcharging wire a downy feather, and if he firſt bring the end near the plate DF, and obſerve the feather to be not at all, or but a very little, affected, and if he then bend round the other end toward the plate AB, *both feathers* will immediately ſtretch out their fibres to the plates, and cling faſt to them, long before the diſcharging ſpark is ſeen. This is a fine proof of the proceſs of diſcharge, which begins by the induction of electricity on the ends of the diſcharging wire; firſt, negative electricity on the end that approaches A, and, in the ſame inſtant, oppoſite electricities at D and the adjoining end of the wire.

156 Beautiful and inſtructive experiment by Profeſſor Richmann.

The following obſervation of Profeſſor Richmann of St Peterſburgh (the gentleman who fell a ſacrifice to electrical ſtudies by a thunder ſtroke from his apparatus) is extremely inſtructive and amuſing. Let a glaſs pane be coated on both ſides, and furniſhed with a ſmall electrometer attached to the coatings. It is repreſented as if ſeen edgewiſe in fig. 30. Let it be charged poſitively (that is, by redundancy) by the coating AB, while DF communicates with the ground. The electrometer A *a* will ſtand out from the plate, and D *d* will hang down cloſe by its coating, as long as DF communicates with the ground. But as the electricity gradually diſſipates by communication to the contiguous air, the ball *a* will gradually, but very ſlowly, fall down. We may judge of the intenſity of the remaining electricity by the deviation of the electrometer, and we may conceive this deviation divided into degrees, indicating not angles, but intenſities, which we conceive as proportional to the redundancy or deficiency which occaſion them.

If we take away the communication with the ground, we ſhall obſerve the ball *a* fall down very ſpeedily, and then more ſlowly, till it reach about half of its firſt elevation. The ball *d* will at the ſame time riſe to nearly the ſame height; the angle between the two electrometers continuing nearly the ſame as at firſt. When *d* has ceaſed to riſe, both balls will very ſlowly deſcend, till the charge is loſt by diſſipation. If we touch DF during this deſcent, *d* will immediately fall down, and *a* will as ſuddenly riſe nearly as much; the angle between the electrometers continuing nearly the ſame. Remove the finger from DF, and *a* will fall, and *d* will riſe, to nearly their former places; and the ſlow deſcent of both will again continue. The ſame thing will happen if we touch AB; *a* will fall down cloſe to the plate, and *d* will riſe, &c. And this alternate touching of the coatings may be repeated ſome hundreds of times before the plate be diſcharged. If we ſuſpend a crooked wire *v m u*, having two pith balls *v* and *u* from an inſulated point *m* above the plate, it will vibrate with great rapidity, the balls ſtriking the coatings alternately; and thus reſtoring the equilibrium by ſteps. Each ſtroke is accompanied by a ſpark.

Theory of it.

All theſe phenomena are not only conſequences of the theory, but their meaſures agree preciſely with the computations deduced from the formulæ in nº 22, 23, 24, accommodated to the caſe by means of nº 135 and 136, as we have verified by repeated trials. But it would occupy much room to trace the agreement here, and would fatigue ſuch readers as are not familiarly converſant with fluxionary calculations. The inquiſitive reader will get full conviction by peruſing Epinus's Eſſay, Appendix i. A very diſtinct notion may be conceived of the whole proceſs, by ſuppoſing that in a minute AB loſes $\frac{1}{10}$th of the unbalanced redundancy actually in it, and conſequently diminiſhes as much in its action. It will be proved afterwards, that the diſſipations in equal times are really in proportion to the ſuperficial repulſions then exerted. We may alſo ſuppoſe, that the action of the redundant fluid, or redundant matter, in either coating, on the external fluid contiguous to it, is to its action on the fluid contiguous to the

the other coating in the conſtant proportion of 10 to 9. We ſelect this proportion for the ſimplicity of the computation. Then the difference of theſe actions is always $\frac{1}{10}$th of the full action on the fluid contiguous to it. This is alſo an exact ſuppoſition in ſome particular caſe, depending on the breadth of the coating and the thickneſs of the pane.

Now, let the primitive unbalanced repulſion between AB and the contiguous fluid of the electrometer be 100, while DF communicates with the ground. The ball *a* will ſtand at 100; the ball *d* will hang touching DF. Then *a*, by loſing $\frac{1}{10}$th, retains only 90, and would ſink to 90°: But as this deſtroys the equilibrium on the other ſide, fluid will enter into DF, ſo as to reduce the deficiency $\frac{1}{10}$th. Therefore nine degrees of fluid will enter; and its action on *a* will be the ſame as if $\frac{9}{10}$ths of 9, or 8,1 had been reſtored to AB. Therefore *a* will riſe from 90 to 98,1; or it will ſink in one minute from 100 to 98,1.

But if we have cut off the communication of DF with the ground, this quantity of fluid cannot come into DF; and the quantity which really comes into it from the air will be to that which eſcapes from A as the attraction on the ſide of DF to the repulſion on the ſide of AB. By the diminution of the repulſion $\frac{1}{10}$th, and the want of 9 degrees of fluid in DF to balance it, DF acquires an attraction for fluid which may be called 9. Therefore, ſince $\frac{1}{10}$th of the primitive repulſion of AB has diſſipated 10 meaſures of fluid in the minute, the attraction of DF will cauſe it to acquire $\frac{1}{10}$th of 9, or 0,9, from the air in the ſame minute. At the end of the minute, therefore, there remains an unbalanced attraction for fluid = 8,1; and conſequently an unbalanced repulſion between the redundant matter in DF, and that in the ball *d*. Therefore *d* will riſe to 8,1. But *a* cannot now be at 98,1; becauſe DF has not acquired 9 meaſures of fluid, but only $\frac{9}{10}$ths of one meaſure. Therefore *a*, inſtead of riſing from 90 to 98,1, will only riſe to 90 + $\frac{9}{10}$ths × $\frac{9}{10}$ths; that is, to 90,81.

At the cloſe of the minute, therefore, *a* is at 90,81, and *d* is at 8,1, and their diſtance is 98,91. In the next minute, AB will loſe $\frac{1}{10}$th of the remaining unbalanced electricity of that ſide, and DF will now acquire a greater proportion than before; becauſe its former unbalanced attraction gets an addition equal to $\frac{9}{10}$ths of the loſs of AB. This will make a larger compenſation in the action on *a*, and *a* will not fall ſo much as before. And becauſe in the ſucceeding minutes the attraction of DF for fluid is increaſing, and the repulſion of AB is diminiſhing, the compenſation in the action on *a*, by the increaſed attraction of DF, continues to increaſe, and the deſcent of *a* grows continually ſlower; conſequently a time muſt come, when the repulſion of AB for fluid is to the attraction of DF for it, nearly in the proportion of 10 to 9. When this ſtate obtains, *d* will riſe no more; becauſe the receipt of fluid by DF, being now $\frac{9}{10}$ths of the loſs by AB, it will exactly compenſate the additional attraction of DF for fluid, occaſioned by that loſs. The next loſs by AB not being ſo great, and the next receipt by DF continuing the ſame, by reaſon of its undiminiſhed attraction, there will be a greater compenſation in the action on *a*, which will prevent its deſcending ſo faſt; and there will be more than a compenſation for the additional attraction of DF for fluid: that is, the fluid which has now come into DF will render it, and alſo the ball *d*, leſs negative than before; and therefore they will not repel ſo ſtrongly. Therefore *d* muſt now deſcend. It is evident, that ſimilar reaſons will ſtill ſubſiſt for the ſlow deſcent of *a*, and the ſlower deſcent of *d*, till all redundancy and deficiency are at an end.

This maximum of the elevation of *d* happens when *a* has deſcended about one half of its elevation; that is, when the unbalanced repulſion of AB is reduced to about one-half. For if one-half of the unbalanced fluid be really taken out of AB, and if DF can get no ſupply whatever, it muſt acquire an attraction correſponding to $\frac{9}{10}$ths of this; and if the ſupply by the air be now opened to it, things will go on in the way already deſcribed, till all is diſcharged.

This account of the proceſs is only an approximation; becauſe we have ſuppoſed the changes to happen in a deſultory manner, as in the popular way of explaining the acceleration of gravity. The riſe of *d* is not at an end till the attraction of DF for fluid is to the repulſion of AB as 19 to 20.

But if we interrupt this progreſs in any period of it, by touching DF, we immediately render it neutral, and *d* falls quite down, in conſequence of receiving a complete ſupply of fluid. But this muſt change the ſtate of AB, and cauſe it to riſe $\frac{9}{10}$ths of the deſcent of *d*. As *a* and *d* were nearly at an equal height before DF was touched, it is plain that *a* will riſe to nearly twice its preſent height; after which, the ſame ſeries of phenomena will be repeated as ſoon as the finger is removed from DF.

If, inſtead of touching DF, we touch AB, the ſame things muſt happen; *a* muſt fall down, and *d* muſt riſe to nearly twice its preſent height, and all will go on as before, after removing the finger. Laſtly, if inſtead of allowing either ſide to touch the *ground* alternately, we only touch it with a *ſmall inſulated body*, ſuch as the wire with the balls *v* and *u*, the ball attached to the ſide touched ſinks, till the electricity is ſhared between the coating and the wire with balls. The ball attached to the other coating riſes $\frac{9}{10}$ths of the ſinking of the firſt ball. The crooked wire ball is now repelled by the coating which it touched, and the other ball is brought near to the other coating, and muſt be attracted by it, becauſe the electricities are oppoſite. This operation evidently tends to transfer the redundant fluid *by degrees* to the ſide where it is deficient. It needs no explanation. We ſhall only mention a thing which we have always obſerved, without being able to account for it. The vibration of the wire acquires a certain rapidity, which continues for a long while, and ſuddenly accelerates greatly, and immediately afterwards ceaſes altogether.

This pretty experiment of Profeſſor Richmann will be found very inſtructive; and will enable us to underſtand the operation of the electrophorus, and to ſee the great miſtake of thoſe who ſay that it is perfectly ſimilar to a diſcharged glaſs plate.

Thus, then, we ſee, that all the claſſes of phenomena, connected with attraction and repulſion, are preciſely ſuch as would reſult from the action of a fluid ſo conſtituted. The complete undiminiſhed action of the cauſe of thoſe phenomena on the other ſide of the interpoſed non-conductor of that cauſe is demonſtrated, and all 157 Electric action *at a diſtance* demonſtrated.

all explanation by the mechanical action of material elaſtic atmoſpheres of variable denſity muſt be abandoned, and the infinitely ſimpler explanation by the attractive and repulſive forces of the fluid itſelf muſt be preferred.

So happily does the Franklinian theory of poſitive and negative electricity explain the phenomena, when a ſuitable notion is formed of the manner of action of this fluid. We cannot but think that this is attained, when, to the general doctrine of Æpinus, we add the ſpecification of the law of action, ſo fully verified by the experiments of Mr Coulomb, which are in the hands of the public, and are of that ſimple nature that any careful experimenter can convince himſelf of their accuracy (Sec n° 144.) We may therefore proceed with ſome confidence, and apply this doctrine even to caſes where experiment does not offer itſelf for proof.

158 Franklin miſtaken in ſuppoſing that a charged plate contains its natural quantity of fluid.

Dr Franklin affirms that electric fluid cannot be thrown into one ſide of the coated pane unleſs it be abſtracted from the other; and that therefore the charged glaſs contains no more than it did before charging. We indeed find that we cannot *charge* the inſide, if the outſide do not communicate with the ground. He proves it alſo by ſaying, that if a perſon, when inſulated, diſcharges a glaſs through his own body, he is not found electrified: And he infers, as a neceſſary conſequence of this, that a ſeries of any number of jars may be charged by the ſame turns of a machine, if we make the outſide of the firſt communicate with the inſide of the ſecond, and the outſide of the ſecond with the inſide of the third; and ſo on; and the outſide of the laſt communicate with the ground. Having made the trial, and having found that more turns of the machine were neceſſary, he attributes this to diſſipation into the air by the communication. But our theory teaches us otherwiſe. We learn from it, that the redundant matter in the plate DF is leſs than the redundant fluid in AB, in the proportion of $n - 1$ to n; and therefore the redundant fluid in the overcharged ſide of the next plate is no greater. The charge or redundancy in the mth jar of the ſeries will therefore be $\overline{\frac{n-1}{n}}\Big|^{m}$. Thus, if n, or the charge of the firſt jar, be 60, the charge of the 10th jar will be nearly 51. Although a coated plate cannot be *charged* unleſs one of the coatings communicate with the ground, it may be *electrified* as much as one of the coatings can be alone. And this is ſeen in our attempt to charge it: For as ſoon as we attempt to electrify one ſide, the other is electrified alſo; for it gives a ſpark which no unelectrified body will do. Alſo, when we diſcharge a jar by an inſulated diſcharger, we always leave it electrical in the ſame way with the body from which it was charged. If a man is not found electrified after having diſcharged a jar through his own body, it is owing to the great ſurface of his body, which reduces the ſimple electrification of a ſide of the jar to a very inſignificant and inſenſible quantity.

159 Miſtake of Wilcke's.

Wilcke (and we believe Franklin before him) maintains, that when the jar has been charged, by connecting one ſide with the prime conductor, and the other with the rubber, it is neutral and inactive on both ſides. But this is not ſo; and a ſlight reflection might have convinced them that it cannot be ſo: if it were, the jar could not be diſcharged. Each ſide, while connected with the machine, muſt be in the condition of the part with which it is connected, and in a diſpoſition to take or give. If the trial be carefully made, it will be found to be *equally active* on both ſides; and the diſcharging rod, having down on its ends, will ſhew this in an unequivocal manner, and ſhew that its condition differs in this reſpect from that of a jar charged in the ordinary way. It is in the maximum ſtate of Richmann's plate, deſcribed in n° 156. when d riſes no more.

160 Charge one jar by the diſcharge of another.

In diſcharging a jar A, if inſtead of the outſide communicating with the inſide by a wire, we make it communicate with the inſide of a ſecond jar B, while the outſide of B is made to communicate with the inſide of A, we ſhall find be charged by the diſcharge of A; and that the diſcharge of A is not complete, the charge 2² always remaining, whatever may have been the magnitude of n.

161 Important inference.

We may infer from this experiment, that when a ſhock is given to a number of perſons a, b, c, &c. we are not to conclude, that the fluid which comes into the deficient ſide of the jar is the ſame which came out of the redundant ſide. The whole, or perhaps only a part, of the moveable fluid in the perſon a goes into b, replacing as much as has paſſed from b into c, &c. Indeed, where the canal is a ſlender wire, we may grant that great part of the individual particles of fluid which were accumulated on the inſide of the jar have gone into the outſide. Perhaps the quantity transferred, even in what we call *a very great diſcharge*, may be but a ſmall proportion of what naturally belongs to a body. This may be the reaſon why a charge will not melt more than a certain length of wire. Mr Cavendiſh aſcribes this to the greater obſtruction in a longer wire; but this does not appear ſo probable. A greater obſtruction would occaſion a longer delay of the transference; and therefore the action of the ſame quantity would be longer continued. He proves, that a metal wire conducts many hundred times faſter than water; yet, when water is diſſipated by a diſcharge, it is found to have actually conducted a *much greater* proportion of the whole charge. We aſcribe it chiefly to this, that, in a ſhort wire, the quantity transferred exceeds the whole quantity belonging to the wire.

162 Leyden phial like a coated pane.

It is ſurely needleſs to prove that the theory of the Leyden phial is the ſame with that of the coated pane. The only difference is, that we are not ſo able to tell the diſpoſition of the accumulated fluid, and the evacuated matter, in every figure. When the phial is of a globular form, and of uniform thickneſs, with an exceedingly ſmall neck, we then knew the diſpoſition more accurately than in a plate. The redundant fluid is then uniformly diſtributed. If we could inſure the uniformity of thickneſs, ſuch a phial would be an excellent UNIT for meaſuring all other charges by; but we can neither inſure this (by the manner of working glaſs), nor meaſure its want of uniformity: whereas we can have mirror plate made of preciſely equal thickneſs, and meaſure it. This, therefore muſt be taken as our unit.

163 Excellent method for verifying the theory.

And here we remark, that this gives us the moſt perfect of all methods for comparing our theory with experiment. We muſt take two plates, of the ſame glaſs and the ſame thickneſs, but of different dimenſions of coated ſurface. We muſt charge both by very long conducting wires on both ſides, and then meaſure how

how often the charge of the one is contained in the other. Mr Cavendiſh has given an unexceptionable method of doing this independent of all theory. As it applies equally to jars, however irregular, we ſhall take it altogether.

Meaſure of a charge.

When a jar is charged, obſerve the electrometer connected with it, and immediately communicate the charge to another equal jar (the perfect equality being previouſly aſcertained by the methods, which will appear immediately). Again note the electrometer. This will give the elevation, which indicates one-half, independent of all theory. Now electrify a jar, or a row of equal jars, to the ſame degree with the firſt, and communicate the charge to a coated mirror plate, diſcharging the plate after each communication, till the electrometer reaches the degree which indicates one-half. This ſhews how often the charge of the plate is contained in that of the jar or row of jars.

Let the charge of the plate be to that of the jars as x to 1. Then, by each communication, the electricity is diminiſhed in the proportion of $\overline{1+x}$ to 1. If m communications have been made, it will be reduced in the proportion of $\overline{1+x}^m$ to 1. Therefore $\overline{1+x}^m = 2$, and $1+x = \sqrt[m]{2}$, and $x = \sqrt[m]{2} - 1$.

When x is ſmall in proportion to 1, we ſhall be very near the truth, by multiplying the number of communications by 1,444, and ſubtracting 0,5 from the product. The remainder ſhews how often the charge of the plate is contained in that of the jars, or $\frac{1}{x}$.

Thus may the perfect equality of two jars be aſcertained; and the one which exceeds, on trial, may be reduced to equality by cutting off a little of the coating. An electrician ſhould have a pair of ſmall jars or phials ſo adjuſted. It will ſerve to diſcover in a minute or two the mark of one-half electricity for any electrometer, and for any degree; as alſo for meaſuring jars, batteries, ſhocks, &c. much more accurately than any other method: becauſe ſuch phials, conſtructed as we ſhall deſcribe immediately, may be made ſo neutral, and ſo retentive, that the quantity which diſſipates during the handling becomes quite inſignificant in proportion to the quantity remaining; whereas, in all experiments with electrometers, conſtructed with the moſt curious attention, the diſſipations are great in proportion to the whole, and are capricious.

164. It was chiefly by this method that the writer of this article, having read Mr Cavendiſh's paper, compared the meaſures given by experiment with thoſe which reſult from an action in the inverſe duplicate ratio of the diſtance. When the charges were moderate, the coincidence was perfect; when the charges were great, the large plates contained a little more. This is plainly owing to their being leſs diſpoſed to diſſipate from the edges.

165

Maxims for conſtructing jars, batteries, &c.

We may now follow with ſome confidence the practical maxims deducible from the theory for the conſtruction of this accumulating apparatus. The theory preſcribes a very conducting coating, in cloſe and uninterrupted contact: It preſcribes an extenſive ſurface, and a thin plate of idio-electric ſubſtance. Accordingly all theſe are in fact attended by a more powerful effect. Metal is found to be far preferable to water, which was firſt employed, having been ſuggeſted by the original experiments of Gray, Kleiſt, and Cunæus. A continuous plating is preſcribed, in preference to ſome methods commonly practiſed; ſuch as filling the jar with braſs duſt, or gold leaf, or covering its ſurface with filings ſtuck on with gum water, or coating the inſide with an amalgam of mercury and tin. This laſt appears, by reflection from the outſide, to give a very continuous coating; but if we hold the jar between the eye and the light, we may perceive that it is only like the covering with a cobweb. Yet there are caſes where theſe imperfect coatings only are practicable, and ſome rare ones where they are preferable. In the medical exhibition of electricity, where the purpoſe intended is ſuppoſed to require the transfuſion of a great quantity of the electric fluid, any thing that can diminiſh the irritating ſmartneſs of the ſpark is deſirable. This is greatly effected by thoſe imperfect coatings. Small ſhocks, which convey the ſame quantity of fluid with the ſharp pungent and alarming ſpark from a large ſurface, are quite ſoft and inoffenſive, greatly reſembling the ſpaſmodic quivering, ſometimes felt in the lip or eye-lid, and will not alarm the moſt fearful patient.

Hint for medical exhibition of electricity.

166

How to prevent the burſting of jars by high charges.

Cloſe contact of the metallic coating is obſerved to increaſe the effect of the charge. But it is alſo found that it greatly increaſes the riſk of burſting the glaſs by ſpontaneous diſcharge through its ſubſtance. An experienced electrician (we think it is Mr Brookes of Norwich) ſays, that ſince he has employed paper covered with tinfoil, with the paper next the glaſs, inſtead of the foil itſelf, he has never had a jar burſt; whereas the accident had been very frequent before. The theory juſtifies this obſervation. Paper is an imperfect conductor, even when ſoaked with flour paſte; and the transfuſion, though rapid, is not inſtantaneous nor deſultory, but begins faintly, and ſwells to a maximum. It operates on the glaſs, like gradual warming, inſtead of the ſudden application of great heat.

167

Very curious obſervation by Mr Cuthbertſon.

Mr Cuthbertſon, an excellent artiſt in all electrical apparatus, and inventor of the beſt air-pump, has made a curious obſervation on this ſubject. He ſays that he has uniformly obſerved, that jars take a much greater charge (nearly one-third), if the inſide be conſiderably damped, by blowing into it with a tube reaching to the bottom (*Nicholſon's Journal*, March 1799).—We muſt acknowledge, that we can form no diſtinct conception of what Mr Cuthbertſon calls *an undulation of the elaſtic atmoſphere*. We do not know whether he means that the atmoſphere is actually undulating as water, or as air in the production of ſound, as its parts being in a reciprocating motion; or whether he only means that this atmoſphere conſiſts of quieſcent ſtrata, alternately denſer and rarer. Nor can we form any notion how either of theſe undulations contributes to the exploſion, or prevents it. We are really but very imperfectly acquainted with that part of the ſcience which ſhould determine the preciſe accumulation that produces the deſultory transference. We mentioned one neceſſary conſequence of the action inverſely as the ſquare of the diſtance, which has ſome relation to this queſtion, *viz.* that a particle, making part of a ſpherical ſurface, is twice as much repelled when it has juſt quitted the ſurface, as when it made part of it, provided its place be immediately ſupplied. And another circumſtance has been frequently mentioned, *viz.* that a greater, and perhaps much greater, force is neceſſary for enabling a particle

particle of fluid to quit the laſt ſeries of particles of the ſolid matter than for producing almoſt any conſtipation. But we are not certain that theſe circumſtances are of ſufficient influence to explain the whole of the event. *Valeant quantum valere poſſint.* Yet we are of opinion that Mr Cuthbertſon has aſſigned the true cauſe, namely, the imperfect coating of the inſide of the glaſs. When we come to the explanation of the eſcape of electricity along imperfect conductors, we hope that it will appear, that the diſpoſition to eſcape muſt be greatly diminiſhed by a charge, which diſpoſes the fluid ſo, that in no place the conſtipation is remarkably greater than in another part very near it, and the denſity changes everywhere ſlowly.

168 Beſt forms for jars, &c.

With reſpect to the form of the coated glaſs, the theory preſcribes that which will occaſion ſuch a diſtribution of the electric fluid as ſhall make its repulſion for the fluid in the canal which connects it with the prime conductor as little as poſſible. In this reſpect it would ſeem that a plate is the beſt, and a globe the worſt: but if both are very thin, the difference cannot be conſiderable. Our experience, however, ſeems to indicate the oppoſite maxim as the moſt proper. We have uniformly found a globe to be far preferable to a plate of the ſame thickneſs, and that a plate was generally the weakeſt form. It muſt be owned that we have not yet been able to aſcertain by the theory what is the exact diſtribution of the redundant fluid in a plate. In a ſphere it muſt be uniformly ſpread over the ſurface. We muſt alſo aſcribe part of the inferiority of the plate to its greater tendency to diſſipation from the edges. If a plate be coated in a ſtar-like form, with ſlender projecting points, we ſhall obſerve them luminous in the dark, almoſt at the beginning of the accumulation; and the plate will diſcharge itſelf by theſe points, over the uncoated part, before it has attained any conſiderable ſtrength. Thoſe forms are leaſt expoſed to this deterioration which have the leaſt circumference to the ſame quantity of ſurface. We have always found that a ſquare coating will not receive a more powerful charge without exploding than a circular one of the ſame breadth, although it contains a fourth more ſurface; and this although any viſible eſcape from the angles be prevented by covering the outline with ſealing wax. Of all forms, therefore, a globe, with a very narrow, but long neck, is the moſt retentive. But it is very difficult to coat the inſide of ſuch a veſſel. The balloons uſed in chemical diſtillations make excellent jars, and can be eaſily coated internally when the neck will admit the hand. The thinneſt of tinfoil may be uſed, by firſt paſting it on paper, and then applying it either with the foil or the paper next the glaſs. It ſhould be cut into guſſets, as in the covering of terreſtrial globes; and they ſhould be put on overlapping about half an inch. The middle of the bottom is then coated with a circular piece. The great bottles for holding the mineral acids are alſo good jars, but inferior to the balloons, becauſe they are very thick in the bottom, and for ſome diſtance from it. A box of balloons contains more effective ſurface than an equal box of jars of the ſame diameter and height of coating.

169 Compendious battery.

The moſt compendious battery may be made in the following manner: Chooſe ſome very flat and thin panes of the beſt crown glaſs, coat a circle (*a b c d*), (fig. 31.) in the middle of both ſurfaces, ſo as to leave a ſufficient border uncoated for preventing a ſpontaneous diſcharge; let each of them have a narrow ſlip of tinfoil *a* reaching from the coating to the edge on one ſide, and a ſimilar ſlip *c* leading to the oppoſite edge on the other ſide. Lay them on each other, ſo that the ſlips of two adjoining plates may coincide. Connect all the ends of theſe ſlips on one ſide together by a ſlip of the ſame foil, or a wire which touches them all. Then, connecting one of theſe collecting ſlips with the prime conductor, and the other with the ground, we may charge and diſcharge the whole together. If the panes be round, or exact ſquares, we may employ as few of them together as we pleaſe, by ſetting the whole in an open frame, like an old-faſhioned plate-warmer; and then turning the ſet which we would employ together at right angles to the reſt. This evidently detaches the two parcels from each other. This battery may be varied in many ways; and if the whole is always to be employed together, we may make it extremely retentive, by covering the uncoated border of the plate with melted pitch, and, while it is ſoft, preſſing down its neighbour on it till the metallic coatings touch. For greater variability this may be done in parcels of the whole.

On the ſame principle, a moſt compendious battery may be made by alternate layers of tinfoil and hard varniſh, or by coating plates of very clear and dry Muſcovy glaſs. But theſe muſt be uſed with caution, leſt they be burſt by a ſpontaneous diſcharge; in which caſe we cannot diſcover where the flaw has happened. They make a ſurpriſing accumulation, without ſhewing any vivid electricity. 170 Another.

We have made a very fine electric phial for carrying about, by forming tin-plate (iron plate tinned) into ſomewhat of a phial ſhape, with a long neck. We then covered this with a coating of fine ſealing wax, about $\frac{1}{10}$th of an inch thick, quite to the end of the neck, and coated the ſealing wax, all but the neck, with tinfoil. It is plain that the ſealing wax is the coated idio-electric, and that the tin-plate phial ſerves for an inner coating and wire. The diſſipation is almoſt nothing if the neck be very ſmall; and it only requires a little caution to avoid burſting by too high a charge. Even this may be prevented by coating the ſealing wax ſo near to the end of the neck, that a ſpontaneous diſcharge muſt happen before the accumulation is too great. 171 Portable jar.

It is well known that the diſcharge happens when the diſcharging balls are at a conſiderable diſtance from each other; therefore only as much is diſcharged as correſponds to that diſtance. This is one cauſe of the reſiduum of a diſcharge which ſometimes is pretty conſiderable. Some experiments require the very utmoſt force of the charge. It is therefore proper to make the diſcharge as cloſe and abrupt as poſſible. But the moſt rapid approach that we can make of the diſcharger is nothing in compariſon with the velocity with which the fluid ſeems to fly off, and will therefore have but ſmall influence in making a more inſtantaneous and complete diſcharge. Theory points out the following method: Let a very thick plate of glaſs (half an inch), of ſeveral inches diameter, be put between the diſcharging balls, which ſhould, in this caſe, be ſmall, and let theſe balls be ſtrongly preſſed againſt it by a ſpring. While the charge is going on, a very ſmall part of the glaſs plate, round 172 Importance of a cloſe diſcharge.

round the points of contact, will receive a weak and useless charge; but this will not hinder the battery from acquiring the same intensity of charge. When this is completed, let the intervening glass plate be briskly withdrawn. The discharge will begin with an intensity which is unattainable in the ordinary manner of proceeding.

173 Lateral explosion. Much has been said of the lateral explosion. It appears, that in some of the prodigious transferences of electricity that have taken place in the discharge of great surfaces through wires barely sufficient to conduct them, flashes of light are thrown off laterally; but the most delicate electrometer, it is said, is not affected. The fact is not accurately narrated; we have always observed a very delicate electrometer to be affected. The passage of such a quantity of fluid is almost equivalent to the co existence of it in any given section of the wire; but it remains there for so short a time, that, acting as an accelerating force, it cannot produce a very sensible motion. It is like the discharging a pistol ball through a sheet of paper hanging loosely. It goes through it without very sensibly agitating it.

174 Proposal for discovering which is redundant electricity. It has sometimes appeared to us probable that, by means of this lateral explosion, the direction of the current may be discovered. Let the jar *a b* (fig. 32.) be discharged by a wire *a c d e b*, interrupted at *c d* by the coating of a very thin plate of talc; let the coating also be very thin. There must be *some* obstruction to the motion, which must cause the fluid to press on the sides or surfaces of the coating, just as the obstruction to the motion of water in a pipe (arising from friction, or even from material obstacles in the pipe) causes the water to press on the sides of the pipe. Therefore if a wire *x s* connect the other coating with the ground, we should expect that fluid will be expelled along this wire, and a charge be given to the plate of talc. Now whether the course in this apparatus be from *b* to *a*, or from *a* to *b*, if any charge be acquired by *c d*, it will *probably* be positive in *c d*, and negative in *x s*; for it is electric fluid that is supposed to pass: therefore we should always have one species of electricity, whether *a* has been charged by glass or by sealing wax; and this species will indicate which is positive. We have said "*probably*"—for it is not impossible that it may be otherwise. If the abstraction at *d* be supposed more powerful than the supplying force at *c*, the same obstruction may perhaps keep the plate *c d* in an *absorbing* state, just as water descending in a vertical pipe, into which it is pressed by a very small head of water in the cistern, instead of pressing the sides of the pipe, rather draws them inwards, as is well known. This seems, at any rate, an interesting experiment; for we must acknowledge, that there still hangs a mysterious curtain before a theory which deduces so much from the presence of a substance which we have never been able to exhibit alone, and where we do not know when it abounds and when it is deficient. It is like the phlogiston of Stahl, or the caloric of Lavoisier. It will be proper to use the thinnest plate of talc to be charged, and to connect it with another coated plate of half the diameter, or less, in order to increase the accumulation. It seems by no means a desperate case.

The theory of coated glass now explained, might have been treated with more precision, and the formulæ deduced in the beginning of this article might have been employed for stating the sum total of the acting forces, and thus demonstrating with precision the truth of the general result; and indeed it was with such a view that they were premised: but they would have been considerably complicated in the present case; for however thin we suppose the tinfoil coatings to be, it is evident from n 92, &c. that each coating will consist of three strata; of which the two outermost are active, and must have their forces stated, and the statement of the force of each stratum would have consisted of three terms. This would have been very embarrassing to some readers; and the force of the conclusion would not, after all, have been much more convincing than we hope the above more loose and popular account has been.

We have hitherto considered the non-electric coatings only, and have not attended to what may chance to obtain in the substance of the coated electrics themselves. May not part, at least, of the redundant fluid be lodged in one superficial stratum of the glass? or, if it do not penetrate it, may it not adhere to the surface, and drive off from the other surface, or stratum, a part of what naturally adheres to it? Till Dr Franklin's notions on the subject became prevalent, no person doubted this. The electric was supposed to contain or to accumulate in its surface all the electricity that we know. But the first suggestion of Dr Franklin's experiments certainly was, that the electric plate or vessel acted merely as an obstacle, preventing the fluid from flying from the body where it was redundant to that where it was deficient. It is therefore an important question in the science, whether the glass or electric concerned in these phenomena serve any other purpose besides the mere prevention of the redundant fluid from flying to the negative plate? 175 Does the charge reside in the coatings or in the glass?

Now it appears, at the very first, that this is the case. For if a glass be coated only on one side, and be electrified on that side, we obtain a strong spark from the other side by bringing the knuckle near it: and this may be obtained for some time from one spot of that surface; and after this we get no more from that spot, but get sparks, with the same vivacity, and in the same number, from any other spot that is opposite to the coating on the other side. In this manner we can obtain a succession of sparks from every inch of surface opposite to the coating, and from no other part. But what puts this question beyond all doubt is, that if we now lay a metal coating on the surface from which the sparks have been drawn in this manner, and make a communication between the two metallic coatings, by means of a bent wire, we obtain a perfect discharge. To complete the proof, we need only observe that this experiment succeeds whether the glass has been electrified by excited glass or by excited sealing-wax. Therefore the coated surface may receive the electric fluid by the coating, as we see plainly that it is abstracted by the coating. The use of the coatings may be nothing more than to act as conductors to every part of the surface of the electric. None of these thoughts escaped the penetrating and sagacious mind of Dr Franklin. He immediately put it to the test of experiment; and, laying a moveable metallic coating on both surfaces, he found the glass charge perfectly well. He lifted off the coatings; which operation was accompanied by flashes 176 It is in the glass.

flaſhes of light between the metallic coverings and the glaſs from which he ſeparated them. Having removed the coatings, he applied others, completed the circle, and obtained a perfect diſcharge, not diſtinguiſhable from what he would have obtained from the firſt coatings.

177 Charged glaſs acquires redundant and deficient ſtrata.

Thus it was demonſtrated, that the glaſs plate itſelf acquired by charging a redundant ſtratum on one ſide, and a deficient ſtratum on the other ſide; and we now ſee, at once, the reaſon why the accumulation turns out greater than what is determined by the theory. The diſtance between the redundant and deficient ſtratum is leſs than the thickneſs of the glaſs; and this, perhaps, is an unknown proportion.

This precious experiment of Dr Franklin was repeated by every electrician, and varied in a thouſand ways. No philoſopher has carried this reſearch farther than Beccaria; and he has given ground for a moſt important diſcovery in the mechanical theory, namely, that the charged glaſs has ſeveral ſtrata, of inconceivable thinneſs, alternately redundant and deficient in electric fluid; and that by continuing the electrification, theſe ſtrata penetrate deeper into the glaſs, and probably increaſe in number. We have not room here to give even an account of his experiments, and muſt refer the philoſophical and curious reader to that part of his valuable Treatiſe where he treats of what he calls *vindicating* or *recovering electricity*; as alſo to a paper by Mr Henly in Phil. Tranſ. for 1766, giving account of experiments on Dutch plates by Mr Lane. The general form of the experiment is this. He puts two plates together; he coats the outer ſurfaces, and charges and diſcharges them as one thick plate. Their inner touching ſurfaces are found ſtrongly electrical after the diſcharge, having oppoſite electricities, and changing theſe electricities, by repeated ſeparations and replacings, in a way ſeemingly very capricious at firſt ſight, but which the attentive reader will find to be according to fixed laws, and agreeably to the ſuppoſition that the ſtrata gradually ſhift their places within the glaſs, very much reſembling what we obſerve on a long glaſs rod which we would render electric by induction. In this caſe, as was obſerved in n° 57. there are obſerved more than one neutral point, &c.

178. Mr Cavendiſh endeavours to give us ſome notion of the diſpoſition of the fluid in the ſubſtance of the glaſs in the following manner: Having ſeparated the coated plate from the machine and from the ground, ſuppoſe a little of the redundant fluid in $B \beta \delta D$ (fig. 33.) equal to the fluid wanting in $E \varepsilon \varphi F$. If we now ſuppoſe all the redundant fluid to be lodged in $b \beta \delta d$, and $e \varepsilon \varphi f$ to hold all the redundant matter, and the two coatings to be in their natural ſtate, a particle p, placed in the middle of the ſurface $b\,d$, will be nearly as much attracted by $\varepsilon e f \varphi$ as it is repelled by $b \beta \delta d$ (exactly ſo if the plates were infinitely extended); and if the coating be removed, keeping parallel and oppoſite to the ſurface that it quits, there will be very little, if any, tendency to fly from the glaſs to the coating: there will rather be ſome diſpoſition in the fluid to quit the coating and fly to the glaſs; becauſe the repulſion of $b \beta \delta d$ is more diminiſhed than the attraction of $\varepsilon e f \varphi$. (n° 42.) But the difference will be very ſmall indeed. (*N. B.* the reſult would be very different if electric action followed a different law. Were it as $\frac{1}{d^3}$, the coating would be much overcharged; and were it as $\frac{1}{d}$, it would be very much undercharged). Now the fact is, that when the coating is carefully removed, it is poſſeſſed of very little electricity, not more than may reaſonably be ſuppoſed to run into it by bringing away one part before another. It is impoſſible to keep it mathematically parallel.

Hence we may conclude that the greateſt part of the redundant fluid is lodged in the glaſs if the plates be thin, and the redundant fluid bear but a ſmall proportion to the natural quantity. Similar reaſoning ſhews that the greateſt part of the deficiency is in the other ſide of the glaſs; and that therefore the coatings are very nearly in their natural ſtate, and merely ſerve the purpoſe of conducting.

We have employed coatings of conſiderable thickneſs, having holes through them, oppoſite to which was ſome gold leaf of the heavieſt ſort, and almoſt free of cracks. We have examined the ſtate of the bottom of thoſe pits in Mr Coulomb's manner, and always found them void of electricity.

Thus we learn that glaſs, and probably all other electrics, acquire redundant and deficient ſtrata as well as the moſt perfect conductors, at the ſame time that they may be impervious to the fluid; and we get ſome mode of conceiving how the rupture happens by a ſtrong charge. This may very probably happen when the ſtrata have formed, in alternate order, ſo deep in the glaſs, that a ſtratum, in which the fluid is crowded cloſe together, may become contiguous to one deprived altogether of fluid. We cannot, however, ſay with confidence, what *ſhould* be the effect of this ſtate of things; or of one conſtipated ſtratum coming in contact with another. 179 Conjecture about the burſting of jars.

This view of the condition of charged glaſs explains (we think) ſeveral phenomena which ſeem not well underſtood by electricians.

The reſiduum of a diſcharge is frequently owing to a charge extending beyond the coating, where the action is conſiderably irregular, or different from what it would be if the plates were infinitely extended. This *outline* charge is taken up by the coated part after a very little while, and may again be diſcharged. But it alſo frequently ariſes from another ſtratum (much thinner, as it will always be) than the exterior one, coming to the ſurface ſome time after the firſt diſcharge, and being now in a condition for being diſcharged. It explains the ſparkling that is perceived *in ſucceſſion* between the parts of a jar that is coated in ſpots, during the charge, and the very ſenſible reſiduum of the charge of ſuch a veſſel. It explains the phenomena of Beccaria's *Electricitas Vindex* (ſee Electricity, *Encycl.* n° 48.), and the great difference that may be found in the different kinds of glaſs in this reſpect. It explains the great difference between the ſenſation occaſioned by a ſpark from a perfectly conducting ſurface of conſiderable extent, and that occaſioned by a ſhock, which conveys the ſame quantity of fluid accumulated in a ſmall ſurface of glaſs. The diſcharge of the firſt is almoſt inſtantaneous, while that of the laſt requires a ſmall moment of time, and is therefore leſs deſultory 180 Several phenomena explained.

and

and abrupt. The one is pungent and ſtartling; but the other is ſofter in the firſt inſtant, and ſwells to a maximum. Therefore, in the medical employment of electricity, when the purpoſe is to be affected by the transfuſion of a great quantity of electric fluid, we ſhould recommend very ſmall ſhocks from a very large ſurface of coated glaſs, very faintly electrified, in place of ſtrong ſparks. Patients of irritable conſtitutions are frequently alarmed by the quickneſs and pungency of ſtrong ſparks: but if the balls of Lane's ſhock-meaſurer be ſet ſo cloſe as to give four or five ſhocks in each turn of a ſeven inch cylinder, the ſhocks are not even diſagreeable. The balls ſhould be made of fine cupelled ſilver: in which caſe, the ſurface will never be hurt by the greateſt diſcharge; whereas the diſcharge of four ſquare feet of coated glaſs will raiſe ſuch a roughneſs on the ſurface of braſs as will cauſe it to ſputter, and deſtroy entirely the regularity of the expenditure of fluid. The ſame conſideration ſhould make us prefer a jar coated entirely with amalgam. This cob-web coating gives a greater ſoftneſs to the ſhock. Laſtly, we ſee why a powerful and permanent electricity was not produced in the tube filled with melted ſealing wax, and treated as mentioned in n° 101. The redundancy and deficiency intended to be produced could only be ſuperficial. And becauſe the wax cooled by degrees from the ſurface to the axis, and the wax is a conductor while liquid, it muſt have taken a charge at laſt; and therefore muſt appear but faintly electrical.

181. This account of the ſtate of charged glaſs promiſes us ſome aſſiſtance in our attempts to conceive what paſſes in the excitation of glaſs by friction. It appears from Beccaria's experiments, that the redundant fluid is lodged in the ſame manner in both caſes; for by rubbing one ſide of a glaſs tumbler, while points were preſented to the oppoſite ſurface, and were connected with a wire that communicated with the ground, he gave it a powerful charge.

182 The quantity of fluid in a body may be exceeding great.

It is obſerved, that when the laminæ of a piece of Muſcovy glaſs are ſeparated, by pulling them aſunder without inſerting any inſtrument between them, they are electrical when ſeparated; one being poſitive, and the other negative. Muſt we not conclude from this, that when conjoined they were in the ſtate of charged glaſs? If we take this view of it, a body may contain a prodigious quantity of electric fluid without exhibiting any appearance of it. Mr Nicholſon found, by a very fair computation from his experiments, that a cubic inch of talc, when ſplit into plates of 0,011 of an inch in thickneſs, and coated with gold leaf, gave a ſhock equal to the emptying 45 conductors, each ſeven inches in diameter and three feet long, electrified ſo that each gave a ſpark at nine inches diſtance. Now, the whole of this was moveable fluid, and no more than what the talc contains when unelectrified: for no more comes into the poſitive ſide than goes out of the negative ſide. Nay, there is no probability that the quantity moveable in our experiments bears a conſiderable proportion to the natural quantity. The quantity of moveable fluid in a man's body is therefore very great: and Lord Mahon is well authoriſed to ſay, that the ſudden diſplacing of this quantity in a *returning ſtroke*, which has been occaſioned by a diſcharge of a cloud in a very diſtant place, is fully adequate to the production of the moſt violent effects. But his Lordſhip has not attended to the circumſtance, that no ſuch diſplacement can happen. The accumulation that can be made in the human body is only ſuperficial; and therefore, altho' the whole fluid of a man's body may change its place, it will not change it with the rapidity that ſeems neceſſary for the violent effects of electricity, except in the very points of communication with the ſurrounding bodies.

We have now ſeen in what ſenſe the idio-electrics may be ſaid to be impervious to the electric fluid. It is moved in them only to very ſmall and imperceptible diſtances. When a conſiderable ſtratum is diſcharged, the fluid does not come from the extremity of it to the point of diſcharge through the glaſs, but through the coating. And when alternate ſtrata of redundant fluid and redundant matter are formed, the particles in each ſhift their places very little, moving perpendicularly to the ſtratum. 183.

184 The impermeability of electrics denied by ſome.

Even this degree of obſtruction has been denied by ſome very active electricians, who have multiplied experiments to prove that the fluid paſſes freely through glaſs, and that the theory of coated electrics is totally different from what Franklin imagines. Mr Lyons of Dover has publiſhed a numerous liſt of ſingular experiments, which he has made with this view, with much trouble, and no ſmall expence. They may all be reduced to this: A wire is brought from the outſide of a phial, charged by the knob, and terminates in a ſharp point at a ſmall diſtance from a thin glaſs plate (it is commonly introduced into a glaſs tube, having a ball at the end, and the point of the wire reaches to the centre of the ball); and another wire is connected with the diſcharging rod, and alſo comes very near (and frequently cloſe) to the other ſide of the glaſs, oppoſite to the pointed wire. With this apparatus he obtains a diſcharge; and therefore ſays that the glaſs is permeable to electricity. But he does not narrate all the circumſtances of the experiment. We have repeated all of them that have any real difference (for moſt of them are the ſame fact in different forms), and we have obtained diſcharges: But they were all very incomplete, except when the glaſs was perforated, which happened very frequently. The diſcharge was never made with a full, bright, undivided ſpark, and loud ſnap; but with ſputtering, and trains of ſparks, continued for a very ſenſible time; and the phial was never deprived of a conſiderable part of its charge: and (which Mr Lyons has taken no notice of) the glaſs is found to be charged, negative on the ſide connected with the poſitive ſide of the phial, and poſitive on the other. This charge was communicated to the glaſs over a pretty conſiderable ſurface round the points immediately oppoſite to the wires. This is quite conformable to the experiments of Dr Franklin and Beccaria, who charged a tumbler by graſping it with the hand, and preſenting the inſide to a point electrified by the prime conductor. The whole experiment is analogous to the one narrated in n° 176.

185 Bars touched like magnets for electricity.

We may conclude our obſervations on coated glaſs with mentioning a curious experiment. A flat ſtick of fine ſealing wax, warmed till it bent pretty readily, was rendered permanently electrical, with a poſitive and negative pole, in a manner analogous to the double touch of magnets. A ſmall jar was taken, having a hemiſphere on the end of its inſide wire, and another on the end

end of a ſtiff wire projecting from the outer coating, and then turned up parallel to the inſide wire; ſo that the two hemiſpheres ſtood equally high, and about three inches aſunder. This jar was electrified ſo weakly, as to run no riſk of a ſpontaneous diſcharge. The flat faces of the two hemiſpheres were now applied to the flat ſide of the ſealing wax, and were moved to and fro along it, overpaſſing both ends about an inch with each hemiſphere. The experiment was very troubleſome; for the phial often diſcharged itſelf along the ſurface of the ſealing wax, and all was to begin again. But, by continuing this operation till the ſealing wax grew quite cold and hard, it acquired a very ſenſible electriciſm, which laſted ſeveral weeks when kept with care; but ſtill it was not much more ſenſible than that of the ſealing wax, which congealed between two globes oppoſitely electrified.

186 Electrophorus. After this application of the theory to the phenomena of coated glaſs, it will not be neceſſary to employ much time in its application to the electrophorus. The general propoſitions from n° 14. to 25. and their companions in n° 38—43, will enable us to ſtate with preciſion (when combined with the law of electric action) the actions of every part of this apparatus; and conſiderable aſſiſtance will be derived from a careful conſideration of our analyſis of Profeſſor Richmann's experiment in n° 156. But we muſt content ourſelves with a general, popular view of theſe particulars, which may be ſufficient for making us underſtand what will be the *kind*, and ſomewhat of the *intenſity*, of the action of its different parts.

The electrophorus conſiſts of three parts. The chief part is the cake ABCD (fig. 34.) of ſome electric; ſuch as gum lac, ſealing wax, pitch, or other reſinous compoſition. This is melted on ſome conducting plate, DCFE, and allowed to congeal; in which ſtate it is found to be negatively electric. Another conducting plate GHBA is laid on it, and may be raiſed up by ſilk lines, or any inſulating handle. We ſhall call ABCD the CAKE, DCFE the SOLE, and GHBA the COVER.

The general appearances not having been ſo ſcientifically claſſed in the article ELECTRICITY as could be wiſhed, we ſhall here narrate them, very briefly, in a way more ſuited to our purpoſe. In comparing the theory with obſervation, it will be proper to make all the three parts of conſiderable thickneſs, and of no great breadth. Although this diminiſhes greatly the moſt remarkable of the actions, it leaves them ſufficiently vivid, and it greatly increaſes the ſmaller changes which are inſtructive in the compariſon. The general facts are,

Phenomena thereof. 1. If the ſole has been inſulated during the congelation of the electric, till all is cold and hard, the whole is found negatively electric, and the finger draws a ſpark from any part of it, eſpecially from the ſole. If allowed to remain in this ſituation, its electricity grows gradually weaker, and at laſt diſappears: but it may be excited again by rubbing the cake with dry warm flannel, or, which is the beſt, with dry and warm cat or hare fur. If the cover be now ſet on the cake by its inſulating handle, but without touching the cover, and again ſeparated from the cake, no electricity whatever is obſerved in the cover.

2. But if it be touched while on the cake, a ſharp pungent ſpark is obtained from it; and if, at the ſame time, the ſole be touched with the thumb, a very ſenſible ſhock is felt in the finger and thumb.

3. After this, the electrophorus appears quite inactive, and is ſaid to be *dead*; neither ſole nor cover giving any ſign of electricity. But,

4. When the cover is raiſed to ſome diſtance from the cake (keeping it parallel therewith), if it be touched while in this ſituation, a ſmart ſpark flies, to ſome diſtance, between it and the finger, more remarkably from the upper ſide, and ſtill more from its edge, which will even throw off ſparks into the air, if it be not rounded off. As this diminiſhes the deſired effects, it is proper to have the edge ſo rounded. This ſpark is not ſo ſharp as the former, and reſembles that from any electrified conductor.

5. The electricity of the cover, while thus raiſed, is of the oppoſite kind to that of the cake, or is poſitive.

6. The electricity of the cover while lying on the cake is the ſame with that of the cake, or negative.

7. The appearances n° 2, 3, 4, may be repeated for a very long time without any ſenſible diminution of their vivacity. The inſtrument has been known to retain its power undiminiſhed even for months. This makes it a ſort of magazine of electricity, and we can take off the electricity of the cake and of the cover as charges for ſeparate jars, the cover, when raiſed, charging like the prime conductor of an ordinary electrical machine; and, when ſet on the cake, charging it like the rubber. This cauſed the inventor, Mr Volta, to give it the name of ELECTROPHORUS.

8. If the ſole be inſulated before putting on the cover, the ſpark obtained from the cover is not of that cutting kind it was before: but the ſame ſhock will be felt if both cake and cover be touched together.

9. If the cover be again raiſed to a conſiderable height, the ſole will be found electrical, and its electricity is that of the cake, and oppoſite to that of the cover.

10. After touching both cover and ſole, if the cover be raiſed and again ſet down, without touching it while aloft, the whole is again inactive.

11. If both cover and ſole be made inactive when joined, they ſhew oppoſite electricities when ſeparated, the ſole having the electricity of the cake.

12. If both cover and ſole be made inactive when ſeparate, they both ſhew the oppoſite to the electricity of the cake when joined.

Let us now attend to the diſpoſition of the electrical fluid in the different parts of the inſtrument in their various ſituations, and to the forces which operate mutually between them. *N. B.* Experiments for examining this inſtrument are beſt made by ſetting the three plates vertically, ſupported on glaſs ſtalks, with leaden feet, to ſteady them. A very ſmall electrometer may be attached to the outer ſurfaces of the cover and ſole. 187 Diſpoſition of the fluid

If the extent of the plates were incomparably greater than their thickneſs, we may infer from n° 92, &c. that the redundant fluid and matter would be diſpoſed in parallel ſtrata, and that the actions would be the ſame at all diſtances. But ſince this is not the caſe, the diſpoſition of the fluid will be ſomewhat different; and whatever it is, the action of any ſtratum will be diminiſhed by an increaſe of diſtance. The following deſcription cannot be very different from the truth:

1. The cake grows negative by cooling; and if it were

188 Explanation of the *primitive ſtate.* were alone, it would have a negative ſuperficial ſtratum on both ſides, of greater thickneſs near the edges; and the fluid would probably grow denſer by degrees to the middle, where it would have its natural denſity. This diſpoſition may be inferred from n° 92, 93, and 98. But it cools in conjunction with the ſole, and the attraction of the redundant matter in the cake; for the moveable fluid in the ſole diſturbs its uniform diffuſion in the ſole, and cauſes it to approach the cake. And becauſe this, in all probability, happens while the cake is ſtill a conductor, the diſpoſition of its fluid will be different from that deſcribed above, and the final diſpoſition of the fluid in the cake and ſole will reſemble that deſcribed in n° 95, where the plates E and A repreſent the cake and ſole. But becauſe we do not know preciſely the gradation of denſity, and aim only at general notions at preſent, it will be ſufficient to conſider the cake and ſole as divided into two ſtrata only; one redundant in fluid, and the other deficient, neglecting the neutral ſtratum that is interpoſed between them in each. The cake, then, conſiſts of a ſtratum AB*ba*A containing redundant matter, and a ſtratum *ab*CD containing redundant fluid: and the ſole has a ſtratum DC*nm* containing redundant fluid, namely, all that belongs naturally to the ſpace DCFE, and a ſtratum *mn*FE containing redundant matter. This may be called the PRIMITIVE STATE of the cake and ſole; and if once changed by communication with unelectrified bodies, it can never be recovered again without ſome new excitement.

189 *Common ſtate.* II. If the ſole be touched by any body communicating with the ground, fluid will come in, till the repulſion of the redundant fluid in the ſole for a ſuperficial particle *y* is equal to the attraction of the redundant matter in the cake for the ſame particle. What has been ſaid concerning infinitely extended plates rendered neutral on one ſide, may ſuffice to give us a notion of the preſent diſpoſition of the fluid in the ſole. The under ſurface will be neutral, and the fluid will increaſe in denſity toward the ſurface DC. The ſole contains more than its natural quantity of fluid, but is neutral by the balance of oppoſite forces. Let it now be inſulated. This diſpoſition of fluid may be called the *common ſtate* of the electrophorus.

190. III. Let the cover GHBA be laid on it. The particle *z*, at the upper ſurface of the cover, muſt be more attracted by the redundant matter in the ſtratum AB*ba* than it is repelled by the redundant fluid in the remoter ſtrata; for the fluid in the cake is leſs than what belongs to it in its natural ſtate, and therefore *z* is attracted by the cake. The redundant fluid which has come into the remote ſide of the ſole is leſs than what would ſaturate the redundant matter of the cake, becauſe it only balances the exceſs of the remote action of this matter above the nearer action of the compreſſed fluid in the ſole; and this ſmaller quantity of redundant fluid acts on *z* at a greater diſtance than that of the redundant matter in the cake. On the whole, therefore, the particle *z*, lying immediately within the ſurface GH, is attracted; therefore ſome will move toward the cake, and its natural ſtate of uniform diffuſion through the cover will be changed into a violent ſtate, in which it will be compreſſed on the ſurface AB, being abſtracted from the ſurface GH. It will now have a ſtratum G*gp*H, containing redundant matter, and another *gp*BA, containing redundant fluid. But this will diſturb the arrrangement which had taken place in the ſole, and had rendered it neutral on the under ſurface. We do not attend to the fluid in the cake, but conſider it as immoveable; for any motion which it can get will be ſo ſmall, that the variations of its action will be altogether inſignificant. The particle *y*, ſituated in that ſurface, will be more repelled by the compreſſed fluid in the ſtratum *gp*CA than it is attracted by the equivalent, but more remote redundant matter in GH*pg*. Fluid is therefore diſpoſed to quit the ſurface EF, and the ſole appears poſitively electric; very little indeed, if the cover be thin. All this may be obſerved by attaching a ſmall Canton's electrometer to the lower ſurface of the ſole, or by touching the ſole with the electrometer of fig. 8. and then trying its electricity by rubbed wax or glaſs.

IV. A particle of fluid *z*, placed immediately without the ſurface GH, will be more attracted by the deficient ſtratum GH*pg* and by AB*ba* than it is repelled by the redundant ſtrata beyond them, and the cover muſt be ſenſibly negative. This is the common ſtate of the whole inſtrument after ſetting on the cover. It is ſlightly poſitive on the lower ſurface of the ſole, and much more ſenſibly negative on the upper ſurface of the cover. A ſmart ſpark will therefore be ſeen between it and the finger, fluid will enter, till the attraction of the redundant matter in AB*ba* is balanced by the repulſion of the redundant fluid in DCFE. 191.

V. A ſpark will now be obtained from the ſole, becauſe it was faintly poſitive before, and there has been added the action of the fluid which has entered into the cover. The fluid in the ſole is therefore diſpoſed to fly to any body preſented to it. But when this has happened, the equilibrium at the ſurface GH is deſtroyed. and that ſurface again becomes negative, and will attract fluid, although the cover already contains more than its natural quantity. A ſmall ſpark will therefore be ſeen between the cover and any conducting body preſented to it. By touching it, the neutrality or equilibrium is reſtored at GH; but it is deſtroyed again at EF, which will again give a poſitive ſpark, which, in its turn, again leaves GH negative. This will go on for ever, in a ſeries of communications continually diminiſhing, ſo as ſoon to become inſenſible, if the three parts of the electrophorus be thin. This makes it proper to make them otherwiſe, if the inſtrument be intended for illuſtrating the theory. 192 *Dead ſtate.*

At laſt the equilibrium is completed at the ſurfaces GH and EF, and both are neutral in relation to ſurrounding bodies, although both the cover and ſole contain more than their natural ſhare of electric fluid. We may call this the NEUTRAL OR DEAD ſtate of the electrophorus.

This ſtate may be produced at once, inſtead of doing it by theſe alternate touches of GH and EF. If we touch at once both theſe ſurfaces, we have a bright, pungent ſpark, and a ſmall ſhock. If this be the object of the experiment, the ſtate N° IV. which gives occaſion to it, may be called the CHARGED ſtate of the electrophorus. 193 *Charged ſtate.*

When the inſtrument has thus been rendered neutral in relation to ſurrounding bodies, it is plain that it may continue in this ſtate for any length of time without any diminution of its capability of producing the other phenomena,

phenomena, provided only that no fluid pafs from the cover to the cake. We do not *fully* underftand what prevents this communication, nor indeed what prevents the rapid efcape from an overcharged body into the air. This caufe, whatever it be, operates here; and the beft way of preventing the diffipation, or the abforption by the cake, is to keep the electrophorus with its cover on. It will come into this neutral ftate by diffipation from the fole, and abforption by the cover, in no very long time; and after this, will remain neutral, retaining its power with great obftinacy, efpecially if the cake and plates are very thin.

194 *Charging or active ftate.* VI. If the cover be now removed to a diftance, both parts of the apparatus will fhew ftrong marks of electricity. The cover contains much redundant fluid, and muft appear ftrongly pofitive, and will give a bright fpark, which may be employed for any purpofe. It may be employed for charging a jar pofitively by the knob, if we juft touch the cover with the knob. The fole will attract fluid, or be negative, although it contain more than its natural quantity of fluid, and it will take a fpark. The fole therefore, in the abfence of the cover, may be employed to charge a jar negatively by the knob. By touching it with the finger, or with the knob of a jar held in the hand, it is reduced to the common ftate defcribed in N° II.; and now all the former experiments may be repeated. We may call this the ACTIVE or the CHARGING ftate.

Electrophorus not a magazine of electricity, but a collecting machine. This ftate of the apparatus has caufed it to get the name *Electrophorus*. Volta, its undoubted inventor, called it *Electroforo perpetuo*; for it *appears*, as has been already obferved, to contain a magazine of electricity. The cover, when removed, will charge a jar held in the hand pofitively; and having done this fervice, it will charge a jar negatively when again fet on the cake. The fole, in the abfence of the cover, will charge a third jar negatively; and then, when the cover, after being touched, is fet down again, it will charge a fourth jar pofitively. It will not be difficult to contrive a fimple mechanifm, connected with the motion of the cover, which fhall connect the joined parts with two jars, and fhall connect them, when feperated, with two others; and thus charge all the four with great expedition. All this is done without any new excitation of the electrophorus. But it is by no means a *magazine* of electricity which it gradually expends: it is a COLLECTOR of electricity from the furrounding bodies, which it afterwards imparts to others, and may be employed to difcharge jars in the fame gradual manner as to charge them.

195. VII. If the electrophorus is not infulated, a fhock may ftill be obtained, by firft touching the fole, and then, without removing the finger, touching the cover: but this will not be fo fmart as when the negative cover is touched at the fame time that we touch the fole, more highly pofitive than when it communicates with the ground. The difference muft, however, be almoft imperceptible when the pieces are thin.

196. VII. If the electrophorus is not infulated, the cover, when put on, will give a fpark in the manner already mentioned, and it will be fomewhat ftronger than when it is infulated; becaufe the fluid is allowed to efcape from the fole, and does not obftruct the entry into the cover. If we then, without removing the finger from the cover, touch the fole, nothing is felt; but if we firft touch the fole, and, without removing the finger from it, touch the cover, we obtain a fhock. This is evident from the theory. By this feries of alternate touches, the period of the electrophorus is completed. The electrophorus is charged, or rendered neutral, by touching the plates when joined; then, by touching both when feparated, the whole is reduced to the common ftate. When feparated, from being in the neutral ftate, they have oppofite electricities, the fole fhewing that of the cake When brought together, each in the common ftate, they have oppofite electricities, the cover fhewing that of the cake.

IX. When, by long expofure to the air without its cover, the electrophorus has loft its virtue, it may be brought again into an active ftate in a variety of ways. 197 How it may be recreated. Its furface may be rendered negative by friction with dry cat or hare fkin, or warm flannel. It may be rendered negative by fetting on it a jar charged negatively on the infide, and then touching the knob with any thing communicating with the ground. This is the moft expeditious method, and will give it a high degree of excitation, if the jar be of fize, and if the electrophorus be covered with a plate of tinfoil which comes into contact all over its furface. This however requires the previous charging of the jar; therefore it will be as expeditious and effectual to connect this furface with the rubber of an electrical machine. We had almoft forgotten to remark, that the effects of bringing the cover edgewife to the cake follow clearly from the theory, as will appear to the attentive reader without further explanation.

The electrophorus has been compared to a charged plate of coated glafs. 198 It is not fimilar to a charged pane. It is true that it *may be brought* into an external ftate which very much refembles a charged pane; namely, when the cover, in its natural ftate, is fet on the electrophorus in its natural ftate: and accordingly it gives a fhock, and the two exterior furfaces become neutral; but the internal conftitution, and the acting forces, are totally and *effentially* different. The two coatings of the pane would not, when feparated, exhibit the appearances of the electrophorus; nor, when touched in their disjoined ftate, will they produce the fame effects when joined. In the operation of coated glafs, the conftant or invariable part, the glafs is not the *agent*, it is merely the *occafion* of the action, by *allowing* the accumulation. In the electrophorus, the electric, which is the conftant invariable part, is the *agent producing* the accumulation. The electrophorus is an original, and a very ingenious and curious electrical machine. Nothing has fo much contributed to fpread fome general, though flight, acquaintance with the mechanical principles of electricity. The numerous dabblers in natural knowledge had been diverted from fcientific purfuit by the variety of the fingular and amufing effects of electricity, and had really attained very little connected knowledge. The effects of the electrophorus *forced* this knowledge on them; becaufe no ufe can be made of it without a pretty clear conception of the difpofition of the electricity, and the kind and intenfity of the actions. It is therefore moft ungrateful in the experimenters who have attained better views, to attempt to rob Mr Volta of the real merit of difcovery, by fhewing that its effects are fimilar to thofe of Mr Symmer's ftockings, or of Cigna's plates, or of Franklin's charged or difcharged glafs panes. And the at-

tempt

tempt deſtroys itſelf: for it ſhews the ignorance or inattention of its author; for the ſimilarity is not real, as will appear clear to any perſon who will examine things minutely and ſcientifically, proceeding in this examination on ſuppoſitions ſimilar to thoſe which we employed in the analyſis of Richmann's experiment. It was indeed in ſubſerviency to this examination that we entered into the detail of that experiment, it being a ſimpler caſe. The accurate examination of Richmann's experiment requires the fluxionary calculus in its refined form. In the preſent queſtion five acting ſtrata are to be conſidered, which renders the formulæ very complicated, and indeed intractable, unleſs we make the plates extremely thin; which, fortunately, is the beſt form of the inſtrument. We have completed this mathematical analyſis; and the popular view here given is the reſult of that computation.

199 *Condenſator* of electricity. The electricians are no leſs obliged to Mr Volta for another machine, or inſtrument, from which the ſtudy of Nature's operations has derived, or may derive, immenſe advantages. We mean the CONDENSER or COLLECTOR of electricity. We refer to the article ELECTRICITY in the *Encyclopædia* for a deſcription of the inſtrument, and ſome account of its effects and properties. The general effect is to render ſenſible an accumulation or deficiency of electric fluid ſo ſlight that it will not affect the moſt delicate electrometer; and it produces (at leaſt in the opinion of Mr Volta) this effect, by employing for the ſole of an electrophorus a body which is an imperfect conductor, ſuch as a plate of well dried marble, or well dried, but not baked, wood; or even a conducting body, covered with a bit of dry taffety or other ſilk. Mr Volta, Cavallo, and others, who have written a great deal on the ſubject, have attempted to ſhew how theſe ſubſtances are preferable (and they certainly are preferable in a high degree) to more perfect inſulators: but not having taken pains to form preciſe notions of the diſpoſition and action of the electric fluid in the ſituations afforded by the inſtrument, their reaſonings have not been very clear. We think that an adequate conception of the eſſentials of the propoſed inſtrument may be acquired by means of the following conſiderations:

200. Furniſh the cover of an electrophorus with a graduated electrometer, which indicates the proportional *degrees of electricity*; electrify it poſitively to any degree, ſuppoſe ſix, while held in the hand, at ſome diſtance, right over a metal plate lying on a wine glaſs as an inſulating ſtand, but communicating with the ground by a wire. Bring it gradually down toward the plate. Theory teaches, and we know it by experiment, that the electrometer will gradually ſubſide, and perhaps will reach to 2° before the electricity is communicated in a ſpark. Stop it before this happens. In this ſtate the attraction of the lying plate produces a compenſation of four degrees of the mutual repulſion of the parts of the cover, by conſtipating the fluid on its under ſurface, and forming a deficient ſtratum above. This needs no farther explanation after what has been ſaid on the charging of coated glaſs plates. Now we can ſuppoſe that the eſcape of the fluid from this body into the air begins as ſoon as electrified to the degree 6, and that it will fly to the lying plate with the degree 2, if brought nearer. If we can prevent this communication to the lying plate, by interpoſing an electric, we may electrify the cover again, while ſo near the metal plate, to the degree 6, before it will ſtream off into the air. If it be now removed from the lying plate, the fluid would raiſe the electrometer to 10, did it not immediately ſtream off; and an electric excitement of any kind which could only raiſe this body to the degree 6 by its intenſity, will, by this apparatus, raiſe it to the degree 10, if only copious enough in extent. If we do the ſame thing when the wire is taken away which connects the lying plate with the ground, we know that the ſame diminution of the electricity of the other plate cannot be produced by bringing it down into the neighbourhood of the lying plate (ſee n° 134, &c. 151, &c.)

Here we ſee the whole theory of Mr Volta's condenſer. Theory thereof. He ſeems to have obſcured his conceptions of it by having his thoughts running upon the electrophorus lately invented by him, and is led into fruitleſs attempts to explain the advantages of the imperfect conductor above the perfect inſulator. But the apparatus is altogether different from an electrophorus, and is more analogous in its operations to a coated plate not charged nor inſulated on the oppoſite ſide; and ſuch a coated plate lying on a table is a complete condenſer, if the upper coating be of the ſame ſize with the plate of the condenſer. All the directions given by Mr Volta for the preparation of the imperfect conductors ſhew, that the effect produced is to make them as perfect conductors as poſſible for any degree of electricity that exceeds a certain ſmall intenſity, but ſuch as ſhall not ſuffer this very weak electricity to clear the firſt ſtep of the conduit. The marble muſt be thoroughly dried, and even heated in an oven, and either uſed in this warm ſtate, or varniſhed, ſo as to prevent the reabſorption of moiſture. We know that marble of ſlender dimenſions, ſo as to be completely dried throughout, will not conduct till it has again become moiſt. A thick piece of marble is rendered ſo, ſuperficially only, and ſtill conducts internally. It is then in the beſt poſſible ſtate. The ſame may be ſaid of dry unbaked wood. Varniſhing the upper ſurface of a piece of marble or wood is equivalent to laying a thin glaſs plate on it. Now this method, or covering the top of the marble, or of a book, or even the table, with a piece of clean dry ſilk, makes them all the moſt perfect condenſators. This juſt view of the matter has great advantages. It takes away the myſterious indiſtinctneſs and obſcurity which kept the inſtrument a quackiſh tool, incapable of improvement. We can now make one incomparably better and more ſimple than any propoſed by the very ingenious inventor. We need only the ſimple moveable plate. Let this be varniſhed on the under ſide with a moderately thick coat of the pureſt and hardeſt *vernis de Martin*, or coach-painters varniſh; and we have a complete condenſator by laying this on a table. If it be connected by a wire with the ſubſtance in which the weak and imperceptible electricity is excited, it will be raiſed (provided there be enough of it of that ſmall intenſity) in the proportion of the thickneſs of the varniſh to the fourth part of the diameter of the plate. This degree of condenſation will be procured by detaching the connecting wire from the inſulating handle of the condenſer, and then raiſing the condenſer from the table. It will then give ſparks, though the original electricity could not ſenſibly affect a flaxen fibre.

It

It muſt be particularly noted, that it can produce this condenſation only when there is fluid to condenſe; that is, only when the weak electricity is diffuſed over a greater ſpace than the plate of the condenſer. In this way it is a moſt excellent collector of the weak atmoſpheric electricity, and of all diffuſed electricity. But to derive the ſame advantage from it *in many very intereſting caſes*, ſuch as the inquiry into the electricity excited in many operations of Nature on ſmall quantities of matter, we muſt have condenſers of various ſizes, ſome not larger than a ſilver penny. To conſtruct theſe in perfection, we muſt uſe the pureſt and hardeſt varniſh, of a kind not apt to crack, and highly coercive. This requires experiment to diſcover it. Spirit varniſhes are the moſt coercive; but by their difference of contraction by cold from that of metals, they ſoon appear froſty, and when viewed through a lens, they appear all ſhivered: They are then uſeleſs. Oil varniſhes have the requiſite toughneſs, but are much inferior in coercion. We have found amber varniſh inferior to copal varniſh in this reſpect, contrary to our expectation. On the whole, we ſhould prefer the fineſt coach-painters varniſh, new from the ſhop, into which a pencil has never been dipped: and we muſt be particularly careful to clear our pencils of moiſture and all conducting matter, which never fails to taint the varniſh. We ſcarcely need remark, that the coat of varniſh on theſe ſmall condenſers ſhould be very thin, otherwiſe we loſe all the advantage of their ſmallneſs.

201 Cavallo's improvement thereof.

Mr Cavallo has ingeniouſly improved Volta's condenſer by connecting the moveable plate, after removal, with a ſmaller condenſer. The effect of this is evident from n° 130. But the ſame thing would have been generally obtained by uſing the ſmall condenſer at firſt, or by uſing a ſtill thinner coat of varniſh.

202. It will readily occur to the reader, that this inſtrument is not inſtantaneous in its operation, and that the application muſt be continued for ſome time, in order to collect the minute electricity which may be excited in the operations of nature. He will alſo be careful that the experiment be ſo conducted that no uſeleſs accumulation is made anywhere elſe. When we expect electricity from any chemical mixture, it never ſhould be made in a glaſs veſſel, for this will take a charge, and thus may abſorb the whole excited electricity, accumulating it in a neutral or inſenſible ſtate. Let the mixture be made in veſſels of a conducting ſubſtance, inſulated with as little contact as poſſible with the inſulating ſupport; for here will alſo be ſomething like a charge. Suſpend it by ſilk threads, or let it reſt on the tops of three glaſs rods, &c.

203 Bennet's *doubler* of electricity.

After this account of the Leyden phial, electrophorus, and condenſer, it is ſurely unneceſſary to employ any time in explaining Mr Bennet's moſt ingenious and uſeful inſtrument called the *doubler of electricity*. The explanation offers itſelf ſpontaneouſly to any perſon who underſtands what has been ſaid already. Mr Cavallo has with induſtry ſearched out all its imperfections, and has done ſomething to remove them, by ſeveral very ingenious conſtructions, minutely deſcribed in his Treatiſe on Electricity. Mr Bennet's original inſtrument may be freed, we imagine, as far as ſeems poſſible, by uſing a plate of air as the intermedium between the three plates of the doubler. Stick on one of the plates three very ſmall ſpherules made from a capillary tube of glaſs, or from a thread of ſealing wax. The other plate being laid on them, reſts on mere points, and can ſcarcely receive any friction which will diſturb the experiment. Mr Nicholſon's beautiful mechaniſm for expediting the multiplication, has the inconveniency of bringing the plates towards each other edgewiſe, which will bring on a ſpark or communication ſooner than may be deſired: but this is no inconvenience whatever in any philoſophical reſearch; becauſe, before this happens, the electricity has become very diſtinguiſhable as to its kind, and the degree of multiplication is little more than an amuſement. The ſpark may even ſerve to give an indication of the original intenſity, by means of the number of turns neceſſary for producing it. If the fine wires, which form the alternate connections in ſo ingenious a manner, could be tipped with little balls to prevent the diſſipation, it would be a great improvement indeed. An alternate motion, like that of a pump-handle, might be adopted with advantage. This would allow the plates to approach each other face to face, and admit a greater multiplication, if thought neceſſary.

204 Diſſipation of electricity from ſharp points.

One of the moſt remarkable facts in electricity is the rapid diſſipation by ſharp points, and the impoſſibility of making any conſiderable accumulation in a body which has any ſuch, projecting beyond other parts of its ſurface. The diſſipation is attended with many remarkable circumſtances, which have greatly the appearance of the actual eſcape of ſome material ſubſtance. A ſtream of wind blows from ſuch a point, and quickly electrifies the air of a room to ſuch a degree, that an electrometer in the fartheſt corner of the room is affected by it. This diſſipation in a dark place is, in many inſtances, accompanied by a bright train of light diverging from the point like a firework. Dr Franklin therefore was very anxious to reconcile this appearance with his theory of plus and minus electricity, but does not expreſs himſelf well ſatisfied with any explanation which had occurred to him. From the beginning, he ſaw that he could not conſider the ſtream of wind as a proof of the eſcape of the electric fluid, becauſe the ſame ſtream is obſerved to iſſue from a ſharp negative point; which, according to his theory, is not diſperſing, but abſorbing it. Mr Cavendiſh has, in our opinion, given the firſt ſatisfactory account of this phenomenon.

To ſee this in its full force, the phenomenon itſelf 205.
muſt be carefully obſerved. The ſtream of wind is plainly produced by the eſcape of ſomething from the point itſelf, which hurries the air along with it; and this draws along with it a great deal of the ſurrounding air, eſpecially from behind, in the ſame manner as the very ſlender thread of air from a blow-pipe hurries along with it the ſurrounding air and flame from a conſiderable ſurface on all ſides. It is in this manner that it gathers the whole of a large flame into one maſs, and, at laſt, into a very point. If the ſmoke of a little roſin thrown on a bit of live coal be made to riſe quietly round a point projecting from an electrified body, continually ſupplied from an electrical machine, the vortices of this ſmoke may be obſerved to curl in from all ſides, along the wire, forming a current of which the wire is the axis, and it goes off completely by the point. But if the wire be made to paſs through a cork fixed in the bottom of a wide glaſs tube, and if its point project not beyond the mouth of the tube, the

the afflux of the air from behind is prevented, and we have no ftream; but if the cork be removed, and the wire ftill occupy the axis of the tube, but without touching the fides, we have the ftream very diftinctly; and fmoke which rifes round the far end of the tube is drawn into it, and goes of at the point of the wire. Now it is of importance to obferve, that whatever prevents the formation of this ftream of wind prevents the diffipation of electricity (for we fhall not fay efcape of electric fluid) from the point. If the point project a quarter of an inch beyond the tube, or if the tube be open behind, the ftream is ftrong, and the diffipation fo rapid, that even a very good machine is not able to raife a Henly's electrometer, ftanding on the conductor, a very few degrees. If the tube be flipped forward, fo that the point is juft even with its mouth, the diffipation of electricity is next to nothing, and does not exceed what might be produced by fuch air as can be collected by a fuperficial point. If the tube be made to advance half an inch beyond the point which it furrounds, the diffipation becomes infenfible. All thefe facts put it beyond a doubt that the air is the caufe, or, at leaft, the occafion of the diffipation, and carries the electricity off with it, in this manner rendering electrical the whole air of a room. The problem is reduced to explain how the air contiguous to a fharp electrified point is electrified and thrown off.

Theory of it.

It was demonftrated in n° 130, that two fpheres, connected by an infinitely extended, but flender conducting canal, are in electrical equilibrium, if their furfaces contain fluid in the proportion of their diameters. In this cafe, the fuperficial denfity of the fluid and its tendency to efcape are inverfely as the diameters (n° 130). Now if, in imagination, we gradually diminifh the diameter of one of the fpheres, the tendency to efcape will increafe in a greater proportion than any that we can name. We know, that when the prime conductor of a powerful table-machine has a wire of a few inches in length projecting from its end, and terminating in a ball of half an inch in diameter, we cannot electrify it beyond a certain degree; for when arrived at this degree, the electricity flies off in fucceffive burfts from this ball. Being much more overcharged than any other part of the body, the air furrounding the ball becomes more overcharged by communication, and is repelled, and its place fupplied by other air, not fo much overcharged, which furrounded the other parts of the body, and is preffed forwards into this fpace by the general repulfion of the conductor and the confining preffure of the atmofphere; otherwife, being alfo overcharged, it would have no tendency to come to this place. Half a turn of the cylinder is fufficient to accumulate to a degree fufficient for producing one of thefe explofions, and we have two of them for every turn of the cylinder, A point may be compared to an incomparably fmaller ball. The conftipation of the fluid, and its tendency to efcape, muft be greater in the fame unmeafurable proportion. This denfity and mutual repulfion cannot be diminifhed, and muft even be increafed, by the matter of the wire forming a cone of which the point is the apex; therefore, if there were no other caufe, we muft fee that it is almoft impoffible to confine a collection of particles, mutually repelling, and conftipated, as thefe are in a fine point.

But the chief caufe feems to be a certain chemical union which takes place between the electric fluid and a correfponding ingredient of the air. In this ftate of conftipation, almoft completely furrounded by the air, the little mafs of fluid muft attract and be attracted with very great force, and more readily overcome the force which keeps the electrified fluid attached to the laft feries of particles of the wire. It unites with the air, rendering it electric in the higheft degree of redundancy. It is therefore ftrongly repelled by the mafs of conftipated fluid which fucceeds it within the point. Thus is the electrified air continually thrown off, in a ftate of electrification, that muft rapidly diminifh the electricity of the conductor. Hence the uninterrupted flow, without noife or much light, when the point is made very fine. When the point is blunt, a little accumulation is neceffary before it attains the degree neceffary for even this minute explofion; but this is foon done, and thefe little explofions fucceed each other rapidly, accompanied by a fputtering noife, and trains of bright fparks. The noife is undoubtedly owing to the atoms of the highly electrified fluid. Thefe are, in all probability, rarefied of a fudden, in the act of electrification, and immediately collapfe again in the act of chemical union, which caufes a fonorous agitation of the air. This electrified air is thus thrown off, and its place is immediately fupplied by air from behind, not yet electrified, and therefore ftrongly drawn forward to the point, from which they are thrown off in their turn. This rapid expanfion and fubfequent collapfing of the air is verified by the experiments of Mr Kinnerfly, related by Dr Franklin, and is feen in numberlefs experiments made with other views in later times, and not attended to. Perhaps it is produced by the great heat which accompanies, or is generated in the transference of electricity; and it is of the fame kind with what occafions the burfting of ftones, fplitting of trees, exploding of metals, &c. by electricity. The expanfion is either inconfiderable, or it is fucceffively produced in very fmall portions of the fubftance expanded; for when metal is exploded in clofe veffels, or under water, there is but a minute portion of gazeous matter produced, and in the diffipation by a very fine point, fufficiently great to give full employment to a powerful machine, the ftream of wind is but very faint, and nine-tenths of this has been dragged along by the really electrified thread of wind in the middle.

206 Electricity unites chemically with air.

From a collation of all the appearances of electricity, we muft form the fame conception of the forces which operate round a point that is negatively electrified, not difperfing, but drawing in electric fluid. It is more completely undercharged than any other part of a body, and attracts the fluid in the furrounding air, and the air in which it is retained, with incomparably greater force. It therefore deprives the contiguous air of its fluid, and then repels it, and then produces a ftream like the overcharged point.

If a conducting body be brought near to any part of an overcharged body, the fronting part of the firft is rendered undercharged; and this increafes the charge of the oppofite part of the overcharged body. It becomes more overcharged in that part, and fooner attains that degree of conftipation that enables the fluid to quit the fuperficial feries of particles, and to electrify ftrongly the contiguous air. The explofion is therefore made in this part in preference to any other; and the 207.
