IN HOC SIGNO VINCES
Berry of Tayfield

SUPPLEMENT

TO THE THIRD EDITION OF THE

ENCYCLOPÆDIA BRITANNICA,

OR, A

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN TWO VOLUMES.

Illuſtrated with Fifty Copperplates.

By GEORGE GLEIG, LL.D. F.R.S. Edin.

NON IGNORO, QUÆ BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUÆ NON OPTIMA, ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.——*Cicero.*

VOL. I.

THE SECOND EDITION, WITH IMPROVEMENTS.

Edinburgh:
PRINTED FOR THOMSON BONAR, PARLIAMENT-SQUARE;
BY *JOHN BROWN*, ANCHOR CLOSE, EDINBURGH.

1803.

[Entered in Stationers Hall.]

TO THE KING.

SIR,

It proceeds from no vain confidence in my own abilities, that I presume to solicit for this WORK *the Protection of a* MONARCH, *who is not more exalted in station, than he is distinguished, among the Potentates of the Earth, by his Taste in Literature, and his Patronage of Science and the Arts.*

In conducting to its conclusion the ENCYCLOPÆDIA BRITANNICA, *I am conscious only of having been uniformly influenced by a sincere desire to do Justice to those Principles of Religion, Morality, and Social Order, of which the Maintenance constitutes the Glory of Your* MAJESTY'S *Reign, and will, I trust, record Your Name to the latest Posterity, as the* Guardian of the Laws and Liberties of Europe.

The French Encyclopédie *has been accused, and justly accused, of having disseminated, far and wide, the seeds of Anarchy and Atheism. If the* ENCYCLOPÆDIA BRITANNICA *shall, in any degree, counteract the tendency of that pestiferous Work, even these two Volumes will not be wholly unworthy of Your* MAJESTY'S *Patronage; and the Approbation of my* SOVEREIGN, *added to the consciousness of my own upright intentions, will, to me, be an ample reward for the many years of labour which I have employed on them, and on the Volumes to which they are Supplementary. I am,*

SIR,

YOUR MAJESTY'S

Most faithful Subject,

And most devoted Servant,

STIRLING, Dec. 10. 1800.

GEORGE GLEIG.

ADVERTISEMENT.

It would ill become me to dismiss these Volumes from my hands without acknowledging that, from many of the most valuable disquisitions which they contain, I can claim no other merit than that of having ushered them into the world.

Those who have read, and who understand, the articles in the Encyclopædia Britannica, which were furnished by Professor Robison of Edinburgh, can hardly need to be informed, that to the same eminent philosopher I am indebted for the valuable articles Arch, Astronomy, Carpentry, Centre, Dynamics, Electricity, Impulsion, Involution *and* Evolution *of Curves*, Machinery, Magnetism, Mechanics, Percussion, Piano-*Forte*, *Centre of* Position, Temperament *in Music*, Thunder, *Musical* Trumpet, Tschirnhaus, and Watchwork, in this Supplement. Of a friend and co-adjutor, whose reputation is so well established as Dr Robison's, I am proud to say, that, while I looked up to him, during the progress of this Work, as to my master in mathematical and physical science, I found him ever ready to support, with all his abilities, those great principles of religion, morality, and social order, which I felt it my own duty to maintain.

To Thomas Thomson, M. D. of Edinburgh, a man of like principles, I am indebted for the beautiful articles Chemistry, Mineralogy, and *Vegetable*, *Animal*, and *Dyeing* Substances; of which it is needless for me to say any thing, since the Public seems to be fully satisfied that they prove their author eminently qualified to teach the science of Chemistry.

The account of the French Revolution, and of the wars which it has occasioned, has been continued in this Supplement by the same Gentlemen by whom that account was begun in the Encyclopædia; and, owing to the cause assigned in the article, probably with the same merits and the same defects.

My thanks are due to Dr William Wright for his continued kindness in communicating much curious botanical information: and to Mr Professor Playfair of the university of Edinburgh, for lending his assistance, occasionally, in the mathematical department; and for writing one beautiful article in that science, which is noticed as his in the order of the alphabet.

In compiling this Supplement, I have made very liberal use of the most respectable literary and scientific journals, both foreign and domestic; of all the late accounts of travels and voyages of discovery, which have obtained, or seem indeed to deserve, the regard of the Public; of different and opposite works on the French revolution, and what are emphatically called *French principles;* and even of the most approved Dictionaries, scientific and biographical. From no Dictionary, however, have I taken, without acknowledgment, any articles, except such as are floating everywhere on the surface of science, and are the property, therefore, of no living author.

After

After all my labour and induftry, which, whatever be thought of my other merits, I am confcious have been great, no man can be more fenfible than myfelf, that the Encyclopædia Britannica, even with the addition of this Supplement, is ftill imperfect. It would continue to be fo, were another Supplement added to this by the moft learned and laborious man on earth ; for perfection feems to be incompatible with the nature of works conftructed on fuch a plan, and embracing fuch a variety of fubjects.

No candid reader will fuppofe that, by expreffing myfelf thus, I mean to cenfure the plan of the Encyclopædia Britannica in particular ; for, to the general excellence of that plan I have elfewhere borne my teftimony, which I have yet feen no reafon to retract. Experience has indeed led me to think, that it is fufceptible of fuch improvements as would enable the principal Editor to carry the work *nearer* to perfection, even with lefs trouble to himfelf ; but the purchafers of the third edition and this Supplement need not regret the want of thofe improvements, for they are fuch as few would difcern, who have not paid the fame attention that I have done to dictionaries of arts, fciences, and literature.

Before I take leave of the reader, I muft account for the omiffion of one or two articles (chiefly biographical) which I had given him reafon to expect in thefe volumes. It was my intention at firft to introduce into the Supplement articles on every fubject which had been admitted into the Encyclopædia itfelf ; and hence in the firft fupplementary volume will be found biographical fketches of men whofe characters, though in fome refpects remarkable, have very little connection with fcience, arts, or literature. From this part of the original plan I was foon obliged to deviate. So many applications were made to me to infert accounts of perfons who, whatever may have been their private virtues, were never heard of in the republic of letters, that I was under the neceffity of excluding from the fecond volume the lives of *all* fuch as had not either been themfelves eminent in literature, or in fome liberal art or fcience, or been confpicuous as the *patrons* of fcience, arts, and literature, in others. Hence the omiffion of the life referred to from Aubigne in the firft volume, and of one or two others to which references are made in the fame way. The life of Mr James Hay Beattie of Aberdeen, whofe originality of genius, ardent love of virtue, and early and extenfive attainments in fcience and literature, raife him almoft to the eminence of Barretier, of whom we have fo pathetic an account from the pen of Johnfon, I omitted with regret ; but I thought not myfelf authorized to publifh what his father had then only diftributed among a few particular friends. For the omiffion of the life of Soame Jenyns I can make no apology : it was the confequence of forgetfulnefs.

For the *errors* of thefe two volumes, whether typographical or of a nature more important, I have perhaps no occafion to folicit greater indulgence than will be voluntarily extended to me by a generous Public. Some errors I have corrected in this fecond impreffion, and fome deficiencies I have fupplied ; but I was reftrained by thofe who are now Proprietors of the Work from making any *addition* to the firft volume, or any confiderable *alteration* in the firft part of the fecond. Hence the different conclufions which the reader will obferve in the articles Galvanism and Torpedo, refpecting the nature of the *Galvanic* power. Of thefe articles, the former was furnifhed by a friend, whofe name I am not at liberty to publifh ; but whofe reafonings appeared to me too worthy of attention to be either omitted or abridged, though they lead to a conclufion which facts more recently afcertained feem to fet afide. Thefe facts I felt it my duty to ftate to the public ; and, under the title Torpedo, I have been enabled to ftate them with the precifion and regularity of arrangement which characterife the writings of Dr Thomfon.

SUPPLEMENT

TO THE

ENCYCLOPÆDIA BRITANNICA.

ABACISCUS, in architecture, the same with ABACUS; for which, see *Encyclopædia*.

ABATIS, or ABATTIS, is, in military language, the name of a kind of retrenchment made of felled trees. When the emergency is sudden, the trees are merely laid lengthwise beside each other, with their branches pointed towards the enemy, to prevent his approach, whilst the trunks serve as a breastwork before those by whom the abatis is raised. When the abatis is meant for the defence of a pass or entrance, the boughs of the trees are generally stripped of their leaves and pointed; the trunks are planted in the ground; and the boughs are interwoven with each other. It is needless to add, that the closer the trees are laid or planted together, the more secure is the defence which they afford; and if, when they are planted, a small ditch be dug towards the enemy, and the earth thrown up properly against the lower part of the abatis, it will be very difficult to pass it if well defended.—*Simes's Military Guide*.

ABBREVIATION OF FRACTIONS, in arithmetic and algebra, is the reducing of them to lower terms; which is done by dividing the numerator and denominator by some number or quantity which will divide both without leaving a remainder of either.

ABERRATION, in optics (in Encycl.), refers the reader to the article OPTICS, n° 17, 136, 173. It should have referred him to OPTICS, n° 17, and 251—256.

ABERRATION of the Visual Ray, is a phenomenon, of which, though some account of it has been given in the Encyclopædia (see ABERRATION, in astronomy; and the article ASTRONOMY, n° 337.), one of the most candid of our correspondents requires a fuller explanation. If such an explanation be requisite to him, it must be much more so to many others; and we know not where to find, or how to devise, one which would be more satisfactory, or more familiar, than the following by Dr Hutton.

"This effect (says he) may be explained and familiarized by the motion of a line parallel to itself, much after the manner that the composition and resolution of forces are explained. If light have a progressive motion, let the proportion of its velocity to that of the earth in her orbit be as the line BC to the line AC; (Plate II. fig. 1.) then, by the composition of these two motions, the particle of light will seem to describe the line BA or DC,

instead of its real course BC; and will appear in the direction AB or CD, instead of its true direction CB. So that if AB represent a tube, carried with a parallel motion by an observer along the line AC, in the time that a particle of light would move over the space BC, the different places of the tube being AB, *ab*, *cd*, CD; and when the eye, or end of the tube, is at A, let a particle of light enter the other end at B; then when the tube is at *ab*, the particle of light will be at *e* exactly in the axis of the tube; and when the tube is at *cd*, the particle of light will arrive at *f*, still in the axis of the tube; and, lastly, when the tube arrives at CD, the particle of light will arrive at the eye or point C, and consequently will appear to come in the direction DC of the tube, instead of the true direction BC: and so on, one particle succeeding another, and forming a continued stream or ray of light in the apparent direction DC. So that the apparent angle made by the ray of light with the line AE is the angle DCE, instead of the true angle BCE; and the difference BCD, or ABC, is the quantity of the aberration."

ABERRATION of the Planets, is equal to their geocentric motion, or, in other words, to the space which each appears to move as seen from the earth, during the time that light employs in passing from the planet to the eye of the observer. Thus the sun's aberration in longitude is constantly 20″, that being the space actually moved by the earth, but apparently by the sun in 8 minutes and 7 seconds, the time in which light passes from the sun to the earth. If then the distance of any planet from the earth be known, the time which light employs in passing from the planet to the earth must likewise be known; for as the distance of the sun is to the distance of the planet, so is 8 minutes and 7 seconds to that time; and the planet's geocentric motion in that time is its aberration, whether it be in longitude, latitude, right ascension, or declination. See ASTRONOMY in this Supplement.

ABOAB, cesses levied, in India, under different denominations, beyond the standard rent.

ABSCISS, ABSCISSE, or *Abscissa*, is a part cut off from a straight line, and terminated at some certain point by an ordinate to a curve; as AP (fig. 2.), or BP (fig. 3.) (Plate II.) The abscis may commence either at the vertex of the curve, or at any other fixed point; and it may be taken either upon the axis or upon the dia-

meter

meter of the curve, or upon any other line drawn in a given position. Hence there are on the same given line or diameter an infinite number of variable abscisses, terminated all at one end by the same fixed point. In the common parabola (fig. 4.), each ordinate PQ has but one abscis AP. In the ellipse or circle (fig. 2.), the ordinate has two abscisses lying on the opposite sides of it. In general, to each ordinate a line of the second kind, or a curve of the first kind, may have two abscisses; a line of the third order, three; a line of the fourth order, four; and so on.

ABSORPTION, in ANATOMY and PHYSIOLOGY, has been sufficiently explained under these articles in the Encyclopædia; but there is another absorbing power possessed by different substances, which is worthy of attention, because it is only by our knowledge of it that we can adapt our clothing to the various climates of the earth. The power to which we allude is that of different substances; such as wool, cotton, silk, and linen, to absorb or attract moisture from the atmosphere. On this subject the reader will find some very instructive experiments detailed (in Encycl.), where perhaps he may not have looked for them, under the title FLANEL.

ABSURDUM, a term made use of by mathematicians when they demonstrate any truth, by showing that its contrary is impossible, or involves an absurdity. Thus Euclid demonstrates the truth of the fourth proposition of the first book of his Elements, by showing that its contrary implies this obvious absurdity—"that two straight lines may inclose a space."

This mode of demonstration is called *reductio ad absurdum*, and is every whit as conclusive as the direct method; because the contrary of every falsehood must be truth, and of every truth, falsehood.

The young geometrician, however, does not, we believe, feel himself so perfectly satisfied with a demonstration of this kind, as with those which, proceeding from a few self-evident truths, conducts him directly, by necessary consequences, to the truth of the proposition to be proved. The reason is, that he has not yet learned to distinguish accurately between the words *false* and *impossible*, *different* and *contrary*. Many *different* assertions may be made relating to the same thing, and yet be all true or all false; but it is impossible to make two assertions directly *contrary* to each other, of which the one shall not be true and the other false. Thus, "snow is white," "snow is cold," are different assertions relating to the same thing, and both true; as, "snow is black," "snow is red," are both false: but let it be remembered, that of the first and second, and of the third and fourth of these assertions, neither is directly *contrary* to the other; nor is any one of them, abstractly considered, *impossible*, or such as a blind man, who had never felt nor heard of snow, might not believe upon ordinary testimony. But were all the men in Europe to tell a native of the interior parts of Africa that snow is a thing at once *white and not white, cold and not cold*, the woolly-headed savage would know as well as the most sagacious philosopher, that of these *contrary* assertions the one *must be true* and the other *must be false*. Just so it is with respect to Euclid's fourth proposition. Had he proved its truth by showing that its contrary involves this proposition, that "the diagonal of a square is commensurate with its side," the skilful geometrician would indeed have admitted the demonstration, because he knows well that the diagonal of a square is *not* commensurate with its side; but the tyro in geometry would have been no wiser than before. He knew from the beginning, that the proposition and its contrary cannot both be true; but which of them is true, and which false, such a demonstration could not have taught him, because he is ignorant of the incommensurability of the diagonal and side of a square. No man, however, is ignorant, that two straight lines cannot inclose a space; and since Euclid shows that the contrary of his proposition implies this absurdity, no man of common sense can entertain a doubt but that the proposition itself must be true.

ACCELERATED MOTION. } See (Encycl.) ACCELERATION; and
ACCELERATING FORCE. } MECHANICS, Sect. VI.—and (this Supplement) DYNAMICS.

ACTION is a term which has been sufficiently explained in the Encyclopædia; but since that article was written, questions have been agitated respecting *agents*, *agency*, and *action*, which, as they have employed some of the most eminent philosophers of the age, and are connected with the dearest interests of man, are certainly entitled to notice in this place.

It is the opinion of Dr Reid, and we have adopted it (see METAPHYSICS, n° 109, &c. Encycl.), that no being can be an *agent*, or perform an *action*, in the proper sense of the word, which does not possess, in some degree, the powers of will and understanding. If this opinion be just, it is obvious, that what are called the powers of nature, such as *impulse*, *attraction*, *repulsion*, *elasticity*, &c. are not, strictly speaking, *powers* or *causes*, but the effects of the agency of some active and intelligent being; and that *physical causes*, to make use of common language, are nothing more than *laws* or *rules*, according to which the *agent* produces the effect.

This doctrine has been controverted by a writer whose acuteness is equalled only by his virtues; and we shall consider some of his objections to it in another place (see CAUSE): but a question of a different kind falls under our present consideration; and perhaps the answer which we must give to it, may go far to remove the objections to which we allude.

Can an agent operate where, either by itself or by an instrument, it is not present? We think not; because agency, or the exertion of power, must be the agency of something. The constitution of the human mind compels us to attribute every action to some *being*; but if a being could act in *one* place from which it is absent, it might do the same in a second, in a third, and in all places; and thus we should have action without an agent: for to be absent from all places is a phrase of the same import as not to exist. But if a living and intelligent being cannot act but where it is either immediately or instrumentally present, much less surely can we attribute events of any kind to the agency of an absent and inanimated body. Yet it has been said, that "we have every reason, which the nature of the subject and of our own faculties can admit of, to believe, that there are among things inanimate such relations, that they may be mutually causes or principles of change to one another, without any exertion of *power*, or any operation of an agent, strictly so called. Such relations, for aught that we know, may take place among bodies at great distances from one another, as well as among bodies

bodies really or seemingly in actual contact; and they may vary both in degree and in kind, according to the distances between the bodies."

That any thing should be a cause or principle of change to another, without the exertion of *power* or the operation of an agent, appears to us a palpable contradiction; and we could as easily conceive any two sides of a triangle to be not greater than the third side, as reconcile such a proposition to that faculty of our minds by which we distinguish truth from falsehood. When we see one body the apparent cause of change in another body, we cannot possibly entertain a doubt of the *exertion of power;* but whether that power be in the body apparently producing the change, or in a distinct agent, is a question to which an answer will not so readily be found. That it is in a distinct agent, we are strongly inclined to believe, not only by the received doctrine concerning the inertia of matter, which, though it has been frequently controverted, we have never seen disproved, but much more by considering the import of an observation frequently introduced to prove the direct contrary of our belief. "We cannot be charged (says the writer whom we have just quoted) with maintaining the absurdity, that there may be an effect without a cause, when we refer the fall of a stone to the ground, and the ebbing and flowing of the sea, to the *influence* of the earth on the stone, and of the sun and moon on the ocean, according to the principle of general gravitation."

We admit the truth of this observation, provided the influence of the sun and moon on the ocean be possible; but, to us at least, it appears impossible, and is certainly inconceiveable. The influence of the sun and moon can here mean nothing but the *action* or *operation* of the sun and moon; but if these two bodies be inanimate, they cannot *act* at all, in the proper sense of the word; and whatever they be, it is obvious that they cannot act *immediately* on an object at such a distance from them as the earth and the ocean. If they be the agents, they must operate by an instrument, as we do when moving objects to which our hands cannot reach; but as it has been shewn elsewhere (see METAPHYSICS, n° 199. and OPTICS, n° 63. Encycl.), that neither air nor æther, nor any other material instrument which has yet been thought of, is sufficient to account for the phenomena of attraction and repulsion, it is surely much more rational to conclude, that the ebbing and flowing of the sea are produced, not by the influence of the sun and moon, but by the power of some distinct agent or agents.

What those agents are, we pretend not to say. If the Supreme Being himself be the immediate author of every change which takes place in the corporeal world, it is obvious that he acts by fixed rules, of which many are apparent to the most heedless observer, whilst the discovery of others is reserved for the reward of the judicious application of the faculties which he has given us. If he employs inferior agents to carry on the great operations of nature, it is surely not difficult to conceive that the powers of those agents which were derived from him, may by him be restrained within certain limits, and their exercise regulated by determined laws, in such a manner as to make them produce the greatest benefit to the whole creation. Nor let it be thought an objection to this theory, that the changes which take place among bodies at great distances from each other, vary both in degree and in kind according to the distances; for this variation, which we acknowledge to be a fact, appears to us wholly unaccountable upon any other hypothesis than that which attributes the different changes to agents distinct from the bodies themselves. Did we perceive all the particles of matter, at all distances, tending towards each other by a fixed law, we might be led to consider mutual attraction as an *essential* property of that substance, and think no more of inquiring into its cause, than we think of inquiring into the cause of extension. But when we find that the same particles, which at one distance seem to attract each other, are at a different distance kept asunder by a power of repulsion, which no force, with which we are acquainted, is able to overcome, we cannot attribute the *principle* or *cause* of these changes to brute matter, but must refer it to some other agent exerting power according to a fixed law.

It is the fashion at present to despise all metaphysical inquiries as abstruse and useless: and on this account we doubt not but some of our readers will turn away from this disquisition with affected disgust, whilst the petulant and unthinking chemist, proud of possessing the secrets of his science, will deem it superfluous to inquire after any other natural agents than those of which he has been accustomed to talk. But with the utmost respect for the discoveries made by modern chemists, which we acknowledge to be both numerous and important, we beg leave to observe, that though these gentlemen have brought to light many events and operations of nature formerly unknown, and have shown that those operations are carried on by established laws, none of them can say with certainty that he has discovered a single agent. The most enlightened of them indeed pretend not to have discovered in one department of science more than Newton discovered in another; for they well know that agents and agency cannot be subjected to any kind of physical experiments. Our very notions of these things are derived wholly from our own consciousness and reflection; and when it is considered what dreadful consequences have in another country resulted from that pretended philosophy which excludes the agency of mind from the universe, it is surely time to inquire whether our consciousness and reflection do not lead us to refer real agency to mind alone. Let this be our apology both to the real and to the affected enemies of metaphysics for endeavouring to draw their attention to the present question. It is a question of the utmost importance, as well to science as to religion: and if the laws of human thought decide it, as we have endeavoured to show that they do, we may without hesitation affirm, that the impious philosophy of France can never gain ground but among men incapable of patient thinking.

ADAMAS, a name given, in astrology, to the moon.

ÆOLUS, in mechanics, a small machine invented by Mr Tidd for refreshing or changing the air in rooms when it becomes too hot or otherwise unfit for respiration. The æolus is so contrived as to supply the place of a square of glass in the window, where it works, with very little noise, like the sails of a wind-mill or a smoke-jack.

AEROLOGY is a branch of science which was de-

 detailed

Afghans. tailed in the Encyclopædia at ſufficient length, and according to the principles which were then generally admitted by chemiſts. Subſequent experiments, however, have ſhown, that ſome of thoſe principles are erroneous, and of courſe that ſome of the opinions advanced in the article AEROLOGY are inconſiſtent with facts. Theſe opinions muſt be corrected; but inſtead of ſwelling this volume with a new article AEROLOGY, we apprehend that it will be more acceptable to our ſcientific readers to refer them for thoſe corrections to the article CHEMISTRY in this Supplement.

AFGHANS, are a people in India who inhabit a province of CABUL or CABULISTAN (ſee Encycl.), and have always been connected with the kingdoms of Perſia and Hindoſtan. They boaſt of being deſcended of Saul the firſt king of Iſrael; of whoſe advancement to the royal dignity they give an account which deviates not very widely from the truth. They ſay indeed, that their great anceſtor was raiſed from the rank of a ſhepherd, not for any princely qualities which he poſſeſſed, but becauſe his ſtature was exactly equal to the length of a rod which the angel Gabriel had given to the prophet Samuel as the meaſure of the ſtature of him whom God had deſtined to fill the throne of Iſrael.

SAUL, whoſe deſcent, according to ſome of them, was of Judah, and according to others of Benjamin, had, they ſay, two ſons, BERKIA and IRMIA, who ſerved David, and was beloved by him. The ſons of Berkia and Irmia were AFGHAN and USBEC, who, during the reigns of David and Solomon, diſtinguiſhed themſelves, the one for his corporeal ſtrength, and the other for his learning. So great indeed was the ſtrength of *Afghan*, that we are told it ſtruck terror even into demons and genii.

This hero uſed frequently to make excurſions to the mountains, where his progeny, after his death, eſtabliſhed themſelves, lived in a ſtate of independence, built forts, and exterminated infidels. When the ſelect of creatures (the appellation which this people give to *Mahomet)* appeared upon earth, his fame reached the *Afghans*, who ſought him in multitudes under their leaders *Khalid* and *Abdul Reſpid*, ſons of *Walid;* and the prophet honouring them with this reception—"Come, O *Muluc*, or Kings!" they aſſumed the title of *Melic*, which they retain to this day.

The hiſtory, from which this abſtract is taken, gives a long and unintereſting detail of the exploits of the Afghans, and of their zeal in overthrowing the temples of idols. It boaſts of the following monarchs of their race who have ſat upon the throne of *Dehli:* Sultan BEHLOLE, *Afghan* LODI, Sultan SECANDER, Sultan IRBAHIM, SHIR SHAH, ISLAM SHAH, ADIL SHAH SUR. It alſo numbers the following kings of *Gaur* deſcended of the Afghan chiefs: SOLAIMAN *Shah Gurzani*, BEYAZID *Shah*, and KUTB *Shah;* beſides whom, their nation, we are told, has produced many conquerors of provinces. The Afghans are ſometimes called *Solaimani*, either becauſe they were formerly the ſubjects of SOLOMON king of Iſrael, or becauſe they inhabit the mountains of Solomon. They are likewiſe called PATANS, a name derived from the *Hindi* verb *Paitna* "to ruſh," which was given to them by one of the Sultans whom they ſerved, in conſequence of the alacrity with which they had attacked and conquered his enemies. The province which they occupy at preſent was formerly called *Roh;* and hence is derived the name of the *Rohillas*. The city which was eſtabliſhed in it by the *Afghans* was called by them *Paiſhwer* or *Paiſher*, and is now the name of the whole diſtrict. The ſects of the Afghans are very numerous; of which the principal are, *Lodi*, *Lohouni*, *Sur*, *Serwani*, *Yuſufzihi*, *Bangiſh*, *Dilazaui*, *Khetti*, *Yaſin*, *Kail*, and *Beloje*. They are *Muſulmans*, partly of the *Sunni*, and partly of the *Shiek* perſuaſion.

Though they are great boaſters, as we have ſeen, of the antiquity of their origin, and the reputation of their race, other *Muſulmans* reject their claim, and conſider them as of modern, and even of baſe, extraction.

This is probably a calumny; for it ſeems inconſiſtent with their attention to the purity of their deſcent—an attention which would hardly be paid by a people not convinced of their own antiquity. They are divided into four claſſes. The firſt is the *pure* claſs, conſiſting of thoſe whoſe fathers and mothers were *Afghans*. The ſecond claſs conſiſts of thoſe whoſe fathers were *Afghans* and mothers of another nation. The third claſs contains thoſe whoſe mothers were *Afghans* and fathers of another nation. The fourth claſs is compoſed of the children of women whoſe mothers were *Afghans* and fathers and huſbands of a different nation. Perſons who do not belong to one of theſe claſſes are not called *Afghans*.

This people have at all times diſtinguiſhed themſelves by their courage, both ſingly and unitedly, as principals and auxiliaries. They have conquered for their own princes and for foreigners, and have always been conſidered as the main ſtrength of the army in which they ſerved. As they have been applauded for virtues, they have alſo been reproached for vices, having ſometimes been guilty of treachery, and of acting the baſe part even of aſſaſſins.

Such is the account of the Afghans publiſhed in the ſecond volume of the Aſiatic Reſearches. It was tranſlated from a Perſian abridgment of a book written in the Puſhto language, and called *The Secrets of the Afghans*, and communicated by Henry Vanſittart, Eſq; to Sir William Jones, then preſident of the Aſiatic Society. Their claim to a deſcent from Saul king of Iſrael, whom they call MELIC TALUT, is probably of not a very ancient date; for the introduction of the angel Gabriel with his rod, gives to the whole ſtory the air of one of thoſe many fictions which Mahomet borrowed from the later rabbins. Sir William Jones, however, though he ſurely gave no credit to this fable, ſeems to have had no doubt but the Afghans are deſcendants of Iſrael. "We learn (ſays he) from ESDRAS, that the ten tribes, after a wandering journey, came to a country called *Arſareth*, where we may ſuppoſe they ſettled: now the *Afghans* are ſaid by the beſt *Perſian* hiſtorians to be deſcended from the *Jews*. They have traditions among themſelves of ſuch a deſcent; and it is even aſſerted, that their families are diſtinguiſhed by the names of *Jewiſh* tribes, although ſince their converſion to *Iſlam*, they ſtudiouſly conceal their origin from all whom they admit not to their *ſecrets*. The *Puſhto* language, of which I have ſeen a dictionary, has a manifeſt reſemblance to the *Chaldaick;* and a conſiderable diſtrict under their dominion is called *Hazareth* or *Hazaret*, which might eaſily have been changed into the word uſed by ESDRAS. I ſtrongly recommend an inquiry into the literature and hiſtory of the *Afghans*."

It

It is to co-operate with this accompliſhed ſcholar that we have inſerted into our Work this ſhort account of that ſingular people; and it is with pleaſure that, upon the authority of Mr Vanſittart, we can add, that a very particular account of the *Afghans* has been written by the late Hafiz Rahmat *Khan*, a chief of the *Rohillahs*, from which ſuch of our readers as are oriental ſcholars may derive much curious information.

ALBATEGNI, an Arabic prince of Batan in Meſopotamia, was a celebrated aſtronomer, about the year of Chriſt 880, as appears by his obſervations. He is alſo called *Muhammed ben Geber Albatani*, *Mahomet the ſon of Geber*, and *Muhamedes Aractenſis*. He made aſtronomical obſervations at Antioch, and at Racah or Aracta, a town of Chaldea, which ſome authors call a town of Syria or of Meſopotamia. He is highly ſpoken of by Dr Halley, as *vir admirandi acuminis, ac in adminiſtrandis obſervationibus exercitatiſſimus.*

Finding that the tables of Ptolemy were imperfect, he computed new ones, which were long uſed as the beſt among the Arabs: theſe were adapted to the meridian of Aracta or Racah. Albategni compoſed in Arabic a work under the title of *The Science of the Stars*, compriſing all parts of aſtronomy, according to his own obſervations and thoſe of Ptolemy. This work, tranſlated into Latin by Plato of Tibur, was publiſhed at Nuremberg in 1537, with ſome additions and demonſtrations of Regiomontanus; and the ſame was reprinted at Bologna in 1645, with this author's notes. Dr Halley detected many faults in theſe editions.—*Phil. Tranſ.* for 1693, N° 204.

In this work Albategni gives the motion of the ſun's apogee ſince Ptolemy's time, as well as the motion of the ſtars, which he makes one degree in 70 years. He made the longitude of the firſt ſtar of Aries to be 18° 2′; and the obliquity of the ecliptic 23° 35′. And upon Albategni's obſervations were founded the Alphonſine tables of the moon's motions; as is obſerved by Nic. Muler, in the *Tab. Friſicæ*, p. 248.

ALDERAIMIN, a ſtar of the third magnitude, in the right ſhoulder of the conſtellation Cepheus.

ALFRAGAN, Alfergani, or *Fargani*, a celebrated Arabic aſtronomer, who flouriſhed about the year 800. He was ſo called from the place of his nativity, Fergan, in Sogdiana, now called Maracanda, or Samarcand, anciently a part of Bactria. He is alſo called *Ahmed* (or *Muhammed*) *ben-Cothair*, or *Katir*. He wrote the Elements of Aſtronomy in 30 chapters or ſections. In this work the author chiefly follows Ptolemy, uſing the ſame hypotheſis, and the ſame terms, and frequently citing him. Of Alfragan's work there are three Latin tranſlations, of which the laſt and beſt was made by Golius, profeſſor of mathematics and oriental languages in the univerſity of Leyden. This tranſlation, which was publiſhed in 1669, after the death of Golius, is accompanied with the Arabic text, and with many learned notes on the firſt nine chapters, which would undoubtedly have been carried to the end, had the tranſlator lived to complete his plan.

ALGORAB, a fixed ſtar of the third magnitude, in the right wing of the conſtellation Corvus.

ALHAZEN, an Arabian aſtronomer, who flouriſhed in Spain about the beginning of the 12th century. See Astronomy, n° 6. *Encycl.*

ALMAMON, was a philoſopher and aſtronomer, who, in the beginning of the 9th century, aſcended the throne of the caliphs of Bagdat. He was the ſon of Harun Al-Raſhid, and grandſon of Almanſor. His name is otherwiſe written *Mamon*, *Almaon*, *Almamun*, *Alamoun*, or *Al-Maimon*. Having been educated with great care, and with a love for the liberal ſciences, he applied himſelf to cultivate and encourage them in his own country. For this purpoſe he requeſted the Greek emperors to ſupply him with ſuch books on philoſophy as they had among them; and he collected ſkilful interpreters to tranſlate them into the Arabic language. He alſo encouraged his ſubjects to ſtudy them; frequenting the meetings of the learned, and aſſiſting at their exerciſes and deliberations. He cauſed Ptolemy's Almageſt to be tranſlated in 827, by Iſaac Ben-honain, and Thabet Ben-korah, according to Herbelot, but, according to others, by Sergius, and Alhazen the ſon of Joſeph. In his reign, and doubtleſs by his encouragement, an aſtronomer of Bagdat, named Habaſh, compoſed three ſets of aſtronomical tables.

Almamon himſelf made many aſtronomical obſervations, and determined the obliquity of the ecliptic to be then 23° 35′ (or 23° 33′ in ſome manuſcripts), but Voſſius ſays 23° 51′ or 23° 34′. He alſo cauſed ſkilful obſervers to procure proper inſtruments to be made, and to exerciſe themſelves in aſtronomical obſervations; which they did accordingly at Shemaſi in the province of Bagdat, and upon Mount Caſius near Damus.

Under the auſpices of Almamon alſo a degree of the meridian was meaſured on the plains of Sinjar or Sindgiar (or, according to ſome, Fingar), upon the borders of the Red Sea; by which the degree was found to contain 56⅔ miles, of 4000 coudees each, the coudee being a foot and a half: but it is not known what foot is here meant, whether the Roman, the Alexandrian, or ſome other. Riccioli makes this meaſure of the degree amount to 81 ancient Roman miles, which value anſwers to 62,046 French toiſes; a quantity more than the true value of the degree by almoſt one-third. Finally, Almamon revived the ſciences in the Eaſt to ſuch a degree, that many learned men were ſound, not only in his own time, but after him, in a country where the ſtudy of the ſciences had been long forgotten. This learned king died near Tarſus in Cilicia, by having eaten too freely of ſome dates, on his return from a military expedition, in the year 833.

ALOE dichotoma, in botany, called by the Dutch *Kooker-boom* or *Quiver tree*, is a native of the ſouthern parts of Africa, and ſeems to be a ſpecies of the Agave or *American aloe* (ſee Agave, Encycl.) It is thus deſcribed by Le Vaillant in his *New Travels into the Interior Parts of Africa*: "The *aloe dichotoma* riſes to the height of 25 or 30 feet; its trunk is ſmooth, and the bark white. When young, and the trunk not more than four or five feet long, it terminates with a ſingle tuft of leaves, which, like thoſe of the ananas, ſpread and form a crown, from the midſt of which all its flowers iſſue. As it grows older, it puſhes out lateral branches, perfectly regular and ſymmetrical, each of which has at its extremity a crown ſimilar to that of the young plant. The kooker-boom thrives much better on mountains than in the plain. Inſtead of long roots penetrating deep into the earth, like thoſe of other trees, it has but a very ſlight one by which it is fixed to the ſoil. Accordingly, three inches of mould are sufficient to enable it to grow upon the very rocks, and attain its utmost beauty; but its root is so feeble a support, that I could throw down the largest with a single kick of my foot. The hordes on the west make their quivers of the trunk of this tree when young, whence is derived the name given it by the planters."

It becomes not us, sitting in our chamber, to controvert a fact in natural history, of the reality of which we never had an opportunity of judging; nor would it be proper, on account of our own scepticism, to suppress the narrative of a traveller, who corrects the narratives of former travellers in terms which nothing should have dictated but the consciousness of his own invariable veracity. Yet we hope to be pardoned for expressing our surprise that, in any part of the world, trees should be found in great numbers 25 or 30 feet high, and shooting out many branches, which have yet so loose a hold of the ground, that the largest of them may be thrown down by the single kick of a man's foot. The reader's surprise will probably equal our's, when he is informed that the author saw one of these trees of which the trunk was ten feet four inches in circumference, whilst its branches overshadowed a space of more than 100 feet in diameter! This tree he assures that he could have *kicked* over. The country, according to his account, is not exempted from storms. He is himself a French philosopher. What a pity then is it that he did not explain to those, who have not had the benefit of being enlightened in that school, upon what principle of mechanics or statics the tree could resist the violence of the elements till it arrived at so enormous a size?

ALPHONSUS X king of Leon and Castile (see *Encycl.*) This prince understood astronomy, philosophy, and history, as if he had been only a man of letters; and composed books upon the motions of the heavens, and on the history of Spain, which are highly commended. "What can be more surprising (says Mariana), than that a prince, educated in a camp, and handling arms from his childhood, should have such a knowledge of the stars, of philosophy, and the transactions of the world, as men of leisure can scarcely acquire in their retirements? There are extant some books of Alphonsus on the motions of the stars, and the history of Spain, written with great skill and incredible care." In his astronomical pursuits he discovered that the tables of Ptolemy were full of errors; and thence he conceived the first of any the resolution of correcting them. For this purpose, about the year 1240, and during the life of his father, he assembled at Toledo the most skilful astronomers of his time, Christians, Moors, and Jews, when a plan was formed for constructing new tables. This task was accomplished about 1252, the first year of his reign; the tables being drawn up chiefly by the skill and pains of Rabbi Isaac Hazan, a learned Jew, and the work called the *Alphonsine Tables*, in honour of the prince, who was at vast expences concerning them. He fixed the epoch of the tables to the 30th of May 1252, being the day of his accession to the throne. They were printed for the first time in 1483, at Venice, by Radtoldt, who excelled in printing at that time. This edition is extremely rare: there are others of 1492, 1521, 1545, &c.

In the Encyclopædia it is said, that the charge of impiety brought against this prince was *unjust*. This was said too confidently, because we know not of any direct proof of his innocence. All that has been said for him by Dr Hutton, one of his ablest apologists, amounts to nothing more than a high degree of probability that the charge was carried by much too far. The charge itself was, that Alphonsus affirmed, "that if he had been of God's privy-council when he made the world, he would have advised him better." Mariana, however, says only in general, that Alphonsus was so bold as to blame the works of Providence, and the construction of our bodies; and he says that this story concerning him rested only upon a vulgar tradition. The Jesuit's words are curious: "Emanuel, the uncle of Sanchez (the son of Alphonsus), in his own name, and in the name of other nobles, deprived Alphonsus of his kingdom by a public sentence; which that prince merited, for daring severely and boldly to censure the works of Divine Providence, and the construction of the human body, as tradition says he did. Heaven most justly punished the folly of his tongue." Though the silence of such an historian as Mariana, in regard to Ptolemy's system, ought to be of some weight, yet we cannot think it improbable, that if Alphonsus did pass so bold a censure on any part of the universe, it was on the celestial sphere, and meant to glance upon the contrivers and supporters of that system. For, besides that he studied nothing more, it is certain that at that time astronomers explained the motions of the heavens by intricate and confused hypotheses, which did no honour to God, nor anywise answered the idea of an able workman. So that, from considering the multitude of spheres composing the system of Ptolemy, and those numerous eccentric cycles and epicycles with which it is embarrassed, if we suppose Alphonsus to have said, "that if God had asked his advice when he made the world, he would have given him better counsel," the boldness and impiety of the censure will be greatly diminished.

Such is the apology made by Dr Hutton for this royal astronomer of Spain; and we hope, for the honour of science, that it is well founded. Still it leaves Alphonsus guilty of great irreverence of language, which is to us wholly unaccountable, if it be really true that he read the Bible fourteen times. We have seen impiety indeed break out lately from very eminent astronomers of a neighbouring nation; but these men read not the Bible, nor any thing else, but the dreams of the eternal sleepers.

ALTERNATE ANGLES. See GEOMETRY (*Encycl.*), Part I. 35.

ALTERNATE *Ratio*, or *Proportion*, is the ratio of the one antecedent to the other, or of one consequent to the other, in any proportion, in which the quantities are of the same kind. So if A : B : : C : D, then alternately, or by alternation A : C : : B : D.

ALTITUDE, PARALLAX OF, is an arch of a vertical circle, by which the true altitude, observed at the centre of the earth, exceeds that which is observed on the surface. See PARALLAX (*Encycl.*) and ASTRONOMY (*Suppl.*)

ALTITUDE *of the Nonagesimal*, is the altitude of the 90th degree of the ecliptic, counted upon it from where it cuts the horizon, or of the middle or highest point of it which is above the horizon, at any time; and is equal to the angle made by the ecliptic and horizon where they intersect at that time.

ALTITUDE

Altitude, Alum.

ALTITUDE *of the Cone of the Earth's or Moon's Shadow*, the height of the ſhadow of the body made by the ſun, and meaſured from the centre of the body. To find it ſay, As the tangent of the angle of the ſun's apparent ſemidiameter is to radius; ſo is 1 to a fourth proportional, which will be the height of the ſhadow in ſemidiameters of the body.

ALUM is a ſalt ſo uſeful in commerce and the arts, that the knowledge of its component parts, and of the beſt method of preparing it, muſt be of importance. In the article CHEMISTRY (Encycl.), the opinions which were then held reſpecting its compoſition, and the practice which was generally followed in its preparation, have been detailed at full length; but ſome of theſe opinions have ſince been controverted, and if they be erroneous, it muſt be expedient to vary in ſome degree the mode of preparation. In particular, the opinion that it is merely an exceſs of acid which prevents the formation of alum by evaporation of the ley, has been ſhown to be falſe by Citizen *Vauquelin*, who contends, of courſe, that the addition of putrid urine to the ley is a very bad practice.

This eminent chemiſt had long ſuſpected, that the cryſtallization of alum is not prevented by an exceſs of acid, and that pot-aſh is not of uſe ſimply to ſaturate this acid, but to perform an office of more importance. To bring his ſuſpicions to the teſt of experiment, he diſſolved very pure ALUMINE in ſulphuric acid of equal purity, and evaporated the ſolution to dryneſs, for the purpoſe of expelling the ſuperabundant acid. He then rediſſolved the dry and pulverulent reſidue in water, and reduced the ſolution to different degrees of ſpecific gravity, with a view to ſeize the point moſt favourable to cryſtallization; but with every poſſible precaution he could obtain nothing but a magma (ſee MAGMA), formed of ſaline plates, without conſiſtence or ſolidity. This ſolution, however, though it conſtantly refuſed to afford cryſtallized alum alone, afforded it immediately by the addition of a few drops of the ſolution of pot-aſh; and as he had employed theſe two ſubſtances in the requiſite proportion, the reſt of the ſolution, to the very end, afforded pure alum, without any mixture of ſulphat of pot-aſh.

Into another portion of the ſame ſolution of pure alumine, he dropped the ſame quantity of carbonat of ſoda as he had added of that of pot-aſh to the former; but no cryſtallization was formed, even by the help of evaporation, nor did lime and barytes poduce any better effect. But if the common opinion that pot-aſh, in the formation of alum, is of uſe only to abſtract the exceſs of acid, be true, ſoda, lime, barytes, and all the ſubſtances which by a more powerful force would take this acid from alum, ought to give the ſame reſult. Another argument preſented itſelf, which ſeemed deciſive: If the alkalies, pot-aſh, and ammoniac, do nothing more than unite to the ſuperabundant acid of the alum, the ſulphats of pot-aſh and of ammoniac ought not to occaſion any change in pure alum in its acidulated ſtate; whereas if theſe alkalies enter as a conſtituent part into the alum, and are neceſſary to its exiſtence, they ought to produce the ſame effects as pure pot-aſh or ammoniac. He therefore added to a third portion of the ſolution of ſulphat of alumine before-mentioned ſome drops of the ſolution of ſulphat of pot-aſh; immediately upon which octahedral cryſtals of alum were formed. The ſulphat of ammoniac preſented the ſame effect.

This reſult gave ſtill greater confirmation to his firſt notions, though it did not yet afford a demonſtration perfectly without objection; for it might have happened that the two ſalts he made uſe of might determine the cryſtallization of the alum, ſimply by abſorbing the ſuperfluous acid, of which they are very greedy; but to determine this poſſible fact, he mixed in the uncryſtallizable ſolution of alumine ſome ſulphat of pot-aſh with exceſs of acid, and obtained a cryſtallization no leſs abundant than with the neutral ſulphat of pot-aſh.

This laſt experiment leaves therefore no doubt with regard to the influence and mode of action of pot-aſh and ammoniac in the fabrication of alum; and this action is ſtill more ſtrongly confirmed by the examination of the alums which have been formed by the proceſſes above related; for in this manner it is proved that they contain conſiderable quantities of the ſulphats of pot-aſh and ammoniac.

Theſe experiments led M. Vauquelin to an examination of the different alums of commerce, of which he found not one that did not afford ſulphat of pot-aſh, or of ammoniac, or of both. His methods of analyſis are very accurate; but to detail them at length would ſwell this article to little purpoſe. To ſuch of our readers as are not chemiſts they would hardly be intelligible; and the experienced chemiſt will deviſe methods of analyſis for himſelf. It may be proper, however, to obſerve, that M. Vauquelin proved, to his own ſatisfaction, that the ſulphat of pot-aſh, or of ammoniac, is neceſſary to render alum capable of being precipitated by its earth, or to cauſe it to paſs, as it were, to the earthy ſtate (A). He proved likewiſe, that ſuch aluminous waters as do not contain pot-aſh, may remain, as long as may be deſired, on their materials, without being ſaturated with too great a quantity of earth, or ſuffering alum to precipitate.

From the whole of his experiments our author drew the following concluſions, which he conſiders as of importance to the arts, to chemiſtry, and to natural hiſtory.

1. It is not, at leaſt in the greateſt number of circumſtances, the exceſs of acid which impedes the cryſtallization of alum, but it is the want of pot-aſh or ammoniac: For it is difficult to imagine that the ſulphuric acid could remain diſengaged after ſo long remaining upon alumine in a ſtate of extreme diviſion, and always ſuperabundant. It is true that the aluminous waters redden the vegetable tinctures; but this property is not owing to a diſengaged acid. This portion of acid is a conſtituent part of theſe waters; and it appears to have more affinity with the neutral ſulphat of alumine than with a new quantity of this earth at the temperature of the atmoſphere.

2. The ſulphat of pot-aſh may be uſed, as well as pure pot-aſh, to cauſe the cryſtallization of alum. It even

---

(A) It may be proper to notice, that Scheele ſeems to have known this long before, and that he mentions it expreſsly in his paper on *Pyrophorus*.

Alum.

even has the advantage over the latter salt, because if the aluminous waters do not really contain a disengaged acid, the pot-ash, in its combination, will precipitate a portion of alumine, and diminish the product of the boiling; whereas the sulphat of pot-ash does not produce the same effect; but if the lixiviums contain disengaged acid, which must very seldom be the case, it is not converted into alum by the sulphat of pot-ash, and is lost with regard to the product. Our author therefore is of opinion, that when the waters really contain an excess of acid, or a very oxided sulphat of iron, the use of pot-ash is preferable to that of the sulphat of pot-ash. But when economy is an object, that in many places it would be profitable to use the sulphat of pot-ash; because it is a salt indirectly produced in many manufactories, where of course it may be obtained for nothing. In particular, the residues of the distillation of aquafortis by the sulphuric acid would be excellent for this operation, and much preferable to putrid urine, because this fluid always contains phosphoric salts, which decompose a portion of the sulphat of alumine, and considerably diminish the product.

3. Alumine cannot be used in the treatment of mother waters, as Bergman proposes. This earth is incapable of favouring the crystallization of alum, besides which, it decomposes a portion of alum by the assistance of ebullition; in which circumstance it seizes the acid necessary to its solution, and precipitates it in the form of that powder which is called alum saturated with its earth.

4. Many alum ores must naturally contain pot-ash, because perfect alum is often obtained from the first crystallization of new alum waters without the addition of this alkali. It is true that an objection may be made with regard to the wood used in calcining these ores, which may be supposed to have furnished the alkali; but it is not probable that the small quantity of wood employed, in comparison to the quantity of ore and the alum it affords, could supply enough of pot-ash for the crystallization.

5. All the earths and stones which have given, or shall hereafter afford, by analysis with the sulphuric acid, perfect alum without addition of pot-ash, must contain this alkali naturally. For it is well proved, that alum cannot exist without pot-ash or ammoniac; and as there is little probability that this last should be found combined in earths or stones, unless perhaps in very rare cases, we may almost constantly be assured, when alum is obtained from any of these substances, that its formation was effected by pot-ash. The quantity of alum will immediately show in what proportion this alkali existed in the substances analysed.

6. The alum of commerce ought not to be considered as a simple salt, but as a combination in the state of a triple and sometimes quadruple salt of sulphat of alumine, sulphat of pot-ash, or of ammoniac. Among these last we may distinguish two species; the one without excess of acid, insoluble in water and insipid, being what is improperly called alum saturated with its own earth; and the other, which contains an excess of acid soluble in water, very sapid and astringent, is the common alum.

There is likewise a pure sulphat of alumine, very astringent, very difficult of crystallization, in the form of brilliant pearl-coloured plates without consistence, and which cannot be rendered insoluble by the addition of a new quantity of its base. This last salt may with the greatest propriety be called the sulphat of alumine.

Alum ‖ Amicable.

7. It follows from the comparative analysis, and the knowledge acquired respecting the different states of the combination of alumine with the sulphuric acid united at the same time with other bases, that we must distinguish seven states in this combination, and that it is necessary to express them according to the rules of the methodical nomenclature. Here follow the series, the nature, and the names of these seven sulphats of alumine.

1. Sulphat of alumine, or the artificial combination of sulphuric acid and alumine. This salt is astringent; it crystallizes in laminæ or flexible leaves, soluble in water. It has never been described nor named by chemists. 2. Acid sulphat of alumine is the foregoing salt, with excess of acid, from which it differs by reddening blue vegetable colours. It is easily made by dissolving that salt in the sulphuric acid, but it is not easy to convert this into the neutral sulphat of alumine but by boiling it a long time with its earth. This salt, like the first, has not been described. 3. Saturated sulphat of alumine and of pot-ash is the alum of the chemists saturated with its earth. It is pulverulent, insipid, insoluble, not crystallizable, and is easily converted into true alum by the addition of sulphuric acid. 4. The acid sulphat of alumine and of pot-ash greatly resembles common alum, and is easily prepared chemically; but M. Vauquelin found no alum but that of La Tolfa, which is exactly of the same nature with it. 5. The acid sulphat of alumine and of ammoniac has all the properties of alum, and may be used for the same purposes; but though it is easily made in the laboratories, our author never found it pure in commerce. 6. The acid sulphat of alumine, pot-ash, and ammoniac. It is remarkable enough, says M. Vauquelin, that this should be the nature of the alum most frequently made in the arts, and that to express its combination so many words should be necessary. This, however, may be avoided, by reserving the name of alum to this substance, which will be sufficient to distinguish it perfectly. 7. The acidulous sulphat of alumine and of pot-ash, our author says, he is less acquainted with than with the preceding series. The name by which he characterizes it was suggested to him, and he thinks it proper, because by adding to the solution a small quantity of pot-ash more than is necessary to obtain octahedral crystals, it manifestly passes to the cubic form.

From these deductions, the physician, the chemist, and the manufacturer, with whom the uses of alum are greatly multiplied, will hereafter possess a knowledge of the substance they employ, and may appreciate its effects on the animal economy, and other bodies to which it is so frequently applied. See *Annales de Chimie*, xxii. 258, and *Nicholson's Journal*, Vol. I. p. 318, &c.

ALUMINE, one of the simple earths. See CHEMISTRY in this *Supplement*.

AMICABLE NUMBERS have been defined, and the first pair of them given in the Encyclopædia. The second pair of amicable numbers are 17296 and 18416; and the third pair are 9363584 and 9437056.

Dr Hutton informs us, that these three pairs of amicable numbers, with the properties from which they receive

ceive their name, were found out by F. Schooten, as appears from Sect. ix. of his *Exercitationes Mathematicæ*. To find the first pair, he puts $4x$ and $4yz$, or a^2x and a^2yz for the two numbers, where $a=2$; then making each of these equal to the sum of the aliquot parts of the other, gives two equations, from which are found the values of x and z, and consequently, assuming a proper value for y, the two amicable numbers themselves $4x$ and $4yz$.

In like manner for the other pairs of such numbers; in which he finds it necessary to assume $16x$ and $16yz$, or a^4x and a^4yz for the second pair, and $128x$ and $128yz$ or a^7x and a^7yz for the third pair.

Schooten then gives this practical rule, from Descartes, for finding amicable rules, viz. assume the number 2, or some power of the number 2, such that if unity or 1 be subtracted from each of these three following quantities, viz. from 3 times the assumed number, also from 6 times the assumed number, and from 18 times the square of the assumed number, the three remainders may be all prime numbers; then the last prime number being multiplied by double the assumed number, the product will be one of the amicable numbers sought, and the sum of its aliquot parts will be the other. That is, if a be put = the number 2, and n some integer number, such that $3a^n-1$, and $6a^n-1$, and $18a^{2n}-1$ be all three prime numbers; then is $\overline{18a^{2n}-1} \times 2a^n$ one of the amicable numbers; and the sum of its aliquot parts is the other.

AMSTERDAM and St Paul, are two islands in the South Sea, lying in the same degree of longitude, and generally confounded with each other. The Dutch navigators have given the name of *Amsterdam* to the northern, and of *St Paul* to the southern island, and Captain Cook conforms to that appellation. Most other English navigators, and particularly Messrs Cox and Mortimer, with Sir George Staunton, reverse the names, calling the southern island Amsterdam, and the other St Paul. At this southern island the Lion man of war stopped on her voyage to China with Lord Macartney, the late ambassador to the court of Pekin, which gave an opportunity to the men of science in the train of the ambassador to examine the island with more skill and attention than probably it had ever been examined before.

Dr Gillan, who was appointed physician to the embassy, as well for his knowledge of chemistry as for his medical skill, is confident that the island of Amsterdam is the product of subterraneous fire, as it bears in every part of it evident marks of volcanic eruption. "On the west and south-west sides (says he) there are four small cones regularly formed, with craters in their centres, in which the lava and other volcanic substances have every appearance of recent formation. The heat continues still so great, and such a quantity of elastic vapours issues through numberless crevices, that there can be no doubt of their having been very lately in a state of eruption. In a thermometer placed upon the surface, the quicksilver rose constantly to 180 degrees, and when sunk a little into the ashes, it advanced to 212 degrees. It certainly would have risen still higher; but the scale being graduated only to the point of boiling water, and the length of the tube proportioned to that extent, the thermometer was immediately withdrawn, lest the increasing expansion of the quicksilver should burst the glass. The ground was felt tremulous under the feet; a stone thrown violently upon it returned a hollow sound; and the heat was so intense for a considerable distance around, that the foot could not be kept for a quarter of a minute in the same position without being scorched. But the great crater on the eastern side, now full of water, is by far the largest here, or perhaps elsewhere, and is of an astonishing size, considerably exceeding in diameter those of Etna or Vesuvius. The quantity of matter to be thrown up, which required so wide an orifice for its passage, and the force with which such matter was impelled, in order to overcome the resistance of the superincumbent earth and sea, must have been indeed prodigious.

"This vast crater, according to the usual method of computing the antiquity of volcanoes, must have been formed at a very remote period. The lava all around its sides is much decomposed, and has mouldered into dust, which lies on the surface in many parts to a considerable depth. The decomposition has supplied a rich soil for the long grass growing on the sides of the crater, and has even spread over most parts of the island. The fibrous roots of the grass, extending in all directions through the decomposed lava and volcanic ashes, and mixed in a decaying state with the vegetable mould, produced from the annual putrefaction of the leaves and stalks, have formed a layer of soil several feet deep all over the island. But as it has nothing except its own weight to compress it together, it is of a light spongy texture, with very little cohesion, and in many places furrowed and intersected by the summer rains, and the torrents occasioned by the melting of the snow which lies upon it in the winter, from three to four feet thick, in all those places where the subterraneous heat is not great enough to prevent its accumulation. In some parts these furrows and cavities are deeper than the level of the common channel; hence they serve the purpose of small natural reservoirs. The water flows into them from all the neighbouring ground; and as their sides are shaded, and almost covered over by the leaves of the long grass, growing from their edges in opposite directions, the rays of the sun are excluded, and very little is lost by evaporation. These reservoirs, however, are very small, and but few in number; the largest could not contain more than three or four hogsheads of water; and there is none else to be found, except in the springs on the sides of the large crater.

"The soil everywhere being light and spongy, and full of holes, formed in it by sea-birds for nests, is very troublesome to walk upon; the foot breaks through the surface, and sinks deep at every step; a circumstance which renders the journey across the island uncommonly fatiguing, although it be scarcely three miles from the edge of the great crater to the opposite west side. There is one place near the centre of the island, extending about 200 yards in length, and somewhat less in breadth, where particular caution is necessary in walking over it. From this spot a hot fresh spring is supposed to derive its source, finding its way through the interstices of the lava to the great crater, and bursting out a little above the water covering its bottom. The heat in this upper spot is too great to admit of vegetation. The surface is covered with a kind of mud or paste formed from the ashes, moistened by steam constantly rising from below. When the mud is removed, the

Amfterdam.

the vapour iffues forth with violence, and in fome parts copioufly. This mud is fo hot, that a gentleman who inadvertently ftepped into it had his foot feverely fcalded by it. The fame caufes which have prevented vegetation on this fpot, have had the fame effect on the four cones recently thrown up. Their furfaces are covered with afhes only; nor is there the leaft appearance even of mofs on the furrounding lava, for the production of which there does not appear to have elapfed a fufficient length of time fince the cones were formed: but this is not the cafe with the lava of the great primary crater; for in thofe parts of it where the edges are more perpendicular, and where confequently the mouldering decompofed earth, having no bafis to fupport it, flides down the fides of the rock, pretty long mofs was generally found growing upon it. All the fprings or refervoirs of hot water, except one only, were brackifh. One fpring derives its fource from the high ground and ridges of the crater. The water in it, inftead of boiling upwards through the ftones and mud, as in the other fprings, flows downward with a confiderable velocity, in a fmall collected ftream. Its temperature has been found not to exceed 112 degrees. The hand could be eafily kept in it for a confiderable time. It is a pretty ftrong chalybeate. The fides of the rock whence it iffues, and of the cavity into which it falls, are incrufted with ochre depofited from it.

"When the great crater is viewed from the high ground, it appears to have been originally a perfect circle, but to have been encroached upon by the fea on the eaftern fide, where the flood tide ftrikes violently. The rocks of lava which formed the edge of the crater on that fide have fallen down. The depth of the water in the crater is about 170 feet, rendering the whole height of the crater, from the bottom to its upper ridge, nearly if not quite 900 feet. The lofty rocks forming this ridge are the higheft parts of the ifland, which feems to have been originally produced by the melted lava flowing down on all fides from hence. Thus there is a gradual flope from the edges of the crater to the fea; and the lava, though very irregular, and lying in mixed ruin and confufion immediately around the crater, affumes a more uniform appearance at fome diftance, layer refting regularly upon layer, with a gradual declivity the whole way down to the fea. This difpofition of the layers is particularly obfervable in the weft fide, where they happen to terminate in an abrupt precipice. The eruptions that took place at different periods appear here diftinctly marked by the different layers that are found with regular divifions between them; the glaffy lava being undermoft, the compact next, the cellular lava next above, over it the volcanic afhes and lighter fubftances, and a layer of vegetable mould covering the whole."

The ifland appears indeed in fuch a ftate of volcanic inflammation, that from the fhips decks at night were obferved, upon the heights of the ifland, feveral fires iffuing out of the crevices of the earth, more confiderable, but in other refpects refembling fomewhat the nightly flames at Pietra Mala, in the mountains between Florence and Bologna, or thofe near Bradley in Lancafhire, occafioned by fome of the coal-pits having taken fire. In the day nothing more than fmoke could be perceived.

The length of the ifland from north to fouth is upwards of four miles, its breadth from eaft to weft about two miles and a half, and its circumference eleven miles, comprehending a furface of about eight fquare miles, or 5120 acres, almoft the whole of which is covered with a fertile foil. The ifland is inacceffible except on the eaft fide, where the great crater forms a harbour, the entrance to which is deepening annually, and might by the aid of art be made fit for the paffage of large fhips. The tides run in and out at the rate of three miles an hour, and rife perpendicularly eight or nine feet on the full and change of the moon; a northerly wind making the higheft tide. The water is eight or ten fathoms deep clofe to the edge of the crater; and in the bafon formed by the crater itfelf, the variation of the compafs was found to be nineteen degrees and fifty minutes weftward of the north pole.

On the ifland, which has no native inhabitants, were found three Frenchmen and two natives of England, who at the end of the American war had emigrated to Bofton. The whole five had come laft from the Ifle of France in the Indian Ocean, and had been left on the ifland of Amfterdam, about five months before the arrival of the Lion, for the purpofe of procuring a cargo of 25,000 feal-fkins for the Canton market, which, as they had already procured 8000, they hoped to complete in about ten months more. The veffel which brought them from the Ifle of France was gone to Nootka Sound, with a view of bringing a quantity of fea-otter fkins to China; and afterwards of calling for the cargo of feal-fkins at this place, to be carried to China likewife; proceeding thus alternately to Nootka and Amfterdam ifland as long as the owners fhould find their account in it.

The feals, whofe fkins are thus an article of commerce, are found here in greater numbers in the fummer than in the winter, when they generally keep in deep water, and under the weeds, which fhelter them from the inclemency of the weather. In the fummer months they come afhore, fometimes in droves of 800 or 1000 at a time, out of which about 100 are deftroyed, that number being as many as five men can fkin and peg down to dry in the courfe of a day. Little of the oil which thefe animals might furnifh is collected, for want of cafks to put it in; part of the beft is boiled, and ferves thofe people inftead of butter. The feal of Amfterdam is the *phoca urfina* of Linnæus. The female weighs ufually from 70 to 120 pounds, and is from three to five feet in length, but the male is confiderably larger. In general they are not fhy: fometimes they plunge into the water inftantly upon any one's approach, but at other times remain fteadily on the rocks, bark, and rear themfelves up in a menacing pofture; but the blow of a ftick upon the nofe feemed fufficient to difpatch them. As the fkins alone were the objects wanted, the carcafes were left on the ground to putrefy at leifure, ftrewed in fuch numbers as to render it difficult to avoid trading on them in walking along. The people thus employed were remarkable for the fqualor and filth of their perfons, clothes, and dwelling; yet none of them feemed defirous of leaving the place before the bufinefs they came upon fhould be completed. One of them, an Englifhman, who had been a confiderable time upon the ifland on a former adventure, gave but an unfavourable account of the weather during the winter months, which are always boifterous, boisterous, with hail and snow; but in summer he acknowledged it to be very fine.

The sea supplies this island with great varieties of excellent fish, particularly a kind of cod, which was equally relished whether fresh or salted. Cray fish were in such abundance on the bar across the entrance into the crater, that at low water they might be taken with the hand; and at the anchorage of the ships, when baskets, in which were proper baits, were let down into the sea, they were in a few minutes drawn up filled with cray fish. This circumstance is the more extraordinary, that in the same place were found abundance of sharks and dog fish of uncommon size, which are known to be so voracious and such enemies to all other fish. The bason of the crater abounds with tench, bream, and perch; and the person who with a hook and line has caught any of these fish in the cold water of the bason, may with a slight motion of his hand let them drop into the adjoining hot spring already mentioned, in which they will be boiled and rendered fit for eating in the space of fifteen minutes. This was often practised by the gentlemen of the embassy, and furnished them at once with a singular amusement and a highly relished repast.

Of all the birds which frequent this island, so extraordinary in its origin, formation, and appearance, not one is common to the same degree of latitude in the northern hemisphere. Of the larger kind were several species of the *albatross*; on examining one of which, distinguished by the name of *exulans*, it was found, that instead of having only the rudiments of a tongue, as naturalists generally suppose, it had one equalling half the length of the bill. Another large bird is likewise common here, called the great *black petrel*, or *procellaria equinoctialis* of Linnæus. It is the determined enemy of the albatross, as well as of the *blue petrel* of Amsterdam, or *procellaria forsteri*. This blue petrel, which is about the size of a pigeon, constitutes the principal food of the seal catchers on the island. During the day-time they hide themselves in the ground, in order to escape, if possible, their destroyer the black petrel. At night they come abroad, and thence are termed *night birds* by the people at Amsterdam; but being fond of flocking to any light, they fall into another snare laid for them by the seal-catchers, who kindle torches to attract them, and then kill them in multitudes. The prettiest of the feathered tribe, inhabiting or visiting Amsterdam, is the silver bird, or *sterna hirundo*, about the size of a large swallow or swift, with a forked or swallow tail. The bill and legs are of a bright crimson colour, the belly white, and the back and wings of a bluish ash colour. This bird subsists chiefly on small fish, which it picks up as they are swimming over the surface of the water.

This singular island lies in 38° 42′ S. Lat. and in 76° 54′ E. Long. from Greenwich. St Paul's, or the island lying in sight and to the northward, differed in appearance materially from Amsterdam. It presented no very high land, or any rising in a conic form; and seemed to be overspread with shrubs or trees of a middling size. It was said to abound with fresh water, but to have no good anchorage near it, nor any place of easy landing.—*Sir George Staunton's Account of an Embassy to the Emperor of China.*

ANACLASTIC CURVES, a name given by M. de Mairan to certain apparent curves formed at the bottom of a vessel full of water, to an eye placed in the air; or the vault of the heavens, seen by refraction through the atmosphere.

ANAPHORA, in astrology, the second house, or that part of the heavens which is 30 degrees from the horoscope. The term *anaphora* is also sometimes applied promiscuously to some of the succeeding houses, as the 5th, the 8th, and the 11th. In this sense *anaphora* is the same as *epanaphora*, and stands opposed to *cataphora*.

ANASTROUS SIGNS, in astronomy, a name given to the *duodecatemoria*, or the twelve portions of the ecliptic, which the signs possessed anciently, but have since deserted by the precession of the equinox.

ANCHOR OF A SHIP, is an instrument which, as it is commonly made, has been sufficiently described in the Encyclopædia. An improvement, however, has been proposed on its construction by Mr James Stuard of the parish of St Anne, Middlesex, who obtained a patent for his invention, dated Feb. 1796.

The whole of this invention consists in making the anchor with one fluke or arm instead of two, and contriving to load that fluke or arm in such a manner as to make it always fall the right way. With this view Mr Stuard would have the shank of the anchor made very short, that it may *cant* the more when suspended by the cable; and he would have the arm and it made of bars in one length, that there may be no shoot or joining in the whole instrument. The bend of the shank and arm he would have rounded, and not angular as in the common anchor; and on this bend he would have a small shackle, or two plates with a small bolt between them, for the buoy-rope to be made fast to. Instead of wood, he proposes for the stock of the anchor a bar of wrought iron, loaded or covered at the ends with knobs of cast iron; and he would have the palm of the fluke or arm either to be composed entirely of cast iron, or to be a cast iron shell filled with lead. This weight of the palm, the shortness of the shank, and the structure of the stock, will no doubt make the anchor fall the right way; which, having no upper fluke, will never be tripped by the cable taking hold of it on the ship's swinging, nor will it prove so dangerous as the common anchor to such vessels as may happen to ground by it.

ANDERSON (Alexander), an eminent mathematician, was born at Aberdeen towards the end of the 16th century. Where he was educated, or under what masters, we have not learned; probably he studied the belles lettres and philosophy in the university of his native city, and, as was the practice in that age of all who could afford it, went afterwards abroad for the cultivation of other branches of science. But wherever he may have studied, his progress in science must have been rapid; for, early in the 17th century, we find him professor of mathematics in the university of Paris, where he published several ingenious works; and among others, 1. *Supplementum Apollonii Redivivi; sive analysis problematis hactenus desiderati ad Apollonii Pergæi doctrinam* περι νευσεων, *a Marino Ghetaldo Patritio Ragusino hujusque, non ita pridem restitutam. In qua exhibetur mechanice æqualitatum tertii gradus sive solidarum, in quibus magnitudo omnino data, æquatur homogeneæ sub altero tantum coefficiente ignoto. supplemento Apollonii Redivivi. Ad clarissimum et ornatissimum virum Marinum Ghetaldum Patritium Ragusinum. In qua ad ea quæ obiter mihi perstrinxit Ghetaldus respondetur, et analytices clarius detegitur. Paris, 1615, in 4to.—3. *Francisci Vietæ Fontenacensis de Æquationum Recognitione et Emendatione Tractatus duo*, with a dedication, preface, and appendix, by himself. Paris, 1615, in 4to.—4. Vieta's *Angulares Sectiones;* to which he added demonstrations of his own. Our professor was cousin-german to Mr David Anderson of Finshaugh, a gentleman who also possessed a singular turn for mathematical knowledge. This mathematical genius was hereditary in the family of the Andersons; and from them it seems to have been transmitted to their descendants of the name of Gregory, who have for so many generations been eminent in Scotland as professors either of mathematics, or, more lately, of the theory and practice of physic. The daughter of the David Anderson just mentioned, was the mother of the celebrated James Gregory, inventor of the reflecting telescope; and observing in her son, while yet a child, a strong propensity to mathematical studies, she instructed him in the elements of that science herself. From the same lady descended the late Dr Reid of Glasgow, who was not less eminent for his knowledge of mathematics than for his writings as a metaphysician.

The precise dates of Alexander Anderson's birth and death, we have not learned either from Dempster, Mackenzie, or Dr Hutton, who seems to have used every endeavour to procure information; nor are such of his relations as we have had an opportunity of consulting, so well acquainted with his private history as we expected to find them.

ANHINGA, in ornithology, a species of the pelicanus, consists of four known varieties; two peculiar to America, one to Senegal, and the fourth to the region about the Cape of Good Hope. This last is thus described by Le Vaillant in his New Travels into the Interior Parts of Africa.

"The denomination of *Slange-Hals-Voogel*, given to it by the Hottentots, characterises the anhinga in a very simple and accurate manner. Buffon, who was struck with the conformation peculiar to birds of this kind, has delineated them by a similar expression. 'The anhinga (says he) exhibits a reptile grafted on the body of a bird.' Indeed there is no person who, upon seeing the head and neck only of an anhinga, while the rest of the body is hid among the foliage of the tree on which it is perched, would not take it for one of those serpents accustomed to climb and reside in trees; and the mistake is so much the easier, as all its tortuous motions singularly favour the illusion. In whatever situation the anhinga may be seen, whether perched on a tree, swimming in the water, or flying in the air, the most apparent and remarkable part of its body is sure to be its long and slender neck, which is continually agitated by an oscillatory motion, unless in its flight, when it becomes immoveable and extended, and forms with its tail a perfectly straight and horizontal line

Plate III.

"The true place which nature seems to have assigned to the anhingas, in the numerous class of the palmipedes, is exactly between the cormorant and the grebe. They partake indeed equally of both these genera of birds, having the straight slender bill and the long neck of the latter; while they approach the former by the conformity of their feet, the four toes of which are joined by a single membrane. They partake also of the cormorant by their flight; having like it the wings larger and fitter for the purpose than those of the grebe, which are short and weak. The tail of the anhinga is extremely long; a characteristic very singular and remarkable in a water fowl, and which ought, it would seem, to render them totally distinct from diving birds, which in general have little or no tail. By this trait they approach still nearer to the cormorants; for tho' the tails of the latter are shorter, the tails of both have a great resemblance to each other, since their quills are equally strong, elastic, and proper to form a rudder when these fowls swim through the water in pursuit of fish, which constitute their principal nourishment. When the anhinga seizes a fish, he swallows it entire if it be small enough, and if too large he carries it off to a rock or the stump of a tree, and fixing it under one of his feet, tears it to pieces with his bill.

"Though water is the favourite element of this bird, it builds its nest and rears its young on rocks and trees; but it takes great care to place them in such a manner, that it can precipitate them into a river as soon as they are able to swim, or the safety of the little family may require it."

The male anhinga differs from the female, which is smaller, in having the whole under part of the body, from the breast to the root of the tail, of a beautiful black, while the latter has the same parts of a yellow isabella colour. It has also, on each side of its neck, a white stripe, which extends from the eye to the middle of its length, and intersects a reddish ground. A very singular characteristic, common to all the anhingas, is that of having the feathers of the tail deeply striated, and as it were ribbed. It is a very sagacious bird, especially when surprised swimming; for its head is the only part which it exposes above the water; and if the sportsman once miss that part, the anhinga plunges out of sight entirely, and never more shows itself but at very great distances, and then no longer at a time than is absolutely necessary for breathing.

ANTECEDENTAL CALCULUS. See CALCULUS in this Supplement.

ANTES, in architecture, small pilastres placed at the corners of buildings.

ANTICS, in architecture, figures of men and animals placed as ornaments to buildings.

ANTICUM, in architecture, a porch; also that part of a temple which lies between the body of the temple and the portico, and is therefore called the outer temple.

ANTIMETER, or REFLECTING SECTOR, an instrument invented by Mr William Garrard, for the purpose of measuring angles, particularly small ones, with a greater degree of accuracy than can be done by Hadley's quadrant or by the sextant.

The frame of this instrument is similar to that of Hadley's quadrant, having two radii, a limb, and braces; but with this difference, that the further radius is produced upwards of four inches beyond the centre of motion of the index; and the great speculum, or what is called the index-glass in Hadley's quadrant, being placed there, is called the *upper centre*. In this instrument there is no provision for the back observation.

The

Antimeter. The horizon-glaſs is like that in Hadley's quadrant; there are two ſight vanes, to ſuit two different ſituations of the large ſpeculum or object glaſs: theſe vanes are adapted to receive a ſmall teleſcope. On the centre of the index, where the index-glaſs of Hadley's quadrant is fixed, is a braſs or bell-metal ſemicircle, two inches in diameter, and one-eighth of an inch thick: this ſemicircle is ſcrewed faſt to the index, in ſuch a manner that the axis of the index is a tangent to it. On the upper centre are two circular braſs plates, which revolve concentrically, either together or ſeparately. The under plate has a lever, or part perpendicular to the plane of the inſtrument, projecting downwards, a little beyond the lower centre: this lever is acted upon by the ſemicircular plate at the lower centre, to which it is always kept cloſe by a ſpring on the other ſide. In the upper of the above mentioned circular plates are two circular perforations or ſlits, through one of which a ſcrew takes into the head of the inſtrument, and through the other a ſcrew takes into the lower moveable plate. The large ſpeculum is faſtened to the upper plate; and by the above mentioned ſcrews the poſition of this glaſs may be altered. A circular plate is fixed to the lower centre by three pillars: in its centre is a nut to admit a ſcrew, by which the plate carrying the large ſpeculum may be faſtened here occaſionally.

The ſcale on the limb is divided into 45 equal parts or degrees, and not into half degrees, as is the caſe in Hadley's quadrant, by reaſon of the double reflection. Theſe diviſions are numbered in a retrograde order; zero being at the extremity of the further radius. Although the limb contains 45 degrees, yet the greateſt angle which can be meaſured, the large ſpeculum remaining fixed to the circular plate, is 10° 18′ 21″.8; the diſtance between the two centres being four inches, and the radius of the ſemicircle one inch. Agreeable to theſe dimenſions, the inventor has given a table exhibiting the value of each primary diviſion on the limb; he hath alſo given a more ample table, adapted to a diſtance between the centres of three times the radius of the ſemicircle, which he ſays hath been found the moſt convenient in practice. If an angle greater than 10° 18′ is wanted, it may be meaſured by the method of *anticipation*, as the inventor calls it, which is as follows: Let the ſcrew which faſtens the two circular plates on the upper centre be made faſt, and looſen the ſcrew which faſtens the upper circular plate to the inſtrument: Now adjuſt the glaſſes by the uſual method; bring forward the index to any given diviſion on the limb, and make it faſt; alſo faſten the ſcrew which was before looſe, and looſen the other ſcrew; then bring the index to zero, and proceed as before.

The inventor gives the following directions for adjuſting and uſing the inſtrument.

The firſt thing to be attended to is, to ſet the horizon-glaſs perpendicular to the plane of the inſtrument, which is performed as follows: Hold the inſtrument with its plane perpendicular to the horizon, and look over backwards into the glaſs and beyond it. If the limb of the inſtrument appears in a right line with its reflection, the glaſs is upright; but if it does not appear ſo, looſen or tighten the little ſcrew on the foot of the glaſs until it be adjuſted: Then with the inſtrument, as in taking an altitude, look through the ſight vane or teleſcope at ſome diſtant object, with the index fixed in any intended ſituation: the two ſcrews at the upper centre being looſe, turn the glaſs about till the ſame object appears nearly in the ſame part of the horizon-glaſs: Next hold it in a horizontal poſition, and adjuſt the object-glaſs or large ſpeculum with the ſcrews which are behind and before, on the foot of it, till the object and its reflection are ſeen in the ſame horizontal line. Laſtly, with the inſtrument upright, turn the tangent-ſcrew belonging to the horizon-glaſs at the back of the inſtrument, until there be a perfect coincidence of the object and its reflection that way, and the adjuſtments are complete.

Antiparallels, Aperture. ANTIPARALLELS, in geometry, are thoſe lines which make equal angles with two other lines, but contrariwiſe; that is, calling the former pair the firſt and ſecond lines, and the latter pair the third and fourth lines, if the angle made by the firſt and third lines be equal to the angle made by the ſecond and fourth, and contrariwiſe the angle made by the firſt and fourth equal to the angle made by the ſecond and third; then each pair of lines are antiparallels with reſpect to each other, viz. the firſt and ſecond, and the third and fourth. So, if AB and AC be any two lines, and FC and FE be two others, cutting them ſo, Plate II. fig. 5.

that the angle B is equal to the angle E,
and the angle C is equal to the angle D;

then BC and DE are antiparallels with reſpect to AB and AC; alſo theſe latter are antiparallels with regard to the two former. It is a property of theſe lines, that each pair cuts the other into proportional ſegments, taking them alternately,

viz. AB : AC : : AE : AD : : DB : EC,
and FE : FC : : FB : FD : : DE : BC.

APERTURE, in optics, has been defined in the Encyclopædia, but no rule was given there for finding a juſt aperture. As much depends upon this circumſtance, our optical readers will be pleaſed with the following practical rule given by Dr Hutton in his Mathematical Dictionary. "Apply ſeveral circles of dark paper, of various ſizes, upon the face of the glaſs, from the breadth of a ſtraw to ſuch as leave only a ſmall hole in the glaſs; and with each of theſe, ſeparately, view ſome diſtant object, as the moon, ſtars, &c. then that aperture is to be choſen through which they appear the moſt diſtinctly.

"Huyghens firſt found the uſe of apertures to conduce much to the perfection of teleſcopes; and he found by experience (*Diopt.* prop. 56.), that the beſt aperture for an object-glaſs, for example of 30 feet, is to be determined by this proportion, as 30 to 3, ſo is the ſquare root of 30 times the diſtance of the focus of any lens to its proper aperture: and that the focal diſtances of the eye-glaſſes are proportioned to the apertures. And M. Auzout ſays he found, by experience, that the apertures of teleſcopes ought to be nearly in the ſub-duplicate ratio of their lengths. It has alſo been found by experience, that object-glaſſes will admit of greater apertures, if the tubes be blacked withinſide, and their paſſage furniſhed with wooden rings.

"It is to be noted, that the greater or leſs aperture of an object-glaſs, does not increaſe or diminiſh the viſible area of the object; all that is effected by this is the admittance of more or fewer rays, and conſequently the more or leſs bright the appearance of the object. But the largeneſs of the aperture or focal diſtance cauſes the

the irregularity of its refractions. Hence, in viewing Venus through a teleſcope, a much leſs aperture is to be uſed than for the moon, or Jupiter, or Saturn, becauſe her light is ſo bright and glaring. And this circumſtance ſomewhat invalidates and diſturbs Azout's proportion, as is ſhown by Dr Hook, Phil. Tranſ. N° 4."

APOCATASTASIS, or, as it ſhould be written, Apokatastasis, is a Greek word employed in the language of aſtronomers, to denote the period of a planet, or the time it takes to return to that point of the zodiac whence it ſet out.

APOTOME, is a term employed by Euclid to denote the difference between two lines or quantities which are only commenſurable in power. Such is the difference between 1 and $\sqrt{2}$, or the difference between the ſide of a ſquare and its diagonal. The doctrine of apotomes in lines, as delivered by this ancient mathematician in the tenth book of his Elements, is a very curious ſubject, and has always been admired by ſuch as underſtood it. The firſt algebraical writers in Europe, ſuch as Lucas de Burgo, Cardan, Tartalea, Stifelius, &c. employed a conſiderable portion of their works on an algebraical expoſition of that which led them to the doctrine of ſurd quantities.

APPARENT conjunction of the planets, is when a right line, ſuppoſed to be drawn through their centres, paſſes through the eye of the ſpectator, and not through the centre of the earth. And, in general, the apparent conjunction of any objects, is when they appear or are placed in the ſame right line with the eye.

Apparent Diameter of a planet or other heavenly body, is not the real length of the diameter of that body, but the angle which it ſubtends at the eye, or under which it appears.

Apparent Diſtance, is that which we judge an object to be from us when ſeen afar off; and which is almoſt always very different from the true diſtance.

Apparent Figure, is the figure or ſhape under which an object appears when viewed at a diſtance; and is often very different from the true figure. Thus a ſtraight line, viewed at a diſtance, may appear but as a point; a ſurface, as a line; and a ſolid, as a ſurface.

Apparent Motion, is either that motion which we perceive in a diſtant body that moves, the eye at the ſame time being either in motion or at reſt; or that motion which an object at reſt ſeems to have, while the eye itſelf only is in motion.

Apparent Place of a Planet, &c. in aſtronomy, is that point in the ſurface of the ſphere of the world where the centre of the luminary appears from the ſurface of the earth.

APPARITION, in aſtronomy, denotes a ſtar's or other luminary's becoming viſible, which before was hid. So, the heliacal riſing, is rather an apparition than a proper riſing.

1 Arch defined.

ARCH, in building, is an artful diſpoſition and adjuſtment of ſeveral ſtones or bricks, generally in a bow-like form, by which their weight produces a mutual preſſure and abutment; ſo that they not only ſupport each other, and perform the office of an entire lintel, but may be extended to any width, and made to carry the moſt enormous weights.

In thoſe mild climates which ſeem to have been the firſt inhabited parts of this globe, mankind ſtood more in need of ſhade from the ſun than of ſhelter from the inclemency of the weather. A very ſmall addition to the ſhade of the woods ſerved them for a dwelling. Sticks laid acroſs from tree to tree, and covered with bruſhwood and leaves, formed the firſt houſes in thoſe delightful regions. As population and the arts improved, theſe huts were gradually refined into commodious dwellings. The materials were the ſame, but more artfully put together. At laſt agriculture led the inhabitants out of the woods into the open country. The connection between the inhabitant and the ſoil became now more conſtant and more intereſting. The wiſh to preſerve this connection was natural, and fixed eſtabliſhments followed of courſe. Durable buildings were more deſirable than thoſe temporary and periſhable cottages—ſtone was ſubſtituted for timber.

2 Hiſtory of architecture connected with arches.

But as theſe improved habitations were gradual refinements on the primitive hut, traces of its conſtruction remained, even when the choice of more durable materials made it in ſome meaſure inconvenient. Thus it happened, that while a plain building, intended for accommodation only, conſiſted of walls, pierced with the neceſſary doors and windows, an ornamented building had, ſuperadded to theſe eſſentials, columns, with the whole apparatus of entablature, borrowed from the wooden building, of which they had been eſſential parts, gradually rendered more ſuitable to the purpoſes of accommodation and elegance.

3 Origin of Greek architecture.

This view of ornamental architecture will go far to account for ſome of the more general differences of national ſtyle which may be obſerved in different parts of the world. The Greeks borrowed many of their arts from their Aſiatic neighbours, who had cultivated them long before. It is highly probable that architecture travelled from Perſia into Greece. In the ruins of Shuſhan, Perſepolis, or Tchilminar, are to be ſeen the firſt models of every thing that diſtinguiſhes the Grecian architectures. There is no doubt, we ſuppoſe, among the learned, as to the great priority of theſe monuments to any thing that remains in Greece; eſpecially if we take into account the tombs on the mountains, which have every appearance of greater antiquity than the remains of Perſepolis. In thoſe tombs we ſee the whole *ordonnance* of column and entablature, juſt as they began to deviate from their firſt and neceſſary forms in the wooden buildings. We have the architrave, frize, and corniche; the far-projecting mutules of the Tuſcan and Doric orders; the modillions no leſs diſtinct; the rudiments of the Ionic capital; the Corinthian capital in perfection, pointing out the very origin of this ornament, viz. a number of long graceful leaves tied round the head of the column with a fillet (a cuſtom which we know to have been common in their temples and banqueting rooms). Where the diſtance between the columns is great, ſo that each had to ſupport a weight too great for one tree, we ſee the columns cluſtered or fluted, &c. In ſhort, we ſee every thing of the Grecian architecture but the ſloped roof or pediment; a thing not wanted in a country where it hardly ever rains.

4 Egyptian,

The ancient Egyptian architecture ſeems to be a refinement on the hut built of clay or unburnt bricks mixed with ſtraw; every thing is maſſive, clumſy, and timid; ſmall intercolumnations, and hardly any projections.

5 Arabian, and

The Arabian architecture ſeems a refinement on the tent. A moſque is like a little camp, conſiſting of a number

Arch.

number of little bell tents, ſtuck cloſe together round a great one. A caravanſeray is a court ſurrounded by a row of ſuch tents, each having its own dome. The Greek church of St Sophia at Conſtantinople has imitated this in ſome degree; and the copies from it, which have been multiplied in Ruſſia as the ſacred form for a Chriſtian church, have adhered to the original model of cluſtered tents in the ſtricteſt manner. We are ſometimes diſpoſed to think that the painted glaſs (a faſhion brought from the Eaſt) was in imitation of the painted hangings of the Arabs.

6 Chineſe architecture.

The Chineſe architecture is an evident imitation of a wooden building. Sir Geo. Staunton ſays, that the ſingular form of their roofs is a *profeſſed* imitation of the cover of a ſquare tent.

In the ſtone-buildings of the Greeks, the roofs were imitations of the wooden ones; hence the lintels, flying corniches, ceilings in compartments, &c.

The pediment of the Greeks ſeems to have ſuggeſted the greateſt improvement in the art of building. In erecting their ſmall houſes, they could hardly fail to obſerve occaſionally, that when two rafters were laid together, from the oppoſite walls, they would, by leaning on each other, give mutual ſupport, as in fig. 1. Nor is it unlikely that ſuch a ſituation of ſtones as is repreſented in fig. 2. would not unfrequently occur by accident to maſons. This could hardly fail of exciting a little attention and reflection. It was a pretty obvious reflection, that the ſtones A and C, by overhanging, leaned againſt the intermediate ſtone B, and gave it ſome ſupport, and that B cannot get down without thruſting aſide A and C, or the piers which ſupport them. This was an approach to the theory of an arch; and if this be combined with the obſervation of fig. 1. we get the diſpoſition repreſented in fig. 3. having a perpendicular joint in the middle, and the *principle of the arch* is completed. Obſerve that this is quite different from the principle of the arrangement in fig. 2. In that figure the ſtones act as wedges, and one cannot get down without thruſting the reſt aſide; the ſame principle obtains in fig. 4. conſiſting of five arch ſtones; but in fig. 3. the ſtones B and C ſupport each other by their mutual preſſure (independent of their own weight), ariſing from the tendency of each lateral pair to fall outwards from the pier. This is the principle of the arch, and would ſupport the key-ſtone of fig. 4. although each of its joints were perpendicular, by reaſon of the great friction ariſing from the horizontal thruſt exerted by the adjoining ſtones.

Plate I.

7 Origin of the arch.

This was a moſt important diſcovery in the art of building; for now a building of any width may be roofed with ſtone.

8 Grecian.

We are diſpoſed to give the Greeks the merit of this diſcovery; for we obſerve arches in the moſt ancient buildings of Greece, ſuch as the temple of the ſun at Athens, and of Apollo at Didymos; not indeed as roofs to any apartment, nor as parts of the ornamental deſign, but concealed in the walls, covering drains or other neceſſary openings; and we have not found any *real* arches in any monuments of ancient Perſia or Egypt. Sir John Chardin ſpeaks of numerous and extenſive ſubterranean paſſages at Tchilminar, built of the moſt exquiſite maſonry, the joints ſo exact, and the ſtones ſo beautifully dreſſed, that they look like one continued piece of poliſhed marble: but he nowhere ſays that they are arched; a circumſtance which we think he would not have omitted—no arched door or window is to be ſeen. Indeed one of the tombs is ſaid to be arch-roofed, but it is all of one ſolid rock. No trace of an arch is to be ſeen in the ruins of ancient Egypt; even a wide room is covered with a ſingle block of ſtone. In the pyramids, indeed, there are two galleries, whoſe roofs conſiſt of many pieces; but their conſtruction puts it beyond doubt that the builder did not know what an arch was: for it is covered in the manner repreſented in fig. 5. where every projecting piece is more than balanced behind, ſo that the whole awkward maſs could have ſtood on two pillars. The Greeks therefore ſeem entitled to the honour of the invention. The arched dome, however, ſeems to have ariſen in Etruria, and originated in all probability from the employment of the augurs, whoſe buſineſs it was to obſerve the flight of birds. Their ſtations for this purpoſe were *templa*, ſo called *a templando*, "on the ſummits of hills." To ſhelter ſuch a perſon from the weather, and at the ſame time allow him a full proſpect of the country around him, no building was ſo proper as a dome ſet on columns; which accordingly is the figure of a temple in the moſt ancient monuments of that country. We do not recollect a building of this kind in Greece except that called the *Lanthern of Demoſthenes*, which is of very late date, whereas they abounded in Italy. In the later monuments and coins of Italy or of Rome, we commonly find the Etruſcan dome and the Grecian temple combined; and the famous pantheon was of this form, even in its moſt ancient ſtate.

It does not appear that the arch was conſidered as a part of the *ornamental* architecture of the Greeks during the time of their independency. It is even doubtful whether it was employed in roofing their temples. In none of the *ancient* buildings where the roof is gone, can there be ſeen any rubbiſh of the vault, or mark of the ſpring of the arch. It is not unfrequent, however, after the Roman conqueſts, and may be ſeen in Athens, Delos, Palmyra, Balbek, and other places. It is very frequent in the magnificent buildings of Rome; ſuch as the Coliſeum, the baths of Diocleſian, and the triumphal arches, where its form is evidently made the object of attention. But its chief employment was in bridges and aqueducts; and it is in thoſe works that its immenſe utility is the moſt conſpicuous. For by this happy contrivance a canal or a road may be carried acroſs any ſtream, where it would be almoſt impoſſible to erect piers ſufficiently near to each other for carrying lintels. Arches have been executed 130 feet wide, and their execution demonſtrates that they may be made four times as wide.

9 It was uſed at firſt only in bridges and aqueducts.

As ſuch ſtupendous arches are the greateſt performances of the maſonic art, ſo they are the moſt difficult and delicate. When we reflect on the immenſe quantity of materials thus ſuſpended in the air, and compare this with the ſmall coheſion which the firmeſt cement can give to a building, we ſhall be convinced that it is not by the force of the cement that they are kept together: they ſtand faſt only in conſequence of the proper balance of all their parts. Therefore, in order to erect them with a well-founded confidence of their durability, this balance ſhould be well underſtood and judiciouſly employed. We doubt not but that this was underſtood in ſome degree by the engineers of antiquity.

10 Difficulty of conſtructing it.

ty; but they have left us none of their knowledge. They muſt have had a great deal of mechanical knowledge before they could erect the magnificent and beautiful buildings whoſe ruins ſtill enchant the world; but they kept it among themſelves. We know that the

11 Skill and myſteries of the Dionyſiacs.

Dionyſiacs of Ionia were a great corporation of architects and engineers, who undertook, and even monopolized, the building of temples, ſtadiums, and theatres, preciſely as the fraternity of maſons in the middle ages monopolized the building of cathedrals and conventual churches. Indeed the Dionyſiacs reſembled the myſtical fraternity now called free maſons in many important particulars. They allowed no ſtrangers to interfere in their employment; they recogniſed each other by ſigns and tokens; they profeſſed certain myſterious doctrines, under the tuition and tutelage of Bacchus, to whom they built a magnificent temple at Teos, where they celebrated his myſteries as ſolemn feſtivals; and they called all other men profane, becauſe not admitted to theſe myſteries. But their chief myſteries and moſt important ſecrets ſeem to be their mechanical and mathematical ſciences, or all that academical knowledge which forms the regular education of a civil engineer. We know that the temples of the gods and the theatres required an immenſe apparatus of machinery for the celebration of ſome of their myſteries; and that the Dionyſiacs contracted for thoſe jobs, even at far diſtant places, where they had not the privilege of building the edifice which was to contain them. This is the moſt likely way of explaining the very ſmall quantity of mechanical knowledge that is to be met with in the writings of the ancients. Even Vitruvius does not appear to have been of the fraternity, and ſpeaks of the Greek architects in terms of reſpect next to veneration. The *Collegium Murariorum*, or incorporation of maſons at Rome, does not ſeem to have ſhared the ſecrets of the Dionyſiacs.

12 The art of building arches underſtood in the middle ages

The art of building arches has been moſt aſſiduouſly cultivated by the aſſociated builders of the middle ages of the Chriſtian church, both Saracens and Chriſtians, and they ſeem to have indulged in it with fondneſs: they multiplied and combined arches without end, placing them in every poſſible ſituation.

Having ſtudied this branch of the art of building with ſo much attention, they were able to erect the moſt magnificent buildings with materials which a Greek or Roman architect could have made little or no uſe of. There is infinitely more ſcientific ſkill diſplayed in a Gothic cathedral than in all the buildings of Greece and Rome. Indeed theſe laſt exhibit very little knowledge of the mutual balance of arches, and are full of groſs blunders in this reſpect; nor could they have reſiſted the ſhock of time ſo long, had they not been almoſt ſolid maſſes of ſtone, with no more cavity than was indiſpenſably neceſſary.

13 Better than by the Greeks and Romans.

14 Defects of the church of St Sophia at Conſtantinople.

Anthemius and Iſidorus, whom the Emperor Juſtinian had ſelected as the moſt eminent architects of Greece for building the celebrated church of St Sophia at Conſtantinople, ſeem to have known very little of this matter. Anthemius had boaſted to Juſtinian, that he would outdo the magnificence of the Roman pantheon, for he would hang a greater dome than it aloft in the air. Accordingly he attempted to raiſe it on the heads of four piers, diſtant from each other about 115 feet, and about the ſame height. He had probably ſeen the magnificent vaultings of the temple of Mars the Avenger, and the temple of Peace at Rome, the thruſts of which are withſtood by two maſſes of ſolid wall, which join the ſide walls of the temple at right angles, and extend ſidewiſe to a great diſtance. It was evident that the walls of the temple could not yield to the preſſure of the vaulting without puſhing theſe immenſe buttreſſes along their foundations. He therefore placed four buttreſſes to aid his piers. They are almoſt ſolid maſſes of ſtone, extending at leaſt 90 feet from the piers to the north and to the ſouth, forming as it were the ſide walls of the croſs. They effectually ſecured them from the thruſts of the two great arches of the nave which ſupport the dome; but there was no ſuch proviſion againſt the puſh of the great north and ſouth arches. Anthemius truſted for this to the half dome, which covered the ſemicircular eaſt end of the church, and occupied the whole eaſtern arch of the great dome. But when the dome was finiſhed, and had ſtood a few months, it puſhed the two eaſtern piers with their buttreſſes from the perpendicular, making them lean to the eaſtward, and the dome and half dome fell in. Iſidorus, who ſucceeded to the charge on the death of Anthemius, ſtrengthened the piers on the eaſt ſide, by filling up ſome hollows, and again raiſed the dome. But things gave way before it was cloſed; and while they were building in one part it was falling in in another. The pillars and walls of the eaſtern ſemicircular end were much ſhattered by this time. Iſidorus ſeeing that they could give no reſiſtance to the puſh which was ſo evidently directed that way, erected ſome clumſy buttreſſes on the eaſt wall of the ſquare which ſurrounded the whole Greek croſs, and was roofed in with it, forming a ſort of cloiſter round the whole. Theſe buttreſſes, ſpanning over this cloiſter, leaned againſt the piers of the dome, and thus oppoſed the thruſts of the great north and ſouth arches. The dome was now turned for the third time, and many contrivances were adopted for making it extremely light. It was made offenſively flat; and, except the ribs, it was roofed with pumice ſtone; but, notwithſtanding theſe precautions, the arches ſettled ſo as to alarm the architects, and they made all ſure by filling up the whole from top to bottom with arcades in three ſtories. The loweſt arcade was very lofty, ſupported by four noble marble columns, and thus preſerved, in ſome meaſure, the church in the form of a Greek croſs. The ſtory above formed a gallery for the women, and had ſix columns in front, ſo that they did not bear fair on thoſe below. The third ſtory was a dead wall filling up the arch, and pierced with three rows of ſmall ill-ſhaped windows. In this unworkmanlike ſhape it has ſtood till now, and is the oldeſt church in the world; but it is an ugly miſhapen maſs, more reſembling an overgrown potter's kiln, ſurrounded with furnaces pieced and patched, than a magnificent temple. We have been thus particular in our account of it, becauſe this hiſtory of the building ſhows that the ancient architects had acquired no diſtinct notions of the action of arches. Almoſt any maſon of our time would know, that as the ſouth arch would puſh the pier to the eaſtward, while the eaſt arch puſhed it to the ſouthward, the buttreſs which was to withſtand theſe thruſts muſt not be placed on the ſouth ſide of the pier, but on the ſouth-eaſt ſide, or that there muſt be an eaſtern as well as a ſouthern buttreſs. No ſuch blunders are to be ſeen in

15 Such as are never found in a Gothic church.

Arch.

in a Gothic cathedral. Some of them appear, to a careless spectator, to be very massive and clumsy; but when judiciously examined, they will be found very bold and light, being pierced in every direction by arcades, and the walls are divided into cells like a honeycomb, so that they are very stiff, while they are very light.

About the middle, or rather towards the end, of last century, when the Newtonian mathematics opened the road to true mechanical science, the construction of arches engrossed the attention of the first mathematicians.

16 Dr Hooke's principle of arches

The first hint of a principle that we have met with is Dr Hooke's assertion, that the figure into which a chain or rope, perfectly flexible, will arrange itself when suspended from two hooks, is, when inverted, the proper form for an arch composed of stones of uniform weight. This he affirmed on the same principle which is made use of in the Encyclopædia Britannica in the article ROOF, § 25. viz. that the figure which a flexible festoon of heavy bodies assumes, when suspended from two points, is, when inverted, the proper form for an arch of the same bodies, touching each other in the same points; because the forces with which they mutually press on each other in this last case, are equal and opposite to the forces with which they pull at each other in the case of suspension.

This principle is strictly just, and may be extended to every case which can be proposed. We recollect seeing it proposed, in very general terms, in the St James's Chronicle in 1759, when plans were forming for Blackfriar's Bridge in London; and since it is perhaps equal, in practical utility, to the most elaborate investigations of the mathematicians, our readers will not be displeased with a more particular account of it in this place.

17 Explained,

Let ABC (fig. 6.) be a parcel of magnets of any size and shape, and let us suppose that they adhere with great force by any points of contact. They will compose such a flexible festoon as we have been speaking of, if suspended from the points A and C. If this figure be inverted, preserving the same points of contact, they will remain in equilibrio. It will indeed be that kind of equilibrium which will admit of no disturbance, and which may be called a *tottering equilibrium*. If the form be altered in the smallest degree, by varying the points of contact (which indeed are points in the *figure of equilibration*), the magnets will no more recover their former position than a needle, which we had made to stand on its point, will regain its perpendicular position after it has been disturbed.

But if we suppose planes *de*, *fg*, *hi*, &c. drawn, that the points of mutual contact *a*, *b*, *c*, each bisecting the angle formed by the lines that unite the adjoining contacts (*fg*, for example, bisecting the angle formed by *a b*, *b c*), and if we suppose that the pieces are changed for others of the same weights, but having flat sides, which meet in the planes *de*, *fg*, *h i*, &c. it is evident that we shall have an arch of equilibration, and that the arch will have some stability, or will bear a little change of form without tumbling down: for it is plain that the equilibrium of the original festoon obtained only in the points *a*, *b*, *c*, of contact, where the pressures were perpendicular to the touching surfaces; therefore if the curve *a*, *b*, *c*, still passes through the touching surfaces perpendicularly, the conditions that are required for equilibrium still obtain The case is quite similar to that of the stability of a body resting on a horizontal plane. If the perpendicular through the centre of gravity falls within the base of the body, it will not only stand, but will require some force to push it over. In the original festoon, if a small weight be added in any part, it will change the form of the curve of equilibration a little, by changing the points of mutual contact. This new curve will gradually separate from the former curve as it recedes from A or C. In like manner, when the festoon is set up as an arch, if a small weight be laid on any part of it, it will bring the whole to the ground, because the shifting of the points of contact will be just the contrary to what it should be to suit the new curve of equilibration. But if the same weight be laid on the same part of the arch now constructed with flat joints, it will be sustained, if the new curve of equilibration still passes through the touching surfaces.

These conclusions, which are very obviously deducible from the principle of the festoon, shew us, without any further discussion, that the longer the joints are, the greater will be the stability of the arch, or that it will require a greater force to break it down. Therefore it is of the greatest importance to have the arch stones as long as economy will permit; and this was the great use of the ribs and other apparent ornaments in the Gothic architecture. The great projections of those ribs augmented their stiffness, and enabled them to support the unadorned copartments of the roof, composed of very small stones, seldom above six inches thick. Many old bridges are still remaining, which are strengthened in the same way by ribs.

Having thus explained, in a very familiar manner, the stability of an arch, we proceed to give the same popular account of the general application of the principle.

Suppose it to be required to ascertain the form of an arch which shall have the span AB (fig. 7.), and the height F 8, and which shall have a road-way of the dimensions CDE above it. Let the figure ACDEB be inverted, so as to form a figure A*cde*B. Let a chain of uniform thickness be suspended from the points A and B, and let it be of such a length that its lower point will hang at, or rather a little below, *f*, corresponding to F. Divide AB into a number of equal parts, in the points 1, 2, 3, &c. and draw vertical lines, cutting the chain in the corresponding points 1, 2, 3, &c. Now take pieces of another chain, and hang them on at the points 1, 2, 3, &c. of the chain A*f*B. This will alter the form of the curve. Cut or trim these pieces of chain, till their lower ends all coincide with the inverted road-way *cde*. The greater lengths that are hung on in the vicinity of A and B will pull down these points of the chain, and cause the middle point *f* (which is less loaded) to rise a little, and will bring it near to its proper height. 18 And applied.

It is plain that this process will produce an arch of perfect equilibration; but some farther considerations are necessary for making it exactly suit our purpose. It is an arch of equilibration for a bridge, that is so loaded that the weight of the arch-stones is to the weight of the matter with which the haunches and crown are loaded, as the weight of the chain A*f*B is to the sum of the weights of all the little bits of chain very nearly. But this proportion is not known beforehand; we must therefore proceed in the following manner: Adapt to the curve produced in this way a thickness

Arch.

nefs of the arch-ftones as great as are thought fufficient to enfure ftability; then compute the weight of the arch ftones, and the weight of the gravel or rubbifh with which the haunches are to be filled up to the road-way. If the proportion of thefe two weights be the fame with the proportion of the weights of chain, we may reft fatisfied with the curve now found; but if different, we can eafily calculate how much muft be added equal to, or taken from, each appended bit of chain, in order to make the two proportions equal. Having altered the appended pieces accordingly, we fhall get a new curve, which may perhaps require a very fmall trimming of the bits of chain to make them fit the road-way. This curve will be infinitely near to the curve wanted.

We have practifed this method for an arch of 60 feet fpan and 21 feet height, the arch-ftones of which were only two feet nine inches long. It was to be loaded with gravel and fhivers. We made a previous computation, on the fuppofition that the arch was to be nearly elliptical. The diftance between the points 1, 2, 3, &c. were adjufted, fo as to determine the proportion of the weights of chain agreeable to the fuppofition. The curve differed confiderably from an ellipfe, making a confiderable angle with the verticles at the fpring of the arch. The real proportion of the weights of chain, when all was trimmed fo as to fuit the road-way, was confiderably different from what was expected. It was adjufted. The adjuftment made very little change in the curve. It would not have changed it two inches in any part of the real arch. When the procefs was completed, we conftructed the curve mathematically. It did not differ fenfibly from this mechanical conftruction. This was very agreeable information; for it fhewed us that the firft curve, formed by about two hours labour, on a fuppofition confiderably different from the truth, would have been fufficiently exact for the purpofe, being in no place three inches from the accurate curve, and therefore far within the joints of the intended arch-ftones. Therefore this procefs, which any intelligent mafon, though ignorant of mathematical fcience, may go through with little trouble, will give a very proper form for an arch fubject to any conditions.

19 The chief defect of the curve found according to this principle.

The chief defect of the curve found in this way is a want of elegance, becaufe it does not fpring at right angles to the horizontal line; but this is the cafe with all curves of equilibration, as we fhall fee by and by. It is not material: for, in the very neighbourhood of the piers, we may give it any form we pleafe, becaufe the mafonry is folid in that place; nay, we apprehend that a deviation from the curve of equilibration is proper. The conftruction of that curve fuppofes that the preffure on every part of the arch is vertical; but gravel, earth, and rubbifh, exert fomewhat of a hydroftatical preffure laterally in the act of fettling, and retain it afterwards. This will require fome more curvature at the haunches of an arch to balance it; but what this lateral preffure may be, cannot be deduced with confidence from any experiments that we have feen. We are inclined to think that if, inftead of dividing the horizontal line AB in the points 1, 2, 3, &c. we divide the chain itfelf into equal parts, the curve will approach nearer to the proper form.

After this familiar ftatement of the general principle, it is now time to confider the theory founded on it more in detail. This theory aims at fuch an adjuftment of the pofition of the arch-ftones to the load on every part of the arch, that all fhall remain in equilibrio, although the joints be perfectly polifhed, and without any cement. The whole may be reduced to two problems. The firft is to determine the vertical preffure or load on every point of a line of a given form, which will put that line in equilibrio. The fecond is to determine the form of a curve which fhall be in equilibrio when loaded in its different points, according to any given law.

20 Theory founded on this principle.

The whole theory is deducible from § 27. of the article Roof. The fundamental propofition in that fection ftates the proportions between the various preffures or thrufts which are exerted at the angles of an affemblage of beams or other pieces of folid heavy matter, freely moveable about thofe angles, as fo many joints, but retaining their pofition by the equilibrium of thofe preffures. It is there demonftrated, "that the thruft at any angle, if eftimated in a horizontal direction, is the fame throughout, and may be reprefented by any horizontal line BT, fig. 8. (Roofs, fig. 10 Pl. CCCCXL); and that if a vertical line QTS be drawn through T, the thruft exerted at any angle D by the piece CD, in its own direction, will then be reprefented by BR, drawn parallel to CD; and in like manner, that the thruft in the direction ED is reprefented by BS, &c.; and, laftly, that the vertical thrufts or loads, at each angle B, C, D, by which all thefe others preffures are excited, are reprefented by the portions QC, CR, RS, of the vertical intercepted by thofe lines; that is, all thefe preffures are to the uniform horizontal thruft as the lines which reprefent them are to BT. The horizontal thruft, therefore, is a very proper unit, with which we may compare all the others. Its magnitude is eafily deduced from the fame propofition; for QS is the fum of all the vertical preffures of the angles, and therefore reprefents the weight of the whole affemblage. Therefore as QS is to BT, fo is the weight of the whole to the horizontal thruft.

21 Accommodated to the conftruction of an arch vault.

To accommodate this theory to the conftruction of a curvilineal arch vault, let us firft fuppofe the vault to be polygonal, compofed of the cords of the elementary arches. Let AVE (fig. 9.) be a curvilineal arch, of which V is the vertex, and VX the vertical axis, which we fhall confider as the axis or abfciffa of the curve, while any horizontal line, fuch as HK, is an ordinate to the curve. About any point C of the curve as a centre defcribe a circle BLD, cutting the curve in B and D. Draw the equal cords CB, CD. Draw alfo the horizontal line CF, cutting the circle in F. Defcribe a circle BCDQ paffing through B, C, D. Its centre O will let in a line COQ, which bifects the angle BCD; and C d, which touches this circle in C, will bifect the angle b C d, formed by the equal cords BC, CD. Draw CLP perpendicular to cb, and DP perpendicular to CD, meeting CL in P. Through L draw the tangent GLM, meeting CD in G, and the vertical line CM in M. Draw the tangent F a, cutting the cords BC, CD, in b and d, and the tangent to the circle BCDQ in c. Laftly, draw d N parallel to bc.

From what is demonftrated in § 27. of the article Roof, it appears, that if BC, CD be two pieces of an equilibrated heavy polygon, and if CF reprefent the horizontal thruft in every angle of the polygon, C d and

C b

Arch.

Cb will severally represent the thrusts exerted by the pieces DC, BC, and that bd, or CN, will represent the weight lying on the angle BCD, by which those thrusts are balanced.

As the reader may not have the article Roof at hand, this equilibrium may be recalled to his remembrance in the following manner: Produce dC to o, so that Co may be equal to Cd. Draw bn to the vertical parallel to dB, and join no. It is evident that $bnoC$ is a parallelogram, and that nC ($= bd$) $=$ CN. Now the thrust or support of the piece BC is exerted in the direction Cb, while that of DC is exerted in the direction Co. These two thrusts are equivalent to the thrust in the diagonal Cn; and it is with this compound thrust that the load or vertical pressure CN is in *immediate* equilibrium.

22 And demonstrated.

Because bCL, NCF, are right angles, and FCL is common to both, the angles bCF and MCL are equal. Therefore the right angled triangles bCF and MCL are similar. And since CF is equal to CL, cb is equal to CM. It is evident that the triangles GCM and dCN are similar. Therefore $CG : Cd = CM : CN$, $= Cb : CN$. Therefore we have $CN = \frac{Cb \times Cd}{CG}$. But because CDP and CLG are right angles, and therefore equal, and the angle GCP is common to the two triangles GCL, PCD, and CD is equal to CL, we have CG equal to CP. Therefore $CN = \frac{Cb \times Cd}{CP}$. Also, since CDP is a right angle, DP meets the diameter in Q, the opposite point of the circumference, and the angle DQC is equal to DCd, or DCb (because bCd is bisected by the tangent), that is, to PCQ (because the right angles bCP, cDO are equal, and cDP is common). Therefore PQ is equal to PC; and if PO be drawn perpendicular to CQ, it will bisect it, and O is the centre of the circle BCDQB.

Now let the points B and D continually approach to C (by diminishing the radius of the small circle), and ultimately coincide with it. It is evident that the circle BCDQ is ultimately the equicurve circle, and that PC ultimately coincides with OC, the radius of curvature. Also $Cb \times Cd$ becomes ultimately Cc^2. Therefore CN, the vertical load on any point of a curve of equilibration, is $= \frac{Cc^2}{\text{Rad. Curv.}}$

It is farther evident, that CF is to Cc as radius to the secant of the elevation of the tangent above the horizon. Therefore we have the load on any point of the curve always proportional to $\frac{\text{Sec.}^2\text{ Elev.}}{\text{Rad. Curv.}}$

This load on every elementary arch of the wall is commonly a quantity of solid matter incumbent on that element of the curve, and pressing it vertically; and it may be conceived as made up of a number of heavy lines standing vertically on it. Thus, if the element Ee of the curve were lying horizontally, a little parallelogram $REer$ standing perpendicularly on it, would represent its load. But as this element Ee has a sloping position, it is plain that, in order to have the same quantity of heavy matter pressing it vertically, the height of the parallelogram must be increased till it meets in $\epsilon\rho$, the line $R\epsilon$ drawn parallel to the tangent EG. It is evident that the angle $RE\rho$ is equal to the angle AEG. Therefore we have $ER : E\rho = \text{Rad.} : \text{Sec. Elev.}$

Arch.

If therefore the arch is kept in equilibrio by the vertical pressure of a wall, we must have the height of the wall above any point proportional to $\frac{\text{Sec.}^3\text{ Elev.}}{\text{Rad. of Curv.}}$

Cor. I. If OS be drawn perpendicular to the vertical CS, CS will be half the vertical cord of the equicurve circle. The angle OCS is equal to cCF, that is, to the angle of elevation. Therefore $1 : \text{Sec. Elev.} = CS : CO$, and the secant of elevation may be expressed by $\frac{CO}{CS}$, and its cube by $\frac{CO^3}{CS^3}$. Therefore the height of wall is proportional to $\frac{CO^3}{CS^3 \times CO}$, or to $\frac{CO^2}{CS^3}$, or $\frac{CO^2}{CS^2 \times CS}$, or to $\frac{\text{Sec.}^2\text{ of Elev.}}{\text{Vert. Cord of Curv.}}$ 23 Corollaries.

Cor. II. If we make the arch $VC = z$, the abscissa $VH = x$, the ordinate $HC = y$, the radius osculi $CO = r$, and the $\frac{1}{2}$ vertical cord $CS = s$, the height of wall pressing on any point is proportional to $\frac{\dot{z}^3}{\dot{y}^3 r}$; or to $\frac{\dot{z}^2}{\dot{y}^2 s}$, or $\frac{\dot{x}^2 + \dot{y}^2}{\dot{y}^2 s}$. Therefore, when the equation of the curve is given, and the height of wall on any one point of it is also given, we can determine it for any other point: for the equation of the curve will always give us the relation of $\dot{z}$, $\dot{x}$, and $\dot{y}$, and the value of r or s. This may be illustrated by an example or two. For this purpose it will generally be most convenient to assume the height above the vertex V for the unit of computation. The thickness of the arch at the crown is commonly determined by other circumstances. At the vertex the tangent to the arch is horizontal, and therefore the cube of the secant is unity or 1. Call the height of wall, at the crown, H, and let the radius of curvature in that point be R, and its half cord R (it being then coincident with the radius), and the height on any other point h. We have $\frac{1}{R} : \frac{\dot{z}^3}{\dot{y}^3 r} = H : h$, and $h = H \times \frac{\dot{z}^3}{\dot{y}^3} \times \frac{R}{r}$. The other formula gives $h = H \times \frac{\dot{z}^2}{\dot{y}^2} \times \frac{R}{s}$.

Examp. 1. Suppose the arch to be a segment of a circle, as in fig. 10. where AE is the diameter, and O the centre. In this arch the curvature is the same throughout, or $\frac{R}{r} = 1$. Therefore $h = H \times \frac{\dot{z}^3}{\dot{y}^3}$, or $= H \times \text{Cube Sec. Elev.}$ 24 Illustrated by examples.

This gives a very simple calculus. To the logarithm of H add thrice the logarithm of the secant of elevation, The sum is the logarithm of h.

It gives also a very simple construction. Draw the vertical CS, cutting the horizontal diameter in S. Draw ST, cutting the radius OC perpendicularly in T. Draw the horizontal line Tz, cutting the vertical in z. Join zo. Make $Cu = Vv$, and draw ux parallel to zo. Cc must be made $= Cx$. The demonstration is evident.

It is very easy to see that if CV is an arch of 60°, and Vv is $\frac{1}{12}$th of VC, the points v and c will be on a level; for the secant of CV is twice CO, and therefore Cc is 8 times Vv, which is $\frac{2}{3}$th of VH.

 The

Arch.

The dotted line $v g c f$ is drawn according to this calculus or conſtruction. It falls conſiderably below the horizontal line in the neighbourhood of c; and then, paſſing very obliquely through c, it riſes rapidly to an unmeaſurable height, becauſe the vertical line through A is its aſſymptote. This muſt evidently be the caſe with every curve which ſprings at right angles with a horizontal line.

It is plain that if vV be greater, all the other ordinates of the curve $v g c f$, reſting on the circumference AVE, will be greater in the ſame proportion, and the curve will cut the horizontal line drawn through v in ſome point nearer to v than c is. Hence it appears that a circular arch cannot be put in eqnilibrio by building on it up to a horizontal line, whatever be its ſpan, or whatever be the thickneſs at the crown. We have ſeen that when this thickneſs is only $\frac{1}{15}$th of the radius, an arch of 120 degrees will be too much loaded at the flanks. This thickneſs is much too ſmall for a bridge, being only $\frac{1}{25}$th of the ſpan CM, whereas it ſhould have been almoſt double of this, to bear the inequalities of weight that may occaſionally be on it. When the crown is made ſtill thinner, the outline is ſtill more depreſſed before it riſes again. There is therefore a certain ſpan, with a correſponding thickneſs at the crown, which will deviate leaſt of all from a horizontal line. This is an arch of about 54 degrees, the thickneſs at the crown being about one-fourth of the ſpan, which is extravagantly great. It appears in general, therefore, that the circle is not a curve ſuited to the purpoſes of a bridge or an arcade, which requires an outline nearly horizontal.

Examp. 2. Let the curve be a parabola AVE (fig. 11.), of which V is the vertex, and DG the directrix. Draw the diameters DCF, GVN, the tangents CK, VP, and the ordinates VF and CN. It is well known that GV is to DC as VP^2 to CK^2, or as CN^2 to CK^2. Alſo 2 GV is the radius of the oſculating circle at V, and 2 DC is one-half of the vertical cord of the oſculating circle at C. Therefore $CN^2 : CK^2$ (or $\dot{y}^2 : \dot{z}^2$) $= R : s$, and $s = \frac{\dot{z}^2}{\dot{y}^2} R$. But C$c$, or $b = H \times \frac{\dot{z}^2 R}{\dot{y}^2 S}$. Therefore

$$b = H \times \frac{\dot{z}^2 \quad R}{\dot{y}^2 \frac{\dot{z}^2}{\dot{y}^2} R}, = H \times \frac{\dot{z}^2 R}{\dot{z}^2 R}, = H. \quad \text{Therefore}$$

$Cc = v$V.

It follows from this inveſtigation, that the back or extrados of a parabolic arch of equilibration muſt be parallel to the arch or ſoffit itſelf; or that the thickneſs of the arch, eſtimated in a vertical direction, muſt be equal throughout; or that the extrados is the ſame parabola with the ſoffit or intrados.

We have ſelected theſe two examples merely for the ſimplicity and perſpicuity of the ſolutions, which have been effected by means of elementary geometry only, inſtead of employing the analytical value of the radius of the oſculatory circle, viz. $\frac{\dot{z}^3}{\dot{y}\ddot{x} - \dot{x}\ddot{y}}$, which would have involved us at leaſt in the elements of ſecond fluxions. We have alſo preferred ſimplicity to elegance in the inveſtigation, becauſe we wiſh to inſtruct the practical engineer, who may not be a proficient in the higher mathematics.

Arch.

25
To find the form of an arch when the figure of its back is given.

The converſe of the problem, namely, to find the form of the arch when the figure of the back of it is given, is the moſt uſual queſtion of the two, at leaſt in caſes which are moſt important and moſt difficult. Of theſe perhaps bridges are the chief. Here the neceſſity of a road-way, of eaſy and regular aſcent, confines us to an outline nearly horizontal, to which the curve of the arch muſt be adapted. This is the moſt difficult problem of the two; and we doubt whether it can be ſolved without employing infinite approximating ſerieſes inſtead of accurate values.

Let $a v e$ (fig. 12.) be the intended outline or extrados of the arch AVE, and let vQ be the common axis of both curves. From c and C, the correſponding points, draw the ordinates $c b$, CH. Let the thickneſs vV at the top be a, the abſciſſa $v b$ be $= \dot{u}$, and VH $= x$, and let the equal ordinates $c b$, CH be y, and the arch VC be z.

Then, by the general theorem, $cC = \frac{\dot{z}^3}{r \dot{y}^3}$, r being the radius of curvature. This, by the common rules, is $= \frac{\dot{z}^3}{\dot{y}\ddot{x} - \dot{x}\ddot{y}}$. This gives us $c\,C = \frac{\dot{y}\ddot{x} - \dot{x}\ddot{y}}{\dot{y}^3}$, or $= \frac{\dot{y}\ddot{x} - \dot{x}\ddot{y}}{\dot{y}^3} \times C$; where C is a conſtant quantity, found by taking the real value of cC in V, the vertex of the curve. But it is evident that it is alſo $= a + x - u$. Therefore $a + x - u = \frac{\dot{y}\ddot{x} - \dot{x}\ddot{y}}{\dot{y}^3} \times C, = \frac{C}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$.

If we now ſubſtitute the true value of u (which is given, becauſe the extrados is ſuppoſed to be of a known form), expreſſed in terms of y, the reſulting equation will contain nothing but x and y, with their firſt and ſecond fluxions, and known quantities. From this equation the relation of x and y muſt be found by ſuch methods as ſeem beſt adapted to the equation of the extrados.

Fortunately the proceſs is more ſimple and eaſy in the moſt common and uſeful caſe than we ſhould expect from this general rule. We mean the caſe where the extrados is a ſtraight line, eſpecially when this is horizontal. In this caſe u is equal to o.

Example. To find the form of the balanced arch AVE (fig. 13.), having the horizontal line $c v$ for its extrados. Plate II

Keeping the ſame notation, we have $u = o$, and therefore $a + x = \frac{C}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$.

Aſſume $\dot{y} = \frac{\dot{x}}{v}$; then $\frac{\dot{x}}{\dot{y}} = v$, and $\frac{C}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$, $= \frac{C v \dot{v}}{\dot{x}}$, that is $a + x = \frac{C v \dot{v}}{\dot{x}}$. Therefore $a\dot{x} + x\dot{x} = C v \dot{v}$; and by taking the fluents, we have $2ax + x^2 = C v^2$; and $v = \sqrt{\frac{2ax + x^2}{C}}$. Conſequently, $\dot{y} = \frac{\sqrt{C}\,\dot{x}}{\sqrt{2ax \times x^2}}$ (being $= \frac{\dot{x}}{v}$). Taking the fluent of this, we have $y = \sqrt{C} \times L\,(2ax + 2x^2$

+ 2

Arch.

$+ 2\sqrt{2ax + x^2})$. But at the vertex, where $x = 0$, we have $y = \sqrt{C} \times L\,(2a)$. The corrected fluent is therefore $y = \sqrt{C} \times L\,\frac{a + x + \sqrt{2ax + x^2}}{a}$.

It only remains to find the constant quantity C. This we readily obtain by selecting some point of the extrados where the values of x and y are given by particular circumstances of the case. Thus, when the span $2s$ and height h of the arch are given, we have $s = \sqrt{C} \times L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)$, and consequently $\sqrt{C} = \frac{s}{L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)}$. Therefore the general value of

$$y = s \times \frac{L\left(\frac{a + x + \sqrt{2ax + x^2}}{a}\right)}{L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)}; = \frac{s}{L\,\frac{a+h+\sqrt{2ah+h^2}}{a}} \times L\,\frac{a + x + \sqrt{2ax + x^2}}{a}.$$

As an example of the use of this formula, we subjoin a table calculated by Dr Hutton of Woolwich for an arch, the span of which is 100 feet, and the height 40; which are nearly the dimensions of the middle arch of Blackfriars Bridge in London.

y	x	y	x	y	x
0	6,000	21	10,381	36	21,774
2	6,055	22	10,858	37	22,948
4	6,144	23	11,368	38	24,190
6	6,324	24	11,911	39	25,505
8	6,580	25	12,489	40	26,894
10	6,914	26	13,106	41	28,364
12	7,330	27	13,761	42	29,919
13	7,571	28	14,457	43	31,563
14	7,834	29	15,196	44	33,299
15	8,120	30	15,980	45	35,135
16	8,430	31	16,811	46	37,075
17	8,766	32	17,693	47	39,126
18	9,168	33	18,627	48	41,293
19	9,517	34	19,617	49	43,581
20	9,934	35	20,665	50	46,000

The figure for this proposition is exactly drawn according to these dimensions, that the reader may judge of it as an object of sight. It is by no means deficient in gracefulness, and is abundantly roomy for the passage of craft; so that no objection can be offered against its being adopted on account of its mechanical excellency.

26 Defects of the Catenarian curve.

The reader will perhaps be surprised that we have made no mention of the celebrated Catenarian curve, which is commonly said to be the best form for an arch; but a little reflection will convince him, that although it is the only form for an arch consisting of stones of equal weight, and touching each other only in single points, it cannot suit an arch which must be filled up in the haunches, in order to form a road-way. He will be more surprised to hear, after this, that there is a certain thickness at the crown, which will put the Catenaria in equilibrio, even with a horizontal road-way; but this thickness is so great as to make it unfit for a bridge, being such that the pressure at the vertex is equal to the horizontal thrust. This would have been about 37 feet in the middle arch of Blackfriars Bridge. The only situation, therefore, in which the Catenarian form would be proper, is an arcade carrying a height of dead wall; but in this situation it would be very ungraceful. Without troubling the reader with the investigation, it is sufficient to inform him that in a Catenarian arch of equilibration the abscissa VH is to the abscissa $v\,h$ in the constant ratio of the horizontal thrust to its excess above the pressure on the vertex.

27 Inutility of the common theory of equilibration.

This much will serve, we hope, to give the reader a clear notion of this celebrated theory of the equilibrium of arches, one of the most delicate and important applications of mathematical science. Volumes have been written on the subject, and it still occupies the attention of mechanicians. But we beg leave to say, with great deference to the eminent persons who have prosecuted this theory, that their speculations have been of little service, and are little attended to by the practitioner. Nay, we may add, that Sir Christopher Wren, perhaps the most accomplished architect that Europe has seen, seems to have thought it of little value: for, among the fragments which have been preserved of his studies, there are to be seen some imperfect dissertations on this very subject, in which he takes no notice of this theory, and considers the balance of arches in quite another way. These are collected by the author of the account of Sir Christopher Wren's family. This man's great sagacity, and his great experience in building, and, still more his experience in the repairs of old and crazy fabrics, had shewn him many things very inconsistent with this theory, which appears so specious and safe. The general facts which occur in the failure of old arches are highly instructive, and deserve the most careful attention of the engineer; for it is in this state that their defects, and the process of nature in their destruction, are most distinctly seen. We venture to affirm, that a very great majority of these facts are irreconcileable to the theory. The way in which circular arches commonly fail, is by the sinking of the crown and the rising of the flanks. It will be found by calculation, that in most of the cases it ought to have been just the contrary. But the clearest proof is, that arches very rarely fail where their load differs most remarkably from that which this theory allows. Semicircular arches have stood the power of ages, as may be seen in the bridges of ancient Rome, and in the numerous arcades which the ancient inhabitants have erected. Now all arches which spring perpendicularly from the horizontal line, require, by this theory, a load of infinite height; and, even to a considerable distance from the springing of the arch, the load necessary for the theoretical equilibrium is many times greater than what is ever laid on those parts; yet a failure in the immediate neighbourhood of the spring of an arch is a most rare phenomenon, if it ever was observed. Here is a most remarkable deviation from the theory; for, as is already observed, the load is frequently not the fourth part of what the theory requires.

Many other facts might be adduced which shew great deviations from the legitimate results from the theory. We hope to be excused, therefore, by the mathematicians for doubting of the justness of this theory. We

Arch.

28
Its defects.

do not think it erroneous, but defective, leaving out circumstances which we apprehend to be of great importance; and we imagine that the defects of the theory have arisen from the very anxiety of the mechanicians to make it perfect. The arch-stones are supposed to be perfectly smooth or polished, and not to be connected by any cement, and therefore to sustain each other merely by the equilibrium of their vertical pressure. The theory ensures this equilibrium, and this only, leaving unnoticed any other causes of mutual action.

The authors who have written on the subject say expressly, that an arch which thus sustains itself must be stronger than another which would not; because when, in imagination, we suppose both to acquire connection by cement, the first preserves the influence of this connection unimpaired; whereas in the other, part of the cohesion is wasted in counteracting the tendency of some parts to break off from the rest by their want of equilibrium. This is a very specious argument, and would be just, if the forces which are mutually exerted between the parts of the arch in its settled state were merely vertical pressures, or, where different, were inconsiderable in comparison with those which are really attended to in the construction.

But this is by no means the case. The forms which the uses for which arches are erected oblige us to adopt, and the loads laid on the different points of the arch, frequently deviate considerably from what are necessary for the equilibrium of vertical pressures. The varying load on a bridge, when a great wagon passes along it, sometimes bears a very sensible proportion to the weight of that point of the arch on which it rests. It is even very doubtful whether the pressures which are occasioned by the weight of the stuff employed for filling up the flanks really act in a vertical direction, and in the proportion which is supposed. We are pretty certain that this is not the case with sand, gravel, fat mould, and many substances in very general use for this purpose. When this is the case, the pressures sustained by the different parts of the arch are often very inconsistent with the theory—a part of the arch is overloaded, and tends to fall in, but is prevented by the cement. This part of the arch therefore acts on the remoter parts by the intervention of the parts between, employing those intermediate parts as a kind of levers to break the arch in a remote part, just as a lintel would be broken. We apprehend that a mathematician would be puzzled how to explain the stability of an arch cut out of a solid and uniform mass of rock. His theory considers the mutual thrusts of the arch stones as in the direction of the tangents to the arch. Why so? because he supposes that all his polished joints are perpendicular to those tangents. But in the present case he has no existing joints; and there seems to be nothing to direct his imagination in the assumption of joints, which, however, are absolutely necessary for employing his theory, because, without a supposition of this kind, there seems no conceiving any mutual abutment of the arch stones. Ask a common, but intelligent, mason what notion he forms of such an arch? We apprehend that he will consider it as no arch, but as a lintel, which may be broken like a wooden lintel, and which resists entirely by its cohesion. He will not readily conceive that, by cutting the under side of a stone lintel into an arched form, and thus taking away more than half of its substance, he has changed its nature of a lintel, or given it any additional strength. Nor would there be any change made in the way in which such a mass of stone would resist being broken down, if nothing were done but forming the under side into an arch. If the lintel be so laid on the piers that it can be broken without its parts pushing the piers aside (which will be the case if it lies on the piers with horizontal joints), it will break like any other lintel; but if the joints are directed downwards, and converging to a point within the arch, the broken stone (suppose it broken at the crown by an overload in that part) cannot be pressed down without forcing the piers outwards. Now, in this mode of acting, the mind cannot trace any thing of the statical equilibrium that we have proceeded on in the foregoing theory. The two parts of the broken lintel seem to push the piers aside in the same manner that two rafters push outwards the walls of a house, when their feet are not held together by a tie-beam. If the piers cannot be pushed aside (as when the arch abuts on two solid rocks), nothing can press down the crown which does not crush the stone.

This conclusion will be strictly true if the arch is of such a form that a straight line drawn from the crown to the pier lies wholly within the solid masonry. Thus if the vault consist of two straight stones, as in fig. 1. or if it consist of several stones, as in fig. 14. disposed in two straight lines, no weight laid on the crown can destroy it in any other way but by crushing it to powder.

29
When it is to be called into the aid of the builder.

But when straight lines cannot be drawn from the overloaded part to the firm abutments through the solid masonry, and when the cohesion of the parts is not able to withstand the transverse strains, we must call the principles of equilibrium to our aid; and in order to employ them with safety, we must consider how they are modified by the excitement of the cohering forces.

The cohesion of the stones with each other by cement or otherwise, has, in almost every situation, a bad effect. It enables an overload at the crown to break the arch near the haunches, causing those parts to rise, and then to spread outwards, just as a Mansarde or Kirb roof would do if the truss beam which connects the heads of the lower rafters were sawn through. This can be prevented only by loading that part more than is requisite for equilibrium. It would be prudent to do this to a certain degree, because it is by this cohesion that the crown always becomes the weakest part of the arch, and suffers more by any occasional load.

We expect that it will be said in answer to all this, that the cohesion given by the strongest cement that we can employ, nay, the cohesion of the stone itself, is a mere nothing in comparison with the enormous thrusts that are in a state of continual exertion in the different parts of an arch. This is very true; but there is another force which produces the same effect, and which increases nearly in the proportion that those thrusts increase, because it arises from them. This is the friction of the stones on each other. In dry freestone this friction considerably exceeds one half of the mutual pressure. The reflecting reader will see that this produces the same effect, in the case under consideration, that cohesion would do; for while the arch is in the act of failing, the mutual pressure of the arch-stones is acting with full force, and thus produces a friction more than adequate

Arch.

adequate to all the effects we have been speaking of.

30 Process of the breaking of an arch.

When these circumstances are considered, we imagine that it will appear that an arch, when exposed to a great overload on the crown (or indeed on any part), divides, of itself, into a number of parts, each of which contains as many arch-stones as can be pierced (so to speak) by one straight line, and that it may then be considered as nearly in the same situation with a polygonal arch of long stones butting on each other like so many beams in a Norman roof (see Roof, n° 49.), but without their braces and ties. It tends to break at all those angles; and it is not sufficiently resisted there, because the materials with which the flanks are filled up have so little cohesion, that the angle feels no load except what is immediately above it; whereas it should be immediately loaded with all the weight which is diffused over the adjoining side of the polygon. This will be the case, even though the curvilineal arch be perfectly equilibrated. We recollect some circumstances in the failure of a considerable arch, which may be worth mentioning. It had been built of an exceedingly soft and friable stone, and the arch stones were too short. About a fortnight before it fell, chips were observed to be dropping off from the joints of the archstones about ten feet on each side of the middle, and also from another place on one side of the arch, about twenty feet from its middle. The masons in the neighbourhood prognosticated its speedy downfal, and said that it would separate in those places where the chips were breaking off. At length it fell; but it first split in the middle, and about 15 or 16 feet on each side, and also at the very springing of the arch. Immediately before the fall a shivering or crackling noise was heard, and a great many chips dropped down from the middle between the two places from whence they had dropped a fortnight before. The joints opened above at those new places above two inches, and in the middle of the arch the joints opened below, and in about five minutes after this the whole came down. Even this movement was plainly distinguishable into two parts. The crown sunk a little, and the haunches rose very sensibly, and in this state it hung for about half a minute. The arch-stones of the crown were hanging by their upper corners. When these splintered off, the whole fell down.

We apprehend that the procedure of nature was somewhat in this manner. Straight lines can be drawn within the arch-stones from A (fig. 15.) to B and D, and from those points to C and E. Each of the portions ED, DA, AB, BC, resist as if they were of one stone, composing a polygonal vault EDABC. When this is overloaded at A, A can descend in no other way than by pushing the angles B and D outwards, causing the portions BC, DE, to turn round C and E. This motion must raise the points B and D, and cause the arch-stones to press on each other at their *inner* joints *b* and *d*. This produced the copious splintering at those joints immediately preceding the total downfal. The splintering which happened a fortnight before arose from this circumstance, that the lines AB and AD, along which the pressure of the overload was propagated, were tangents to the soffit of the arch in the points F, H, and G, and therefore the strain lay all on those corners of the arch-stones, and splintered a little from off them till the whole took a firmer bed. The subsequent phenomena are evident consequences of this distribution and modification of pressure, and can hardly be explained in any other way; at least not on the theoretical principles already set forth: for in this bridge the loads at B and D were very considerably greater than what the equilibrium required; and we think that the first observed splintering at H, F, and G, was most instructive, showing that there was an extraordinary pressure at the inner joints in those places, which cannot be explained by the usual theory.

Not satisfied with this single observation, after this way of explaining it occurred to us, and not being able to find any similar fact on record, the writer of this article got some small models of arches executed in chalk, and subjected them to many trials, in hopes of collecting some general laws of the internal workings of arches which finally produce their downfal. He had the pleasure of observing the above mentioned circumstances take place very regularly and uniformly, when he overloaded the models at A. The arch always broke at some place B considerably beyond another point F, where the first chipping had been observed. This is a method of trial that deserves the attention both of the speculatist and the practitioner.

If these reflections are any thing like a just account of the procedure of nature in the failure of an arch, it is evident that the ingenious mathematical theory of equilibrated arches is of little value to the engineer. We ventured to say as much already, and we rested a good deal on the authority of Sir Christopher Wren. He was a good mathematician, and delighted in the application of this science to the arts. He was a celebrated architect; and his reports on the various works committed to his charge, show that he was in the continual habit of making this application. Several specimens remain of his own methods of applying them. The roof of the theatre of Oxford, the roof of the cupola of St Paul's, and in particular the mould on which he turned the inner dome of that cathedral, are proofs of his having studied this theory most attentively. He flourished at the very time that it occupied the attention of the greatest mechanicians of Europe; but there is nothing to be found among his papers which shows that he had paid much regard to it. On the contrary, when he has occasion to deliver his opinion for the instruction of others, and to explain to the Dean and Chapter of Westminster his operations in repairing that collegiate church, this great architect considers an arch just as a sensible and sagacious mason would do, and very much in the way that we have just now been treating it: (See *Account of the Family of Wren*, p. 356, &c.) Supported therefore by such authority, we would recommend this way of considering an arch to the study of the mathematician; and we would desire the experienced mason to think of the most efficacious methods for resisting this tendency of arches to rise in the flanks. Unfortunately there seems to be no precise principle to point out the place where this tendency is most remarkable.

We are therefore highly pleased with the ingenious contrivance of Mr Mylne, the architect of Blackfriars Bridge in London, by which he determines this point with precision, by making it impossible for the overloaded arch to spring in any other place. Having thus confined

confined the failure to a particular ſpot, he with equal art oppoſes a reſiſtance which he believes to be ſufficient; and the preſent condition of that noble bridge, which does not in any place ſhow the ſmalleſt change of ſhape, proves that he was not miſtaken. Looking on this work as the firſt, or at leaſt the ſecond, ſpecimen of maſonic ingenuity that is to be ſeen in the world, we imagine that our readers will be pleaſed with a particular account of its moſt remarkable circumſtances.

31
Conſtruction of Blackfriars Bridge.
Plate III.

The ſpan *k a* (fig. 16.) of the middle arch is 100 feet, and its height OV is 40, and the thickneſs KV of the crown is ſix feet ſeven inches. Its form is nearly elliptical; the part AVZ being an arch of a circle whoſe centre is C, and radius 56 feet, and the two lateral portions A *k* B and Z *a* E being arches deſcribed with a radius of 35 feet nearly. The thickneſs of the pier at *a b* is 19 feet. The thickneſs of the arch increaſes from the crown V to Y, where it is eight or nine feet. All the arch-ſtones have their joints directed to the centres of their curvature. The joints are all joggled, having a cubic foot of hard ſtone let half way into each. By this contrivance the joints cannot ſlide, nor can any weight laid on the crown ever break the arch in that part, if the piers do not yield; for a ſtraight line from the middle of KV to the middle of the joint YI is contained within the ſolid maſonry, and does not even come near the inner joints of the arch-ſtones. Therefore the whole reſiſts like one ſtone, and can be broken only by cruſhing it. The joint at Z is very nearly perpendicular to a line YF drawn to the outer edge of the foundation of the pier. By this it was intended to take off all tendency of the preſſure on the joint *d* Z to overſet the pier; for if we ſuppoſe, according to the theory of equilibration, that this preſſure is neceſſarily exerted perpendicularly to the joint, its direction paſſes through the fulcrum at F, round which it is thought that the pier muſt turn in the act of overſetting. This precaution was adopted in order to make the arch quite independent of the adjoining arches; ſo that although any of them ſhould fall, this arch ſhould run no riſk.

Still farther to ſecure the independence of the arch, the following conſtruction was practiſed to unite it into one maſs, which ſhould riſe altogether. All below the line *a b* is built of large blocks of Portland ſtone, dove-tailed with ſound oak. Four places in each courſe are interrupted by equal blocks of a hard ſtone called *Kentiſh rag*, ſunk half way in each courſe. Theſe act as joggles, breaking the courſes, and preventing them from ſliding laterally.

The portion *a* Y of the arch is joggled like the upper part. The interior part is filled up with large blocks of Kentiſh rag, forming a kind of courſed rubble-work, the courſes tending to the centres of the arch. The under corner of each arch-ſtone projects over the one below it. By this form it takes faſt hold of the rubble-work behind it. Above this rubble there is conſtructed the inverted arch I *e* G of Portland ſtone. This arch ſhares the preſſure of the two adjoining arches, along with the arch-ſtones in Y *a* and in G *b*. Thus all tend together to compreſs and keep down the rubble-work in the heart of this part of the pier. This is a very uſeful precaution; for it often happens, that when the centres of the arches are ſtruck, before the piers are built up to their intended height, the thruſt of the arches ſqueezes the rubble-work horizontally, after the mortar has ſet, but before it has dried and acquired its utmoſt hardneſs. Its bond is broken by this motion, and it is ſqueezed up, and never acquires its former firmneſs. This is effectually prevented by the preſſure exerted by the back of the inverted arch.

Above this counter arch is another maſs of courſed rubble, and all is covered by a horizontal courſe of large blocks of Portland ſtone, butting againſt the back of the arch-ſtone ZI and its correſponding one in the adjoining arch. This courſe connects the feet of the two arches, preſerves the rubble-work from too great compreſſion, and protects it from ſoaking water. This laſt circumſtance is important; for if the water which falls on the road-way is not carried off in pipes, it ſoaks through the gravel or other rubbiſh, reſts on the mortar, and keeps it continually wet and ſoft. It cannot eſcape through the joints of good maſonry, and therefore fills up this part like a funnel.

Suppoſing the adjoining arch fallen, and all tumbled off that is not withheld by its ſituation, there will ſtill remain in the pier a maſs of about 3500 tons. The weight of the portion VY is about 2000 tons. The directions of the thruſts RY and YF are ſuch, that it would require a load of 4500 tons on VY to overturn the pier round F. This exceeds VY by 2500 tons; a weight incomparably greater than any that can ever be laid on it.

Such is the ingenious conſtruction of Mr Mylne. It evidently proceeds on the principles recommended above; principles which have occurred to his experience and ſagacious mind during the courſe of his extenſive practice. We have ſeen attempts by other engineers to withſtand the horizontal thruſts of the arch by means of counter arches inſerted in the ſame manner as here, but extending much farther over the main arch; but they did not appear to be well calculated for producing this effect. A counter arch ſpringing from any point between Y and V has no tendency to hinder that point from riſing by the ſinking of the crown; and ſuch a counter arch will not reſiſt the preciſely horizontal thruſt ſo well as the ſtraight courſe of Mr Mylne.

32
Origin of Gothic arches.

The great incorporation of architects who built the cathedrals of Europe departed entirely from the ſtyles of ancient Greece and Rome, and introduced another, in which arcades made the principal part. Not finding in every place quarries from which blocks could be raiſed in abundance of ſufficient ſize for forming the far-projecting corniches of the Greek orders, they relinquiſhed thoſe proportions, and adopted a ſtyle of ornament which required no ſuch projections: and having ſubſtituted arches for the horizontal architrave or lintel, they were now able to erect buildings of vaſt extent with ſpacious openings, and all this with very ſmall pieces of ſtone. The form which had been adopted for a Chriſtian temple occaſioned many interſections of vaultings, and multiplied the arches exceedingly. Conſtant practice gave opportunities of giving every poſſible variety of theſe interſections, and taught the art of balancing arch againſt arch in every variety of ſituation. An art ſo multifarious, and ſo much out of the road of ordinary thought, could not but become an object of fond ſtudy to the architects moſt eminent for ingenuity

nuity and invention. Becoming thus the dupes of their own ingenuity, they were fond of difplaying it even when not neceffary. At laft arches became their principal ornament, and a wall or ceiling was not thought dreffed out as it fhould be till filled full of mock arches, croffing and butting on each other in every direction. In this procefs in their ceilings they found that the projecting mouldings, which we now call the Gothic tracery, formed the chief fupports of the roofs. The plane furfaces included between thofe ribs were commonly vaulted with very fmall ftones, feldom exceeding fix or eight inches in thicknefs. This tracery therefore was not a random ornament. Every rib had a pofition and direction that was not only proper, but even neceffary. Habituated to this fcientific arrangement of the mouldings, they did not deviate from it when they ornamented a fmooth furface with mock arches; and in none of the highly ornamented *ancient* buildings will we find any falfe pofitions. This is by no means the cafe in many of the modern imitations of Gothic architecture, even by our beft architects. Ignorant of the directing principle, or not attending to it, in their ftucco work, they pleafe the unfkilled eye with pretty radiated figures; but in thefe we frequently fee fuch abutments of mouldings as would infallibly break the arches, if thefe mouldings were really performing their ancient office, and fupporting a vaulting of confiderable extent. Nay, this began even before the Gothic ftyle was finally abandoned. Several inftances are to be found in the highly enriched vaultings of New College, and Chrift Church in Oxford, in St George's Chapel at Windfor, and Henry the VII's Chapel in Weftminfter.

33 Degeneracy of that ftyle.

We call the middle ages rude and barbarous; but there was furely much knowledge in thofe who could execute fuch magnificent and difficult works. The working drafts which were neceffary for fuch varieties of oblique interfections muft have required confiderable fkill, and would at prefent occupy many very expenfive volumes of *mafons jewels* and *carpenters manuals*, and the like. All this knowledge was kept a profound fecret by the corporation, and on its breaking up we had all to learn again.

There is no appearance, however, that thofe architects had ftudied the theory of equilibrated arches. They had adopted an arch which was very ftrong, and permitted confiderable irregularities of preffure—we mean the pointed arch. The very deep mouldings with which it was ornamented, made the arch ftones very long in proportion to the fpan of the arch. But they had ftudied the mutual thruft of arches on each other with great care; and they contrived to make every invention for this purpofe become an ornament, fo that the eye *required* it as a neceffary part of the building. Thus we frequently fee fmall buildings having buttreffes at the fides. Thefe are neceffary in a large vaulted building, for withftanding the outward thruft of the vaulting; but they are ufelefs when we have a flat ceiling within. Pinnacles on the heads of the buttreffes are now confidered as ornaments; but originally they were put there to increafe the weight of the buttrefs: even the great tower, in the centre of a cathedral, which now conftitutes its great ornament, is a load almoft indifpenfably neceffary, for enabling the four principal columns to withftand the combined thruft of the aifles, of the nave, and tranfepts. In fhort, the more

34 Great fkill of the ancient Gothic architects.

closely we examine the ornaments of this architecture, the more fhall we perceive that they are effential parts, or derived from them by imitation: and the more we confider the whole ftyle of it, the more clearly do we fee that it is all deduced from the relifh for arcades, indulged in the extreme, and pufhed to the limit of poffibility of execution.

35 Dome or cupola

THERE is another fpecies of arch which muft not be overlooked, namely, the DOME or CUPOLA, with all its varieties, which include even the pyramidal fteeple or fpire.

It is evident that the erection of a dome is alfo a fcientific art, proceeding on the principles of equilibration, and that thefe principles admit and require the fame or fimilar modifications, in confequence of the cohefion and friction of the materials. At firft fight, too, a dome appears a more difficult piece of work than a plain arch; but when we obferve potters kilns and glafshoufe domes and cones of vaft extent, erected by ordinary bricklayers, and with materials vaftly inferior in fize to what can be employed in common arches of equal extent, we muft conclude that the circumftance of curvature in the horizontal direction, or the abutment of a circular bafe, gives fome affiftance to the artift. Of this we have complete demonftration in the cafe of the cone. We know that a vaulting in the form of a pent roof could not be executed to any confiderable extent, and would be extremely hazardous, even in the fmalleft dimenfions; while a cone of the greateft magnitude can be raifed with very fmall ftones, provided only that we prevent the bottom from flying out, by a hoop, or any fimilar contrivance. And when we think a little of the matter, we fee plainly, that if the horizontal fection be perfectly round, and the joints be all directed to the axis, they all equally endeavour to flide inwards, while no reafon can be offered why any individual ftone fhould prevail. They are all wedges, and operate only as wedges. When we confider any fingle courfe, therefore, we fee that it cannot fall in, even though it may be part of a curve which could not ftand as a common arch; nay, we fee that a dome may be conftructed having the convexity of the curve, by the revolution of which it is formed, turned towards the axis, fo that the outline is concave. We fhall afterwards find that this is a ftronger dome by far than if the convexity were outwards, as in a common arch. We fee alfo that a cone may be loaded on the top with the greateft weight, without the fmalleft danger of forcing it down, fo long as the bottom courfe is firmly kept from burfting outwards. The ftone lanthern on the top of St Paul's cathedral in London weighs feveral hundred tons, and is carried by a brick cone of eighteen inches thick, with perfect fafety, as long as the bottom courfe is prevented from burfting outwards. The reafon is evident: The preffure on the top is propagated along the cone in the direction of the flant fide; and, fo far from having any tendency to break it in any part, it tends rather to prevent its being broken by any irregular preffure from foreign caufes.

36 Of eafier conftruction than a plain arch.

For the fame reafons the octagonal pyramids, which form the fpires of Gothic architecture, are abundantly firm, although very thin. The fides of the fpire of Salifbury cathedral are not eight inches thick after the octagon is fully formed. It is proper, however, to direct

37 Proper conftruction of octagonal pyramids.

Arch.

rect the joints to the axis of the pyramid, and to make the coursing joints perpendicular to the slant side, because the projecting mouldings which run along the angles are the abutments on which the whole pannel depends. A considerable art is necessary for supporting those pannels or sides of the octagon which spring from the angles of the square tower. This is done by beginning a very narrow pointed arch on the square tower at a great distance below the top; so that the legs of the arch being very long, a straight line may be drawn from the top of the keystone of the arch through the whole archstones of the legs. By this disposition the thrusts arising from the weight of these four pannels are made to meet on the massive masonry in the middle of the sides of the tower, at a great distance below the springing of the spire. This part, being loaded with the great mass of perpendicular wall, is fully able to withstand the horizontal thrust from the legs of those arches. In many spires these thrusts are still farther resisted by iron bars which cross the tower, and are hooked into pieces of brass firmly bedded in the masonry of the sides.

38 Examples of such construction.

There is much nice balancing of this kind to be observed in the highly ornamented open spires; such as those of Brussels, Mechlin, Antwerp, &c. We have not many of this sort in Britain. In those of great magnitude, the judicious eye will discover that parts, which a common spectator would consider as mere ornaments, are necessary for completing the balance of the whole. Tall pinnacles, nay, even pillars carrying entablatures and pinnacles, are to be seen standing on the middle of the slender leg of an arch. On examination, we find that this is necessary, to prevent the arch from springing upwards in that place by the pressure at the crown. The steeple of the cathedral of Mechlin was the most elaborate piece of architecture in this taste in the world, and was really a wonder; but it was not calculated to withstand a bombardment, which destroyed it in 1578.

Such frequent examples of irregular and whimsical buildings of this kind, show that great liberties may be taken with the principle of equilibration without risk, if we take care to secure the base from being thrust outwards. This may always be done by hoops, which can be concealed in the masonry; whereas, in common arches, these ties would be visible, and would offend the eye.

It is now time to attend to the principle of equilibrium, as it operates in a simple circular dome, and to determine the thickness of the vaulting when the curve is given, or the curve when the thickness is given.

Plate II.

Therefore, let B *b* A (fig. 17.) be the curve which produces the dome by revolving round the vertical axis AD.

39 Stability of a dome depends on principles

We shall suppose this curve to be drawn through the middle of all the arch-stones, and that the coursing or horizontal joints are every where perpendicular to the curve. We shall suppose (as is always the case) that the thickness KL, HI, &c. of the arch-stones is very small in comparison with the dimensions of the arch. If we consider any portion HA *b* of the dome, it is plain that it presses on the course, of which HL is an arch-stone, in a direction *b* C perpendicular to the joint HI, or in the direction of the next superior element β *b* of the curve. As we proceed downwards, course after course, we see plainly that this direction must change, because the weight of each course is superadded to that of the portion above it, to complete the pressure on the course below. Through B draw the vertical line BCG, meeting β *b*, produced in C. We may take *b c* to press the pressure of all that is above it, propagated in this direction to the joint KL. We may also suppose the weight of the course HL united in *b*, and acting on the vertical. Let it be represented by *b* F. If we form the parallelogram *b* FGC, the diagonal *b* G will represent the direction and intensity of the whole pressure on the joint KL. Thus it appears that this pressure is continually changing its direction, and that the line, which will always coincide with it, must be a curve concave downward. If this be precisely the curve of the dome, it will be an equilibrated vaulting; but so far from being the strongest form, it is the weakest, and it is the limit to an infinity of others, which are all stronger than it. This will appear evident, if we suppose that *b* G does not coincide with the curve A *b* B, but passes without it. As we suppose the arch-stones to be exceedingly thin from inside to outside, it is plain that this dome cannot stand, and that the weight of the upper part will press it down, and spring the vaulting outwards at the joint KL. But let us suppose, on the other hand, that *b* G falls within the curvilineal element *b* B. This evidently tends to push the arch-stone inward, towards the axis, and would cause it to slide in, since the joints are supposed perfectly smooth and slipping. But since this takes place equally in every stone of this course, they must all abut on each other in the vertical joints, squeezing them firmly together. Therefore, resolving the thrust *b* G into two, one of which is perpendicular to the joint KL, and the other parallel to it, we see that this last thrust is withstood by the vertical joints all around, and there remains only the thrust in the direction of the curve. Such a dome must therefore be firmer than an equilibrated dome, and cannot be so easily broken by overloading the upper part. When the curve is concave upwards, as in the lower part of the figure, the line *b* C always falls below *b* B, and the point C below B. When the curve is concave downwards, as in the upper part of the figure, '*b* C' passes above, or without *b* B. The curvature may be so abrupt, that even *b'* G' shall pass without '*b* B, and the point G' is above B'. It is also evident that the force which thus binds the stones of a horizontal course together, by pushing them towards the axis, will be greater in flat domes than in those that are more convex; that it will be still greater in a cone; and greater still in a curve whose convexity is turned inwards: for in this last case the line *b* G will deviate most remarkably from the curve. Such a dome will stand (having polished joints) if the curve springs from the base with any elevation, however small; nay, since the friction of two pieces of stone is not less than half of their mutual pressure, such a dome will stand, although the tangent to the curve at the bottom should be horizontal, provided that the horizontal thrust be double the weight of the dome, which may easily be the case if it do not rise high.

40 Different from that of a common arch

Thus we see that the stability of a dome depends on very different principles from that of a common arch, and is in general much greater. It differs also in another very important circumstance, viz. that it may be open in the middle: for the uppermost course, by tending

ing equally in every part to ſlide in toward the axis, preſſes all together in the vertical joints, and acts on the next courſe like the key ſtone of a common arch. Therefore an arch of equilibration, which is the weakeſt of all, may be open in the middle, and carry at top another building, ſuch as a lanthern, if its weight do not exceed that of the circular ſegment of the dome that is omitted. A greater load than this would indeed break the dome, by cauſing it to ſpring up in ſome of the lower courſes; but this load may be increaſed if the curve is flatter than the curve of equilibration: and any load whatever, which will not cruſh the ſtones to powder, may be ſet on a truncate cone, or on a dome formed by a curve that is convex toward the axis; provided always that the foundation be effectually prevented from flying out, either by a hoop, or by a ſufficient maſs of ſolid pier on which it is ſet. We have mentioned the many failures which happened to the dome of St Sophia in Conſtantinople. We imagine that the thruſt of the great dome, bending the eaſtern arch outward as ſoon as the pier began to yield, deſtroyed the half dome which was leaning on it, and thus, almoſt in an inſtant, took away the eaſtern abutment. We think that this might have been prevented without any change in the injudicious plan, if the dome had been hooped with iron, as was practiſed by Michael Angelo in the vaſtly more ponderous dome of St Peter's at Rome, and by Sir Chriſtopher Wren in the cone and the inner dome of St Paul's at London.

41 Excellency of the dome of St Paul's.

The weight of the latter conſiderably exceeds 3000 tons, and they occaſion a horizontal thruſt which is nearly half this quantity, the elevation of the cone being about 60°. This being diſtributed round the circumference, occaſions a ſtrain on the hoop $= \frac{7}{2 \times 22}$ of the thruſt, or nearly 238 tons. A ſquare inch of the worſt iron, if well forged, will carry 25 tons with perfect ſafety; therefore a hoop of 7 inches broad and $1\frac{1}{4}$ inches thick will completely ſecure this circle from burſting outwards. It is, however, much more completely ſecured; for beſides a hoop at the baſe of very nearly theſe dimenſions, there are hoops in different courſes of the cone which bind it into one maſs, and cauſe it to preſs on the piers in a direction exactly vertical. The only thruſts which the piers ſuſtain are thoſe from the arches of the body of the church and the tranſepts. Theſe are moſt judiciouſly directed to the entering angles of the building, and are there reſiſted with inſuperable force by the whole lengths of the walls, and by four ſolid maſſes of maſonry in the corners. Whoever conſiders with attention and judgment the plan of this cathedral, will ſee that the thruſts of theſe arches, and of the dome, are incomparably better balanced than in St Peter's church at Rome. But to return from this ſort of digreſſion.

42 Theory of the curves proper for domes.

We have ſeen that if bG, the thruſt compounded of the thruſt bC, exerted by all the courſes above HILK, and if the force bF, or the weight of that courſe, be everywhere coincident with bB, the element of the curve, we ſhall have an equilibrated dome; if it falls within it, we have a dome which will bear a greater load; and if it falls without it, the dome will break at the joint. We muſt endeavour to get analytical expreſſions of theſe conditions. Therefore draw the ordinates $b\delta b''$, BDB″, CdC″. Let the tangents at b and b' meet the axis in M, and make MO, MP, each equal to bc, and complete the parallelogram MONP, and draw OQ perpendicular to the axis, and produce bF, cutting the ordinates in E and e. It is plain that MN is to MO as the weight of the arch HAh to the thruſt bc which it exerts on the joint KL (this thruſt being propagated through the courſe HILK); and that MQ, or its equal be, or δd, may repreſent the weight of the half AH.

Let AD be called x, and DB be called y. Then $be = \dot{x}$, and eC $= \dot{y}$ (becauſe bc is in the direction of the element βb). It is alſo plain, that if we make $\dot{y}$ conſtant, BC is the ſecond fluxion of x, or BC $= \ddot{x}$, and be and BE may be conſidered as equal, and taken indiſcriminately for $\dot{x}$. We have alſo bC $= \sqrt{\dot{x}^2 + \dot{y}^2}$. Let d be the depth or thickneſs HI of the arch-ſtones. Then $d\sqrt{\dot{x}^2 + \dot{y}^2}$ will repreſent the trapezium HL: and ſince the circumference of each courſe increaſes in the proportion of the radius y, $dy\sqrt{\dot{x}^2 + \dot{y}^2}$ will expreſs the whole courſe. If $\int$ be taken to repreſent the ſum or aggregate of the quantities annexed to it, the formula will be analogous to the fluent of a fluxion, and $\int dy\sqrt{\dot{x}^2 + \dot{y}^2}$ will repreſent the whole maſs, and alſo the weight of the vaulting down to the joint HI. Therefore we have this proportion $\int dy\sqrt{\dot{x}^2 + \dot{y}^2} : dy\sqrt{\dot{x}^2 + \dot{y}^2} = be : b\text{F}, = be : \text{CG}, = \delta d : \text{CG}, = \dot{x} : \text{CG}$. Therefore CG $= \frac{dy\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}}$.

If the curvature of the dome be preciſely ſuch as puts it in equilibrium, but without any mutual preſſure in the vertical joints, this value of OG muſt be equal to CB, or to $\ddot{x}$, the point G coinciding with B. This condition will be expreſſed by the equation $\frac{dy\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} = \ddot{x}$, or, more conveniently, by $\frac{dy\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} = \frac{\ddot{x}}{\dot{x}}$.

But this form gives only a tottering equilibrium, independent of the friction of the joints and the coheſion of the cement. An equilibrium, accompanied by ſome firm ſtability, produced by the mutual preſſure of the vertical joints, may be expreſſed by the formula $\frac{dy\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} > \frac{\ddot{x}}{\dot{x}}$, or by $\frac{dy\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} = \frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$, where t is ſome variable poſitive quantity, which increaſes when x increaſes. This laſt equation will alſo expreſs the equilibrated dome, if t be a conſtant quantity, becauſe in this caſe $\frac{\dot{t}}{t}$ is $= o$.

Since a firm ſtability requires that $\frac{dy\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}}$ ſhall be greater than $\ddot{x}$, and CG muſt be greater than CB: Hence we learn, that figures of too great curvature, whoſe ſides deſcend too rapidly, are improper. Alſo,

ſince

since stability requires that we have $\frac{dy\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\ddot{x}}$ greater than $\int dy\sqrt{\dot{x}^2+\dot{y}^2}$, we learn that the upper part of the dome must not be made very heavy. This, by diminishing the proportion of b F to b C, diminishes the angle $c\,b$ G, and may set the point G above B, which will infallibly spring the dome in that place. We see here also, that the algebraic analysis expresses that peculiarity of dome-vaulting, that the weight of the upper part may even be suppressed.

The fluent of the equation $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}} = \frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$ is most easily found. It is $\mathrm{L}\int dy\sqrt{\dot{x}^2+\dot{y}^2} = \mathrm{L}\,\dot{x} + \mathrm{L}\,t$, where L is the hyperbolic logarithm of the quantity annexed to it. If we consider $\dot{y}$ as constant, and correct the fluent so as to make it nothing at the vertex, it may be expressed thus, $\mathrm{L}\int dy\sqrt{\dot{x}^2+\dot{y}^2} - \mathrm{L}a = \mathrm{L}\dot{x} - \mathrm{L}\dot{y} + \mathrm{L}\,t$. This gives us $\mathrm{L}\frac{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}{a} = \mathrm{L}\frac{\dot{x}}{\dot{y}}\,t$, and therefore $\frac{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}{a} = t\frac{\dot{x}}{\dot{y}}$.

This last equation will easily give us the depth of vaulting, or thickness d of the arch, when the curve is given. For its fluxion is $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{a} = \frac{\dot{t}\dot{x} + t\ddot{x}}{\dot{y}}$, and $d = \frac{a\dot{t}\dot{x} + at\ddot{x}}{y\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$, which is all expressed in known quantities; for we may put in place of t any power or function of x or of y, and thus convert the expression into another, which will still be applicable to all sorts of curves.

Instead of the second member $\frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$, we might employ $\frac{p\ddot{x}}{\dot{x}}$, where p is some number greater than unity. This will evidently give a dome having stability; because the original formula $\frac{dy\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}$ will then be greater than $\ddot{x}$. This will give $d = \frac{pa\dot{x}^{p-1}\ddot{x}}{y\dot{y}^p\sqrt{\dot{x}^2+\dot{y}^2}}$. Each of these forms has its advantages when applied to particular cases. Each of them also gives $d = \frac{a\ddot{x}}{\dot{y}\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$ when the curvature is such as is in precise equilibrium. And, lastly, if d be constant, that is, if the vaulting be of uniform thickness, we obtain the form of the curve, because then the relation of $\ddot{x}$ to $\dot{x}$ and to $\dot{y}$ is given.

The chief use of this analysis is to discover what curves are improper for domes, or what portions of given curves may be employed with safety. Domes are generally built for ornament; and we see that there is great room for indulging our fancy in the choice. All curves which are concave outwards will give domes of great firmness: They are also beautiful. The Gothic dome, whose outline is an undulated curve, may be made abundantly firm, especially if the upper part be convex and the lower concave outwards.

The chief difficulty in the case of this analysis arises from the necessity of expressing the weight of the incumbent part, or $\int dy\sqrt{\dot{x}^2+\dot{y}^2}$. This requires the measurement of the conoidal surface, which, in most cases, can be had only by approximation by means of infinite serieses. We cannot expect that the generality of practical builders are familiar with this branch of mathematics, and therefore will not engage in it here; but content ourselves with giving such instances as can be understood by such as have that moderate mathematical knowledge which every man should possess who takes the name of engineer.

The surface of any circular portion of a sphere is very easily had, being equal to the circle described with a radius equal to the chord of half the arch. This radius is evidently $= \sqrt{\dot{x}^2+\dot{y}^2}$.

In order to discover what portion of a hemisphere may be employed (for it is evident that we cannot employ the whole) when the thickness of the vaulting is uniform, we may recur to the equation or formula $\frac{dy\dot{x}\sqrt{\dot{x}^2-\dot{y}^2}}{\ddot{x}} = \int dy\sqrt{\dot{x}^2+\dot{y}^2}$. Let a be the radius of the hemisphere. We have $\dot{x} = \frac{ay\dot{y}}{\sqrt{a^2-y^2}}$, and $\ddot{x} = \frac{a^2\dot{y}^2}{\overline{a^2-y^2}|^{\frac{3}{2}}}$. Substituting these values in the formula, we obtain the equation $y^2\sqrt{a^2-y^2} = \int\frac{a^2y\dot{y}}{\sqrt{a^2-y^2}}$. We easily obtain the fluent of the second member $= a^3 - a^2\sqrt{a^2-y^2}$, and $y = a\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$. Therefore if the radius of the sphere be one, the half breadth of the dome must not exceed $\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$, or 0,786, and the height will be 618. The arch from the vertex is about 51° 49′. Much more of the hemisphere cannot stand, even though aided by the cement, and by the friction of the coursing joints. This last circumstance, by giving connection to the upper parts, causes the whole to press more vertically on the course below, and thus diminishes the outward thrust; but it at the same time diminishes the mutual abutment of the vertical joints, which is a great cause of firmness in the vaulting. A Gothic dome, of which the upper part is a portion of a sphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very strong, and not ungraceful.

43 Dome of St Peter's at Rome.

But the public taste has long rejected this form, and seems rather to select more elevated domes than this portion of a sphere; because a dome, when seen from a small distance, always appears flatter than it really is. The dome of St Peter's is nearly an ellipsoid externally, of which the longer axis is perpendicular to the horizon. It is very ingeniously constructed. It springs from the base perpendicularly, and is very thick in this part. After rising about 50 feet, the vaulting separates into two thin vaultings, which gradually separate from each other. These two shells are connected together by thin partitions, which are very artificially dovetailed in both, and thus form a covering which is extremely stiff, while it is very light. Its great stiffness was necessary for enabling the crown of the dome to carry the elegant stone lanthern

lanthern with ſafety. It is a wonderful performance, and has not its equal in the world; but it is an enormous load in compariſon with the dome of St Paul's, and this even independent of the difference of ſize. If they were of equal dimenſions, it would be at leaſt five times as heavy, and is not ſo firm by its gravity; but as it is connected in every part by iron bars (lodged in the ſolid maſonry, and well ſecured from the weather by having lead melted all round them), it bids fair to laſt for ages, if the foundations do not fail.

Plate II. If a circle be deſcribed round a centre placed anywhere in the tranſverſe axis AC (fig. 18. N° 1.) of an ellipſe, ſo as to touch the ellipſe in the extremities B, *b*, of an ordinate, it will touch it internally, and the circular arch B *a b* will be wholly within the elliptical arch BA *b*. Therefore, if an elliptical and a ſpherical vaulting ſpring from the ſame baſe, at the ſame angle with the horizon, the ſpherical vaulting will be within the elliptical, will be flatter and lighter, and therefore the weight of the next courſe below will bear a greater proportion to the thruſt in the direction of the curve; therefore the ſpherical vaulting will have more ſtability. On the contrary, and for ſimilar reaſons, an oblate elliptical vaulting is preferable to a ſpherical vaulting ſpringing with the ſame inclination to the horizon. (Fig. 18. N° 2).

44 Dimenſions of the beſt form of a dome.

Perſuaded, that what has been ſaid on the ſubject convinces the reader that a vaulting perfectly equilibrated throughout is by no means the beſt form, provided that the baſe is ſecured from ſeparating, we think it unneceſſary to give the inveſtigation of that form, which has a conſiderable intricacy; and ſhall content ourſelves with merely giving its dimenſions. The thickneſs is ſuppoſed uniform. The numbers in the firſt column of the table expreſs the portion of the axis counted from the vertex, and thoſe of the ſecond column are the lengths of the ordinates.

AD	DB	AD	DB	AD	DB
0,4	100	610,4	1080	2990	1560
3,4	200	744	1140	3442	1600
11,4	300	904	1200	3972	1640
26,6	400	1100	1260	4432	1670
52,4	500	1336	1320	4952	1700
91,4	600	1522	1360	5336	1720
146,8	700	1738	1400	5756	1740
223,4	800	1984	1440	6214	1760
326,6	900	2270	1480	6714	1780
465,4	1000	2602	1520	7260	1800

The curve delineated in fig. 19. is formed according to theſe dimenſions, and appears deſtitute of gracefulneſs; becauſe its curvature changes abruptly at a little diſtance from the vertex, ſo that it has ſome appearance of being made up of different curves pieced together. But if the middle be occupied by a lanthern of equal, or of ſmaller weight, this defect will ceaſe, and the whole will be elegant, nearly reſembling the exterior dome of St Paul's in London.

45 Advantages of dome-vaulting.

It is not a ſmall advantage of dome-vaulting that it is lighter than any that can cover the ſame area. If, moreover, it be ſpherical, it will admit conſiderable varieties of figure, by combining different ſpheres. Thus, a dome may begin from its baſe as a portion of a large hemiſphere, and may be broken off at any horizontal courſe, and then a ſimilar or a greater portion of a ſmaller ſphere may ſpring from this courſe as a baſe. It alſo bears being interſected by cylindrical vaultings in every direction, and the interſections are exact circles, and always have a pleaſing effect. It alſo ſprings moſt gracefully from the heads of ſmall piers, or from the corners of rooms of any polygonal ſhape; and the arches formed by its interſections with the walls are always circular and graceful, forming very handſome ſpandrels in every poſition. For theſe reaſons Sir Chriſtopher Wren employed it in all his vaultings, and he has exhibited many beautiful varieties in the tranſepts and the aiſles of St Paul's, which are highly worthy of the obſervation of architects. Nothing can be more graceful than the vaultings at the ends of the north and ſouth tranſepts, eſpecially as finiſhed off in the fine inſide view publiſhed by Gwynn and Wale.

46 Effects of cement and friction in dome vaulting.

We conclude this article with obſerving, that the connection of the parts, ariſing from cement and from friction, has a great effect on dome-vaulting. In the ſame way as in common arches and cylindrical vaulting, it enables an overload on one place to break the dome in a diſtant place. But the reſiſtance to this effect is much greater in dome-vaulting, becauſe it operates all round the overloaded part. Hence it happens that domes are much leſs ſhattered by partial violence, ſuch as the falling of a bomb or the like. Large holes may be broken in them without much affecting the reſt; but, on the other hand, it greatly diminiſhes the ſtrength which ſhould be derived from the mutual preſſure in the vertical joints. Friction prevents the ſliding in of the arch ſtones which produces this mutual preſſure in the vertical joints, except in the very higheſt courſes, and even there it greatly diminiſhes it. Theſe cauſes make a great change in the form which gives the greateſt ſtrength; and as their laws of action are but very imperfectly underſtood as yet, it is perhaps impoſſible, in the preſent ſtate of our knowledge, to determine this form with tolerable preciſion. We ſee plainly, however, that it allows a greater deviation from the beſt form than the other kind of vaulting, and domes may be made to riſe perpendicular to the horizon at the baſe, although of no great thickneſs; a thing which muſt not be attempted in a plane arch. The immenſe addition of ſtrength which may be derived from hooping, largely compenſates for all defects; and there is hardly any bounds to the extent to which a very thin dome-vaulting may be carried, when it is hooped or framed in the direction of the horizontal courſes. The roof of the Halle du Bled at Paris is but a foot thick, and its diameter is more than 200, yet it appears to have abundant ſtrength. It is, on the whole, a noble ſpecimen of architecture.

47 The iron bridge at Sunderland deſcribed.

We muſt not conclude this article without taking notice of that magnificent and elegant arch which has been erected in caſt iron at Weremouth, near Sunderland, in the county of Durham. The inventor and architect is Rowland Burdon, Eſq; one of the repreſentatives of that county in the preſent Parliament.

This arch is a ſegment of a circle whoſe diameter is about 444 feet. The ſpan or cord of the arch is 236 feet, and its verſed ſine or ſpring is 34 feet. It ſprings at the elevation of 60 feet from the ſurface of the river

Arch. ver at low water, so that vessels of 200 or perhaps 300 tons burden may pass under it in the middle of the stream, and even 50 feet on each side of it.

The sweep of the arch consists of a series of frames of cast iron, which butt on each other, in the same manner as the voussoirs of a stone arch. One of these frames or blocks (as we shall call them in future) is represented in fig. 1. as seen in front. It is cast in one piece; and consists of three pieces or arms BC, BC, BC, the middle one of which is two feet long, the upper being somewhat more, and the lower somewhat less, because their extremities are bounded by the radius drawn from the centre of the arch. These arms are four inches square, and are connected by other pieces KL, of such length that the whole length of the block is five feet in the direction of the radius. Each arm has a flat groove on each side, which is expressed by the darker shading, three inches broad and three-fourths of an inch deep. A section of this block, through the middle of KL, is represented by the light-shaded part BBB, in which the grooves are more distinctly perceived. These grooves are intended for receiving flat bars of malleable iron, which are employed for connecting the different blocks with each other. Fig. 2 represents two blocks united in this manner. For this purpose each arm has two square bolt-holes. The ends of the arms being nicely trimmed off, so that the three ends butt equally close on the ends of the next block; and the bars of hammered iron being also nicely fitted to their grooves, so as to fill them completely, and have their bolt holes exactly corresponding to those in the blocks, they are put together in such a manner that the joints or meetings of the malleable bars may fall on the middle between the bolt-holes in the arms. Flat headed bolts of wrought iron are then put through, and keys or forelocks are driven thro' the bolt-tails, and thus all is firmly wedged together, binding each arm between two bars of wrought iron. These bars are of such length as to connect several blocks.

Plate IV.

In this manner a series of about 125 blocks are joined together, so as to form the precise curve that is intended. This series may be called a rib, and it stands in a vertical plane. The arch consists of six of these ribs, distant from each other five feet. These ribs are connected together so as to form an arch of 32 feet in breadth, in the following manner:

Fig. 3. represents one of the bridles or cross pieces which connect the different ribs, as it appears when viewed from below. It is a hollow pipe of cast iron, four inches in diameter, and has at each end two projecting shoulders, pierced with a bolt-hole near their extremities, so that the distance between the bolt-holes in the shoulders of one end is equal to the distance between the holes in the arms of the blocks, or the holes in the wrought iron bars. In the middle of the upper and of the under side of each end may be observed a square prominence, more lightly shaded than the rest. These projections also advance a little beyond the flat of the shoulders, forming between them a shallow notch, about an inch deep, which receives the iron of the arms, where they butt on each other, and thus gives an additional firmness to the joint. The manner in which the arms are thus grasped by these notches in the bridles is more distinctly seen in fig. 2. at the letter H in the middle of the upper rail.

The rib having been all trimmed and put together, so as to form the exact curve, the bolts are all taken out, and the horizontal bridles are then set on in their places, and the bolts are again put in and made fast by the forelocks. The bolts now pass through the shoulders of the bridles, through the wrought iron bars, and through the cast iron arm that is between them, and the forelocks bind all fast together. The manner in which this connection is completed is distinctly seen in fig. 2. which shews in perspective a double block in front, and a single block behind it. The butting joints of the two front blocks are at the letters E, E, E; the holes in the shoulders of the horizontal cross pieces are at H.

48 Its construction simple and judicious.

This construction is beautifully simple and very judicious. A vast addition of strength and of stiffness is procured by lodging the wrought iron bars in grooves formed in the cast iron rails; and for this purpose it is of great importance to make the wrought iron bars fill the grooves completely, and even to be so tight as to require the force of the forelocks to draw them home to the bottom of the grooves. There can be no doubt but that this arch is able to withstand an enormous pressure, as long as the abutments from which it springs do not yield. Of this there is hardly any risk, because they are masses of rock, faced with about four or five yards (in some places only) of solid block masonry. The mutual thrusts of the frames are all in the direction of the rails, so that no part bears any transverse strain. We can hardly conceive any force that can overcome the strength of those arms by pressure or crushing them. The manner in which the frames are connected into one rib, effectually secures the butting joints from slipping; and the accuracy with which the whole can be executed, secures us against any warping or deviation of a rib from the vertical plane.

But when we consider the prodigious span of this arch, and reflect that it is only five feet thick, it should seem that the most perfect equilibration is indispensably necessary. It is but like a film, and must be so supple that an overload on any part must have a great tendency to bend it, and to cause it to rise in a distant part; and this effect is increased by the very firmness with which the whole sticks together. The overloaded part acts on a distant part, tending to break it with all the energy of a long lever. This can be prevented only by means of the stiffness of the distant part. It is very true, the arch cannot break in the extrados except by tearing asunder the wrought iron bars which connect the blocks along the upper rail, and each of these requires more than a hundred tons to tear it asunder; yet an overload of five tons on any rib at its middle will produce this strain at twenty feet from the sides, supposing the sides held firm in their position. It were desirable therefore that something were done to stiffen the arch at the sides, by the manner of filling up the spandrels, or space between the arch and the road-way. This is filled up in a manner that is extremely light and pleasing to the eye, namely, by large cast iron circles, which touch the extrados of the arch and touch the road-way. The road-way rests on them as on so many hoops, while they rest on the back of the arch, and also touch each other laterally. We cannot think that this contributes to the strength of the arch; for these hoops will be easily compressed at the points of contact,

49 Though in one particular capable, perhaps, of improvement.

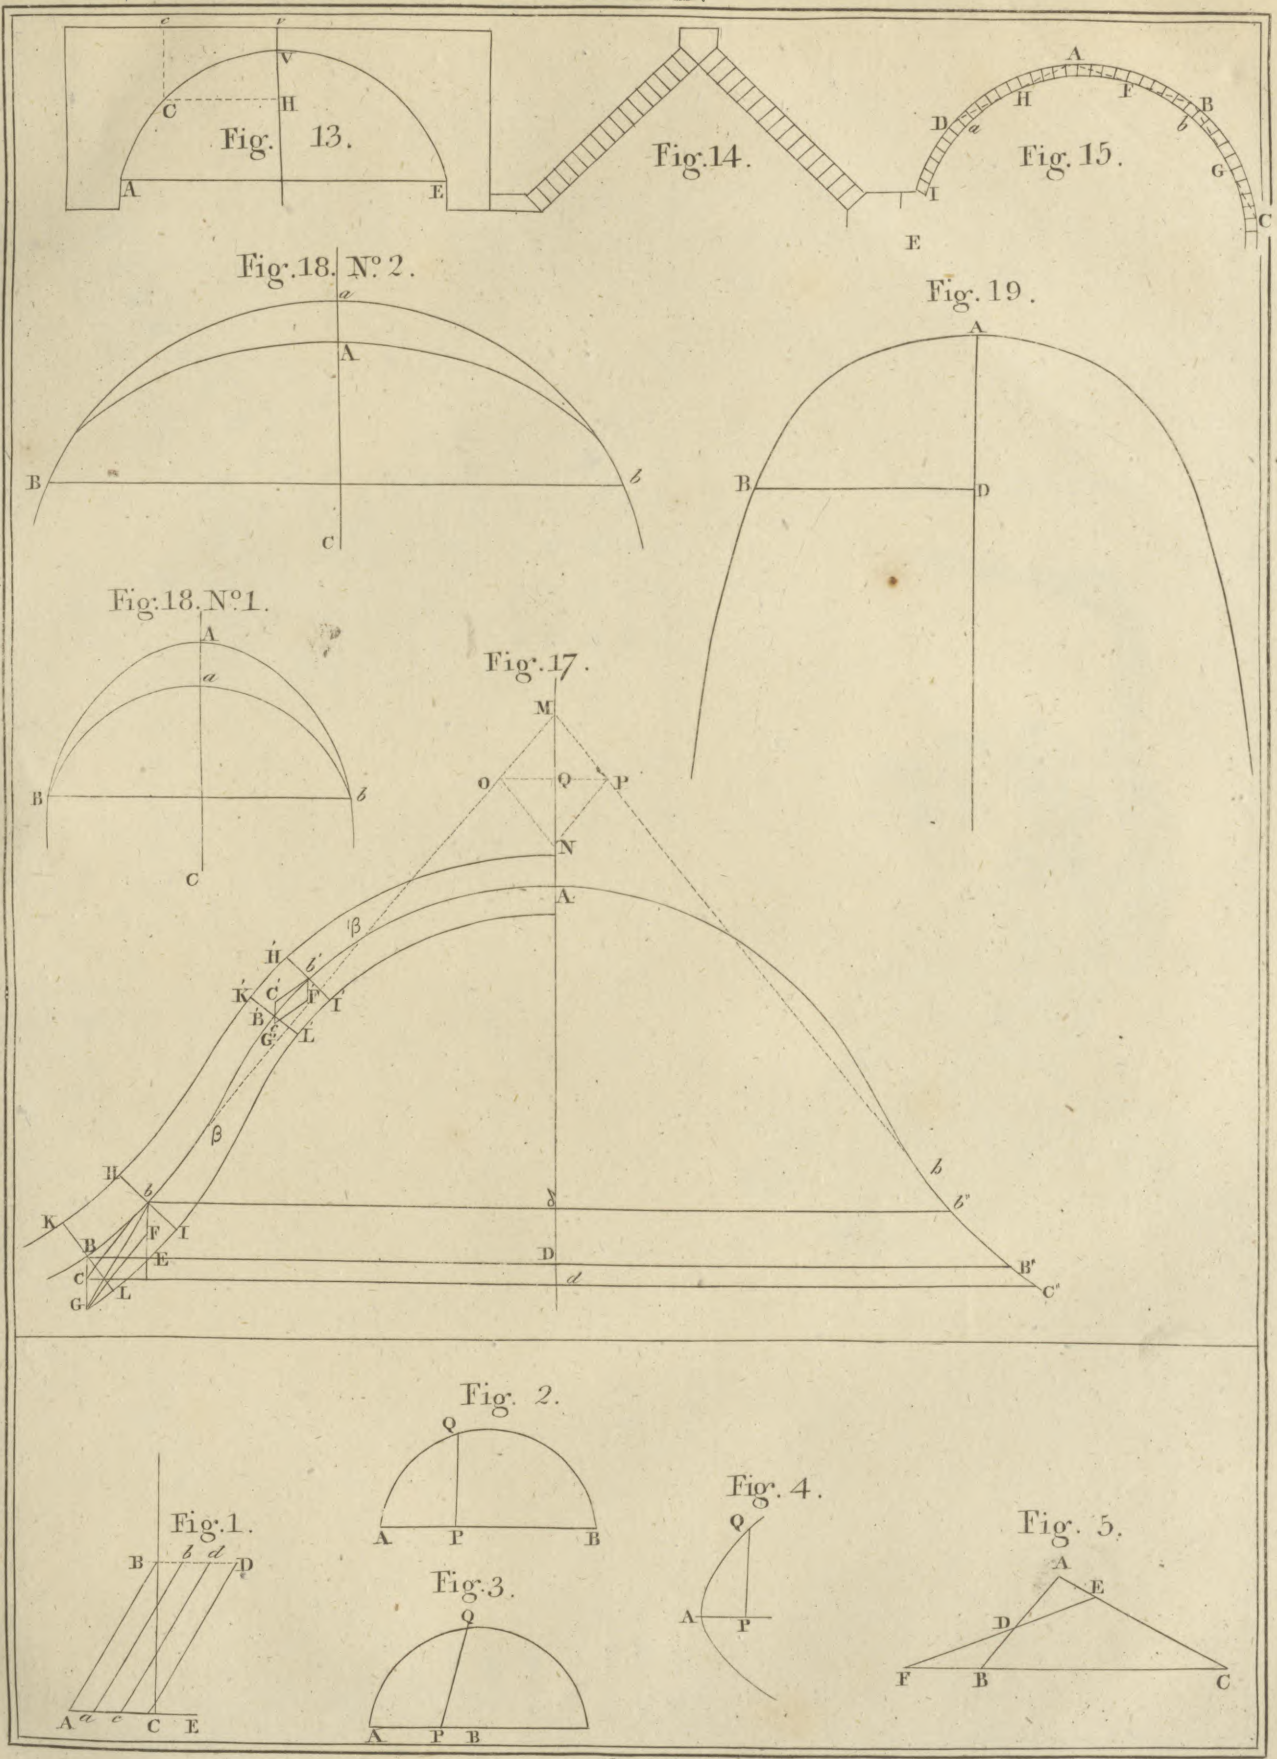
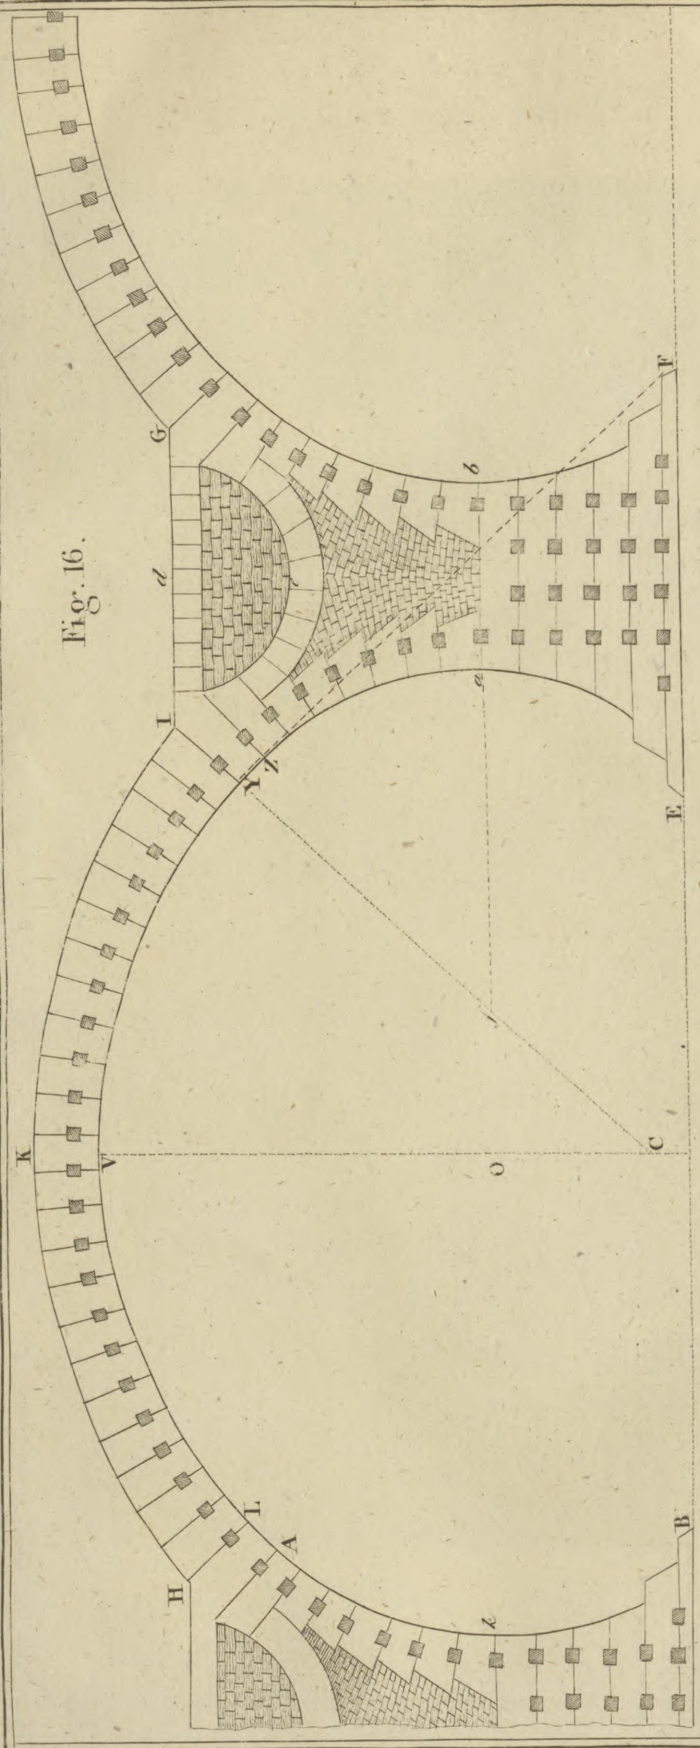
PLATE II.

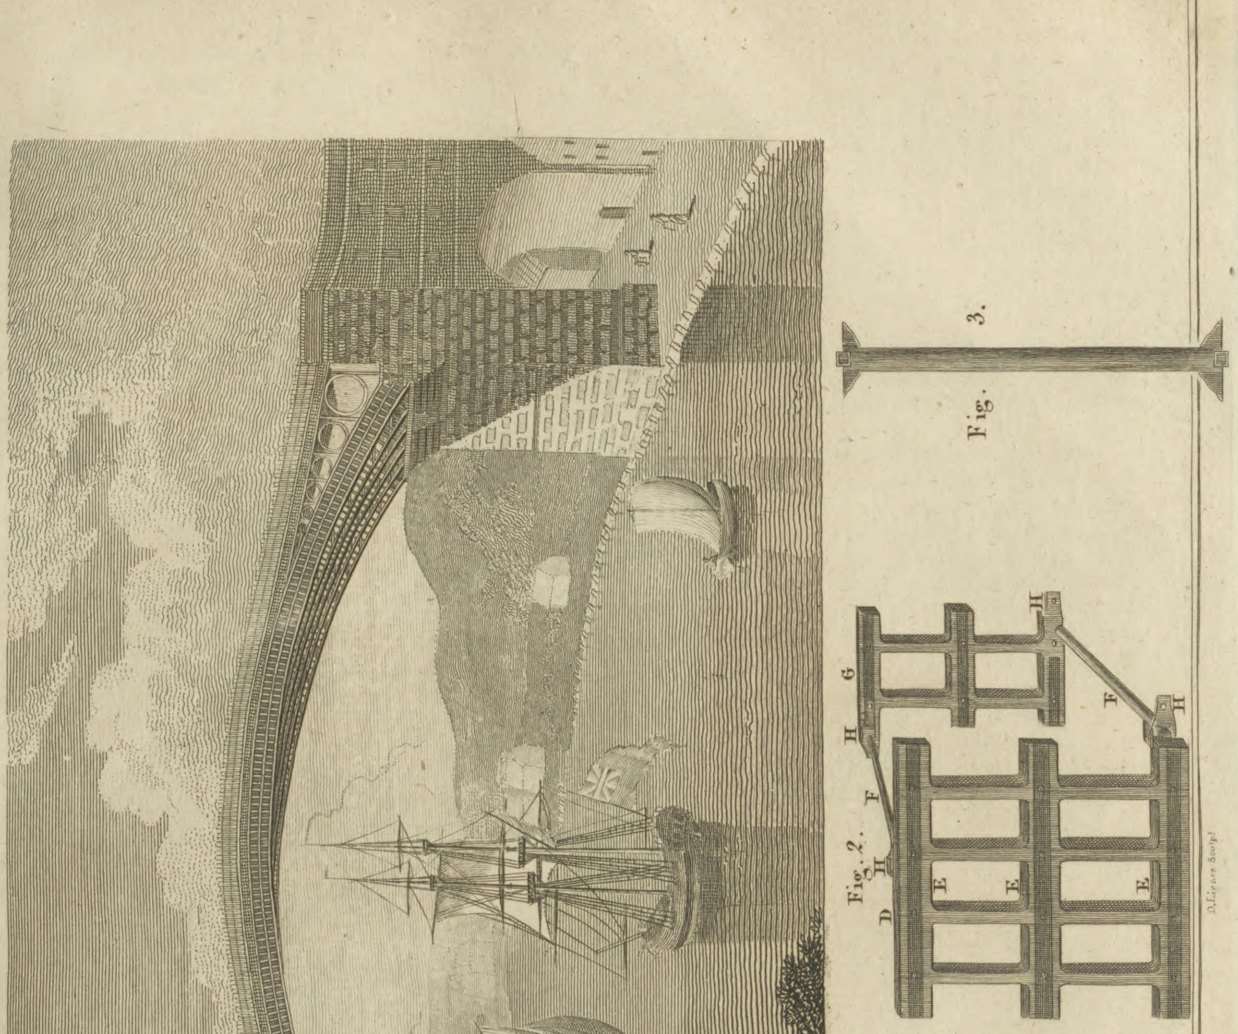


D. Lizars sculp.



MALE ANHINGA

IRON BRIDGE



contact, and, changing their shape, will oppose very little resistance. We think that this part of the arch might have been greatly stiffened and strengthened, by connecting it with the road-way by trussed frames, in the same way that a judicious carpenter would have framed a roof. If a strong cast iron pillar had been made to rest on the arch at about 20 feet from the impost, and been placed in the direction of a radius, the top of this pillar might have been connected by a diagonal bar of wrought iron with the impost of the arch, and with the crown of the arch by another string or bar of the same materials. These two ties would cause the radial pillar to press strongly on the back of the arch, and they must be torn asunder before it could bend in that place in the smallest degree. Supposing them of the same dimensions as the bars in the arms, their position would give them near ten times the force for resisting the strain produced by an overload on the crown.

This beautiful arch contains only 260 tons of iron, of which about 55 are wrought iron. The superstructure is of wood, planked over a-top. This floor is covered with a coating of chalk and tar, on which is laid the materials for the carriage road, consisting of marle, limestone, and gravel, with foot-ways of flag-stones at the sides. The weight of the whole did not exceed a thousand tons; whereas the lightest stone arch which could have been erected would have weighed fifteen thousand. It was turned on a very light but stiff scaffolding, most judiciously constructed for the preservation of its form, and for allowing an uninterrupted passage for the numerous ships and small craft which frequent the busy harbour of Sunderland. The mode of framing the arch was so simple and easy, that it was put up in ten days! without an accident; and when all was finished, and the scaffolding removed, the arch did not sensibly change its form. The whole work was executed in three years, and cost about L. 26,000.

ARCHITECTURE is an art of so much importance, and capable of so many embellishments, as to have employed the attention and talents of men of science in almost every age, and in every country. It is generally thought to have been carried to the utmost perfection among the Greeks and Romans; and it has been the aim of the most eminent architects of modern times to imitate with fidelity the buildings of those accomplished nations. There is, however, another species of architecture, which was introduced into Europe in the middle ages, and is of such a nature as to strike every unprejudiced observer with admiration and astonishment. The architecture to which we allude has been called, perhaps with little propriety,

Gothic ARCHITECTURE. It is that which is to be viewed in all our ancient cathedrals, and in other large buildings which have been erected from the middle of the 12th to the beginning of the 16th century. That such edifices have been constructed on principles of science, has been shewn elsewhere (see ROOF, *Encycl.* and ARCH, in this *Suppl.*): but a question still presents itself to the inquisitive mind, "How came such structures to be thought of by a people whom we are accustomed to call ignorant and barbarous?" This question has occupied the attention of many ingenious men, who have attributed the Gothic style of building, some to necessity, and others to an imitation of the works of nature. That, where materials are bad, larger edifices can be erected in the Gothic than in the Grecian style, has been made sufficiently evident in the articles to which we have referred; and that necessity is the parent of invention, is an adage which has been too long received to be now called in question. But whence came the peculiarities of the Gothic ornaments in building, the pointed arch, and the double row of clustered pillars composed of slender shafts, which, reaching from the ground almost to the roof of the building, are there spread out in all directions, forming the ribs or *groins* of a vaulted roof?

The most satisfactory solution of this question which we have seen, is in a memoir published in the fourth volume of the Transactions of the Royal Society of Edinburgh, by Sir JAMES HALL, Bart. with whose permission the following abstract is laid before our readers.

"Although the connection between beauty and utility be still involved in such obscurity, that we are unable to decide concerning the universality of that connection, of one thing we are certain, that, in a work intended to answer some useful purpose, whatever visibly counteracts that purpose always occasions deformity. Hence it is, that, even where ornament is principally intended, the ostensibly useful object of the work, if it have any such, must be provided for, in the first place, in preference to every other consideration.

"But in most useful works, some parts occur, the shape of which is quite indifferent with respect to the proposed utility, and which, therefore, the artist is at liberty to execute as he pleases: a liberty which has opened a wide field to the taste and invention of ingenious men of every age and country, who have turned their attention to the composition of ornaments; and whose exertions have been more or less influenced by the state of civilization in which they lived. It would seem, however, if we may judge by those various efforts, that little has been effected by mere human ingenuity; since we see that recourse has been had, almost universally, to nature, the great and legitimate source of beauty; and that ornament has been attained by the imitation of objects, to which she has given a determinate and characteristic form.

"Where the materials employed are themselves possessed of variety and elegance, the attainment of this object requires little or no alteration of their natural forms. Thus cups are made of shells, of cocoa-nuts, or of ostrich eggs; the character and beauty of which depend upon the natural form of the materials: and in the case of the bottles used by the Roman Catholic pilgrams, an example occurs of an utensil, in which the natural form has undergone little or no variation, since it consists of the hard outward skin of a gourd, of the same shape in which it grew upon the plant (A). This last class of forms has been introduced, by imitation, into works composed

(A) "Even in this case, however, the natural form undergoes a certain degree of modification, by the device employed to produce the neck of the bottle. The fruit, while small and tender, is surrounded with a string, which remaining during its growth, prevents the part, thus bound, from swelling with the rest."

Architecture.

composed of shapeless materials. Thus we have silver cups in the form of those made of shells, and fruit-dishes of stoneware in the form of baskets.

"As stone is not naturally possessed of any peculiar shape, and as the useful object proposed, by structures formed of it, may be accomplished in various ways, very great latitude is left to the invention of the artist. We see, accordingly, that in every country where much refinement has been introduced, great pains have been bestowed in ornamenting stone buildings with figures representing various natural objects; whilst the building itself has been executed in imitation of a structure, composed of materials which naturally possess a determinate and characteristic form. Such was the method followed by the architects of ancient Greece, who constructed temples, and other public edifices, in imitation of a rustic fabric, composed of square beams, supported upon round posts or stems of trees, and who derived the numerous ornaments of that beautiful style from circumstances which would naturally take place in such a structure.

"A faint and distant resemblance, however, of the original, has generally been found to answer all the end proposed by the imitation; a resemblance, which may sometimes be traced in the general distribution of the edifice, sometimes in its minute parts, and not unfrequently in both.

"But the forms of nature thus introduced have been greatly modified by those of masonry. For though stone is by nature shapeless, yet, in the course of practice, many peculiar forms have been long established, and currently employed, in working it; such as straight lines, plain surfaces, square angles, and various mouldings used to soften the effect of abrupt terminations: all of which, originating in motives of mechanical convenience, and of simple ornament, had, in very early times, been appropriated to masonry, and considered as essential in every finished work of stone; so that, when the imitation of nature was introduced, these masonic forms still maintained their ground, and, being blended with the forms of nature, the two classes reciprocally modified each other.

"This combination of art with nature, of which we see the most perfect example in the Corinthian capital, produces what are called architectonic forms, in which the variety of nature, being subjected to the regularity of art, the work acquires that peculiar character which, in a natural object, we consider as offensive, under the name of *formality*; but which, in architecture, we admire as a beauty, under the name of *symmetry*: thus, we reprobate the formality of an avenue, and praise the symmetry of a colonnade.

"Such is the nature of architectonic imitation; a device which probably originated in accident, but to which architecture is indebted for its highest attainments."

As the stone edifices of ancient Greece were constructed in imitation of a wooden fabric, composed of square beams laid at right angles on round posts or stems of trees, Sir James conceives that the Gothic fabrics with pointed arches have been executed in imitation of a rustic dwelling, constructed in the following manner: Suppose a set of round posts driven firmly into the ground in two opposite rows, the interval between the neighbouring posts in the same row being equal to that between the rows, and each post being raised above the ground to a height equal to three of those intervals; then a set of long and flexible rods of willow being applied to each post, let them be thrust into the ground at its base, and bound to it by two tyings, one near the ground, and another at two-thirds of its height; the rods being left loose from this last point upwards, and free to be moved in any direction. Let three rods be connected with each outside corner post, and five with each of the others, and let their position be such as to cover the inside of the post, so that when seen from between the rows the lower part of each post shall be concealed from the view, and present the appearance of a bundle of rods (fig. 1.)

Plate V.

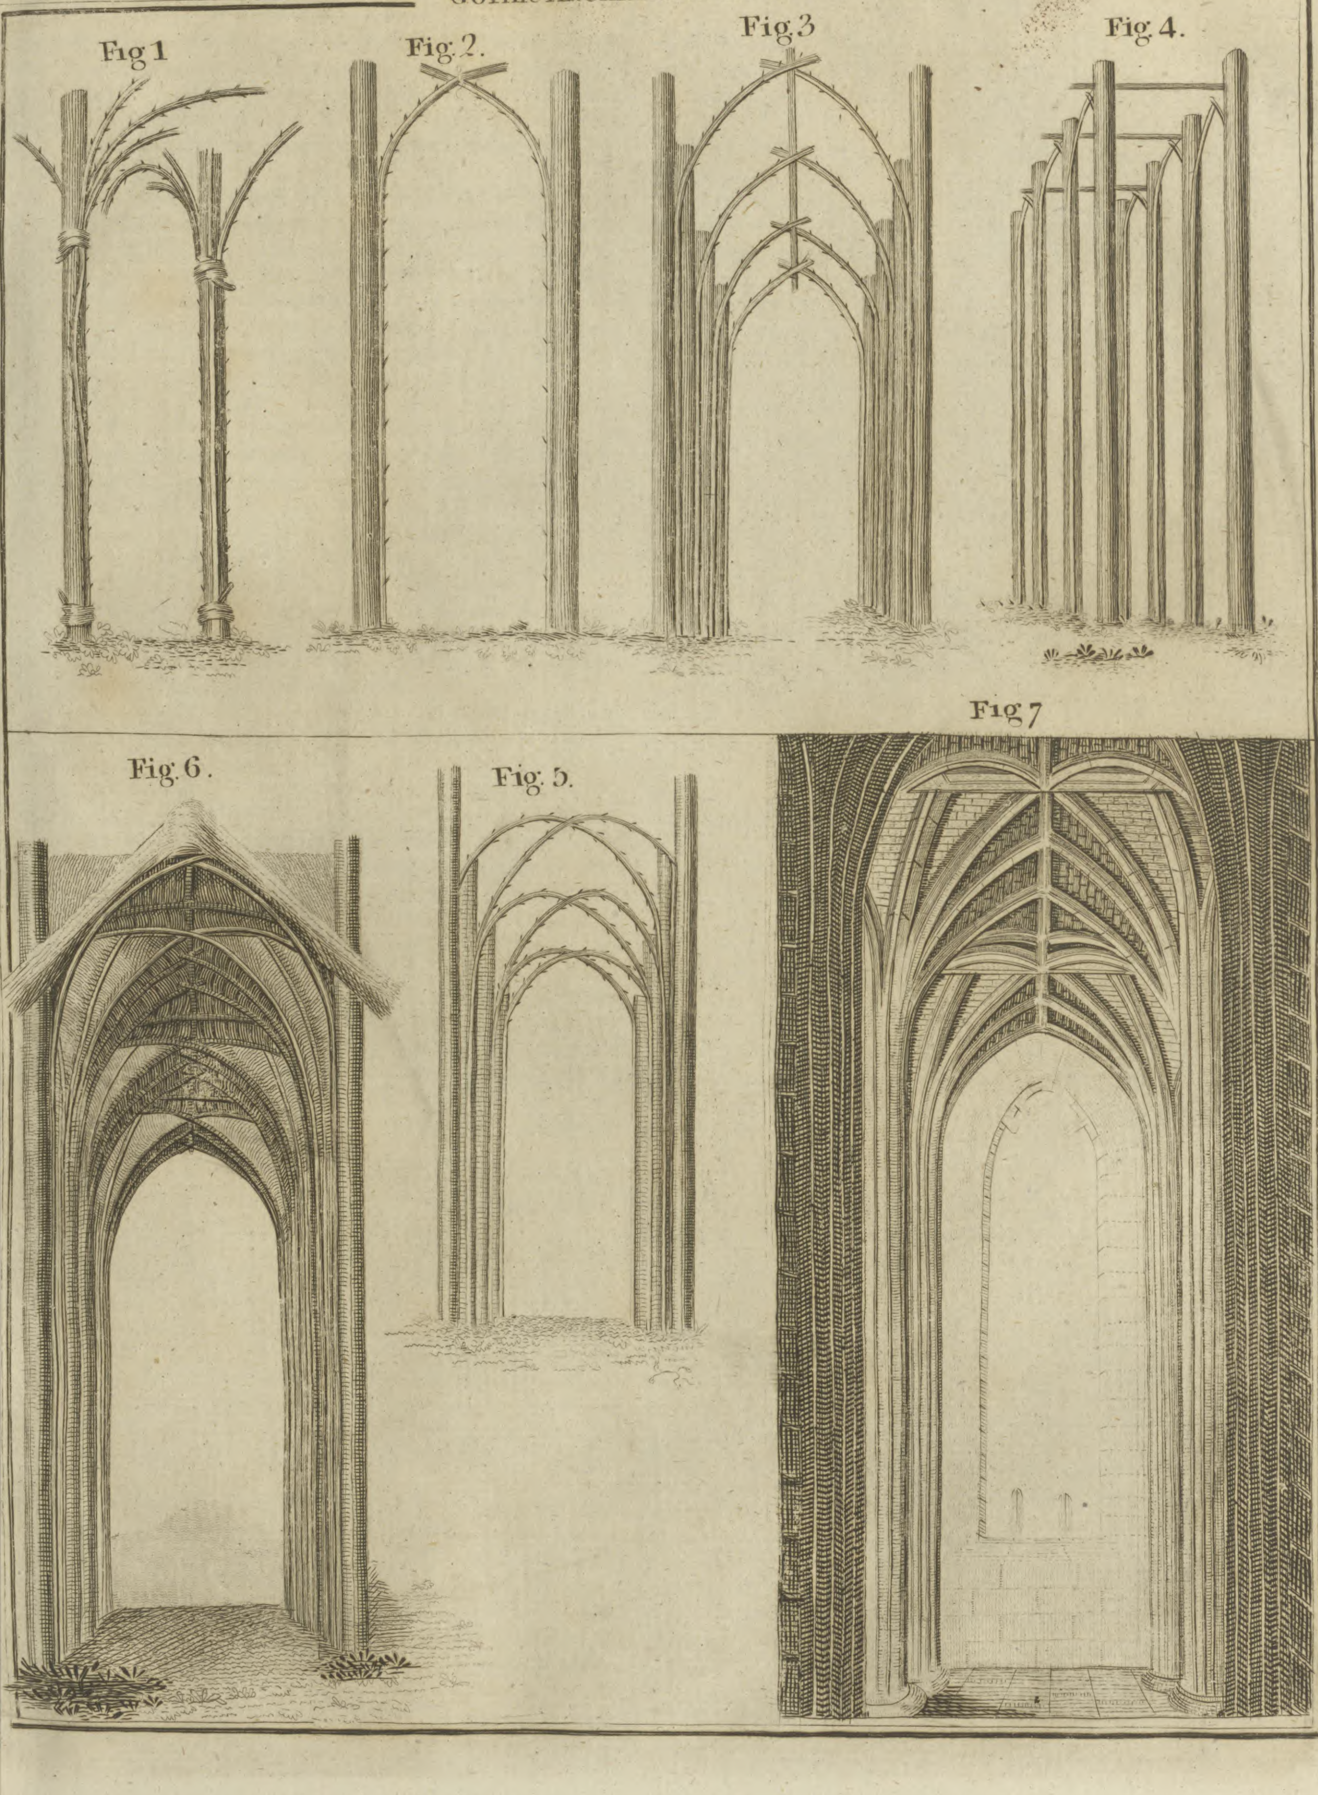
Things being thus disposed, the skeleton of a thatched roof may be formed by means of the loose ends of the rods. A rod from one of the posts being so bent as to meet a similar one from the post immediately opposite to it, in the middle of the space between them, let the two rods be made to cross each other, and let them be bound together at their crossing (fig. 2.), and we shall have the exact form of the Gothic arch The same being done with each pair of opposite posts, and a set of pointed arches being formed, let them be connected together by means of a straight pole laid upon the forks of the crossing rods, and bound to each of them, as in fig. 3: then let a loose rod be brought from each of any two contiguous posts in the same row, so as to form a pointed arch, similar to that just described, and nearly of the same height. This being done with every two contiguous posts (fig. 4), and a new set of pointed arches being thus produced, standing opposite to each other in pairs, let each pair be bound by a horizontal pole lying on the opposite forks, and crossing the longitudinal pole described above.

"Two of the rods of each corner post, and three of those of each of the others, being thus disposed of, we have one of each corner post and two of each middle post still to employ, which is done as follows: A pair of these unoccupied rods being brought from any two posts which stand diagonally to each other, and made to meet in the middle, not as in the first case crossing in an angle, but side by side, forming a semicircle, and joined together after the manner of a hoop; and the same being done with every pair of diagonal posts (fig. 5.), the whole rods will have been employed.

"In this manner a frame would be constructed fit to support thatch or other covering; and such a one has probably been often used. It would seem, however, that, for the sake of strength, the number of rods has been increased in each cluster, by the introduction, between every two of them, of an additional rod, which rising with them to the roof, still continues its middle position, as they spread asunder, and meets the horizontal pole at an intermediate point. This is shown in fig. 6. which is drawn with its covering of thatch; and, from the imitation of a dwelling so constructed, we may easily trace the three leading characteristics of Gothic architecture, the pointed arch, the clustered column, and the branching roof, as exhibited in fig. 7."

Upon the same principles Sir James Hall, with much ingenuity, accounts for the peculiar forms of the Gothic door, the Gothic window, and the pointed spire: but it is not our intention to supersede the necessity of having recourse to his memoir, but to excite the desire of

GOTHIC ARCHITECTURE PLATE V.



of our readers to peruſe as well that paper as a larger work which he promiſes on the ſame ſubject, and in which we doubt not but they will find both entertainment and inſtruction. We ſhall conclude this article, therefore, with an experimental proof of the juſtneſs of his hypotheſis.

In the greater part of our late attempts at Gothic architecture, it is allowed by every man of taſte that we have failed. The failure is to be accounted for by the buildings having been conſtructed upon no conſiſtent principle, applicable to every part of them, but upon a ſervile copying of ancient edifices, of which the ſtructure was little underſtood by the copiers. Sir James Hall, however, by applying his theory to practice, has conſtructed a building in this ſtyle, which has far ſurpaſſed, he ſays, his own expectation, and has certainly gained the approbation of every man of taſte and ſcience by whom we have had occaſion to hear it mentioned. "A ſet of poſts of aſh, about three inches in diameter, were placed in two rows, four feet aſunder, and at the interval of four feet in the rows; then a number of ſlender and tapering willow rods, ten feet in length, were applied to the poſts, and, in the manner which we have deſcribed, formed into a frame, which being covered with thatch, produced a very ſubſtantial roof, under which a perſon can walk with eaſe.

"This little ſtructure exhibits, in miniature, all the characteriſtic features of the Gothic ſtyle. It is in the form of a croſs, with a nave, a choir, and a north and ſouth tranſept. The thatch, being ſo diſpoſed on the frame as not to hide the rods of which it is compoſed, they repreſent accurately the pointed and ſemicircular arches, and all the other peculiarities of a groined roof."

ARCTUS, a name given by the Greeks to two conſtellations of the northern hemiſphere, by the Latins called *Ursa Major* and *Minor*, and by us the *Greater* and *Leſſer Bear*.

Binary ARITHMETIC. See *Binary Arithmetic*, Encycl.

Duodecimal Arithmetic, is that which proceeds from 12 to 12, or by a continual ſubdiviſion according to 12. This is greatly uſed by moſt artificers in calculating the quantity of their work; as bricklayers, carpenters, painters, tilers, &c.

Harmonical Arithmetic, is ſo much of the doctrine of numbers as relates to the making the compariſons, reductions, &c. of muſical intervals.

Arithmetic of infinites, is the method of ſumming up a ſeries of numbers, of which the number of terms is infinite. This method was firſt invented by Dr Wallis, as appears by his treatiſe on that ſubject; where he ſhows its uſes in geometry, in finding the areas of ſuperficies, the contents of ſolids, &c. But the method of fluxions, which is a kind of univerſal arithmetic of infinities, performs all theſe more eaſily, as well as a great many other things, which the former will not reach.

Logiſtical Arithmetic, a name ſometimes employed for the arithmetic of ſexageſimal fractions, uſed in aſtronomical computations. Shakerly, in his *Tabulæ Britannicæ*, has a table of logarithms adapted to ſexageſimal fractions, which he calls *logiſtical logarithms:* and the expeditious arithmetic, obtained by means of them, he calls *logiſtical arithmetic*. The term *logiſtical arithmetic*, however, or *logiſtics*, has been uſed by Vieta and others for the rules of computations in algebra.

Political Arithmetic. See *Political Arithmetic*, Encycl.

Sexageſimal Arithmetic. See Arithmetic *(Hiſt.)* Encycl.

Tetractic Arithmetic, is that in which only the four characters 0, 1, 2, 3, are uſed. A treatiſe of this kind of arithmetic is extant by Erhard or Echard Weigel. But both this and binary arithmetic are little better than curioſities, eſpecially with regard to practice; as all numbers are much more compendiouſly and conveniently expreſſed by the common decuple ſcale.

Univerſal Arithmetic, is the name given by Newton to the ſcience of algebra; of which he left at Cambridge an excellenc treatiſe, being the text-book drawn up for the uſe of his lectures, while he was profeſſor of mathematics in that univerſity.

ARITHMETICAL complement, of a logarithm, is what the logarithm wants of 10·00000, &c. and the eaſieſt way to find it is, beginning at the left hand, to ſubtract every figure from 9, and the laſt from 10.

ARTEDI (John), was born in the year 1705, in the province of Angermania, in Sweden. From nature he inherited an ardent paſſion for all branches of natural hiſtory, but he excelled moſt in that branch of it which is termed *itchthyology*. In 1724 he went to ſtudy at the univerſity of Upſal, where ſome years afterwards he gained the friendſhip of the immortal Linnæus, who narrates the principal events of his life in the following animated terms.

"In 1728 (ſays Linnæus) I came from Lund to Upſal. I wiſhed to devote myſelf to medicine. I inquired who, at that univerſity, excelled moſt for his knowledge: every one named Artedi. I was impatient to ſee him. I found him pale, and in great diſtreſs for the loſs of his father, with his thin hair neglected. He reſembled the portrait of Ray the naturaliſt. His judgment was ripe, his thoughts profound, his manners ſimple, his virtues antique. The converſation turned upon ſtones, plants, animals. I was enchanted with his obſervations, equally ingenious and new; for at the very firſt he was not afraid to communicate them to me with the utmoſt frankneſs. I deſired his friendſhip, he aſked mine. From that moment we formed a friendſhip; which we cultivated with the greateſt ardour for ſeven months at Upſal. I was his beſt friend, and I never had any who was more dear to me. How ſweet was that intimacy! With what pleaſure did we ſee it increaſe from day to day! The difference, even of our characters, was uſeful to us. His mind was more ſevere, more attentive; he obſerved more ſlowly, and with greater care. A noble emulation animated us. As I deſpaired of ever becoming as well inſtructed in chemiſtry as he, I abandoned it; he alſo ceaſed to ſtudy botany with the ſame ardour, to which I had devoted myſelf in a particular manner. We continued thus to ſtudy different branches of ſcience; and when one of us excelled the other, he acknowledged him for his maſter. We diſputed the palm in ichthyology; but ſoon I was forced to yield, and I abandoned that part of natural hiſtory to him, as well as the amphibia. I ſucceeded better than he in the knowledge of birds and inſects, Artedi. infects, and he no longer tried to excel in these branches. We marched together as equals in lithology, and the history of quadrupeds. When one of us made an observation, he communicated it to the other: scarce a day passed in which one did not learn from the other some new and interesting particular. Thus emulation excited our industry, and mutual assistance aided our efforts. In spite of the distance of our lodgings, we saw each other every day. At last I set out for Lapland; he went to London. He bequeathed to me his manuscripts and his books.

"In 1735 I went to Leyden, where I found Artedi. I recounted my adventures; he communicated his to me. He was not rich, and therefore was unable to be at the expence of taking his degrees in physic. I recommended him to Seba, who engaged him to publish his work on fishes. Artedi went to join him at Amsterdam.

"Scarcely had I finished my *Fundamenta Botanica*. I communicated it to him; he let me see his *Philosophia Ichthyologica*. He proposed to finish as quickly as possible the work of Seba, and to put the last hand to it. He showed me all his manuscripts which I had not seen. I was pressed in point of time, and began to be impatient as being detained so long. Alas! if I had known this was the last time I should see him, how should I have prolonged it!

"Some days after, as he returned to sup with Seba, the night being dark, he fell into the canal. Nobody perceived it, and he perished. Thus died, by water, this great ichthyologist, who had ever delighted in that element."

Of the works of this eminent naturalist there have been two editions, of which the former was published by Linnæus in 1738, and the latter by Dr Walbaum of Lubeck, in the years 1788, 1789, and 1792. This edition, which is by much the most valuable, is in three volumes 4to; of which the first contains the history of the science of ichthyology, commencing several years before the Christian era, and coming down to the present times. The second presents to the reader the *Philosophia Ichthyologica* of Artedi, improved by Walbaum, who was benefited by the writings of Monro, Camper, Kætseuter, and others. Here also are added tables containing the system of fishes by Ray, Dale, Schaeffir, Linnæus, Gowan, Scopola, Klein, and Gronovius. The third volume, which completes the collection of Artedi's works, contains the technical definitions of the science. After the generic and individual characters come the names and Latin phrases of Artedi; the synonymes of the best naturalists; the vulgar names in English, German, Swedish, Russian, Danish, Norwegian, Dutch, and Samoyed; the season and the countries where every kind is found, their varieties, their description, and observations. The modern discoveries, even to our own times, are added; so that in this part is collected the observations of Gronovius, Brunich, Penant, Forster, Klein, Bloch, Gmelin, Hasselquist, Broussonet, Leske, Buish, Linnæus, and other great examiners of nature.

ASTRONOMY

IS a science which has been cultivated from the earliest ages, and is conversant about the most sublime objects of inquiry which can employ the mind of man. It has accordingly been treated at great length in the Encyclopædia Britannica; but, in the opinion of some of the most judicious readers of that work, the compiler of the system which is there delivered has failed in his attempt to give a perspicuous and connected view of the science in its present state of improvement. This defect

1 Object of this article. it is our duty to remedy. Our object, therefore, in this supplementary article, will be to bring into one point of view the physical science which may be derived from the consideration of the celestial motions; that is, to deduce from the general laws of those motions the inferences with respect to their supposed causes, which constitute the philosophy of the astronomer.

The causes of all phenomena are not only inferred from the phenomena, but are characterised by them; and we can form no notion of their nature but what we conceive as competent to the phenomena themselves. The astronomical phenomena are assumed to be the motions of the *bodies*, which we call the *sun*, the *planets*, the *comets*, &c. The notion which we express by the word *body* in the present case, is supposed to be the same with that which we form of other objects around us, to which we give the same name; such as stones, sticks, the bodies of animals, &c. Therefore the notion which we have of the causes of the celestial motions must be the same with that which we have of the causes of motion in those more familiar bodies. All men seem to have agreed in giving the name FORCES, or MOVING FORCES, to the causes of those familiar motions. This is a figurative or metaphorical term. The true and original meaning of it is, the exertion which we are conscious of making when we ourselves put other bodies in motion. Force, when used without figure, always signifies the exertion of a living and acting thing. We are more interested in those productions of motion than in any other, and our recollections of them are more numerous. Hence it has happened that we use the same term to express the cause of bodily motion in general, and say that a magnet has force, that a spring has force, that a moving body has force.

2 Metaphorical use of the term *force*.

Our own force is always exerted by the intervention of our own body; and we find that the same exertion by which we move a stone, enables us to move another man; therefore we conceive his body to resemble a stone in this respect, and that it also requires the exertion of force to put it in motion. But when we reflect on our employment of force for producing motion in a body, we find ourselves puzzled how to account for the motion of our own bodies. Here we perceive no intervening exertion but that of willing to do it; yet we find that we cannot move it as we please. We also find that a greater motion requires a greater exertion. It is therefore to this exertion that the reflecting man restrains the term *force*; and he acknowledges that every other use of it is metaphorical, and that it is a resemblance

blance in the ultimate effect alone which dispoſes us to employ the term in ſuch caſes: but we find no great inconvenience in the want of another term.

We farther find, that our exertion is neceſſary, not only for producing motion where there was none before, but alſo for producing any change of motion; and accurate obſervation ſhews us, that the ſame force is required for changing a motion by any given quantity, as for producing that quantity where there was none before.

Laſtly, we are conſcious of exerting force when we reſiſt the exerted force of another; and that an exertion, perfectly ſimilar to this, will prevent ſome very familiar tendencies to motion in the bodies around us: thus an exertion is neceſſary for carrying a weight, that is, for preventing the fall of that weight.

All theſe reſemblances between the effects of our forcible exertions and the changes of motion which accompany the meeting, and ſometimes the mere vicinity of other bodies, juſtify us in the uſe of this figurative language. The reſemblance is found to be the more perfect as we obſerve it with more care, and, in ſhort, appears to be without exception. Bodies are therefore ſaid to *act* on each other, to *reſiſt* each other, to *reſiſt a change of motion*, &c.

Therefore, wherever we obſerve a change of motion, we infer the exiſtence and exertion of a changing force; and we infer the direction of that exertion from the direction of the change; and the quantity of the exertion, or intenſity of the force, from the quantity of the change.

The ſtudy of the cauſes of the celeſtial motions is therefore hardly different from the ſtudy of the motions themſelves; ſince the agency, the kind, and the degree of the moving force, are immediate inferences from the exiſtence, the kind, and the quantity of the change of motion.

3 Our notion of a moving power.

Our notion of a moving power is that of a power which produces motion, that is, a ſucceſſive change of place. Continuation of the motion produced is therefore involved in the very notion of the production of motion; therefore the continued agency of the moving power, or of any power, is not neceſſary for the continuation of the motion. Motion is conſidered as a ſtate or condition of the body; there is not any exertion of power therefore in the continuation of motion: But every change is indicative of a changing cauſe; and when the change is the ſame, in all its circumſtances, the cauſe is neceſſarily conceived to be the ſame, or equal.

The condition of a body, in reſpect of motion, can differ from that of another equal body only in its direction and in its velocity. If the directions are the ſame, the difference of conditions can only be in the difference of velocity. One body has a determination, by which it would deſcribe ten feet uniformly in a ſecond, if nothing changed this determination; the other has a determination, by which it would deſcribe twenty

4 Meaſure of moving forces.

feet in a ſecond. Each of theſe determinations are ſuppoſed to be the effects of forces acting ſimilarly in every reſpect. Therefore theſe determinations are the only meaſures of theſe two forces; that is, moving forces are conceived by us as having the proportion of the velocities which they produce in a body by acting in a manner perfectly ſimilar.

We can conceive a force acting equally or unequally. If we ſuppoſe it to act equally or uniformly, we ſuppoſe that in equal times it produces equal effects; that is, equal determinations, or equal changes of determination. We have no other notion of equality or uniformity of action. Therefore it muſt produce equal augmentations or diminutions of velocity in equal times; therefore it muſt produce an *uniformly* accelerated or retarded motion. Uniformly accelerated or retarded motion is, therefore, the mark of uniform or unvaried action.

5 Accelerated motion the mark of unvaried action;

In ſuch a motion, the changes of velocity are proportional to the times from the beginning of the action; and if the motion has begun from reſt, the whole acquired velocities are proportional to the times from the beginning of the motion. In this caſe, the ſpaces deſcribed are as the ſquares of the times from the beginning of the motion; and thus we arrive at an oſtenſible mark of the unvaried action of a moving force, viz. ſpaces increaſing in the duplicate ratio of the times: for ſpace and time are all that we can immediately obſerve in any motion that is continually varying; the velocity or determination is only an inference, on the ſuppoſition that the motion continues unchanged for ſome time, or that all action ceaſes for ſome time.

This abſtract reaſoning is perfectly agreeable to every phenomenon that we can obſerve with diſtinctneſs. Thus we cannot, or at leaſt we do not, conceive the weight of a body to vary its action during the fall. We conſider this weight as the cauſe of the fall—as the moving force—and we conceive it to act uniformly. And, in fact, a body falling freely, deſcribes ſpaces which are proportional, not to the times, but to the ſquares of the times, and the fall is a motion uniformly accelerated. In like manner, the motion of a body riſing in the air, in oppoſition to gravity, is uniformly retarded.

6 And gives a meaſure of the acquired velocity.

This kind of motion alſo gives us a certain meaſure of the acquired velocity, although there is not, in fact, any ſpace obſerved to be uniformly deſcribed during any time whatever. In this motion we know that the final determination, produced by the accumulated or continued action of the unvaried force, is ſuch that the body would deſcribe uniformly twice the ſpace which it has deſcribed with the accelerated motion.

And it is by this method that we obtain the ſimpleſt meaſure of any moving force, and can compare it with another. If we obſerve that by the action of one force (known to be uniform by the ſpaces being proportional to the ſquares of the times) ten feet have been deſcribed in a ſecond, and that by the uniform action of another force eighty feet are deſcribed in two ſeconds, we know that the laſt force is double of the firſt: for in the ſecond motion, 80 feet were deſcribed in two ſeconds, and therefore 20 feet of this were deſcribed in the firſt ſecond (becauſe the motion is uniformly accelerated; and at the end of a ſecond, the firſt body had a determination by which it would deſcribe 20 feet uniformly in a ſecond; and the ſecond body had acquired a determination by which it would have deſcribed 40 feet uniformly in the next ſecond, had not the moving force continued to act on it, and made it really deſcribe 60 feet with an accelerated motion.

Becauſe halves have the ſame proportions with the units of which they are the halves, it is plain that we may take the ſpaces, deſcribed in equal times with motions uniformly accelerated, as meaſures of the forces which have produced thoſe motions. The velocities generated are, however, the beſt meaſures.

7 Meaſure of the velocity produced by action not uniform.

When the actions of forces are not uniform, it is more difficult to learn what is the meaſure of the velocity produced by their accumulated action. But it can be determined with equal accuracy; that is, we can determine what is the velocity which *would have been produced* by the uniform action of the force during the ſame time, and therefore we obtain a meaſure of the force. Mathematicians are farther able to demonſtrate, that if forces vary their continued action in any manner whatever, the proportion of the ſpaces deſcribed by two bodies in equal times approaches nearer and nearer to the proportion of the ſpaces which they would deſcribe in thoſe times by the uniform action of the forces, as the times themſelves are ſmaller; and therefore whenever we can point out the ultimate ratio of the ſpaces deſcribed in equal times, theſe times being diminiſhed without end, we obtain the ratio of the forces.

Plate VI.

Motions may be changed, not only in quantity, by acceleration or retardation, but alſo in direction, by deflecting a body from its former direction. When a body, moving uniformly in the direction AB (fig. 1.), has its motion changed in the point B, and, inſtead of deſcribing BC uniformly in the next moment with the former velocity, deſcribes BD uniformly in that moment, it is plain that the motion BD will be the ſame, whether the body had begun to move in A, or in F, or in G, or in B, provided only that its determination to move, or its velocity, be the ſame in all thoſe points. Complete the parallelogram BCDE. It is well known, that if one force act on the body which would make it deſcribe BC, and another which would make it deſcribe BE, the body will deſcribe BD. Hence we learn, that when a body has the motion BC changed into the motion BD, it has been acted on in the point B by a force which would have cauſed a body at reſt in B to deſcribe BE. Thus we can diſcover the intenſity and direction of the tranſverſe force which produces any deflection from the former direction. In general, the force is that which would have produced in a body at reſt that motion BE, which, when compounded with the former motion BC, produces the new motion BD.

8 Intenſity and direction of deflecting forces.

Theſe two principles, viz. 1ſt, that forces are proportional to the velocities which they produce in the ſame circumſtances, and, 2d, the compoſition of motion or forces, will ſerve for all the phyſical inveſtigations in aſtronomy. All the celeſtial motions are curvilineal, and therefore are inſtances of continual deflection, and of the continual action of tranſverſe or deflecting forces. We muſt therefore endeavour to obtain a general meaſure of ſuch continual deflecting forces.

9 Meaſure of theſe forces obtained.

Let two bodies A and *a* (fig. 2.) deſcribe in the ſame time the arches AC, *a c* of two circles. They are deflected from the tangents AB, *a b*. Let us ſuppoſe that the direction of the deflecting forces is known to be that of the chords AE, *a e* of theſe circles. Let theſe be called the DEFLECTIVE CHORDS. Draw CB, *c b* parallel to AE, *a e*, and CD, *c d* parallel to AB, *a b*. Join AC, *a c*, CE, and *c e*. It is plain that the angle BAC is equal to the angle CEA in the alternate ſegment. Therefore ACD is alſo equal to it; and, becauſe the angle CAD is common to the two triangles CAD and EAC, theſe two triangles are ſimilar, and $AD : AC = AC : AE$, and $AD = \frac{AC^2}{AE}$. For ſimilar reaſons $ad = \frac{ac^2}{ae}$. But AD and *a d* are reſpectively equal to BC and *b c*. Therefore $BC = \frac{AC^2}{AE}$, and $bc = \frac{ac^2}{ae}$. Therefore $BC : bc = \frac{AC^2}{AE} : \frac{ac^2}{ae}$, or $BC : bc = AC^2 \times ae : ac^2 \times AE$. But BC and *b c* being reſpectively equal to AD and *a d*, are equal to the ſpaces through which the deflecting forces would have impelled the bodies from a ſtate of reſt in the time of deſcribing the arches AC, *a c*. Therefore, when theſe times are diminiſhed without end, the *ultimate* ratio of AD and *a d* is the ratio of the forces which deflect the bodies in the points A and *a*. But it is evident that the ultimate ratio of AC to *a c* is the ratio of the velocity in the point A to the velocity in the point *a*; becauſe theſe arches are ſuppoſed to be deſcribed in the ſame or equal times. Therefore the deflecting forces, by which bodies are made to deſcribe arches of circles, are to each other as the ſquares of the velocities directly, and as the deflective cords of thoſe circles inverſely. This ratio may be expreſſed ſymbolically thus, $F : f = \frac{V^2}{C} : \frac{v^2}{c}$; or thus, in a proportional equation, $f \doteq \frac{v^2}{c}$.

It is eaſy to ſee that in this laſt formula *f* expreſſes directly the line *b c*, or the ſpace through which the body is actually made to deviate from rectilineal motion in the time of deſcribing the arch *a c*. It is a third proportional to *a e* the deflective chord, and *a c* the arch of the circumference deſcribed in a ſmall moment of time. This is the meaſure afforded immediately by obſervation. We have obſerved the arch AC that is deſcribed, and know the direction and the length of AE from ſome circumſtances of the caſe. The formula which comes to us, when treating this queſtion by the help of fluxions, is $f = \frac{2v^2}{c}$. This is perhaps a more proper expreſſion of the phyſical fact; for it expreſſes twice the line *b c*, or the meaſure of the velocity which the deflecting force would have generated in the body by acting on it during the time of its deſcribing the arch *a c*. But it is indifferent which meaſure we take, provided we always take the ſame meaſure. The firſt mathematicians, however, have committed miſtakes by mixing them.

The planets, however, do not deſcribe circles: but all the curves which can be deſcribed by the action of finite deflecting forces are of ſuch a nature, that we can deſcribe a circle through any point, having the ſame tangent, and the ſame curvature which the planetary curve has in that point, and which therefore ultimately coaleſces with it. This being the caſe, it is plain that the planet, while paſſing through a point of the curve, and deſcribing an indefinitely ſmall arch of it, is in the ſame condition as if deſcribing the coincident arch of the equicurve circle. Hence we obtain this moſt general propoſition, that *the tranſverſe force by which a planet is made to deſcribe any curve, is directly as the ſquare of its velocity, and inverſely as the deflective chord of the equicurve circle.*

Farther: The velocity of a body in any point A (fig.

(fig. 2.) of the curve, is equal to that which the deflective force in that point would generate in the body by acting uniformly on it along AF, one-fourth part of the deflective cord AE of the equicurve circle. It is the same which the body would acquire at F, after a uniformly accelerated motion along AF.

For it is certain that there is some length AF, such that the velocity acquired at F is the same with the velocity in the point A of the curve. Draw FG parallel to the tangent, and join AG. Make the arch ACI = 2AF. Then, because the space described with a uniformly accelerated motion is one half of the space which would be uniformly described with the final velocity, the arch ACI would be uniformly described with the velocity which the body has at A in the time that AF is described with the uniformly accelerated motion; and the arch AB will be to the arch AI as the time of describing AB to that of describing AI; that is, as the time of falling through AD to that of falling through AF. But the motion along AF being uniformly accelerated, the spaces are as the squares of the times. Therefore AD is to AF as the square of the arch AC to the square of the arch AI. But AD is to AF as the square of the chord AC is to the square of the chord AG. Therefore the arch AC is to the chord AC as the arch AI is to the chord AG. But the arch and chord AC are ultimately in the ratio of equality. Therefore the chord AG is equal to the arch AI. Therefore AG is double of AF. But because the triangles FAG and GAE are similar, AF is to AG as AG to AE; and therefore AE is double of AG and quadruple of AF. Therefore the velocity at A in the curve is that which would be produced by the uniform impulse of the deflecting force along the fourth part of the deflective chord of the equicurve circle.

10 Two useful affections of curvilineal motions. These two affections or properties of curvilineal motions are of the most extensive use, and give an easier solution of most questions than we obtain by the more usual methods, and deserve to be kept in remembrance by such as engage much in the discussion of questions of this kind.

Thus the investigation of the forces which regulate the planetary motions is reduced to the task of discovering the velocity of the planet in the different points of its orbit, and the curvature in those points, and the position of the deflective chords.

11 Physical science of astronomy. The physical science of astronomy must consist in the discovery of the general laws which can be affirmed with respect to the exertion of those forces, whether with respect to their direction or the intensity of their action. If the mechanician can do more than this, and show that every motion that is observed is an immediate or remote consequence of those general laws, he will have completed the science, and explained every appearance.

12 Completed by Newton and This has accordingly been done by Sir Isaac Newton and his followers. Sir Isaac Newton has discovered the general laws which regulate the exertions of those forces which produce the planetary motions, by reasoning from general phenomena which had been observed with a certain precision before his time; and has also shown that certain considerable deviations from the generality which he supposed to be perfect were necessary consequences of the very universality of the physical law, although the phenomenon was not so general as was at first imagined. He has gone farther, and has pointed out some other minute deviations which must result from the physical law, but which the art of observation was not then sufficiently advanced to discover in the phenomena. This excited the efforts of men of science to improve the art of astronomical observation; and not only have the intimations of Newton been verified by modern observation, but other deviations have been discovered, and, in process of time, have also been shown to be consequences of the same general law of agency: And, at this present day, there is not a single anomaly of the planetary motions which has not been shown to be a modification of one general law which regulates the action; and therefore characterises the nature of that single force which actuates the whole system of the sun, and his attending planets and comets. 13 His followers.

It was a most fortunate circumstance that the constitution of the solar system was such that the deviations from the general law are not very considerable. The case might have been far otherwise, although the law, or nature of the planetary force, were the same, and the system had been equally harmonious and beautiful. Had two or three of the planets been vastly larger than they are, it would have been extremely difficult to discover any laws of their motion sufficiently general to have led to the suspicion or the discovery of the universal law of action, or the specific circumstance in the planetary force which distinguishes it from all others, and characterises its nature. But the three laws of the planetary motions discovered by Kepler were so nearly true, at least with respect to the primary planets, that the deviations could not be observed, and they were thought to be exact. It was on the supposition *that they were exact*, that Newton affirmed that they were only modifications of one law still more general, nay universal.

We shall follow in order the steps of this investigation.

Sir Isaac Newton took it for granted, that the sun and planets consisted of matter which resembled those bodies which we daily handle, at least in respect of their mobility; and that the forces which agitate them, considered merely as moving forces, but without considering or attending to their mode of operation, were to be inferred, both as to their direction and as to their intensity, from the changes of motion which were ascribed to their agency. He first endeavoured to discover the *direction* of that transverse force by which the planets are made to discover curve lines. Kepler's first law furnished him with ample means for this discovery. Kepler had discovered, that *the right line joining the sun and any planet described areas proportional to the times.* Newton demonstrated, that if a body was so carried round a fixed point situated in the plane of its motion, that the right line joining it with that point described areas proportional to the times, the force which deflected it from an uniform rectilineal motion was continually directed to that fixed point. This makes the 2d proposition of his immortal work *The Mathematical Principles of Natural Philosophy*, and it is given in the article ASTRONOMY of the Encyclopædia Britannica, § 260. 14 The steps by which they proceeded.

Hence Sir Isaac Newton inferred, that the primary planets were retained in their orbits by a force continually directed to the sun; and, because Kepler's law of motion was also observed by the secondary planets in in their revolutions round their refpective primary planets, this inference was extended to them.

15 Centripetal forces. From the circumftance that the planetary deflecting forces in the different points of the orbit are always directed toward one point as to a centre, they have been called CENTRIPETAL FORCES.

16 Velocity of a planet in the different points of its orbit. From this propofition may be deduced a corollary which eftablifhes a general law of the motion of any planet in the different parts of its orbit, namely, that the velocity which a planet has in the different points of its path are inverfely proportional to the perpendiculars drawn from the fun on the tangents to the orbit in thofe points refpectively. For, let AB, $a\,b$ (fig. 3.) be two arches (extremely fmall), defcribed in equal times, thefe arches muft be ultimately proportional to the velocities with which they are defcribed. Let SP, S p be perpendicular to the tangents AP, $a\,p$. The triangles ASB, a S b are equal, becaufe equal areas are defcribed by the *radii vectores* SA, S a, in equal times: but in equal triangles, the bafes AB, $a\,b$, are reciprocally as their heights SP, Sp, or AB : $a\,b$ = Sp : SP.

This corollary gives us another expreffion of the ratio of the centripetal forces in different points A and a of a curve. We faw by a former propofition, that the force at A (fig. 2.) is to the force at a as $AC^2 \times a\,e$ to $a\,c^2 \times AE$, which we may exprefs thus: $F : f = V^2 \times c : v^2 \times C$. If we exprefs the perpendiculars SP, S p (in fig. 3.) by the fymbols P, p, we have $V^2 : v^2 = p^2 : P^2$, and therefore $F : f = p^2 \times c : P^2 \times C$. *The centripetal forces in different points of an orbit are in the ratio compounded of the inverfe duplicate ratio of the perpendiculars drawn to the tangents in thofe points from the centre of forces, and the inverfe ratio of the deflective chords of the equicurve circles.*

17 Law of action of the centripetal force, We are now in a condition to determine the law of action of the centripetal force by which a planet is retained in its orbit round the fun, or the relation which fubfifts between the intenfity of its action and the diftance of the planet from the fun: for we know the elliptical figure of the orbit, and we can draw a tangent to it in any point, and a perpendicular from the fun to that tangent.

Kepler's fecond law or obfervation of the planetary motions was, that *each primary planet defcribed an ellipfe, having the fun in one focus.* It is eafy to fhow, even without any knowledge of the geometrical properties of the ellipfe, what is the proportion of the intenfities of the deflecting force at the aphelion and perihelion (fee fig. 4.) At thofe two points of the orbit, the motion of the planet is at right angles to the line joining it with the fun. Therefore, fince the areas defcribed in equal times are equal, the arches defcribed in equal times muft be inverfely at the diftances from the fun; or the velocities muft be inverfely as the diftances from the fun. But the curvature in the aphelion and perihelion is the fame; and therefore the diameters of the equicurve circles in thofe points are equal. But thofe diameters are, in this particular cafe, what we called the deflective chords. Therefore, calling the aphelion and perihelion diftances D and d, the velocities in the aphelion and perihelion V and v, let the common deflective chord be C. Then we have $F : f = V^2 \times C : v^2 \times C, = V^2 : v^2, = d^2 : D^2$. That is, the forces which deflect the planet in the aphelion and perihelion are inverfely as the fquares of the diftances from the fun. A perfon almoft ignorant of mathematics may fee the truth of this by looking into a table of natural verfed fines. He will obferve, that the verfed fine of one degree is quadruple the verfed fine of half a degree, and fixteen times the verfed fine of a quarter of a degree; in fhort, that the verfed fines of fmall arches are in the proportion of the fquares of the arches. Now fince the arches defcribed in equal times are inverfely as the diftances, their verfed fines are inverfely as the fquares of the diftances. But thefe verfed fines are the fpaces through which the centripetal forces at the aphelion and perihelion deflect the planet from the tangent. Therefore, &c.

Thus we have found, that in the aphelion and perihelion the centripetal force acts with an intenfity that is proportional to the fquares of the diftances inverfely. As thefe are the extreme fituations of a planet, and as the proportion of the aphelion and perihelion diftances are confiderably different in the different planets, and yet this law of action is obferved in them all, it is reafonable to imagine that it holds true, not in thofe fituations only, but in every intermediate fituation. But a conjecture, however probable, is not fufficient, when we aim at accurate fcience, and it is neceffary to examine whether this law of action is really obferved in every point of the elliptical orbit.

For this purpofe it is neceffary to mention fome geometrical properties of the ellipfe. Therefore let ADBE (fig. 4.) be the elliptical orbit of a planet or comet, having the fun in the focus S. Let AB be the tranfverfe axis, and DE the conjugate axis, and C the centre. Let P be any point of the ellipfe. Draw PS through the focus. Draw the tangent PN, and SN from the focus, perpendicular to PN. Draw PQ perpendicular to PN, meeting the tranfverfe axis in Q. Draw QO parallel to PN, meeting PS in O. Alfo draw QR perpendicular to PS. Bifect PO in T. 18 Demonftrated with refpect to the earth,

It is demonftrated in the treatifes of conic fections, that PO is one half of the chord of the equicurve or ofculating circle drawn through the point P. Therefore PO is one half of the deflective chord of the planetary orbit. It is alfo demonftrated, that PR is one half of the parameter or *latus rectum* of the tranfverfe axis AB, or that it is the third proportional to AC and DC. Therefore PR or D r is of the fame conftant magnitude, in whatever part of the circumference the point P is taken.

It is evident that the triangles NSP, RPQ, and QPO, are all fimilar, by reafon of the parallels PN, QO, and the right angles SNP, PRQ, PQO. Therefore we have PR : PQ = PQ : PO. Therefore $PR : PO = PR^2 : PQ^2, = SN^2 : SP^2$. Therefore $PR \times SP^2 = PO \times SN^2$. But the *latus rectum* L is equal to twice PR, and the deflective chord C is equal to twice PO. Therefore $L \times SP^2 = C \times SN^2$. But we have feen, that when a curve is defcribed by means of a centripetal force, fo that areas are defcribed proportional to the times, and therefore the velocities are reciprocally proportional to the perpendiculars drawn from the centre of forces to the tangents, the forces are inverfely proportional to $C \times SN^2$. Therefore, in the elliptical motion of the planets, the forces are inverfely proportional to $L \times SP^2$; and fince L is a conftant quantity, the centripetal forces are inverfely proportional to SP^2, or to the fquares of the diftances from the fun.

Thus

Thus it appears that, with reſpect to any individual planet, the centripetal force which continually deflects it from the tangent to its orbit diminiſhes in the inverſe duplicate ratio of the diſtance from the ſun. The ſame thing is obſerved to be very nearly true in the moon's motion round the earth, and in the motion of ſuch ſatellites of Jupiter and Saturn as deſcribe orbits which are ſenſibly elliptical. It is alſo obſerved in the motion of the comets, at leaſt in that which appeared in 1682 and in 1759.

19 Obſerved in the motion of the moon, &c.

It was therefore very natural for Sir Iſaac Newton to examine whether the like diminution of force obtained in the action of this force on different planets; that is, whether the deflection of the earth from the tangent of its orbit was to the ſimultaneous deflection of Jupiter as the ſquare of Jupiter's diſtance from the ſun to the ſquare of the earth's diſtance. This was very probable, but by no means certain. Its probability is very great indeed, when we know that a comet moves ſo in its orbit that its deflections in equal times are inverſely as the ſquares of its diſtances from the ſun, and that the comet paſſes through the orbits of all the planets; and when at the ſame diſtance from the ſun as any one of them, it ſuffers the ſame deflection with it. Newton therefore calculated the actual ſimultaneous deflections of the different planets, and found them agreeable to this law. But it was deſirable to obtain a demonſtration of this important propoſition in general terms. This was ſupplied by Kepler's third general obſervation of the motions, viz. that *the ſquares of the periodic times of the different planets were proportional to the cubes of their mean diſtances from the ſun.* The orbits of the planets are ſo nearly circular, that we may ſuppoſe them exactly ſo in the preſent queſtion, without any remarkable error. In this caſe, then, the deflective chords are the diameters of the orbits (for DS is equal to AC), and are proportional to the diſtances, which are their halves. The centripetal forces, being proportional to $\frac{v^2}{c}$, are proportional to $\frac{v^2}{d}$, when d is the radius of the orbit, or the mean diſtance from the ſun. But the velocity in a circular orbit is as the circumference directly, and as the time of a revolution inverſely. Therefore, inſtead of v^2, we may write $\frac{d^2}{t^2}$, and then the forces will be proportional to $\frac{d^2}{t^2 d}$, or to $\frac{d}{t^2}$; that is, directly as the diſtances, and inverſely as the ſquares of the times of revolution. But, by Kepler's obſervation, t^2 is proportional to d^3. Therefore the centripetal forces are proportional to $\frac{d}{d^3}$, or to $\frac{1}{d^2}$; that is, inverſely as the ſquares of the mean diſtances from the ſun.

20 And demonſtrated in general terms.

But ſince the orbits of the planets are not accurate circles, this determination is but an approximation to the truth, and therefore inſufficient for the foundation of ſo important a propoſition; at any rate, it will not apply to the comets, whoſe orbits are very far from being circular. We muſt obtain a more accurate demonſtration.

Therefore draw SD (fig. 4.) to the extremity of the conjugate axis, and biſect it in t. About S, with the radius SD, deſcribe the circle DFG. Let Dd, Dδ be equal ſmall arches of the ellipſe and the circle. Join dS, δS. It is well known that DS is half of the chord of the equicurve circle at D, and therefore Dt is one fourth part of it. It has been demonſtrated, that the velocity in any point D of a curve, deſcribed by means of a deflecting force, is that which the force in that point would communicate to it by uniformly impelling it along the fourth part of the deflective chord, that is, along Dt. But if a body revolved round S in a circle DFG, its velocity in that circle would be that which the deflecting force would communicate to it by uniformly impelling it along one-fourth of the diameter, that is, along Dt. Therefore the planet, if projected in the direction Dδ, with the velocity which it has in the point D of the ellipſe, would deſcribe the circle DFG by the action of the centripetal force. Farther, it would deſcribe it in the ſame time that it deſcribes the ellipſe; for becauſe the velocities are equal, the areas DSd, DSδ are deſcibed in the ſame time. But the baſes Dd, Dδ being equal, theſe areas are as their heights Sn (or CD), and SD (or CA). But becauſe the diameter of the circle is equal to AB, the area of the whole ellipſe is to the area of the circle as CD is to CA; that is, as the area DSd to the area DSδ deſcribed in the ſame time. Therefore the elliptical and circular areas are ſimilar portions of the ellipſe and circle; and therefore the times of deſcribing them are ſimilar portions of the whole revolutions in the ellipſe and in the circle. Therefore theſe revolutions are performed in equal times.

And thus it follows, that if all the planets and comets were projected, when at their mean diſtances from the ſun, perpendicularly to the *radii vectores*, they would deſcribe circles round the ſun, and the ſquares of their periodic times would be proportional to the cubes of their mean diſtances from the ſun, as Kepler has obſerved; and therefore the centripetal forces would be inverſely as the ſquares of their diſtances from the ſun.

They are not different forces therefore which retain the different planets in their reſpective orbits, but one force, acting by the ſame law upon them all. We may either conceive it as an attractive force, exerted by the ſun, or as a tendency in each planet; nay, nothing hinders us from conceiving it as a force external, both to ſun and planets, impelling them towards the ſun. It may be the impulſe of a ſtream of fluid moving continually towards the ſun. Sir Iſaac Newton did not concern himſelf with this queſtion, but contented himſelf with the diſcovery of the law according to which its action was exerted. The ſteps of this inveſtigation ſhewed him, that a body, projected in any direction whatever, and with any velocity whatever, and ſubjected to the action of a force directed to the ſun, and inverſely proportional to the ſquare of the diſtance from the ſun, will neceſſarily deſcribe a conic ſection, having the ſun in the focus. This will be a parabola, if the velocity of projection be that which the centripetal force in that place would communicate to the body by acting on it uniformly along a line equal to half its diſtance from the ſun. If the velocity be greater than this, the path will be a hyperbola; if the velocity be leſs than this, the path will be an elliptical orbit, in which the body will revolve for ever round the ſun.

21 All the planets retained in their reſpective orbits by one and the ſame force.

The 3d Keplerean law is alſo obſerved in the revolutions of the ſatellites of Jupiter, Saturn, and the lately diſcovered

discovered planet; and we must infer from it, that they are retained in their orbits round their respective primary planets, by forces whose intensity decreases according to the same law of the distances. Also the elliptical motion of the moon round the earth, shews that the force by which she is retained in her orbit varies in the same proportion of the distances. But when we compare the motion of a satellite of Jupiter with that of one of the satellites of the other two planets, we find that the proportion does not hold. We shall find that, at equal distances from Jupiter and Saturn, the force toward Jupiter is almost thrice as great as the force toward Saturn. We shall also find that the force toward Jupiter is three hundred times greater than the force which retains the moon in its elliptical orbit round the earth, when acting at the same distance.

Since a force directed to the sun, and inversely as the square of the distance, is thus found to pervade all the planetary orbits, it is highly improbable that it will not affect the secondary planets also. The moon accompanies the earth in its motion round the sun. It may appear sufficient for this purpose, that the moon be retained in its orbit by a force directed to the earth. Were the moon connected with the earth by a rope or chain, this would be true; for the earth could get no motion without dragging the moon along with it: but it is quite otherwise with bodies moving in free space, without any material connections. When a body that is moving uniformly in a straight line is accompanied by another which describes around it areas proportional to the times, the force which continually deflects this satellite is always directed to the moving central body.

22
The satellites of all the planets subjected to this solar action.

This is easily seen; for whatever be the mutual action of two bodies, and their relative motions in consequence of this action, if the same velocity be impressed at once on both bodies in the same direction, their mutual actions and relative motions will be the same as they would have been without this common impulse. Thus every thing is done in a ship that is sailing steadily in the same manner as if she were at rest. If therefore the moon be observed to describe areas round the earth, which are *precisely* proportional to the times, while the earth moves in an orbit round the sun, we must infer that the moon receives, in every instant, an impulse the same in every respect with what the earth receives at the same instant; or that the moon is acted on by a force parallel to the earth's distance from the sun, and proportional to the square of that distance inversely. Now this is very nearly true of the lunar motions; and we must infer that the moon is subjected to this solar action, or this tendency to the sun. The same must be affirmed of the satellites of the other planets.

But a force inversely proportional to the square of the earth's distance from the sun is not what the universality of the law requires: It must be inversely as the square of the moon's distance from the sun; and it must not be parallel to the earth's distance from the sun, but must be directed toward the sun; and therefore, in the quadratures, it must converge to the earth's *radius vector*. Therefore, since a force having the above mentioned conditions will allow the description of areas round the earth exactly proportional to the times, a force acting on the moon, inversely proportional to the square of her distance from the sun, and directed exactly to the sun, is incompatible with the accurate elliptical motion round the earth.

23
How their regularity of the moon's motion

At new moon, her tendency to the sun exceeds the earth's tendency to him, and this excess will diminish her tendency to the earth, and her motion will be less incurvated, so that she will retire a little from the earth. At full moon, the earth's tendency to the sun exceeds the moon's tendency to him, and the earth will separate a little from the moon, so that the relative orbit will again be less incurvated. In the quadratures, the impulse on the moon is indeed equal to that on the earth, but not parallel, and tends to make the moon approach the earth, and increase the curvature of her orbit. In other situations of the moon, this want of equality and parallelism of the forces acting on the earth and moon, must produce other disturbances of the regular elliptical motion.

Newton saw this at once; and, to his great delight, he saw that the great deviations from regular motion, which had been discovered by Ptolemy and Tycho Brahé, called the *Annual Equation*, the *Variation*, and the *Evection*, were such as most obviously resulted from the regular influence of the sun on the moon. The first deviation from the regular elliptical motion is occasioned by the increase of the sun's disturbing force as the earth approaches the perihelion; and it enlarges the lunar orbit, by diminishing the tendency to the earth, and increases the periodic time. The second arises from the *direction* of the disturbing force, by which it accelerates the moon's angular motion in the second and fourth quadrants of her orbit, and retards it in the first and third. The last affects the eccentricity of the orbit, by changing the ratio of the whole or compound tendency of the moon to the earth in her perigee and apogee. This success incited him to an accurate examination of the consequences of this influence.

24
May be calculated with precision.

It is the boast of this discovery of the law of the planetary deflections, that all its effects may be calculated with the utmost precision. The part of the moon's deflection toward the sun, which is neither equal nor parallel to the simultaneous deflection of the earth, may be separated from the part which is equal and parallel to it, and it may be called the sun's disturbing force. Its proportion to the moon's deflection towards the earth may be accurately ascertained, and its inclination to the line of the moon's motion in every point of her orbit may be pointed out. This being done, the accumulated effect of this disturbing force after any given time, however variable, both in direction and intensity during this time, may be determined by the 39th and other propositions of the first book of the Mathematical Principles of Natural Philosophy. And thus may the moon's motion, when so disturbed, be determined and compared with her motion really observed.

All this has been done by Sir Isaac Newton with the most astonishing address and sagacity, *sua mathesi facem preferente*, partly in the Principia, and partly in his Lunæ Theoria. This investigation, whether we consider the complete originality of the whole process, or the ingenuity of the method, or the sagacity in seeing and clearly discriminating the different circumstances of the question, or the wonderful fertility of resource, or the new and most refined mathematical principles and methods that he employed—must ever be considered as the most brilliant specimen of human invention and reasoning that ever was exhibited to the world.

In this investigation Newton not only determined the quantity,

quantity, the period, and the changes of those inequalities, which had been so considerable and remarkable as to be observed by former astronomers, and this with an exactness far surpassing what could ever be attained by mere observation; but he also pointed out several other periodical inequalities, which were too small, and too much implicated with the rest, ever to be discovered or to be separated from them. We do not say that he completed the theory of the lunar motions; but he pointed out the methods of investigation, and he furnished all the means of prosecuting it, by giving the world the elements of a new species of mathematics, without which it would have been in vain to attempt it. Both this new mathematics, and the methods of applying it to such questions, have been assiduously studied and improved by the great mathematicians of this century; and the lunar theory has been carried to such a degree of perfection, that we can compute her place in the heavens for any past age without deviating above one minute of a degree from the actual observation.

25 The secular equation of the moon's mean distance

There is one empirical equation of the moon's motion which the comparison of ancient and modern eclipses obliges the astronomers to employ, without being able to deduce it, like the rest, *à priori*, from the theory of an universal force inversely proportional to the square of the distance. It has therefore been considered as a stumbling block in the Newtonian philosophy. This is what is called *the secular equation of the moon's mean motion.* The mean motion is deduced from a comparison of distant observations. The time between them, being divided by the number of intervening revolutions, gives the average time of one revolution, or the mean lunar period. When the ancient Chaldean observations are compared with those of Hipparchus, we obtain a certain period; when those of Hipparchus are compared with some in the 9th century, we obtain a period somewhat shorter; when the last are compared with those of Tycho Brahé, we obtain one still shorter; and when Brahé's are compared with those of our day, we obtain the shortest period of all—and thus the moon's mean motion appears to accelerate continually; and the accelerations appear to be in the duplicate ratio of the times. The acceleration for the century which ended in 1700 is about 9 seconds of a degree; that is to say, the whole motion of the moon during the 17th century must be increased 9 seconds, in order to obtain its motion during the 18th; and as much must be taken from it, or added to the computed longitude, to obtain its motion during the 16th; and the double of this must be taken from the motion during the 16th, to obtain its motion during the 15th, &c. Or it will be sufficient to calculate the moon's mean longitude for any time past or to come by the secular motion which obtains in the present century, and then to add to this longitude the product of 9 seconds, multiplied by the square of the number of centuries which intervene. Thus having found the mean longitude for the year 1200, add 9 seconds, multiplied by 36, for six centuries. By this method we shall make our calculation agree with the most ancient and all intermediate observations. If we neglect this correction, we shall differ more than a degree from the Chaldean observations of the moon's place in the heavens.

The mathematicians having succeeded so completely in deducing all the observed inequalities of the planetary motions, from the single principle, that the deflecting forces diminished in the inverse duplicate ratio of the distances, were fretted by this exception, the reality of which they could not contest. Many opinions were formed about its cause. Some have attempted to deduce it from the action of the planets on the moon; others have deduced it from the oblate form of the earth, and the translation of the ocean by the tides; others have supposed it owing to the resistance of the ether in the celestial spaces; and others have imagined that the action of the deflecting force requires time for its propagation to a distance: But their deductions have been proved unsatisfactory, and have by no means the precision and evidence that have been attained in the other questions of physical astronomy. At last M. de la Place, of the Royal Academy of Sciences at Paris, has happily succeeded, and deduced the secular equation of the moon from the Newtonian law of planetary deflection. It is produced in the following manner:

26 Deduced from the Newtonian law of planetary deflection.

Suppose the moon revolving round the earth undisturbed by any deflection toward the sun, and that the time of her revolution is exactly ascertained. Now let the influence of the sun be added. This diminishes her tendency to the earth in opposition and conjunction, and increases it in the quadratures: but the diminutions exceed the augmentations both in quantity and duration; and the excess is equivalent to $\frac{1}{179}$th of her tendency to the earth. Therefore this diminished tendency cannot retain the moon in the same orbit; she must retire farther from the earth, and describe an orbit which is less incurvated by $\frac{1}{179}$th part; and she must employ a longer time in a revolution. The period therefore which we observe, is not that which would have obtained had the moon been influenced by the earth alone. We should not have known that her natural period was increased, had the disturbing influence of the sun remained unchanged; but this varies in the inverse triplicate ratio of the earth's distance from the sun, and is therefore greater in our winter, when the earth is nearer to the sun. This is the source of the annual equation, by which the lunar period in January is made to exceed that in July nearly 24 minutes. The angular velocity of the moon is diminished in general $\frac{1}{179}$, and this numerical coefficient varies in the inverse ratio of the cube of the earth's distance from the sun. If we expand this inverse cube of the earth's distance into a series arranged according to the sines and cosines of the earth's mean motion, making the earth's mean distance unity, we shall find that the series contains a term equal to $\frac{3}{2}$ of the square of the eccentricity of the earth's orbit. Therefore the expression of the diminution of the moon's angular velocity contains a term equal to $\frac{1}{179}$ of this velocity, multiplied by $\frac{3}{2}$ of the square of the earth's eccentricity; or equal to the product of the square of the eccentricity, multiplied by the moon's angular velocity, and divided by 119,33 ($\frac{2}{3}$ of 179). Did this eccentricity remain constant, this product would also be constant, and would still be confounded with the general diminution, making a constant part of it: but the eccentricity of the earth's orbit is known to diminish, and its diminution is the result of the universality of the Newtonian law of the planetary deflections. Although this diminution is exceedingly small, its effect on the lunar motion becomes sensible by accumulation in the course of ages. The eccentricity diminishing, the diminution

nution of the moon's angular motion muſt alſo diminiſh, that is, the angular motion muſt increaſe.

During the 18th century, the ſquare of the earth's eccentricity has diminiſhed 0,0000015325, the mean diſtance from the ſun being = 1. This has increaſed the angular motion of the moon in that time 0,00000001285. As this augmentation is gradual, we muſt multiply the angular motion during the century by the half of this quantity, in order to obtain its accumulated effect. This will be found to be 9″ very nearly, which exceeds that deduced, from a moſt careful compariſon of the motion of the laſt two centuries, only by a fraction of a ſecond!

As long as the diminution of the ſquare of the eccentricity of the earth's orbit can be ſuppoſed proportional to the time, this effect will be as the ſquares of the times. When this theory is compared with obſervations, the coincidence is wonderful indeed. The effect on the moon's motion is periodical, as the change of the ſolar eccentricity is, and its period includes millions of years. Its effect on the moon's longitude will amount to ſeveral degrees before the ſecular acceleration change to a retardation.

Thoſe who are not familiar with the diſquiſitions of modern analyſis, may conceive this queſtion in the following manner.

Let the length of a lunar period be computed for the earth's diſtance from the ſun for every day of the year. Add them into one ſum, and divide this by their number, the quotient will be the mean lunar period. This will be found to be greater than the arithmetical medium between the greateſt and the leaſt. Then ſuppoſe the eccentricity of the earth's orbit to be greater, and make the ſame computation. The average period will be found ſtill greater, while the medium between the greateſt and leaſt periods will hardly differ from the former. Something very like this may be obſerved without any calculation, in a caſe very ſimilar. The angular velocity of the ſun is inverſely as the ſquare of his diſtance. Look into the ſolar tables, and the greateſt diurnal motion will be found 3673″, and the leaſt 3433″. The mean of theſe is 3553″, but the medium of the whole is 3548″. Now make a ſimilar obſervation in tables of the motion of the planet Mars, whoſe eccentricity is much greater. We ſhall find that the medium between the greateſt and leaſt exceeds the true medium of all in a much greater proportion.

27 Certainty and utility of this law. Thus has the patient and aſſiduous cultivation of the Newtonian diſcoveries explained every phenomenon, and enabled us to foreſee changes in them which no examination of the paſt appearances, unaſſiſted by this theory, could have pointed out, and which muſt have exceedingly embarraſſed future aſtronomers. This great but ſimple law of deflection repreſents every phenomenon of the ſyſtem in the moſt minute circumſtances. Far from fearing that future experience may overturn this law, we may reſt aſſured that it will only confirm it more and more; and we may confide in its moſt remote conſequences as if they were actually obſerved.

28 Reciprocal deflection of the earth and moon, and of the ſun and planets, It is diſcovered by obſervation, that the deflection of the moon to the earth, and of the planets to the ſun, are accompanied by an equal and oppoſite deflection of the earth to the moon, and of the ſun to the planets.

The tendency of the earth to the moon is plainly indicated by the riſe of the waters of the ocean under the moon, and on the oppoſite ſide of the earth. Sir Iſaac Newton tried what ſhould be the reſult of a tendency of the water to the moon. His inveſtigation of this queſtion was very ſimilar to that in his lunar theory. We may conceive the moon to be one of many millions of particles of a fluid, occupying a globe as big as the lunar orbit. Each will feel a ſimilar diſturbing force, which will diminiſh its tendency to the earth in the neighbourhood of the place of conjunction and oppoſition, and will increaſe it in the neighbourhood of the quadratures. They cannot therefore remain in equilibrio in their ſpherical form; they muſt ſink in the quadratures, and riſe in the conjunction and oppoſition, till their greater height compenſates for the diminiſhed weight of each particle. In like manner, the waters of the ocean muſt ſink on thoſe parts of the earth where the moon is ſeen in the horizon, and muſt riſe in thoſe which have the moon in the zenith or nadir. All theſe effects are not only to be ſeen in general, but they may all be calculated, and the very form pointed out which the ſurface of the ocean muſt aſſume; and thus a tendency of every particle of the ocean to the moon, inverſely proportional to the ſquare of its diſtance from it, gives us a theory of the ebbing and flowing of the ſea. This is delivered in ſufficient detail in the article Tide of the Encyclopædia Britannica, and therefore need not be inſiſted on in this place. The ſame inference muſt be drawn from the preceſſion of the equinoxes produced by the action of the moon on the protuberant matter of our equatorial regions. See Preceſſion in the *Encycl.* 29 Proved by the ebbing and flowing of the ſea,

30 And by different computations of the ſun's place in the heavens. But the mutual tendency of the earth and moon is clearly ſeen in a phenomenon that is much more ſimple. If we compute the ſun's place in the heavens, on the ſuppoſition that the earth deſcribes areas proportional to the times, we ſhall find it to agree with obſervation at every new and full moon: But at the firſt quarter the ſun will be obſerved about 9 ſeconds too much advanced to the eaſtward; and at the laſt quarter he will be as much to the weſtward of his calculated place. In all intermediate poſitions, the deviation of the obſerved from the computed place of the ſun will be 9 ſeconds, multiplied by the ſine of the moon's diſtance from conjunction or oppoſition. In ſhort, the appearances will be the ſame as if it were not the earth which deſcribed areas proportional to the times round the ſun, but that a point, lying between the earth and moon, and very near the earth's ſurface, were deſcribing the ellipſe round the ſun, while the earth and moon revolve round this point in the courſe of a lunation, having the point always in the line between them, in the ſame manner as if they were on the extremities of a rod which turns round this point, while the point itſelf revolves round the ſun.

This then is the fact with reſpect to the motions; and the earth in a month deſcribes an orbit round this common centre of the earth and moon. It cannot do this unleſs it be continually deflected from the tangent to this orbit; therefore it is continually deflected toward the moon: and the momentum of this deflection, that is, its quantity of motion, is the ſame with that of the moon's deflection, becauſe their diſtances from the common centre are as their quantities of matter inverſely.

Appearances perfectly ſimilar to theſe oblige us to affirm

affirm that the ſun is continually deflected toward the planets. Aſtronomical inſtruments, and the art of obſerving, have been prodigiouſly improved ſince Sir Iſaac Newton's time; and the moſt ſcrupulous attention has been paid to the ſun's motion, becauſe it is to his place in the univerſe that continual reference is made in computing the place of all the planets. He is ſuppoſed at reſt in the common focus of all their orbits; and the *obſerved* diſtance of a planet from the ſun is always conſidered as the *radius vector*. If this be not the caſe, the orbital motions contained in our tables are not the abſolute motions of the planets, nor the deflections from the tangents the real deflections from abſolute rectilineal motion; and therefore the forces are not ſuch as we infer from thoſe miſtaken deflections. Accordingly Sir Iſaac Newton, induced by certain metaphyſical conſiderations, aſſumed it as a law of motion, that every action of a body A on another body B, is accompanied by an equal and contrary action of B on A. We do not ſee the propriety of this aſſertion as a metaphyſical axiom. It is perfectly conceivable that a piece of iron will always approach a magnet when in its neighbourhood; but we do not ſee that this obliges us to aſſert, that *therefore* the magnet will alſo approach the iron. Thoſe who explain the phenomena of magnetiſm by the impulſe of a fluid, muſt certainly grant that there is no metaphyſical neceſſity for another ſtream of fluid impelling the magnet toward the iron. And accordingly this, and the ſimilar reciprocity in the phenomena of electricity, have *always* been conſidered as deductions of experimental philoſophy; yet we obſerve the ſame reciprocity in all the actions of ſublunary bodies; and Newton's third law of motion is received as true, and admitted as a principle of reaſoning. But we apprehend that it was haſty in this great philoſopher, and unlike his ſcrupulous caution, to extend it to the planetary motions. He did, however, extend it, and aſſerted, that as each planet was deflected toward the ſun, the ſun was equally (in reſpect of momentum) deflected toward each planet, and that his real motion was the compoſition of all thoſe ſimultaneous deflections. He aſſerted that there was a certain point round which the ſun and his attending planets revolved; and that the orbit of a planet, which our meaſurements determined by continual reference to the ſun as to a fixed body, was not the true orbit, but conſiſted of the contemporaneous orbits of that planet and of the ſun round this fixed point. Any little ſector of the apparent orbit was greater than the correſponding ſector of the planet's true orbit in abſolute ſpace, and the apparent motion was compounded of the true motion of the planet, and the oppoſite to the true motion of the ſun. After a moſt ingenious and refined inveſtigation, he ſhewed that, notwithſtanding this great difference of the Keplerean laws from the truth, the inference, with reſpect to the law of planetary deflection, is juſt, and that not only the apparent deflections are in the inverſe duplicate ratio of the diſtances from the ſun, but that the real deflections vary in the ſame ratio of the diſtances from the fixed point, and alſo from the ſun; for he ſhewed that the diſtances from the ſun were in a conſtant ratio to the diſtances from this point. He ſhewed alſo that the ſame forces which produced the contemporaneous revolution of a planet and the ſun round the centre of the ſyſtem, would produce a revolution of the planet in a ſimilar orbit round the ſun (ſuppoſed to be held faſt in his place) at the ſame diſtance which really obtains between them, with this ſole difference, that the periodic time will be longer, in the ſubduplicate ratio of the quantity of matter in the ſun to the quantity of matter of the ſun and planet together. Areas will be deſcribed proportional to the times, and the orbit will be elliptical; but the ratio of the ſquares of the periodic times will not be the ſame with the ratio of the cubes of the diſtances, unleſs all the planets are equal.

31 Obſervations on the third law of motion.

32 Newton's extenſion of that law

Thus was the attention of aſtronomers directed to a number of *apparent* irregularities in the motion of the earth, which muſt reſult from this derangement of the ſun, which they had imagined to remain ſtedfaſt in his place. They were told what to expect, and on what poſitions of the planets the kind and quantity of every irregularity depended. This was a moſt inviting field of obſervation to a curious ſpeculatiſt; but it required the niceſt and moſt expenſive inſtruments, and an uninterrupted ſeries of long continued obſervations, ſufficient to occupy the whole of a man's time. Fortunately the accurate determination of the ſolar and lunar motions were of the utmoſt importance, nay, indiſpenſably neceſſary for ſolving the famous problem of the longitude of a ſhip at ſea: and thus the demands of commercial Europe came in aid of philoſophical curioſity, and occaſioned the erection of obſervatories, firſt at Greenwich, and ſoon after at Paris and other places, with eſtabliſhments for aſtronomers, who ſhould carefully watch the motions of the ſun and moon, not neglecting the other planets.

33 Confirmed by obſervation.

The fortunate reſult of all this ſolicitude has been the complete eſtabliſhment of the Newtonian conjecture (for ſo we muſt ſtill think it), and the verification of Newton's aſſertion, that action was accompanied, through the whole ſolar ſyſtem, by an equal and contrary reaction. All the inequalities of the ſolar motion predicted by Newton have been obſerved, although they are frequently ſo complicated that they could never have been detected, had not the Newtonian theory directed us when to find any of them pretty clear of complication, and how to aſcertain the accumulated reſult of them all in any ſtate of combination.

But in the courſe of this attention to the motions of the ſun and moon, the planets came in for a ſhare, and conſiderable deviations were found, from the ſuppoſition that all their deflections were directed to the ſun, and were in the inverſe duplicate ratio of their diſtances. The nice obſervation ſhewed, that the period of Jupiter was ſomewhat ſhorter than Kepler's law required.

A ſlight reflection ſhewed that this was no inconſiſtency; becauſe the common centre of the conjoined orbits of the ſun and Jupiter was ſenſibly diſtant from the centre of the ſun, namely, about the 1100th part of the *radius vector*; and therefore the real deflection was about a 2200th part leſs than was ſuppoſed. It was now plain that the diſtances to which the Keplerean law muſt be applied, are the diſtances, not from the ſun, but from the fixed point round which the ſun and planets revolve. This difference was too ſmall to be obſerved in Kepler's time; but the ſeeming error is only a confirmation of the Newtonian philoſophy.

But there are other irregularities which cannot be explained in this manner. The planetary orbits change their position; their aphelia advance, their nodes recede, their inclination to each other vary. The mean motions of Saturn and Jupiter are subject to considerable changes, which are periodical.

34 Deflection of the planets towards each other.

Sir Isaac Newton had no sooner discovered the universality and reciprocity of the deflections of the planets and the sun, than he also suspected that they were continually deflected towards each other. He immediately obtained a general notion of what should be the more general results of such a mutual action. They may be conceived in this way.

Plate VI.

Let S (fig. 5.) represent the sun, E the earth, and I Jupiter, describing concentric orbits round the centre of the system. Make $IS : EA = EI^2 : SI^2$. Then, if IS be taken to represent the deflection of the sun toward Jupiter, EA will represent the deflection of the Earth to Jupiter. Draw EB equal and parallel to SI, and complete the parallelogram EBAD. ED will represent the disturbing force of Jupiter. It may be resolved into EF, perpendicular to ES, and EG in the direction of SE. By the first of these the earth's angular motion round the sun is affected, and by the second its deflection toward him is diminished or increased.

35 General result of such mutual action.

In consequence of this first part of the disturbing force, the angular motion is increased, while the earth approaches from quadrature to conjunction with Jupiter (which is the case represented in the figure), and is diminished from the time that Jupiter is in opposition till the earth is again in quadrature, westward of his opposition. The earth is then accelerated till Jupiter is in conjunction with the sun; after which it is retarded till the earth is again in quadrature.

The earth's tendency to the sun is diminished while Jupiter is in the neighbourhood of his opposition or conjunction, and increased while he is in the neighbourhood of his stationary positions. Jupiter being about 1000 times less than the sun, and 5 times more remote, IS must be considered as representing $\frac{1}{25000}$th of the earth's deflection to the sun, and the forces ED and EG are to be measured on this scale.

In consequence of this change in the earth's tendency to the sun, the aphelion sometimes advances by the diminution, and sometimes retreats by the augmentation. It advances when Jupiter chances to be in opposition when the earth is in its aphelion; because this diminution of its deflection towards the sun makes it later before its path is brought from forming an obtuse angle with the *radius vector*, to form a right angle with it. Because the earth's tendency to the sun is, on the whole, more diminished by the disturbing force of Jupiter than it is increased, the aphelion of the earth's orbit advances on the whole.

In like manner the aphelia of the inferior planets advance by the disturbing forces of the superior: but the aphelion of a superior planet retreats; for these reasons, and because Jupiter and Saturn are larger and more powerful than the inferior planets, the aphelia of them all advance while that of Saturn retreats.

In consequence of the same disturbing forces, the node of the disturbed planet retreats on the orbit of the disturbing planet; therefore they all retreat on the ecliptic, except that of Jupiter, which advances by retreating on the orbit of Saturn, from which it suffers the greatest disturbance. This is owing to the particular position of the nodes and the inclinations of the orbits.

The inclination of a planetary orbit increases while the planet approaches the node, and diminishes while the planet retires from it.

M. de la Place has completed this deduction of the planetary inequalities, by explaining a peculiarity in the motions of Jupiter and Saturn, which has long employed the attention of astronomers. The accelerations and retardations of the planetary motions depend, as has been shewn, on their configurations, or the relative quarters of the heavens in which they are. Those of Mercury, Venus, the Earth, and Mars, arising from their mutual deflections; and their more remarkable deflections to the great planets Jupiter and Saturn, nearly compensate each other, and no traces of them remain after a few revolutions: but the positions of the aphelia of Saturn and Jupiter are such, that the retardations of Saturn sensibly exceed the accelerations, and the anomalistic period of Saturn increases almost a day every century: on the contrary, that of Jupiter diminishes. M. de la Place shews, that this proceeds from the position of the aphelia, and the almost perfect commensurability of their revolutions; five revolutions of Jupiter making 21,675 days, while two revolutions of Saturn make 21,538, differing only 137 days.

36 A peculiarity explained in the motion of Jupiter and Saturn.

Supposing this relation to be exact, the theory shews that the mutual action of these planets must produce mutual accelerations and retardations of their mean motions, and ascertains the periods and limits of the secular equations thence arising. These periods include several centuries. Again, because this relation is not precise, but the odd days nearly divide the periods already found, there must arise an equation of this secular equation, of which the period is immensely longer, and the maximum very minute. He shews that this retardation of Saturn is now at its maximum, and is diminishing again, and will, in the course of years, change to an acceleration.

This investigation of the small inequalities is the most intricate problem in mechanical philosophy, and has been completed only by very slow degrees, by the arduous efforts of the greatest mathematicians, of whom M. de la Grange is the most eminent. Some of his general results are very remarkable.

He demonstrates, that since the planets move in one direction, in orbits nearly circular, no mutual disturbances make any permanent change in the mean distances and mean periods of the planets, and that the periodic changes are confined within very narrow limits. The orbits can never deviate sensibly from circles. None of them ever has been or will be a comet moving in a very eccentric orbit. The ecliptic will never coincide with the equator, nor change its inclination above two degrees. In short, the solar planetary system oscillates, as it were, round a medium state, from which it never swerves very far.

37 Oscillation of the planetary system.

This theory of the planetary inequalities, founded on the universal law of mutual deflection, has given to our tables a precision, and a coincidence with observation, that surpasses all expectation, and insures the legitimacy of the theory. The inequalities are most sensible in the motions of Jupiter and Saturn; and these present themselves in such a complicated state, and their periods are so long, that ages were necessary for discovering them by mere observation. In this respect, therefore, the theory has outstripped the observations on which it is founded.

38 Authenticity of the Indian aftronomy.

founded. It is very remarkable, that the periods which the Indians affign to thefe two planets, and which appeared fo inaccurate that they hurt the credit of the fcience of thofe ancient aftronomers, are now found precifely fuch as muft have obtained about three thoufand years before the Chriftian era; and thus they give an authenticity to that ancient aftronomy. The periods which any nation of aftronomers affign to thofe two planets would afford no contemptible mean for determining the age in which it was obferved.

The followiug circumftance is remarkable: Suppofe Jupiter and Saturn in conjunction in the firft degree of Aries; twenty years after, it will happen in Sagittarius; and after another twenty years, it will happen in Leo. It will continue in thefe three figns for 200 years. In the next 200 it will happen in Taurus, Capricornus, and Virgo; in the next 200 years, it will happen in Gemini, Aquarius, and Libra; and in the next 200 years, it will happen in Cancer, Pifces, and Scorpio: then all begins again in Aries. It is highly probable that thefe remarkable periods of the oppofitions of Jupiter and Saturn, progreffive for 40 years, and ofcillating during 160 more, occafioned the aftrological divifion of the heavens into the four *trigons*, of fire, air, earth, and water. Thefe relations of the figns, which compofe a trigon, point out the repetitions of the chief irregularities of the folar fyftem.

39 Origin of the aftrological divifion of the heavens.

M. de la Place obferves (in 1796), that the laft difcovered planet gives evident marks of the action of the reft; and that when thefe are computed and taken into the account of its bygone motions, they put it beyond doubt that it was feen by Flamftead in 1690, by Mayer in 1756, and by Monnier in 1769.

40 Action of the comets.

We have hitherto overlooked the comets in our account of the mutual difturbances of the folar fyftem. Their number is very great, and they go to all quarters of the univerfe: but we may conclude, from the wonderful regularity of the planetary motions, when all their own mutual actions are taken into account, that the quantity of matter in the comets is very inconfiderable. They remain but a fhort time in the neighbourhood of the planets, and they pafs them with great rapidity. Some of them have come very near to Jupiter, but left no trace of their action in the motions of his fatellites. They doubtlefs contribute, in general, to make the apfides of the planetary orbits advance.

41 They are affected by the planets.

On the other hand, the comets may be confiderably affected by the planets. The very important phenomenon of the return of the comet of 1682, which was to decide whether they were revolving planets defcribing ellipfes, or bodies which came but once into the planetary regions, and then retired for ever, caufed the aftronomers to confider this matter with great care. Halley had fhewn, in a rough way, that this comet muft have been confiderably affected by Jupiter. Their motion near the aphelion muft be fo very flow, that a very fmall change of velocity or direction, while in the planetary regions, muft confiderably affect their periods. Halley thought that the action of Jupiter might change it half a year. Mr Clairaut, by confidering the difturbing forces of Jupiter and Saturn through the whole revolution, fhewed that the period then running would exceed the former nearly two years (618 days), and affigned the middle of April 1759 for the time of its perihelion. It really paffed its perihelion on the 12th of March. This was a wonderful precifion, when we reflect that the comet had been feen but a very few days in its former apparitions.

A comet obferved by Mr Profperin and others in 1771 has greatly puzzled the aftronomers. Its motions appear to have been extremely irregular, and it certainly came fo near Jupiter, that his momentary influence was at leaft equal to the fun's. It has not been recognifed fince that time, although there is a great probability that it is continually among the planets.

42 Confequence of a comet and planet meeting.

It is by no means impoffible, nor highly improbable, that in the courfe of ages, a comet may actually meet one of the planets. The effect of fuch a concourfe muft be dreadful; a change of the axis of diurnal rotation muft refult from it, and the fea muft defert its former bed and overflow the new equatorial regions. The fhock and the deluge muft deftroy all the works of man, and moft of the race. The remainder, reduced to mifery, muft long ftruggle for exiftence, and all remembrance of former arts and events muft be loft, and every thing muft be invented anew. There are not wanting traces of fuch devaftations in this globe: ftrata and things are now found on mountain tops which were certainly at the bottom of the ocean in former times; remains of tropical animals and plants are now dug up in the circumpolar regions. *Tempora mutantur, et nos mutamur in illis.*

It is plain, that when we know the direction and the intenfity of the difturbing force, we can tell what will be the accumulated effect of its action for any time. The direction is eafily determined by means of the diftance: but how fhall we determine the intenfity? Since we fee that the whole waters of the ocean are deflected toward the moon, and have fuch probable evidence that planetary deflection is mutual; it follows that the moon is deflected towards *every* drop of water, and that *all* the matter in one body is deflected towards *all* the matter in another body; and therefore that the deflection towards the fun or a planet is greater or lefs in proportion to its quantity of matter. Newton indeed thought it unreafonable to fuppofe that a planet was deflected to the centre of the fun, which had no diftinguifhing phyfical property; and thought it more probable that the deflection of a planet to the fun was the accumulated deflection of every particle in the planet to every particle in the fun. But he was too fcrupulous to take this for granted. He therefore endeavoured to difcover what would be the fenfible deflection of one fphere to another, when each confifted of matter, every particle of which was deflected to every particle of the other with an intenfity inverfely proportional to the fquare of the diftance from it. By help of a moft beautiful and fimple procefs, he difcovered, that the tendency of a particle of matter to a fpherical furface, fhell, or folid, of uniform denfity at equal diftances from the centre, was the fame as if all the particles in the furface, fhell, or folid, were united in its centre: hence it legitimately followed, that the mutual tendency of fpherical furfaces, fhells, or folids, was proportional to the quantities of matter in the attracting body, and inverfely as the fquare of the diftance of their centres; and thus the law of attraction, competent to every particle of planetary matter, was the fame with that which *was obferved* among fpherical bodies confifting of fuch matter. And it is remarkable, that the inverfe duplicate ratio

43 Tendency of fpherical bodies towards each other directly as the quantity of matter, and inverfely as the fquare of the diftance of their centres.

tio of the diſtances is the only law that will hold, both with reſpect to ſingle particles and to globes compoſed of ſuch particles. He alſo demonſtrated, that a particle placed within a ſphere was not affected by all the ſhell, which was more diſtant than itſelf from the centre, being equally attracted on every ſide, and that it tended toward the centre of a homogenous ſphere, on the ſurface of which it was placed, with a force proportional to its diſtance from the centre.

Newton ſaw a caſe in which it was poſſible to diſcover whether the tendency of the matter of which the planets conſiſted was directed to a mathematical centre void of any phyſical properties, or whether it was the reſult of its united tendency to all the matter of the planet. He demonſtrated that if the earth conſiſted of matter which tended to the centre, it behoved it to aſſume the form of an elliptical ſpheroid, in conſequence of the centrifugal force ariſing from its diurnal motion, and that the polar axis muſt be to its equatorial diameter as 577 to 578; but if every particle tends to every other particle in the inverſe duplicate ratio of the diſtance from it, the form muſt ſtill be elliptical, but more protuberant, and the polar axis muſt be to the equatorial diameter as 230 to 231. Then only will a column of water from the pole to the centre balance a column from the equator to the centre. He alſo ſhewed what ſhould be the vibrations of pendulums in different latitudes, on both ſuppoſitions. Mathematicians were eager therefore to make thoſe experiments on pendulums, and to determine the figure of the earth by the meaſurement of degrees of the meridian in different latitudes. The reſult of their endeavours has been decidedly in favours of the mutual tendency of all matter. This has been farther confirmed by the obſervations of the mathematicians who meaſured the degrees of the meridian in Peru, and by Dr Maſkelyne in Britain, who found that a pendulum ſuſpended in the neigbourhood of a great and ſolid mountain, ſenſibly deviated from the true vertical, and was deflected toward the mountain.

44 Proportional quantities of matter in the ſun and planets determined.

From a collective view of all theſe circumſtances, Sir Iſaac Newton concluded, with great confidence, that the deflection toward any planet was the united deflection toward every particle of matter contained in it. This enabled him to determine the intenſity of the planetary diſturbing forces, by previouſly aſcertaining the proportions of their quantities of matter. This proportion, the diſcovery of which ſeems above our reach, is eaſily aſcertained in all thoſe bodies which have others revolving round them: for the deflection of the revolving body, being occaſioned by all the matter in the central body, will be proportional *(cæteris paribus)* to the quantity of matter in the central body, and therefore will give us a meaſure of that quantity. Would we compare the quantity of matter in Jupiter with the quantity of matter in the ſun, we have only to ſuppoſe that a planet revolves round the ſun at the diſtance of Jupiter's fourth ſatellite. Kepler's third law will tell us the time of its revolution. The diſtances, in this caſe, being the ſame, the centripetal forces, and conſequently the quantities of matter in the central bodies, will be inverſely as the ſquares of the periodic times of the revolutions around them. In this way have the quantities of matter been determined for the Sun, the Earth, Jupiter, Saturn, and the laſt diſcovered planet. If the quantity in the Earth be conſidered as the unit, we have,

The Earth - - - - -	1
The newly diſcovered planet -	17,75
Saturn - - - - - -	86,16
Jupiter - - - - - -	317,1
The Sun - - - -	338343.

Thus we ſee that the ſun is incomparably bigger than any planet, having more than a thouſand times as much matter as Jupiter, the moſt maſſy of them all. There is a conſiderable uncertainty, however, in the proportion to the ſun, becauſe we do not know his diſtance nearer than within $\frac{1}{100}$th part. The proportions of the reſt to each other are more accurate. The quantities of matter in Mercury and Mars can only be gueſſed at: the quantity in Mercury may be called 0,1, and Mars may be called 0,12. Venus is ſuppoſed nearly equal to the Earth. This is concluded from the effect which ſhe produces on the preceſſion of the equinoxes and the equation of the ſun's motion. The moon is ſuppoſed to be about $\frac{1}{70}$th of the earth, from the effect ſhe produces on the tides and the preceſſion of the equinoxes, compared with thoſe produced by the ſun.

45 Sun's place and the tranſit of a planet determined exactly.

When theſe quantities of matter are introduced into the computation of the planetary inequalities, and the intenſity of the diſturbing forces aſſumed accordingly, the reſults of the computations tally ſo exactly with obſervation, that we can now determine the ſun's place for any moment within two or three ſeconds of a degree, and are certain of the tranſit of a planet within one beat of the clock!

Jam dubios nulla caligine prægravat error;
Queis ſuperum penetrare domos atque ardua cœli
Scandere ſublimis genii conceſſit acumen.

HALLEY.

46 Progreſs of Newton's diſcovery

Sir Iſaac Newton having already made the great diſcovery of an univerſal and mutual deflection of all the matter in the ſolar ſyſtem, was one day ſpeculating on this ſubject, and comparing it with other deflections which he obſerved among bodies, ſuch as magnets, &c. He conſidered terreſtrial gravity as a force of this kind. By the weight of terreſtrial bodies they kept united with the earth. By its weight was the water of the ocean formed into a ſphere. This force extended, without any remarkable diminution, to the tops of the higheſt mountains. Might it not reach much farther? May it not operate even at the diſtance of the moon? In the ſame manner that the planetary force deflects the moon from the tangent to her orbit, and cauſes her to deſcribe an ellipſe, the weight of a cannon ball deflects it from the line of its direction, and makes it deſcribe a parabola. What if the deflecting force which incurvates her path towards the earth be the ſimple weight of the moon? If the weight of a body be the ſame with the general planetary force, it will diminiſh as the ſquare of its diſtance from the earth increaſes. Therefore, ſaid he to himſelf, ſince the diſtance of the moon from the centre of the earth is about 50 times greater than the diſtance of the ſtone which I throw from my hand, and which is deflected 16 feet in one ſecond, the weight of this ſtone, if taken up to the height of the moon, ſhould be reduced to the 2500th part, and ſhould there deflect $\frac{1}{2500}$th of 16 feet in a ſecond; and the moon ſhould deflect

deflect as much from the tangent in a second. Having the dimensions, as he thought, of the moon's orbit, he immediately computed the moon's deflection in a second; but he found it considerably different from what he wished it to be. He therefore concluded that the planetary force was not the weight of the planet. For some years he thought no more of it: but one day, in the Royal Society, he heard an account read of measurements of a degree of the meridian, which shewed him that the radius of the earth and the distance of the moon were very different from what he had believed them to be. When he went home he repeated his computation, and found, that the deflection of a stone was to the simultaneous deflection of the moon as the square of the moon's distance from the centre of the earth to the square of the stone's distance. Therefore the moon is deflected by its weight; and the fall of a stone is just a particular instance of the exertion of the universal planetary force. This computation was but roughly made at first; but it was this coincidence that excited the philosopher to a more attentive review of the whole subject. When every circumstance which can affect the result is taken into account, the coincidence is found to be most accurate. The fall of the stone is not the full effect of its weight; for it is diminished by the rotation of the earth round its axis: It is also diminished by the weight of the air which it displaces: It is also diminished by its tendency to the moon. On the other hand, the moon does not revolve round the earth, but round a common centre of the earth and moon, and its period is about $\frac{1}{110}$th shorter than if it revolved round the earth; and the moon's deflection is affected by the sun's disturbing force. But all these corrections can be accurately made, and the ratio of the full weight of the stone to the full deflection of the moon ascertained. This has been done.

Terrestrial gravity therefore, or that power by which bodies fall or press on their supports, is only a particular instance of that general tendency by which the planets are retained in their orbits. Bodies may be said to *gravitate* when they give indications of their being *gravis* or heavy, that is, when they fall or press on their supports; therefore the planets may be said to gravitate when they give similar indications of the same tendency by their curvelineal motions. The general FACT, that the bodies of the solar system are mutually deflected toward each other, may be expressed by the verbal noun GRAVITATION. Gravitation does not express a quality, but an event, a deflection, or a pressure.

The weight of a terrestrial body, or its pressure on its support, is the effect of the accumulated gravitation of all its particles; for bodies of every kind of matter fall equally fast. This has been ascertained with the utmost accuracy by Sir Isaac Newton, by comparing the
47 The universal law of gravitation,
vibrations of pendulums made of every kind of matter. Therefore their united gravitation is proportional to their quantity of matter; and we have concluded, that every atom of terrestrial matter is heavy, and equally heavy. We extend this conclusion to the sun and planets, and say, that the observed gravitation of a planet is the united gravitation of every particle. Therefore Sir Isaac Newton inferred, from a collected view of all the phenomena, that *all matter gravitates to* all matter with a force in the inverse duplicate ratio of the distance.

But we do not think that this inference is absolutely certain. We acknowledge that the experiments on pendulums, consisting of a vast variety of terrestrial matter, all of which performed their oscillations in equal times, demonstrate that the acceleration of gravity on those pendulums was proportional to their quantities of matter, and that equal gravitation may be affirmed of all terrestrial matter.

The elliptical motion of a planet is full proof that the accelerating power of its gravity varies in the inverse duplicate ratio of the distance; and the proportionality of the squares of the periods to the cubes of the distances, shews that the whole gravitations of the planets vary by the same law. But this third observation of Kepler might have been the same, although the gravitation of a particle of matter in Jupiter had been equal to that of a particle of terrestrial matter, provided that all the matter in Jupiter did not gravitate. If $\frac{1}{25}$th of Jupiter had been such gravitating matter, his deflection from the tangent of his orbit would have been the same as at present, and the time of his revolution would have been what we observe. In order that the third law of Kepler may hold true of the planetary motions, no more is required than that the accumulated gravitation of the planet be proportional to its quantity of matter, and thus the matter which does not gravitate will be compensated by the superior gravitation of the rest.

But because we have no authority for saying that there is matter which gravitates differently from the rest, or which does not gravitate, we are intitled to suppose that gravity operates alike on all matter.

And this is the ultimatum of the Newtonian philosophy, that the solar system consists of bodies composed of matter, every particle of which is, in fact, continually deflected by its weight toward every other particle in the system; and that this deflection, or actual deviation, or actual pressure, tending to deviation from uniform rectilineal motion, is in the inverse duplicate ratio of the distance. 48 Which is the ultimatum of his philosophy.

This doctrine has been called *the system of universal gravitation*; and it has been blamed as introducing an unphilosophical principle into science. Gravitation is said to be an occult quality; and therefore as unfit for the explanation of phenomena as any of the occult qualities of Aristotle. But this reproach is unfounded; gravitation does not express any quality whatever, but a matter of fact, an event, an actual deflection, or an actual pressure, producing an actual deflection of the body pressed. These are not occult, but matters of continual observation. True, indeed, Newton does not deny, although he does not positively say, that this deflection, pressure, or gravitation, is an effect having a cause. *Gravity* is said to be this cause. Gravity is the *being gravis or heavy*, and gravitation is the *giving indications of being heavy*. Heaviness therefore is the word which expresses *gravitas*, and our notion of the cause of the planetary deflections is the same with our notion of heaviness. This may be indistinct and unsatisfactory to a mind fastidiously curious; but nothing can be more familiar. The planet is deflected, *because it is heavy*. We are supposed to explain the fall of a stone through water very satisfactorily, and without having recourse to any occult quality, when we say that it is heavier than the water; and we explain the rise of a piece of cork, when we say that it is not so heavy as the water. 49 Objections to the law of gravitation ill-founded.

The

The explanations of the mutual actions of the planets are equally ſatisfactory, founded on the ſame principles, and equally free from all ſophiſtry or employment of occult cauſes. The weight of a body is not its heavineſs, but the effect of its heavineſs. It is a gravitation, an actual preſſure, indicated by its balancing the ſuppoſed heavineſs of another body, or by its balancing the known elaſticity of a ſpring, or by balancing any other natural power. It is ſimilar to the preſſure which a magnet exerts on a piece of iron. This may perhaps be produced by the impulſe of a ſtream of fluid; ſo may the weight of a heavy body. But we do not concern ourſelves with this queſtion. 50 Our knowledge of that law ſatisfactory. We gain a moſt extenſive and important knowledge by our knowledge of this univerſal law; for we can now explain every phenomenon, by pointing out how it is contained in this law; and we can predict the whole events of the ſolar ſyſtem with unerring exactneſs. This ſhould ſatisfy the moſt inquiſitive mind.

But, *nitimur in vetitum, ſemper cupimuſque negata.* There ſeems to be a fatal and ruinous diſpoſition in the human mind, a ſort of *priapiſm* of the underſtanding, that is irritated by every interdict of natural imperfection. We would take a microſcope to look at light; we would *know* what *knowing* is, and we would *weigh heavineſs.*

All who are acquainted with the writings of Ariſtotle have ſome notion of his whimſical opinions on this ſubject. He imagines that the planets are conducted in their orbits by a ſort of intelligences, ὥσπερ ψυχαι, which 51 Vain attempts to account for it. animate the orbs that wheel them round. Although this crude conception met with no favour in later times, another, not more reaſonable, was maintained by Leibnitz, who called every particle of matter a *monad*, and gave it a perception of its ſituation in the univerſe, of its diſtance and direction from every other, and a power and will to move itſelf in conformity to this ſituation, by certain conſtant laws. This ὥσπερ ψυχη in the Monad is nothing but an aukward ſubſtitute for the principle of gravitation, which the learned inſiſted that Newton placed in every particle of matter as an innate power, and which they reprobated as unphiloſophical. But in what reſpect this perception and active propenſity is better, we do not perceive. It is more complex, and involves every notion that is reprehenſible in the other; and it offers no better explanation of the phenomena.

But Newton is equally anxious with other philoſophers not to aſcribe gravity to matter as an innate inherent property. In a letter to Dr Bently, he earneſtly requeſts him not to charge him with ſuch an abſurd opinion. It is an avowed principle, that nothing can *act* on any thing that is at a diſtance; and this is conſidered as an intuitive axiom. But it is ſurely very obſcure; for we cannot obtain, or at leaſt convey, clear notions of the terms in which it is expreſſed. The word *act* is entirely figurative, borrowed from animal exertions; it is therefore unlike the expreſſion of any thing intitled to the appellation of *intuitive.* If we try to expreſs it without figure, we find our confidence in its certainty greatly diminiſhed. Should we ſay that the condition of a body A cannot depend on another body B that is at diſtance from it, we believe that no perſon will ſay that he makes this aſſertion from perceiving the abſurdity of the contrary propoſition. In the demonſtration, as it is called, of the perſeverance of a body in a ſtate of reſt, the only argument that is offered is, that no cauſe can be aſſigned why it ſhould move in one direction rather than in another: but ſhould any one ſay that another body is near it, to the right hand, and that this is a ſufficient reaſon for its moving that way, we know no method by which this aſſertion can be ſhewn to be falſe.

Such, however, has been the uniform opinion of philoſophers. *Nihil movetur* (ſays Leibnitz) *niſi a contigua et moto.* The celebrated mathematician Euler having diſcovered, as he thought, the production of a preſſure, like gravity, from motion, ſays, "as motion may ariſe from preſſing powers, ſo we have ſeen that preſſing powers may ariſe from motion. We ſee that both exiſt in the univerſe. It is the buſineſs of a philoſopher to diſcover, by reaſon and obſervation, which is the origin of the other. It is incompatible with reaſon that bodies ſhould be poſſeſſed of inherent tendencies; much more that powers ſhould exiſt independently. Farther, that philoſopher muſt be reckoned to have aſſigned the true cauſes of phenomena, who demonſtrates that they ariſe from motion; for motion, once exiſting, muſt be preſerved for ever. In the preſent inſtance (a certain whimſical fact of a ball running round the inſide of a hoop) we ſee how a preſſing power may be derived from motion; but we cannot ſee how powers can exert themſelves, or be preſerved, without motion. Wherefore we may conclude that gravity, and all other powers, are derived from motion; and it is our buſineſs to inveſtigate from what motions of what bodies each obſerved power derives its origin."

Accordingly many attempts have been made to trace the planetary deflections to their origin in the motion of ſome impelling matter; but theſe attempts could not be ſucceſsful, becauſe they are all built on hypotheſes. It has been aſſumed, that there is a matter diffuſed through the celeſtial ſpaces; that this matter is in motion, and by its impulſe moves the planets: but the only reaſon that can be given for the exiſtence of this matter is the difficulty we find in explaining the planetary deflections without it. Even if the legitimate conſequences of this hypotheſis were conſiſtent with the phenomena, we have not advanced in our knowledge, nor obtained any explanation. We have only learned, that the appearances are ſuch as would have obtained had ſuch a matter exiſted and acted in this manner. The obſerved laws of the phenomena are as extenſive as thoſe of the hypotheſis; therefore it teaches us nothing but what we knew without it.

But this is not all that can be ſaid againſt thoſe attempts; *their legitimate conſequences are inconſiſtent with the phenomena.* By legitimate conſequences we mean the laws of motion. Theſe muſt be admitted, and are admitted, by the philoſopher who attempts to explain the planetary motions by impulſe. It would be ridiculous to ſuppoſe a matter to fill the heavens, having laws of impulſe different from thoſe that are obſerved by common matter, and which laws muſt be *contrived* ſo as to anſwer the purpoſe. It would be more ſimple at once to aſſign thoſe *pro re nata* laws to the planets themſelves. 52 Inconſiſtency of ſome of theſe accounts with the phenomena.

Yet ſuch was the explanation which the celebrated Deſcartes offered by his hypotheſis of vortices, in which the planets were immerſed and whirled round the ſun. It

53 Vortices of Descartes. It is astonishing that so crude a conception ever obtained any partisans; yet it long maintained its authority, and still has zealous defenders. Till Sir Isaac Newton saw the indispensable necessity of mathematical investigation in every question of matter in motion, no person had taken the trouble of giving any thing like a distinct description of those vortices, the circumstances of their motion, and the manner of their action; all determined with that precision that is required in the explanation: for this must always be kept in mind, that we want an explanation of the precise motions *which have been observed*, and which will enable us to predict those which are yet to happen. Men were contented with some vague notion of a *sort* of similarity between the effects of such vortices and the planetary motions in a few general circumstances; and were neither at the trouble to consider how these motions were produced, nor how far they tallied with the phenomena. Their account of things was only fit for careless chat, but unworthy of the attention of a naturalist. But since this explanation came from a person deservedly very eminent, it was respected by Newton, and he honoured it with a serious examination.

54 Examined by Newton. It is to this examination alone that we are indebted for all the knowledge that we have of the constitution of a fluid vortex, of the motions of which it is susceptible, of the manner in which it can be produced, the laws of its circulation, and the effects which it can produce. We have this account in Sir Isaac Newton's Principles of Natural Philosophy; and it contains many very curious and interesting particulars, which have been found of great service in other branches of mechanical philosophy. But the result of the examination was fatal to the hypothesis; shewing that the motions which were possible in the vortices, and the effects which they must produce, are quite incompatible with the appearances in the heavens. We do not know one person who has acquired any reputation as a mechanician that now attempts to defend it; nor do we know of any other person besides Newton who has attempted to explain mathematically how the circulation of a fluid can produce the revolution of a planet, if we except Mr Leibnitz, the celebrated rival of the British philosopher.

55 Hypothesis of Leibnitz. This gentleman published in the Leipsic Review in 1689, three years after the publication of the *Principia*, an attempt to explain the elliptical motion of the planets, and the description of areas proportional to the times, by the impulse of a vortex. It must not be passed over in this place, because it acquired great authority in Germany, and many of that country still affirm that Leibnitz is the discoverer of the law of planetary gravitation, and of the mechanical constitution of the solar system. We cannot help thinking this explanation the most faulty of any, and a most disingenuous plagiarism from the writings of Newton.

Mr Leibnitz supposes a fluid, circulating round the sun in such a manner that the velocity of circulation in every part is inversely as its distance from the sun. (*N. B.* Newton had shewn that such a circulation was possible, and that it was the only one which could be generated in a fluid by an action proceeding from the centre). Leibnitz calls this *harmonical circulation.* He supposes that the planet adopts this circulation in every part of its elliptical orbit, obeying without any resistance the motion of this fluid. He does not ascribe this to the impulse of the fluid, saying *expressly* that the planet follows its motion, *non abrepta tamen, sed tranquilliter quasi natante.* The planet therefore has no tendency to persevere in its former state of motion. Why therefore does it not follow this harmonic motion exactly, and describe a circle *tranquilliter natans?* This is owing, says Leibnitz, to its centrifugal force, by which it perseveres in a state of rectilineal motion. It has no tendency to preserve its former velocity, but it perseveres in its former direction. The planet therefore is not like common matter, and has laws of motion peculiar to itself; it was needless therefore to employ any impulse to explain its motions. But to proceed: This centrifugal force must be counteracted in every point of the orbit. Leibnitz therefore supposes that it is also urged toward the centre by a solicitation like gravity or attraction. He calls it the *paracentric force.* He computes what must be its intensity in different parts of the orbit, in order to produce an elliptical motion, and he finds that it must be inversely as the square of the distance from the centre (for this reason he is frequently quoted by Bernoulli, Wolff, and others, as the discoverer of the law of gravitation). But Leibnitz arrives at this result by means of several mathematical blunders, either arising from his ignorance at that time of fluxionary geometry, or from his perceiving that an accurate procedure would lead him to a conclusion which he did not wish: for we have seen (and the demonstration is adopted by Leibnitz in all his posterior writings of this kind), that if the ordinary laws of motion are observed, a body, actuated by this paracentric force alone, will describe an ellipse, performing both its motion of harmonic circulation, and its motion of approach to and recess from the centre, without farther help. Therefore, if the harmonic circulation is produced by a vortex, a force inversely as the square of the distance from the centre, combined with the harmonic circulation, will produce a motion entirely different from the elliptical. It is demonstrated, that the force which is necessary for describing circles at different distances, with the angular velocity of the different parts of the orbit, is not in the inverse duplicate, but in the inverse triplicate, ratio of the distances. This must have been the nature of his paracentric force, in order to counteract the centrifugal force arising from the harmonic circulation. Therefore Leibnitz has not arrived at his conclusion by just reasoning, nor can be said to have discovered it. He says, *Video hanc propositionem innotuisse viro celiberrimo Isaaco Newtono, licet non possim judicare quomodo ad eam pervenerit.* This is really somewhat like impudence. — 56 Disingenuity of the author.

The *Principia* were published in 1686. They were reviewed at Leipsic, and the Review published in 1687. Leibnitz was at that time the principal manager of that Review. When Newton published, Leibnitz was living at Hanover, and a copy was sent him within two months of its publication, by Nicholas Facio, long before the Review. The language of the Review has several singularities, which are frequent in Leibnitz's own composition; and few doubt of its being his writing. Besides, this proposition in the *Principia* had been given to the Royal Society several years before, and was in the records before 1684. These were all seen by Leibnitz when in England, being lent him by his friend Collins.

We think that the opinion which a candid person must form of the whole is, that Leibnitz knew the proposition,

poſition, and attempted to demonſtrate it in a way that would make it paſs for his own diſcovery; or that he only knew the enunciation, without underſtanding the principles. His harmonic circulation is a clumſy way of explaining the proportionality of areas to the times; and even this circulation is borrowed from Newton's diſſertation on the Carteſian vortices, which is alſo contained in the Leipſic Review above mentioned. Leibnitz was by this time a competitor with Newton for the honour of inventing the fluxionary mathematics, and was not guiltleſs of acts of diſingenuity in aſſerting his claim. He publiſhed at the ſame time, in the ſame Review, an almoſt unintelligible diſſertation on the reſiſtance of fluids, which, when examined by one who has learned the ſubject by reading the *Principia* of Newton, affords an enigmatical deſcription of the very theory publiſhed by Newton, as a neceſſary part of his great work.

But beſides all the above objections to Leibnitz's theory of elliptical motion, we may aſk, What is this paracentric force? He calls it like gravity. This is preciſely Newton's doctrine. But Leibnitz ſuppoſes this alſo to be the impulſe of a fluid. It would have been enough had he explained the action of this fluid, without the other circulating harmonically. He defers this explanation, however, to another opportunity. It muſt have very ſingular properties: it muſt impel the planet without diſturbing the other fluid, or being diſturbed by it. He alſo defers to another opportunity the explaining how the ſquares of the periodic times of different planets are proportional to the cubes of the mean diſtances; for this is quite incompatible with the harmonic circulation of his vortex. This would make the ſquares of the periods proportional to the diſtances. He has performed neither of theſe promiſes. Several years after this he made a correction of one of his mathematical blunders, by which he deſtroyed the whole of his demonſtration. In ſhort, the whole is ſuch a heap of obſcure, vague, inconſiſtent aſſumptions, and ſo replete with mathematical errors, that it is aſtoniſhing that he had the ignorance or the effrontery to publiſh it.

57 Hypotheſis of Le Sage.

There is another hypotheſis that has acquired ſome reputation. M. le Sage of Geneva ſuppoſes, that there paſſes through every point of the univerſe a ſtream of fluid, in every direction, with aſtoniſhing velocity. He ſuppoſes that, in the denſeſt bodies, the vacuity is incomparably more bulky than the ſolid matter; ſo that a ſolid body ſomewhat reſembles a piece of wire cage-work. The quantity of fluid which paſſes through will be incomparably greater than that of the intercepted fluid; but the impulſe of the intercepted fluid will be ſenſibly proportional to the quantity of ſolid matter of the body. A ſingle body will be equally impelled in every direction, and will not be moved; but another body will intercept ſome fluid. Each will intercept ſome from the other; and the impulſe on B, that is intercepted by A, will be nearly proportional to the matter in A, and inverſely proportional to the ſquare of its diſtance from B; and thus the two bodies will appear to tend toward each other by the law of gravitation.

M. le Sage publiſhed this in a work called *Chimie Mechanique*, and read lectures on this doctrine for many years in Geneva and Paris to crowded audiences. It is alſo publiſhed by Mr Prevoſt in the Berlin Memoirs, under the name of *Lucrece Newtonien*; and there are many who conſider it as a good explanation of gravitation: for our part, we think it inconceivable. The motions of the planets, with undiminiſhed velocity, for more than four thouſand years, appears incompatible with the impelling power of this fluid, be its velocity what it will. The abſolute preciſion of the law of gravitation, which does not ſhew the ſmalleſt error during that time, is incompatible with an impulſe which cannot be *exactly* proportional to the quantity of matter, nor to the reciprocal of the ſquare of the diſtance, nor the ſame on a body moving with the rapidity of the comet of 1680 in its perihelion, as on the planet Saturn, whoſe motion is almoſt incomparably ſlower. What is the origin of the motion of this fluid? Why does it not deſtroy itſelf by mutual impulſe, ſince it is continually paſſing through every point? &c.

58 Ether of Newton ſolves no difficulties.

We have already obſerved that Newton expreſſed the ſame anxiety to avoid the ſuppoſition of action among bodies at a diſtance. *He* alſo *ſeemed* to ſhow ſome diſpoſition to account for gravitation by the action of a contiguous fluid. This is the ſubterfuge ſo much recurred to by precipitate ſpeculatiſts, by the name of the *ether of Sir Iſaac Newton*. He ſuppoſes it highly elaſtic, and much rarer in the pores of bodies, and in their vicinity, than at a diſtance; therefore exceedingly rare in the ſun, and denſer as we recede from him. Being highly elaſtic, and repelled by all bodies, it muſt impel them to that ſide on which it is moſt rare; therefore it muſt impel them toward the ſun. This is enough of its general conſtitution to enable us to judge of its fitneſs for Newton's purpoſe. It is wholly unfit; for ſince it is fluid, unequally denſe and elaſtic, its particles are not in contact. Particles that are elaſtic, and in a ſtate of compreſſion, and in contact, cannot be fluid; they muſt be like ſo many blown bladders compreſſed in a box; therefore they are not in contact; therefore they are elaſtic by mutual repulſion; that is, by acting on each other at a diſtance. It is indifferent whether this diſtance is a million of miles, or the millionth part of a hair's breadth; therefore this fluid does not free Newton from the ſuppoſition which he wiſhes to avoid. Nay, it can be demonſtrated, that in order to form a fluid which ſhall vary in denſity from the ſun to the extremity of the ſolar ſyſtem, there muſt be a mutual repulſion *extending to that diſtance*. This is introducing millions of millions of the very difficulties which Newton wiſhed to avoid; for each particle preſents the ſame difficulty with a planet.

We would now aſk theſe atomical philoſophers, why they have, in all ages, been ſo anxious to trace the celeſtial motions to the effects of impulſe? They imagine that they have a clear perception of the communication of motion by impulſe, while their perception of the production of it in any other way is obſcure. Seeing, in a very numerous and familiar collection of facts, that motion *is* communicated by impulſe, they think that it is communicated in no other way, and that impulſe is the only moving power in nature.

59 Our notion of impulſe not clearer than of gravitation.

But is it true that our notion of impulſe is more clear than that of gravitation? Its being more familiar is no argument. A cauſe may be real, though it has exerted itſelf but once ſince the beginning of time. In no caſe do we *perceive* the exertion of the cauſe; we only perceive the change of motion. The conſtitution of our mind

mind makes us conſider this as an effect, indicating a cauſe which is inherent in that body which we always ſee aſſociated with that change. Granting that our perception of the perſeverance of matter in its ſtate of motion is intuitive, it by no means follows that the body A in motion muſt move the body B by ſtriking it. The moment it ſtrikes B, all the metaphyſical arguments for A's continuance in motion are at an end, and they are not in the leaſt affected by the ſuppoſition that A and B ſhould continue at reſt after the ſtroke; and we may defy any perſon to give an argument which will prove that B will be moved; nay, the very exiſtence of B may, for any thing we know to the contrary, be a ſufficient reaſon for the ceſſation of the motion of A. The production of motion in B, by the impulſe of A, muſt therefore ſtand on the ſame foundation with every other production of motion. It indicates a moving power in A; but this inherent power ſeems to have no dependence on the motion of A: (See what is contained in n° 81. of the article PHYSICS, and n° 67. of OPTICS of the *Encycl.*) We ſee there a motion produced in B without impulſe, and taken from A, ſimilar in every reſpect to every caſe of impulſe; and we ſee that the motion of A is neceſſary for producing ſuch a motion in B as is obſerved in all caſes of impulſe, merely in order that the moving power, which is inherent in A, whether it be in reſt or in motion, may act during a ſufficient time. Our confidence in the communication of motion, in the caſe mentioned there, is derived entirely from experience, which informs us that A poſſeſſes a moving power totally different from impulſe. Our belief of the impelling power of matter therefore does not neceſſarily flow from our intuitive knowledge of the perſeverance of matter, although it gives us the knowledge of this perſeverance. It is like a mathematical demonſtration, a road to the diſcovery of the property of figure, but not the cauſe of that property. The impulſion of matter is merely a fact, like its gravitation, and we know no more of the one than of the other.

It is not a clearer perception, therefore, which has procured this preference of impulſion as the ultimate explanation of motion, and has given riſe to all the fooliſh hypotheſes of planetary vortices, ethers, animal ſpirits, nervous fluids, and many other crude contrivances for explaining the abſtruſe phenomena of nature.

60 Impulſe rarely obſerved.

Nor does it deſerve any preference on account of its greater familiarity. Juſt the contrary; for one fact of undoubted impulſe, we ſee millions where no impulſe is obſerved. Conſider the motion produced by the exploſion of gunpowder. Where is the original impulſe? Suppoſe the impulſe of the firſt ſpark of fire to be immenſe, how comes it that a greater impulſe is produced by a greater quantity of gunpowder, a greater quantity of quieſcent matter? The ultimate impulſe on the bullet ſhould be leſs on this account. Here are plain exertions of moving powers, which are not reducible to impulſe. Conſider alſo the facts in animal motion. Reflect alſo, that there has been more motion, without any obſerved impulſe, produced in the waters of a river ſince the beginning of the world, than by all the impulſe that man has ever obſerved. Add to theſe, all the motions in magnetiſm, electricity, &c. Impulſe is therefore a phenomenon which is comparatively rare.

Have we ever obſerved motion communicated by pure impulſe, without the action of forces at a diſtance? This appears to us very doubtful. Every one acquainted with Newton's diſcoveries in optics will grant, that the colours which appear between two object-glaſſes of long teleſcopes, when they are preſſed together, demonſtrate that the glaſſes do not touch each other, except in the place where there is a black ſpot. It requires more than a thouſand pounds to produce a ſquare inch of this ſpot. Therefore every communication of motion between two pieces of glaſs, which can be produced by one of them ſtriking the other, is produced without impulſe, unleſs their mutual preſſure has exceeded 1000 pounds on the ſquare inch of the parts which act on each other. Nay, ſince we ſee that a black ſpot appears on the top of a ſoap bubble, in the middle of the coloured rings, we learn that there is a certain thickneſs at which light ceaſes to be viſibly reflected; therefore the black ſpot between the glaſſes does not prove that they touch in that part; therefore we cannot ſay that any force whatever can make them touch. The ultimate repulſion may be inſuperable. If this be the caſe, the production of motion by impulſe is, in every inſtance, like the production of motion between the magnets in n° 81. of the article PHYSICS in the *Encycl.* and is of the ſame kind with the production of motion by gravity.

61 Intervening fluids mually difficulties.

Therefore no explanation of gravitation can be derived from any hypotheſis whatever of intervening fluids. They only ſubſtitute millions of bodies for one, and ſtill leave the action *e diſtanti* the ſame difficulty as before. It is not in the leaſt neceſſary that we ſhall be able to conceive how a particle of matter can be influenced by another at a diſtance; if we have diſcovered in every inſtance the preciſe degree and direction of the effect of this influence, we have made a moſt important addition to our knowledge of nature; and our ſucceſs in the caſe of the power of gravity ſhould make us aſſiduous in our endeavours to diſcover, from the phenomena, the laws which regulate the other actions *e diſtanti*, which obſervation is daily finding out. A knowledge equally accurate of the law of magnetic and electric action may enable us to give theories of magnetiſm and electricity equally exact with the Newtonian theory of gravitation.

Having, we hope, evinced the truth of this theory, by following out the inveſtigations to which Newton was gradually led, we might proceed to conſider, in order, the complicated and ſubordinate phenomena which depend on it. The lunar and planetary inequalities are the ſubjects that naturally come firſt in our way; but they have already been explained in all the detail that this conciſe account will admit, as they occurred to Newton as teſts of the truth of his conjecture. If the law be ſuch as he ſuſpected, its conſequences muſt be ſo and ſo; if the celeſtial motions do not agree with them, the law muſt be rejected. We ſhall not repeat any thing therefore on this head, but confine our obſervations to ſuch applications of the theory of univerſal gravitation, as newly diſcovered objects, or the improvement of aſtronomical obſervation and of fluxionary analyſis, have enabled us to make ſince the time of Newton.

The ſubſerviency of the eclipſes of Jupiter's ſatellites to geography and navigation had occaſioned their motions to be very carefully obſerved, ever ſince theſe uſes of them were firſt ſuggeſted by Galileo, and their

 theory

theory is as far advanced as that of the primary planets. It has peculiar difficulties. Being very near to Jupiter, the great deviation of his figure from perfect sphericity makes the relation between their distances from his centre and their gravitations toward it vastly complicated. But this only excited the mathematicians so much the more to improve their analysis; and they saw, in this little system of Jupiter and his attendants, an epitome of the solar system, where the great rapidity of the motions must bring about in a short time every variety of configuration or relative position, and thus give us an example of those mutual disturbances of the primary planets, which require thousands of years for the discovery of their periods and limits. We have derived some very remarkable and useful pieces of information from this investigation; and have been led to the discovery of the eternal durability of the solar system, a thing which Newton greatly doubted of.

62 Eternal durability of the solar system

Mr Pound had observed long ago, that the irregularities of the three interior satellites were repeated in a period of 437 days; and this observation is found to be just to this day.

247 revolutions of the	first occupy	437d.	3h.	44′
123	second	437	3	42
61	third	437	3	36
26	fourth	435	14	16

This naturally led mathematicians to examine their motions, and see in what manner their relative positions or configurations, as they are called, corresponded to this period: and it is found, that the mean longitude of the first satellite, *minus* thrice the mean longitude of the second, *plus* twice the mean longitude of the third, always made 180 degrees. This requires that the mean motion of the first, added to twice that of the third, shall be equal to thrice the mean motion of the second. This correspondence of the mean motions is of itself a singular thing, and the odds against its probability seems infinitely great; and when we add to this the particular positions of the satellites in any one moment, which is necessary for the above constant relation of their longitudes, the improbability of the coincidence, as a thing quite fortuitous, becomes infinitely greater. Doubts were first entertained of the coincidence, because it was not indeed accurate to a second. The result of the investigation is curious. When we follow out the consequences of mutual gravitation, we find, that although neither the primitive motions of projection, nor the points of the orbit from which the satellites were projected, were *precisely* such as suited these observed relations of their revolutions and their contemporaneous longitudes; yet, if they differed from them only by very minute quantities, the mutual gravitations of the satellites would in time bring them into those positions, and those states of mean motion, that would induce the observed relations; and when they are once induced, they will be continued for ever. There will indeed be a small equation, depending on the degree of unsuitableness of the first motions and positions; and this causes the whole system to oscillate, as it were, a little, and but a very little way on each side of this exact and permanent state. The permanency of these relations will not be destroyed by any secular equations arising from external causes; such as the action of the fourth satellite, or of the sun, or of a resisting medium; because their mutual actions will distribute this equation as it did the original error.

This curious result came into view only by degrees, as analysis improved and the mathematicians were enabled to manage more complicated formulas, including more terms of the infinite serieses that were employed to express the different quantities. It is to M. de la Grange that we are indebted for the completion of the discovery of the permanency of the system in a state very little different from what obtains in any period of its existence. Although this required all the knowledge and address of this great mathematician, in the management of the most complicated analysis, the evidence of its truth may be perceived by any person acquainted with the mere elements of fluxionary geometry. The law of the composition of forces enables us to express every action of the mutual forces of the sun and planets by the sines and cosines of circular arches, which increase with an uniform motion, like the perpetual lapse of time. The nature of the circle shows, that the variations of the sines aud cosines are proportional to the cosines and sines of the same arches. The variations of their squares, cubes, or other powers, are proportional to the sines or cosines of the doubles or triples, or other multiples of the same arches. Therefore since the infinite serieses which express those actions of forces, and their variations, include only sines and cosines, with their powers and fluxions, it follows, that all accumulated forces, and variations of forces, and variations of variations, through infinite orders, are still expressible by repeated sums of sines or cosines, corresponding to arches which are generated by going round and round the circle. The analyst knows that these quantities become alternately positive and negative; and therefore, in whatever way they are compounded by addition of themselves, or their multiples, or both, we must always arrive at a period after which they will be repeated with all their intermediate variations. It may be extremely difficult, it may be impossible, in our present state of mathematical knowledge, to ascertain all those periods. It has required all the efforts of all the geniuses of Europe to manage the formulas which include terms containing the fourth and fifth powers of the eccentricities of the planetary orbits. Therefore the periods which we have already determined, and the limits to which the inequalities expressed by secular equations arrive, are still subjected to smaller corrections of incomparably longer periods, which arise from the terms neglected in our formulas. But the correction arising from any neglected term has a period and a limit; and thus it will happen that the system works itself into a state of permanency, containing many intervening apparent anomalies. The elliptical motion of the earth contains an anomaly or deviation from uniform circular motion; the action of Jupiter produces a deviation from this elliptical motion, which has a period depending on the configuration of the three bodies; Saturn introduces a deviation from this motion, which has also a period; and so on.

There is another accurate adjustment of motions which has attracted attention, as a thing in the highest degree improbable, in events wholly independent on each other. This is the exact coincidence of the period of the moon's revolution round the earth with that of her rotation round her own axis. The ellipticity or oval shape of the moon differs so insensibly from a sphere, that

that if the original rotation had differed considerably from the period of revolution, the pendular tendency to the earth could never have operated a change: but if the difference between those two motions was so small that the pendular tendency to the line joining the centres of the earth and moon was able to overcome it after some time, the pole of the lunar spheroid would deviate a little from the line joining the earth and moon, and then be brought back to it with an accelerated motion; would pass it as far on the other side, and then return again, vibrating perpetually to each side of the mean position of the *radius vector*. The extent of this vibration would depend on the original difference between the motion of rotation and the mean motion of revolution. This difference must have been very small, because this *pendular vibration* is not sensible from the earth. The observed LIBRATION of the moon is precisely what arises from the inequality of her orbital motion. For the same reasons, the effects of the secular equations of the moon (which would, in the course of ages, have brought her whole surface into our view, had her rotation been strictly uniform) are counteracted by her pendular tendency, which has a force sufficient to alter her rotation by nearly the same slow and insensible changes that obtain in her mean motions. The same causes also preserve the nodes of her equator and of her orbit in the same points of the ecliptic. The complete demonstration of this is perhaps the most delicate and elegant specimen that has been given of the modern analysis. We owe it to M. de la Grange: and he makes it appear that the figure of the moon is not that which a fluid sphere would acquire by its gravitation to the earth; it must be the effect of a more considerable ellipticity, or internal inequality of density.

63 Depends on the law of planetary deflection,

This permanency of the system, within very narrow limits of deviation from its present state, depends entirely on the law of planetary deflection. Had it been directly or inversely as the distance, the deviations would have been such as to have quickly rendered it wholly unfit for its present purposes. They would have been very great, had the planetary orbits differed much from circles; nay, had some of them moved in the opposite direction. The selection of this law, and this form of the orbits, strikes the mind of a Newton, and indeed any heart possessed of sensibility to moral or intellectual excellence, as a mark of wisdom prompted by benevolence. But De la Place and others, infected with the *Theophobia Gallica* engendered by our licentious desires, are eager to point it out as a mark of fatalism. They say that it is essential to all qualities that are diffused from a centre to diminish in the inverse duplicate ratio of the distance. But this is false, and *very false*: it is a mere geometrical conception. We indeed say, that the density of illumination decreases in this proportion; but who says that this is a quality? Whether it be considered as the emission of luminous corpuscles, or an undulation of an elastic fluid, it is not a quality emanating from a centre: and even in this estimation, it seems gratuitous, whether we shall consider the base of the luminous pyramid, or its whole contents, as the expression of the quantity. Nay, if all qualities must diminish at this rate, all action *e distanti* must do the same; for when the distances bear any great proportion to the diameters of the particles, their action deviates insensibly from this law, and is perceived only by the accumulation of its effects after a long time. It is only thus that the effects of the oblate figure of Jupiter are perceived in the motion of his satellites. The boasted sound philosophy, which sees fatal necessity where the *most successful students of nature* saw moral excellence, has derived very little credit or title to the name of *wisdom*, by letting loose all those propensities of the human heart which are essentially destructive of social happiness.

64 And evinces the wisdom of the Creator.

These propensities were always known to lurk in the heart of man; and those surely were the wisest who laboured to keep them in check by the influence of moral principles, and particularly by cherishing that disposition of the human heart which prompts us to see contrivance wherever we see nice and refined adjustment of means to ends; and, from the admirable beauty of the solar system, to cry out,

"These are thy glorious works, Parent of good!
"Almighty, thine this universal frame,
"Thus wond'rous fair; thyself how wond'rous then!
"Unspeakable, who sitt'st above these heavens,
"To us invisible, or dimly seen
"In these thy lowest works; yet these declare
"Thy goodness beyond thought, and power divine."

Par. Lost, b. v.

"But wandering oft, with brute unconscious gaze,
"Man marks not THEE, marks not the mighty hand
"That, ever busy, wheels the silent spheres."

THOMSON.

The most important addition (in a philosophical view) that has been made to astronomical science since the discovery of the aberration of light and the nutation of the earth's axis, is that of the rotation of Saturn's ring.

65 Saturn's ring.

The ring itself is an object quite singular; and when it was discovered that all the bodies which had any immediate connection with a planet were heavy, or gravitated toward that planet, it became an interesting question, what was the nature of this ring? what supported this immense arch of heavy matter without its resting on the planet; what maintains it in perpetual concentricity with the body of Saturn, and maintains its surface in one invariable position?

The theory of universal gravitation tells us what things are possible in the solar system; and our conjectures about the nature of this ring must always be regulated by the circumstance of its gravitation to the planet. Philosophers had at first supposed it to be a luminous atmosphere, thrown out into that form by the great centrifugal force arising from a rotation; but its well defined edge, and, in particular, its being two very narrow rings, extremely near each other, yet perfectly separate, rendered this opinion of its constitution more improbable.

66 Discovery of Dr Herschel relating to it.

Dr Herschel's discovery of brighter spots on its surface, and that those spots were permanent during the whole time of his observation, seems to make it more probable that the parts of the ring have a solid connection. Mr Herschel has discovered, by the help of those spots, that the ring turns round its axis, and that this axis is also the axis of Saturn's rotation. The time of rotation is 10h. $32\frac{1}{4}'$. But the other circumstances are not narrated with the precision sufficient for an accurate comparison with the theory of gravity. He informs us, that the radii of the four edges of the ring are 590, 751, 774, 830, of a certain scale, and that the angle

angle ſubtended by the ring at the mean diſtance from the earth is $46\frac{2}{5}''$. Therefore its elongation is $23\frac{1}{5}'$. The elongation of the ſecond Caſſinian ſatellite is $56''$, and its revolution is 2d. 17h. 44′. This ſhould give, by the third law of Kepler, 17h. 10′ for the revolution of the outer edge of the ring, or rather of an atom of that edge, in order that it may maintain itſelf in equilibrio. The ſame calculation applied to the outer edge of the inner ring gives about 13h. 36′; and we obtain 11h. 16′ for the inner edge of this ring. Such varieties are inconſiſtent with the permanent appearance of a ſpot. We may ſuppoſe the ring to be a luminous fluid or vapour, each particle of which maintains its ſituation by the law of planetary revolution. In ſuch a ſtate, it would conſiſt of concentric ſtrata, revolving more ſlowly as they were more remote from the planet, like the concentric ſtrata of a vortex, and therefore having a relative motion incompatible with the permanency of any ſpot. Beſides, the rotation obſerved by Herſchel is too rapid even for the innermoſt part of the ring. We think therefore that it conſiſts of cohering matter, and of conſiderable tenacity, at leaſt equal to that of a very clammy fluid, ſuch as melted glaſs.

We can tell the figure which a fluid ring muſt have, ſo that it may maintain its form by the mutual gravitation of its particles to each other, and their gravitation to the planet. Suppoſe it cut by a meridian. It may be in equilibrio if the ſection is an ellipſe, of which the longer axis is directed to the centre of the planet, and very ſmall in compariſon with its diſtance from the centre of the planet, and having the revolution of its middle round Saturn, ſuch as agrees with the Keplerean law. Theſe circumſtances are not very conſiſtent with the dimenſions of Saturn's inner ring. The diſtance between the middle of its breadth and the centre of Saturn is 670, and its breadth is 161′, nearly one-fourth of the diſtance from the centre of Saturn. De la Place ſays, that the revolution of the inner ring obſerved by Herſchel is very nearly that required by Kepler's law: but we cannot ſee the grounds of this aſſertion. The above compariſons with the ſecond Caſſinian ſatellite ſhows the contrary. The elongation of that ſatellite is taken from Bradley's obſervations, as is alſo its periodic time. A ring of detached particles revolving in 10h. $32\frac{1}{4}'$ muſt be of much ſmaller diameter than even the inner edge of Saturn's ring. Indeed the quantity of matter in it might be ſuch as to increaſe the gravitation conſiderably; but this would be ſeen by its diſturbing the ſeventh and ſixth ſatellites, which are exceedingly near it.

67
Its probable conſiſtency

We cannot help thinking therefore that it conſiſts of matter which has very conſiderable tenacity. An equatorial zone of matter, tenacious like melted glaſs, and whirled briſkly round, might be thrown off, and, retaining its great velocity, would ſtretch out while whirling, enlarging in diameter and diminiſhing in thickneſs or breadth, or both, till the centrifugal force was balanced by the united force of gravity and tenacity. We find that the equilibrium will not be ſenſibly diſturbed by conſiderable deviations, ſuch as unequal breadth, or even want of flatneſs. Such inequalities appear on this ring at the time of its diſparition, when its edge is turned to the ſun or to us. The appearances of its different ſides are then conſiderably different.

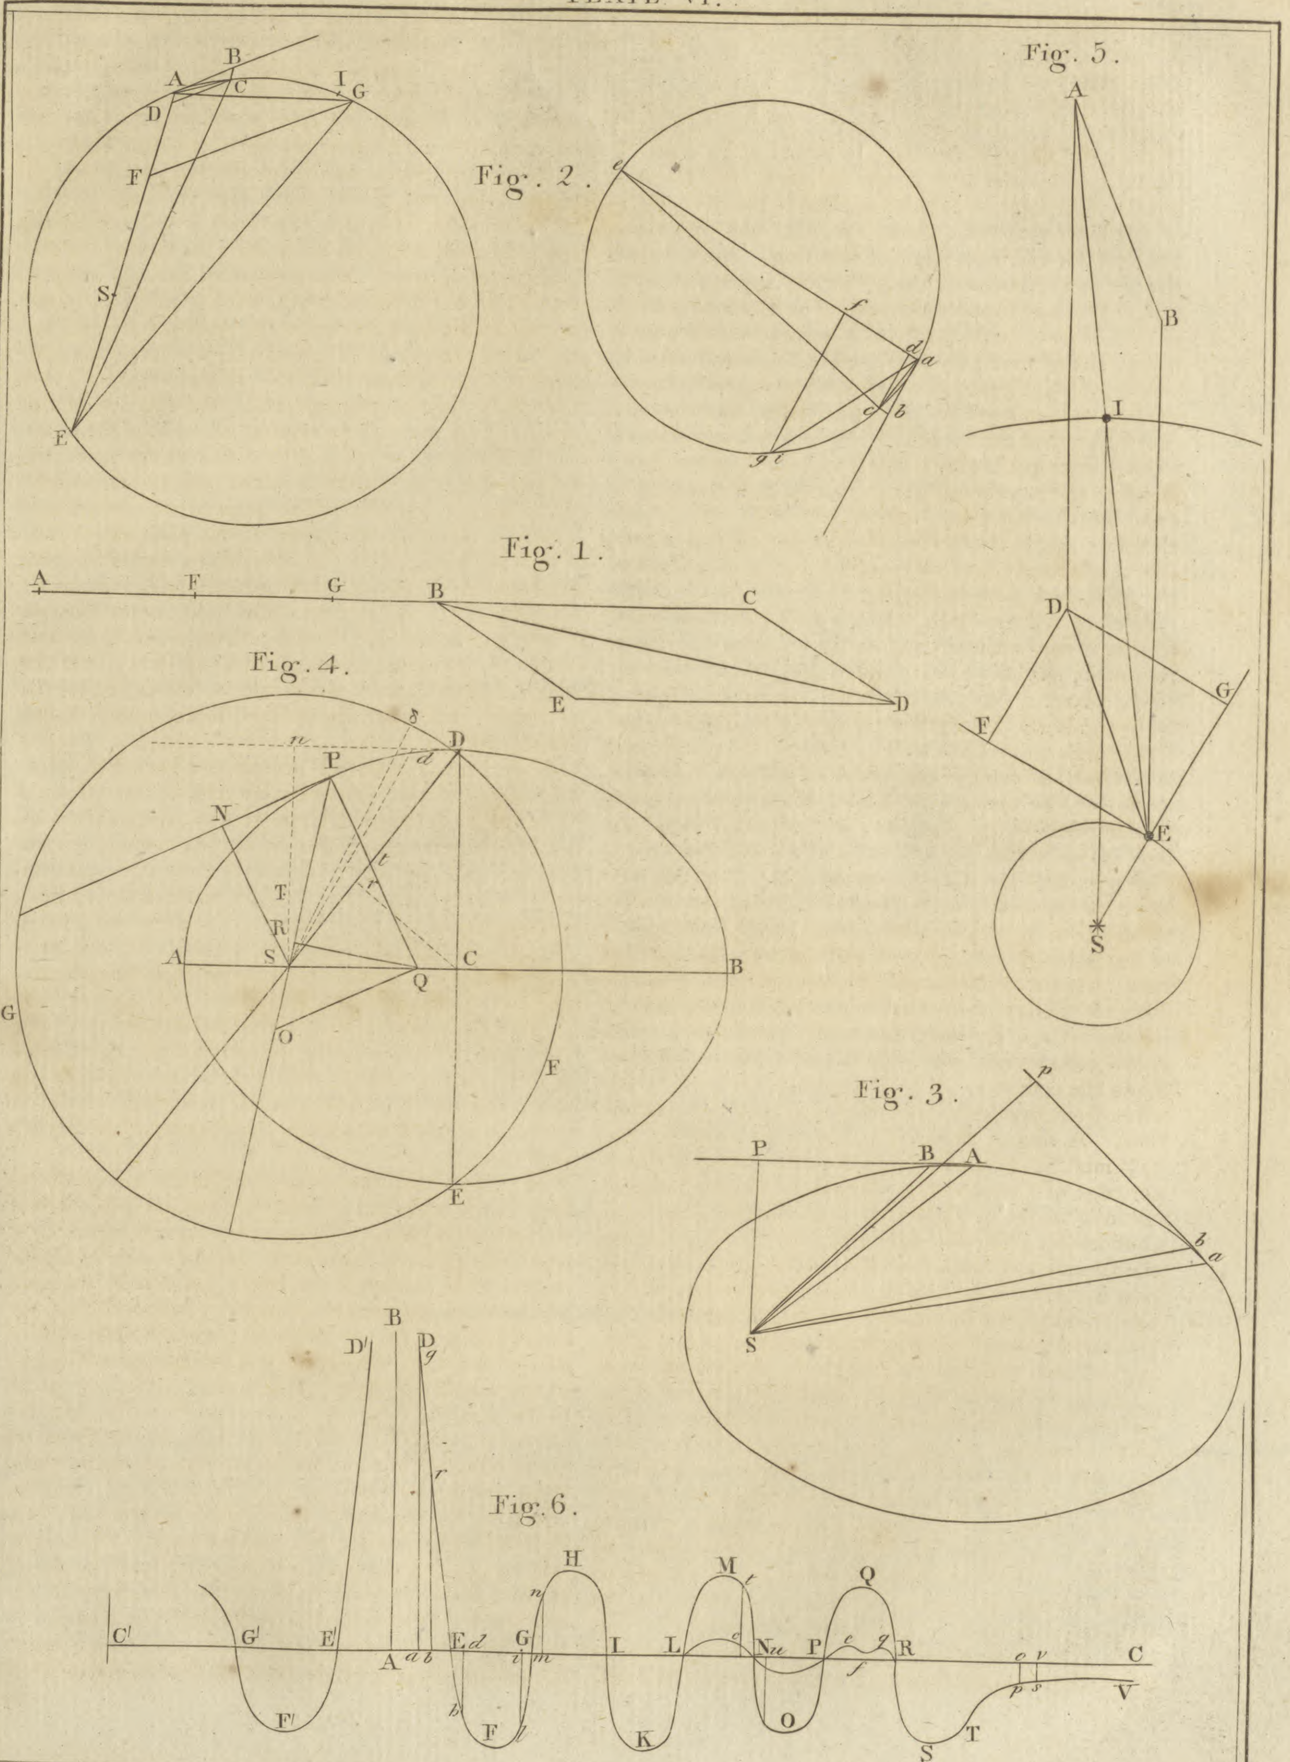
Such a ring or rings muſt have an oſcillatory motion round the centre of Saturn, in conſequence of their mutual action, and the action of the ſun, and their own irregularities: but there will be a certain poſition which they have a tendency to maintain, and to which they will be brought back, after deviating from it, by the ellipticity of Saturn, which is very great. The ſun will occaſion a nutation of Saturn's axis and a preceſſion of his equinoxes, and this will drag along with it both the rings and the neighbouring ſatellites.

The atmoſphere which ſurrounds a whirling planet cannot have all its parts circulating according to the third law of Kepler. The mutual attrition of the planet, and of the different ſtrata, ariſing from their different velocities, muſt accelerate the ſlowly moving ſtrata, and retard the rapid, till all acquire a velocity proportional to their diſtance from the axis of rotation; and this will be ſuch that the momentum of rotation of the planet and its atmoſphere remains always the ſame. It will ſwell out at the equator, and ſink at the poles, till the centrifugal force at the equator balances the weight of a ſuperficial particle. The greateſt ratio which the equatorial diameter can acquire to the polar axis is that of four to three, unleſs a coheſive force keeps the particles united, ſo that it conſtitutes a liquid, and not an elaſtic fluid like air; and an elaſtic fluid cannot form an atmoſphere bounded in its dimenſions, unleſs there be a certain rarity which takes away all elaſticity. If the equator ſwells beyond the dimenſion which makes the gravitation balance the centrifugal force, it muſt immediately diſſipate.

If we ſuppoſe that the atmoſphere has extended to this limit, and then condenſes by cold, or any chemical or other cauſe different from gravity, its rotation neceſſarily augments, preſerring its former momentum, and the limit will approach the axis; becauſe a greater velocity produces a greater centrifugal force, and requires a 68
greater gravitation to balance it. Such an atmoſphere And origin.
may therefore deſert, in ſucceſſion, zones of its own matter in the plane of its equator, and *leave* them revolving in the form of rings. It is not unlikely that the rings of Saturn may have been furniſhed in this very way; and the zones having acquired a common velocity in their different ſtrata, will preſerve it; and they are ſuſceptible of irregularities ariſing from local cauſes at the time of their ſeparation, which may afford permanent ſpots. 69

It may furniſh the means of diſcovering the nature of light.

We think that the rotation of Saturn's ring affords ſome hopes of deciding a very important queſtion about the nature of light. If light be the propagation of elaſtic undulations, its velocity depends entirely on the elaſticity and denſity of the fluid: but if it be the emiſſion of corpuſcles, their velocity may be affected by other cauſes. The velocity of Saturn's ring is $\frac{59}{63}$ of that of the earth in its orbit, and therefore about $\frac{1}{10000}$ of the velocity of light. The weſtern extremity (to us in the northern regions) is moving from us, and the eaſtern is moving toward us. If light, by which we ſee it, be reflected like an elaſtic ball from an elaſtic body, there will be an exceſs in the velocity of the light by which we ſee the eaſtern limb above the velocity of the light by which we ſee the weſtern limb. This exceſs will be $\frac{1}{2500}$ of the mean velocity of light. This ſhould be diſcovered by a difference in the refraction of the two lights. If an acromatic priſm could be made to refract fourteen degrees, and if Saturn be viewed through a teleſcope with this priſm placed before it, there ſhould



D. Lizars sculpt

be a change of ſhape amounting to ſixteen ſeconds; if the axis of the priſm be parallel to the longer axis of the ring, it will diſtort it prodigiouſly, and give it an oblique poſition.

A ſimilar effect will be produced by placing the priſm between the eye-glaſs and the image in the focus of the object-glaſs.

Our expectation is founded on this unqueſtionable principle in dynamics, that when a particle of light paſſes through the active ſtratum of a tranſparent body which refracts light toward the perpendicular, the addition made to the ſquare of its velocity by the refracting forces is equal to the ſquare of the velocity which thoſe forces would communicate to a particle at reſt on the ſurface of this refracting ſtratum of the tranſparent body. Therefore if the velocity of the incident light be increaſed, the ratio of the ſine of incidence to the ſine of refraction will be diminiſhed. It is conſonant to common ſenſe, that when the incident light has a greater velocity, it paſſes more rapidly through the attracting ſtratum, and a ſmaller addition is made to the velocity. When the velocity of the incident light is 10000 times greater than that of the earth's annual motion, the ſine of incidence is to the ſine of refraction in glaſs as 20 to 31, or as 10000 to 15500. If this be increaſed $\frac{1}{2500}$, making it 10004, the ratio will be that of 10004 to 15502,62, or of 10000 to 15496,4. The difference between the refractions of the light from the eaſtern and weſtern extremities of the ring will be, to all ſenſe, the ſame, if the velocity of the one be diminiſhed to 9998, and the other increaſed to 10002.

We may juſt add here, by the way, that the action of another body may conſiderably change the conſtitu-
70 Probable reaſon why we ſee no atmoſphere about the moon.
tion of this atmoſphere. Thus, ſuppoſing that the moon had originally an atmoſphere, the limit will be that diſtance from the moon where the centrifugal force, ariſing from the moon's rotation, added to the gravitation to the earth, balances the gravitation to the moon. If the moon be $\frac{1}{70}$th of the earth, this limit will be about $\frac{1}{9}$th of the moon's diſtance from the earth. If at this diſtance the elaſticity of the atmoſphere is not annihilated by its rarefaction, it will be all taken off by the earth, and accumulate round it. This may be the reaſon why we ſee no atmoſphere about the moon.

What has been ſaid in the article Tide (*Encycl.*), will explain the trade-winds on the earth and in Jupiter and Saturn. On the earth they are increaſed by the expanſion of the air by heat. This cauſes it to riſe in the parts warmed by the ſun, and flow off toward the poles, where it is again cooled and condenſed. The under ſtratum of colder and denſer air is continually flowing in from the poles. This having leſs velocity of circulation than the equatorial parts of the earth, muſt have a relative motion contrary to that of the earth, or from eaſt to weſt, and this muſt augment the current produced by gravitation.

Thus we ſee that all the mechanical phenomena of the ſolar ſyſtem, whether relating to the revolutions round the various centres of gravitation, or to the figure of the planets and the oſcillations of the fluids which cover them, or to the rotations round their reſpective axes—are neceſſary conſequences of one ſimple principle of a gravitation in every particle, decreaſing in the reciprocal duplicate ratio of the diſtance. We ſee that this, combined with a primitive projection, will produce every motion that we obſerve. It was not neceſſary, as Copernicus imagined, to impreſs three motions on the earth: one, by which it was made to revolve round the ſun; a ſecond, cauſing it to turn round an axis inclined to that of its orbit; and a third, by which this axis deſcribed that conic ſurface which forms the preceſſion of the equinoxes. One impulſe, not paſſing through the centre of the earth, nor in the plane of the ecliptic, will produce the two firſt motions, and the protuberant matter produced by the rotation will generate the third motion, by the tendency of its parts to the other heavenly bodies. Without this principle, the elliptic motion of the planets and comets, their various inequalities, ſecular or periodical, thoſe of the moon and of the ſatellites of Jupiter, the preceſſion of the equinoxes, the nutation of the earth's axis, the figure of the earth, the undulations of its ocean—all would have been imperfectly known, as matters of fact, wholly different from each other, and ſolitary and unconnected. It is truly deſerving admiration, that ſuch an immenſe variety of important phenomena flow ſo palpably from one principle, of ſuch ſimplicity, and ſuch univerſality, that no phenomenon is now left out unexplained, and predicted with a certainty almoſt equal to actual obſervation.

71 All the mechanical phenomena of the ſolar ſyſtem flow from one ſimple principle.

Quæ toties animos veterum torſêre ſophorum,
Quæque ſcholas hodie rauco certamine vexant,
Obvia conſpicimus, nubem pellente Matheſi.
Surgite mortales, terrenas mittite curas,
Atque hinc cæligenæ vires dignoſcite mentis,
A pecudum vitâ longe lateque remotæ.

Aſtrothemata || Aſymmetry.

ASTROTHEMATA, the places or poſitions of the ſtars, in an aſtrological ſcheme of the heavens.

ASTROTHESIA, is uſed by ſome for a conſtellation or collection of ſtars in the heavens.

ASTRUM, or Astron, a conſtellation or aſſemblage of ſtars: in which ſenſe it is diſtinguiſhed from *Aſter*, which denotes a ſingle ſtar. Some apply the term, in a more particular ſenſe, to the Great Dog, or rather to the large bright ſtar in his mouth.

ASYMMETRY, the want of proportion, otherwiſe called *incommenſurability*, or the relation of two quantities which have no common meaſure, as between 1 and $\sqrt{2}$, or the ſide and diagonal of a ſquare.

Aſymptotes.

ASYMPTOTES (ſee *Encycl.*) are, by ſome, diſtinguiſhed into various orders. The aſymptote is ſaid to be of the firſt order, when it coincides with the baſe of the curvilinear figure; of the ſecond order, when it is a right line parallel to the baſe; of the third order, when it is a right line oblique to the baſe; of the fourth order, when it is the common parabola, having its axis

axis perpendicular to the baſe; and, in general, of the $n+2$ order, when it is a parabola whoſe ordinate is always as the n power of the baſe. The aſymptote is oblique to the baſe, when the ratio of the firſt fluxion of the ordinate to the fluxion of the baſe approaches to an aſſignable ratio, as its limit; but it is parallel to the baſe, or coincides with it, when this limit is not aſſignable.

ATTAR OF ROSES. See *Roses, Otter of*, both in the Encyclopædia and in this Supplement.

AVANT FOSS, or *Ditch of the Counterſcarp*, in fortification, is a wet ditch ſurrounding the counterſcarp on the outer ſide, next to the country, at the foot of the glacis. It would not be proper to have ſuch a ditch if it could be laid dry, as it would then ſerve as a lodgment for the enemy.

AUBIGNE. See STUART in this Supplement.

AUMIL, in Bengal, a native collector or manager of a diſtrict on the part of government.

AUTENIQUA, a large and beautiful country in Africa, lying to the eaſt of the Cape of Good Hope, and inhabited, part of it, by Dutch coloniſts. The word *Auteniqua* ſignifies, in the Hottentot language, "a man loaded with honey:" a name which is not improperly given to the country, ſince, as you enter it from the Cape, you cannot proceed a ſtep without ſeeing a thouſand ſwarms of bees. The flowers on which they feed ſpring up in myriads; and your attention is engaged, and your courſe ſuſpended, by the mixed odours which exhale from them, by their colours and variety, and by the pure cool air which you breathe. Nature has made theſe enchanting regions like fairy land. The calyxes of all the flowers abound with excellent juices, from which the bees extract the honey that they everywhere depoſite in hollow rocks and trees.

This country was viſited in 1782 by M. Vaillant, who calls it the moſt delightful region in the univerſe; and ſays, that, as he approached it, he beheld, from the top of a very high mountain, an immenſe valley, adorned with agreeable hills, variegated in an infinite number of ſhapes, and extending in an undulating manner as far as the ſea; whilſt enamelled meads, and the moſt beautiful paſtures, ſtill added to the magnificent ſcene. It abounds with ſmall rivulets, which, flowing down from the mountains, run into the ſea through an hundred different channels. The water of theſe rivulets has the colour of Madeira wine, and a ferruginous taſte; but our traveller did not examine whether this taſte and colour proceed from their flowing through ſome mine in their paſſage, or from the roots and leaves of trees which they carry along with them.

The whole of Auteniqua, from the chain of mountains which divides it from the country of that race of Hottentots called *Gonaquas* to the ſea, is inhabited by ſeveral planters, who rear a number of cattle, make butter, cut down timber, and collect honey; all of which they tranſport to the Cape: but it appears that they make not the moſt of their ſituation. "Can it be believed (ſays M. Vaillant), that the directors of the Company, for their own uſe, ſhould order ſhips to be ſent every year from Amſterdam, loaded with planks and boards of every kind, whilſt in this country there are immenſe foreſts, and the moſt beautiful trees in the world? This abſurdity, however, is not at all aſtoniſhing. The Company gratuitouſly furniſhes the governor and all the officers with whatever wood they have occaſion for; and it is delivered to them at their houſes without any expence. The governor therefore has no *perſonal* intereſt to extend his views to this part of the adminiſtration, and to aboliſh an abuſe ſo prejudicial to the colony."

But the coloniſts themſelves muſt be a very indolent and ſtupid kind of people; ſince, if our traveller deſerves credit, they neglect advantages with which the perſonal intereſt of the governor cannot poſſibly interfere. "I was filled with indignation (ſays M. Vaillant) to ſee people, who have wood within their reach, employ it in commerce, and not have the courage to build for themſelves habitable houſes. They live in wretched hovels, conſtructed of wicker-work, daubed over with clay; the ſkin of a buffalo, fixed at the four corners to as many ſtakes, ſerves them for a bed; and the door, which is at the ſame time a window, is ſhut by a mat; while two or three mutilated chairs, a few pieces of plank, a kind of table, and a pitiful box of two feet ſquare, form all the furniture of theſe colonial habitations. Thus is the picture of the moſt profound miſery contraſted with the charms of this terreſtrial paradiſe; for the beauties of theſe regions extend even beyond Auteniqua. The people, however, though their houſes be bad, live well. They have game and ſalt-water fiſh in abundance; and enjoy excluſively, over all the other cantons of theſe colonies, the advantage of having, for the whole year without interruption, vegetables of every kind in their gardens. For this they are indebted to the excellence of the ſoil, and to its being naturally watered by ſmall ſtreams, which croſs each other in a thouſand different directions, and, as one may ſay, lay the four ſeaſons under contribution to fertilize Auteniqua. Theſe ſtreams, which frequently overflow their banks, but never dry up, proceed from a cauſe well known; the high mountains towards the eaſt, which are covered with foreſts, ſtop the clouds and the fogs carried from the ſea, and this occaſions very abundant rains."

In theſe mountainous regions, which, as well as the plain, our author comprehends under the denomination of *Auteniqua*, there are multitudes of elephants, buffaloes, panthers, hyenas, and antelopes of every ſpecies; and all theſe animals are hunted and killed by the natives, as well for food as for the protection of their flocks and herds from ſuch of them as are beaſts of prey. Our author has eaten the fleſh of every one of them except the hyena; and declares, that the foot of an elephant, baked after the Hottentot manner, is one of the moſt delicious morſels that he ever taſted. He gives directions for hunting them all; but warns his readers from attacking elephants when he finds them in droves, for then, he ſays, they are invincible. He even thinks it exceedingly dangerous for one man, however well armed, to attack a ſingle elephant in the plain. The buffalo he deſcribes, contrary to moſt other travellers, as a timid animal, which never reſiſts till his ſituation becomes deſperate; and he thinks that there would be no difficulty in training him, if caught when a calf, to the yoke like the bullocks of Europe.

The kites and vultures of this country, our traveller repreſents as in the higheſt degree voracious and fierce, inſomuch that it is hardly poſſible to fright them from their prey. He had on one occaſion killed two buffaloes, which

Auteniqua. which he ordered to be cut into very ſmall pieces, that they might be more eaſily ſalted, and expoſed afterwards to the air and the ſun. His wagons, as well as the buſhes and trees which ſurrounded him and his people, were loaded with the bloody fragments of theſe two animals, and they had begun their operation of ſalting; but on a ſudden, while they were not expecting it, they found themſelves attacked by flights of kites and vultures, which, without exhibiting the leaſt ſymptoms of fear, perched in the midſt of them. The kites were above all the moſt impudent. They ſeized upon the morſels of fleſh, and even contended furiouſly with his people. "When they had each carried away (ſays he) a pretty large piece, they retired to ſome branch, at the diſtance of ten paces from us, and devoured it before our eyes. Though we fired our fuſees they were not frightened, but returned inceſſantly to the charge; ſo that finding our powder waſted in vain, we reſolved to keep them off with large poles until our proviſions ſhould be quite dry. This manœuvre, which for a long time haraſſed my people, did not prevent us from being plundered without mercy; but had we not employed it, nothing would have remained to us of our two buffaloes."

This battle with the kites took place on the confines of the Dutch ſettlements; but when M. Vaillant had with difficulty paſſed over the mountains which bound them, the proſpects became more magnificent, the ſoil ſeemed to be more fruitful and rich, nature appeared to be more majeſtic and grand, and the lofty mountains preſented on all ſides more charming and delightful points of view than any that he had ever before met with. Theſe ſcenes, contraſted with the dry and parched fields of the Cape, made him exclaim, he ſays, in ecſtacy, "What! ſhall theſe ſuperb regions be eternally inhabited by tigers and lions? What ſpeculator, with the ſordid view only of eſtabliſhing a kind of centre for commerce, could have preferred the ſtormy Table Bay to the numberleſs roads and commodious harbours which are to be found on the eaſtern coaſts of Africa? Thus (continues he) was I reflecting within myſelf, whilſt I was climbing the mountain, and forming vain wiſhes for the conqueſt of this beautiful country, which the indolent policy of the European nations will perhaps never gratify."

If his deſcription of its beauties and fertility be not greatly exaggerated, it is indeed wonderful that either the Dutch or ſome other maritime power of Europe has not long ago taken poſſeſſion of it. After he had paſſed the mountain, one could not, he ſays, chooſe a more agreeable or advantageous ſpot than that upon which he then was for eſtabliſhing a thriving colony. The ſea advances through an opening of about a thouſand paces in breadth, and penetrates into the country to the diſtance of more than two leagues and a half. The baſon which it forms is more than a league in extent (he does not ſay whether in breadth or in circumference); and the whole coaſt, both on the right and the left, is bordered with rocks, which intercept all communication with it. The land is watered by limpid and refreſhing ſtreams, which flow down on all ſides from the eaſtern mountains; and theſe mountains, crowned with majeſtic woods, extending as far as the baſon, and winding round it with a number of ſinuoſities, exhibit a hundred groves, which are naturally variegated, and each more agreeable than another. Auteniqua.

The author proceeding forwards about two days journey, arrived at a bay known to navigators by the name of the Bay of *Agoa*, but called by the coloniſts *Blettenberg's* Bay, from its having been viſited ſome time before by a Governor Blettenberg, who ordered his name, together with the year and day of his arrival, to be engraven on a ſtone column. This bay is a little beyond the limits of the country called Auteniqua; but it is not foreign from the purpoſe of this article to inſert in this place our traveller's account of it, and of the country around it.

The bay itſelf, he ſays, is very ſpacious, and has a ſufficient depth of water for the largeſt veſſels. The anchoring ground is ſure, and boats can ſail to a beautiful part of the ſhore, which is not confined by the rocks, as they are all there detached from one another. By advancing a league along the coaſt, the crews would arrive at the mouth of a conſiderable river called the *Queur-Boom*, where they would find water. Refreſhments might be procured from the inhabitants of the environs; and the bay would ſupply them with excellent fiſh, with which it abounds.

This bay is one of thoſe places where government might eſtabliſh warehouſes and repoſitories for timber; and it is for this reaſon that we have introduced it to notice in this article. The foreſts around it, ſays M. Vaillant, are everywhere magnificent, and the trees could be more eaſily cut down than anywhere elſe; for it is not to ſteep mountains that one muſt go for wood, as at Auteniqua; it is here ready at hand; and during the fine monſoon might be tranſported to the Cape with little trouble and no riſk. The inexhauſtible and fertile lands in the neighbourhood of the bay, if once cultivated, would produce abundant crops, and draw together a great number of intelligent planters, on account of the ready communication which they would have with the Cape. In a word, the Company, continues he, have nothing to do ſo much for their own intereſt as to form here a proper eſtabliſhment. To the general profits of ſuch an inſtitution, would be added thoſe of individuals, which could not fail to be of great importance. They might, for example, cut down a certain tree called *ſtinking wood*, and export it to Europe, where it would undoubtedly be ſoon preferred to mahogany and every other kind of wood employed by cabinet makers.

The Hottentots, who in ſcattered *kraals* inhabit this delightful country, our author deſcribes as a faithful, gentle, and rather timid race. He affirms that they have no religious impreſſions whatever, nor any notion of ſuperior powers who govern the world. But this, if not a wilful falſehood dictated by the philoſophy of France, is probably a miſtake ariſing from his ſcanty knowledge of their language, and total ignorance of the meaning of their religious ceremonies. His great maſter, as well as the maſter of his ſect, *Lucretius*, might have taught him, that fear, if not a better principle, will generate the notion of ſuperior beings in the minds of ſavages; and from fear, by his own account, the inhabitants of Auteniqua are far from being free. He likewiſe affirms, and ſeems to conſider it as much to their credit, that this race of gentle beings, ſo far from being

Automaton

a prey to the paſſion of jealouſy (as other travellers have repreſented the Hottentots in general), are ſo obliging, as to lend their wives to travellers who viſit them, and that they actually accommodated his Hottentots in this way. Auteniqua, as laid down in M. Vaillant's map, lies between 32° 30′ and 34° 50′ of ſouth latitude, and between 20° and 23° 40′ of eaſt longitude; and his rout through the country was from ſouth-weſt to north-eaſt, or nearly ſo.

AUTOMATON. Under this title and that of ANDROIDES full credit was allowed in the *Encyclopædia Britannica* to the ſtory of M. de Kempel's mechanical *cheſs-player*, and a detail at ſome length was given of the feats of that figure, as well as of ſome other ſurpriſing *automata*. No man more readily admits the powers of the ſkilful mechanician than the writer of this ſhort article; but having many years ago detected the impoſition which was practiſed on the public in ſome parts of Scotland by a circumforaneous mountebank, who exhibited a figure apparently capable of writing a certain number of words, he has ever ſince ſuſpected impoſture in all automata which appear to have the power of varying their motions according to circumſtances. With reſpect to the *cheſs-player*, there is now ſufficient evidence that his ſuſpicions were well founded.

In the deſcription of this figure (*Encycl.* Vol. I. p. 787.), "it is ſaid that the automaton could not play unleſs M. de Kempel or his ſubſtitute was near it to direct its moves. A ſmall box during the game was frequently conſulted by the exhibiter; and herein conſiſted the ſecret, which he ſaid he could in a moment communicate." The ſecret was indeed ſimple: "A well taught boy, very thin and ſmall of his age, was concealed in this box almoſt immediately under the cheſs-board, and agitated the whole machine." This we learn from Thomas Collinſon, Eſq; who was let in- to the ſecret at Dreſden by a gentleman of rank and talents, named *Joſeph Freidrick Freyhere*, by whom the *vitality* and *ſoul* of the cheſs-playing figure had ſome time before been completely diſcovered. Mr Collinſon, finding that Dr Hutton had given the ſame credit with us to the reality of mechanical cheſs-playing, undeceived his friend, by communicating the diſcovery of Freyhere in a letter, which the Doctor has with great propriety publiſhed in the *Addenda* to his Mathematical Dictionary. Mr Collinſon adds, and we doubt not with truth, that, "even after this abatement of its being ſtrictly an automaton, much ingenuity remains to the contriver." This was in ſome degree true of the mechaniſm of the writing figure, of which the compiler of this article detected the bungling impoſture of the two exhibiters. The figure itſelf, with all the principles of its motion, were very ingeniouſly conſtructed; but the two men who exhibited it were ignorant and awkward, and could not conceal from a ſcrutinizing eye, that the automaton wrote ſometimes well and ſometimes ill, and never wrote at all when they were both preſent to the company. It was by inſiſting upon ſeeing them both together, and threatening to expoſe the cheat to the whole town, that the preſent writer prevailed upon him who appeared to be the principal exhibiter, to confeſs in private that his companion was concealed behind a ſcreen, and to ſhow how, from thence, he directed the movements of the figure.

Automaton, Axis.

CONJUGATE AXIS, or *Second Axis*, in the ellipſe and hyperbola, is the diameter paſſing through the centre, and perpendicular to the tranſverſe axis; and is the ſhorteſt of all the conjugate diameters.

Tranſverſe Axis, in the ellipſe and hyperbola, is the diameter paſſing through the two foci and the two principal vertices of the figure. In the hyperbola it is the ſhorteſt diameter, but in the ellipſe it is the longeſt.

B.

Bahrdt.

BAHRDT (Dr Carl Friedirich) was ſo deeply concerned in a combination of philoſophers formed, as they ſaid, for the advancement of ſcience and virtue, that an account of his life muſt be intereſting, if it were only to ſhow the effects of this philoſophic culture on his own morals. We truſt therefore that our readers will be pleaſed, perhaps improved, by the following narrative, taken from documents the moſt authentic, by a man* whoſe communications on other ſubjects do credit to this volume.

* See Profeſſor Robiſon of Edinburgh's *Proofs of a Conſpiracy againſt all the Religions and Governments of Europe.*

Carl Friedirich Bahrdt was, in 1741, born at Leipſig, where his father, then a pariſh miniſter, and afterwards profeſſor of theology, died in 1775. It is natural to ſuppoſe that ſuch a parent would be at due pains to inſtil into the mind of his ſon the principles of piety, virtue, and patriotiſm, which is indeed a branch of virtue; but if ſo, he lived to ſee that his labour had been in vain. While yet at college, where the courſe of his ſtudies was calculated to fit him for the important office of preaching the goſpel, the young man enliſted as a huſſar in the Pruſſian ſervice; but being bought off, he returned to the univerſity, where, in 1761, he was admitted to the degree of M. A. Soon afterwards he became catechiſt in his father's church, was a popular preacher, and in 1765 publiſhed ſermons, and ſome controverſial writings, which evinced that he poſſeſſed both learning and genius. Neither learning nor genius, however, nor both united, could attach him to the cauſe of virtue, or make him obſerve even the common rules of decorum; for immediately after this publication he began to indulge in conviviality, and to give ſcope to his reſentments in anonymous paſquinades, in the higheſt degree bitter and offenſive. From the ſhafts of his malice no perſon was ſafe. Profeſſors, magiſtrates, and

Bahrdt. and clergyman, had indeed his chief notice; but he condescended occasionally to attack students, and spared not even his own comrades or his friends.

Whilst he was thus labouring to make enemies of all to whom he was known, unfortunately, for his own character, his temperament was what the atomical philosophers (who can explain every thing by ethers and vibrations) call sanguine; and he was, as he himself acknowledged, a passionate admirer of the ladies. Coming home from his midnight revels, he frequently met in his way a young girl neatly dressed in a rose-coloured silk jacket and train, and a costly sable bonnet; and one evening, after having, as he says, indulged freely in some old Rhenish, he saw her home to her lodgings. Some time after this interview, the mistress of the house (a Madam Godschusky) came into his room, and said that the poor *maiden* whom he had debauched was pregnant. This was a misfortune *which he could not help;* but as it would ruin his character if known, he gave to the old lady a bond for 200 dahlers (about L.40 sterling), to be paid by instalments of twenty-five, to keep the matter secret. "The girl (he says) was *sensible* and *good;* and as her conversation, for which he had already paid, was agreeable, he did not discontinue his acquaintance."

It could not be supposed that such visits, by a clergyman, would pass unobserved, however cautiously made, in the midst of a town, of which the inhabitants had been the indiscriminate objects of his satire; and he could hardly be surprised when told by a friend, that one Bel, a magistrate whom he had lampooned, was accquainted with the whole affair, and would bring it into a court of justice, unless the bond was immediately retired.

This bond was the only evidence which could be produced against Bahrdt, but it was sufficient to blast his character in Leipsig, and must therefore by any means be removed out of the way. To accomplish this, however, was a matter of some difficulty; for neither he nor his friend could raise the money. In this dilemma they fell upon a contrivance worthy of themselves. They invited Madam Godschusky to meet them in another house to receive the 200 dahlers due to her by Bahrdt; but when she was ushered into the room, and found no person waiting for her but Bahrdt's friend, she could not be prevailed upon to produce the bond till the money should be put into her hands, together with a present to herself. The *Gentleman* tried to intimidate her. He drew his sword; showed her how men fence; made pushes at the wall and then at her: but finding that she could not be frightened out of her senses, he threw away his sword, and endeavoured to take the bond from her by force. It was some time before he prevailed; but at last getting the paper out of her pocket, he tore it in pieces, opened the door of a closet in which Bahrdt was concealed, and said, "There, you b——; there is the honourable fellow whom you and your whore have bullied; but it is with me you have now to do, and you know that I can bring you to the gallows."

Bahrdt, from whose memoirs of himself this story is taken, admits that there was a great squabble on the occasion; but he went home, comforting himself with the belief that he should now have no farther trouble from Madam Godschusky or her girl. He chanced, however, to be mistaken. The magistrate Bel had some how been made acquainted with this nefarious transaction, and brought it into court on the day that our hero was to make some very reverend appearance at church. The case of Bahrdt was now hopeless; for after some unsuccessful attempts of his poor father to save him, he was obliged to give in his gown and band, and to quit Leipsig.

Bahrdt. To a parent the public disgrace of a child is one of the severest calamities to which human nature is liable; but for this calamity the father of Bahrdt must have been long prepared, as his son appears to have been remarkably undutiful. Of this we have one memorable instance recorded by himself. His father, he says, was severe, and his own temperament hasty, so that he sometimes forgot himself. "One day (continues he) I laid a loaded pistol on the table, and told him that he should meet with that if he went on so; but I was then only SEVENTEEN!"

On his being obliged to leave the place of his nativity, the friends of Bahrdt, and in particular Semler, an eminent theological writer, who had formed a very favourable opinion of his talents, were assiduous in their endeavours to procure an establishment for him elsewhere; but his high opinion of himself, his impetuous and precipitant temper, and that satirical habit which he had so freely indulged in his outset in life, made their endeavours long ineffectual. At last he got a professorship at Erlangen, then at Ersurth, and in 1771 at Giessen. But in each of these places he was no sooner settled than he got into disputes with his colleagues and with the established church; for he was a strenuous partizan of the innovations then attempted to be made in the doctrines of Christianity. In his publications, which were generally anonymous, he did not trust to rational discussion alone, but had recourse to ridicule and personal anecdotes, and indulged in the most cutting sarcasms and gross scurrility.

His love for convivial company continuing, his income was insufficient for the craving demand. Finding therefore that anecdote and slander always procured readers, and possessing a wonderful activity and facility in writing, he never ceased from publishing lampoons and satires, in which he spared neither friends nor foes. But it was impossible to prevent these publications from being traced to their author; and his avowed theological writings being such as could not be suffered in a professor of divinity, the host of enemies which he had been at so much pains to raise against himself, were furnished with sufficient grounds for subjecting his conduct to legal cognizance; even the very students at Giessen were shocked at some of his liberties.

The consequence of all this was, that, after much wrangling in the church judicatories, he was just about to be dismissed from his professorship, when he got an invitation to Marschlins in Switzerland to superintend an academy.

To Marschlins he went about the year 1776, and began his new career by forming the seminary after the model of an academy which had some time before been set up in the principality of Anhalt Dessau by one Basedow, a man of talents and learning, who gave to it the appellation of PHILANTHROPINE. The plan of this academy was very different from those of the universities; for its author professed to consider languages, sciences, and the ornamental exercises, as mere accessories, Bahrdt. ries, his aim being to form the young mind to the love of mankind and of virtue, by a courfe of moral education certainly fpecious, and apparently unexceptionable. To make this novel inftitution the more extenfively ufeful, the rules by which the education was to be conducted were framed in fuch a manner as, it was thought, would remove from the minds of Catholics, Lutherans, and Calvinifts, all uneafinefs refpecting the faith of their children, as it related to thofe particular tenets which feparated them into different communions. It was even propofed to banifh from the philanthropine all *pofitive* religion whatever, and to inftruct the youth educated there in the principles only of natural, or, as it was called, *philofophical religion*.

This plan was peculiarly fuited to Bahrdt's tafte, becaufe it left him at liberty to introduce into his academy any fyftem of religious or irreligious opinions that he pleafed; a liberty of which he refolved to avail himfelf, and, though now a doctor in theology, to outftrip, in licentioufnefs, even the founder of the philanthropine, who was not in orders. By meditating on the workings of his own mind, he had by this time formed his theory of human nature, which was indeed very fimple. "The leading propenfities of the human mind (he fays) are three; inftinctive liberty, inftinctive activity, and inftinctive love." By thefe expreffions we fuppofe he means, "innate *love* of liberty, inftinct prompting to action, and the fexual appetite:" and he immediately adds, that "if a man is obftructed in the gratification of any of thefe propenfities, he fuffers an injury. The bufinefs therefore of a good education is to teach us how they are to be gratified in the higheft degree."

That fuch an education would be approved of by the uncorrupted natives of Switzerland was hardly to be expected; and Bahrdt foon found his fituation at Marfchlins as uncomfortable as it had been at Gieffen. "The Grifons (he fays) were a ftrong inftance of the immenfe importance of education. They knew nothing but their handicrafts; and their minds were as coarfe as their perfons." He quarrelled with them all, and was obliged to abfcond after lying fome time in prifon.

From Marfchlins he went to Durkheim, a town in the Palatinate, where his father had been minifter, and where his literary talents were well known. After fome little time he got an affociation formed for erecting and fupporting a *Philanthropine* or houfe of education. A large fund was collected; and he was enabled to travel into Holland and England to engage pupils, and was furnifhed with proper recommendations.

In London he gained the friendfhip of a clergyman, whom he reprefents as a perfon in the higheft degree accomplifhed. "With found judgment (fays Bahrdt), great genius, and correct tafte, he was perfectly a man of the world. He was my friend, and the only perfon who warmly interefted himfelf for my inftitution. To his earneft and repeated recommendations I owe all the pupils that I got in England, and many moft refpectable connections; for he was univerfally efteemed as a man of learning and of the moft unblemifhed character. He was my friend, my conductor, and I may fay my preferver; for when I had not bread for two days, he took me to his houfe, and fupplied all my wants."

For fo much kindnefs the reader doubtlefs fuppofes that the heart of Bahrdt overflowed with gratitude; but if fuch be his opinion, he is a ftranger to the principles of thofe who have on the continent of Europe affociated for the purpofe of enlightening the world. This amiable man, whofe character is here fo juftly drawn, was afterwards depicted by the monfter whom he had faved from perifhing by hunger, as a wretch loft to all fenfe of fhame and decency, as an apoftate from the Chriftian faith, and as a notorious frequenter of the London brothels! Fortunately he was able to vindicate his character completely from this flanderous abufe, and to convict Bahrdt of having publifhed what *could not poffibly be true*. Bahrdt.

This ungrateful liar returned from England, and carried into execution his plan of the Philanthropine. The caftle of Count Leining Hartzburgh at Heidefheim, having gardens, park, and every handfome accommodation, had been fitted up for it; and in 1778 it was confecrated by a folemn religious feftival. But his old misfortunes purfued him. He had indeed no colleagues with whom he could quarrel; but his *avowed* publications became every day more obnoxious; and when any of his *anonymous* pieces had a great run, he could not fo far ftifle his vanity as to conceal that he was the author. Of thefe pieces fome were fhocking to decency, and others fo horribly injurious to the characters of the moft refpectable men in the ftate, that he was continually under the correction of the courts of juftice. It was hardly poffible for a man of letters to be in his company, and not fuffer by it; for it was his conftant practice to attribute every ftep which he took towards atheifm, to the force of the arguments urged by fome of his friends.

To be his friend, or to obtain his applaufe, was indeed fo great a misfortune, that when the reader fees any perfon celebrated by Dr Bahrdt, in the beginning of a book, for found fenfe, profound judgment, accurate reafoning, or praifed for acts of friendfhip to himfelf, he may be affured, that before the clofe of the book this man fhall be reprefented as having in private converfation convinced the author, that fome doctrine, cherifhed and venerated by all Chriftians, is a piece of knavifh fuperftition.

Dr Bahrdt had married, while at Gieffen, a woman with a fmall fortune: but fuch a ftranger was he to the delicacies of wedded love, fo loft indeed to all fenfe of decency, that he contrived one day to entice his wife *naked* into the bath in the garden of his Philanthropine, where, in the water, he, being alfo *naked*, toyed with her in the fight of all his pupils. It was his boaft that he held his opinions independent of all mankind, and was indifferent whether they procured him praife or reproach; but it appears from this fact, that he was equally regardlefs of the praife or cenfure which might be attached to his actions; for furely the groffeft hog that ever before him battened in the Epicurean fty would not have prefented fuch an exhibition to boys.

The confequence of all this was, that he was obliged to fly from Heidefheim, leaving his fureties in the Philanthropine to pay about 14,000 dahlers, befides debts without number to his friends. He was imprifoned at Dienheim; but being foon releafed, he fettled at Halle, where he funk to be the keeper of a tavern and billiard-table. His houfe became of courfe the refort and the bane of the ftudents in the univerfity, and he was obliged to leave the city. He had fomehow got money fufficient to purchafe a little vineyard, pleafantly fituated

Bahrdt. ted in the neighbourhood. This he fitted up with every accommodation that could invite the ftudents, and called it *Bahrdt's Ruhe* (Bahrdt's repofe); where he lived for two years, directing the operations of a fecret fociety called the German Union, for rooting out Superstition and Prejudices, and for advancing true Christianity.

With Bahrdt's qualifications for advancing the interefts of genuine Chriftianity, the Chriftian reader is already fufficiently accquainted; but he will not wonder at his appointment to this high office, when he is informed that the German Union is nothing more than a fpawn of the fecret fociety of *Illuminati* (fee Illuminati in this Supplement); and that its object is to abolifh the religion of the gofpel, and to teach in its ftead the fatalifm of the Stoics. With this view Chriftianity is confidered in the union as a myftical fociety, and its Divine Founder as the grand mafter of a lodge! The apoftles Peter, James, John, and Andrew, were the elect, brethren of the *third* degree, and initiated into all the myfteries. The remaining apoftles were only of the *fecond* degree; and the feventy-two, of the *firft*: a degree into which ordinary Chriftians may be admitted, and prepared for farther advancement. The great myftery is, that J—— C—— was a naturalist, and taught the doctrine of a fupreme mind, the fpectator but not the governor of the world.

To propagate thefe impious and abfurd notions, Bahrdt publifhed many books of the moft antichriftian tendency, and fome of them calculated to make their readers fhake off all moral obligation. But the labours of the fociety were not confined to religion: it inculcated on its members the moft dangerous maxims of civil conduct: for, as we learn from Bahrdt himfelf, the objects at which the Union aimed were—*Advancement of fcience—a general intereft and concern for arts and learning—excitement of talents—check of fcribbling—good education*—liberty—equality—*hofpitality*—delivery of many from misfortunes—*union of the learned—and at laft—perhaps—Amen.*

What the meaning of this enigmatical conclufion is we can only guefs; and we agree with the real philofopher from whom we have taken this account, that our conjectures cannot be favourable. Bahrdt was a villain, and could be affociated only with villains, whofe affairs he managed with the help of an old man, who lived at bed and board in his houfe for about fix fhillings a-week, and difcharged the office of fecretary to the Union.

When he had toiled in this caufe near two years, fome of the fecrets of the Union tranfpired; his former conduct and his conftant imprudence made him fufpected; his affociated friends lodged informations againft him; his papers were feized; and he himfelf was fent to prifon, firft at Halle and then at Magdeburgh. After fomething more than a year's confinement, he was fet at liberty, and returned to his *Ruhe*, not, alas! to live at eafe, or to exhibit fymptoms of repentance, but to lie down on a fick-bed, where, after many months fuffering of increafing pain, he died on the 23d of April 1793, the moft wretched and loathfome victim of unbridled fenfuality.

Such were the fruits of the German Union, and of that illumination which was to refine the heart of man, and bring to maturity the feeds of native virtue, which are choaked in the heart by fuperftition and defpotifm. Dr Bahrdt affected to be the enlightener and reformer of the world; and affirmed that all the evils of life originated from defpotifm and fuperftition. "In vain (fays he) do we complain of the inefficacy of religion. All pofitive religion is founded on injuftice. No prince has a right to prefcribe or fanction any fuch fyftem; nor would he do it, were not the priefts the firmeft pillars of his tyranny, and fuperftition the ftrongeft fetters for his fubjects. He dares not fhow Religion as fhe is, pure and undefiled—fhe would charm the eyes and the hearts of mankind, would immediately produce true morality, would open the eyes of freeborn man, would teach him what are his rights and who are his oppreffors, and princes would vanifh from the face of the earth."

Therefore, without troubling ourfelves with the truth or falfehood of his religion of nature, and affuming it as an indifputable point, that Dr Bahrdt has feen it in this natural and fo effective purity, it is furely a very pertinent queftion, "Whether has the fight produced on his mind an effect fo far fuperior to the acknowledged faintnefs of the impreffion of Chriftianity on the bulk of mankind, that it will be prudent to adopt the plan of the German Union, and at once put an end to the divifions which fo unfortunately alienate the minds of profeffing Chriftians from each other?" The account here given of Dr Bahrdt's life feems to decide the queftion.

But it will be faid that we have only related fo many inftances of the quarrels of priefts and their flavifh adherents with Dr Bahrdt. Let us view him in his ordinary conduct, not as the champion and martyr of illumination, but as an ordinary citizen, a hufband, a father, a friend, a teacher of youth, a clergyman.

When Dr Bahrdt was a parifh minifter, and prefident of fome inferior ecclefiaftical diftrict, he was empowered to take off the cenfures of the church from a young woman who had born a baftard child. By violence he again reduced her to the fame condition, and efcaped cenfure by the poor girl's dying of a fever before her pregnancy was far advanced, or even legally documented. On the night of the folemn farce of confecrating his Philanthropine, he debauched the maid-fervant, who bore twins, and gave him up for the father. The thing was not judicially proved, but was afterwards made fufficiently evident by letters found among his papers, and publifhed by one of his friends in the Union. Having fupported thefe infants, in a pitiful manner, for little more than a year, he caufed them to be taken away from their mother, during night, fome time in the month of February 1780; and they were found expofed, the one at Ufstein, and the other at Worms, many miles diftant from each other, and almoft frozen to death.

So much for the purity of his morals and his religion, as he appears in the character of a father and of a clergyman. His *decency* as a hufband, and his gratitude to his friend, we have already feen; and we fhall now fee his kindnefs and fidelity. After wafting the greateft part of his wife's little fortune, he was fo provoked becaufe her brother would not give him up the remainder, amounting to about L.110, that he ever afterwards treated her with the greateft cruelty, and exhibited her to contempt and ridicule in two infamous novels. At Halle he brought a miftrefs into the houfe, and committed to her the care of his family, confining his wife and daughter to their own apartment;

Bahrdt, Bailly. apartment; and the laſt thing which he did was to ſend for a bookſeller, who had publiſhed ſome of his vileſt pieces, and, without a thought of his injured wife, recommend his ſtrumpet and her children to his protection.

"Think not, indignant reader (ſays Arbuthnot), that this man's life is uſeleſs to mortals." It ſhows in a ſtrong light the falſity of all his declamations in favour of his ſo much praiſed natural religion and univerſal kindneſs and humanity. No man of the party writes with more perſuaſive energy, and, though his petulance and precipitant ſelf-conceit lead him frequently aſtray, no man has occaſionally put all the arguments of theſe philoſophers in a clearer light; yet we ſee that all is falſe and hollow. He is a vile hypocrite, and the real aim of all his writings is to make money, by foſtering the ſenſual propenſities of human nature, although he ſees and feels that the completion of the plan of the German Union would be an event more deſtructive and lamentable than any that can be pointed out in the annals of ſuperſtition. We will not ſay that all the partiſans of illumination are hogs of the ſty of Epicurus like this wretch; and it would be extremely unjuſt to conſider his vices as the effects of his illumination. He was ſenſual, ungrateful, and profane, before he was admitted into the order of the *Illuminati;* but had the views of that order been ſuch as were held out to the world at large, its ſagacious founder would not have initiated a wretch ſo notoriouſly profligate as Dr Bahrdt. Their views, however, being to govern mankind thro' the medium of their ſenſual appetites, and to reign in hell, rather than ſerve in heaven, they could not have employed a better inſtrument. Dr Bahrdt was a true diſciple of illumination; and though his torch was made of the coarſeſt materials, and ſerved only to diſcover ſights of woe, the horrid glare darted into every corner, rouſing hundreds of filthy vermin, and directing their flight to the rotten carrion, where they could beſt depoſite their poiſon and their eggs. Whilſt the more decent members of the Union laboured to pervert the refined part of mankind by declamations on the rights of man and the bleſſings of liberty, Bahrdt addreſſed himſelf to readers of all deſcriptions, and aſſailed at once the imagination and the appetites. He taught them, that religion is an impoſture; that morality is convenience; and, with blaſphemy peculiar to himſelf, that he and his order, by their licentious doctrines, were to *complete the plan and aim of* J—— C——.

BAILLY (Jean-Sylvian), who made ſuch a figure during the firſt years of the French revolution, was born at Paris on the 15th of September 1736, of a family which had been diſtinguiſhed painters during four ſucceſſive generations. He was bred to the ſame profeſſion, but ſhowed an early taſte for poetry and the belles lettres. Chancing, however, to become acquainted with the geometer La Caille, this circumſtance decided his genius, and he thenceforth devoted himſelf to the cultivation of ſcience. He calculated the orbit of the comet of 1759; and on the 29th of January 1763 was received into the Academy of Sciences. In that year he publiſhed an uſeful and laborious compilation, being the reduction of the obſervations made by La Caille in 1760 and 1761, on the zodiacal ſtars. He likewiſe began to conſider the theory of Jupiter's ſatellites, and, in the competition for this prize queſtion of 1764, had a formidable rival in La Grange, who already promiſed to become the firſt mathematician in Europe. The reſults of his inveſtigations were collected into a treatiſe publiſhed in 1766, containing alſo the hiſtory of that part of aſtronomy. In 1771 he gave a moſt curious and important memoir on the light of the ſatellites, and introduced a degree of accuracy till then unknown in the obſervations of their eclipſes. Bailly.

His ſtudies were not confined to the abſtract ſciences; for he cultivated letters with ſucceſs. His eloges of Charles V. of Corneille, of Leibnitz, of Moliere, and afterward thoſe of Cook, La Caille, and Greſſet, were much admired. His eloquence pointed him out as a proper perſon to fill the charge, vacant in 1771, of ſecretary to the Academy of Sciences; and, under the patronage of Buffon, he ſtood candidate for that enviable place. He failed: but it was the high birth and promiſing talents of the young Condorcet, joined to the active influence of D'Alembert, that carried the prize.

In 1775 appeared the firſt volume of the Hiſtory of Aſtronomy, which indeed ſtrews the path of ſcience with flowers, and in every reſpect is a moſt valuable work—full of animated deſcription, of luminous narrative, and intereſting detail. His very peculiar ideas concerning the early ſtate of Upper Aſia gave riſe to an ingenious correſpondence and diſcuſſion with the veteran philoſopher Voltaire, the ſubſtance of which ſoon appeared in two volumes, intitled, "Letters on the Origin of Sciences," and "Letters on the Atlantide of Plato." If imagination ſhone forth in theſe eſſays, erudition was no leſs conſpicuous in a great work compoſed in the years 1781 and 1782, on the fables and religious creeds of antiquity; which ſtill exiſts in manuſcript, and the publication of which would aſſuredly extend the fame of its author, and gratify the learned world. His opinions on ſome points happening to coincide with the theories of Buffon, he contracted with that celebrated naturaliſt a cloſe friendſhip, which was diſſolved by Bailly's uncourtly oppoſition to the election of the Abbé Maury into the *Academie Françaiſe.* Of that academy he had been choſen ſecretary in 1784; and he was admitted, in the following year, into the Academy of Inſcriptions and Belles Lettres; the only inſtance, ſince Fontenelle, of the ſame perſon being at once a member of all the three academies. In the meantime, the other volumes of the Hiſtory of Aſtronomy ſucceſſively appeared, and that capital work was completed in 1787 by the Hiſtory of the Indian and Oriental Aſtronomy; a production of ſingular acuteneſs, reſearch, and nice calculation.

In 1784 he made an elegant report to the Academy of Sciences on the animal magnetiſm of Meſmer; and in 1786 another report, which diſplays the judgment and humanity of its author, on a project for a new *hotel-dieu* or infirmary.

We now approach the eventful period which ſummoned Bailly from his retirement, to enter on a political career, that was full of difficulty and danger, and for which his habits and ſtudies appear not to have fitted him. He had ſeen, as others ſaw, the defects of the old government of France. His heart panted for civil and eccleſiaſtical liberty; but unfortunately, like many other philoſophers both in his own country and in this, he had formed notions of that bleſſing which experience ſhould have taught him can never be realiſed among beings

Bailly. ings so imperfect as the bulk of mankind. When the states-general were summoned to meet, he was on the 26th of April 1789 nominated secretary by the electors of Paris, and then appointed one of the deputies. He was chosen president of the *Tiers Etat*; and when that chamber was constituted the National Assembly, he continued in the chair, and concurred in all the levelling decrees which laid the foundation of the present misery of his country, as well of most other countries of Europe.

After the taking of the Bastile, when the king was removed to Paris on the 15th of July, Bailly was called by public acclamation to the head of that city, with the title of *Mayor*. In his several functions he acted with integrity, courage, and moderation. He reached the summit of glory:—but how mutable, alas! is human grandeur! That middle course of conduct, the *aurea mediocritas*, at which virtue aims, is fitted to please neither of the contending parties in the midst of revolutions; and such proved the ruin of Bailly. His popularity began to decline, and was at length changed into inveterate enmity by an unfortunate accident. On the 17th of July 1791, the populace having collected tumultuously to demand the abolition of monarchy, Bailly was ordered by the National Assembly to disperse the mob. He was obliged to proceed to the Champ-de-Mars at the risk of his life; and, in spite of all his exertions and forbearance, some shots were fired by the soldiery. It was no longer desirable to hold his perilous charge, and on the 16th of November following he give way to the ascending reputation of Petion. The impaired state of his health, too, rendered it expedient to retire from the focus of turbulence. He spent the year 1792 and part of 1793 in travelling through different provinces of France. During this period he wrote memoirs of the events which he had witnessed, and in which he had often been a principal actor. These come down only to the 2d of October 1789, but would make a large quarto volume; and La Lande, from whose *Eloge de Bailly* this article is taken, gives us hopes that the manuscript will be published. He was advised by his friends to withdraw from France, but he chose rather, like Socrates, to submit to the injustice and ingratitude of his country. At the nod of a vulgar tyrant he was arrested, summarily condemned by a sanguinary tribunal, and on the 15th of November 1793 was delivered over to appease the vengeance of an incensed and indiscriminate populace. His sufferings were studiously protracted, but he bore them with the calmness and magnanimity of a sage. Nature recoils at the recital of such barbarities.

In 1787 M. Bailly married the widow of one who had been during 25 years his intimate friend; a woman more qualified by her age and condition to inspire respect than the passion of love. He was tall in his person, of a serious deportment, and joined firmness to sensibility. Never did philosopher distinguish himself in so many different lines, nor acquire such deserved reputation in them all. His disinterestedness was pure and unaffected; and during his magistracy he spent a part of his fortune in relieving the wants of the poor. His virtue remained as untainted in his various public stations as in the sweet retirement of domestic life.

Such is the encomium passed upon this philosopher and statesman by no less a man than the celebrated astronomer M. DE LA LANDE; but to those who are not infected with the *mania* of freedom, it will doubtless appear greatly exaggerated. That M. Bailly was a man of eminence in the republic of letters, is known to all the learned of Europe; that in his political conduct he meant to promote the good of his country, it would certainly be presumptuous in us to deny; and that he suffered unjustly, is incontrovertible: But let it be remembered that he suffered in a storm, which he exerted all his abilities to raise; and that he set an example of injustice, when he concurred in the degradation of the privileged orders, and in the violent confiscation of the property of the church.

BALIOL (John), the competitor with Bruce for the crown of Scotland, was not (as he is said to have been in the *Encyclopædia*) the brother of King ALEXANDER, but the great grandson of David Earl of Huntington, third son of King David I.

BALLISTIC PENDULUM, an ingenious machine invented by Benjamin Robins, for ascertaining the velocity of military projectiles, and consequently the force of fired gunpowder. It consists of a large block of wood, annexed to the end of a strong iron stem, having a cross steel axis at the other end, placed horizontally, about which the whole vibrates together like the pendulum of a clock. The machine being at rest, a piece of ordnance is pointed straight towards the wooden block or ball of this pendulum, and then discharged: the consequence is this—the ball discharged from the gun strikes and enters the block, and causes the pendulum to vibrate more or less according to the velocity of the projectile or the force of the blow; and by observing the extent of the vibration, the force of that blow becomes known, or the greatest velocity with which the block is moved out of its place, and consequently the velocity of the projectile itself which struck the blow and urged the pendulum. *Hutton's Dictionary.*

BANKA (see BANCA, *Encycl.*) is noted throughout Asia for its tin mines. It lies opposite to the river Palambang, in the island of Sumatra, on which the sovereign of Banka, possessor also of the territory of Palambang, keeps his constant residence. This prince maintains his authority over his own subjects, and his independence of the neighbouring sovereigns, chiefly by the assistance of the Dutch, who have a settlement and troops at Palambang, and enjoy the benefit of a contract with the king of Banka for the tin which his subjects procure from that island. Such at least was the case in 1793, when Lord Macartney touched at Banka on his way to China. At that period the sovereign compelled his subjects, and probably does so at present, to deliver the tin to him at a low price, and sold it to the Dutch at a small advance, pursuant to his contract. Those miners, from long practice, have arrived at great perfection in reducing the ore into metal, employing wood as fuel in their furnaces, and not fossile coal, or *coak*, which is seldom so free from sulphur as not to affect the malleability of the metal. It is sometimes preferred therefore to European tin at the Canton market; and the profit upon it to the Dutch company was, at the period mentioned above, supposed to have long been not less than L. 150,000 a-year. Into whose hands this trade has now fallen we know not; probably it is in a great degree neglected.

BANTAM, the capital of a kingdom of the same name in the island of Java, is, in the *Encyclopædia*, said

to

to be a large town with a good harbour and fortified castle. Sir George Staunton, however, who visited Bantam since that article was published, gives a very different account both of the town and of its harbour. Once indeed it was a place of considerable consequence, being the great mart for pepper and other spices, whence they were distributed to the rest of the world. The chief factory of the English as well as Dutch East India Company was settled there. The merchants of Arabia and Hindostan resorted to it. Its sovereigns were so desirous of encouraging trade, by giving security to foreign merchants against the violent and revengeful disposition of the natives, that the crime of murder was never pardoned when committed against a stranger, but might be commuted by a foreigner for a fine to the relations of the deceased. This place flourished for a considerable time; but the Dutch having conquered the neighbouring province of Jacatra, where they since have built Batavia, and transferred their principal business to it, and the English having removed to Hindostan and China, and trade in other respects having taken a new course, Bantam was reduced to a poor remnant of its former opulence and importance. Other circumstances have accelerated its decline. The bay is so choaked up with daily accessions of new earth washed down from the mountains, as well as by coral shoals extending a considerable way to the eastward, that it is inaccessible at present to vessels of burden; even the party who went there from the Lion, the ship which carried Lord Macartney to China, was obliged to remove from her pinnace into a canoe, in order to reach the town. With the trade of Bantam the power of its sovereign declined. In his wars with other princes of Java he called in the assistance of the Dutch; and from that period he became in fact their captive. He resides in a palace built in the European style, with a fort garrisoned by a detachment from Batavia, of which the commander takes his orders not from the king of Bantam, but from a Dutch chief or governor, who lives in another fort adjoining the town, and nearer to the sea-side. His Bantamese majesty is allowed, however, to maintain a body of native troops, and has several small armed vessels, by means of which he maintains authority over some parts of the south of Sumatra. His subjects are obliged to sell to him all the pepper they raise in either island, at a low price, which he is under contract with the Dutch to deliver to them at a small advance, and much under the marketable value of that commodity. The present king joins the spiritual to the temporal power, and is high priest of the religion of Mahomet; with which he mingles, indeed, some of the rites and superstitions of the aboriginal inhabitants of Java; adoring, for instance, the great banyan, or Indian fig-tree, which is likewise held sacred in Hindostan, and under which religious rites might be conveniently performed; in like manner, as all affairs of state are actually transacted by the Bantamese under some shadowing tree by moon-light. To complete the ruin of Bantam, a fire some time ago destroyed most of the houses, and few have been since rebuilt.

BANYAN-TREE. See FICUS, *Encycl.*

BRITISH BARILLA, is the name given by Mr James King of Newcastle upon Tyne, to a material invented by him to supply the place of Spanish barilla in the making of crown window-glass, broad window-glass, and glass-bottles, as also in the manufacturing of soap and alum. For these purposes he affirmed that it answered much better than any other material then in use; and in consequence of that affirmation he obtained a patent for his invention, dated March 4. 1780.

Though we can hardly allow to this invention all the merit claimed for it by its fond author, yet as it *may* be of use to different manufacturers, we shall lay before our readers his method of making the British barilla. It is as follows: "Take a certain quantity of ashes obtained by burning the loppings or branches of ash, oak, beech, elm, alder, or any other kind of green wood or bramble: Take an equal quantity of the ashes obtained by burning the green vegetables known by the name of fern, brecon, bean and pea-straw, whins, common field and high-way thistles, the stalks of rape or mustard-seed, or the bent or rushes that grow by the sea-shore." Though we know not in what qualities the ashes obtained from the former substances differ from those obtained from the latter, the author, as if the difference was very great, directs these equal quantities to be mixed together, sifted through a fine sieve, and laid upon a boarded floor, where a quantity of soapers waste-ashes, equal to the whole compound mass, is to be added to it, and well mixed with it by means of a shovel or other instrument. To this mixture of vegetable ashes and soapers waste-ashes is to be added a quantity of fine quick-lime, in the proportion of one hundred weight to twelve hundred of the blended ashes, and the lime and ashes are to be well mixed together. After this the whole is to be put into an iron pan, into which is to be poured a quantity of sea-water sufficient, says the author, to dissolve the ashes and lime; and the whole is to be stirred with an iron rake till it incorporate. This being done, a coal fire is to be lighted up under the pan, and kept burning for two days and two nights without intermission, additional quantities of sea-water being constantly supplied to impregnate the materials with saline matter sufficient for calcination in a reverberating furnace or calcar. In this calcar the saline mass, which was boiled in the pan, is by intense heat to be dissolved, and kept in a state of fusion for the space of an hour; during which time the volatile part flies off, and leaves remaining a fixed alkaline salt, which, cooled in iron pans, is the British barilla, and has the appearance of Spanish barilla. See BARILLA, *Encycl.*

BARTHELEMI (Jean Jacques), the Nestor of French literature, was a man so eminent for his knowledge of antiquities, that every classical reader must be interested in his fate. He was born, we believe, at Paris about the latter end of the year 1715; and being educated for the service of the church, he became prior of Courcay, keeper of the medals and antiques in the French king's cabinet, and in 1747 was elected a member of the Academy of Inscriptions. From that period his life was wholly devoted to letters; and in recording the principal events of it, we can only enumerate, in their order, his various publications.

A dissertation of his on the river Pactolus was read 1748 (*Hist. de l'Acad.* X. 29.); Reflections on a Medal of Xerxes, King of Arsamata (*Mem. de l'Acad.* XXXVII. 171.), found, or said to be found, by Fourmont in the temple of Apollo Anycleus (XXXIX. 129.); Essay on Numismatic Palæography, *ib.* 223; Dissertation on two Samaritan Medals of Antigonus

Barthelemi.

King of Judea, *ib.* 257; Remarks on ſome Inſcriptions publiſhed by different authors, XLV. 99; Diſſertation on Arabic Coins, *ib.* 143; by which it appears that the Mohammedan princes copied the heads of Greek and Roman ones on their coins, and gave Arabic inſcriptions of their own names on the reverſe. On the Ancient Alphabet and Language of Palmyra, *ib.* 179; on the Ancient Monuments of Rome, the reſult of a tour in Italy to collect medals for the royal cabinet, to which he added 300, XLIX. 151; on ſome Phœnician Monuments, and the Alphabets formed from them, LIII. 23. The characters on the written mountains, which he here cites, have been proved of no value; and he illuſtrates the conformity between the Phœnician and the Egyptian characters from the latter on the bandages of the mummies. Explanation of the Moſaic Pavement of the Temple of Præneſte, *ib.* 149; of which there have been four engravings ſince its firſt diſcovery in 1650, and which Barthelemi refers to the voyage of Adrian into Egypt. It may be of that date, but there is no reaſon to ſuppoſe that it repreſents any thing more than an Egyptian landſcape. The form of letters determines the date in the judgment of the learned Abbé. On the Relations of the Egyptian, Phœnician, and Greek Languages, LVII. 383; on ſome Medals publiſhed by different authors, LIX. 270; Explanation of an Inſcription under a Bas-relief in the Biſhop of Carpentras's Library, 1767, *ib.* 365; on the Number of Pieces repreſented in one Day on the Theatre at Athens, LXXII. 286; three Comedies, as many Tragedies, a Satire, and a Petite Piece; Remarks on ſome medals of the Emperor Antoninus ſtruck in Egypt, LXXX. 484. 1775 (A).

His interpretation of the Phœnician inſcription at Malta, LIII. 23, was controverted by our learned linguiſt, Mr Swinton, in Philoſ. Tranſact. LIV. art. xxii. p. 119; in farther remarks, *ib.* art. lxx. p. 393.

In 1792 he publiſhed a diſſertation on an ancient Greek inſcription, containing an account of expences of the public feaſts under the archontate of Glaucippus, 410 years before Chriſt.

The intimate acquaintance which he had cultivated with claſſical antiquity, enabled him, in the cloſe of a long life, to compoſe that *chef-d'œuvre*, the "Travels of the Younger Anacharſis into Greece" in the middle of the fourth century before the vulgar era. In repreſenting the curioſity of a Scythian ſavage (for we cannot conſider in any other light the man who put muſic and the exceſſes of the table on the ſame level), he takes occaſion to interweave very curious and inſtructive details on the laws, religion, manners, cuſtoms, and general ſpirit, of a great nation, as well as its progreſs in arts and ſciences. The epoch which he has choſen is that of letters and arts, combining the age of Pericles with that of Alexander, the revolution which changed the appearance of Greece, and ſoon after overturned the empire of Perſia. The introduction comprehends the 1250 years elapſed from the age of Cecrops to the ſuppoſed era of Anacharſis, in two intervals; the firſt reaching to the commencement of the Olympiads, the ſecond to the capture of Athens by the Lacedemonians. The hiſtory of the Athenians commences about 150 years after the firſt Olympiad, including the age of Solon, or that of legiſlation; that of Themiſtocles and Ariſtides, or that of glory, of luxury, and arts. In the ſecond, ſpeaking of war, his obſervation, that "the example of one nation, that prefers death to ſlavery, is too important and too inſtructive to be paſſed in ſilence," ſhould have preſerved him from the horrors of a long confinement in an advanced age, from which he was delivered only to die. But arts, ſciences, and literature, are alike forgotten and overwhelmed in France. In the third interval, ſpeaking of the corruption of manners introduced by Pericles to ſupport his power, he has this obſervation, applicable to every ſtate: "Corrupted morals are not reſtored but by the loſs of liberty, which brings that poverty inconſiſtent with ſoftneſs, and inſeparable from abſtemiouſneſs, if not that rigid principle of a healthy mind, which is properly called *virtue.*" In this period, though the arts were encouraged, philoſophy was neglected.

In this diverſified undertaking, where the picture of ancient Greece, in its minuteſt parts, both of public and private uſe, is brought before our eyes, the Abbé is frequently more brilliant than ſolid, and occaſionally loſes the ſubſtance of a reflection in purſuit of ſomething ingenious to add to it. The plans, views, and maps, are executed with great ſpirit and accuracy by Mr Barber, a young man of very promiſing talents; and to the charts many uſeful tables are added. The beauties of the claſſics are diffuſed in a very pleaſing manner, and interſperſed with anecdotes little known.

Such was the man whom the French government detained in priſon for months, and releaſed on the fall of Robeſpierre. As he concurred in the revolution, we know of no cauſe for his impriſonment but the mildneſs of his diſpoſition, and the jealouſy of that tyrant, which purſued, with relentleſs cruelty, every man ſuſpected of being a friend to peace. Of the perſecution of Barthelemi, in the extremity of old age, the convention itſelf ſeemed to be aſhamed; for it unanimouſly voted him a penſion as ſome recompence for his ſufferings. But, alas! the recompence came too late: the old man lived but a few months after his liberation, having died at Paris on the 4th of May 1795; and the day after the following tribute was paid to his memory by Duſſaulx, in the national convention:

"Legiſlators, your liberality conferred honour on the latter days of the life of our reſpectable fellow citizen, Barthelemi. Our ſucceſſors, I have no doubt, will conſecrate his memory ſo ſoon as the period fixed by the law ſhall permit them. May his old friend, however, be permitted, in a few words, to point out the rare qualities of that Neſtor of French literature? It might, perhaps, be ſufficient to tell you, as Xenophon ſaid with ſo much ſimplicity of one of his moſt illuſtrious contemporaries, that Barthelemi was an excellent man in all reſpects. In fact, thoſe who knew him were at a loſs which to admire moſt—his immortal Anacharſis, or his own life. His policy conſiſted in goodneſs; his ſcience was an immenſe treaſure of every thing that could purify the morals, perfect the taſte, render man more

(A) The references here are to the duodecimo edition of the Memoirs of the Academy of Inſcriptions.

more dear to man, and contribute to the ſplendour of his country. A ſingle trait will convince you of the mildneſs of his philanthropic mind: 'Why is it not permitted (he often ſaid) to a mortal to bequeath proſperity to his fellow-creatures?' After having been overwhelmed with the favours of fortune, which came unexpectedly and unſought, he became poor; yet his character, far from ſinking under the preſſure, acquired new reſpect; and he proved that poverty, ſupported with dignity, is not leſs honourable than wealth accompanied with benevolence. Perſecuted, as all virtuous and enlightened citizens were, he carried with him to the dungeon of that tyranny which you have ſo glorioufly deſtroyed, the conſtancy and ſerenity of Socrates. It was there that the venerable old man offered to his companions in misfortune the magnificent ſpectacle of a good man ſtruggling with adverſity. I have ſaid that he was rich; but let us not forget that he was not rich at the expence of the unfortunate, and that he adopted all the branches of his numerous family. The republic has gained by that family good citizens, who ſerve her in the moſt uſeful and brilliant manner. Barthelemi felt that the period of his diſſolution was approaching; yet though exhauſted by long fatigue, and bending beneath the weight of 80 years, his ſenſibility was ſtill vigorous, and your juſt decrees made the cloſing ſcene of his life happy. When he heard that you were endeavouring to repair the ills under which ſo many thouſand innocent men laboured, he lifted up his hands to heaven, and exclaimed, 'Glory to God—honour to the national convention—I have lived long enough!' In the preſent poſture of affairs, the country demands all your attention. I ſhall therefore confine myſelf to requeſt the favour due to the manes of the illuſtrious Barthelemi. One of his nephews, I do not mean your reſpectable ambaſſador at Baſle, but the citizen Courcey, has, for 25 years, diſcharged all the duties of a ſon to his uncle, and for a long time has performed the functions of keeper of the medals and antiquities of the national cabinet. I move, that the citizen Courcey be appointed to that office, which he has already proved himſelf ſo worthy to fill."

Whatever became of this motion, which was referred to the committee of public inſtruction, the cruelty of the government purſued the family; and the late baniſhment of his other nephew by the directory, of which he was a member, ſurpaſſes, if poſſible, the injuſtice of Robeſpierre to the uncle. But their crimes were the ſame: both Barthelemis were men of mild diſpoſitions and friends to peace.

BARYTES, one of the earths. See CHEMISTRY in this Supplement, Part I. Chap. iv.

BASTER, the name given by the Dutch at the Cape of Good Hope to the offspring of a white man and Hottentot woman.

BAT, an animal which has been deſcribed under its generic name VESPERTILLIO in the *Encycl.* but ſince that article was written, we have met with an account of a new ſpecies, ſo very ſingular, that, if the veracity of our author can be depended on, it is well intitled to a place here. This ſpecies was diſcovered in the country of the Nimiquas, in the interior of Africa, by *M. Vaillant*, during the courſe of his ſecond travels, and is by him called the *oreillar* bat. To this title it has indeed a very good claim; for it has, he ſays, four ears, or at leaſt the external part of four ears, each ear being double; the outer fold, which ſerves as a covering to the inner, is very ample, being two inches eight lines high, and nearly as broad when ſtretched out. On the noſe alſo a membrane ſtands erect, one inch four lines in height, which might be taken for another ear, as it has exactly the ſhape of one. This membrane, as well as the ears and wings of the animal, are of a ruſty red, paler below than above. The body is only three inches long, and is covered with very fine greyiſh hair. Its width, from the tip of one wing to that of the other, is eight inches. The reader will pardon me, ſays our author, for inſerting theſe trifling details of meaſurement, of which I am not more fond than himſelf; but they appeared to me neceſſary here, to convey an accurate idea of the extraordinary length of the ears of this animal, which are certainly larger in proportion than thoſe of any other we are acquainted with, ſince they are only four lines, or the third part of an inch, ſhorter than the body itſelf.

BATAVIA, the capital of the Dutch ſettlements in the Eaſt Indies, has been already deſcribed under the article JAVA in the Encyclopædia. The following account of it, however, as well as of the country around it, and the manners and cuſtoms of its various inhabitants, as they preſented themſelves to Sir George Staunton in March 1793, will probably prove acceptable to many of our readers.

The city of Batavia, including the ſuburbs, conſiſts of near eight thouſand houſes, inhabited by Dutch, Chineſe, and natives of Java. The houſes of the Chineſe are low, and crammed with people. The Dutch houſes are well built, clean, and ſpacious, and their conſtruction for the moſt part well ſuited to the climate. The doors and windows are wide and lofty. The ground floors are covered with flags of marble, which being ſprinkled frequently with water, give a pleaſant coolneſs to the apartment; but a conſiderable proportion of thoſe was untenanted, which denoted a declining ſettlement. Among other circumſtances which announced the ſame, were thoſe of the Company's veſſels lying uſeleſs in the road, for want of cargoes to fill, or men to navigate them; no ſhips of war to protect their commerce, even againſt pirates who attacked their veſſels ſometimes in the ſight of Batavia road; an invaſion threatened from the Iſle of France; the place in no condition of defence, particularly againſt an enemy leſs affected by the climate than Europeans; ſometimes as many of the troops in hoſpitals as fit for duty; commiſſioners expected from Holland to reform abuſes. Such a commiſſion, implying a general ſuſpicion, could not be welcome; nor was it quite certain whether, in ſome minds, its arrival, or that of the enemy, was deprecated the moſt cordially.

The fortifications of Batavia, though a place of ſo much importance, were not, when Sir George ſaw them, ſuch as would be deemed formidable in Europe; but when the difficulties were conſidered of forcing the paſſage of the river, or of landing troops on other parts of the iſland, it might perhaps be thought of greater ſtrength than it would at the firſt view have credit for. The defences of the river were the water fort, ſituated at its entrance, having mounted or diſmounted fourteen guns and two howitzers. It conſiſted of a parapet, originally well conſtructed, retained

by

Batavia.

by a wall; but the parapet was much neglected, and the wall nearly destroyed by the constant working of the sea. This fort was protected on the land side by a noxious swamp, and towards the sea, on the north-west, by extensive flats, over which even boats could not pass. The only good approach was that by the channel, which it sees and defends. The next work upon the river was on the west shore, about a quarter of a mile from the water fort. It is a battery mounting seven guns, bearing down the river. Opposite to this was a battery of six guns, facing the river, and two to the eastward. This formed one flank of a line that occupied the low land to the north-east of the town. The line was a low breast-work of earth, that was scarcely discoverable. The canals which intersect the town joined the great canal or river, at the distance of half a mile from the entrance. Below the junction a boom was laid of wood, armed with iron spikes. A little above was the castle, a regular square fort, but without ravelins or other outworks. It had two guns mounted on each flank, and two, or sometimes three, on each face: they were not *en barbette*, nor properly *en embrasure*, but in a situation between both, having both their disadvantages without the advantage of either. The wall was of masonry, about 24 feet high. It had no ditch, but a canal surrounded it at some distance. It had no cordon. The length of the exterior side of the work was about 700 feet. The town is rectangular, three quarters of a mile long, and half a mile broad, inclosed by a wall of about 20 feet in height. Small projections were constructed, of various forms, at intervals of about 350 feet. These generally mounted three guns each. It was also surrounded by a canal, having several sluices. At short distances from the town, three or four small star forts of earth were erected in particular passes, perhaps for defence against the inhabitants of the island.

The establishment of regular troops was 1200 Europeans, of whom 300 were to be artillery, the rest infantry. But as it was found impossible, on account of the climate, to keep the number complete, recourse was had to the natives, of whom 500 were employed; so that the establishment of European regulars was reduced to 700. There were also 300 volunteers of the town, who were formed into two companies, but they were not disciplined. Their regulars were very numerous, consisting of enrolled natives of Java, who were never embodied, and of Chinese, of whom the Dutch were so jealous as to arm them with lances only. Much dependence was not to be placed on the exertions of either of these bodies in favour of the Dutch; and as they lose many of their European troops every year, their establishment appeared too small for any effectual resistance. The chief protection of their ill-manned vessels lying here, must be from the fortified island of Onrust, well situated to command the channel that affords the principal passage into the road. The work upon that island was of a pentagonal form; its bastions were small and low, not more than 12 feet the highest, and not always connected by curtains. A few batteries were lately constructed on the outside of this work, that bore towards the sea. On these and on the bastions about 40 guns were mounted in different directions. South of these was another island, at the distance of a few hundred yards, on which two batteries, mounting together 12 guns, had been lately erected.

The castle is built of coral rock, brought from some of the adjoining islands, composed of that material; and has the advantage of a fortification of brick, in which cannon ball is apt to bury itself without spreading splinters or shattering the wall. A part of the town wall is built of lava, which is of a dark blue colour, of a very hard dense texture, emits a metallic sound, and resembles very much some of the lava of Vesuvius. It is brought from the mountains in the centre of Java, where a crater is still smoking. No stone of any kind is to be found for many miles behind the city of Batavia. Marble and granite are brought thither from China, in vessels belonging to that country, commonly called *junks*, which generally sail for Batavia from the ports of the provinces of Canton and Fokien, on the southern and south-east coasts of that empire, laden chiefly with tea, porcelain, and silks.

The chief protection of Batavia against the attacks of a foreign enemy, arises from the havoc which it is well known the climate would make amongst European troops. This was acknowledged to Lord Macartney by some of the Dutch officers themselves, and even by one of the counsellors of the Indies. Such indeed is the climate, that there have been very few examples of strangers remaining long in Batavia without being attacked by fever, which is the general denomination in that place for illness of every kind. Europeans soon after their arrival first become languid and feeble, and in a few weeks, or even in a few days, are taken seriously ill. The disorder at first is commonly a tertian ague, which after two or three paroxysms becomes a double tertian, and then a continued remittent, that frequently carries off the patient in a short time. Many fall victims to the second or third fit; but in these cases a constant delirium, and a great determination of the blood to the brain, accompany the other symptoms. In some it begins in a quotidian form, with regular intermissions for a day or two; and then becomes a continued remittent, attended with the same fatal consequences as the former. Of the Europeans of all classes who come to settle at Batavia, it is supposed that not half the number always survives the year. The place resembles in that respect a field of battle or a town besieged. The frequency of deaths renders familiar the mention of them, and little signs are shewn of emotion or surprise on hearing that the companion of yesterday is to-day no more. It is probable, female Europeans suffer less at Batavia than the men. The former seldom expose themselves to the heat of the sun, make frequent use of the cold bath, and live more temperately than the other sex.

But it is not to those who have lately arrived from Europe that this havoc is wholly confined. The greatest number of the Dutch settlers, even those who had resided long in the country, appeared wan, weak, and languid, as if labouring with the "disease of death." Their place of residence, indeed, is situated in the midst of swamps and stagnated pools, from whence they are every morning saluted with "a congregation of foul and pestilential vapours," whenever the sea breeze sets in, and blows over this morass. The meridian sun raises from the shallow and muddy canals, with which the town is intersected, deleterious miasmata into the air; and the trees, with which the quays and streets are crowded, emit noxious exhalations in the night.

The general reputation of the unhealthiness of Bata-

Batavia. via is indeed ſuch as to deter even Dutchmen, who can reſide at home with any comfort, from coming to it, notwithſtanding the temptation of fortunes to be quickly amaſſed in it. From this circumſtance it happens, that offices and profeſſions are often neceſſarily entruſted to perſons little qualified to fill them. One of the clergymen, and the principal phyſician of the place, were both ſaid to have originally been barbers. The United Provinces furniſh even few military recruits. The reſt are chiefly Germans, many of whom are ſaid to have been kidnapped into the ſervice. Though nominally permitted, after a certain length of time, to return home, they are in fact compelled to enliſt for a longer time, the pay being too ſcanty to allow them to ſave enough to defray the expence of their paſſage to Europe. The government is accuſed of the barbarous policy of intercepting all correſpondence between thoſe people and their mother country; by which means they are deprived of the conſolation of hearing from their friends, as well as of the chance of receiving ſuch aſſiſtance as might enable them to get home.

Difficult, however, as it is, on account of the climate, to recruit the army, ſuch is the deſire of accumulating wealth in a foreign land, that it draws annually great numbers of Chineſe as well as of Dutch to Batavia. Both indeed belong generally to the humbler claſſes of life, and are bred in ſimilar habits of induſtry in their own country; but the different circumſtances that attend them after their arrival in Batavia put an end to any further reſemblance between them. The Chineſe have there no way of getting forward but by the continuance of their former exertions in a place where they are more liberally rewarded, and by a ſtrict economy in the preſervation of their gains. They have no chance of advancing by favour, nor are public offices open to their ambition; but they apply to every induſtrious occupation, and obtain whatever either care or labour can accompliſh. They become in town retailers, clerks, and agents; in the country they are farmers, and are the principal cultivators of the ſugar-cane. They do at length acquire fortunes, which they value by the time and labour required to earn them. So gradual an acquiſition makes no change in their diſpoſition or mode of life. Their induſtry is not diminiſhed, nor their health impaired. The Dutch, on the contrary, who are ſent out by the Company to adminiſter their affairs in Aſia, become ſoon ſenſible that they have the power, wealth, and poſſeſſions of the country at their diſpoſal. They who ſurvive mount quickly into offices that are lucrative, and not to them laborious. They riſe to the dignity of governor-general and counſellors of the Indies, as the members of the Batavian government are called. Their influence likewiſe enables them to ſpeculate in trade with vaſt advantage. The drudgery and detail of buſineſs are readily undertaken by the Chineſe; while their principals find it difficult, under ſuch new circumſtances, to retain their former habits, or to reſiſt a propenſity to indolence and voluptuouſneſs, though often attended with the ſacrifice of health, if not of life. Convivial pleaſures, among others, are frequently carried to exceſs.

In ſeveral houſes of note throughout the ſettlement, the table is ſpread in the morning at an early hour: beſide tea, coffee, and chocolate, fiſh and fleſh are ſerved for breakfaſt; which is no ſooner over than Madeira, claret, gin, Dutch ſmall beer, and Engliſh porter, are laid out in the portico before the door of the great hall, and pipes and tobacco preſented to every gueſt, and a bright braſs jar placed before him to receive the phlegm which the tobacco frequently draws forth. This occupation continues ſometimes with little interruption till near dinner time, which is about one o'clock in the afternoon. It is not very uncommon for one man to drink a bottle of wine in this manner before dinner; and thoſe who have a predilection for the liquor of their own country ſwallow ſeveral bottles of Dutch ſmall beer, which they are told dilutes their blood, and affords plenty of fluids for a free perſpiration. Immediately before dinner, two men ſlaves go round with Madeira wine, of which each of the company takes a bumper as a tonic or whetter of the appetite. Then follow three females, one with a ſilver jar containing water, ſometimes roſe-water, to waſh; a ſecond with a ſilver baſon and low cover of the ſame metal, pierced with holes, to receive the water after being uſed; and the third with towels for wiping the hands. During dinner a band of muſic plays at a little diſtance: the muſicians are all ſlaves, and pains are taken to inſtruct them. A conſiderable number of female ſlaves attend at table, which is covered with a great variety of diſhes; but little is received, except liquors, into ſtomachs already cloyed. Coffee immediately follows dinner. The 24 hours are here divided, as to the manner of living, into two days and two nights; for each perſon retires, ſoon after drinking coffee, to a bed, which conſiſts of a mattraſs, bolſter, pillow, and chintz counterpane, but no ſheets; and puts on his night dreſs, or muſlin cap and looſe long cotton gown. If a bachelor, which is the caſe of much the greateſt number, a female ſlave attends to fan him while he ſleeps. About ſix they riſe, dreſs, drink tea, take an airing in their carriages, and form parties to ſpend the evening together to a late hour. The morning meetings conſiſt generally of men, the ladies ſeldom chooſing to appear till evening.

Few of theſe are natives of Europe, but many are deſcended from Dutch ſettlers here, and are educated with ſome care. The features and outlines of their faces are European; but the complexion, character, and mode of life, approach more to thoſe of the native inhabitants of Java. A pale languor overſpreads the countenance, and not the leaſt tint of roſe is ſeen in any cheek. While in their own houſes they dreſs like their ſlaves, with a long red checkered cotton gown deſcending to the ankles, with large wide ſleeves. They wear no head-dreſs, but plait their hair, and faſten it with a ſilver bodkin on the top of the head, like the country girls in ſeveral cantons of Switzerland. The colour of their hair is almoſt univerſally black; they anoint it with the oil of the cocoa nut, and adorn it with chaplets of flowers. When they go abroad to pay viſits, or to take an airing in their carriages, and particularly when they go to their evening parties, they dreſs magnificently, in gold and ſilver ſpangled muſlin robs, with a profuſion of jewels in their hair, which, however, is worn without powder. They never attempt to mould or regulate the ſhape by any fancied idea of elegance, or any ſtandard of faſhion; and conſequently formed a ſtriking contraſt with ſuch few ladies as were lately arrived from Holland, who had powdered hair and fair complexions, had contracted their waiſts with ſtays, wore

Batavia. wore large head-dreſſes and hoops, and perſevered in the early care of forcing back the elbows, chin, and ſhoulders. Every native lady is conſtantly attended by a female ſlave handſomely habited, who, as ſoon as her miſtreſs is ſeated, ſits at her feet before her, on the floor, holding in her hands her miſtreſs's gold or ſilver box, divided into compartments, to contain areca nut, cardamom ſeeds, pepper, tobacco, and ſlacked lime; all which, mixed together in due proportions, and rolled within a leaf of betel, conſtitute a maſticatory of a very pungent taſte, and in general uſe. When in the public aſſemblies the ladies find the heat diſagreeable, they retire to free themſelves from their coſtly but inconvenient habits, and return without ceremony in a more light and looſe attire, when they are ſcarcely recognizable by ſtrangers. The gentlemen follow the example; and throwing off their heavy and formal dreſſes, appear in white jackets, ſometimes indeed adorned with diamond buttons. The elderly gentlemen quit their periwigs for nightcaps. Except in theſe moments the members of this government have always combined their perſonal gratification with the eaſtern Policy of ſtriking awe into vulgar minds, by the aſſumption of exterior and excluſive diſtinctions. They alone, for inſtance, appear abroad in crimſon velvet. Their carriages are diſtinguiſhed by peculiar ornaments. When met by others, the latter muſt ſtop and pay homage to the former. One of the gates of the city is opened only to let them paſs. They certainly ſucceed in ſupporting abſolute ſway over a vaſt ſuperiority in number of the deſcendants of the original inhabitants of the country, as well as of the ſlaves imported into it, and of the Chineſe attracted to it by the hope of gain; thoſe claſſes, though healthy, active, and as if quite at home, readily obeying a few emaciated Europeans. Such is the conſequence of dominion once acquired; the prevalence of the mind over mere bodily exertions, and the effect of the combination of power againſt divided ſtrength.

The native Javaneſe are in general too remote from civilization to have any wants that are not eaſily ſatisfied in a warm and fertile climate. No attempt is made to enſlave their perſons; and they find the government of the Dutch leſs vexatious than that of others, who divide ſome ſhare of the ſovereignty of the iſland with them. The ſultan of Mataran rules to the eaſt, the emperor of Java in the centre, and the king of Bantam to the weſt; while the coaſt and effective power almoſt entirely belong to Holland. Thoſe other ſovereigns are deſcended from foreigners alſo; being Arabians, who imported the Mahometan religion into Java, and acquired the dominion of the country; a few inhabitants in the mountains excepted, who have preſerved their independence and their faith, and among other articles that of the tranſmigration of ſouls. According to the Dutch accounts, nothing can be more tyrannic than thoſe Mahometan rulers. The Emperor is ſaid to maintain his authority by an army of many thouſand men diſperſed throughout his territories, beſide a numerous female guard about his perſon. Theſe military ladies are trained, it ſeems, to arms, without neglecting thoſe accompliſhments which may occaſion a change in the occupation of ſome among them, rendering them the companions, inſtead of being the attendants, of his Imperial majeſty. This ſingular inſtitution may owe its origin to the facility of obtaining recruits, if it be true, as the ſame accounts pretend, that the number of female births exceeds very conſiderably that of males in Java.

Batavia. Moſt of the ſlaves are imported into it from Celebes and other eaſtern iſlands. They do not form a corps, or have any bond of union: nor is the general conduct of their owners towards them calculated to aggravate the misfortune of being the property of others. They are not forced to exceſſive labour. They have ſufficient ſuſtenance; but many of the males among them, who had formerly perhaps led an independent life till made captives in their wars, have been found to take offence againſt their maſters upon very ſlight occaſions, and to wreak their vengeance by aſſaſſination. The apprehenſion of ſuch an event is among the motives for preferring at Batavia female ſlaves for every uſe to which they can be applied; ſo that the number purchaſed of them much exceeds that of the other ſex. The ſlaves when determined on revenge often ſwallow, for the purpoſe of acquiring artificial courage, an extraordinary doſe of opium, and ſoon becoming frantic as well as deſperate, not only ſtab the objects of their hate, but ſally forth to attack in like manner every perſon they meet, till ſelf-preſervation renders it neceſſary to deſtroy them. They are ſaid in that ſtate to be *running a muck;* and inſtances of it are not more common among ſlaves than among free natives of the country, who, in the anguiſh for loſing their money, effects, and ſometimes their families, at gaming, to which they are violently addicted, or under the preſſure of ſome other paſſion or misfortune, have recourſe to the ſame remedy, with the ſame fatal effects.

In the country round Batavia the eye looks in vain for the common animals and vegetables which it had been daily accuſtomed to meet in Europe. The moſt familiar bird about the houſe of the ambaſſador's hoſt was the crown bird, as it was called at Batavia, which was not, however, the *ardea pavonina* of Linnæus, but the *columba criſtata*, having nothing except its creſt in common with the former. The ſame gentleman had alſo at his country-houſe ſome large caſſowary birds, which, though long in his poſſeſſion, and having the appearance of tameneſs, ſometimes betrayed the fierceneſs of their nature, attacking with their ſtrong bill thoſe who approached too near them. The vegetation of the country is likewiſe new. Even the parterres in the gardens are bordered, inſtead of boxwood, by the Arabian jeſſamine, of which the fragrant flowers adorn the pagodas of Hindoſtan. The Dutch, who are ſo fond of gardens in Holland, have transferred that taſte, where it can certainly be cultivated with more ſucceſs, and indulge it to a great extent at their houſes a little way from the city of Batavia; but ſtill within that fenny diſtrict, concerning which an intelligent gentleman upon the ſpot uſed the ſtrong expreſſion, that the air was peſtilential and the water poiſonous. Yet the country is everywhere ſo verdant, gay, and fertile; it is interſperſed with ſuch magnificent houſes, gardens, avenues, canals, and draw-bridges; and is ſo formed in every reſpect to pleaſe, could health be preſerved in it—that a youth coming juſt from ſea, and enraptured with the beauty of every object he ſaw around him, but mindful of the danger there to life, could not help exclaiming, "what an excellent habitation it would be for immortals!"

The moſt tolerable ſeaſon here is from March or April

pril to November; when the rains begin, and laſt the reſt of the year. The ſea breeze ſets in about ten o'clock in the morning, and continues till four or five in the afternoon. It becomes then calm till ſeven or eight, when the land breeze commences, and continues at intervals till day-break, followed by a calm for the remaining hours of the 24. Fahrenheit's thermometer was, in Batavia road, during the Lion's remaining there, from 86° to 88°, and in the town from 88° to 92°; but its variations by no means correſponded to the ſenſations produced by the heat on the human frame; the latter being tempered by any motion of the air, which circumſtance has little effect upon the thermometer. Nor are the animal ſufferings here from heat to be meaſured by its intenſeneſs at any given moment of the day, but by its perſiſting through the night; when, inſtead of diminiſhing, as it does in colder countries, ſometimes 20 degrees, it keeps generally here within four or five of what it attains in the ſhade, when the ſun is at its higheſt elevation.

The native Javaneſe derive, however, one advantage at leaſt from an atmoſphere not ſubject to the viciſſitudes of temperature experienced in the northern parts of Europe, where diſeaſes of the teeth are chiefly prevalent; as they are here entirely exempt from ſuch complaints. Their habit of living chiefly on vegetable food, and of abſtaining from fermented liquors, no doubt contributes to this exemption; yet ſuch is the caprice of taſte, that jet black is the favourite colour and ſtandard of beauty for the teeth amongſt them, comparing to monkeys thoſe who keep them of the natural colour. They accordingly take care to paint, of the deepeſt black, all their teeth, except the two middle ones, which they cover with gold leaf. Whenever the paint or gilding is worn off, they are as attentive to replace it on the proper teeth, as the belles of Europe are to purify and whiten theirs.

We have mentioned the rich vegetation of the country and the gardens which the Dutch have planted. In theſe gardens or orchards they cultivate the nutmeg, the clove, the camphor, and the cinnamon trees, together with the pepper plant, which, creeping like a vine, is ſupported on a living tree. It is a ſpecies of the pepper plant that affords the leaf called *betel*, chewed ſo univerſally by the ſouthern Aſiatics, and ſerving for the incloſure of a few ſlices or bits of the areca, from thence erroneouſly called the *betel nut*. The areca nut tree is among the ſmalleſt of the tribe of palms, but comes next in beauty to the mountain cabbage tree of the Weſt Indies, the latter differing chiefly in its ſize and amazing height from the areca nut tree, the diameter of whoſe jointed trunk ſeldom exceeds four inches, or height 12 feet. But the ſymmetry of each is perfect; the columns of a temple cannot be more regular than the trunk, which riſes without a branch, while the broad and ſpreading leaves which crown the top form the ornamented capital. The areca nut, when dried, has ſome ſimilitude in form and taſte to the common nutmeg, but is of a leſs ſize.

It would have been very extraordinary, and very culpable, in Sir George Staunton, and Dr Gillan phyſician to the embaſſy, if they had not, when on the ſpot, inquired into the truth of Foerſch's account of the *upas* or poiſon tree of Java (ſee *Poison Tree of Java*, Encycl.) But the moſt minute inquiries were made reſpecting it; and the reſult of them was, that no ſuch tree is known at Batavia, and certainly does not exiſt where Foerſch has planted it. It is indeed a common opinion at Batavia, that there exiſts in that country a vegetable poiſon, which, rubbed on the daggers of the Javaneſe, renders the ſlighteſt wounds incurable; though ſome European practitioners have of late aſſerted that they had cured perſons ſtabbed by thoſe weapons, but not without having taken the precaution of keeping the wound long open, and procuring a ſuppuration. One of the keepers of the medical garden at Batavia aſſured Dr Gillan, that a tree diſtilling a poiſonous juice was in that collection, but that its qualities were kept ſecret from moſt people in the ſettlement, leſt the knowledge of them ſhould find its way to the ſlaves, who might be tempted to make an ill uſe of it. In the ſame medical garden, containing it ſeems hurtful as well as grateful ſubſtances, is found alſo the plant from whence is made the celebrated gout remedy, or moxa of Japan, mentioned in the works of Sir William Temple, and deſcribed in the Encyclopædia under the titles of Artemisia and Moxa.

The whole country abounds with eſculent fruits, and, amonſt others, with the mangoſteen, which is ripe in March, and is conſidered as the moſt delicious of all fruits (ſee Garcinia, *Encycl.)* Pine apples are in Java planted not in gardens, but in large fields; and are carried like turneps in heaps upon carts to market, and ſold for conſiderably leſs than a penny each, where money is cheaper than in England. It was a common practice to clean ſwords, or other inſtruments of ſteel or iron, by running them through pine apples, as containing the ſtrongeſt and cheapeſt acid for diſſolving the ruſt that covered them. Sugar ſold for about five-pence a pound. All ſorts of proviſions were cheap, and the ſhips crews fed on freſh meat every day.

The ſerpents and noxious reptiles in Java have been mentioned elſewhere; but Sir George Staunton aſſures us, that not many accidents happen from them. Among the pagan Javaneſe, the crocodile, he ſays, is an object not only of fear, but alſo of religious veneration, to which offerings are made as to a deity. When a Javaneſe feels himſelf diſeaſed, he will ſometimes build a kind of coop, and fill it with ſuch eatables as he thinks moſt agreeable to the crocodiles. He places the coop upon the bank of the river or canal, in the perfect confidence that, by the means of ſuch offerings, he will get rid of his complaints; and perſuaded, that if any perſon could prove ſo wicked as to take away thoſe viands, ſuch perſon would draw upon himſelf the malady for the cure of which the offering was made. According to Sir George Staunton, Batavia road lies in 6° 10′ ſouth lat. and 106° 51′ eaſt long. from Greenwich.

BEER is a liquor ſo palatable to the natives of Britain, and, when properly made, ſo wholeſome, eſpecially in long voyages at ſea, that Mr Thornton of Eaſt Smithfield obtained a patent, dated April 15. 1778, for inventing a method of reducing *malt* and *hops* to an eſſence or extract, from which beer may be made anywhere, either at ſea or in diſtant countries. Though we do not perceive any great degree of ingenuity diſplayed in this invention, yet as the account of it is ſhort, we ſhall lay it before our readers.

His method then of preparing an eſſence or extract of malt and hops is, by the tranſmitted heat of compreſſed

pressed vapour of boiling water, and a proper apparatus for that purpose. This apparatus may be made of iron, tin, or copper: it consists of a boiler of any dimensions, a double vessel, and conducting tubes. The double vessel consists of one vessel placed within another, and fitted tight at their rims. The upper vessel forms the upper part of the under vessel, and contains the liquor to be evaporated. The under vessel is everywhere inclosed except at an aperture communicating with the boiler, and at another aperture communicating with the conducting tubes; and is constructed so as not to allow any part of the vapour condensed into drops within it to escape, except back again into the boiler: it is not so extensive as to act as a common refrigeratory, and yet is capacious enough to prevent the liquor boiling over. The aperture communicating with the boiler is large enough to freely admit the vapour from the boiler into the under vessel; and the aperture communicating with the conducting tubes is of a proper size to allow of the vapour in the under vessel being compressed, to a degree capable of transmitting to the liquor to be evaporated a proper heat, and at the same time to serve as a passage for more heat than is necessary to keep up that degree of compression. The conducting tubes are to convey this superfluous heat or vapour, to be used for farther purposes, or immediately out of the building.

BEETLE, an insect described in the Encyclopædia under the name given to it by naturalists, SCARABÆUS. Since that aticle was published, we have met with an account of a nondescript species, which is furnished with very singular armour for its own defence. It was brought to M. Vaillant in the interior parts of Africa by a Nimiqua woman, and is by him called a superb beetle, not to be found in any cabinet of Europe. "While I was examining this beautiful insect (says he) with attention, I felt my face suddenly wetted by a caustic liquor, of a very strong alkaline smell. The sprinkling was accompanied by a sort of explosion, loud enough to be heard at some distance. Unfortunately some of the liquor entered one of my eyes, and occasioned such insupportable pain, that I thought I should have lost the sight of it. I was obliged to keep it covered for several days, and bathe it from time to time with milk. In every part of my face that the alkaline liquor had touched, I felt the pain of a burn; and everywhere the skin changed to a deep brown, which wore out only by degrees and a long time after. This will not be surprising to many, who already are acquainted with the same property in several insects of the same genus; for instance, in that beautiful golden green buprestis, which is so common in our kitchen gardens in Europe: but as the insect of which I am here speaking is much larger, and inhabits a very hot country, it is natural that the effect produced by it should be more striking; tho' the liquor which our golden buprestis ejects at its enemy occasions a very sensible smart, and its smell is considerably pungent."

The naturalists Dorci and Olivier have given, in their Entomology, the figure of this African insect, which our author communicated to them, but they have given it erroneously. The human face, observable on its anterior corcelet in their figure, does not exist in nature; but M. Vaillant having given no figure of it himself, we cannot gratify our readers with a correct representation.

BEGAH, a land measure in Bengal, about one-third of an English acre.

BEHADER *(Valiant)*, a title of honour conferred by the Mogul emperors upon either Mahomedans or Hindoos, and placed after their name or other title.

BEHEM (Martin), though hitherto little talked of, was one of the most enterprising men that ever lived, and deserves to have his name transmitted with reverence to the latest posterity. Born at Nuremberg, an Imperial city in the circle of Franconia, of a noble family not yet extinct, he had the best education which the darkness of that age would permit him to have; and the studies to which from his infancy he was most addicted, were those of geography, astronomy, and navigation. As he advanced in life, he often thought of the existence of the antipodes and of a western continent, of which he was ambitious to make the discovery.

Filled with this great idea, in 1459 he paid a visit to Isabella, daughter of John I. king of Portugal, at that time regent of the duchy of Burgundy and Flanders; and having informed her of his designs, he procured a vessel, in which, sailing westward, he was the first European who is known to have landed on the island of Fayal. He there established in 1460 a colony of Flemings, whose descendants yet exist in the Azores, which were for some time called the Flemish Islands. This circumstance is proved, not only by the writings of contemporary authors, but also by the manuscripts preserved in the records of Nuremberg; from the Latin of which the following is translated: "Martin Behem tendered his services to the daughter of John king of Lusitania, who reigned after the death of Philip of Burgundy, surnamed the *Good;* and from her procured a ship, by means of which, having sailed beyond all the then known limits of the Western Ocean, he was the first who in the memory of man discovered the island of Fayal, abounding with beech trees, which the people of Lusitania call *faye;* whence it derived its name. After this he discovered the neighbouring islands, called by one general name the *Azores*, from the multitude of hawks which build their nests there (for the Lusitanians use this term for hawks, and the French too use the word *essos* or *esores* in their pursuit of this game); and left colonies of the Flemish on them, when they began to be called Flemish Islands (A)."

After

(A) Although this record is contrary to the generally received opinion, that the Azores were discovered by Gonsalva Velho, a Portuguese, yet its authenticity seems unquestionable. It is confirmed not only by several contemporary writers, and by Wagenseil, one of the most learned men of the last century, but likewise by a note written on parchment in the German language, and sent from Nuremberg, a few years ago, to M. Otto, who was then investigating the discovey of America. The note contained, with other things, the following facts: "Martin Beham, Esq; son of Mr Martin Beham of Scoperin, lived in the reign of John II. king of Portugal, in an island which he discovered, and called the island of *Fayal*, one of the Azores, lying in the Western Ocean, Behem.

After having obtained from the regent a grant of Fayal, and resided there about twenty years, Behem applied in 1484 (eight years before Columbus's expedition) to John II. king of Portugal, to procure the means of undertaking a great expedition towards the south-west. This prince gave him some ships, with which he discovered that part of America which is now called Brazil; and he even sailed to the Straits of Magellan, or to the country of some savage tribes whom he called Patagonians, from the extremities of their bodies being covered with a skin more like a bear's paws than human hands and feet.

A fact so little known, and apparently so derogatory to the fame of Columbus, ought not to be admitted without sufficient proof; but the proofs which have been urged in support of its authenticity are such as cannot be controverted. They are not only the letters of Behem himself, written in 1486, and preserved in the archives of Nuremberg, but likewise the public records of that city; in which we read that "Martin Behem, traversing the Atlantic Ocean for several years, examined the American islands, and discovered the strait which bears the name of Magellan before either Christopher Columbus or Magellan sailed those seas; whence he mathematically delineated, on a geographical chart, for the king of Lusitania, the situation of the coast around every part of that famous and renowned strait long before Magellan thought of his expedition."

This wonderful discovery has not escaped the notice of contemporary writers. The following passage is translated from the Latin chronicle of Hartman Schedl: "In the year 1485, John II. king of Portugal, a man of a magnanimous spirit, furnished some galleys with provisions, and sent them to the southward, beyond the Straits of Gibraltar. He gave the command of this squadron to James Canus, a Portuguese, and Martin Behem, a German of Nuremberg in Upper Germany, descended of the family of Bonna: a man very well acquainted with the situation of the globe; blessed with a constitution able to bear the fatigues of the sea; and who, by actual experiments and long sailing, had made himself perfectly master with regard to the longitudes and latitudes of Ptolemy in the west. These two, by the bounty of Heaven, coasting along the Southern Ocean, and having crossed the equator, got into the other hemisphere, where, facing to the eastward, their shadows projected towards the south and right hand. Thus, by their industry, they have opened to us another world hitherto unknown, and for many years attempted by none but the Genoese, and by them in vain. Having finished this cruize in the space of 26 months, they returned to Portugal with the loss of many of their seamen by the violence of the climate."

Besides this evidence of the first discovery of America having been made by Behem, we find the following particulars in the remarks made by Petrus Mateus on the canon law, two years before the expedition of Columbus: "*Primæ navigationes*, &c. The first Christian voyages to the newly discovered islands became frequent under the reign of Henry, son of John, king of Lusitania. After his death Alphonsus V. prosecuted the design; and John, who succeeded him, followed the plan of Alphonsus, by the assistance of Martin Behem, a very skilful navigator; so that in a short time the name of Lusitania became famous over the whole world." Cellarius, one of the most learned men of his age, says expresly, "*Behaimeus non modo*, &c. Bœhm did not think it enough to survey the island of Fayal, which he first discovered, or the other adjacent islands which the Lusitanians call *Azores*, and we, after the example of Bœhm's companions, call *Flemish* islands, but advanced still farther and farther south, until he arrived at the remotest strait, through which Ferdinand Magellan, following his track, afterwards sailed, and called it after his own name."

All these quotations, which cannot be thought tedious, since they serve to prove a fact almost unknown, seem to demonstrate, that the first discovery of America is due to the Portuguese and not to the Spaniards; and that the chief merit belongs to a German astronomer. The expedition of Ferdinand Magellan, which did not take place before the year 1519, arose from the following fortunate circumstance: This person, being in the apartment of the king of Portugal, saw there a chart of the coast of America drawn by Behem, and at once conceived the bold project of following the steps of this great navigator. Jerome Benzon, who published a description of America in 1550, speaks of this chart; a copy of which, sent by Behem himself, is preserved in the archives of Nuremberg. The celebrated astronomer Riccioli, though an Italian, yet does not seem willing to give his countryman the honour of this important discovery. In his *Geographia Reformata*, book iii. p. 90. he says, "Christopher Columbus never thought of an expedition to the West Indies until his arrival in the island of Madeira, where, amusing himself in forming and delineating geographical charts, he obtained information from Martin Bœhm, or, as the Spaniards say, from Alphonsus Sanches de Huelva, a pilot, who had chanced to fall in with the island afterwards called *Dominica*." And in another place: "Let Bœhm and Columbus have each their praise; they were both excellent navigators; but Columbus would never have thought of his expedition to America, had not Bœhm gone there before him. His name is not so much celebrated as that of Columbus, Americus, or Magellan, although he is superior to them all."

That Behem rendered some very important services to the crown of Portugal, is put beyond all controversy by the recompence bestowed on him by King John; of which the following account has been given to the public from the archives of Nuremberg. "In the year 1485, on the 18th of Feb. in Portugal, in the city of Allasavas, and in the church of St Salvador, after the mass, Martin Behem of Nuremberg was made a knight, by the hands of the most puissant Lord John II. king of Portugal, Algarve, Africa, and Guinea; and his chief squire was the king himself, who put the sword in his belt; and the Duke of Begia was his second squire, who put on his right spur; and his third squire was Count Christopher de Mela, the king's cousin, who put on his left spur; and his fourth squire was Count Martini Marbarinis, who put on his iron helmet; and the king himself gave him the blow on the shoulder, which was done in the presence of all the princes, lords, and knights of the kingdom; and he espoused the daughter of a great lord, in consideration of the important services he had performed; and he was made governor of the island of Fayal."

These marks of distinction, conferred on a stranger, could

Behem.

could not be meant as a recompence for the discovery of the Azores, which was made twenty years before, but as a reward for the discovery of Congo, from whence the Chevalier Behem had brought gold and different kinds of precious wares. This discovery made much greater impression than that of a western world made at the same time, but which neither increased the wealth of the royal treasury, nor satisfied the avarice of the merchants.

In 1492 the Chevalier Behem, crowned with honours and riches, undertook a journey to Nuremberg, to visit his native country and his family. He there made a terrestrial globe, which is looked on as a masterpiece for that time, and which is still preserved in the library of that city. The outline of his discoveries may there be seen, under the name of western lands; and from their situation it cannot be doubted that they are the present coasts of Brazil, and the environs of the Straits of Magellan. This globe was made in the same year that Columbus set out on his expedition; therefore it is impossible that Behem could have profited by the works of that navigator, who besides went a much more northerly course.

After having performed several other interesting voyages, the Chevalier Behem died at Lisbon in July 1506, regretted by every one, but leaving behind him no other work than the globe and chart which we have just been speaking of. The globe is made from the writings of Ptolemy, Pliny, Strabo, and especially from the account of Mark Paul the Venetian, a celebrated traveller of the 13th century; and of John Mandeville, an Englishman, who, about the middle of the 14th century, published an account of a journey of 33 years in Africa and Asia. He has also added the important discoveries made by himself on the coasts of Africa and America.

From these circumstantial accounts, but very lately brought to light, there can be little doubt, we think, but that America was discovered by Martin Behem. Dr Robertson is indeed of a different opinion: but great as we willingly acknowledge his authority to be, we may differ from him without presumption, since he had it not in his power to consult the German documents to which we have appealed, and has himself advanced facts not easily to be reconciled to his own opinion. He allows that Behem was very intimate with Christopher Columbus; that he was the greatest geographer of his time, and scholar of the celebrated John Müller, or Regiomontanus; that he had discovered, in 1483, the kingdom of Congo, upon the coast of Africa; that he made a globe which Magellan made use of; that he drew a map at Nuremberg, containing the particulars of his discoveries; and that he placed in this chart land which is found to be in the latitude of Guiana. He adds indeed, without proof, that this land was a fabulous island; but if authentic records are to give place to bare assertion, there is an end of all historical evidence. If Behem took for an island the first land which he discovered, it was a mistake surely not so gross as to furnish grounds for questioning his veracity, or for withholding from him for ever that justice which has been so long delayed.

But this very delay will by some be thought a powerful objection to the truth of Behem's claim to the discovery of America; for if it was really discovered by him, why did not he leave behind him some writing to confirm the discovery to himself? and why did not the court of Portugal, so jealous of the discovery of the new world, protest against the exclusive claim of the Spaniards?

To these objections we may reply, that, however plausible they may at first appear, they do not in the smallest degree invalidate the positive evidence which we have urged for the Chevalier Behem's being the real discoverer of the new world; for it would surely be very absurd to oppose the *difficulty of assigning motives* for *certain* actions performed at a remote period, to the *reality* of *other* actions for which we have the testimony of a cloud of contemporary witnesses. Supposing it were true, therefore, that Behem had left behind him no writing claiming to himself the discovery of any part of the continent of America, the only inference which could be drawn from his silence would be, either that he was a man of great modesty, or that his mind was intent only on the acquisition of knowledge to himself, without feeling the usual impulse to communicate that knowledge to others. But it is not true that he has left behind him no claim of this discovery to himself. The letters to which we have appealed, and which are preserved in the archives of Nuremberg, together with the globe and map, which he certainly made, furnish as complete a confirmation of his claim as could have been furnished by the most elegant account of his voyages.

For the silence of the Portuguese, many reasons might be assigned. The discoveries of Columbus were made so much farther north than those of Behem, that, in an age when geographical knowledge was so very limited, both Spaniards and Portuguese might very naturally believe that the country discovered by the former of these navigators had no connection with that discovered by the latter. At any rate, the Portuguese, whose discoveries proceeded from avarice, were satisfied with scraping together gold wherever they could find it; and finding it in Africa, they thought not of searching for it in a more distant region, till the success of the Spaniards shewed them their mistake.

One thing more is worthy of attention. The long stay of Columbus at Madeira makes his interview with Behem more than probable. It is impossible that he should have neglected seeing a man so interesting, and who could give him every kind of information for the execution of the plan which he had formed. The mariners who accompanied the Chevalier Behem might also have spread reports at Madeira and the Azores concerning the discovery of which they had been witnesses. What ought to confirm us in this is, that Mariana says himself (book xxvi. chap. iii.), that a certain vessel going to Africa, was thrown by a gale of wind upon certain unknown lands; and that the sailors at their return to Madeira had communicated to Christopher Columbus the circumstances of their voyage. All authors agree that this learned man had some information respecting the western shores; but they speak in a very vague manner. The expedition of the Chevalier Behem explains the mystery (B).

BEREANS,

(B) For the greater part of this memoir we are indebted to M. Otto's paper on the discovery of America, published

Bereans.

BEREANS, in ancient church hiftory, the inhabitants of Berea. They are highly commended in Scripture for their ready reception of the gofpel, upon a fair and impartial examination of its agreement with the Old Teftament prophecies. Sopater, a Berean, attended the apoftle Paul to Afia. Acts xvii. 10—13. and xx. 4.

Bereans, in modern church hiftory, a fect of Proteftant diffenters from the church of Scotland, who take their title from, and profefs to follow, the example of the ancient Bereans, in building their fyftem of faith and practice upon the Scriptures alone, without regard to any human authority whatever.

Doctrines.

The Bereans agree with the great majority of Chriftians, both Proteftants and Catholics, refpecting the doctrine of the Trinity, which they hold as a fundamental article of the Chriftian faith; and they alfo agree in a great meafure with the *profeffed* principles of both our eftablifhed churches refpecting predeftination and election, though they allege that thefe doctrines are not confiftently taught in either church. But they differ from the majority of all fects of Chriftians in various other important particulars. Such as,

1. Refpecting our knowledge of the Deity. Upon this fubject, they fay that the majority of profeffed Chriftians ftumble at the very threfhold of revelation; and, by admitting the doctrine of natural religion, natural confcience, natural notices, &c. not founded upon revelation, or derived from it by tradition, they give up the caufe of Chriftianity at once to the infidels; who may juftly argue, as Mr Paine in fact does in his Age of Reafon, that there is no occafion for any revelation or word of God, if man can difcover his nature and perfections from his works alone. But this, the Bereans argue, is beyond the natural powers of human reafon; and therefore our knowledge of God is from revelation alone; and that without revelation man would never have entertained an idea of his exiftence.

2. With regard to faith in Chrift, and affurance of falvation through his merits, they differ from almoft all other fects whatfoever. Thefe they reckon *infeparable*, or rather the *fame*; becaufe, they argue, God hath exprefsly declared, "He that believeth fhall be faved;" and therefore it is not only abfurd, but impious, and in a manner calling God a liar, for a man to fay, "*I believe* the Gofpel, but *have doubts* neverthelefs of my own falvation." With regard to the various diftinctions and definitions that have been given of different kinds of faith, they argue, that "there is nothing incomprehenfible or obfcure in the meaning of this word as ufed in Scripture; but that as faith, when applied to human teftimony, fignifies neither more nor lefs than the mere fimple belief of that teftimony as true, upon the authority of the teftifier: fo, when applied to the teftimony of God, it fignifies precifely the belief of his teftimony, and refting upon his veracity alone, without any kind of collateral fupport from concurrence of any other evidence or teftimony whatever." And they infift, that as this faith is the gift of God alone, fo the perfon to whom it is given is as confcious of poffeffing it, as the being to whom God gives life is of being alive; and therefore he entertains no doubts either of his faith or his confequent falvation through the merits of Chrift, who died and rofe again for that purpofe. In a word, they argue, that the Gofpel would not be what it is held forth to be, "glad tidings of great joy," if it did not bring full perfonal affurance of eternal falvation to the believer: which affurance, they infift, "is the prefent infallible privilege and portion of every individual believer of the Gofpel." Thefe definitions of faith, and its infeparable concomitant affurance, they prove by a variety of texts, which our room permits us not to quote.

3. Confiftently with the above definition of faith, they fay, that the fin againft the Holy Ghoft, which has alarmed and puzzled fo many in all ages, is nothing elfe but *unbelief;* and that the expreffion, that "it fhall not be forgiven, neither in *this world* nor that which is to come," means only, that a perfon dying in infidelity would not be forgiven, neither under the former difpenfation by Mofes (the then *prefent* difpenfation, kingdom, or government of God), nor under the Gofpel difpenfation, which, in refpect of the Mofaic, was a kind of future world or kingdom to come.

4. The Bereans interpret a great part of the Old Teftament prophecies, and in particular the whole of the Pfalms, excepting fuch as are merely hiftorical or laudatory, to be typical or prophetical of Jefus Chrift, his fufferings, atonement, mediation, and kingdom: and they efteem it a grofs perverfion of thefe Pfalms and prophecies to apply them to the experiences of private Chriftians. In proof of this, they not only urge the words of the apoftle, that "no prophecy is of any private interpretation," but they infift that the whole of the quotations from the ancient prophecies in the New Teftament, and particularly thofe from the Pfalms, are exprefsly applied to Chrift. In this opinion many other claffes of Proteftants agree with them.

5. Of the abfolute all-fuperintending fovereignty of the Almighty, the Bereans entertain the higheft ideas, as well as of the uninterrupted exertion thereof over all works in heaven, earth, and hell, however unfearchable by his creatures. "A God without election (they argue), or choice in all his works, is a god without exiftence—a mere idol—a non-entity. And to deny God's election, purpofe, and exprefs will in all his works, is to make him inferior to ourfelves." For farther particulars refpecting the Berean doctrines, we muft refer the reader to the works of Meffrs Barclay, Nicol, Brookfhank, &c.

Origin.

The Bereans firft affembled as a feparate fociety of Chriftians in the city of Edinburgh in autumn 1773, and foon after in the parifh of Fettercairn. The opponents of the Berean doctrines allege, that this new fyftem of faith would never have been heard of, had not Mr Barclay, the founder of it, been difappointed of a fettlement in the church of Scotland. A refpectable clergyman of the eftablifhed church has even hinted fomething to this purpofe in Sir John Sinclair's Statiftical Account, Vol. IX. p. 599. But the Bereans, in anfwer to this charge, appeal not only to Mr Barclay's doctrine,

---

publifhed firft in the fecond volume of the American Tranfactions, and afterwards by Nicholfon in N° II. and III. of his Journal.

Bereans doctrine, uniformly preached in the church of Fettercairn, and many other places in that neighbourhood, for fourteen years before that benefice became vacant; but likewise to two different treatises, containing the same doctrines, published by him about ten or twelve years before that period. They admit, indeed, that, previous to May 1773, when the general assembly, by sustaining the king's presentation in favour of Mr Foote, excluded Mr Barclay from succeeding to the church of Fettercairn (notwithstanding the almost unanimous desire of the parishioners), the Bereans had not left the established church, or attempted to erect themselves into a distinct society; but they add, that this was by no means necessary on their part, until by the assembly's decision they were in danger of being not only deprived of his instructions, but of being scattered as sheep without a shepherd. And they add, that it was Mr Barclay's open and public avowal, both from the pulpit and the press, of those peculiar sentiments which now distinguish the Bereans, that was the first and principal, if not the only, cause of the opposition set on foot against his settlement in Fettercairn.

Practice. Having thus given a concise view of the origin and distinguishing doctrines of Bereanism, it only remains to mention a few particulars relative to the practice of the Bereans as a Christian society. Infant baptism they consider as a divine ordinance instituted in the room of circumcision; and they think it absurd to suppose that infants, who all agree are admissible to the kingdom of God in heaven, should nevertheless be incapable of being admitted into His visible church on earth. They commemorate the Lord's supper in general once a-month; but as the words of the institution fix no particular period, they sometimes celebrate it oftener, and sometimes at more distant periods, as may suit their general convenience. In observing this ordinance, they follow the primitive apostolic plan, without any previous days of fasting or preparation; as they apprehend that such human institutions only tend to make an idol of the ordinance, and to lead people to entertain erroneous ideas of its superior solemnity and importance. Equal and universal holiness in all manner of conversation, they recommend at all times, as well as at the table of the Lord. They meet every Lord's day for the purpose of preaching, praying, and exhortation to love and good works. With regard to the admission and exclusion of members, their method is very simple. When any person, after hearing the Berean doctrines, professes his belief and assurance of the truths of the Gospel, and desires to be admitted into their communion, he is cheerfully received upon his profession, whatever may have been his former manner of life. But if such an one should afterwards draw back from his good profession or practice, they first admonish him; and if that has no effect, they leave him to himself. They do not think that they have any power to deliver up a backsliding brother to Satan. That text and other similar passages, such as, "Whatsoever ye shall bind on earth shall be bound in heaven," &c. they consider as restricted to the apostles and to the inspired testimony alone, and not to be extended to any church on earth, or any number of churches or of Christians, whether deciding by a majority of votes or by unanimous voices. Neither do they think themselves authorised, as a Christian church, to enquire into each others political opinions, any more than to examine into each others notions of philosophy. They both recommend and practise, as Christian duties, submission to lawful authority; but they do not think that a man, by becoming a Christian, or joining their society, is under any obligation, by the rules of the Gospel, to renounce his rights of private judgment upon matters of public or private importance. Upon all such subjects they allow each other to think and act as each may see it his duty. And they require nothing more of their members than a uniform and steady profession of the apostolic faith, and a suitable walk and conversation. With regard to feet-washing and the like practices, which some other sects of Christians consider as duties, the Bereans are of opinion that they are by no means obligatory. They argue, that the example given by our Saviour of washing the feet of his disciples was not an institution of an ordinance, but merely a familiar instance, taken from the custom of the country, and adopted by our Lord on that occasion, to teach his followers that they ought at all times to be ready to perform even the meanest offices of kindness to each other.

Bereans, Berkenhout.

Present state. It may not be improper to add to the above delineation of the principles and practice of the Bercans, that their doctrine has found converts in various places of Scotland, England, and America; and that they have congregations in Edinburgh, Glasgow, Paisley, Stirling, Crieff, Dundee, Arbroath, Montrose, Fettercairn, Aberdeen, and other towns in Scotland; as well as in London and various places in England; not to add Pennsylvania, the Carolinas, and other States in America.

The above account of the doctrines, origin, practice, and present state of this society, has been given to us by the founder himself.

BERKENHOUT (Dr John), was about the year 1730 born at Leeds in Yorkshire, and educated at the grammar-school in that town, His father, who was a merchant, and a native of Holland, intended him for trade; and with that view sent him at an early age to Germany, in order to learn foreign languages. After continuing a few years in that country, he made the tour of Europe in company with one or more English noblemen. On their return to Germany they visited Berlin, where Mr Berkenhout met with a near relation of his father's, the Baron de Bielfeldt, a nobleman then in high estimation with Frederick the Great king of Prussia; distinguished as one of the founders of the Royal Academy of Sciences at Berlin, and universally known as a politician and a man of letters. With this relation our young traveller fixed his abode for some time; and, regardless of his original destination, became a cadet in a Prussian regiment of foot. He soon obtained an ensign's commission, and in the space of a few years was advanced to the rank of captain. He quitted the Prussian service on the declaration of war between England and France in 1756, and was honoured with the command of a company in the service of his native country. When peace was concluded in 1760, not choosing, we suppose, to lead a life of inactivity on half-pay, he went down to Edinburgh, and commenced student of physic. During his residence at that university, he published his *Clavis Anglica Linguæ Botanicæ*; a book of great utility to all students of botany.

Having continued some years at Edinburgh, Mr Ber-

Berkenhout. kenhout went to the univerſity of Leyden, where he was admitted to the degree of M. D. in the year 1765. On this occaſion he publiſhed a theſis, intitled, *Diſſertatio medica inauguralis de Podagra*, which he dedicated to his relation Baron de Bielfeldt. Returning to England, Dr Berkenhout ſettled at Iſleworth in Middleſex, and ſoon after publiſhed his *Pharmacopœia Medici*, the third edition of which was printed in 1782. In 1778 he was ſent by government with the commiſſioners to America. Neither the commiſſioners nor their ſecretary were ſuffered by the congreſs to proceed further than New York. Dr Berkenhout, however, found means to penetrate as far as Philadelphia, where the congreſs was then aſſembled. He appears to have remained in that city for ſome time without moleſtation: but at laſt they began to ſuſpect that he was ſent by Lord North for the purpoſe of tampering with ſome of their leading members. The Doctor was immediately ſeized and committed to priſon.

How long he remained a ſtate priſoner, or by what means he obtained his liberty, we are not informed; but we find from the public prints, that he rejoined the commiſſioners at New York, and returned with them to England. For this temporary ſacrifice of the emoluments of his profeſſion, and in conſideration of his having, in the ſervice of his ſovereign, committed himſelf to the mercy of a congreſs of enraged republicans, he obtained a penſion.

Many years previous to this event, Dr Berkenhout had publiſhed his *Outlines of the Natural Hiſtory of Great Britain and Ireland*, in three volumes 12mo; a work which eſtabliſhed his reputation as a naturaliſt. In the year 1773 he wrote a pamphlet, intitled, *An Eſſay on the Bite of a Mad Dog, in which the Claim to Infallibility of the Principal Preſervative Remedies againſt the Hydrophobia is examined.* This pamphlet is inſcribed to Sir George Baker, and deſerves to be univerſally read.

In the year following Dr Berkenhout publiſhed his *Symptomatology;* a book which is too univerſally known to require any recommendation.

At the beginning of the year 1788 he publiſhed a work, intitled, *Firſt Lines of the Theory and Practice of Philoſophical Chemiſtry*, which he dedicated to Mr Eden, now Lord Auckland, who had been one of the commiſſioners whom he accompanied to America.

Theſe, we believe, are the Doctor's principal publications in the line of his profeſſion; but he wrote on many other ſubjects with equal ability. His tranſlation of *Count Teſſin's Letters*, which was his firſt publication, and dedicated to the preſent king when prince of Wales, evinces his knowledge of the Swediſh language, and ſhews him to have been a good poet. His *Eſſay on Ways and Means*, proves him to have been better acquainted with the ſyſtem of taxation than moſt other men who have written on the ſubject. His biographical powers appear in his *Biographia Literaria;* and in all his works are ſufficient proofs of his claſſical learning, and that the Italian, French, German, and Dutch languages, were familiar to him. He poſſeſſed likewiſe a very conſiderable degree of mathematical ſcience, which he acquired in the courſe of his military ſtudies; and to thoſe more ſolid attainments he is ſaid to have added no ſmall ſkill in the fine arts of painting and muſic. This eminent man, who, for the variety and promptitude of his knowledge, has been compared to the Admirable Crichton, died on the 3d of April 1791.

Bernoulli ‖ Bezout.

BERNOULLI (John), a celebrated mathematician, was born at Baſil the 7th of Auguſt 1667. His father intended him for trade; but his own inclination was at firſt for the belles lettres, which, however, like his brother James, whoſe life is given in the Encyclopædia, he left for mathematics. He laboured with his brother to diſcover the method uſed by Leibnitz, in his eſſays on the differential calculus, and gave the firſt principles of the integral calculus. Our author, with Meſſrs Huygens and Leibnitz, is ſaid to have been the firſt who gave the ſolution of the problem propoſed by James Bernoulli, concerning the catenary, or curve formed by a chain ſuſpended by its two extremities. But for more on this ſubject, ſee Arch in this Supplement.

John Bernoulli had the degree of doctor of phyſic at Baſil, and two years afterward was named profeſſor of mathematics in the univerſity of Groningen. It was here that he diſcovered the mercurial phoſphorus, or luminous barometer; and where he reſolved the problem propoſed by his brother concerning iſoperimetricals.

On the death of his brother James, the profeſſor at Baſil, our author returned to his native country, againſt the preſſing invitations of the magiſtrates of Utrecht to come to that city, and of the univerſity of Groningen, who wiſhed to retain him. The Academic Senate of Baſil ſoon appointed him to ſucceed his brother, without aſſembling competitors, and contrary to the eſtabliſhed practice; an appointment which he held during his whole life.

In 1714 was publiſhed his treatiſe on the management of ſhips; and in 1730 his memoir on the elliptical figure of the planets gained the prize of the Academy of Sciences. The ſame Academy alſo divided the prize for their queſtion concerning the inclination of the planetary orbits, between our author and his ſon Daniel. See Bernoulli (Daniel), *Encycl.*

John Bernoulli was a member of moſt of the academies of Europe, and received as a foreign aſſociate of that of Paris in 1699. After a long life ſpent in conſtant ſtudy and improvement of all the branches of the mathematics, he died full of honours, the 1ſt of January 1748, in the 81ſt year of his age. Of five ſons which he had, three purſued the ſame ſciences with himſelf. One of theſe died before him; the two others, Nicolas and Daniel, he lived to ſee become eminent, and much reſpected in the ſame ſciences.

The writings of this great man were diſperſed through the periodical memoirs of ſeveral academies, as well as in many ſeparate treatiſes. And the whole of them were carefully collected and publiſhed at Lauſanne and Geneva, 1742, in 4 vols 4to. He was of undoubted eminence; but even in ſcience he was a haſty man, and certainly envious of the fame of Newton.

BETELGUESE, a fixed ſtar of the firſt magnitude, in the right ſhoulder of Orion.

BEZOUT (Stephen), a celebrated French mathematician, member of the Academies of Sciences and the Marine, and examiner of the guards of the marine and of the eleves of artillery, was born at Nemours the 31ſt of March 1730. In the courſe of his ſtudies he met with ſome books of geometry, which gave him a taſte for that ſcience; and the Eloges of Fontenelle, ſhewed him the honours attendant on talents and the love

love of the ſciences. His father in vain oppoſed the ſtrong attachment of young Bezout to the mathematical ſciences. April 8. 1758, he was named adjoint-mechanician in the French Academy of Sciences; having before that ſent them two ingenious memoirs on the integral calculus, and given other proofs of his proficiency in mathematics. In 1763, he was named to the new office of examiner to the marine, and appointed to compoſe a ſyſtem of mathematics for their uſe; and in 1768, on the death of M. Camus, he ſucceeded as examiner of the artillery eleves.

Bezout fixed his attention more particularly to the reſolution of algebraic equations; and he firſt found out the ſolution of a particular claſs of equations of all degrees. This method, different from all former ones, was general for the cubic and biquadratic equations, and juſt became particular only at thoſe of the 5th degree. Upon this work our author laboured from 1762 till 1779, when he publiſhed it. He compoſed two courſes of mathematics; the one for the marine, the other for the artillery. The foundation of theſe two works was the ſame; the applications only being different, according to the two different objects: theſe courſes have every where been held in great eſtimation. In his office of examiner he diſcharged the duties with great attention, care, and tenderneſs. A trait of his juſtice and zeal is remarkable in the following inſtance: During an examination which he held at Toulon, he was told that two of the pupils could not be preſent, being confined by the ſmall-pox: he himſelf had never had that diſeaſe, and he was greatly afraid of it; but as he knew that if he did not ſee theſe two young men, it would much impede their improvement, he ventured to their bed-ſides to examine them, and was happy to find them ſo deſerving of the hazard into which he put himſelf for their benefit.

Mr Bezout lived in this employment for ſeveral years, beloved of his family and friends, and reſpected by all, enjoying the fruits and the credit of his labours. But the trouble and fatigues of his offices, with ſome perſonal chagrines, had reduced his ſtrength and conſtitution; he was attacked by a malignant fever, of which he died Sept. 27. 1783, in the 54th year of his age, regretted by his family, his friends, the young ſtudents, and by all his acquaintance in general.

The books publiſhed by him were: 1. Courſe of Mathematics for the uſe of the Marine, with a Treatiſe on Navigation, 6 vols in 8vo, Paris, 1764. 2. Courſe of Mathematics for the Corps of Artillery, 4 vols in 8vo, 1770. 3. General Theory of Algebraic Equations, 1779.

His papers printed in the volumes of the Memoirs of the Academy of Sciences are: 1. On curves, whoſe rectification depends on a given quantity, in the volume for 1758. 2. On ſeveral claſſes of equations that admit of an algebraic ſolution, 1762. 3. Firſt volume of a courſe of mathematics, 1764. 4. On certain equations, &c. 1764. 5. General reſolution of all equations, 1765. 6. Second volume of a courſe of mathematics, 1765. 7. Third volume of the ſame, 1766. 8. Fourth volume of the ſame, 1767. 9. Intergration of differentials, &c. vol. 3. Sav. Etr. 10. Experiments on cold, 1777.

BINOMIAL, a quantity conſiſting of two terms or members, connected by either of the ſigns + and —. See ALGEBRA, def. 9. *Encycl.*

Impoſſible or *Imaginary* BINOMIAL, is a binomial which has one of its terms an impoſſible or an imaginary quantity; as $a + \sqrt{-b}$.

BINOMIAL Curve, is a curve whoſe ordinate is expreſſed by a binomial quantity, as the curve whoſe ordinate is $x^a \times \overline{b + d x^c}|^e$. Stirling, Method. Diff. p. 58.

BINOMIAL Line, or *Surd*, is that in which at leaſt one of the parts is a ſurd. Euclid, in the tenth book of his Elements, enumerates ſix kinds of binomial lines or ſurds, viz.

First binomial $3 + \sqrt{5}$,
2d binomial $\sqrt{18} + 4$,
3d binomial $\sqrt{24} + \sqrt{18}$,
4th binomial $4 + \sqrt{3}$,
5th binomial $\sqrt{6} + 2$,
6th binomial $\sqrt{6} + \sqrt{2}$.

BINOMIAL Theorem. See ALGEBRA, Chap. VII. Sect. iii. (*Encycl.* Vol. I.); and *Infinite SERIES*, (Vol. XVII.) The reader who wiſhes for a fuller account of this famous theorem, may find it in Dr Hutton's Mathematical Tracts, Vol. I.

BIRD-CATCHING, is an art which, as it is practiſed by means of bird-lime, nets, decoys, &c. has been ſufficiently explained in the Encyclopædia. But there is another method of catching birds alive, by means of a *fuſee* or *muſket*, which was invented by M. Vaillant during his travels in Africa, and is ſufficiently ingenious to deſerve a place here. It is as follows:

Put a ſmaller or larger quantity of powder into your fuſee according as circumſtances may require. Immediately above the powder place the end of a candle of ſufficient thickneſs, ramming it well down; and then fill the barrel with water up to the mouth. When at a proper diſtance you fire a muſket thus loaded at a bird, you will only *ſtun* it by watering and moiſtening its feathers; and if you be alert, you may eaſily lay hold of it before it have time to ſpoil its plumage by fluttering. Our author admits, that in his firſt attempts he often put too much powder, or too thick a piece of candle into his fuſee, or fired at too ſhort a diſtance; and when any one of theſe miſtakes was committed, he generally found the candle entire in the animal's belly; but after a ſhort apprenticeſhip he acquired ſufficient ſkill to adjuſt matters ſo as that the water impelled by the powder went directly to the mark, whilſt the tallow being lighter than the water fell ſhort of it. If this method be indeed practicable (for not being ſportſmen we have not made trial of it), it may on many occaſions aid the reſearches of the ornithologiſt.

BIRDS-Neſts, in cookery. See *Encycl.* and CAP and BUTTON in this *Suppl.*

BLACK (Joſeph, M. D.), who has been ſtyled the father of pneumatic chemiſtry, and who, in that department of ſcience, had certainly no ſuperior, was born at Bourdeaux in France, in the year 1728. His father was a native of Ireland, but went to Bourdeaux to carry on the buſineſs of a wine-merchant; though with what ſucceſs he carried it on we have not learned. Where young Black received his claſſical education we know not; but at an early period of life he was ſent to the Univerſity of Glaſgow, and ſtrongly recommended to Dr Cullen, who adviſed him to ſtudy phyſic, and undertook, with that ardour which characteriſed his mind, to render him every ſervice in his power.

At that period Cullen read lectures on chemiſtry in the College of Glaſgow with great and deſerved applauſe; and Black becoming one of his favourite pupils, was allowed the free uſe of his laboratory, and aſſiſted him in his experiments; by which means he acquired a decided taſte for this branch of natural philoſophy. In 1754 he took the degree of doctor of phyſic in the univerſity of Edinburgh, where he had ſtudied for ſome time; and the choice which he made in regard to the ſubject of his inaugural diſſertation gave a proof of his attachment to chemical purſuits. It was *De humore acido a cibis orto et magneſia alba.* The principles of the doctrine which he brought forward in this theſis he afterwards fully explained in a paper read the next year before a ſociety in Edinburgh, and publiſhed in the ſecond volume of *Eſſays Phyſical and Literary*, 1756; containing experiments on magneſia alba, quick-lime, and alkaline ſubſtances. In this paper, by an ingenious and philoſophical ſeries of reſearches, he evidently proved the exiſtence of an aerial fluid, which he called *fixed air*, the preſence of which gave mildneſs, and its abſence cauſticity, to alkalies and calcareous earths. This noble diſcovery certainly paved the way to all that important knowledge reſpecting aerial bodies which has done ſo much honour to the names of a Cavendiſh, a Prieſtley, and a Lavoiſier, and which have made chemical philoſophy aſſume an entirely new form.

In the year 1756, on the removal of Dr Cullen to Edinburgh, Dr Black became profeſſor of medicine and lecturer on chemiſtry in the univerſity of Glaſgow. Next year he enriched the ſcience of chemiſtry with the curious doctrine of *latent heat*, in which he explained, in what has been hitherto reckoned a clear and ſatisfactory manner, the connection of heat with fluidity, the phenomena of freezing and boiling, and the manner in which they affect the thermometer. Theſe diſcoveries, the reſult of great natural ſagacity and experimental ſkill, certainly laid the foundation of all thoſe important facts relating to this part of chemiſtry which were afterwards brought to light by ſeveral of the moſt eminent philoſophers of the preſent period, and would alone be ſufficient to give celebrity to the name of Black. His reputation indeed was now raiſed ſo high, that a vacancy having taken place in the chemical chair of Edinburgh, by the removal of Dr Cullen, in 1765, to another department, Dr Black was looked up to as the only man capable of ſuſtaining, in this branch of ſcience, the ſuperiority which that celebrated ſchool of medicine had acquired in all others. He was therefore elected to ſucceed Cullen, and for many years diſcharged the duties of the office with univerſal approbation, being much admired for the care, perſpicuity, and elegance, with which he communicated inſtruction in his lectures, and his neatneſs and accuracy in performing experiments. Very complete manuſcript copies of his lectures were taken by many of his ſtudents, particularly in the early part of his teaching, when they contained a great deal of matter then little known to the chemical world; and theſe copies, read with avidity by the lovers of this ſcience, have greatly contributed to ſecure to him the honour of thoſe diſcoveries, and that original mode of reaſoning, which he ſcarcely ever made public in any other form. His lectures have lately been reviſed by his friend Dr Robiſon of Edinburgh; and, enriched with many valuable notes by that genuine philoſopher, are now in the preſs, and will ſpeedily be publiſhed.

After his election to the chemical chair, Dr Black publiſhed nothing but a paper on the Effect of Boiling upon Water, in diſpoſing it to freeze more readily, printed in the ſixty-fifth volume of the Philoſophical Tranſactions for 1774; and an Analyſis of the Water of ſome Hot Springs in Iceland, in the Philoſophical Tranſactions of Edinburgh for 1791. The latter contains ſome obſervations, highly intereſting to the chemiſt, on the formation of the ſiliceous ſtone depoſited by theſe wonderful ſprings; and has long been conſidered as a model of neatneſs and accuracy in the analyſis of mineral waters. Two of his letters on chemical ſubjects have been publiſhed by Crell and Lavoiſier.

Dr Black was long a ſtrenuous oppoſer of the new theories in chemiſtry; but he at length became an avowed convert to the principles of the French chemiſts, and did not heſitate to make amends by his applauſe for his former oppoſition. He never diſtinguiſhed himſelf as a practical phyſician. His manners were ſimple, his temper cold and reſerved, and his habits of life adapted to his own convenience. He was never married; and died ſuddenly, in his ſixty-ſecond year, on the 6th of December 1799, his health having been in a declining ſtate for ſome time before. He was a member of the Royal Societies of London and Edinburgh, and of the Imperial Academy of Sciences at St Peterſburgh; and by the intereſt of Lavoiſier he was choſen one of the eight foreign members of the Academy of Sciences of Paris, when that academy was Royal, and when a philoſopher of Britain could be a member of it without incurring diſgrace.

By thoſe who knew Dr Black intimately, and are capable of forming an eſtimate of the powers of his mind, he is believed to have been capable of becoming in chemiſtry what Newton was in mechanical philoſophy; but an unconquerable indolence, though it could not prevent him from doing his duty as profeſſor, reſtrained him not only from employing, as he might have done, his admirable talents in enlarging the boundaries of ſcience, but even from aſſerting his claim to diſcoveries which were certainly his. Of theſe we hope to have ſome account from his friend the editor of his lectures.

BLACKLOCK (Dr Thomas) deſerves, on ſo many accounts, to have the principal incidents of his life recorded in this work, that to omit ſuch an article from our liſt of biographical ſketches would be unpardonable negligence. We cannot, however, propoſe to write of him any thing which has not been written before, by an author who has repeatedly appeared before the public, and on each appearance has gained poſſeſſion of the public heart. We ſhall therefore content ourſelves with inſerting in this place a ſhort abridgment of the elegant account of the life and writings of Dr Blacklock, which was prefixed to that edition of his works which was publiſhed in 1793; and if we thus leſſen our own labour, we are conſcious that we ſhall at the ſame time increaſe the pleaſure of our readers.

Thomas Blacklock was in 1721 born at Anan, in the county of Dumfries in Scotland, but his parents were natives of the bordering county of Cumberland; ſo that, though a native of Scotland, his deſcent was Engliſh. His father was a bricklayer, and his mother the daughter of a conſiderable dealer in cattle. Both were reſpectable in their characters, and poſſeſſed, tho'

Blacklock. moving in an humble ſphere, a conſiderable degree of knowledge and urbanity. Their ſon was not quite ſix months old when he loſt his eye-ſight in the ſmall-pox, which rendered him as complete a ſtranger to the viſible world as if he had been blind from the hour of his birth. It rendered him likewiſe incapable of learning any of the mechanical arts; and therefore his father kept him at home, and with the aſſiſtance of ſome friends foſtered that inclination which, at a very early period, he ſhewed for books. This was done by reading to him firſt the ſimple ſort of publications which are commonly put into the hands of children, and then ſeveral of our beſt authors, ſuch as Milton, Spencer, Prior, Pope, and Addiſon. His companions, whom his early gentleneſs and kindneſs of diſpoſition, as well as their compaſſion for his misfortune, ſtrongly attached to him, were very aſſiduous in their good offices, in reading to inſtruct and amuſe him. By their aſſiſtance he acquired ſome knowledge of the Latin tongue, but he never was at a grammar-ſchool till at a more advanced period of life. Poetry was even then his favourite reading; and he found an enthuſiaſtic delight in the works of the beſt Engliſh poets, and in thoſe of his countryman Allan Ramſay. Even at an age ſo early as twelve he began to write poems, one of which is preſerved in the collection that was publiſhed after his death, and is not perhaps inferior to any of the premature compoſitions of boys aſſiſted by the beſt education, which are only recalled into notice by the future fame of their authors.

He had attained the age of nineteen when his father was killed by the accidental fall of a malt-kiln belonging to his ſon-in-law. This loſs, heavy to any one at that early age, would have been, however, to a young man poſſeſſing the ordinary means of ſupport, and the ordinary advantages of education, comparatively light; but to him—thus ſuddenly deprived of that ſupport on which his youth had leaned—deſtitute almoſt of every reſource which induſtry affords to thoſe who have the bleſſings of ſight—with a body feeble and delicate from nature, and a mind congenially ſuſceptible—it was not ſurpriſing that this blow was doubly ſevere, and threw on his ſpirits that deſpondent gloom to which he then gave way in the following pathetic lines, and which ſometimes overclouded them in the ſubſequent period of his life:

> " Dejecting proſpect! ſoon the hapleſs hour
> " May come; perhaps this moment it impends,
> " Which drives me forth to penury and cold,
> " Naked, and beat by all the ſtorms of heav'n,
> " Friendleſs and guideleſs to explore my way;
> " Till on cold earth this poor unſhelter'd head
> " Reclining, vainly from the ruthleſs blaſt
> " Reſpite I beg, and in the ſhock expire."

He lived with his mother for about a year after his father's death, and began to be diſtinguiſhed as a young man of uncommon parts and genius. Theſe were at that time unaſſiſted by learning; the circumſtances of his family affording him no better education than the ſmattering of Latin which his companions had taught him, and the peruſal and recollection of the few Engliſh authors which they, or his father in the intervals of his profeſſional labours, had read to him. Poetry, however, though it attains its higheſt perfection in a cultivated ſoil, grows perhaps as luxuriantly in a wild one. To poetry, as we have before mentioned, he was devoted from his earlieſt days; and about this time ſeveral of his poetical productions began to be handed about, which conſiderably enlarged the circle of his friends and acquaintance. Some of his compoſitions being ſhewn to Dr Stevenſon, an eminent phyſician of Edinburgh, who was accidentally at Dumfries on a profeſſional viſit, that gentleman formed the benevolent deſign of carrying him to the Scotch metropolis, and giving to his natural endowments the aſſiſtance of a claſſical education. He came to Edinburgh in the year 1741, and was enrolled a ſtudent of divinity in the univerſity there, though at that time without any particular view of entering into the church. In that univerſity he continued his ſtudies under the patronage of Dr Stevenſon till the year 1745, when he retired to Dumfries, and reſided in the houſe of Mr M'Murdo, who had married his ſiſter, during the whole time of the civil war, which then raged in the country, and particularly diſturbed the tranquillity of the metropolis. When peace was reſtored to the nation, he returned to the univerſity, and purſued his ſtudies for ſix years longer. During this laſt reſidence in Edinburgh, he obtained, among other literary acquaintance, that of the celebrated David Hume, who attached himſelf warmly to Mr Blacklock's intereſts, and was afterwards particularly uſeful to him in the publication of the 4to edition of his Poems, which came out by ſubſcription in London in the year 1756. Previouſly to this, two editions in 8vo had been publiſhed at Edinburgh, the firſt in 1746, and the ſecond in 1754.

In the courſe of his education at Edinburgh, he acquired a proficiency in the learned languages, and became more a maſter of the French tongue than was then common in that city. For this laſt acquiſition he was chiefly indebted to the ſocial intercourſe to which he had the good fortune to be admitted in the houſe of Provoſt Alexander, who had married a native of France. At the univerſity he attained a knowledge of the various branches of philoſophy and theology, to which his courſe of ſtudy naturally led, and acquired at the ſame time a conſiderable fund of learning and information in thoſe various departments of ſcience and belles lettres, from which his want of ſight did not abſolutely preclude him.

In 1757, he began a courſe of ſtudy, with a view to give lectures in oratory to young gentlemen intended for the bar or the pulpit. On this occaſion he wrote to Mr Hume, informed him of his plan, and requeſted his aſſiſtance in the proſecution of it. But Mr Hume doubting the probability of its ſucceſs, he abandoned the project; and then, for the firſt time, adopted the decided intention of going into the church of Scotland. After applying cloſely for a conſiderable time to the ſtudy of theology, he paſſed the uſual trials in the preſbytery of Dumfries, and was by that preſbytery licenſed a preacher of the goſpel in the year 1759. As a preacher he obtained high reputation, and was fond of compoſing ſermons, of which he has left ſome volumes in manuſcript, as alſo a Treatiſe on Morals.

The tenor of his occupations, as well as the bent of his mind and diſpoſitions, during this period of his life, will appear in the following plain and unſtudied account, contained in a letter from a gentleman, who was then his moſt intimate and conſtant companion, the Rev. Mr Jameſon, Blacklock. Jameson, formerly minister of the Episcopal chapel at Dumfries, afterwards of the English congregation at Dantzic, and who lately resided, and perhaps yet resides, at Newcastle upon Tyne.

"His manner of life (says that gentleman) was so uniform, that the history of it during one day, or one week, is the history of it during the seven years that our personal intercourse lasted. Reading, music, walking, conversing, and disputing on various topics, in theology, ethics, &c. employed almost every hour of our time. It was pleasant to hear him engaged in a dispute, for no man could keep his temper better than he always did on such occasions. I have known him frequently very warmly engaged for hours together, but never could observe one angry word to fall from him. Whatever his antagonist might say, *he* always kept his temper. '*Semper paratus et refellere sine pertinacia, et refelli sine iracundia.*' He was, however, extremely sensible to what he thought ill usage, and equally so whether it regarded himself or his friends. But his resentment was always confined to a few satirical verses, which were generally burnt soon after.

"I have frequently admired with what readiness and rapidity he could sometimes make verses. I have known him dictate from thirty to forty verses, and by no means bad ones, as fast as I could write them; but the moment he was at a loss for a rhime or a verse to his liking, he stopt altogether, and could very seldom be induced to finish what he had begun with so much ardour."

This account sufficiently marks that eager sensibility, chastened at the same time with uncommon gentleness of temper, which characterised Dr Blacklock, and which indeed it was impossible to be at all in his company without perceiving. In the science of mind, this is that division of it which perhaps one would peculiarly appropriate to poetry, at least to all those lighter species which rather depend on quickness of feeling, and the ready conception of pleasing images, than on the happy arrangement of parts, or the skilful construction of a whole, which are essential to the higher departments of the poetical art. The first kind of talent is like those warm and light soils which produce their annual crops in such abundance; the last, like that deeper and firmer mould on which the roots of eternal forests are fixed. Of the first we have seen many happy instances in that sex which is supposed less capable of study or thought; from the last is drawn that masculine sublimity of genius which could build an Iliad or a Paradise Lost.

Dr Blacklock could never dictate till he stood up; and as his blindness made walking about without assistance inconvenient or dangerous to him, he fell insensibly into a vibratory sort of motion of his body, which increased as he warmed with his subject, and was pleased with the conceptions of his mind. This motion at last became habitual to him; and though he could sometimes restrain it when on ceremony, or on any public appearance, such as preaching, he felt a certain uneasiness from the effort, and always returned to it when he could without impropriety. This appearance he describes in a short poem, in which he gives a ludicrous picture of himself; a picture indeed, of which, though the outlines are true, the general effect is greatly overcharged. Though his features were hurt by the disease which deprived him of sight, there was a certain placid expression in his countenance, which marked the benevolence of his heart, and was calculated to procure to him individual attachments and general regard.

In 1762 he married Miss Sarah Johnston, daughter of Mr Joseph Johnston surgeon in Dumfries; a connection which formed the great solace and blessing of his future life, and gave him, with all the tenderness of a wife, all the zealous care of a guardian and a friend. This event took place a few days before his being ordained minister of the town and parish of Kircudbright, in consequence of a presentation from the crown, obtained for him by the earl of Selkirk, a benevolent nobleman, whom Mr Blacklock's situation and genius had interested in his behalf. But the inhabitants of the parish, whether from that violent aversion to patronage, which was then so universal in the southern parts of Scotland, from some political disputes which at that time subsisted between them and his noble patron, or from those prejudices which some of them might naturally enough entertain against a pastor deprived of sight, or perhaps from all these causes united, were so extremely disinclined to receive him as their minister, that after a legal dispute of nearly two years, it was thought expedient by his friends, as it had always been wished by himself, to compromise the matter, by resigning his right to the living, and accepting a moderate annuity in its stead. With this slender provision he removed in 1764 to Edinburgh; and to make up by his industry a more comfortable and decent subsistence, he adopted the plan of receiving a certain number of young gentlemen as boarders into his house, whose studies in languages and philosophy he might, if necessary, assist. In this situation he continued till the year 1787, when he found his time of life and state of health required a degree of quiet and repose, which induced him to discontinue the receiving of boarders. In 1767 the degree of doctor in divinity was conferred on him by the university and Marischal college of Aberdeen.

In the occupation which he thus exercised for so many years of his life, no teacher was perhaps ever more agreeable to his pupils, nor master of a family to its inmates, than Dr Blacklock. The gentleness of his manners, the benignity of his disposition, and that warm interest in the happiness of others which led him so constantly to promote it, were qualities that could not fail to procure him the love and regard of the young people committed to his charge; while the society, which esteem and respect for his character and his genius often assembled at his house, afforded them an advantage rarely to be found in establishments of a similar kind.

In this mixed society he appeared to forget the privation of sight, and the melancholy which it might at other times produce in his mind. He entered, with the cheerful playfulness of a young man, into all the sprightly narrative, the sportful fancy, and the humorous jest that rose around him. Next to conversation, music was perhaps the source of his greatest delight; for he not only relished it highly, but was himself a tolerable performer on several instruments, particularly the flute. He generally carried in his pocket a small *flageolet*, on which he played his favourite tunes; and was not displeased when asked in company to play or to sing them; a natural feeling for a blind man, who thus adds a scene to the drama of his society.

Of

Blacklock.

Of the happineſs of others, however, we are incompetent judges. Companionſhip and ſympathy bring forth thoſe gay colours of mirth and cheerfulneſs which they put on for a while, to cover perhaps that ſadneſs which we have no opportunity of witneſſing. Of a blind man's condition we are particularly liable to form a miſtaken eſtimate; we give him credit for all thoſe gleams of delight which ſociety affords him, without placing to their full account thoſe dreary moments of darkſome ſolitude to which the ſuſpenſion of that ſociety condemns him. Dr Blacklock had from nature a conſtitution delicate and nervous, and his mind, as is almoſt always the caſe, was in a great degree ſubject to the indiſpoſition of his body. He frequently complained of a lowneſs and depreſſion of ſpirits, which neither the attentions of his friends, nor the unceaſing care of a moſt affectionate wife, were able entirely to remove. The imagination we are ſo apt to envy and admire ſerves but to irritate this diſorder of the mind; and that fancy in whoſe creation we ſo much delight, can draw, from ſources unknown to common men, ſubjects of diſguſt, diſquietude, and affliction. Some of his later poems expreſs a chagrin, though not of an ungentle ſort, at the ſuppoſed failure of his imaginative powers, or at the faſtidiouſneſs of modern times, which he deſpaired to pleaſe.

" Such were his efforts, ſuch his cold reward,
" Whom once thy partial tongue pronounc'd a bard;
" Excurſive, on the gentle gales of ſpring,
" He rov'd, whilſt favour imp'd his timid wing;
" Exhauſted genius now no more inſpires,
" But mourns abortive hopes, and faded fires;
" The ſhort-liv'd wreath, which once his temples grac'd,
" Fades at the ſickly breath of ſqueamiſh taſte;
" Whilſt darker days his fainting flames immure
" In cheerleſs gloom and winter premature."

Theſe lines are, however, no proof of "exhauſted genius," or "faded fires." "Abortive hopes," indeed, muſt be the lot of all who, like Dr Blacklock, reach the period of old age. In early youth the heart of every one is a poet; it creates a ſcene of imagined happineſs and deluſive hopes; it clothes the world in the bright colours of its own fancy; it refines what is coarſe, it exalts what is mean; it ſees nothing but diſintereſtedneſs in friendſhip; it promiſes eternal fidelity in love. Even on the diſtreſſes of its ſituation it can throw a certain romantic ſhade of melancholy that leaves a man ſad, but does not make him unhappy. But at a more advanced age, "the fairy viſions fade," and he ſuffers moſt deeply who has indulged them the moſt.

About the time that theſe verſes were written, Dr Blacklock was, for the firſt time, afflicted with what to him muſt have been peculiarly diſtreſsful. He became occaſionally ſubject to deafneſs, which, though he ſeldom felt it in any great degree, was ſufficient, in his ſituation, to whom the ſenſe of hearing was almoſt the only channel of communication with the external world, to cauſe very lively uneaſineſs. Amidſt theſe indiſpoſitions of body, however, and diſquietudes of mind, the gentleneſs of his temper never forſook him, and he felt all that reſignation and confidence in the Supreme Being which his earlieſt and his lateſt life equally acknowledged. In ſummer 1791 he was ſeized with a feveriſh diſorder, which at firſt ſeemed of a ſlight, and never roſe to a very violent kind; but a frame ſo little robuſt as his was not able to reſiſt it, and after about a week's illneſs it carried him off on the 7th day of July 1791. His wife ſurvives him, to feel, amidſt the heavy affliction of his loſs, that melancholy conſolation which is derived from the remembrance of his virtues.

The writings of Dr Blacklock conſiſted principally of poems, which were publiſhed in 4to in the year 1793; and to that edition was added, *An Eſſay on the Education of the Blind, tranſlated from the French of M. Hauy.* But beſides his avowed works, we have reaſon to believe that he was the author of many articles in the ſecond edition of the *Encyclopædia Britannica*, though we cannot ſay with certainty what thoſe articles were. If our memory does not deceive us, we have been informed that the preface to that edition was furniſhed by him; and we have elſewhere attributed to him, on the beſt authority, the article BLIND, and the *Notes* to the article MUSIC: but he undoubtedly contributed much more to the work, aud was one of the principal guides of the proprietors.

Blair.

BLAIR (Dr Hugh), was born in Edinburgh, on the 7th day of April 1718. His father, John Blair, a reſpectable merchant in that city, was a deſcendant of the ancient family of Blair in Airſhire, and grandſon of the famous Mr Robert Blair miniſter of St Andrew's, chaplain to Charles I. and one of the moſt zealous and diſtinguiſhed clergymen of the period in which he lived. This worthy man, though firmly attached to the cauſe of freedom, and to the Preſbyterian form of church government, and though actively engaged in all the meaſures adopted for their ſupport; yet, by his ſteady, temperate conduct, commanded the reſpect even of his opponents. In preference to all the other eccleſiaſtical leaders of the covenanting party, he was ſelected by the king himſelf to fill an office which, from the circumſtances of the time, gave frequent acceſs to the royal perſon; "becauſe (ſaid his majeſty) that man is pious, prudent, learned, and of a meek and moderate calm temper." His talents ſeem to have deſcended as an inheritance to his poſterity. For of the two ſons who ſurvived him, David, the eldeſt, was a clergyman of eminence in Edinburgh, father to Mr Robert Blair miniſter of Athelſtonford, the celebrated author of the poem intitled *The Grave*; and grandfather to his majeſty's ſolicitor general for Scotland, whoſe maſculine eloquence and profound knowledge of law have, in the public eſtimation, placed him indiſputably at the head of the Scottiſh bar. From his youngeſt ſon Hugh, who engaged in buſineſs as a merchant, and had the honour to fill a high ſtation in the magiſtracy of Edinburgh, ſprung the learned clergyman who is the ſubject of this narrative..

The views of Dr Blair, from his earlieſt youth, were turned towards the church; and his education received a ſuitable direction. After the uſual grammatical courſe at ſchool, he entered the humanity claſs in the univerſity of Edinburgh in October 1730, and ſpent eleven years at that celebrated ſeminary, aſſiduouſly employed in the literary and ſcientific ſtudies preſcribed by the church of Scotland to all who are to become candidates for her licence to preach the goſpel. During this important period, he was diſtinguiſhed among his companions both for diligence and proficiency; and obtained from the profeſſors under whom he ſtudied repeated teſtimonies of approbation. One of them deſerves

Blair.

ſerves to be mentioned particularly, becauſe, in his own opinion, it determined the bent of his genius towards polite literature. An eſſay Περι του καλου, or, *On the Beautiful*, written by him when a ſtudent of logic in the uſual courſe of academical exerciſes, had the good fortune to attract the notice of profeſſor Stevenſon, and, with circumſtances honourable to the author, was appointed to be read in public at the concluſion of the term or ſeſſion. This mark of diſtinction made a deep impreſſion on his mind; and the eſſay which merited it he ever after recollected with partial affection, and preſerved to the day of his death as the firſt earneſt of his fame.

At this time Dr Blair commenced a method of ſtudy which contributed much to the accuracy and extent of his knowledge, and which he continued to practiſe occaſionally even after his reputation was fully eſtabliſhed. It conſiſted in making abſtracts of the moſt important works which he read, and in digeſting them according to the train of his own thoughts. Hiſtory, in particular, he reſolved to ſtudy in this manner; and, in concert with ſome of his youthful aſſociates, he conſtructed a very comprehenſive ſcheme of chronological tables, for receiving into its proper place every important fact that ſhould occur. The ſcheme deviſed by this young ſtudent for his own private uſe was afterwards improved, filled up, and given to the public by his learned friend Dr John Blair, prebendary of Weſtminſter, in his valuable work, "The Chronology and Hiſtory of the World."

In the year 1739, Dr Blair took his degree of A.M. On that occaſion he printed and defended a theſis, *De Fundamentis et Obligatione Legis Naturæ*, which contains a ſhort but maſterly diſcuſſion of this important ſubject, and exhibits in elegant Latin an outline of the moral principles which have been ſince more fully unfolded and illuſtrated in his Sermons.

The univerſity of Edinburgh, about this period, numbered among her pupils many young men who were ſoon to make a diſtinguiſhed figure in the civil, the eccleſiaſtical, and the literary hiſtory of their country. With moſt of them Dr Blair entered into habits of intimate connection, which no future competition or jealouſy occurred to interrupt, which held them united through life in their views of public good, and which had the moſt beneficial influence on their own improvement, on the progreſs of elegance and taſte among their contemporaries, and on the general intereſts of the community to which they belonged.

On the completion of his academical courſe, he underwent the cuſtomary trials before the preſbytery of Edinburgh, and received from that venerable body a licence to preach the Goſpel on the 21ſt of October 1741. His public life now commenced with very favourable proſpects. The reputation which he brought from the univerſity was fully juſtified by his firſt appearances in the pulpit; and, in a few months, the fame of his eloquence procured for him a preſentation to the pariſh of Coleſſie in Fife, where he was ordained to the office of the holy miniſtry on the 23d of September 1742. But he was not permitted to remain long in this rural retreat. A vacancy in the ſecond charge of the Canongate, a ſuburb of Edinburgh, furniſhed to his friends an opportunity of recalling him to a ſtation more ſuited to his talents. And, though one of the moſt popular and eloquent clergymen in the church was placed in competition with him, a great majority of the electors decided in favour of this young orator, and reſtored him in July 1743 to the bounds of his native city.

Blair.

In this ſtation Dr Blair continued eleven years, diſcharging with great fidelity and ſucceſs the various duties of the paſtoral office. His diſcourſes from the pulpit in particular attracted univerſal admiration. They were compoſed with uncommon care; and, occupying a middle place between the dry metaphyſical diſcuſſion of one claſs of preachers, and the looſe incoherent declamation of another, they blended together, in the happieſt manner, the light of argument with the warmth of exhortation, and exhibited captivating ſpecimens of what had hitherto been rarely heard in Scotland, the poliſhed, well-compacted, and regular didactic oration.

In conſequence of a call from the town-council and general-ſeſſion of Edinburgh, he was tranſlated from the Canongate to Lady Yeſter's, one of the city churches, on the 11th of October 1754: and on the 15th day of June 1758, he was promoted to the High Church of Edinburgh, the moſt important eccleſiaſtical charge in Scotland. To this charge he was raiſed at the requeſt of the Lords of Council and Seſſion, and of the other diſtinguiſhed official characters who have their ſeats in that church. And the uniform prudence, ability, and ſucceſs, which, for a period of more than forty years, accompanied all his miniſterial labours in that conſpicuous and difficult ſtation, ſufficiently evince the wiſdom of their choice.

Hitherto his attention ſeems to have been devoted almoſt excluſively to the attainment of profeſſional excellence, and to the regular diſcharge of his parochial duties. No production of his pen had yet been given to the world by himſelf, except two ſermons preached on particular occaſions; ſome tranſlations, in verſe, of paſſages of Scripture for the pſalmody of the church; and a few articles in the Edinburgh Review; a publication begun in 1755, and conducted for a ſhort time by ſome of the ableſt men in the kingdom. But ſtanding as he now did at the head of his profeſſion, and releaſed by the labour of former years from the drudgery of weekly preparation for the pulpit, he began to think ſeriouſly on a plan for teaching to others that art which had contributed ſo much to the eſtabliſhment of his own fame. With this view, he communicated to his friends a ſcheme of lectures on compoſition; and having obtained the approbation of the univerſity, he began to read them in the college on the 11th of December 1759. To this undertaking he brought all the qualifications requiſite for executing it well; and along with them a weight of reputation, which could not fail to give effect to the leſſons he ſhould deliver. For, beſides the teſtimony given to his talents by his ſucceſſive promotions in the church, the univerſity of St Andrew's, moved chiefly by the merit of his eloquence, had in June 1757 conferred on him the degree of D. D. a literary honour which at that time was very rare in Scotland. Accordingly his firſt courſe of lectures was well attended, and received with great applauſe. The patrons of the univerſity, convinced that they would form a valuable addition to the ſyſtem of education, agreed in the following ſummer to inſtitute a rhetorical claſs, under his direction, as a permanent part of their academical eſtabliſhment: and on the 7th of April 1762, his Majeſty was graciouſly pleaſed "to erect and endow a pro-

Blair.

professorship of rhetoric and belles lettres in the university of Edinburgh; and to appoint Dr Blair, in consideration of his approved qualifications, regius professor thereof, with a salary of L.70." The lectures which he read as professor of rhetoric, he published in 1783, when he retired from the labours of the office; and the general voice of the public has pronounced them to be a most judicious, elegant, and comprehensive system of rules for forming the style and cultivating the taste of youth.

About the time in which he was occupied in laying the foundations of this useful institution, he had an opportunity of conferring another important obligation on the literary world, by the part which he acted in rescuing from oblivion the poems of Ossian. It was by the solicitation of Dr Blair and Mr John Home, that Mr Macpherson was induced to publish his *Fragments of Ancient Poetry;* and their patronage was of essential service in procuring the subscription which enabled him to undertake his tour through the Highlands for collecting the materials of Fingal, and of those other delightful productions which bear the name of Ossian. To these productions Dr Blair applied the test of genuine criticism; and soon after their publication gave an estimate of their merits in *a Dissertation*, which, for beauty of language, delicacy of taste, and acuteness of critical investigation, has few parallels. It was printed in 1763, and spread the reputation of its author throughout Europe.

The great objects of his literary ambition being now attained, his talents were for many years consecrated solely to the important and peculiar employments of his station. It was not till the year 1777 that he could be induced to favour the world with a volume of the Sermons which had so long furnished instruction and delight to his own congregation. But this volume being well received, the public approbation encouraged him to proceed: four other volumes followed at different intervals, the last of which was published after his death; and all of them experienced a degree of success of which few publications can boast. They circulated rapidly and widely wherever the English tongue extends; they were soon translated into almost all the languages of Europe; and his present Majesty, with that wise attention to the interests of religion and literature which distinguishes his reign, was graciously pleased to judge them worthy of a public reward. By a royal mandate to the Exchequer in Scotland, dated July 25th 1780, a pension of L.200 a-year was conferred on their author, which continued unaltered till his death.

In that department of his professional duty which regarded the government of the church, Dr Blair was steadily attached to the cause of moderation. From diffidence, and perhaps from a certain degree of inaptitude for extemporary speaking, he took a less public part in the contests of ecclesiastical politics than some of his contemporaries; and, from the same causes, he never would consent to become moderator of the General Assembly of the Church of Scotland. But his influence among his brethren was extensive: his opinion, guided by that sound uprightness of judgment, which formed the predominant feature of his intellectual character, had been always held in high respect by the friends with whom he acted; and, for many of the last years of his life, it was received by them almost as a law. The great leading principle in which they cordially concurred with him, and which directed all their measures, was to preserve the church, on the one side, from a slavish, corrupting dependance on the civil power; and, on the other, from a greater infusion of democratical influence than is compatible with good order, and the established constitution of the country.

The reputation which he acquired in the discharge of his public duties, was well sustained by the great respectability of his private character. Deriving from family associations a strong sense of clerical decorum, feeling on his heart deep impressions of religious and moral obligation, and guided in his intercourse with the world by the same correct and delicate taste which appeared in his writings, he was eminently distinguished through life by the prudence, purity, and dignified propriety of his conduct. His mind, by constitution and culture, was admirably formed for enjoying happiness. Well balanced in itself by the nice proportion and adjustment of its faculties, it did not incline him to any of those eccentricities, either of opinion or of action, which are too often the lot of genius:—free from all tincture of envy, it delighted cordially in the prosperity and fame of his companions: sensible to the estimation in which he himself was held, it disposed him to dwell at times on the thought of his success with a satisfaction which he did not affect to conceal: inaccessible alike to gloomy and to peevish impressions, it was always master of its own movements, and ready, in an uncommon degree, to take an active and pleasing interest in every thing, whether important or trifling, that happened to become for the moment the object of his attention. This habit of mind, tempered with the most unsuspecting simplicity, and united to eminent talents and inflexible integrity, while it secured to the last his own relish of life, was wonderfully calculated to endear him to his friends, and to render him an invaluable member of any society to which he belonged. Accordingly there have been few men more universally respected by those who knew him, more sincerely esteemed in the circle of his acquaintance, or more tenderly beloved by those who enjoyed the blessing of his private and domestic connection.

In April 1748, he married his cousin Katharine Bannatine, daughter of the Rev. James Bannatine, one of the ministers of Edinburgh. By her he had a son who died in infancy, and a daughter who lived to her twenty-first year, the pride of her parents, and adorned with all the accomplishments that became her age and sex. Mrs Blair herself, a woman of great good sense and spirit, was also taken from him a few years before his death, after she had shared with the tenderest affection in all his fortunes, and contributed near half a century to his happiness and comfort.

Dr Blair had been naturally of a feeble constitution of body; but as he grew up his constitution acquired greater firmness and vigour. Though liable to occasional attacks from some of the sharpest and most painful diseases that afflict the human frame, he enjoyed a general state of good health; and, through habitual cheerfulness, temperance, and care, survived the usual term of human life.—For some years he had felt himself unequal to the fatigue of instructing his very large congregation from the pulpit; and, under the impression

which

Blair, Bleaching. which this feeling produced, he has been heard at times to ſay with a ſigh, " that he was left almoſt the laſt of his contemporaries." Yet he continued to the end in the regular diſcharge of all his other official duties, and particularly in giving advice to the afflicted, who, from different quarters of the kingdom, ſolicited his correſpondence. His laſt ſummer was devoted to the preparation of the laſt volume of his ſermons; and, in the courſe of it, he exhibited a vigour of underſtanding and capacity of exertion equal to that of his beſt days. He began the winter pleaſed with himſelf on account of the completion of this work; and his friends were flattered with the hope that he might live to enjoy the acceſſion of emolument and fame which he expected it would bring. But the ſeeds of a mortal diſeaſe were lurking unperceived within him. On the 24th of December 1800, he complained of a pain in his bowels, which, during that and the following day, gave him but little uneaſineſs; and he received as uſual the viſits of his friends. On the afternoon of the 26th, the ſymptoms became violent and alarming:—he felt that he was approaching the end of his appointed courſe: and retaining to the laſt moment the full poſſeſſion of his mental faculties, he expired on the morning of the 27th, with the compoſure and hope which become a Chriſtian paſtor.

The lamentation for his death was univerſal and deep through the city which he had ſo long inſtructed and adorned. Its magiſtrates, participating in the general grief, appointed his church to be put in mourning; and his colleague in it, Dr Finlayſon, from whom this account of his life is borrowed*, preached his funeral ſermon, in which his character is drawn in a maſterly manner, though with the almoſt unavoidable partiality of friendſhip.

* *Blair's Sermons*, vol. v.

If we, who know Dr Blair only in his writings, might preſume to eſtimate his intellectual character, we ſhould ſay that he poſſeſſed a ſound judgment rather than what could be called a vigorous mind; that he had more taſte than genius; and that he taught ſucceſsfully, as far as it can be taught, *the art of poetry*, though he could not himſelf have been a poet. His moral character was amiable and reſpectable, though he ſeems, even from a hint dropt by his biographer, to have been in a ſlight degree tinctured with vanity. But this was ſurely a venial weakneſs; for where is the head that would be wholly unaffected by the fumes of incenſe burnt before it for fifty years?

BLEACHING. Since the article *Bleaching* in the Encyclopædia was written, very great improvements have been introduced into the art. Of theſe improvements we ſhall proceed to give an account.

1 Diſcovery of the oxy-muriatic acid.

Mr Scheele of Sweden diſcovered the oxy-muriatic acid, or dephlogiſticated muriatic acid, as he called it, about the year 1774, and ſoon after obſerved its effects on vegetable colours. His method of procuring it was as follows: In a ſand-bath is to be placed a glaſs retort, in which muriatic acid has been poured upon manganeſe; to this ſmall receivers are to be adapted capable of containing about twelve ounces each, into which is to be poured about two drachms of water, without any other lute than a ſlip of blotting-paper about the neck of the retort. In about a quarter of an hour a yellow air is perceived in the receiver, which is to be taken off. If the paper has been properly applied, the air ruſhes out forcibly; the receiver muſt be quickly ſtopped, and another applied. Thus many receivers may be filled with the dephlogiſticated muriatic acid; but it is neceſſary to place the retort in ſuch a manner that the drops which riſe into its neck may be able to fall back. The water ſerves to retain the vapours of the acid. "I uſe (ſays he) many receivers, that I may not be obliged to repeat a ſimilar diſtillation for every experiment. It is not proper to employ large ones, becauſe every time they are opened a great part of the acid is diſſipated in the air. What I ſubmitted to examination with this dephlogiſticated muriatic acid was placed in the neck of the receiver, which I had ſtopped. The cork was turned yellow as by aquafortis. Paper tinged with turnſol became almoſt white; all red, blue, and yellow flowers, as alſo green plants, turned yellow in a ſhort time, and the water in the receiver was changed into pure but weak muriatic acid. Neither alkalis nor acids were able to reſtore the colours of the flowers, or of the plants."

M. Berthollet, in 1785, proved that this acid was compoſed of muriatic acid combined with oxygen; and that when it had deprived vegetable matters of their colour, it was reduced to the ſtate of common muriatic acid; that is, it had loſt the oxygen with which it was united. This oxygen had combined with the colouring particles of the vegetable matter, and had rendered them colourleſs. After making theſe obſervations, it occurred to him that the oxy-muriatic acid might produce the ſame effect upon thoſe particles which give colour to thread and cloth, and which it is the object of bleaching to deſtroy. "At firſt (ſays he) I made uſe of water highly impregnated with this acid; and I renewed it when it was exhauſted, until the thread or cloth appeared white; but I ſoon perceived that they were conſiderably weakened, and that they were entirely loſing their ſolidity. I then weakened the liquor a little, and I ſucceeded in bleaching cloth without damaging it. But it ſpeedily became yellow by keeping, eſpecially if it was warmed, or paſſed through an alkaline ley. I reflected upon the circumſtances of common bleaching, and I endeavoured to imitate its proceſs, becauſe I thought the oxygenated muriatic acid might act in the ſame manner as the expoſition of the cloth in the meadows, which alone does not ſuffice, but which appears only to diſpoſe the colouring parts of the cloth to be diſſolved by the alkali of the ley. I examined dew, not only that which falls from the atmoſphere, but alſo that which comes from the nocturnal tranſpiration of plants; and I obſerved that both of them were impregnated with oxygen, ſufficiently to deſtroy the colour of paper ſlightly tinged with turnſol.

2 Its application to bleaching.

Ann. de Chim. II. 158.

"I therefore employed leys, and the action of oxygenated muriatic acid, alternately, and I then obtained a permanent white; and as, at the finiſhing of the common bleaching, the cloth is paſſed through four milk, or through ſulphuric acid diluted with a very large quantity of water, I alſo tried paſſing the cloth through a very dilute ſolution of ſulphuric acid, and I obſerved that the white was thereby rendered more clear. As ſoon as I made uſe of the leys intermediately, I found that it was not neceſſary to employ a concentrated liquor, or to let the cloth, at every immerſion, remain long therein: by this I avoided two inconveniencies, which would have rendered this proceſs impoſſible to be be practiſed in the large way. The firſt is the ſuffocating odour of the liquor, which it would be very inconvenient, and even dangerous, to reſpire for any length of time, and which has diſcouraged many perſons who tried to uſe it; the ſecond is, the danger of weakening the cloth. I now alſo left off mixing any alkali with the oxygenated muriatic acid, as I had practiſed in the greateſt part of my firſt trials.

"This is nearly the ſtate in which my experiments were, when I made ſome trials in the preſence of the celebrated Mr Watt. A ſingle view ſufficed for a philoſopher whoſe genius has been exerciſed ſo long upon the arts. In a ſhort time Mr Watt wrote to me from England, that even in the firſt operation he had bleached five hundred pieces of cloth at Mr Grigor's, who has a large bleaching-ground at Glaſgow, and who continues to make uſe of the new proceſs. In the mean time M. Bonjour, who had hitherto aſſiſted me in my experiments, and who joins great ſagacity to a moſt extended knowledge of chemiſtry, aſſociated himſelf with Mr Conſtant, at Valenciennes, in order to form an eſtabliſhment in that city."

M. Caillau made a great number of experiments at Paris reſpecting this new mode of bleaching; but the greateſt part of theſe experiments was made upon cotton, which is more eaſy to bleach, and does not require leys ſo often or ſo ſtrong as flax or hemp. He alſo went to St Quentin, to perform the operation upon the cloth of that country; but he found that all the cloths, which he had bleached to the ſatisfaction of the manufacturers, became again of a reddiſh colour when they were expoſed to a common ley, or even when they were left for ſome time in a warehouſe. Several ſimilar complaints were made by other perſons; and M. Berthollet himſelf had obſerved the ſame thing in his own experiments. M. Bonjour, however, and M. Welter, affirmed that the cloth which they had bleached preſerved its colour perfectly. M. Berthollet ſoon found, that the imperfection in his bleaching was owing to the manner in which he had uſed the leys. "I had contented myſelf (ſays he), in thoſe trials on ſmall pieces which I made in my laboratory, to pour the hot alkaline ſolution into a veſſel where I placed the pieces: it there became cool very rapidly, and therefore did not act with ſufficient power; but when I let theſe pieces remain in the liquor, which I kept nearly in a boiling heat during the ſpace of two or three hours, they were then no longer ſubject to the above mentioned defects: it was therefore merely the weakneſs of the leys which had occaſioned the accidents which were experienced by Meſſrs Caillau, Décroiſille, and myſelf. It is neceſſary that the colour of the cloth ſhould not be changed by the laſt ley, and this is the ſureſt mark that the bleaching is finiſhed; nevertheleſs, after this laſt action of the ley, it is proper to put the cloth, for a few moments, in the bleaching liquor.

Ann. de Chim. II. 158.

"After this laſt immerſion, it is neceſſary to plunge the cloth in ſour milk, or in water acidulated with ſulphuric acid. I do not know the moſt convenient proportion of ſulphuric acid; but it appeared to me that we might ſucceſsfully, and without danger, make uſe of one part, in weight, of this acid to fifty of water. We muſt keep the cloths during about half an hour in this liquor warmed; after which it is proper to ſqueeze them well, and plunge them directly into common water; for if the evaporation ſhould take place, the ſulphuric acid, becoming thereby concentrated, would corrode them. The cloths being then well waſhed, require only to be dried and dreſſed in the ordinary manner, according to their different ſorts.

"It is of the utmoſt importance to take care that the water is not too ſtrongly impregnated with the ſulphuric acid.

"The bleaching of cotton cloth is much eaſier and ſhorter; two leys, or at moſt three, and as many immerſions in the bleaching liquor, are ſufficient for them. As they are bleached ſo eaſily, it is advantageous, when there are flaxen, hempen, and cotton cloths, to be bleached, to reſerve for the cotton the liquors which have been previouſly weakened by the cloths of flax or hemp; for it is economical to exhauſt the liquors as much as poſſible, and thoſe which are conſiderably weakened ſtill ſuffice for the cotton, although they have ſcarcely any action upon hemp or flax.

"Thread, in the common way of bleaching, is attended with a far greater number of difficulties than cloth; becauſe of the immenſe number of ſurfaces which it is neceſſary to preſent ſucceſſively to the action of the atmoſphere. Some part of theſe difficulties occur in bleaching with the oxygenated muriatic acid; nevertheleſs, in the end, it is more advantageous with reſpect to thread than with reſpect to cloth. M. Welter has formed at Liſle, with two partners, an eſtabliſhment for bleaching thread, with great ſucceſs, and he has already begun ſome others. He has found that ten or twelve leys, and as many immerſions, are required for ſome ſorts of thread; and, that the thread may be ſurrounded with the liquor, it is neceſſary to place it, quite looſely, in a baſket, which permits the liquor to penetrate to all its ſurfaces; when the liquor is much weakened, it is ſtill fit to be uſed for the bleaching of cotton.

"I had, in the beginning of my experiments, tried whether the vapour would not be preferable to the oxygenated muriatic acid in a liquid ſtate, and I obſerved that it bleached with greater quickneſs; but, whatever precautions I employed, it appeared to me that a conſiderable loſs of it took place; that thoſe parts of the cloths which were the moſt expoſed to it were ſubject to be weakened; and that it was more difficult to obtain an equal whiteneſs throughout.

"To prevent all the accidents which may reſult from the liquor acting with too great power, it is important to have a means of meaſuring its force. M. Décroiſille thought of uſing, for that purpoſe, a ſolution of indigo in ſulphuric acid. He takes one part of indigo, reduced into fine powder, and eighteen parts of concentrated ſulphuric acid; this mixture is put into a matraſs, which is kept, during ſome hours, in a water-bath; when the ſolution is finiſhed, it is diluted with a thouſand parts of water. To try the power of the oxygenated muriatic acid, one meaſure of this ſolution is put into a graduated glaſs tube, and ſome of the liquor is gradually added to it, until the colour of the indigo is deſtroyed. We muſt firſt determine how many meaſures of a liquor, the goodneſs of which has been aſcertained by experiments made upon cloth, are neceſſary to deſtroy the colour of one meaſure of the ſolution of indigo, and this number will ſerve to eſtimate the reſpective ſtrength of all the liquors which it may be neceſſary

Bleaching. ceffary to compare with it. Mr Watt employs, in the fame manner, a folution of cochineal."

3 Method of procuring the acid for bleaching.

M. Berthollet recommended the following method of procuring the oxy-muriatic acid: "If we have good oxide of manganefe, formed in fmall cryftals, and containing but little extraneous matter, the proportions of the fubftances to be fubmitted to diftillation are the following: Six ounces of calx of manganefe reduced to powder; one pound of common falt, alfo reduced to powder; twelve ounces of concentrated fulphuric acid, or oil of vitriol; from ten to twelve ounces of water.

"When thefe materials are prepared, we muft carefully mix the oxide of manganefe with the common falt, and introduce the mixture into the diftilling veffel placed upon a fand bath: we muft then pour upon it the fulphuric acid, previoufly diluted (and of which the heat occafioned by its mixture with water is diffipated), and immediately apply to the mouth of the matrafs the tube which is to conduct the gas into the intermediate veffel.—It muft not be forgot, that in this operation the lutes require particular attention.

"The fize of the veffels fhould be fuch, that the diftilling matrafs may be about one-third empty; and, for the quantity above mentioned, the tub fhould hold 100 quarts of water; there fhould alfo be an empty fpace of about 10 quarts, in order that when the gas lodges itfelf in the cavities intended to receive it, the water may have a free fpace to rife in.

"Before the commencement of the operation, the pneumatic tub muft be filled with water. The mixture being made, the gas, which very foon begins to difengage itfelf, drives out the atmofpherical air which is in the apparatus; when it is judged that the atmofpheric air has paffed into the cavities, it is to be drawn off by means of a bent tube, which is to be introduced fucceffively under each cavity: to drive out the water which has entered into the tube, this laft is to be forcibly blown into. The operation is then fuffered to go on without fire until it is perceived that the bubbles come over but flowly: then a little fire is to be applied, which is not to be haftily increafed at the beginning, but may be gradually augmented, fo that at the end of the operation the matter may be brought to a boiling ftate. It is known to be nearly finifhed when the tube by which the gas is difengaged, and the intermediate veffel, become hot. When the gas is difengaged only in a fmall quantity, the fire may be withdrawn; and when the diftilling veffel retains but a gentle warmth, it is to be unluted, and warm water is to be poured upon the refidue, that it may remain in folution, and thereby be more eafily poured out.

"The operation is longer or fhorter according to the quantity of materials: with that above mentioned, it fhould laft five or fix hours; it is proper not to haften it, that a larger quantity of gas may be drawn off. A fingle perfon is able to manage feveral diftillations at the fame time; to each of which may be given much larger quantities of materials than thofe which have been pointed out.

"The intermediate veffel by degrees becomes filled with a liquor, which is pure, though weak, muriatic acid; neverthelefs, we may perform the operation feveral times without extracting it: but when it is fuppofed that there is not fufficient empty fpace, this acid is to be drawn off by means of a fyphon, and, when we have collected a fufficient quantity of it, it may be fubftituted for the mixture of vitriolic acid and common falt in the operation we have defcribed, if we have no other ufe to make of it. That there may pafs but a fmall quantity of muriatic acid, not oxygenated, the firft tube ought to form a right angle, or even an obtufe one, with the body matrafs.

"During the operation, the agitator muft be from time to time put in motion, to favour the abforption of the gas by the water; when it is finifhed, the liquor is of a proper ftrength to ufe in bleaching; or we may put a lefs quantity of water in the tub, and then dilute the liquor according to the proportion already mentioned.

"In this ftate of concentration, although the liquor has a pretty ftrong odour, it neverthelefs is not hurtful, nor even very unpleafant, to thofe who ufe it: it is, however, proper to conduct it into the troughs where the cloths are placed by means of wooden canals, which are to be connected with the faufet or tube which is at the lower part of the tub."—The following is a defcription of the apparatus:

Plate VII. fig. 1.

ABCD is a reverberatory furnace, having, on a line with B, many fmall openings in its circumference, to ferve as chimneys; within which, upon a fand-bath *a*, is placed a matrafs *b*, the neck of which ftands out above the furnace, running through the opening D; which is to be clofed with clay. The mouth F, of the neck of the matrafs, is clofed by a cork G, through the middle of which paffes a tube H, which forms a communication between the infide of the matrafs *b*, and the intermediate veffel K, where it alfo paffes through a cork I, which clofes one of the three openings of that veffel. The corks G and I ought to be prepared before-hand, and well fitted to each end of the tube of communication H, which is to be fo difpofed that it may be fitted in immediately after the mixture is made in the matrafs.

The intermediate veffel K is about an eighth part full of water; into it is plunged the tube of fafety L, to prevent danger from regurgitation. This tube ought to be fo high, that the weight of the water which enters into it, by the preffure of the gas, may be great enough to caufe the gas to pafs into the pneumatic tub NOP, by the tube of communication M, which is plunged therein, and reaches to the bottom, where it is bent horizontally, fo that the gas may be emitted under the firft of the three wooden, or (if they can be procured) ftoneware, cavities, or receivers, which are placed in the infide of the tub, one above the other. O is a handle which ferves to turn the agitator E, the movement of which facilitates the combination of the gas with the water. P is a fpigot and faufet to draw off the liquor.

4 Method of bleaching.

It is neceffary to prepare the cloth by leaving it to foak for 24 hours in water, or, which is better, in fome old ley. Afterwards it fhould be fubmitted to the action of one or two good leys; becaufe all the colouring part which may be extracted by the leys would elfe, without any advantage, confume a part of that liquor, which it is important to be as fparing of as poffible. After this, the cloth is to be carefully wafhed; then it is to be placed in the troughs, without any part being preffed or confined, in fuch a manner that it may be thoroughly impregnated with the liquor which is to run

Bleaching. run thereon. The troughs, as well as the tub, ought to be conſtructed without iron; for that metal, being ruſted by the oxygenated muriatic acid, would produce iron moulds, which could not be taken out but by means of ſalt of ſorrel.

The firſt immerſion ought to be longer than the others; it may be continued for three hours, after which the cloth is to be taken out; it is to be again ſubmitted to the action of ley, and then placed in a trough, that freſh liquor may be poured thereon: it is ſufficient that this immerſion, and the following ones, continue half an hour. When the cloth is taken from the trough, the liquor is to be wrung out, it is to be again ſubmitted to the ley, and afterwards to freſh immerſions. The ſame liquor may ſerve until its ſtrength is exhauſted: when it is much weakened, there may be ſome freſh liquor added to it. When the cloth appears white, except ſome black threads and the liſts, it is to be impregnated with black ſoap, and then ſtrongly rubbed; after which it is to be ſubmitted to the laſt ley and the laſt immerſion. We cannot determine what number of leys and immerſions may be neceſſary, becauſe it varies according to the nature of the cloth: neverthleſs, the limits of this number are between four and eight for linen or hempen cloths.

The manufacturers at Javelle, to whom M. Berthollet had communicated this proceſs, ſoon after publiſhed, in different journals, that they had diſcovered a particular liquor which had the property of bleaching cloth by an immerſion of ſome hours only. The change they had made in the proceſs, performed in their preſence, conſiſted in putting ſome alkali into the water which receives the gas; this enables the liquor to become much more concentrated, ſo that it may be diluted with ſeveral times its own quantity of water before it is uſed.

"Theſe are the proportions which yielded me (ſays Berthollet), a liquor ſimilar to the pretended Javelle ley: two ounces and a half of common ſalt, two ounces of ſulphuric acid, ſix drachms of calx of mangaueſe, and, in the veſſel where the gas is to be concentrated, one pound of water, and five ounces of potaſh, which ſhould be diſſolved in the water. The Javelle liquor has a ſomewhat reddiſh appearance, occaſioned by a ſmall quantity of manganeſe, which either paſſes in the diſtillation, becauſe an intermediate veſſel is not uſed, or exiſts in the potaſh; moſt kinds of which contain it, as I have well convinced myſelf.

"This liquor may be diluted with from ten to twelve parts of water; and, after this, it bleaches more ſpeedily than the liquor itſelf; but without ſpeaking of the imperfections of the method which is deſcribed in the publications from Javelle, and which can only ſuffice for cotton, we are not able to bleach near the ſame quantity of cloth with the oxygenated muriatic acid combined in this manner with an alkali, as might be bleached with the ſame quantity of that acid mixed with water alone; becauſe there is formed a portion of that neutral ſalt which is known at preſent by the name of oxygenated muriat of potaſs, and in which the oxygen becomes concentrated. Now all the oxygen which enters into the compoſition of this ſalt is rendered uſeleſs for bleaching; becauſe the oxygenated muriat of potaſh does not deſtroy colours."

This method of bleaching was very ſoon adopted in Britain, and is now almoſt univerſal among bleachers. A great many changes have been made in the proceſs; one of the moſt important of which is ſubſtituting lead veſſels for wooden ones, which, beſides weakening its action exceedingly, were very ſoon deſtroyed by the acid. We believe, too, that the bleachers very generally add ſome alkali to the acid, notwithſtanding the ſtrong objections which Mr Berthollet has made to that manner of bleaching.

This method of bleaching has been found to anſwer remarkably well: the only objection that has been made to it is, that the cloth is apt to be weakened. And this, no doubt, muſt be the caſe, if care be not taken to prevent the acid from being too much concentrated: but we have little doubt that, with a ſufficient degree of caution, it will prove as ſafe as any other whatever; and, in point of expedition, there cannot ſurely be any compariſon drawn between the old mode of bleaching and the new.

5 Theory of bleaching.

It remains for us now to conſider whether the new diſcoveries in chemiſtry do not throw ſome rays of light upon the theory of bleaching; for it is only by perfecting the theory that we can advance with certainty in our practical improvements.

It has been already obſerved, in the article Bleaching (*Encycl.*), that cloth, after being bleached, was a good deal lighter than it had been before that operation: It follows, therefore, that it muſt have been deprived of ſomething during the bleaching. Cloth bleached by means of the oxy-muriatic acid likewiſe undergoes a loſs of weight; ſo that, in all probability, both modes act in preciſely the ſame manner.

If raw linen or thread be boiled in a ſolution of cauſtic alkali, properly diluted, it gives out ſomething which tinges the ley of a deep brown, and at the ſame time the alkali loſes its cauſticity. If the linen be boiled in another ſimilar ſolution, it communicates the ſame colour, and even a third may be ſlightly tinged; but after this, alkalies, unleſs ſo much concentrated as to injure the texture of the cloth, have no effect on it whatever. If the linen be now plunged into oxy-muriatic acid, properly prepared, and allowed to remain till it begins to become white, and then plunged into an alkaline ley, the alkali loſes its cauſticity, and aſſumes the ſame deep colour that the firſt ley did. Here, then, we have two alkaline ſolutions; the one ſaturated with colouring matter before the action of the oxy-muriatic acid on the linen, the other after it. When theſe ſolutions are ſaturated with an acid, a yellow-coloured precipitate is obtained, which when dried aſſumes the appearance of a black powder. Preciſely the ſame ſubſtance is obtained from both ſolutions. This colouring matter is almoſt inſoluble in water. Pure or cauſtic potaſs diſſolves about double its own weight of it; carbonat of potaſs not ſo much.

Hence we ſee the uſe of alkalies in bleaching. The colouring matter is not ſoluble in water, but part of it is ſoluble in alkali. However, after the alkali has exhauſted all its power, the linen is not white: colouring matter therefore exiſts in it, which alkalies cannot act upon. But after being plunged in oxy-muriatic acid, it alſo becomes ſoluble in acids. Here, then, is the uſe of that acid in bleaching—it communicates ſomething to the colouring matter which renders it ſoluble in alkali. This ſomething, we have already ſeen, is oxygen. It follows, Bleaching. follows, therefore, that before the greater part of the colouring matter of linen can be extracted by alkalies, it must be combined with oxygen. It is in producing this combination that the use of the exposure to the sun and air consists; and it is because the oxy-muriatic acid produces it almost instantaneously, that the new mode of bleaching is so much more expeditious than the old.

If into the alkaline solution of the colouring matter lime-water be poured, there takes place a copious precipitate, which consists of the lime and colouring matter combined. Lime, therefore, has a stronger affinity for the colouring matter than alkali has; and as the compound of lime and the colouring matter is not very soluble in water, lime-water might be used to deprive the alkaline ley of the colouring matter which it has imbibed; after which it might be used again. Care, however, must be taken, that no lime-water remains in the ley; otherwise it might precipitate and fix the colouring matter on the linen, after which it would be very difficult to remove it.

6
Nature of the colouring matter of linen.

From an alkaline ley, saturated with the colouring matter of linen yarn, Mr Kirwan, by means of muriatic acid, precipitated the colouring matter. He found it to possess the following properties: When suffered to dry for some time on a filter, it assumed a dark green colour, and felt somewhat clammy like moist clay. "I took (says he) a small portion of it, and added it to 60 times its weight of boiling water, but not a particle of it was dissolved. The remainder I dried in a sand heat; it then assumed a shining black colour, became more brittle, but internally remained of a greenish yellow, and weighed one ounce and a half.

Irish Transf. 1789.

"By treating eight quarts more of the saturated ley in the same manner, I obtained a further quantity of the greenish deposite; on which I made the following experiments:

"1st, Having digested a portion of it in rectified spirit of wine, it communicated to it a reddish hue, and was in a great measure dissolved: but by the affusion of distilled water the solution became milky, and a white deposite was gradually formed; the black matter dissolved in the same manner.

"2dly, Neither the green nor the black matter was soluble in oil of turpentine or linseed oil by a long-continued digestion.

"3dly, The black matter being placed on a red hot iron, burned with a yellow flame and a black smoke, leaving a coaly residuum.

"4thly, The green matter being put into the vitriolic, marine, and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the latter, but did not seem in the least diminished.

"Hence it appears, that the matter extracted by alkalies from linen yarn is a peculiar sort of resin, different from pure resins only by its insolubility in essential oils, and in this respect resembling lacs. I now proceed to examine the power of the different alkalies on this substance. Eight grains of it being digested in a solution of crystallized mineral alkali, saturated in the temperature of 60°, instantly communicated to the solution a dark brown colour; two measures (each of which would contain 11 pennyweights of water) did not entirely dissolve this substance. Two measures of the mild vegetable alkali dissolved the whole.

"One measure of caustic mineral alkali, whose specific gravity was 1,053, dissolved nearly the whole, leaving only a white residuum. Bleaching.

"One measure of caustic vegetable alkali, whose specific gravity was 1,039, dissolved the whole.

"One measure of liver of sulphur, whose specific gravity was 1,170, dissolved the whole.

"One measure of caustic volatile alkali dissolved also a portion of this matter."

The colouring matter of cotton is much more soluble in alkali than that of linen; hence the greater facility with which cotton is bleached.

From these observations, the great importance of alkalies in bleaching, and the necessity of regulating the strength, and ascertaining the purity, of the leys made use of, must be apparent. Manufacturers, therefore, lie under very great obligations to Mr Kirwan, who has lately examined the alkaline matters used in bleaching with his usual accuracy and abilities. The result of his experiments was as follows:

Table of the quantity of mere alkali in 100 Avoirdupois pounds of the following substances. *Irish Transf.* 1789.

One hundred lbs.	*Mineral Alkali.*
Crystallized soda	20 lbs.
Sweet barilla	24
Mealy's cunnamara kelp	3,437
Ditto desulphurated by fixed air	4,457
Strangford kelp	1,25
One hundred lbs.	*Vegetable Alkali.*
Dantzic pearl ash	63,33 lbs.
Clarke's refined ash	26,875
Cashup	19,376
Common raw Irish weed-ash	1,666
Ditto slightly calcined	4,666

When linen is allowed to remain for some time in oxy-muriatic acid, it becomes white. It is evident, then, that when the colouring matter of linen is saturated with oxygen, it becomes colourless: But linen bleached in this manner very soon becomes yellow, especially when exposed to heat. Berthollet, to whose ingenious experiments and observations we are indebted for the greater part of the above remarks, has given the following explanation of the cause of this change: He distilled the colouring matter of linen, and obtained a thick oil, a little ammonia, and $\frac{24}{100}$ of carbon remained behind. The oil contained carbon; and he supposed that carbonic acid gas, and carbonated hydrogen gas, were disengaged. He concluded in consequence, that one-third of this colouring matter was carbon. The other ingredient in the oil was hydrogen; for Lavoisier has proved that oil is composed of oxygen and hydrogen. The colouring matter of linen, then, is composed principally of carbon and hydrogen.

Oxygen combines with hydrogen at a lower temperature than it does with carbon; for if a considerable quantity of oxy-muriatic acid be mixed with a solution of sugar (a substance which consists chiefly of carbon and hydrogen), and the liquor be evaporated, there remains behind little else than carbon, the hydrogen having combined with oxygen and formed water, which had passed off in the form of vapour. Now, whenever a quantity of hydrogen is separated from a body principally

Bleaching.

cipally composed of hydrogen and carbon, that body assumes a brown or yellow colour, because the carbon becomes predominant; and this colour becomes the deeper the greater the proportion of the carbon is, compared to that of the hydrogen; and at last, when nothing but carbon remains, it becomes quite black.

It is probable, then, that when the oxy-muriatic acid renders linen white, a quantity of oxygen has combined with the colouring particles; but that this oxygen gradually enters into a combination with the hydrogen, and forms water which passes off; that then the carbon becomes predominant, and the linen in consequence assumes a yellow colour*.

7 Bleaching of wool and silk.

The same method does not succeed in bleaching wool and silk which answers for linen and cotton. One would be disposed to think that these substances are bleached rather by losing oxygen than by absorbing it. Wool, for instance, is rendered white very quickly when exposed to the fumes of sulphurous acid, which we know has a strong affinity for oxygen, and soon saturates itself with it. But what passes during the whitening of animal matters has never yet been properly inquired into, though it would not only greatly elucidate *bleaching*, but *dyeing* likewise, and throw much light upon some of the obscurest parts of chemistry. A great improvement, however, has lately been made by M. Baumé in the manner of bleaching silk. Of this improvement we shall proceed to give an account†.

† See the memoir in the *Ann. de Chim.* xvii. 156. and abridged in *Nicholson's Journal*, I. 32. from which last we have taken our account of it.

8 New mode of whitening silk.

Before the silk is wound off the cocons in which the silk worms are enclosed, it is necessary to kill the insects, otherwise they would in all probability eat thro' it and destroy it. This is commonly done by exposing the cocons, properly wrapped up, for two hours to the heat of about 158 degrees of Fahrenheit in an oven; after which they are kept for a certain time in a mass to preserve their heat, and effectually destroy such of the insects as might have escaped the power of the oven. The effect of this process is, that the silk is hardened, and is more difficult to wind off than before. Hence the product of silk is less by one ninth part in quantity, and inferior in quality to what might have been obtained by winding off without this previous baking. M. Baumé, not only from these views, but likewise because the silk which has not been baked proves susceptible of a greater lustre, was induced to destroy the chrysalis by spirit of wine. For this purpose he disposes them in a wooden box in a stratum six inches deep: upon each square foot half a pint of spirit of wine is to be sprinkled with a small watering-pot made for that purpose. The liquid is to be equally distributed, but it is not necessary that all the cocons should be wetted. They are then to be mixed by hand. In the next place another stratum is to be formed over the first, nearly of the same depth, which is to be sprinkled and treated as before. By this method of proceeding, the box becomes filled, and must then be covered, and left for 24 hours; during which time they become spontaneously heated to about 100 degrees, and the vapour of the spirit of wine exerts itself with wonderful activity. After this treatment they must be spread out to dry, which happens in a short time, and is absolutely necessary previous to winding off.

The spirit of wine to be used in this operation ought to be of the specific gravity .847, at the temperature of 55 degrees. It is of the greatest importance to use that spirit only which has been kept in vessels of glass, of tinned copper, or of pure tin. Leaden vessels are absolutely to be rejected; wooden vessels tinge the spirit, which gives the silk a degree of colour of considerable permanency, and very inimical to the bleaching process.

The silk is wound off upon a reel, while the cocons are kept immersed in water almost boiling. Upon this part of the process M. Baumé remarks, 1. That the dead cocons must be separated. These are known by the brown or black spots on their surface. 2. That well-water, which on account of its clearness is almost universally used in the silk manufactories, mostly contains nitre, and is extremely prejudicial to the bleaching process. The presence of nitrous acid gives a yellow colour, which resists bleaching and even scouring; he therefore recommends river-water. 3. In some countries a small quantity of alum is used. Neither this nor any other saline substance is of the least advantage to the colour, beauty, or quality of the silk.

At the four places of contact of the silk upon the reel, all the threads stick together. It is absolutely necessary that this should be remedied. The method consists in soaking the silk in a sufficient quantity of warm water, at about 90 degrees, for about two hours; after which the threads are to be separated by opening the hanks upon a pin, and lightly rubbing the parts which cohere. When the silk is dry, it is to be loosely folded in its original form, and is ready for bleaching.

The silk while wet is soft, and part of its gummy matter is in such a state, that its threads would readily adhere, if wrung while warm for the purpose of clearing it of the water. After such improper treatment there would be no other remedy than to soak it again in warm water.

The apparatus for bleaching the silk consists of a stone-ware vessel, nearly of a conical form, capable of holding about 12 gallons, having a large opening at the one end, and a smaller of about an inch diameter at the other end. Common pottery cannot be used in this operation, because it is soon rendered unserviceable by the action of the muriatic acid, and the stone-ware itself is not very durable. This vessel must be carefully examined, to ascertain that it does not leak in the slightest degree; after which the inside is to be rubbed with a pumice-stone, to clear it of asperities which might break the threads. A cover of the same material is to be fitted on by grinding; and the smaller aperture, which in the use is the lowest, is to be closed with a good cork, in the middle of which is thrust a small glass tube about a quarter of an inch in diameter; this is likewise stopped with a cork, excepting at the time when it is required to draw off the liquid contents of the jar. A small perforated false bottom is placed within the vessel, to prevent this tube from being obstructed.

Six pounds of yellow raw silk are to be disposed in the earthen pot; upon this is to be poured a mixture, previously made, of 48 pounds of spirit of wine of the specific gravity .867, with 12 ounces of very pure marine acid, absolutely exempt from all presence of nitrous acid, and of the specific gravity 1.114. The pot is then to be covered, and the whole left in digestion till the following day, or until the liquor, which at first assumes a fine green colour, shall begin to assume that of a dusky brown.

The acidulated spirit is then to be drawn off, clear spirit

ſpirit of wine poured upon the ſilk, and drawn off repeatedly until it paſſes colourleſs. The ſilk is then ſuffered to drain without ſtirring it. In this ſtate it is ready for a ſecond infuſion.

Forty-eight pounds of ſpirit of wine, acidulated with 12 ounces of marine acid, are now to be poured on the ſilk, and the whole ſuffered to remain for 24 hours or longer, until the ſilk becomes perfectly white. The time required for this ſecond infuſion is commonly longer than for the firſt: it ſometimes amounts to two, three, or even ſix days, according to circumſtances, particularly the temperature and the nature of the ſilk. Silk which has been in the oven is in general more difficult to bleach.

When the ſilk has thus obtained its utmoſt degree of whiteneſs, the acidulated ſpirit is to be drawn off into a ſeparate veſſel. This fluid is but ſlightly coloured, and may be uſed again in the firſt infuſion of other yellow ſilk, with the addition of ſix ounces more of marine acid. The receiving veſſel is to be removed, and another clean veſſel ſubſtituted in its place. The ſilk is then ſprinkled with clean ſpirit, and occaſionally preſſed down with the hand. As ſoon as the ſpirit of wine comes off abſolutely colourleſs, a third infuſion is to be made by pouring upon the ſilk 48 pounds of the pure ſpirit without acid, which is to remain till the following day: it is then to be drawn off, and reſerved for waſhing other ſilk after the firſt infuſion.

After the ſilk has been left to drain, and affords no more ſpirit, it ſtill retains its own weight of that fluid. This is recovered by ſprinkling the ſilk with a ſmall quantity of very clear river-water at a time. While the water applies itſelf and ſubſides along the ſilk, it drives the ſpirit of wine before it, ſo that the firſt portions which flow from the tube are ſcarcely diminiſhed in ſtrength. The addition of water is to be continued until nothing but mere water comes off below.

In this ſituation the ſilk is found to be well bleached, but ſtill retains a portion of marine acid ſufficient to render it harſh to the touch, and after a time brittle. It muſt be waſhed off with water. The beſt method is to put the ſilk looſely into a coarſe woollen bag, which is to be ſecured looſely in another cloth like a ſmall bed or pillow, then placed in a baſket, and left in a running ſtream for five or ſix hours; but where the convenience of a ſtream is wanting, the earthen pot containing the ſilk is to be covered with a cloth, and water pumped through it for five or ſix hours, or until that which iſſues from the lower aperture gives no red colour to the tincture of turnſol. At this period the lower opening is to be cloſed, and the veſſel filled with water, which muſt be changed once or twice in 24 hours.

Though the mineral acids are the moſt powerful and deſtructive of all ſaline ſubſtances, yet they may be applied to ſilk when diluted with ſpirit of wine in very conſiderable doſes. In trials made to aſcertain the maximum, two ounces of marine acid were added to one pound of ſpirit of wine, without altering the ſilk. Two drams of marine acid cauſe a very perceptible alteration in one pound of ſilk.

Spirit of wine which has been mixed with nitrous acid cannot be uſed in bleaching, even though afterwards rectified upon an alkali, becauſe it ſtill retains a portion of nitrous gas. Pure ſpirit of wine without acid extracts a fine yellow colour from ſilk, which does not ſeparate for years, even though expoſed to the ſun's light. Yellow ſilk expoſed to the ſun, loſes its colour in a ſhort time. The acidulated ſpirit which has been uſed in the infuſion of ſilk, is changed by expoſure to the ſun, but not in ſuch a manner as to be rendered fit for uſe a ſecond time. In order to obtain a beautiful white colour, it is eſſential that the ſilk ſhould be immerſed in a large quantity of the fluid, eſpecially at the firſt infuſion. Without this management it would become neceſſary to make three infuſions in the acidulated ſpirit. When the firſt infuſion is well managed, the ſilk will have loſt all its yellow colour, and become conſiderably white, at the ſame time that the liquor will have begun to change colour a little. As long as it continues of a fine green, it is certain that it has not exhauſted its whole action upon the ſilk. The duration of this firſt infuſion may be longer or ſhorter, without inconvenience, according to the temperature. When the temperature is at 77° of Fahrenheit, the firſt infuſion is often made in 10 or 12 hours. In ſmall experiments the heat of the atmoſphere may be ſupplied by the water bath; in which caſe all the infuſions are eaſily made in the courſe of a day.

When the firſt infuſion is finiſhed, and the liquor drawn off, the ſilk appears greeniſh: the ſubſequent waſhings in ſpirit of wine clear it of the liquor it retained. This ſprinkling ſhould be made with the watering pot, otherwiſe the quantity poured will be greater, and the management more waſteful.

Pieces of gauze and entire garments of ſilk have been ſucceſsfully bleached in this way.

The fineſt natural white ſilks are rendered infinitely whiter by this proceſs. Spirit of wine alone has the property of depriving yellow ſilk of its colour, which it brings to the ſtate of the naturally white ſilk. In this ſtate the ſilk is diſpoſed to acquire a greater degree of brightneſs by a ſingle infuſion in the acidulated ſpirit. This proceſs has its advantages over the other, to which it is alſo inferior in certain reſpects; concerning neither of which the author has entered into any detail.

The colouring matter was found to be a reſin perfectly animalized, affording by diſtillation the ſame products as other animal matters, and the concrete volatile alkali.

Silk whitened by ſcouring may be dried freely in the air without affecting its luſtre. This is not the caſe with the ſilk bleached in the gum: if it be left at liberty to dry in the air, it reſembles white flax without any luſtre. The beauty of this ſilk conſiſts in its ſhining brilliancy; to ſecure which it muſt be dried in a ſtate of tenſion. Mr Baumé has contrived a ſimple machine for this purpoſe. It conſiſts of a ſtrong ſquare frame of wood ſtanding upright upon feet: the upper horizontal bar is ſix feet long, and has ſix iron pins driven through it at equal diſtances, ſo as to project on each ſide for the purpoſe of receiving twelve bobbins. The lower horizontal bar is moveable up and down in a mortice, by means of a ſcrew at each end: it is furniſhed with ſix holes adapted to receive as many pins to correſpond with thoſe above. The ſkains of ſilk are to be dreſſed and arranged upon wooden pins, as they are taken out of the ſack from waſhing. As ſoon as there are twelve together, they are to be wrung with a ſtaff; after which the ſkains are to be hung one by one upon as many bobbins put upon the upper pins of the ſquare frame.

Bleaching. frame. Another bobbin with tails is to be inserted in the lower loop of the ſkain, and faſtened to the correſponding pin of the lower bar, by means of a ſtrap and hook, which need not be deſcribed to ſuch as are ſlightly acquainted with mechanical objects. When the machine is thus ſupplied with ſkains on both ſides, the lower bar of the frame is to be preſſed down by the ſcrews until the ſilk is moderately ſtretched. When it is dry, the ſcrews are to be equally ſlackened, the ſkains taken off and folded with a ſlight twiſt, that they may not become entangled.

To complete the deſcription of this proceſs, it only remains to ſhow how to recover the alcohol, and enſure the purity of the acids made uſe of.

9 Method of recovering the alcohol uſed,

The alcohol which has been uſed in bleaching ſilk is acid, and loaded with colouring matter. In this ſtate it cannot be again uſed. There are two methods of diſtilling it which have their reſpective advantages and inconveniences.

By the firſt the acid is loſt; which is ſaturated with potaſs, in order that the diſtillation may be afterwards performed in a copper alembic. A ſolution of potaſs is to be poured into the acid ſpirit, and ſtirred about to promote the ſaturation. Carbonic acid is diſengaged with ſtrong efferveſcence from the alkali; and the point of ſaturation is known by the uſual teſt, that the fluid does not redden the tincture of turnſol. The diſtillation is then to be made in the copper alembic, and the alcohol reſerved in proper veſſels.

In the ſecond proceſs for diſtilling without alkali, the acid ſpirit is diſtributed into a great number of glaſs retorts, placed in the ſand bath, on the gallery of a furnace. The firſt product is ſcarcely acid; but what follows is more and more ſo, and muſt be kept in veſſels of glaſs or ſtone-ware, which become embarraſſing on account of their number. The fluid which remains in the retorts has the colour of beer ſlightly turbid, and contains the greateſt part of the marine acid. It muſt be poured into one or more retorts, and concentrated by heat gradually applied. The firſt liquor which comes over is ſlightly red, turbid, and ſcarcely acid. This is to be thrown away, and the receivers changed. The ſucceeding product is the colourleſs marine acid, of an aromatic ſmell reſembling the buds of poplar. The reſin of the ſilk remains in the retort decompoſed by the acid. The marine acid thus obtained is weaker than it originally was; which is in fact of little conſequence, as it is pure, and may be ſafely uſed, either by increaſing the doſe proportional to its diminiſhed ſtrength, or by concentrating it if required in the uſual way. If this diſtillation be made in a ſilver alembic, inſtead of retorts of glaſs, and a capital and worm of pure tin be annexed, the alcohol will be obtained ſo ſlightly acid as ſcarcely to redden the tincture of turnſol; but it is ſufficiently acid to receive injury if preſerved in a copper veſſel.

10 And of preparing a pure muriatic acid.

As to the acid, Mr Baumé obſerves that the muriatic acid of commerce is unfit for the purpoſe. It was formerly prepared with the marine ſalt of the ſaltpetre manufacturers; and even when it is made with good ſalt, the decompoſition is effected with common vitriolic acid which contains nitrous acid. Marine acid mixed with a ſmall quantity of nitrous acid does not prevent the ſilk from being beautifully whitened: it even accelerates the proceſs conſiderably, and in the moſt ſatisfactory manner. But the alcohol, every time it is uſed and rectified, becomes charged with the acid and gas of nitre, which aſſume the characters of the nitrous anodyne liquor. In this ſtate neither diſtillations nor repeated rectifications from alkali are ſufficient to ſeparate the nitrous matter from the alcohol. Then it is that the ſucceſs of the operator vaniſhes, with a degree of rapidity equal to the advances which encouraged his hopes at the commencement.

To purify common ſulphuric acid, 100 pounds of it are to be mixed in a large baſon of copper with the ſame quantity of river-water, and ſtirred with a wooden ſpatula. The mixture inſtantly becomes heated to the boiling water point, and a great quantity of red vapour is diſengaged, which has the ſmell of aqua-regia, and ariſes from the nitric and muriatic acids. When this mixture is made, it is proper to immerſe the baſon to a ſuitable depth in a large veſſel of water, to haſten the cooling. As ſoon as it is ſufficiently cooled, it is to be drawn off into bottles, and left to become clear during ſeveral days. It is in the next place to be decanted, and conveyed into retorts by a ſyphon funnel, and the rectification proceeded upon until it becomes perfectly white. Towards the end of the operation a ſmall quantity of ſulphur ſublimes in the neck of the retort. Inſtead of receivers, a ſmall glaſs cup is placed beneath the aperture of each retort, in order to facilitate the diſſipation of the nitric and muriatic acids. When the acid in the retorts is ſufficiently cooled, it is poured a ſecond time into the copper baſon, and mixed with 100 pounds of river-water, as at firſt, and again concentrated in the retorts till it becomes perfectly clear. The muriatic acid is to be diſengaged from common ſalt by the application of this acid in the uſual manner.

11 Bleaching paper.

The oxy-muriatic acid is alſo uſed very generally for bleaching paper, or rather the ſtuff out of which paper is made. It has been alleged, and we believe with ſome truth, that ſince this mode of whitening paper was introduced into this country, the ſtrength of paper is much inferior to what it was formerly. If this be really the caſe, perhaps it is owing to the uſe of too concentrated an acid.

We ſhall finiſh this article with Mr Chaptal's account of this proceſs, who was the firſt perſon that introduced it. "Blotting paper (ſays he), by being put into oxygenated muriatic acid, is bleached without ſuffering any injury; and rags of coarſe bad cloth, ſuch as are uſed in the paper manufactories to make this kind of paper, may be bleached by this acid, and will then furniſh paper of a very ſuperior quality. I bleached by it an hundred weight of paſte, intended to be made into blotting paper, and the increaſe of value in the product was computed at 25 *per cent.* whereas the expence of the operation, when calculated in the ſtricteſt manner, amounted only to 7 *per cent.*

12 Mode of whitening old books,

"The property poſſeſſed by this acid, of bleaching paper without injuring its texture, renders it very valuable for reſtoring old books and ſmoked prints. The latter, when diſcoloured to ſuch a degree that the ſubject of them could hardly be diſtinguiſhed, were re-eſtabliſhed and revived, in ſo aſtoniſhing a manner that they appeared to be new; and old books, ſoiled by that yellow tinge which time always produces, may be ſo completely renewed, that one might ſuppoſe them to be juſt come out of the preſs. The ſimple immerſion of a

 print

print in oxygenated muriatic acid (leaving it therein a longer or a ſhorter time, according to the ſtrength of the liquor) is all that is required for bleaching it; but when a book is to be bleached, ſome farther precautions are to be uſed. As it is neceſſary that the acid ſhould wet every one of the leaves, the book muſt be completely ſpread open, and then, by letting the boards of the binding reſt upon the ſides of the veſſel, the paper only will be immerſed in the liquor. If any of the leaves ſtick together they muſt be carefully ſeparated, that all of them may be equally impregnated. The liquor takes a yellow tinge, the paper grows white; and after two or three hours the book may be taken out of the liquor, and ſoaked in clean water, which ſhould be changed from time to time, in order to waſh out the acid with which the book is impregnated, and alſo to deprive it of the diſagreeable ſmell it has contracted.

"The above method, which is the firſt I made uſe of, has generally ſucceeded pretty well: too often, however, the leaves of my books have had a motley appearance, and ſometimes ſeveral pages were not at all bleached; I was therefore obliged to have recourſe to the following more certain proceſs. I began by unſewing the books, and reducing them into ſheets; theſe ſheets I placed in diviſions made in a leaden veſſel, by means of thin ſlips of wood, ſo that the leaves when laid flat were ſeparated from each other by very ſmall intervals. I then put the acid into the veſſel, pouring it againſt the ſide, that the leaves might not be diſturbed; and when the operation was finiſhed, I drew off the acid by means of a cock fixed in the bottom of the veſſel. I then filled the veſſel with clean water, which waſhed the leaves, and took off the ſmell of the oxygenated acid. They may then be dried, ſmoothed, and new bound. In this manner I have reſtored many valuable books, which had become worthleſs from the bad ſtate they were in.

13 And prints. "When I had to bleach prints ſo torn to pieces that they conſiſted only of fragments fitted together, and paſted upon paper, I was afraid I might loſe ſome of theſe fragments in the liquor, becauſe they ſeparate from the paper by the ſoftening of the paſte: in that caſe therefore I took the precaution of encloſing the print in a large cylindrical bottle, which I turned upſide-down, fixing its mouth to that of a veſſel in which I had put a mixture proper for diſengaging oxygenated muriatic gas. This gas fills the inſide of the bottle, and, acting upon the print, takes off the ſtains, ink-ſpots, &c. while the fragments remain paſted to the paper, and conſequently keep their reſpective places."

BLOCKS (*Encycl.* Plate XCV. fig. 5.) *a* Repreſents a ſingle block, and *b*, *c*, two double ones of different kinds, without ſtraps; *e*, *f*, two double tackle blocks, iron bound, the lower one, *f*, being fitted with a ſwivel; *g*, a double iron block with a large hook; *h*, a ſmall block; *i*, a top block; *k*, a voyal block; *l*, a clew garnet block; *m*, the cat block, employed to draw the anchor up to the cat-head. See *Cat-Heads*, Encycl.

Cape or Large Snouted BOAR, a ſpecies of the genus Sus, which, according to M. Vaillant, differs from every known ſpecies, and has not been accurately deſcribed by any writer of natural hiſtory. Buffon, indeed, in the Supplement to his Hiſtory of Quadrupeds, has given a figure of it; but nothing like the head of the animal is diſcoverable, ſays our author, in that figure, all its characteriſtics having been omitted by the draughtſman. M. Vaillant, during his laſt travels in Africa, ſhot a monſtrous boar of this ſpecies on the banks of Fiſh river, and in the country of the *Greater Nimiquas*. He deſcribes it in the following terms: Its ſnout, inſtead of being taper and in the form of a proboſcis, is, on the contrary, very broad and ſquare at the end. It has ſmall eyes, at a very little diſtance from each other, level with the ſurface, and near the top of the forehead. On each cheek a very thick cartilaginous ſkin projects horizontally, being about three inches long and as many broad. At firſt ſight you would be tempted to take theſe excreſcences for the ears; particularly as the real ears of the animal, ſticking as it were to the neck, which is very ſhort, are partly concealed by an enormous mane, the briſtles of which, in colour red, brown, and greyiſh, are 16 inches in length on the ſhoulders. Directly below theſe falſe ears is a bony protuberance on each ſide, projecting more than an inch, ſerving the animal to ſtrike with to the right and left. The boar has, beſides, four tuſks, of the nature of ivory, two in each jaw: the upper ones are ſeven or eight inches long; very thick at the baſe, and terminating in an obtuſe point, grooved, and riſing perpendicularly as they iſſue from the lips: the lower ones are much ſmaller, and ſo cloſe to the upper ones when the mouth is ſhut, that they appear as one. The head is a truly hideous object. It is ſcarcely leſs ſo than that of the hippopotamus, to which at firſt view it appears to have a ſtriking reſemblance. Syſtematiſts, accuſtomed to view nature only according to rules eſtabliſhed by themſelves, will be far from acknowledging this animal to be a boar; for not to mention its large ſnout, it wants inciſive teeth in both jaws. Notwithſtanding its wide muzzle, it ploughs up the earth to ſeek for roots, on which it feeds. It is very active, though large and bulky; running with ſuch ſpeed, that the Hottentots give it the name of the *runner*.

Plate VII.

BONNET (Charles), was deſcended from a French family, who being compelled, on account of their religious principles, to emigrate from their native country, eſtabliſhed themſelves at Geneva in the year 1572. His grandfather was advanced to the magiſtracy in that city, and adorned by his integrity an eminent ſtation. His father, who preferred the ſtation of a private citizen, paid unremitted attention to the education of his ſon, who was born on the 13th of March 1720; and Charles, at a very early period, recompenſed his father's aſſiduity, by the amiableneſs of his diſpoſition, and the rapid progreſs he made in general literature. When he was about 16 years of age, he applied himſelf, with great eagerneſs, to the peruſal of *Le Spectacle de la Nature*; and this work made ſuch a deep impreſſion on his mind, that it may be ſaid to have directed the taſte and the ſtudies of his future life. What that publication had commenced, was confirmed by the work of *La Pluche*; but having accidentally ſeen the treatiſe of *Reaumur* upon inſects, he was in a tranſport of joy. He was very impatient to procure the book; but as the only copy in Geneva belonged to a public library, and as the librarian was reluctant to intruſt it in the hands of a youth, it was with the utmoſt difficulty that he could obtain his end.

By

By the possession of this treasure, our assiduous youth was enabled to make several new and curious experiments, which he communicated to Reaumur himself; and the high applause he gained from so great a naturalist added fresh vigour to his assiduity.

In compliance with his father's desires, he applied himself, though with much reluctance, to the study of the law. The works of *Burlamaqui* pleased him the most, on account of the perspicuous and philosophic manner in which the subject was treated: the institutes of *Heineccius* gave him some courage also, as he perceived order and connection; but the Roman law terrified him as the *hydra of Lerna*. Notwithstanding his application to these authors, he still continued attached to natural history, and was very active in making experiments. The experiments which demonstrate that tree-lice propagate without copulation, was communicated by Reaumur to the Academy of Sciences; and this circumstance occasioned an epistolary correspondence between M. Bonnet and that great naturalist. This was doubtless very flattering to a youth of twenty years. The letter of Reaumur was accompanied with a present of that very book which he had borrowed with so much difficulty two years before.

Animated by such distinguished marks of approbation, he diligently employed every moment he could steal from the study of jurisprudence to the completion of his natural history of the tree-louse; to experiments on the respiration of catterpillars and butterflies, which he discovered to be effected by stigmata, or lateral pores; to an examination of the construction of the tænia or tape-worm; in frequent correspondence with Reaumur; and in assisting Trembley in his discoveries and publication concerning millepedes, &c. Having in the year 1743 obtained the degree of doctor of laws, he relinquished a pursuit which he had commenced with so much reluctance. In the same year he was admitted a fellow of the Royal Society, to which he had communicated a treatise on insects.

Bonnet being now liberated from his other pursuits, applied himself, without intermission, to collecting together his experiments and observations concerning the tree-louse and the worm, which he published in 1744 under the title of *Insectology*. This work acquired deserved approbation from the public, and was honoured by the commendation of the celebrated B. de Jussieu. He was reproached, however, in a periodical publication, with having paid too little attention to the delicacy of his reader; though his patience and accuracy were acknowledged to be deserving of praise. Such unremitted application and labour could not fail of becoming injurious to his health. Inflammations, nervous fever, sore eyes, &c. compelled him to relinquish the use of the microscope and the study of insects. This prevention was so extremely mortifying to a man of his taste and activity of mind, that he was thrown into a deep melancholy, which could only be subdued by the resolution inspired by philosophy, and the consolations of religion: these gradually roused him from a dejected state of mind. About the end of the year 1746 our philosopher was chosen member of the Literary Institution at Bologna, which introduced him to a correspondence with the famed Zanotti, who may be deemed the Fontenelle of Italy.

In the year 1747 he undertook a very difficult work on the leaves of plants; which, of all his publications in natural history, bore the strongest marks of originality, both with respect to the manner in which his experiments were made, and the discoveries resulting from them. His extreme attachment to natural history gradually led him to a study of a very different nature; speculative philosophy now engaged his whole attention. The first fruits of his meditations in this department was his *Essay on Psychology*. In this work the principal facts observable in human nature, and the consequences resulting from them, are stated in a concise and conspicuous manner. He contemplated man from the first moment of his existence, and pursued the developement of his senses and faculties from simple growth up to intelligence. The work, which was published without his name, met with great opposition, and was criticised with severity; but the censures were directed more against his expressions than his principles; nor were they of sufficient importance to impede the general acceptance of the publication.

His analysis of the mental faculties was simply a developement of the ideas contained in the preceding work. It engaged his incessant attention for the space of five years; nor was it completed before 1759. It is somewhat singular that both he and the Abbé de Condillac should have illustrated their principles by the supposition of a statue, organized like the human body, which they conceived to be gradually inspired with a soul, and the progressive developement of whose powers they carefully traced. In the year 1760 this work was published at Copenhagen, by order and at the expence of Frederick V. and it was followed in 1762 by contemplations on organized bodies. In this the author had three principal objects before him: the first was to give a concise view of every thing which appears interesting in natural history, respecting the origin, developement, and reproduction of organized bodies; the second was to confute the two different systems founded upon the Epigenesis; and the third was to explain the system of Germs, indicate the ground upon which it was founded, its correspondence with facts, and the consequences resulting from it. This work was received with much satisfaction by natural philosophers. The Academy of Berlin, which had proposed the same subject as a prize question for 1761, declared that they considered the treatise as the offspring of close observation and profound reasoning; and that the author would have had an indubitable right to the prize, if he had confined his labours to the precise statement of the question. It must also be recorded, to the honour of the great *Malesherbes*, that he reversed the interdict which the public censor had laid upon this book, under the pretext that it contained dangerous principles.

The Contemplation of Nature appeared in 1764. In this work the author first enlarged upon the common conceptions entertained concerning the existence and perfections of God; and of the order and uniformity observable in the universe. He next descends to man, examines the parts of his composition, and the various capacities with which he is endowed. He next proceeds to the plants; assembles and describes the laws of their economy; and, finally, he examines the insects, indicates the principal circumstances in which they differ from larger animals, and points out the philosophical inferences that may legitimately be deduced from these

these differences; and he concludes with obfervations refpecting the induftry of infects. This work being of a popular nature, the author fpared no pains in beftowing upon it thofe ornaments of which it was fufceptible. The principles which he thus difcovered and explained, induced him to plan *a fyftem of moral philofophy;* which, according to his ideas, confifted folely in the obfervance of that relation in which man is placed, refpecting all the beings that furround him. The firft branch would have comprehended, various means which philofophy and the medical fcience have difcovered for the prevention of difeafe, the prefervation and augmentation of the corporeal powers, and the better exertion of their force: in the fecond, he propofed to fhew, that natural philofophy has a powerful tendency to embellifh and improve our mind, and augment the number of our rational amufements, while it is replete with beneficial effects refpecting the fociety at large. To manifeft the invalidity of opinions, merely hypothetical, he undertook, in the third place, to examine, whether there were not truths within the compafs of human knowledge, to which the moft fceptical philofopher muft be compelled to yield his confent, and which might ferve as the bafis of all our reafonings concerning man and his various relations. He then would have directed his attention to a firft caufe, and have manifefted how greatly the idea of a Deity and Supreme Lawgiver favoured the conclufions which reafon had drawn from the nature and properties of things: but it is deeply to be regretted that his health, impaired by inceffant labour, would not permit him to complete the defign.

His laft publication was the *Palingenefis*, which treats of the prior exiftence and future ftate of living beings.

Of his publications in natural hiftory, thofe deemed the moft excellent are, his Treatife on the beft Means of Preferving Infects and Fifh in Cabinets of Natural Hiftory; a Differtation on the Loves of the Plants; fundry pieces on the Experiments of *Spallanzani*, concerning the Reproduction of the Head of the Snail; a Differtation on the *Pipa*, or Surinam Tod; and different Treatifes on Bees.

In the year 1783 he was elected honorary member of the Academy of Sciences at Paris; and of the Academy of Sciences and the Belles Lettres at Berlin.

Much of his time was employed in a very extenfive correfpondence with fome of the moft celebrated natural philofophers and others. Of this number were *Reaumur*, *De Geer* the Reaumur of Sweden, *Du Hamel*, the learned *Haller*, the experimental philofopher *Spallanzani*, *Van Swieten*, *Merian*, and that ornament of Switzerland the great *Lambert*. He entertained, however, the utmoft averfion to controverfy. He thought that no advantage to be obtained by it could compenfate for the lofs of that repofe which he valued, with Newton, as the *rem prorfus fubftantialem*. He never anfwered remarks that were made to the prejudice of his writings, but left the decifion with the public; yet, ever ready to acknowledge his errors, he was fincerely thankful to every one who contributed to the perfection of his works. He was ufed to fay that one confeffion, *I was in the wrong*, is of more value than a thoufand ingenious confutations.

His literary occupations, and the care he was obliged to take of his health, prevented him from travelling. He delighted in retirement, and every hour was occupied in the improvement of his mind. The laft 25 years of his life were fpent in the fame rural fituation where he had paffed the greater part of his early days; yet notwithftanding the purfuit of literature was his fupreme delight, he never refufed to fufpend his ftudies, when the good of his country feemed to demand his fervices.

He was chofen in 1752 member of the Grand Council in the republic of Geneva: and he affifted regularly at their deliberations till the year 1768, where he diftinguifhed himfelf by his eloquence; his moderation, united with firmnefs; by his good fenfe and penetration in cafes of difficulty; and by the zeal with which he endeavoured to reclaim his fellow-citizens to that ancient fimplicity of manners which had been fo conducive to the welfare of the ftate, and to the love of virtue, fo effential to the exiftence of genuine liberty. His conduct, in every cafe, was confiftent with his principles. He took no pains to accumulate wealth, but remained fatisfied with a fortune equal to his moderate wants, and to the exercife of his benevolence. The perfect correfpondence between his extenfive knowledge and virtuous deeds procured him univerfal efteem.

In the year 1788 evident fymptoms of an *hydrops pectoris* manifefted themfelves; and from this time he gradually declined. He fuftained his indifpofition with unremitted cheerfulnefs and compofure. After various fluctuations, ufual in that complaint, he died on the 20th of May 1793, in the 73d year of his age; retaining his prefence of mind to the laft moment, adminiftering comfort to furrounding friends and relatives, and attempting to alleviate the diftrefs of his difconfolate wife, in whofe arms he expired.

As a demonftration of the high value placed upon his labours and talents by the literati, we have only to remark, that he was member of moft of the learned focieties of Europe.

BOOK-KEEPING, is an art of which the importance is univerfally known; and as commonly practifed, it has been fufficiently explained in the Encyclopædia Britannica. But fince that ariticle was written, a great improvement has been introduced into the art, or rather a new method of book-keeping has been invented by Mr EDWARD THOMAS JONES of the city of Briftol, accountant, who calls it the *Englifh fyftem of book-keeping;* and thinks that by it accounts may be more regularly kept, and errors in accounts more eafily detected, than by any other method hitherto known. We are much inclined to be of his opinion; and fhall therefore lay before our redears his defcription of this method, as we find it in the fpecification of the patent which was granted to him January 26. 1796.

The Englifh Syftem of Book-Keeping requires three books, called a *day-book* or *journal*, an *alphabet*, and a *ledger*, which muft be ruled after the following method, *viz.* the day-book to have three columns on each page, for receiving the amount of the tranfactions; one column of which to receive the amount of debits and credits, one column to receive the debits only, and one column to receive the credits only; or it may be ruled with only two columns on each page, one column to receive the amount of the debits, and one column to receive the amount of the credits. There muft alfo be on each page of the day-book four other columns ruled, two

two on the left side next the amount of the debits, and two on the right side next the amount of the credits, for receiving the letter or mark of posting, and the page of the ledger to which each amount is to be posted.

The alphabet need not be ruled at all; but must contain the name of every account in the ledger, the letter that is annexed to it as a mark of posting, and the page of the ledger.

The ledger must be ruled with three, four, five, or seven columns on each page, as may be most agreeable, for receiving the amounts of the different transactions entered in the day-book. And the process for using these books, or making up books of accounts on this plan, is as follows:

When a person enters into trade, whether by himself or with copartners, he must have an account opened with himself in the ledger; entering first in the day-book, and then to the credit of his account in the ledger, the amount of the property he advances into trade: The account may be headed either with his name only, or else called his stock-account.

If you buy goods, give the person credit of whom you purchase; when you sell goods, debit the person to whom said goods are sold. If you pay money, debit the person to whom paid, not only for what you pay, but also for any discount or abatement he may allow, and give the cashier credit for the neat amount paid. If you receive money, credit the person of whom you receive it, not only for what he pays, but also for any discount or abatement you may allow, and debit the cashier for the neat amount received; taking care in these entries to have nothing mysterious or obscure, but merely a plain narrative of the fact, introducing not one useless word, and avoiding every technical term or phrase except the words debit and credit, which are full and comprehensive, and the only terms that are applicable to every transaction, and may be affixed to every entry.

But as a hurry of business will sometimes take place in almost every counting-house, which may cause the entries to be made to the debit instead of the credit of an account in the day-book, and to the credit instead of the debit, Mr Jones has endeavoured as much as possible to counteract the evil, by having only one column for receiving the amount of every transaction, whether debits or credits, at the instant of making the entry; and, for the convenience of separating the debits from the credits, previous to posting, which is necessary to prevent confusion and perplexity, he has two other columns on the same page; that on the left side into which the amount of every debit must be carefully entered, and that on the right for the amount of the credits, which columns must be cast up once a month. The column of debits and credits of itself forming one amount; the column for the debits producing a second amount; and the column of credits a third amount; which second and third amounts added together, must exactly agree with the first amount, or the work is not done right.

By this means the man of business may obtain monthly such a statement of his affairs as will show how much he owes for that month, and how much is owing to him; and the debits being added together for any given time, with the value of the stock of goods on hand, will, when the amount of the credit is subtracted therefrom, shew the profits of the trade.

Our author now proceeds to the process of posting: which begins with opening an account in the ledger with every person to whose debit or credit there has been an entry made in the day-book; affixing to each account a letter, which is to be used as a mark of posting. The person's name, place of abode, and the folio of the ledger, must then be entered in the alphabet, with the same letter prefixed to each name as is affixed to the account in the ledger. Next, the page of the ledger on which each account is opened (and which will be seen in the alphabet) must be affixed to each amount in the day-book, in the column for that purpose. The date and amount of each debit must then be posted in the columns for receiving it in the ledger, on the left or debit side of that account to which it relates; entering, as a mark of posting in the day-book, against each amount, the same letter that is affixed to the account in the ledger, to which said amount may be posted. Observing that the debits of January, February, March, &c. must be posted into the column for those months in the ledger, and the credits must also be posted in like manner, filling up each account in the centre, at the expiration of every month, with the whole amount of the month's transactions; thus having, in a small space, the whole statement of each person's account for the year; in the columns to the right and left the amount separately of each transaction; and in the centre a monthly statement.

Having described the process of this method of book-keeping, he thus shews how to examine books kept by this method, so as to ascertain, to an absolute certainty, if the ledger be a true representation of the day-book; *i. e.* not only if each transaction be correctly posted, as to the amount thereof, but also if it be rightly entered to the debit or credit of its proper account. This examination differs from the modes that have heretofore been practised, as well in expedition as in the certain accuracy which attends the process; it being only necessary to cast up the columns through the ledger debits and credits, according to the examples given; and the amount of those columns, if right, must agree with the columns in the day-book for the same corresponding space of time. These castings should take place once a month; and if the amounts do not agree, the posting must then, but not else, be called over: and when the time, whether it be one, two, three, or four months, that is allotted to each column of the ledger is expired, the amount of each column should be put at the bottom of the first page, and carried forward to the bottom of the next, and so on to the end of the accounts; taking care that the amount in the day-book, of each month's transactions, be brought into one gross amount for the same time.

But although this process must prove that the ledger contains the whole contents of the day-book, and neither more nor less, yet it is not complete without the mode of ascertaining if each entry be posted to its right account; which may be ascertained by the following method: He has laid down a rule that a letter, which may be used alphabetically in any form or shape that is agreeable, shall be affixed to each account in the ledger, and the same letter prefixed to the names in the alphabet, these letters being used as marks of posting, and affixed to each account in the day-book as it is posted: it is only necessary therefore to compare and see that the letter affixed to each entry in the day-book is the

same

Book-keeping, Boscovich.

ſame as is prefixed to the ſame name in the alphabet; a difference here ſhews of courſe an error, or elſe it muſt be right.

At the end of the year, or at any other time, when perſons balance their accounts, if there be no objections to the profits of the trade appearing in the books, the ſtock of goods on hand at prime coſt may be entered in the day-book, either the value in one amount, or the particulars ſpecified, as may be moſt expedient, and an account opened for it in the ledger, to the debit of which it muſt be poſted. The caſting up of the ledger muſt then be completed: and when found to agree with the day-book, and the amount placed at the bottom of each column, ſubtract the credits from the debits, and it will ſhew the profit of the trade; unleſs the credits be the greater amount, which will ſhew a loſs. In taking off the balances of the ledger, one rule muſt be obſerved, and it cannot be done wrong: As you proceed, firſt ſee the difference between the whole amounts of the credits and debits on each page for the year, with which the difference of the outſtanding balances of the ſeveral accounts on each page muſt exactly agree, or the balances will not be taken right. By this means every page will be proved as you proceed, and the balances of ten thouſand ledgers, on this plan, could not unobſervedly be taken off wrong.

BOSCOVICH (Roger Joſeph), one of the moſt eminent mathematicians and philoſophers of the preſent age, was born of virtuous and pious parents, on the 11th of May 1711, in the city of Raguſa, the capital of a ſmall republic of the ſame name, lying on the eaſtern coaſt of the Adriatic Sea. At baptiſm, the name of Roger was given him, to which he added that of Joſeph when he received the ſacrament (A) of confirmation.

He ſtudied Latin grammar in the ſchools which were taught by the Jeſuits in his native city. Here it ſoon appeared that he was endued with ſuperior talents for the acquiſition of learning. He received knowledge with great facility, and retained it with equal firmneſs. None of his companions more readily perceived the meaning of any precept than he; none more juſtly applied general rules to the particular caſes contained under them. He enounced his thoughts with great perſpicuity, and came ſoon to compoſe with propriety and elegance. His application was equal to his capacity, and his progreſs was rapid. At the beginning of the 15th year of his age, he had already gone through the grammar claſſes with applauſe, and had ſtudied rhetoric for ſome months. His moral behaviour had likewiſe been very good: he was reſpectful and obedient to his parents and maſters, affable and obliging to his equals, and exemplary in all the duties of religion. It was now time for him to determine what courſe he would ſteer through life; nor did he heſitate long in coming to a reſolution.

The Jeſuit fathers, by teaching the ſciences to youth, were very uſeful, and at the ſame time had a fine opportunity of obſerving their ſcholars, and of drawing into their ſociety thoſe boys who ſeemed fit for their purpoſe. Such a ſubject as the young Boſcovich could not eſcape their attention. They ſhewed him particular kindneſs, to which he was not inſenſible. He had an ardent thirſt for learning; to advance in which he felt himſelf capable; and he thought he could nowhere have a better opportunity of gratifying this laudable inclination than in their order, in which ſo many perſons had ſhone in the republic of letters. Accordingly, with the conſent of his parents, he petitioned to be received among them; and his petition was immediately granted, becauſe it was deſired by thoſe to whom it was made.

It was a maxim with the Jeſuits to place their moſt eminent ſubjects at Rome, as it was of importance for them to make a good figure on that great theatre. Wherefore, as Roger's maſters had formed great expectations of him, they procured his being called to that city; whither he was ſent in the year 1725, and entered the noviceſhip with great alacrity. This noviceſhip was a ſpace of two years, in which the candidate made a trial of his new ſtate of life; and in the mean time his new ſuperiors obſerved him, and deliberated whether or not they would admit him into their body. During theſe two years, the novice was principally employed in exerciſes of piety, in ſtudying books of Chriſtian morality, and in becoming perfectly acquainted with the rules and conſtitutions of the order. After theſe two years were paſt, the Jeſuits were willing to retain Boſcovich, and he was no leſs deſirous of remaining with them. He therefore paſſed to the ſchool of rhetoric; in which, for two other years under the moſt expert maſters of the ſociety, young men perfected themſelves in the arts of writing and ſpeaking, which was of ſo great conſequence to perſons who were deſtined to treat ſo much with their neighbours. Here Boſcovich became perfectly well acquainted with all the claſſical authors, and applied with ſome predilection to Latin poetry.

After this he removed from the noviciate to the Roman College, in order to ſtudy philoſophy, which he did for three years. In order to underſtand the doctrine of phyſics, it was neceſſary to premiſe the knowledge of the elements of geometry, which is alſo otherwiſe proper for forming the mind, and for giving to it a true taſte for truth. Here it was that our young philoſopher came to be in his true element; and it now appeared how extremely fit his genius was for this kind of ſtudy. His maſter, though he was able and expert, inſtead of leading him on, was ſcarcely able to keep pace with him, and his condiſciples were left far behind. He likewiſe found the application of the mathematics to natural philoſophy pleaſant and eaſy. From all this, before the end of the three years, he had made a great advancement in phyſical and mathematical knowledge; and his great merit was generally acknowledged by his companions, and well known to his ſuperiors. He had already begun to give private leſſons on mathematics.

According to the ordinary courſe followed by the Jeſuits, their young men, after ſtudying philoſophy, were

(A) For this article we are indebted to a dignified clergyman of the church of Rome, who was one of Boſcovich's favourite pupils.

Boſcovich. were wont to be employed in teaching Latin and the belles lettres for the ſpace of five years, that ſo they might become ſtill better acquainted with polite learning, and arrive at the ſtudy of theology and the prieſthood at a riper age. But as Roger had diſcovered extraordinary talents for geometrical ſtudies, it was thought by his ſuperiors that it would be a pity to detain him from his favourite purſuits in a drudgery for which ſo many others were fit enough. He was therefore diſpenſed with from teaching thoſe ſchools, and was commanded to commence the ſtudy of divinity.

During the four years that he applied to that ſublime ſcience, he ſtill found ſome leiſure for geometry and phyſics; and even before that ſpace was ended, he was named profeſſor of his beloved mathematics.

He was now placed in an office for which he was ſuperlatively fit, and for which he had a particular predilection. Beſides having ſeen all the beſt modern productions on mathematical ſubjects, he ſtudied diligently the ancient geometricians, and from them learned that exact manner of reaſoning which is to be obſerved in all his works. Although he himſelf perceived eaſily the concatenation of mathematical truths, and could follow them into their moſt abſtruſe receſſes, yet he accommodated himſelf with a fatherly condeſcenſion to the weaker capacities of his ſcholars, and made every demonſtration clearly intelligible to them. When he perceived that any of his diſciples were capable of advancing faſter than the reſt, he himſelf would propoſe his giving them private leſſons, that ſo they might not loſe their time; or he would propoſe to them proper books, with directions how to ſtudy them by themſelves, being always ready to ſolve difficulties that might occur to them.

To the end that he might be the more uſeful to his ſcholars, he took time from higher purſuits to compoſe new elements of arithmetic, algebra, plain and ſolid geometry, and of plain and ſpheric trigonometry; and although theſe ſubjects had been well treated by a great many authors, yet Boſcovich's work will always be eſteemed by good judges as a maſterly performance, well adapted to the purpoſe for which it was intended. To this he afterwards added a new expoſition of conic ſections; in which, from one general definition, he draws, with admirable perſpicuity, all the properties of thoſe three moſt uſeful curves. He had meditated a complete body of pure and mixed mathematics, in which were to be comprehended treatiſes on muſic, and on civil and military architecture; but from accompliſhing this he was prevented by other neceſſary occupations.

According to the cuſtom of ſchools, every claſs in the Roman College, towards the end of the ſcholaſtic year, gave to the public ſpecimens of their proficiency. With this view Boſcovich publiſhed yearly a diſſertation on ſome intereſting phyſico-mathematical ſubject. The doctrine of this diſſertation was defended publicly by ſome of his ſcholars, aſſiſted by their maſter. At theſe literary diſſertations there was always a numerous concourſe of the moſt learned men in Rome. His new opinions in philoſophy were here rigorouſly examined and warmly controverted by perſons well verſed in phyſical ſtudies: but he propoſed nothing without ſolid grounds; he had foreſeen all their objections, anſwered them victoriouſly, and always came off with great applauſe and increaſe of reputation. He publiſhed likewiſe diſſertations on other occaſions; and theſe works, though ſmall in ſize, are very valuable both for the matter they contain, and alſo for the manner in which it is treated. The principal ſubjects of theſe diſſertations are the following: The ſpots in the ſun; the tranſit of mercury under the ſun; the geometrical conſtruction of ſpheric trigonometry; the aurora borealis; a new uſe of the teleſcope for the determination of celeſtial objects; the figure of the earth; the arguments made uſe of by the ancients to prove the rotundity of the ſame; the circles which are called oſculators; the motion of bodies projected in a ſpace void of reſiſtance; the nature of infinities and of infinitely little quantities; the inequality of gravity in different parts of the earth; the annual aberration of the fixed ſtars; the limits of the certainty to which aſtronomical obſervations can arrive; a diſcuſſion on the whole of aſtronomy; the motion of a body attracted by certain forces towards an immoveable centre in ſpaces void of reſiſtance; a mechanical problem on the ſolid of greateſt attraction; a new method of uſing the obſervation of the phaſes in the lunar eclipſes; the cycloid; the logiſtic and certain other curve lines; the forces that are called *living*; the comets; the flux and reflux of the ſea; light; whirlwinds; a demonſtration and illuſtration of a paſſage in Newton concerning the rainbow; the demonſtration and illuſtration of a method given by Euler, regarding the calculation of fractions; the determination of the orbits of a planet by means of catoptrics, certain conditions of its motions being given; the centre of gravity and that of magnitude; the atmoſphere of the moon; the law of continuity, and the conſequences of it in the elements of matter and their forces; the law of the forces that exiſt in nature; lenſes and dioptrical teleſcopes; the perturbation which appears to be cauſed mutually by Jupiter and Saturn, and that chiefly about the time of their conjunction; the diviſibility of matter and the elements of bodies; the objective micrometer;—beſides other ſubjects of the like nature, of which he has treated in ſeparate pieces, or in communications inſerted in the tranſactions of literary ſocieties or academies, he being a member of thoſe that are moſt famous in Europe. It was in ſome of the above-mentioned diſſertations that Boſcovich made known firſt to the world his ſentiments concerning the nature of body, which he afterwards digeſted into a regular theory, which is juſtly become ſo famous among the learned.

Father Noceti, another Jeſuit, had compoſed two excellent poems on the rainbow and the aurora borealis. Theſe poems were publiſhed with learned annotations by Boſcovich; in which, among other things, he with great ſagacity diſcovers errors in optics into which De Dominis, Kepler, and others, had fallen.

His countryman, Benedict Stay, after having publiſhed the philoſophy of Deſcartes in Latin verſe, attempted the ſame with regard to the more modern and more true philoſophy, and has executed it with wonderful ſucceſs, to the admiration of all good judges. The two firſt volumes of this elegant and accurate work were publiſhed with annotations and ſupplements by Boſcovich. Theſe ſupplements are ſo many ſhort diſſertations on the moſt important parts of phyſics and mathematics. Here is to be found a ſolution of the problem of the centre of oſcillation, to which Huygens had

Boscovich. had come by a wrong method; here he confutes Euler, who had imagined that the *vis inertiæ* was necessary in matter; here he refutes the ingenious efforts of Riccati on the Leibnitzian opinion of the forces called *living*. He likewise shews the falsehood of the mathematical prejudice, according to which the right line is considered as essentially more simple than curves, and makes it appear that the notion of the said right line is commonly accompanied with many paradoxes. He demonstrates, by the doctrine of combinations, some beautiful theorems concerning the space occupied by the small masses of body, with many useful observations on space and time.

Benedict XIV. who was a great encourager of learning, and a beneficent patron of learned men, was not ignorant how valuable a subject Rome possessed in Boscovich; and this pope gave him many proofs of the esteem he had for him. Two fissures which had been perceived in the cupola of the church of St Peter's on the Vatican had occasioned some alarm. The pope desired Boscovich and some other mathematicians to make their observations, and give their opinion on the same. They obeyed, and their opinion was printed. They shewed that there was no cause to apprehend danger; but, for greater security, they proposed certain precautions, which were adopted and put in execution.

The high opinion which the pope had formed of his talents, and the favour in which he was with Cardinal Valenti, minister of state, proved hinderances to his going to America, for which a proposal was made to him by the court of Lisbon. Some differences had long subsisted between Spain and Portugal concerning the boundaries of their respective dominions in that great continent; and John V. of Portugal wished that Boscovich would go over and make a topographical survey of the country in dispute. He was not unwilling to undertake such a task, which was entirely to his taste; and he was resolved at the same time to measure a degree of the meridian in Brazil, which might be compared with that measured at Quito by the French academicians Bouguer and Condamine, with the Spaniards Ulloa and Doy. But the pope hearing of this proposal, signified to the Portuguese minister at Rome, that his master must needs excuse him for detaining Boscovich in Italy, where he had occasion for him, and could by no means consent to part with him.

Accordingly a commission was given to Boscovich by Benedict to correct the maps of the papal estate, and to measure a degree of the meridian passing through the same. This he performed with great accuracy, assisted by F. Christopher Maire an English Jesuit, and likewise a great mathematician. Their map was engraved at Rome, and is perhaps the most exact piece of the kind that ever was printed, as all the places are laid down from triangular observations made by the ablest hands. Boscovich also published, in a quarto volume in Latin, an account of the whole expedition, which appeared at Rome in the year 1755, and was afterwards printed at Paris in French in the year 1770. Here he gives a detail of their observations and of the methods they followed, and likewise of the difficulties they encountered, and how they were surmounted. One of these embarrassed them a good deal at the time, but was afterwards matter of diversion to them and others. Some of the inhabitants of the Apennines, seeing them pass from hill to hill with poles and strange machines, imagined that they were magicians come among their mountains in search of hidden treasures, of which they had some traditions: and as tempests of thunder and hail happened about the same time, they supposed that these calamities were caused by the sorceries of their new visitants. They therefore insisted that Boscovich and Maire should depart; and it was not easy to convince them that their operations were harmless. In this work there is inserted a description of the instruments made use of in determining the extent of the degree of the meridian; and the whole work may be extremely useful to practical geometricians and astronomers.

In the year 1757 the republic of Lucca intrusted Boscovich with the management of an affair which was to them of considerable importance. Between that republic and the regency of Tuscany there had arisen a disagreeable dispute concerning the draining of a lake, and the direction to be given to some waters near the boundaries of the two states. The Lucchese senate chose our philosopher to treat of this business on their part. He repaired to the spot, considered it attentively, and drew up a writing, accompanied with a map, to shew more clearly what appeared to him most equitable and most advantageous for both parties. In order to enforce his reasons the more effectually, it was thought proper that he should go to Vienna, where the Emperor Francis I. who was likewise grand duke of Tuscany, resided. He was so successful in this negociation, that he obtained every thing that Lucca desired, and at the same time acquired great esteem at the Imperial court. In proof of this, the Empress Queen made his opinion be asked concerning the stability of the Cesarean library, and the repairs to be made in it; which he gave in writing, and it was received with thanks, as being very well grounded.

When he had concluded the affair which had brought him to Vienna, he foresaw that, for a month or two, the snows in the Alps would not allow him to return to Italy. He therefore resolved to employ that time in completing his system of natural philosophy, on which he had been meditating for the space of thirteen years. He published his work on that great subject in the beginning of the year 1758, in the above-mentioned city. We shall in the end give an account of that celebrated system, and here go on with our narration.

On his return to Lucca, he not only met with the approbation of all he had done for the interest of the republic; but also the senate, in testimony of their gratitude, made him presents, and enrolled him in the number of their nobility, which was the greatest honour they had in their power to confer on him.

He, who was thus useful to foreigners, could not refuse to be serviceable to his own country when an occasion of being so offered itself. The British ministry had been informed, that ships of war, for the French, had been built and fitted out in the sea-ports of Ragusa, and had signified their displeasure on that account. This occasioned uneasiness to the senate of Ragusa, as their subjects are very sea-faring, and much employed in the carrying-trade; and therefore it would have been inconvenient for them to have caused any disgust against them in the principal maritime power. Their countryman Boscovich was desired to go to London, in order to satisfy that court on the above-mentioned head; and

Bofcovich. and with this defire he complied cheerfully on many accounts. His fuccefs at London was equal to that at Vienna. He pleaded the caufe of his countrymen effectually there, and that without giving any offence to the French, with whom Ragufa foon after entered into a treaty of commerce.

Bofcovich came to London the more willingly, as he was defirous of converfing with the learned men of Britain. He was received by the prefident and principal members of the Royal Society with great refpect; and to that great body he dedicated his poem on the eclipfes of the fun and moon, which was printed on this occafion at London, in the year 1760. This is one of his works on which he himfelf put the greateft value, and it has been much efteemed by the learned. An edition of it was publifhed at Venice the year following, and a third at Paris, which is the moft correct: a tranflation of it into French has likewife been publifhed at Paris. In this very elegant Latin poem he gives an exact compend of aftronomy, which ferves as an introduction to the fubject; he then explains all that belongs to the doctrine of eclipfes, and their ufe in geography; he confiders the phenomena that are obferved in the eclipfes of the fun, and likewife of the moon; he propofes a theorem, which is his own, concerning the diftribution of light refracted from the atmofphere of the earth by the fhadow of the moon, which happens in the lunar eclipfes; he explains the phenomenon of the reddifh colour which often appears in the moon when fhe is eclipfed, of which a fufficient explication had not before been given: this the author draws from the fundamental doctrine of Newton's theory concerning light and colours; and hence takes occafion to give a clear idea of the principal confequences of the faid theory. All this is clothed with a beautiful poetical drefs, and is adorned with pleafant epifodes, not to mention the learned annotations which are fubjoined. This poem was compofed, for the moft part, whilft the author was in journeys, or by way of amufement, when he was obliged to wait for the opportunities of making aftronomical obfervations.

The fellows of the Royal Society invited Bofcovich to accompany fome of their number to America, to obferve the tranfit of Venus, which was to happen in the year 1762; but being otherwife engaged, he could not accept of that invitation. He intended, however, by all means to obferve that remarkable phenomenon, and had fixed on Conftantinople as a proper place for doing fo. He was conducted thither in a Venetian man of war, and much honoured by one of the baylos of that republic, who commanded the veffel; but, to his great regret, they arrived too late. He returned, by land, in the company of the Englifh ambaffador; and a relation of that journey was publifhed in French and afterwards in Italian.

During thefe journeys, Bofcovich's place in the Roman College was well filled by fome of thofe whom he himfelf had trained up in mathematical learning. He was now called by the fenate of Milan to teach mathematics in the univerfity of Pavia, with the offer of a very confiderable falary. He and his fuperiors thought proper to accede to this propofal, and he was received without being fubjected to any previous examination; which was always obferved, excepting in fuch an extraordinary cafe, by the decrees of the univerfity. Here he taught, with great applaufe, for the fpace of fix years, having at the fame time the care of the obfervatory of the Royal College of Brera. About the year 1770, the Emprefs Queen made him profeffor of aftronomy and optics in the Palatine fchools of Milan; requiring of him, however, that he fhould continue to improve the obfervatory of Brera; which, under his direction, became one of the moft perfect in Europe. Bofcovich.

Here he was extremely happy, teaching the fciences, applying to his favourite ftudies, and converfing and correfponding with men of learning and of polifhed manners; when an event happened which caufed to him the moft fenfible affliction. In the year 1773, the fociety to which he belonged, and to which he had been from his youth warmly attached, was, to his great regret and difappointment, abolifhed. They who had been Jefuits were allowed no longer to teach publicly; nor was there any exception made in favour of Bofcovich, neither (fuch was his humour then) would he have accepted of it, though it had been offered him. Propofals were made to him by feveral perfons of diftinction: and, after fome deliberation, he chofe Paris for his place of abode; to which he was induced by the circumftance of his being intimately acquainted with the prime minifter at that court. He had not been many months at Paris when the univerfity of Pifa fent him an invitation to go thither, in order to profefs aftronomy. But the French minifter, underftanding this, declared to the minifter of Tufcany, that it was the intention of his moft Chriftian majefty to make his dominions agreeable to Bofcovich, by giving him liberal appointments. In fact he was foon naturalized, and two large penfions were beftowed on him: the one as an honourable fupport, to the end that he might profecute his fublime ftudies at his eafe and in affluence; the other as a falary annexed to a new office, created in his favour, under the name of *Director of Optics for the Sea Service*, and with the fole obligation of perfecting the lenfes which are ufed in achromatical telefcopes.

At Paris he remained ten years, applying principally to optics, and much regarded, not only by the moft reafonable men of letters, but likewife by the princes and minifters, both of France and of other nations. But the greateft men are not exempt from being envied. Some of the French were difpleafed that a foreigner fhould appear fuperior to themfelves; others of them could not forget that Bofcovich had difcovered and expofed their miftakes. The irreligion which prevailed too much among thofe who bore the name of philofophers, was difagreeable to him. Thefe, and other fuch circumftances, made him wearied of Paris, and he defired to revifit his friends in Italy; for which purpofe he obtained leave of abfence for two years.

The firft place in Italy in which he made any ftay was at Baffano, a town in the territories of Venice. Here, mindful of his obligations, he printed what he had been preparing for the prefs during his ftay in France; and this compofes five volumes in large octavo, and is a treafure of optical and aftronomical knowledge. The fubjects treated of in thefe volumes are as follow: A new inftrument for determining the refracting and diverging forces of diaphanous bodies; a demonftration of the falfehood of the Newtonian analogy between light and found; the algebraic formulæ regarding the focufes of lenfes, and their applications for calculating the fpheri-

Boſcovich. city of thoſe which are to be uſed in achromatical teleſcopes; the corrections to be made in ocular lenſes, and the errors of the ſphericity of certain glaſſes; the cauſes which hinder the exact union of the ſolar rays by means of the great burning glaſſes, and the determination of the loſs ariſing from it; the method of determining the different velocities of light paſſing through different mediums by means of two dioptrical teleſcopes, one common, the other of a new kind, containing water between the objective glaſs and the place of the image; a new kind of objective micrometers; the defects and inutility of a dioptrical teleſcope propoſed and made at Paris, which gives two images of the ſame object, the one direct, the other inverſe, with two contrary motions of moveable objects; maſſes floating in the atmoſphere, as hail of an extraordinary ſize, ſeen on the ſun with the teleſcope, and reſembling ſpots; the aſtronomical refractions, and various methods for determining them; various methods for determining the orbits of comets and of the new planet, with copious applications of theſe doctrines to other aſtronomical ſubjects, and ſtill more generally to geometry and to the ſcience of calculation; the errors, the rectifications, and the uſe of quadrants, of ſextants, of aſtronomical ſectors, of the meridian line, of teleſcopes called the inſtruments of tranſits, of the meridian, and of the parallactic machine; the trigonometrical differential formulæ, which are of ſo much uſe in aſtronomy; the uſe of the micrometical rhombus, extended to whatever oblique poſition; the error ariſing from refractions in uſing the aſtronomical ring for a ſundial, and the correction to be made; the appearing and the diſappearing of Saturn's ring; the methods of determining the rotation of the ſun by means of the ſpots, propoſed formerly by the author, and now perfected; the greateſt exactneſs poſſible in determining the length of a pendulum oſcillating every ſecond of middle time by the compariſon of terreſtrial and celeſtial gravity; a compend of aſtronomy for the uſe of the marine, containing the elements of the heavenly motions, and of the aſtronomical inſtruments to be explained to a prince in the courſe of one month; a method for determining the altitude of the poles with the greateſt exactneſs, by means of a gnomon alone, where other inſtruments are not to be had; the determination of the illuminated edge of the moon to be obſerved on the meridian; a method of uſing the retrograde return of Venus to the ſame longitude, for determining the leſs certain elements of her orbit; a method for correcting the elements of a comet, of which the longitude of the node is given, and the inclination of the orbit has been found nearly; another method for the ſame purpoſe, and for finding the elliptical orbit, when the parabolic one does not agree with the obſervations; a method for correcting the elements of a planet by three obſervations; the projection of an orbit inclined in the plane of the ecliptic; the projection of an orbit inclined in any other plane; the calculation of the aberration of the ſtars, ariſing from the ſucceſſive propagation of light; ſome beautiful theorems belonging to triangles, which are of great uſe in aſtronomy, reduced to moſt ſimple demonſtrations.

After having ſeen the impreſſion of theſe five volumes finiſhed, Boſcovich left Baſſano, made an excurſion to Rome, and viſited his old friends there and in other places of Italy. He then took up his abode at Milan, and applied to the reviſing of ſome of his old works, and to the compoſing of new ones. He ſet himſelf particularly to prepare annotations and ſupplements to the remaining two volumes of Stay's Modern Philoſophy, which he had not had time to publiſh ſooner, and which he lived not to publiſh. Boſcovich.

He was happy at Milan in the neighbourhood of Brera, where was his favourite obſervatory; and in the company of many friends, who were become the more dear to him by his long abſence from them. But he began to conſider, with grief, that his two years of abſence were drawing to an end. He was very unwilling to leave Italy and return to France. He thought of applying for a prolongation of his abſence; he thought of making intereſt at the Imperial court for ſome honourable commiſſion, which might be a pretext to him for remaining at Milan: but he was afraid that the propoſal of never returning to France might appear indelicate and ungrateful to a nation from which he was receiving conſiderable penſions. He apprehended that thoſe perſons at Paris who had before oppoſed him, would take occaſion to tax him with ingratitude, and that hence his reputation would be tarniſhed. Theſe, and other ſuch thoughts, occaſioned a great perplexity of mind, which was followed by a deep melancholy; and this could not be alleviated by the advice and comfort of his friends, becauſe by degrees he became incapable of hearing reaſon, his ideas being quite confuſed, and his imagination diſordered. To this diſagreeable change the ſtate of his health perhaps contributed. A gout had been wandering for ſome time through his body, and he had caught a ſevere cold; nor would he admit of medical aſſiſtance, of which he had always been very diffident. It may alſo be that his long and intenſe application had hurt the organs of the brain, which in ſome manner are ſubſervient to the uſe of reaſon as long as the ſoul is united to the body. Be that as it will, during the laſt five months of his life, this great man, who had been ſo far ſuperior in reaſoning to his ordinary fellow-creatures, was much inferior to every one of them who is endued with the right uſe of the underſtanding. He had indeed ſome lucid intervals, and once there were hopes of a recovery; but he ſoon relapſed, and an impoſthume breaking in his breaſt, put an end to his mortal exiſtence. He died at Milan on the 13th of February 1787, in the 76th year of his age.

He was tall in ſtature, of a robuſt conſtitution, of a pale complexion. His countenance was rather long, and was expreſſive of cheerfulneſs and good humour. He was open, ſincere, communicative, and benevolent. His friends ſometimes regretted that he appeared to be too irritable, and too ſenſible of what might ſeem an affront or neglect, which gave himſelf unneceſſary uneaſineſs. He was always unſtained in his morals, obedient to his ſuperiors, and exact in the performance of all Chriſtian duties, as became a Catholic prieſt, and in the obſervance of the particular rules of his order. His great knowledge of the works of Nature made him entertain the higheſt admiration of the power and wiſdom of their Creator. He ſaw the neceſſity and advantages of a divine revelation, and was ſincerely attached to the Chriſtian religion; having a ſovereign contempt of the preſumption and fooliſh pride of unbelievers, and being fully perſuaded that we cannot make a more noble uſe of our underſtanding than by ſubjecting it humbly to the authority of the Supreme Being, who knows numberleſs

Boſcovich. berleſs truths far beyond the utmoſt limits of our narrow comprehenſion, and who may juſtly require our belief of any of them that he ſees fit to propoſe to us.

The death of our philoſopher, who truly deſerved that name, was heard with regret by the learned through Europe, and more than ordinary reſpect has been paid to his memory. At Raguſa funeral exequies were performed for him with great ſolemnity by order of the ſenate, who aſſiſted at them in a body; on which occaſion an eloquent oration in praiſe of him was pronounced. By a decree of the ſame ſenate, a Latin inſcription to his honour, engraved on marble, was placed in the principal church of their city. Of this inſcription the following is a copy:

This inſcription was compoſed by his friend and countryman the celebrated poet Benedict Stay. Zamagna, another of his countrymen, who had likewiſe been his fellow-jeſuit, publiſhed a panegyric on him in elegant Latin. A ſhort encomium of him is to be found in the *Eſtratto della Litteratura Europea*; and another, in form of a letter, was directed by M. de la Lande to the Pariſian journaliſts, and by them given to the public. A more full elogium has been written by M. Fabroni; and another is to be met with in the journal of Modena; a third was publiſhed at Milan by the Abbate Ricca; and a fourth at Naples by the Dr Julius Bajamonti, of which a ſecond edition was made in the year 1790. Of this laſt chiefly uſe has been made here.

But what muſt ſecure to Boſcovich the eſteem of poſterity are his works, of the greater part of which we have

Boſcovich.

have already taken notice. We have mentioned, 1. His Elements of Mathematics, with his Treatiſe on Conic Sections; 2. His many diſſertations publiſhed during his profeſſorſhip in the Roman college; 3. His account of his Survey of the Pope's Eſtate; 4. His Theory of Natural Philoſophy; 5. His Poem on the Eclipſes; 6. His five volumes printed at Baſſano.

To theſe we may add his hydrodynamical pieces. He had made a particular ſtudy of the force of running water, and of its effects in rivers; and he was often conſulted concerning the beſt means to prevent rivers from corroding their banks, and from overflowing the neighbouring plains, which often happens in Italy, where the Alps and Apennines pour down ſo many impetuous ſtreams. He gave a writing on the damages done by the Tiber at Porto Felice; another on the project of turning the navigation to Rome from Fiumicino to Maccarcſe; a third on two torrents in the territory of Perugia; a fourth on the bulwarks on the river Panaro; a fifth on the river Sidone, in the territory of Placentia; a ſixth on the entrance into the ſea of the Adige. He wrote other ſuch works on the bulwarks of the Po; on the harbours of Ancona, of Rimini, of Magna Vacca, and Savona, beſides others, almoſt all which were printed. He had likewiſe received a commiſſion from Clement XIII. to viſit the Pomptin lakes, on the draining of which he drew up his opinion in writing, to which he added further elucidations at the deſire of Pius VI. On theſe occaſions he ſhewed how uſeful philoſophy may be to the public; and of this he gave another proof when it was referred entirely to his judgement to determine whether or not the cupola of the cathedral of Milan could bear the weight of a very high ſpire, which it was propoſed to raiſe on it, and which was actually erected according to his directions.

His application to abſtruſe ſtudies did not hinder him from paying ſome attention to what is more pleaſant. We have ſeen that he was a poet: he was alſo well acquainted with hiſtory, and particularly with that of the Greeks and Romans, and with their antiquities. He wrote a diſſertation on an ancient villa diſcovered in his time upon the Tuſculan Hill, and on an ancient dial found there; which diſſertation was publiſhed at Rome in a literary journal. He wrote likewiſe three letters on the obeliſk of Cæſar Auguſtus, two of which were printed with his own name, and the third under the name of another.

Beſides all theſe works that were given to the public in his lifetime, many writings of his remained in manuſcript in the hands of different perſons, and particularly with his friend M. Gaetani, and many more with Count Michael de Sorgo, a Raguſan ſenator, who inherited all his papers that were in his own hands at his death. Theſe, it is hoped, have either been already ſent to the preſs or will be ſo; as nothing came from the pen of Boſcovich which was not uſeful and deſerving to ſee the light.

It now remains that we give an account of his Theory of Natural Philosophy; and in doing this we ſhall, in the *firſt* place, lay before our readers a view of this ſyſtem. We ſhall, in the *ſecond* place, relate, from what principles and by what ſteps it was deduced. We ſhall, *thirdly*, take notice of the principal objections made to it, and ſubjoin the author's anſwers to the ſame. We ſhall, *finally*, ſhew how happily it may be applied to explain the general properties of matter, as well as the particular qualities of all the claſſes of bodies, which have been examined according to what it teaches.

Boſcovich's Syſtem of Natural Philoſophy.

1 View of Boſcovich's ſyſtem of natural philoſophy.

I. In this ſyſtem, therefore, the whole maſs of matter, of which all the bodies of the univerſe are compoſed, conſiſts of an exceeding great, yet ſtill finite number of ſimple, indiviſible, inextended, atoms. Theſe atoms are endued with *repulſive* and *attractive* forces, which vary and change from the one to the other, according to the diſtance between them, in the following manner: In the leaſt and innermoſt diſtances they repel one another; and this repulſive force increaſes beyond all limits as the diſtances are diminiſhed, and is conſequently ſufficient for extinguiſhing the greateſt velocity, and for preventing the contact of the atoms. In the ſenſible diſtances, this force is *attractive* and decreaſes, at leaſt ſenſibly, as the ſquares of the diſtances increaſe, conſtituting univerſal gravity, and extending beyond the ſphere of the moſt diſtant comets. Between this innermoſt repulſive force and the outermoſt attractive one, in the inſenſible diſtances, many varieties and changes of the force, or determination to motion, take place: for the repulſive force decreaſes as the diſtance increaſes. At a certain diſtance it comes to vaniſh entirely; and, when that diſtance is increaſed, attraction begins, increaſes, becomes leſs, vaniſhes; and the diſtance becoming greater, the force becomes repulſive, increaſes, leſſens, and vaniſhes as before. Many varieties and changes of this kind happen in the inſenſible diſtances, ſometimes more rapidly, ſometimes more ſlowly, and ſometimes one of the forces may come to nothing, and then return back to the ſame without paſſing to the other. For all this there is full room in the diſtances that are inſenſible to us, ſeeing the leaſt part of ſpace is diviſible *in infinitum*. Beſides theſe repulſive and attractive forces, our atoms have that *vis inertiæ* which is admitted by almoſt all modern philoſophers. Theſe atoms, endued with theſe forces, conſtitute the whole ſubſtance of Boſcovich's ſyſtem; which, however ſimple and ſhort it may appear to be, has numberleſs and very wonderful conſequences, as we ſhall ſee afterwards. But, that a more clear idea of the whole theory may be eaſily formed, we ſhall make uſe of a geometrical figure well accommodated to that purpoſe. The right line C'AC is an axis, from which, in the point A, is drawn the right line AB at right angles. AB is conſidered as an *aſymptote;* on each ſide of which the two curves, quite ſimilar and equal, DEFGHIKLMNOPQRSTVU on the one ſide, and D'E'F'G' on the other, are placed. Now, if ED be ſuppoſed to be *aſymptotical*, and be extended, it will ſtill approach to BA, but will never come to touch it. This curve ED approaches to the axis C'C, comes to it in E, cuts it and departs to a certain diſtance in F, after which it again approaches the ſame axis and cuts it in G. In like manner it forms the arches GHI, IKL, LMN, NOP, PQL. At laſt it goes on in T *p s* V, which is aſymptotical, and approaches to the axis; ſo that the diſtances from it are in a duplicate reciprocal proportion of the diſtances from the right line BA. If from any points of the axis, as from *a*, *b*, *d*, we raiſe the per-

2 The whole theory expreſſed by a geometrical curve. Plate VI. fig. 6.

Boscovich's System of Natural Philosophy.

perpendiculars *a g*, *b r*, *d h*, the segments of the axis A *a*, A *b*, A *d*, are called *abscisses*, and represent the distances of any two points of matter from one another; and the perpendiculars *a g*, *b r*, *d h*, are called *ordinates*, and exhibit the repulsive or attractive force, according as it lies on the same side with D, or on the other side of the axis.

Now it is evident that, in this form of the curve line, the *ordinate a g* will be increased beyond whatever limits, if the abscis A *a* be lessened likewise beyond whatever limits; that if this abscis be increased to A *b*, the *ordinate* will be lessened, and will pass into *b r*, which will still be lessened as it approaches from *b* to E, where it will come to nothing; that then, the axis being increased to A *d*, the *ordinate* will change its direction into *b h*, and, on the opposite side, will increase at first to F, then it will decrease through *i l* as far as G, where it will again vanish, and again change its direction in *m n* to the former; and that, in the same manner, it will vanish and change its directions in all the sections I, L, N, P, R, until the *ordinates o p*, *v s*, become of a constant direction, and decrease, at least sensibly, in a reciprocal duplicate proportion of the abscisses A *o*, A *v*. Wherefore, it is manifest, that by such a curve are expressed our forces; at first *repulsive* and increasing beyond all limits, the distances being lessened in like manner, and which decrease, the same distances being augmented; then vanish, change their direction, and become *attractive*; vanish again, and become *repulsive*; till at last, at sensible distances, they remain on the side opposite to D, and are *attractive* in a duplicate reciprocal proportion of the distances.

We may also observe that the *ordinates* may increase or decrease rapidly, as in *y v*, *z t*, or slowly, as in *v x*, *z c*; and, consequently, that the forces may increase or decrease in like manner. We may add, that the curve may return back without intersecting, or even touching, the axis, as in *f*, and may return after having touched the same axis.

Although this curve expresses very clearly the *repulsive* and *attractive* forces of our system, yet, at first sight, it may appear to be a complicated irregular line. But the author shews that his curve is uniform and regular, and may be expressed by one uniform algebraical equation; which it will be necessary for us to consider, in order to give satisfaction to our readers, and to do justice to the theory.

3
The simplicity of this curve proved.

Wherefore, from what we have seen, the curve must have the following six conditions: *1st*, It must be regular and simple, and not composed of an aggregate of arches of different curves. *2dly*, It is necessary that it cut the axis C′AC in certain given points only, at two equal distances on each side AE′, AE, AG′, AG, and so on. *3dly*, That to every *abscis* an *ordinate* correspond. *4thly*, That if we take equal *abscisses* on each side of A, they have equal *ordinates*. *5thly*, That the right line AB be an *asymptote*, the area BAED being asymptotical, and consequently infinite. *6thly*, That the arches terminated by any two intersections may be varied at pleasure, and recede to any distance from the axis C′AC, and approach at pleasure to whatever arches of whatever curves, cutting them, touching them, or osculating them, in any place and manner.

In order to find an algebraical formula expressing the nature of a curve line that would answer all these six conditions, let us call the ordinate y, the abscis x, and let it be made $x x = z$. Then let us take the values of all the abscisses AE, AG, AI, &c. with the negative sign, and let the sum of the squares of all these values be called a, the sum of the products of every two squares b, the sum of the products of every three, c, and so on; and let the product of all of them be called f, and the number of the same values m. All this being supposed, let it be made $z^m + a z^{m-1} + b z^{m-2} + c z^{m-3}$ &c. $+ f = \mathrm{P}$. If we suppose P equal to nothing, it is clear that all the roots of that equation will be real and positive; that is, the squares only of the quantities AE, AG, AI, &c. which will be the values of z; and therefore, as it is $x = \pm \sqrt{z}$, because it is $x x = z$, it is likewise clear that the values of x will be both AE, AG, AI, positive, and A′E′, A′G′, &c. negative.

This being done, let any quantity be multiplied by z, providing it hath no common divisor with P, lest z vanishing, it likewise might vanish; and having made x an infinitesim of the first order, it may become an infinitesim of the same, or of a lower order, as will be whatever formula $z^r + g z^{r-1} + h z^{r-2}$ &c. $+ l$; which, being supposed equal to o, may have as many imaginary, and as many and whatever real roots, providing none of them be those of AG, AE, AI, &c. either positive or negative. If then the whole formula be multiplied by z, let this product be called Q.

If we make $\mathrm{P} - \mathrm{Q}\, f = o$, this equation will satisfy the five first conditions above mentioned; and the value of Q being properly determined, the sixth condition also may be complied with.

For, in the first place, seeing the value P and Q are made equal to o, they have no common root, and therefore no common divisor. Hence this equation cannot be reduced to two by division; and therefore it is not composed of two equations, but is simple, and therefore exhibits one simple continued curve, which is not composed of any others; which is the first condition.

Secondly, The curve thus expressed will cut the axis C′AC in all the points E′, G, I, &c. and G′, &c. and in them only: for it will cut that axis only in those points in which $y = o$, and in all of them. Moreover, where it will be $y = o$, it will also be $\mathrm{Q}\, y = o$; and therefore, because of $\mathrm{P} - \mathrm{Q}\, y = o$, it will be $\mathrm{P} = o$. But this will happen only in those points in which z will be one of the roots of the equation $\mathrm{P} = o$; that is, as we have seen above, in the points E, G, I, or E′, G′, &c.: wherefore, only in those points will y vanish, and the curve cut the axis. Again, that the same curve will cut it in all these points, is clear from this, that in them all it will be $\mathrm{P} = o$. Wherefore it will likewise be $\mathrm{Q}\, y = o$; but it will not be $\mathrm{Q} = o$, seeing there is no common root of the equations $\mathrm{P} = o$ and $\mathrm{Q} = o$: it must therefore be $y = o$, and the curve will cut the axis: and thus the second condition is satisfied.

Besides, whereas it is $\mathrm{P} - \mathrm{Q}\, x = o$, it will be $y = \frac{\mathrm{P}}{\mathrm{Q}}$. the abscis x being, however, determined, we will have a certain determinate quantity for z; and thus P, Q, will be determined, and the only two of the kind. Wherefore y also will be sole and determined; and therefore to every abscis z, one only ordinate y will correspond. This is the third condition.

Again, whether x be assumed positive or negative, pro-

Boſcovich's Syſtem of Natural Philoſophy.

providing it be of the ſame length, ſtill the value $z = xx$ will be the ſame, and therefore the values of both P and Q will be the ſame: wherefore y will ſtill be the ſame. Taking, therefore, equal abſciſſes z on both ſides of A, the one poſitive, the other negative, they will have equal correſponding ordinates. This is the fourth condition.

If x be leſſened beyond all limits, whether it be poſitive or negative, z likewiſe will be leſſened beyond all limits, and will become an infiniteſim of the ſecond order: wherefore, in the value P, all the terms will decreaſe *in infinitum*, except in y, becauſe all the reſt beſides it are multiplied by z; and thus the value P will be as yet finite. But the value Q, which has the formula multiplied by z, will be leſſened *in infinitum*, and will be an infiniteſim of the ſecond order: therefore $\frac{P}{Q} = y$ will be augmented *in infinitum*, ſo as to become an infinite of the ſecond order. Wherefore the curve will have the right line AB for an *aſymptote*, and the area BAED will increaſe *in infinitum*: and if the ordinate y be aſſumed poſitive on the ſide AB, and expreſs repulſive forces, the aſymptotic arch ED will lie on the ſame ſide AB. This is the fifth condition.

Now the value Q can be varied in infinite manners; ſo that ſtill the conditions for which it was aſſumed may be fulfilled; and therefore the arches of the curve intercepted by the interſections may be varied in infinite manners; ſo that the firſt five conditions of the curve may be implemented: whence it follows that they may be ſo varied that the ſixth condition may alſo be anſwered.

For if there be given, however many, and whatever arches of whatever curve, providing they be ſuch that they recede always from the aſymptote AB, and thus no right line parallel to that aſymptote cut theſe arches in more than one point, and in them let there be taken as many points as you pleaſe, and as near one another; it will be eaſy to aſſume ſuch a value of P, that the curve ſhall paſs through all theſe points, and the ſame may be varied infinitely; ſo that ſtill the curve will paſs through all the ſame points.

Let the number of points aſſumed be what you pleaſe $= r$, and, from every one of ſuch points, let right lines be drawn parallel to AB, as far as the axis C'AC, which muſt be the ordinates of the curve that is ſought; and let the abſciſſes from A to the ſaid ordinates be called M^1, M^2, M^3, &c. and the ordinates $'N^1, 'N^2, 'N^3$, &c. Let there now be taken a certain quantity $Az^r + Bz^{r-1} + Cz^{r-2} + Gz$, and let this quantity be ſuppoſed equal to R. Then let another ſuch quantity T be aſſumed, ſo that z vaniſhing, whatſoever term of it may vaniſh, and ſo that there be no common diviſor of the value of P, and of the value of R + T: which may be eaſily done, ſeeing all the diviſors of the quantity P are known. Let it now be made Q = R + T, and then the equation of the curve will be $P - Ry - Ty = o$. After this, let there be put in the equation M_1, M_2, M_3, ſucceſſively for x, and N_1, N_2, N_3, &c. for y; we will have a number of equations equal to r, which will contain the values of A, B, C, ... G, each of them of one dimenſion, in number likewiſe equal to r; and, beſides, we will have the given values of M_1, M_2, &c. N_1, N_2, N_3, &c. and the arbitrary values which in T are the coefficients of z.

By theſe equations, which are in number r, it will be eaſy to determine the values A, B, C, . . G, which are likewiſe in number r, aſſuming in the firſt equation, according to the uſual method, the value A, and ſubſtituting it in all the following equations; by which means the equations will become $r-1$. Theſe, again, by throwing out the value B, will be reduced to $r-2$, and ſo on until we come to one only; in which the value Q being determined by means of it, going back, all the preceding values will be determined, one by each equation.

The values A, B, C, ... G, being in this manner determined, in the equation $P - Ry - Ty = o$, or $P - Qy = o$, it is clear that the values M_1, M_2, M_3, &c. being ſucceſſively put for x, the values of the ordinate y muſt ſucceſſively be N_1, N_2, N_3, &c.; and, therefore, that the curve muſt paſs through theſe given points in thoſe given curves; and ſtill the value Q will have all the preceding conditions. For z being leſſened beyond whatever limits, every one of its terms will be leſſened beyond whatever limits, ſeeing all the terms of the value of T are leſſened which were thus aſſumed, and likewiſe the terms of the value R are leſſened, which are all multiplied by z; and, beſides this, there will be no common diviſor of the quantities P and Q, ſeeing there is none of the quantity P and R + T.

But if two of the neareſt of the points aſſumed in the arches of the curves, on the ſame ſide of the axis, be ſuppoſed to accede to one another beyond whatever limits, and at laſt to coincide, which will be done by making two M equal, and likewiſe two N equal; then the curve ſought will touch the arch of the given curve; and if three ſuch points coincide, they will *oſculate* it: nay, as many points as we pleaſe may be made to meet together where we pleaſe; and thus we may have *oſculations* of what order we pleaſe, and as near one another as we pleaſe, the arch of the given curve approaching as we pleaſe, and at whatever diſtances we pleaſe, to whatever arches of whatever curves, and yet ſtill preſerving all the ſix conditions required for expreſſing the law of the repulſive and attractive forces. And whereas the value of T can be varied in infinite manners, the ſame may be done in an infinite number of ways; and therefore a ſimple curve, anſwering the given conditions, may be found out in an infinite number of ways. *Q. E. F.*

What we have ſaid will, we hope, ſatisfy our readers, and eſpecially thoſe of them who are in the leaſt acquainted with high geometry, that Boſcovich's curve is ſimple, regular, and uniform; and that therefore the law of repulſive and attractive forces, expreſſed by it, is ſimple and regular.

II If this ſyſtem were a mere hypotheſis, it would ſtill be very ingenious, and, from what we ſhall ſay afterwards, would ſtill be well adapted for explaining the phenomena of nature. But its author is far from looking upon it as an arbitrary ſuppoſition; he aſſures us that he was led to it by a chain of ſtrict reaſoning, from evident principles. We ſhall now give an abridgement of that reaſoning from his Diſſertations on the Law of *Continuity*, and from his Theory of Natural Philoſophy.

Proofs of the theory.

He tells us, then, that in the examination of Leibnitz's opinion of the *vires vivæ*, he came to conſider the colliſion of bodies, and took for example two equal bodies A proceeding with ſix degrees of velocity, and B following with the velocity of 12: after the colliſion, 4

Boscovich's System of Natural Philosophy.

sion, they proceed jointly with the common velocity 9. Now, in the moment of collision, it either happens that A passes abruptly from the velocity 6 to the velocity 9, without passing through the velocity 7 and 8, and B passes from 12 of velocity to 9, without passing through 11 and 10; or else there must be some cause which accelerates the one and retards the other before they come to contact. In the first case, the law of continuity is broken; in the second, immediate contact of bodies would be rejected. Maclaurin saw this difficulty, and mentioned it in his work on *Newton's Discoveries*, l. 1. c. 4. He, not having courage to recede from the common opinion, allowed a breach, in such cases, of the law of continuity; but Boscovich maintains the universality of the law of continuity; and holds that no bodies touch one another really and mathematically, but only physically and sensibly to us.

5 The law of continuity proved

The law of continuity is that by which variable quantities, passing from one magnitude to another, pass through all the intermediate magnitudes, without ever abruptly passing over any of them. This law Boscovich proves to be universal, in the first place, from induction. Thus we see that the distances of two bodies can never be changed without their passing through all the intermediate distances. We see the planets move with different velocities and directions; but in this they still observe the law of continuity. In heavy bodies projected, the velocity decreases and increases through all the intermediate velocities: the same happens with regard to elasticity and magnetism. No body becomes more or less dense without passing through the intermediate densities. The light of the day increases in the morning and decreases at night through all the intermediate possible degrees. In a word, if we go through all nature, we shall see the law of continuity strictly take place, if all things be rightly considered. It is true, we sometimes make abrupt passages in our minds; as when we compare the length of one day with that of another immediately following, and say that the second is two or three minutes longer or shorter than the former, passing all at once, in our way of speaking, round the globe; but if we take all the longitudes, we shall find days of all the intermediate lengths. We likewise sometimes confound a quick motion with an instantaneous one: thus, we are apt to imagine that the ball is thrown abruptly out of the gun; but, in truth, some space of time is required for the gradual inflammation of the powder, for the rarefaction of the air, and for the communication of motion to the ball. In like manner, all the objections made against the law of continuity may be solved to satisfaction.

6 A breach of this law impossible.

But however strong this argument from judgment may appear to be, yet Boscovich goes farther, and maintains, that a breach of this law, in the proper cases, is metaphysically impossible. This argument he draws from the very nature of continuity. It is essential to continuity that, where one part of the thing *continued* ends and another part begins, the limit be common to both. Thus, when a geometrical line is divided into two, an indivisible point is the common limit to both: thus time is *continued;* and therefore where one hour ends, another immediately begins, and the common limit is an indivisible instant. Now, as all variations in variable quantities are made in time, they all partake of its continuity; and hence none of them can hasten by an abrupt passage from one magnitude to another, without passing through the intermediate magnitudes. As we cannot pass from the sixth hour to the ninth without passing through the seventh and eighth; because, if we did, there would be a common limit between the sixth hour and the ninth, which is impossible: so likewise you cannot go from the distance 6 to the distance 9 without passing through the distances 7 and 8; because, if you did, in the instant of passage you would be both at the distance 6 and at the distance 9, which is impossible. In like manner, a body that is condensed or rarefied cannot pass from the density 6 to the density 9, or *vice versa*, without passing through the densities 7 and 8; because, in the abrupt passage, there would be two densities, 6 and 9, in the same instant. The body must pass through all the intermediate densities. This it may do quickly or slowly, but still it must evidently pass through them all. The like may be said of all variable quantities; and thence we may conclude, that the law of continuity is universal.

7 Objections to this law answered.

But, in creation, is there not an instance of an abrupt passage from *non-existence* to *existence?* No, there is not; because before existence a *being* is nothing, and therefore incapable of any state. In creation, a *being* does not pass from one state to another abruptly; it passes over no intermediate state: it begins to exist and to have a state, and existence is not divisible. Do we not, at least, allow of an abrupt passage from repulsive to attractive forces in our very theory itself? We do not. Our repulsive forces diminish, through all the intermediate magnitudes, down to nothing; through which, as a limit, they pass to attraction. In the building of a house or ship, neither of them is augmented abruptly; because the additions made to them are effected solely by a change of distances between the parts of which they are composed: and all the intermediate distances are gone through. The like may be said of many other such cases; and still the law of continuity remains firm and constant.

8 Impossibility of contact between bodies.

Let us now apply this doctrine to the case above mentioned of the collision of two bodies. We say that the body B cannot pass from the velocity 6 to the velocity 9 without passing through the velocities 6 and 7; because if it did, in the moment of contact of the two superficies it would have the velocities 6 and 9. Now a body cannot have two velocities at the same instant. For if it had two *actual* velocities at the same time, it would be in two different places at the same time: if it had two different *potential* velocities or determinations to a certain velocity, it would be capable of being, after a given time, in two places at once—both which are impossible. It is therefore necessary that it go through the velocities 7 and 8, and through all the parts of them. What we have said of the bodies A and B may be said universally of all bodies. Therefore no two bodies in motion can come to immediate contact; but their velocities must undergo the successive necessary change before contact. And as the velocity to be extinguished may be increased beyond all limits, an adequate cause to effect this extinction must be admitted.

9 Repulsive forces

This naturally leads us to the interior repulsive forces of our system; for the cause retarding the one body and accelerating the other must be a *force*, because by this we mean a determination to motion; and it must be repulsive, because it acts *from* the body; and it must increase

Bofcovich's Syftem of Natural Philofophy. increafe beyond all limits, feeing the velocity of the incurring bodies may be increafed beyond all limits. It muft likewife be mutual, becaufe action and reaction are always equal, as may be proved by induction.

10 In extended atoms. From thefe repulfive forces Bofcovich deduces the inextenfion of his atoms: for this repulfion being common to all matter, muft caufe a perfect fimplicity in the firft elements of body. If thefe elements were extended, and confequently compounded of particles of an inferior order, thefe particles might poffibly be feparated, and then they might meet, and an abrupt paffage from one velocity to another might take place, which we have excluded from nature by induction, and by a pofitive argument.

Befides this, by rejecting the extenfion of the firft elements of matter, we get rid at once of all the difficulties arifing from continued extenfion in body, which have always perplexed the philofophers, and have never been fatisfactorily explained. If the elements of matter are extended, each of them may be divided *in infinitum*, and each part may ftill be divided *in infinitum*. Can this divifion be actually made by the power of God or not? Can there be one *infinite* in number greater than another? Can there be a *compound* without a *fimple* of the fame kind? Thefe difficulties regard not fpace, which is no real being; but they would regard matter if it had continued extenfion. All thefe perplexities are removed by maintaining, as Bofcovich does, that the firft elements of bodies are perfectly fimple, and therefore inextended (A).

11 Attractive forces. With regard to the exterior attractive forces of our fyftem, there can be no queftion; feeing they conftitute univerfal gravity, the effects of which we fee and feel every day. But between the interior repulfive and exterior attractive forces we muft admit many tranfitions from repulfion to attraction, and from attraction back to repulfion, in infenfible diftances, which are indicated to us by cohefion, fermentation, evaporation, and other phenomena of nature. And thus we have given, in fhort, Bofcovich's proofs of his whole fyftem.

12 Objections to the fyftem anfwered. III. This fyftem has been well received by the learned in Europe, and has contributed much to render its author famous; yet many objections againft it have been propofed. Some are ftartled at the rejection of all immediate contact between bodies: and indeed Bofcovich is perhaps the firft of mankind who advanced that opinion; but he allows that bodies approach fo near to one another, as to leave no fenfible diftance between them; and his repulfive forces make the fame impreffion on the nerves of our fenfes as the folid bodies could do. And therefore this opinion of his, however new, is nowife contrary to the teftimony of our fenfes. He only removes a prejudice which was before univerfal.

Some fay, that they cannot even form an idea of an inextended atom, and that Bofcovich reduces all matter to nothing: but certainly extenfion is not neceffary for the effence of a *being*, as muft be allowed by all thofe who hold that fpirits are inextended. Becaufe all the bodies that fall under our fenfes are extended, we are apt to look upon extenfion as effential to matter: but this error may be corrected by reflection, and an idea of an inextended atom may be formed, by confidering the nature of a mathematical point, which is the limit of any two contiguous parts of a line.

Others again have faid, that if the elements of matter were void of extenfion, there would be no difference between body and fpirit. But the difference between body and fpirit does not confift in the having or not having extenfion; but in this, that the atoms of matter are endued with repulfive and attractive forces, which fpirit has not; and fpirit has a capacity of thought and volition which bodies have not.

We may here obferve, that among the ancients Zeno, and among the moderns Leibnitz, held, that the firft principles of matter are inextended points. But both held this opinion with the inconfiftency, that they maintained the continued extenfion of bodies, without ever being able to fhew how continued extenfion could arife from inextended elements.

It has been objected likewife, that our repulfive and attractive forces are no better than the occult qualities of the Peripatetics. The like objection has been made to Newton's attraction: but the anfwer is eafy. We obferve the effects, and take notice of them: for them we muft admit an adequate caufe, without being able to determine, whether that caufe is an immediate law of the Creator, or fome mediate inftrument that he makes ufe of for that purpofe.

Some are unwilling to give up the idea of motion occafioned by immediate impulfe: but can they fhow a good reafon why *fome diftance* may not occafion motion as well as *no diftance?* Thefe are the principal objections that have been made againft the Bofcovichian fyftem.

IV. Before we proceed to the explication of phenomena by means of our theory, we muft advert, that in the curve expreffing this theory, the abfciffes denote the diftances between the atoms that are under confideration; the ordinates give the prefent *force*, and the area between any two of thefe ordinates gives the fquare of the velocity generated between them; the arches are either repulfive or attractive, according as they fall upon the fame fide with the afymptotic curve EG, or on the oppofite fide. 13 Obfervations with regard to the curve

We muft, in the next place, confider the paffages from one fide of the axis to the other. Sometimes the paffage is from repulfion to attraction, at other times from attraction to repulfion. The firft are called *limits of cohefion*, becaufe a particle removed from that limit returns back to it; becaufe if it is removed to a greater diftance it is attracted back, and if it is removed nearer it is repelled back. The fecond are called *limits of noncohefion*; 14 Limits of cohefion, &c.

(A) If a particle of matter is not extended, in what refpect does it differ from a point of fpace? Says Bofcovich, it is endowed with attractive and repulfive forces. What is this *it* before it is thus endowed? Does it *then* differ from a point of fpace? We can form no notion of any fuch difference. But a point of fpace, confidered as an individual, is diftinguifhed from another individual only by its fituation; it is therefore immoveable, but matter is moveable. Have thefe forces, then, which make matter an object of fenfe, any fubftratum, any thing in which they are inherent as qualities? What are the things which thefe qualities diftinguifh from each other as individuals?

Boscovich's System of Natural Philosophy. *cohesion*; because a particle removed thence to a greater distance is repelled still further, and if removed nearer it is attracted still nearer. Of the first kind are E, I, N; of the second are G, L. Likewise, when the curve touches the axis, it may either be an attractive part of the curve, or a repulsive part. These limits may be nearer one another, or farther away; and the limits of cohesion may be stronger or weaker, according as the forces near them are greater or less.

Boscovich considers minutely the effects of these varieties of limits and forces; first with regard to two points, then with regard to three and four, demonstrating the great variety of forces that may arise from these various combinations, and shewing how from simple atoms a great variety of bodies may be formed. He particularly proves, that, from the various position of the atoms, they may either always repel or always attract other atoms, or do neither. Four atoms may form a pyramid, eight may form a cube, and so on, in regular or irregular figures. Particles of the lowest order may compose particles of a second order, these of a third, and so on. This he exemplifies by a library, in which the letters of the books should be composed of small points, placed so near one another as that their distance could not be perceived without the help of a microscope. Here the letters will be composed of points, the words of letters, and all the variety of books on different subjects, and in different languages, would be composed of words. In like manner, he says, his atoms may compose particles, these may compose others of different orders, of which may be formed various bodies, animal, vegetable, air, fire, water, earth, whole planets, central bodies, the whole universe.

15 Composition of bodies.

16 The system applied to account for

But to be more particular, our author proceeds to apply his system to mechanics, and demonstrates, with his usual accuracy and originality, what regards the centre of gravity, action and reaction, the collision of bodies, the centre of equilibrium, and of oscillation. Of these subjects he treats in the second part of his *Theoria*; to which we must refer our learned readers, as it cannot be easily abridged.

17 Impenetrability,

In the third part of the same work he proceeds to account for the general properties of matter, beginning with *impenetrability*. This naturally flows from the interior repulsive forces, which prevent the compenetration of any two points. Besides, as the least part of space is divisible *in infinitum*, it is infinitely improbable that any two points should ever meet, seeing they have an infinite number of other lines in which they can move, besides the one that would join them. But an apparent compenetration might take place, if one body should meet another with so great a velocity as not to give time to the repulsive forces to exert their action. Thus an iron ball may pass swiftly near a strong magnet, without being sensibly attracted by it, which it would be if it moved more slowly. Thus a ball from a gun passes through a piece of wood so quickly as to make only a passage for itself, without breaking the neighbouring parts, which it would do were its motion more slow. Of this kind of compenetration we have a resemblance in *light* passing through pellucid bodies.

18 Cohesion,

Cohesion has never been well accounted for by any philosopher before Boscovich. From his system it follows naturally, as we have seen in speaking of the limits of cohesion; for when two atoms are placed in a limit of that kind, they necessarily cohere more or less strongly, according as that limit is stronger or weaker. From the cohesion of the atoms arises the cohesion of compounded particles, and consequently of sensible bodies.

From the cohesion of particles arises the extension of bodies; because there must always be space between the particles. However, it is evident that this extension is not formed of a continuity of matter; though it may appear to be so to our senses, which cannot perceive the small intermediate distance between the parts of some bodies, and much less the distances between the simple elements of which they are composed. 19 Extension,

Extension of bodies involves *figurability*; because every extended body must be surrounded by some superficies of a certain figure; but the superficies of bodies can never be accurately determined, upon account of the inequalities in all surfaces. We take, however, that figure for the true one which the body appears to come nearest. Thus we call the earth a globe, notwithstanding the hills and valleys that are on it. 20 Figure,

Under the same figure, and of the same magnitude, there may be contained very different quantities of matter. Hence we come to the consideration of *density*. That body is most dense which contains in the same space the greatest number of atoms, and *vice versa*.

This density may be increased beyond any given limits by the nearer approach of the atoms to one another. Hence a body of any given magnitude, however small, may come to be divisible beyond any given limits. 21 Density,

Mobility, which is likewise reckoned among the general properties of body, is essential to our system, seeing an essential part of it consists in *forces*, which are determinations to motion, at least in certain distances. 22 Mobility,

Universal gravity in sensible distances is likewise a branch of our theory. On which subject it may be observed, that perhaps our curve, after it has extended beyond the sphere of the comets most distant from the sun, may depart from its asymptotical nature, and approach to the axis, intersect it, and pass to repulsion. This would effectually answer the objection made by some against Newton's attraction, when they allege, that, from his opinion, it would follow, that the fixed stars, and all matter, would be drawn together into one mass. If such a repulsion takes place, it may soon pass again into attraction, and form limits of cohesion; so that our sun may be in such a limit with regard to the fixed stars, and our planetary system make only a small part of the whole universe. And this may suffice concerning the general properties of matter. 23 Gravity,

Let us now descend to some particular classes of bodies, of which some are fluid, others solid. The parts of fluid bodies are easily separated, and easily moved round one another, because they are spherical and very homogeneous; and hence their forces are directed more to their centres than to one another, and their motions through one another are less obstructed. Between the particles of some of them there is very little attraction, as in fine sand or small grains of seed, which approach much to fluidity. The particles of some others of them attract one another sensibly, as do those of water, and still more those of mercury. This variety arises from the various combinations of the particles themselves, of which we have already taken notice. But in air the particles 24 Fluidity,

Boſcovich's Syſtem of Natural Philoſophy.

particles repel one another very ſtrongly; and hence comes that great rarefaction, when it is not compreſſed by an external force. Its particles muſt be placed in ample limits of repulſion.

25 Solidity,

Solid bodies are formed of parallelopipeds, fibres, and of irregular figures. This occaſions a greater coheſion than in fluids, and prevents the motion of the parts round one another; ſo that when one part is moved all the reſt follow. Of theſe bodies ſome are harder, whoſe particles are placed in limits which have ſtrong repulſive arches within them; others are ſofter, whoſe particles have thoſe arches of repulſion weaker.

26 Softneſs, flexibility, and elaſticity.

Some are flexible, the particles of which are placed in limits that have weak arches of repulſion and attraction on each ſide; and if thoſe arches are ſhort, the particles may come to new limits of coheſion, and remain bent: but if the arches are longer, the former repulſion and attraction will continue to act, and bring back the body to its former poſition; nay, in doing this with an accelerated velocity, the parts will paſs their former limits, and vibrate backwards and forwards, as may be ſeen in a bended ſpring. Thus elaſticity is accounted for.

27 Viſcoſity.

Viſcous bodies ſtand in the middle between ſolid and fluid. Their particles have leſs coheſion than the firſt, and more than the ſecond: they ſtick to other bodies by an attraction which their particles have from their compoſition. In like manner water itſelf ſticks to ſome bodies, and is repelled by others. All which ariſes from the different compoſition of the particles, which gives a variety of reſpective forces.

28 Organization.

What appears very wonderful in nature, is the compoſition of organic bodies. But if we conſider that particles may be ſo formed, that they may repel ſome and attract others, the whole of vegetation, nutrition, and ſecretion, may be underſtood, and follows from our ſyſtem. And as one particle may attract another in one part only, and repel it in every other ſituation, hence may be gathered the orderly ſituation of the particles in many cryſtallizations. The great variety of repulſive and attractive forces, or limits of coheſion, of the poſition of atoms, and of combinations of particles, will account for all theſe phenomena.

29 Chemical operations.

The chemical operations, which are ſo curious in themſelves, and ſo uſeful to ſociety, are well explained by Boſcovich's ſyſtem, and ſerve as a confirmation of its truth. Of this we ſhall give ſome inſtances. When ſome ſolids are thrown into ſome liquids, there happens to be a greater attraction between the particles of the ſolid and of the liquid than there is between the particles of the ſolid itſelf. Hence the particles of the ſolid are detached and ſurrounded by the fluid; this mixture retaining the form of globules, and therefore continuing to be fluid. This is called *ſolution*. But when the ſolid particles are covered to a certain depth, the attractive forces ceaſe on account of the different diſtances, and no more of the ſolid is detached. Then the fluid is ſaid to be *ſaturated*. If into this mixture another ſolid be put, the particles of which attract the fluid more ſtrongly, and perhaps at greater diſtances than the particles of the former; then the fluid will abandon the former and cleave to the latter, diſſolving them, and the particles of the former will fall to the bottom in the form of powder, into which they had been reduced by the ſolution. This ſeparation is called *precipitation*. Perhaps rain ariſes from a precipitation of this kind, when the aqueous particles are left by the air, which is more ſtrongly attracted by ſome other particles floating in the atmoſphere.

Boſcovich's Syſtem of Natural Philoſophy.

Fluids of the ſame ſpecific gravity are eaſily mixed; and even though the ſpecific gravity be different, the particles of the one attract thoſe of the other, in ſuch a manner that they ſeem to form one fluid by a kind of ſolution. Nay, it happens that two fluids mixed together form a ſolid, becauſe their particles come to be in the limits of coheſion. They may even occupy leſs ſpace than they did before, by being attracted into leſs diſtances between their parts.

Fermentation is a neceſſary conſequence of our ſyſtem. For when bodies, whoſe particles, by the variety of their compoſition, are endued with different forces, come to be mixed, there muſt ariſe an agitation of the parts, and an oſcillation among them; ſometimes greater, ſometimes leſs, according to the nature of the particles. This agitation is ſtopped by the expulſion of ſome particles, by the intruſion of others into vacant ſpaces, and by the impreſſion of external bodies; but always there is a change in what remains, becauſe there is a new diſpoſition of particles.

30 Fire and fuſion, &c.

Fire conſiſts in a violent fermentation of ſulphureous matter, eſpecially when it meets with the matter of light in any quantity. This fermentation agitates ſtrongly the parts of other bodies, ſeparates them from one another, and often throws them into a ſtate of fuſion; the coheſion between their parts being broken, and they being thrown into a circular motion. In this ſtate they may be often mixed together, ſo as to form one body; they may be again ſeparated by the action of the ſame fire, which evaporates ſome of them ſooner, ſome later. Hence the art of ſmelting metals.

When, in the agitation occaſioned by fire, ſome of the particles are thrown out into an arch of repulſion, they may fly off and evaporate. Sometimes the whole body may be thrown into a ſtrong repulſion and volatilization, or a ſudden exploſion take place; when, before the particles are near an equilibrium, a ſmall force may occaſion a great change; as the foot of a bird may occaſion the fall of a great rock, which was before almoſt detached from a mountain. In evaporation, the bodies that remain aſſume a particular figure, as all ſalts do; and this upon account of their particles having certain parts only that attract one another, and conſequently occaſion a particular diſpoſition. All theſe chemical operations evidently prove that there are in nature repulſive and attractive forces between the particles of bodies at ſmall diſtances: which greatly confirms our whole ſyſtem.

31 Light.

Boſcovich holds, that light is an *effluvium*, emitted with great velocity from the luminous bodies by a ſtrong repulſion. He explains all the moſt remarkable properties of this extroardinary matter according to his own principles, and that with great acuteneſs. On this ſubject it is obſervable, that Newton ſaw the neceſſity of admitting repulſive forces for the reflexion of light, which extend at ſome diſtance from the reflecting ſurface, and therefore reſemble the repulſive forces of our theory.

32 Electricity and magnetiſm.

Our author gives likewiſe a probable explication of electricity, according to Franklin's ingenious hypotheſis, and likewiſe of magnetiſm, deducing the whole of the appearances from various attractions and repulſions.

He

Boscovich's System of Natural Philosophy. He supposes that fire and the electrical fluid differ only in this, that fire is in actual fermentation, and not so the electrical fluid.

33 Sensation. Finally, he explains our bodily sensations, in which he agrees pretty much with other philosophers; excepting in this, that what they attribute to the immediate contact of bodies, or of certain particles emitted from them, he ascribes to attractions and repulsions; which indeed are particularly fit for causing that motion in our nerves, which is supposed to take place in the organs of sensation, and to be thence communicated to the brain.

It is to be observed, that although Boscovich maintains that the very first elements of matter are void of extension; yet he allows, that of these elements, combined in a certain manner, may be formed extended particles of various figures, the parts of which may be so coherent as to be inseparable by any power in nature.
34 Reconciliation of this with other systems, By these means the opinion of those philosophers, who are so fond of extended particles, may be in so far gratified. Nay, the Peripatetics may, if they please, adopt Boscovich's inextended atoms for their *Materia Prima* without any inconsistency; and his repulsive and attractive forces may serve for their *substantial forms.* And as God can make impressions on our senses independently of the atoms, their absolute accidents may in some sense be admitted. Nor would some such extraordinary exertions of Divine Power favour idealism in the ordinary course of nature.

But what is of more consequence, it is more than probable, that had Newton lived to be acquainted with the Boscovichian theory, he would have paid to it a very great regard. This we may conjecture from what he says in his last question of optics; where, after having mentioned those things which might be explained by an attractive force, succeeded by a repulsive one on a change of the distances, he adds, "And if all these things are so, then all nature will be very simple, and consistent with itself, effecting all the great motions of the heavenly bodies by the attraction of gravity, which is mutual between all those bodies, and almost all the less motions of its particles by another certain attractive and repulsive force, which is mutual between those particles."
35 Especially that of Newton. And a little after, treating of the elementary particles, he says: "Now it seems that these elementary particles not only have in themselves the *vis inertiæ*, and those passive laws of motion which necessarily arise from that force, but that they likewise perpetually receive a motion from certain active principles; such as gravity, and the cause of fermentation, and of the cohesion of bodies. And I consider these principles, not as occult qualities, which are feigned to flow from the specific forms of things, but as universal laws of nature, by which the things themselves were formed. For that truly such principles exist, the phenomena of nature shew, although what may be their causes has not as yet been explained. To affirm that every species of things is endued with specific occult qualities, by which they have a certain power, is indeed to say nothing; but to deduce two or three general principles of motion from the phenomena of nature, and then to explain how the properties and action of all corporeal things follow from those principles, this truly would be to have made a great advancement in philosophy, although the causes of those principles were not as yet known. Wherefore I do not hesitate to maintain the above said principles of motion, seeing they extend widely through all nature." From this passage we may safely conclude, that the great British philosopher would have been highly pleased, had he seen all nature so well explained by the one simple law of forces proposed by the Ragusan.

Boscovich himself was so fully convinced of the truth of his system, that he was wont to make use of the following comparison: When a letter has been written in occult characters, and we are endeavouring to decypher it, we make various suppositions of alphabets; and when we have found one according to which the whole letter comes to have a reasonable meaning, agreeable to all the circumstances of time, place, persons, and things, we can entertain no doubt of our having discovered the true key of the cypher—so, said he, my system explains so well all the phenomena to which it has been properly applied, that I must flatter myself that I have discovered the true key of nature. 36 Comparison of this system to the key of a cypher.

The being accustomed to contemplate so deeply the universe and the materials of which it is composed, made Boscovich see most clearly the evident necessity of admitting an all-powerful, intelligent, self-existent Being, for the creation of those materials, and for the arrangement of them into their present beautiful form. He was at a loss to find words strong enough to express his surprise, that there should be any man, not to say any one pretending to the name of philosopher, who could be so deaf as not to hear the voice of nature loudly proclaiming its Author from all, even the least of its parts. He gives us his sentiments on this, the most important of all subjects, in the appendix to his *Theoria,* in which he treats of God and of the soul of man. 37 Existence of God.

There, in the first place, he shows the absurdity of their opinion, who maintain that this world may have been the work of *chance,* the effect of a jumble of self-existent, self-moving atoms; because chance is an empty word without a real meaning. Whatever exists has its determinate cause, and can only be called *fortuitous* by us on account of our ignorance of that cause. Besides this, though the number of atoms composing this world is finite, yet their possible combinations are many times *infinitely infinite:* for they may be placed in infinite places of an infinite line; of these lines there is an infinite number in every *plane,* and of these planes there is an infinite number in space. Again, these points may have an infinite number of velocities in an infinite number of directions. From all this it is evident, that the combinations in which the points of matter may be, is infinite in a high degree, whereas *duration* can be infinite in only one dimension. Hence it is infinitely improbable that ever the present combination of things could come out by chance. And this is so much the more infinitely improbable, because the disorderly, chaotic combinations are infinitely more than the regular ones. The whole of matter might roll about in a blind motion for a boundless eternity, without ever being capable to produce one single mushroom. 38 The world cannot be the effect of chance;

Moreover, had matter been in motion from all eternity, every atom would have described an infinite line, and then a part of that line would be assignable at an infinite distance from the point of space in which the atom is at present: but an infinite line can never be run over; therefore the atom could never have come to its present

Boscovich's System of Natural Philosophy.

present place; and therefore the supposition is absurd. Nothing successive can be eternal with a *past* eternity, though it can continue without end. God alone can be eternal and actually infinite; but his eternity and infinity are beyond our comprehension.

39 Nor have existed from eternity.

Neither can the world have existed of itself in any thing like to its present form from all eternity; for matter is perfectly indifferent to numberless states, and to its present state it must be determined. This present state is perfectly incapable of determining itself, because this determination must be previous to its existence. It must be determined by the preceding state, which is also incapable of determining itself, and for its determination we must have recourse to the state before. Thus, though we go back to eternity, we shall still find a nullity of determination; now an infinite sum of *nothing* is *nothing*: and therefore as the present state of things could have no determination, it could not possibly exist.

It is therefore evident that there must be a Determiner extrinsic to the material word. This Determiner must have an infinite knowledge of all the possible combinations, and an infinite elective creative power to chuse and create freely the combination he pleased, in that point of eternity that he chose, with all the numberless circumstances that are agreeable to him.

40 Attributes of God which appear in the creation.

And here what a vast field of contemplation is laid open to a philosophic mind! What a truly infinite knowledge was requisite to foresee so many ends, and so many means requisite for obtaining those ends, as are contained in the creation! Let us consider light, for example, which was to be emitted for so many ages from so many luminous bodies, with so great velocity, so as to penetrate so many mediums with different degrees of reflectibility and refrangibility, with so many other wonderful qualities; at the same time, so many bodies were to be perfectly fitted for reflecting this light in a certain manner, and the animal eye was to be so formed as to have a picture of visible objects painted on the bottom of it.—How many particular combinations were necessary for all this? What shall we say of the so many herbs, flowers, trees, and animal bodies, as there are on this our earth? All their kinds and species, all the series of their individuals, all their parts and particles, were foreseen, intended, and contrived, by one act of the Divine Mind. Again, how wonderful are the heavenly bodies, of what surprising magnitude, moving in the most beautiful order, at an immense distance from one another? To say nothing of the numberless creatures that are beyond the reach of the best telescope, or below that of the microscope. He who reflects ever so little on these things, must necessarily see the most evident proofs of an infinite power, wisdom, and providence; and he must be filled with admiration and awful respect for the Creator and Ruler of the universe.

41 Natural religion.

Nor are we unconcerned spectators of this grand scene. God has been pleased to make us enter deeply into his great plan of creation. He singled us out among an infinite number of possible human beings, in order to call us into existence at a fixed period; and he has made a vast number of his creatures contribute to the formation of these wonderful machines, our bodies, as likewise to our nourishment, to our preservation, to our necessities, conveniences, and gratifications. Every moment that we exist, we are enjoying a great number of benefits, expresly designed for us by that Supreme Being. This evidently demands from us the highest degree of gratitude, love, and obedience.

Boshmen.

42 Revelation.

Let us go a step still farther: Is it not very reasonable to suppose, that our God, who affords us so many instances of his beneficence towards us in the natural order, will also, out of compassion to our weakness and ignorance, have favoured us with a more full and explicit manifestation of himself, of our duties towards him, and of his intentions concerning us? According to Boscovich and all true philosophers, reason itself alone, and true philosophy, point out to us the probability at least of God's having given us a still better and surer guide, by whose direction we may attain to that perfect happiness which we naturally thirst after, and to which we must have been designed by our Maker. This is probable from reason alone; and of this great fact we are ascertained by unquestionable authority.

BOSHMEN have been generally described as a distinct race of Hottentots, who are enemies to the pastoral life (see Boshies-*Men*, Encycl.) This M. Vaillant affirms to be a mistake; and we think he has completely proved that it is so. "These infamous wretches (says he) do not form a particular nation, nor are they a people who have had their origin in the places where they are now found. *Boshmen* is a name composed of two Dutch words, which signify *bush-men*, or *men of the woods;* and it is under this appellation that the inhabitants of the Cape, and all the Dutch in general, whether in Africa or America, distinguish those malefactors or assassins who desert from the colonies, in order to escape punishment. In a word, they are what in the British and French West India islands are called *Maroon Negroes*. These Boshmen, therefore, far from being a distinct species, are only a promiscuous assemblage of mulattoes, negroes, and mastizos, of every species, and sometimes of Hottentots and basters (see BASTER, *Supplement*), who all differing in colour, resemble each other in nothing but in villany. They are land pirates, who live without laws and without discipline, abandoned to the utmost misery and despair; base deserters, who have no other resources but plundering and crimes. They retire to the steepest rocks and the most inaccessible caverns, and there they pass their lives. From these elevated places they command an extensive prospect over the surrounding plains, lie in wait for the unwary traveller and the scattered flocks, pour down upon them with the velocity of an arrow, and suddenly falling upon the inhabitants and their cattle, slaughter them without distinction. Loaded with booty, and whatever they can carry with them, they then repair to their gloomy caves, which they never quit till, like the lions, hunger again impels them to fresh massacres. But as treachery always marches with a trembling step, and as the presence of one resolute person is sufficient to overawe whole troops of these banditti, they carefully shun those plantations where they are certain that the owners themselves reside. Artifice and cunning, the usual resources of timid souls, are the only means which they employ, and the only guides that accompany them in their expeditions."—*Vaillant's Travels into the Interior Parts of Africa* (A).

BOSWELL

(A) Since this article was first published, a different account has been given of the *Boshmen* or BOJESMANS by Mr

Boswell.

BOSWELL (James), known to the learned world as the author of a life of Dr Johnson and of several other valuable works, was born, we believe, at Auchinleck in Airshire, in 1740. The family from which he sprung was ancient and honourable. At the time of his birth his father was a well employed lawyer at the Scotch bar; but was afterwards raised to the dignity of Judge, and filled that important station with acknowledged learning, probity, and honour. His title was Lord Auchinleck, taken from his family inheritance; and he died in 1782: on which occasion Dr Johnson wrote an elegant and instructive letter to the subject of this brief memorial; of which we shall transcribe a passage that alludes to some slight domestic differences, which did not happen in vain, since they gave rise to such salutary advice:

"Your father's death had every circumstance that could enable you to bear it. It was at a mature age, and it was expected; and as his general life had been pious, his thoughts had, doubtless, for many years past, been turned upon eternity. That you did not find him sensible must doubtless grieve you; his disposition towards you was undoubtedly that of a kind, though not of a fond father. Kindness, at least actual, is in our own power, but fondness is not; and if, by negligence or imprudence, you had extinguished his fondness, he could not at will rekindle it. Nothing then remained between you but mutual forgiveness of each other's faults, and mutual desire of each other's happiness."

The occasion of this family dissention is unknown to us. It might originate in the difference of their political principles, Mr Boswell being a zealous Tory, and his father, as he represents him, a rancorous Whig; or it may have arisen from the celebrated Douglas cause, which set many friends at variance in Scotland, and in which, though Lord Auchinleck and his son took the same side, they took it with very different degrees of ardour. The Judge saw not the propriety of illuminating his windows when the cause was finally decided by the House of Peers; and to compel him to illuminate, the advocate got possession of a Chinese *gong*, and at the head of a number of young men and boys patrolled the streets of Edinburgh, and made a loud and exulting noise at the windows of his father's house, where there was no symptom displayed of the general joy.

In 1762 Mr Boswell made his first journey to London; where, under the auspices of Dodsley the bookseller, he published, "The Cub at Newmarket, a Tale." By the title of *Cub* he meant to characterise himself, as the reader will perceive in the following lines, which we shall give as a specimen of the poem:

> Lord Eglintoune, who loves, you know,
> A little dash of whim, or so,
> By chance a curious Cub had got,
> On Scotia's mountains newly caught.

During his stay in London Mr Boswell was introduced to Dr Johnson, with whom it is well known he continued to live in intimacy from that time till Johnson's death in 1784; and this intimacy procured him the friendship of Burke, Goldsmith, Sir Joshua Reynolds, and many other men of eminence, who composed what was called *The Literary Club*. In the latter end of 1765 he became acquainted with General Paoli when on his travels; and after his return he published, in 1768 or 1769, his account of Corsica, with the "Journal of a Tour to that Island."

Of this work, which gained him some distinction in the world, his great friend Johnson writes thus: "Your history is like all other histories, but your journal is in a very high degree curious and delightful. There is between the history and the journal that difference which there will always be found between notions borrowed from without and notions generated within. Your history was copied from books; your journal rose out of your own experience and observation. You express images which operated strongly upon yourself, and you have impressed them with great force upon your readers. I know not whether I could name any narrative by which curiosity is better excited or better gratified."

In 1770 Mr Boswell, who was then in good practice at the Scotch bar, married an amiable woman, by whom he had two sons and three daughters, who survived him. In 1773 he was chosen a member of the Literary Club; and in the autumn of the same year he visited the Hebrides in company with his illustrious friend Johnson; after whose death he published a very entertaining account of their tour, the places they saw, the characters with whom they conversed, and their own remarks on the different conversations. To many persons, both in England and Scotland, this book gave great offence, as it brought before the public the unguarded talk of private social circles; but it surely furnished much entertainment, as it exhibited a more faithful picture of Hebridian manners than the British public had ever before seen.

In 1784, when Mr Fox's famous India bill was before Parliament, Mr Boswell published a "Letter to the People of Scotland on the Present State of the Nation;" in which he contends, that no charter would be safe if that bill should pass into a law; and more than insinuates, that the principle of it was equally inimical to the liberties of the subject and to the prerogative of the king. Dr Johnson seems to have thought of that bill as he did; for having read the letter, he writes to the author his approbation of it in the following words: "I am very much of your opinion; and, like you, feel great indignation at the indecency with which the king is every day treated. Your paper contains very considerable knowledge of the history and of the constitution, very properly produced and applied."

In 1785, Mr Boswell quitted the Scotch bar, and went to reside in London, where he continued till the day of his death. Having entered himself in one of the inns of court, and studied the English law, he became a barrister in England: but we have reason to believe that

---

Mr Barrow, who travelled into the interior of Southern Africa in 1797 and 1798. According to him, they are a distinct race, extremely savage, who neither cultivate the ground nor breed cattle, but subsist in part on the natural produce of their country, and supply its deficiency by depredations on the colonists on one side, and the neighbouring tribes of people that are more civilized than themselves, on the other.

Bofwell.

that his practice there was not fo fuccefsful as it had been in his own country. He enjoyed, however, more completely than he could do in Edinburgh, the converfation of the great, the wife, the witty, and the good; and fuch converfation he always valued above wealth. He frequently vifited his native country, and efpecially Auchinleck, the feat of his anceftors; and foon after his return from one of thofe vifits he was feized with a diforder which proved fatal, on Tuefday the 19th of May 1795.

Such were the principal events in the life of Mr Bofwell. Of his character, it would be difficult to fay *much more* than he has faid himfelf in his "Journal of a Tour to the Hebrides;" and which may, with fome propriety, be copied here:

"I have given a fketch of Dr Johnfon. My readers may wifh to know a little of his fellow-traveller. Think, then, of a gentleman of ancient blood; the pride of which was his predominant paffion. He was then in his 33d year, and had been about four years happily married. His inclination was to be a foldier; but his father, a refpectable Judge, had preffed him into the profeffion of the law. He had travelled a good deal, and feen many varieties of human life. He had thought more than any body fuppofed, and had a pretty good ftock of general learning and knowledge. He had all Dr Johnfon's principles, with fome degree of relaxation. He had rather too little than too much prudence; and his imagination being lively, he often faid things of which the effect was very different from the intention. He refembled fometimes

'The beft good man, with the worft-natur'd mufe.'

"He cannot deny himfelf the vanity of finifhing with the encomium of Dr Johnfon, whofe friendly partiality to the companion of this tour, reprefents him as one 'whofe acutenefs would help my inquiry, and whofe gaiety of converfation, and civility of manners, are fufficient to counteract the inconveniences of travel, in countries lefs hofpitable than we have paffed.'

Few of Mr Bofwell's friends, we believe, could add much to this candid confeffion. His enemies, if he had any, might dwell upon his failings; but his failings were few, and injurious to no perfon. In his character good nature was predominant. He appeared to entertain fentiments of benevolence to all mankind, and to be incapable of *intentionally* injuring a human being. His converfation-talents were always pleafing, and often fafcinating. But can we wonder at this in him who, with a capacity to learn, had been the companion of Johnfon for more than 20 years? His attachment to the Doctor for fo long a period, was a meritorious perfeverance in the defire of knowledge. To it the world is indebted for the moft finifhed picture of an eminent man that ever was executed. We know there are objections to the *mode* of giving the life of Johnfon. It has been thought that ignorance has been wantonly expofed, and the privacy of focial life endangered. We fhall not enter deeply into this queftion. All that we can certainly affirm is, that the work has been read with avidity and pleafure; and that he who does not wifh to read it again may be fufpected to be deficient in tafte and in temper.

Mr Bofwell has been accufed of vanity; but when this accufation is brought againft him, it fhould not be forgotten that he enjoyed advantages which rendered that confpicuous in him from which no man can claim an exemption. We know not the man who would not have been vain to poffefs fo much of Dr Johnfon's converfation, and proud to give it to the world, in hopes that he who venerated Johnfon would not be unthankful to his biographer. From the Doctor, however, he appeared to his friends to have imbibed a portion of melancholy, of which indeed he complained himfelf during the laft two or three years of his life; and he flew for relief where perhaps it is beft to be found, to the fociety of the learned and the gay. Here, as he confeffes, he "had rather *too little* than too much *prudence*;" and, with more attachment to the activity of rural life, he might, probably, have lengthened his days. But as his "belief in revelation was unfhaken," and his religious impreffions deep, and recurring frequently, let us hope that he has now attained that ftate from which imperfection and calamity are alike excluded.

Botany bay, Bouguer.

BOTANY-BAY. See *New Holland*, Encycl.; and *New South Wales* in this Supplement.

BOUGUER (Peter), an eminent mathematician and mechanical philofopher, was born at Croific, in Lower Bretagne, on the 10th of February 1698. His father John Bouguer, who was likewife a confiderable mathematician, was then profeffor royal of hydrography at that port; and under him young Bouguer ftudied mathematics, and the application of them to fhip-building, almoft from the period when he began to fpeak; fo that he was a proficient in thefe fciences before he had reached beyond the years of childhood. He was, however, removed from Croific to the Jefuits college at Vannes, where, at 13 years of age, he triumphed, in a public conteft, over a profeffor of mathematics, who had advanced a mathematical propofition erroneoufly. Two years after this he loft his father, whom he was appointed to fucceed in the office of hydrographer, after being publicly examined, and giving the moft complete proof of his being duly qualified to fill the vacant chair. He was indeed qualified by prudence as well as by fcience; for however furprifing it may be, he filled it both with dignity and with abilities, though then not more than 15 years of age.

In the years 1727, 1729, and 1731, he gained the prizes fucceffively propofed by the Academy of Sciences for effays on the beft way of equipping fhips with mafts, on the beft method of obferving at fea the height of the ftars, and on the moft advantageous way of obferving the declination of the magnetic needle or the variation of the compafs. In 1729 he publifhed an *Optical Effay upon the Gradation of Light*, in which he examined the intenfity of light, and determined its degrees of diminution in paffing through different pellucid mediums, and particularly in traverfing the earth's atmofphere. Of this effay, which was written upon a fubject that till then had not attracted the attention of philofophers, the reader will find fome account in the *Encyclopædia Britannica*, under the title Optics, n° 32, &c.

In 1730 Bouguer was removed from the port of Croific to that of Havre. In 1731 he obtained, in the Academy of Sciences, the place of affociate geometrician, vacant by the promotion of Maupertuis to that of penfioner; and in 1735 he was promoted to the office of penfioner-aftronomer. The fame year he was fent on the commiffion to South America, along with Meffrs Godin, Bouguer. Godin, Condamine, and Jeuffieu, to determine the meafure of the degrees of the meridian, and the figure of the earth. In this painful and troublefome bufinefs of ten years duration, chiefly among the lofty Cordelier mountains, our author, befides attending to the object of the voyage, made many fcientific obfervations; viz. on the effect of the Cordeliers on the polarity of the magnetic needle; on the expanfion and contraction of metals and other fubftances, by the fudden and alternate changes of heat and cold among thofe mountains; and on the refraction of the atmofphere from the tops of the fame, with the fingular phenomenon of the fudden increafe of the refraction, when the ftar can be obferved below the line of the level. He likewife afcertained the laws of the denfity of the air at different heights, from obfervations made at different points of thofe enormous mountains; he difcovered that the mountains have an effect upon a plummet, though he did not affign the quantity of that effect; he found out a method of eftimating the errors committed by navigators in determining their route; gave a new conftruction of the log for meafuring a fhip's way; and made feveral other ufeful improvements. M. Bouguer made at different times fome important experiments on the famous reciprocation of the pendulum; he invented in 1747 the Heliometer (fee that article *Encycl.*); and made many difcoveries relating to the intenfity of light (for which fee Optics-*Index*, Encycl.) His unremitting application to ftudy undermined his health, and he died on the 15th of Auguft 1758, in the 61ft year of his age.

Of his works which have been publifhed, the chief are, 1. The Figure of the Earth, determined by the Obfervations made in South America, 1749, in 4to. 2. Treatife on Navigation and Pilotage, Paris, 1752, in 4to. This work has been abridged by M. La Caille, in one volume 8vo, 1768. 3. Treatife on Ships, their Conftruction and Motions, in 4to, 1756. 4. Optical Treatife on the Gradation of Light, firft in 1729, then a new edition in 1760, in 4to.

His papers that were inferted in the Memoirs of the Academy are very numerous and important: as, in the Memoirs for 1726, comparifon of the force of the folar and lunar light with that of candles; 1731, obfervations on the curvilinear motion of bodies in mediums; 1732, upon the new curves called the *lines of purfuit*; 1733, to determine the fpecies of conoid, to be conftructed upon a given bafe which is expofed to the fhock of a fluid, fo that the impulfe may be the leaft poffible; determination of the orbit of comets; 1734, comparifon of the two laws which the earth and the other planets muft obferve in the figure which gravity caufes them to take; on the curve lines proper to form the arches in domes; 1735, obfervations on the equinoxes; on the length of the pendulum; 1736, on the length of the pendulum in the torrid zone; on the manner of determining the figure of the earth by the meafure of the degrees of latitude and longitude; 1739, on the aftronomical refractions in the torrid zone; obfervations on the lunar eclipfe of the 8th September 1737, made at Quito; 1744, fhort account of the voyage to Peru by the members of the Royal Academy of Sciences, to meafure the degrees of the meridian near the equator, and from thence to determine the figure of the earth; 1745, experiments made at Quito and divers other places in the torrid zone, on the expanfion and contraction of metals by heat and cold; on the problem of the mafting of fhips; 1746, treatife on fhips, their ftructure and motions; on the impulfe of fluids upon the fore parts of pyramidoids, having their bafe a trapezium; continuation of the fhort account given in 1744 of the voyage to Peru for meafuring the earth; 1747, on a new conftruction of the log, and other inftruments for meafuring the run of a fhip; 1748, of the diameters of the larger planets; the new inftrument called a *heliometer*, proper for determining them, with obfervations of the fun; obfervation of the eclipfe of the moon the 8th of Auguft 1748; 1749, fecond memoir on aftronomical refractions, obfeved in the torrid zone, with remarks on the manner of conftructing the tables of them; figure of the earth determined by MM. Bouguer and Condamine, with an abridgment of the expedition to Peru; 1750, obfervation of the lunar eclipfe of the 13th December 1750; 1751, on the form of bodies moft proper to turn about themfelves, when they are pufhed by one of their extremities, or any other point; on the moon's parallax, with the eftimation of the changes caufed in the parallaxes by the figure of the earth; obfervation of the lunar eclipfe the 2d of December 1751; 1752, on the operations made by feamen, called *corrections*; 1753, obfervation of the paffage of Mercury over the fun the 6th of May 1753; on the dilatations of the air in the atmofphere; new treatife of navigation, containing the theory and practice of pilotage, or working of fhips; 1754, operations, &c. for diftinguifhing, among the different determinations of the degree of the meridian near Paris, that which ought to be preferred; on the direction which the ftring of a plummet takes; folution of the chief problems in the working of fhips; 1755, on the apparent magnitude of objects; fecond memoir on the chief problems in the working of fhips; 1757, account of the treatife on the working of fhips; on the means of meafuring the light.

Bouguer, Bread.

BREAD is fo effential an article of food that every ufeful method of making it fhould be generally known. Much has accordingly been faid on that fubject (*Encycl.*) under the titles Baking, Barm, Bread, and Yeast: but, fince the laft of thefe articles was publifhed, we have feen, in Dr Townfon's *Travels in Hungary*, a method of making bread at Debretzen; of which, as it may fometimes be adopted with advantage in this country, an account may, with propriety, be inferted here.

In the baking of this bread, a fubftitute is ufed for yeaft, which is thus made: Two good handfuls of hops are boiled in four quarts of water: this is poured upon as much wheaten bran as can be well moiftened by it: to this are added four or five pounds of leaven; when this is only warm, the mafs is well worked together to mix the different parts. This mafs is then put in a warm place for 24 hours; and after that, it is divided into fmall pieces about the fize of a hen's egg, or a fmall orange, which are dried by being placed upon a board, and expofed to a dry air, but not to the fun; when dry, they are laid by for ufe, and may be kept half a year. This is the ferment; and it may be ufed in the following manner: For a baking of fix large loaves, fix good handfuls of thefe balls, broken into fragments, are taken and diffolved in feven or eight quarts of warm water. This is poured through a fieve into one end of the bread trough, and three quarts more of warm water are poured through the fieve after it, and what remains

Bread. remains in the ſieve is well preſſed out. This liquor is mixed up with ſo much flour as to form a maſs of the ſize of a large loaf: this is ſtrewed over with flour; the ſieve, with its contents, is put upon it, and then the whole is covered up warm, and left till it has riſen enough, and its ſurface has begun to crack: this forms the leaven. Then 15 quarts of warm water, in which ſix handfuls of ſalt have been diſſolved, are poured through the ſieve upon it, and the neceſſary quantity of flour is added, and mixed and kneaded with the leaven: this is covered up warm, and left for about an hour. It is then formed into loaves, which are kept in a warm room half an hour; and after that, they are put in the oven, where they remain two or three hours, according to the ſize. The great advantage of this ferment is, that it may be made in great quantities at a time, and kept for uſe. Might it not on this account be uſeful on board of ſhips, and likewiſe for armies when in the field?

Bread, in whatever way it is made, is a dear article; and it may be a deſirable object to many of our readers to know at what price the baker can afford to ſell it. This depends upon the price of wheat, the quantity of flour which the wheat may give, the loſs at the mill, the expence of grinding, and the expence of baking.

Of the price of wheat we can ſay nothing with preciſion, becauſe it varies according to the goodneſs or badneſs of the crop, and other circumſtances; but a buſhel of Eſſex wheat, Wincheſter meaſure, may be taken, on an average, as weighing 60 lb. Sixty pounds of wheat will yield, excluſive of the loſs in grinding and dreſſing, 45½ lb. of that kind of flour which is called *ſeconds*; which alone is uſed, through the greateſt part of England, for bread, and which makes, indeed, the beſt of all bread, though not the whiteſt. A peck of this flour, weighing 14 lb. will take up between ſix and ſeven pints of water, and give 18 lb. of excellent bread; or a buſhel of flour, weighing 56 lb. will yield 72 lb. of bread. The expence of baking a buſhel of ſuch flour is, in Eſſex and ſome other Engliſh counties, about ninepence; viz. yeaſt, on an average, twopence; ſalt, before the late tax, one halfpenny; and baking, ſixpence.

But *ſeconds* is not all that is got from wheat. A buſhel of 60 lb. of wheat gives, beſides 45½ lb. of ſeconds, 13 lb. of offal, i. e. of *pollards* and *bran*; for the utmoſt loſs in grinding and dreſſing a buſhel of wheat ſhould not exceed 1 pound 8 ounces. The millers, indeed, uſually reckon on two pounds of loſs; but we can ſay, with the utmoſt confidence, that the actual loſs is rather leſs than we have ſtated it. A correſpondent of ours, on whoſe accuracy we can depend, weighed, in 1795, two buſhels, Wincheſter meaſure, the one of white and the other of red wheat, and found the weight of them both to be 122 lb. This wheat was ground by his own ſervants, and it yielded 121½ lb. of meal, ſo that there was here but ½ lb. loſt of two buſhels, or of 122 lb. in grinding. He admits that he ſuffered the ſtones to turn too cloſe, and that the loſs ſhould therefore have been ſomewhat greater. The meal was dreſſed, as the wheat had been ground, under his own eye; and every poſſible precaution being taken to prevent his being deceived in the reſult, he had of flour, or *ſeconds*, 93½ lb. and of bran and pollard 25¼ lb.; ſo that he loſt, of two buſhels, but 2¼ lb. both in grinding and dreſſing. The offal, or bran and pollard, being dreſſed in a bolting mill, yielded as follows:

Sharps -	6 lb.	0 oz.
Fine pollard	5	8
Coarſe pollard	7	8
Broad bran	5	8
Altogether	24	8

There was loſt, therefore, in bolting, only one pound; and of the ſharps, about three pounds, if ſifted, would have been good flour. Indeed were the ſharps and fine pollard to be added to the flour, the bread would, perhaps, be better, and more wholeſome, than without ſuch addition. From theſe data, which we believe to be very accurate, it will be eaſy to calculate, if the price of wheat be given, what ſhould be the price of flour per buſhel and peck, the price of bread per pound, and the quantity of bread that ſhould be ſold for a ſhilling.

It is a fact, however, which ſhould be attended to, that loaves are not always of the ſame weight, though made of equal quantities of the very ſame dough. This was fully aſcertained ſome years ago at Paris. On a violent complaint that the bread was not always of the ſame ſtandard weight, the bakers of the city were called before the police officers. They admitted the fact, that loaves, baked at the ſame time, and in the ſame oven, were ſeldom, if ever, of the ſame weight; but they inſiſted that they contained, each, the ſtandard quantity of dough, and that the variety of weight among them muſt proceed from ſome cauſe, which they did not pretend to aſcertain. The matter was referred to the Royal Academy of Sciences, which appointed one of its members to ſuperintend, for ſome days, the whole proceſs of baking. This being done, it was found that, of loaves baked in a large oven, thoſe were always heavieſt which occupied the centre of the oven, and that the bakers were innocent of the crime with which they were charged. The fact, we think, may eaſily be accounted for. Even in an oven there muſt be ſome condenſation of ſteam; and, from the very ſhape of the oven, the greateſt quantity muſt be condenſed towards the centre. Hence the loaves in the centre are neceſſarily wetter and heavier than thoſe round the circumference, if the plain of the oven has been equally heated.

Bread of Rice might occaſionally be of great uſe in many countries during a ſcarcity of wheat; but the method of making it is not generally known. It is indeed impoſſible to make bread of the flour of rice, which is harſh and dry like ſand or aſhes, by treating it in the manner in which wheat-flour is commonly treated; and therefore it has been propoſed to mix it with an equal quantity of the flour of rye. But this method of uſing the flour of rice is a very uncertain remedy in caſe of want; ſince we can have no rice-bread if we have not rye. We are taught, however, in the *Journal des Sciences, des Lettres, et des Arts*, how to make excellent bread from rice alone, by a method which the author of the memoir ſays he learned from the natives of America.

According to this method of making the wiſhed-for bread, the firſt thing to be done to the rice is, to reduce it to flour, by grinding it in a mill, or, if we have not a mill, it may be done in the following manner: Let

Let a certain quantity of water be heated in a saucepan or caldron; when the water is near boiling, let the rice we mean to reduce into flour be thrown into it: the vessel is then to be taken off the fire, and the rice left to soak till the next morning. It will then be found at the bottom of the water, which is to be poured off, and the rice put to drain upon a table placed in an inclined position. When it is dry, it must be beat to powder, and passed through the finest sieve that can be procured.

When we have brought the rice into flour, we must take as much of it as may be thought necessary, and put it into the kneading trough in which bread is generally made. At the same time we must heat some water in a saucepan or other vessel, and, having thrown into it some handfuls of rice, we must let them boil together for some time: the quantity of rice must be such as to render the water very thick and glutinous. When this glutinous matter is a little cooled, it must be poured upon the rice-flour, and the whole must be well kneaded together, adding thereto a little salt, and a proper quantity of leaven. We are then to cover the dough with warm cloths, and to let it stand that it may rise. During the fermentation, this paste (which, when kneaded, must have such a proportion of flour as to render it pretty firm) becomes so soft and liquid that it seems impossible it should be formed into bread. It is now to be treated as follows:

While the dough is rising, the oven must be heated; and, when it is of a proper degree of heat, we must take a stewpan of tin, or copper tinned, to which is fixed a handle of sufficient length to reach to the end of the oven. A little water must be put into this stewpan, which must then be filled with the fermented paste, and covered with cabbage or any other large leaves, or with a sheet of paper. When this is done, the stewpan is to be put into the oven, and pushed forward to the part where it is intended the bread shall be baked; it must then be quickly turned upside down. The heat of the oven acts upon the paste in such a way as to prevent its spreading, and keeps it in the form the stewpan has given it.

In this manner pure rice-bread may be made; it comes out of the oven of a fine yellow colour, like pastry which has yolk of eggs over it. It is as agreeable to the taste as to the sight; and may be made use of, like wheat-bread, to put into broth, &c. It must, however, be observed, that it loses its goodness very much as it becomes stale.

It may be here remarked, that the manner in which Indian corn is used in some countries, for making bread, can only produce (and does in fact produce) very bad dough, and of course very bad bread. To employ it advantageously, it should be treated like rice; and it may then be used, not only for making bread, but also for pastry.

BREWING is an art of vast importance, and has accordingly been explained in the Encyclopædia Britannica. A few improvements, however, have been made in the art, which, though not noticed in that Work, seem to be worthy of general attention, and, therefore, to deserve a place in this Supplement. The first, of which we shall give an account, is an invention of Mr WILLIAM KER of *Kerfield*, in the county of Tweedale, for the saving of hops, and, at the same time, giving to the liquor, whether ale, beer, or porter, a superior flavour and quality.

The steam which arises from the boiling copper is known to be strongly impregnated with the essential oil of the hops, in which their flavour consists. Instead, therefore, of allowing it to escape and evaporate, as it does in the common mode of brewing, Mr Ker contrives to preserve and condense it, by means of a winding-pipe fixed to the copper, similar to the worm of a still, or by a straight pipe passing through cold water, or any other cooling medium. The oil and water, thus obtained, are returned into the worts when boiled, or the oil, after being separated from the water, along with which it had been exhaled, is returned into the worts after they are boiled; and the watery part, which, after the oil is separated, still continues impregnated with the aromatic taste and bitter of the hop, is returned into the next copper or boiling-vessel; and so on from one copper or boiling-vessel into another. By this process a considerable part of the hop and flavour, which is lost in the ordinary mode of brewing, is preserved: the flavour of the liquor is improved by the preservation of the finer parts of the aromatic oil: and the ale and beer are better secured from any tendency to acidity or putrefaction, and therefore must be fitter for home consumption and exportation. For this invention, which is certainly simple, and we think rational, Mr Ker obtained a patent, dated March 4. 1788.

On the 4th of June 1790, Mr JOHN LONG of *Longville*, in the county of *Dublin*, Ireland, obtained a patent for an improvement in brewing, resembling, in one particular, this invention of Mr Ker's. To his invention, however, he gives the name of *an entire new method*, in *all the essential parts*, of brewing good malt liquor; and therefore, as it comprehends the whole process of brewing, we shall lay it before our readers in the words of its author.

"1. For the better extracting from malt, place near a mash-tun a shallow copper or other vessel that will readily heat; the curb of which to be on a level with the tun, and to contain from two to six hogsheads, according to the dimension of the tun, more or less; and, at the lower end of the copper, have a cock from two to five inches diameter, more or less, to conduct the heated liquor from the copper into a tube which passes down the external part of the tun, and enters it through an aperture about six inches from the bottom; then forming two revolutions, more or less, through the body of the tun, and communicating its heat to the wort as it passes through the tube; and then, at a convenient distance from the place it first entered, it runs from the tun into a cistern or tub, situate as near as convenient to the copper or heating-vessel. In the tub or cistern is to be placed a pump, for the purpose of conveying the cooler liquor back to the copper or heating-vessel again; there to receive the heat of 208 degrees, more or less (which it will require after the first half-hour), and then convey it through the mashing-tun as before, and in the same manner, as long as the working brewer or distiller may think necessary, to raise the mashing tun to any degree of heat required. By adhering to the foregoing process, the first liquor may, with the greatest safety, be let upon the malt from 20 to 30 degrees lower than the present practice; by which means it operates with gentleness, opens and expands

pands the malt and raw corn, and prepares it for the reception of sharper or warmer liquor, so as to extract the whole of the saccharine quality from the malt and raw corn. By the foregoing method, the mashing-tun, instead of losing its first heat (which it does by the present practice), continues to increase in heat every moment, by conveying the heated liquor through the tube into the tun; by which means, at the end of two hours, the working brewer or distiller can have the tun brought to any degree of heat he shall think best suited to the different qualities of the malt or raw corn. Persons who would wish to save expence, may heat their mashing-tun at the side or bottom by a large piece of metallic substance made fire proof, and fixed therein; which, in some degree, will answer the end proposed, but with great trouble and delay.

"2. To prevent the wort from receiving a disagreeable flavour while in the under-back, a tube must be placed at the cock of the mashing-tun, to receive the wort as it comes off, and convey it to a great cistern or refrigeratory, which is supplied with a stream of water. The wort, passing through that medium in a spiral tube, soon loses that heat which so often proves prejudicial to the brewer and distiller in warm weather: then pass it from the tube into a vessel in which pumps are placed, to return the worts into the copper for the purpose of boiling off. All vessels for receiving the cold wort must be placed lower than the source whence the wort comes.

"3. As the great object of long boiling the wort is remedied, by my invention of taking the extract from the hops in a separate manner from the worts, I boil my worts no longer than from 15 to 20 minutes; and, by pursuing that method, I save much time and fuel, and regulate my lengths accordingly.

"4. I steep my hops, the preceding day to which they are to be used, in a copper or other vessel, with as much fluid, blood-warm, as will cover the hops, where it is to remain over a slow fire at least 14 hours, close covered; the copper at the tenth hour not to be of a greater heat than 175 degrees, continuing slow until the last hour. Then I bring the copper gradually to a simmer or slow boil; in which state I let it remain about 10 minutes, and then run off the fluid; and this I do at the same time the first wort is boiled off, that they may both pass together through the refrigeratory into the fermentation or working tun. After the foregoing operation, I cover the hops again with other liquor, and bring the copper to boil as soon as convenient, and let it remain in that state a considerable time, until the second worts are boiled off. Then I pass the hop-fluid with the wort, the same as in the first instance; and, if there is a third wort, I boil my hops a third time with small worts, and pass it off as before; by which means I gradually obtain the whole of the essential oil and pleasing bitter from the hops, which is effectually preserved in the beer.

"5. To cool worts. When the wort is boiled off, it is conducted from the cock of the copper or boiler into a tube of a proper dimension, which passes the wort from the cock to the large cistern or refrigeratory, and there performs several revolutions, in a spiral manner, through the same tube; which is immersed in constant supply of cold water, where it loses the greatest part of its heat in a short time, and thence continues a straight course through the tube, a little elevated and of a suitable length, placed in brick-work, until it meets a small refrigeratory, supplied with colder water from a reservoir made for that purpose at the head of the works; whence a continual stream runs on the surface of the tube down to the great refrigeratory, cooling the wort as it passes, in order to enable the working brewer or distiller to send it into the backs or working-tuns at whatever degree of heat he shall think proper. There is no other difference between brewer and distiller in this process, but that the distiller immediately passes the strong wort from the mashing-tun to the back, thro' the same machinery above inserted, and the tubes may be made of lead, or any other metallic substance.

"6. To enable me to brew in the warm summer months, I sink my backs or working-tuns at least to a level with the ground, but if deeper the better, and cover them closely by an arch made of bricks, or other materials, that will totally exclude the atmospheric air from them. I place them as near as possible to a spring or sand-drain, as their depth will naturally draw the water thence, which must be so contrived as to pass or flow round the backs or tuns. I then introduce a large tube, which passes through the tuns, and keeps the wort several degrees lower than can possibly be done by the present practice; by which means I can produce a complete fermentation even in the dog-days.

"7. In cold or frosty weather, if the tun and backs should lose the first heat, intended to carry it through the process by the foregoing method, you may convey a supply of warm or boiling water by the tube, which passes through the body of the backs or tun, communicating its heat, which rises to any degree the working brewer shall think proper: by pursuing this method, in the coldest season, I never want a fermentation."

We regret that we cannot with propriety state to our readers, under this article, a summary of Mr Richardson of Hull's *Philosophical Principles of Brewing;* for as the author has a new edition of his work in the press, it is our duty rather to refer to it, than to quote from a former edition, which contains not his last improvements. See FERMENTATION and MALT, in this Supplement.

BRIDEALE. See SCOTALE in this Supplement.

BRIDGE. See that article *(Encycl.)*, and ARCH in this Supplement. A *wooden*-bridge, of large span, should be constructed on the principles explained under the title ROOF (*Encycl.*) See also CENTRE (*Suppl.*)

BRINDLEY (James), was born at Tunsted, in the parish of Wormhill, Derbyshire, in 1716. His father was a small freeholder, who dissipated his property in company and field amusements, and neglected his family. In consequence, young Brindley was left destitute of even the common rudiments of education, and till the age of 17 was casually employed in rustic labours. At that period he bound himself apprentice to one Bennet, a mill-wright at Macclesfield, in Cheshire, where his mechanical genius presently developed itself. The master being frequently absent, the apprentice was often left for weeks together to finish pieces of works concerning which he had received no instruction; and Bennet, on his return, was often greatly astonished to see improvements in various parts of mechanism, of which he had no previous conception. It was not long before the millers discovered Brindley's merits, and preferred

Brindley. ferred him in the execution of their orders to the master or any other workman. At the expiration of his servitude, Bennet being grown into years, he took the management of the business upon himself, and by his skill and industry contributed to support his old master and his family in a comfortable manner.

In process of time Brindley set up as a mill-wright on his own account; and by a number of new and ingenious contrivances greatly improved that branch of mechanics, and acquired a high reputation in the neighbourhood. His fame extending to a wider circle, he was employed, in 1752, to erect a water-engine at Clifton, in Lancashire, for the purpose of draining some coal mines. Here he gave an essay of his abilities in a kind of work for which he was afterwards so much distinguished, driving a tunnel under ground through a rock nearly 600 yards in length, by which water was brought out of the Irwell for the purpose of turning a wheel fixed 30 feet below the surface of the earth. In 1755 he was employed to execute the larger wheels for a silk mill at Congleton: and another person, who was engaged to make other parts of the machinery, and to superintend the whole, proving incapable of completing the work, the business was entirely committed to Brindley; who not only executed the original plan in a masterly manner, but made the addition of many curious and valuable improvements, as well in the construction of the engine itself, as in the method of making the wheels and pinions belonging to it. About this time, too, the mills for grinding flints in the Staffordshire potteries received various useful improvements from his ingenuity.

In the year 1756 he undertook to erect a steam engine, upon a new plan, at Newcastle-under-Line; and he was, for a time, very intent upon a variety of contrivances for improving this useful piece of mechanism. But from these designs he was, happily for the public, called away to take the lead in what the event has proved to be a national concern of capital importance—the projecting the system of canal navigation. The Duke of Bridgewater, who had formed his design of carrying a canal from his coal-works at Worsley to Manchester, was induced by the reputation of Mr Brindley to consult him on the execution of it; and having the sagacity to perceive, and strength of mind to confide in, the original and commanding abilities of this self-taught genius, he committed to him the management of the arduous undertaking. The nature of this enterprise has already been described (*Encycl.* vol. IV. p. 80.); it is enough here to mention, that Mr Brindley, from the very first, adopted those leading principles, in the projecting of these works, which he ever after adhered to, and in which he has been imitated by all succeeding artists. To preserve as much as possible the level of his canals, and to avoid the mixture and interference of all natural streams, were objects at which he constantly aimed. To accomplish these, no labour or expence was spared; and his genius seemed to delight in overcoming all obstacles by the discovery of new and extraordinary contrivances.

The most experienced engineers upon former systems were amazed and confounded at his projects of aqueduct bridges over navigable rivers, mounds across deep valleys, and subterraneous tunnels; nor could they believe in the practicability of some of these schemes till they saw them effected. In the execution, the ideas he followed were all his own; and the minutest, as well as the greatest, of the expedients he employed, bore the stamp of originality. Every man of genius is an enthusiast. Mr Brindley was an enthusiast in favour of the superiority of canal navigations above those of rivers; and this triumph of art over nature led him to view with a sort of contempt the winding stream, in which the lover of rural beauty so much delights. This sentiment he is said to have expressed in a striking manner at an examination before a committee of the House of Commons, when, on being asked, after having made some contemptuous remarks relative to rivers, what he conceived they were created for? he answered, "to feed navigable canals." A direct rivalry with the navigation of the Irwell and Mersey was the bold enterprize of his first great canal; and since the success of that design, it has become common, all over the kingdom, to see canals accompanying, with insulting parallel, the course of navigable rivers.

After the successful execution of the Duke of Bridgewater's canal to the Mersey, Mr Brindley was employed in the revived design of carrying a canal from that river to the Trent, through the counties of Chester and Stafford. This undertaking commenced in the year 1766; and from the great ideas it opened to the mind of its conductor, of a scheme of inland navigation which should connect all the internal parts of England with each other, and with the principal sea-ports, by means of branches from this main stem, he gave it the emphatical name of the *grand trunk*. In executing this, he was called upon to employ all the resources of his invention, on account of the inequality and various nature of the ground to be cut through: in particular, the hill of Harecastle, which was only to be passed by a tunnel of great length, bored through strata of different consistency, and some of them mere quicksand, proved to be a most difficult, as well as expensive, obstacle, which, however, he completely surmounted. While this was carrying on, a branch from the grand trunk, to join the Severn near Bewdly, was committed to his management, and was finished in 1772. He also executed a canal from Droitwich to the Severn; and he planned the Coventry canal, and for some time superintended its execution; but on account of some difference in opinion, he resigned that office. The Chesterfield canal was the last undertaking of the kind which he conducted, but he only lived to finish some miles of it. There was, however, scarcely any design of canal-navigation set on foot in the kingdom, during the latter years of his life, in which he was not consulted, and the plan of which he did not either entirely form, or revise and improve. All these it is needless to enumerate; but, as an instance of the vastness of his ideas, it may be mentioned, that on planning a canal from Liverpool to join that of the Duke of Bridgewater at Runcorn, it was part of his intention to carry it, by an aqueduct bridge, across the Mersey, at Runcorn Gap, a place where a tide, sometimes rising fourteen feet, rushes with great rapidity through a sudden contraction of the channel. As a mechanic and engineer, he was likewise consulted on other occasions; as with respect to the draining of the low lands in different parts of Lincolnshire and the Isle of Ely, and to the cleansing of the docks of Liverpool from mud. He pointed out a method, Brindley. method, which has been fucceſsfully practifed, of building fea-walls without mortar; and he was the author of a very ingenious improvement of the machine for drawing water out of mines by the contrivance of a lofing and a gaining bucket.

The intenfity of application which all his various and complicated employments required, probably fhortened his days; as the number of his undertakings, in fome degree, impaired his ufefulnefs. He fell into a kind of chronic fever, which, after continuing fome years, with little intermiffion, at length wore out his frame, and put a period to his life on September 27. 1772, in the 56th year of his age. He died at Tunhurft, in Staffordfhire, and was buried at New Chapel in the fame county.

In appearance and manners, as well as in acquirement, Mr Brindley was a mere peafant. Unlettered, and rude of fpeech, it was eafier for him to devife means for executing a defign than to communicate his ideas concerning it to others. Formed by nature for the profeffion he affumed, it was there alone that he was in his proper element; and fo occupied was his mind with his bufinefs, that he was incapable of relaxing in any of the common amufements of life. As he had not the ideas of other men to affift him, whenever a point of difficulty in contrivance occurred, it was his cuftom to retire to his bed, where, in perfect folitude, he would lie for one, two, or three days, pondering the matter in his mind till the requifite expedient had prefented itfelf. This is that true infpiration which poets have almoft exclufively arrogated to themfelves, but which men of original genius in every walk are actuated by, when, from the operation of the mind acting upon itfelf, without the intrufion of foreign notions, they create and invent.

A remarkably retentive memory was one of the effential qualities which Mr Brindley brought to his mental operations. This enabled him to execute all the parts of the moft complex machine in due order, without any help of models or drawings, provided he had once accurately fettled the whole plan in his mind. In his calculations of the powers of machines, he followed a plan peculiar to himfelf; but, indeed, the only one he could follow without inftruction in the rules of art. He would work the queftion fome time in his head, and then fet down the refult in figures. Then taking it up in this ftage, he would again proceed by a mental operation to another refult; and thus he would go on by ftages till the whole was finifhed, only making ufe of figures to mark the feveral refults of his operations. But though, by the wonderful powers of native genius, he was thus enabled to get over his want of artificial method to a certain degree; yet there is no doubt that when his concerns became extremely complicated, with accounts of various kinds to keep, and calculations of all forts to form, he could not avoid that perplexity and embarraffment which a readinefs in the proceffes carried on by pen and paper can alone obviate. His eftimates of expence have generally proved wide of reality; and he feems to have been better qualified to be the contriver, than the manager of a great defign. His moral qualities were, however, highly refpectable. He was far above envy and jealoufy, and freely communicated his improvements to perfons capable of receiving and executing them; taking a liberal fatisfaction in forming a new generation of engineers able to proceed with the great plans in the fuccefs of which he was fo deeply interefted. His integrity and regard to the advantage of his employers were unimpeachable. In fine, the name of Brindley will ever keep a place among that fmall number of mankind who form eras in the art or fcience to which they devote themfelves, by a large and durable extenfion of its limits.

Briffot. BRISSOT (J. P.), acted fo confpicuous a part in the French revolution, that a fair detail of the principal events of his life would undoubtedly be acceptable to all our readers. A fair detail, however, of fuch a life, we believe it impoffible at prefent to give; for characters like Briffot's are almoft always mifreprefented both by their friends and by their enemies; and till the troubles which they have excited, or in which they have been engaged, have long fubfided, the impartial truth is nowhere to be found.

In a fulfome panegyric, under the denomination of *The Life of J. P. Briffot*, faid to be written by himfelf, we are told, that he was born January 14. 1754; and that his father was a *traiteur*, or "the keeper of an eating-houfe," but in what place we are not informed. Our author, however, affures us that the old man was in eafy circumftances, and that he employed all the means refulting from them to give to his numerous family a good education. The fubject of this memoir was intended for the bar; but not relifhing the ftudies neceffary to fit him for the profeffion of the law, or, if we choofe to believe him, having a mind too *pure* and *upright* for the ftudy of *chicane*, he relinquifhed the purfuit after five years of drudgery!

To relieve his wearinefs and difguft, he applied himfelf, he fays, to literature and the fciences. The ftudy of the languages was above all others his favourite purfuit. Chance brought him acquainted with two Englifhmen on their travels through France: he learned their language; and this circumftance, he tells us, decided his fate.

"It was at the commencement of my paffion for that language (continues he) that I made the metamorphofis of a diphthong in my name which has fince been imputed to me as fo heinous a crime. Born the thirteenth child of my family, and the fecond of my brothers in it, I bore, for the fake of diftinction, according to the cuftom of Beauce, the name of a village in which my father poffeffed fome landed property. This village was called *Ouarville*, and Ouarville became the name by which I was known in my own country. A fancy ftruck me that I would caft an Englifh air upon my name; and accordingly I fubftituted, in the place of the French diphthong *ou*, the *w* of the Englifh, which has precifely the fame found." For this puerile affectation, which was certainly not criminal, he juftifies himfelf by the example of the literati of the 16th and 17th centuries, who made no fcruple of Grecifing and Latinifing their appellatives.

Having profecuted his ftudies for two years, he had an application from the Englifh proprietor of a paper then much in circulation, and intitled *Le Courier de l'Europe*. This man having drawn upon himfelf an attack from government, felt and yielded to the neceffity of printing his paper at Boulogne-fur-mer. It was his wifh to render it interefting to the French in the department of mifcellaneous intelligence; which he therefore wifhed to fubmit to the fuperintendency and arrangement of

Briffot.

of Briffot, who reprefents himfelf as for fome moments hefitating. The profeffion of a journalift, fubject to a licenfer, was repugnant to his principles; yet it fecured his independence, and put into his power the means of profecuting an inveftigation of conftitutions and of the fciences. After fome ridiculous reafoning from the original ftations of *Bayle*, *Poftel*, and *Rouffeau*, he at laft accepted of the employment, and became enamoured of it, "becaufe (fays he) it enabled me to ferve talents and virtue, and, as it were, to inoculate the French with the principles of the Englifh conftitution.

This employment, however, did not laft for any length of time. The plan of the proprietor of the *Courier* was overthrown by adminiftration, and Briffot quitted Boulogne to return to his firft ftudies. Having informed us of this fact, he makes an extravagant pretence to unfullied virtue, and calls upon the inhabitants of the city which he had left to bear witnefs, not only that he had *no vices*, but that he had not even the *feeds* of any one of the vices which his adverfaries, it feems, had laid to his charge.

"Doubtlefs (fays he), too eager to publifh my ideas, I conceived that the proper moment had arrived, and I felt an inclination to commence with an important work. Revolting, from the very inftant of my beginning to reflect, againft religious and political tyranny, I folemnly protefted, that thenceforward I would confecrate my whole life to their extirpation. Religious tyranny had fallen under the redoubled ftrokes of Rouffeau, of Voltaire, of Diderot, and of D'Alembert. It became neceffary to attack the fecond;" and this was a tafk which the vanity of Briffot led him to confider as referved for him.

What Voltaire and his friends meant by religious tyranny, and how they conducted their attacks againft it, are matters, alas! too well known to all Europe; and as our author chofe thefe philofophers for his guides, we might infer, without much degree of miftake, what he underftood by political tyranny, and by what means he meditated its extirpation. But he has not left us to make this difcovery by inference.

"It became neceffary (fays he) to break in pieces the political idol, which, under the name of *monarchy*, practifed the moft violent defpotifm; but to attack it openly, was to expofe the affailant without the poffibility of ferving mankind. It was by a fide blow that it was to be wounded moft effectually;" and therefore he refolved to begin his operations by attacking fome of thofe abufes which might be reformed without apparently fhaking the authority of the prince.

Our readers, at leaft the fober part of them, will probably think that this mode of attack is not peculiar to Briffot, but that it has been practifed, or attempted to be put in practice, by afpiring demagogues in all ages and countries, who have uniformly begun their career of innovation by exciting the public mind againft thofe abufes in government, of which the exiftence cannot wholly be denied. The fubject to which our author thought fit to call the attention of his countrymen, was the criminal jurifprudence: a fubject, fays he, which, with the exception of fome particulars that had been fuccefsfully inveftigated by Beccaria and Servan, no writer had thoroughly confidered in a philofophical point of view. Thinking himfelf fully equal to this tafk, he drew up a general plan; and in the year 1780 publifhed his Theory of Criminal Laws, in two vols 8vo. This work, favourably received by foreigners, applauded by fome journalifts, and pulled to pieces by others, procured him the friendfhip of the warmeft advocates for human liberty, in whofe opinion the defects of his plan were highly pardonable, on account of the energy confpicuous in his remarks. This publication was foon followed by two difcourfes which gained the prize in 1782 at the academy of Chalons-fur-Marne; the one upon the reform of the criminal laws, and the other on the reparation due to innocent perfons unjuftly accufed.

It is natural to fuppofe that the government beheld with an evil eye thefe writings, which, under pretext of dragging into light the abufes of the criminal laws, infinuated dangerous principles on the nature of government in general.

His next work was intitled, *A Philofophical Library of the Criminal Laws*, in 10 vols; the true object of which was to difseminate in France thofe principles of liberty which guided the Englifh and the Americans in framing and expounding their laws.

But the ftudy of legiflation and politics had not entirely drawn him off from that of other fciences; fuch as chemiftry, phyfics, anatomy, theology, &c. Thefe he conftantly cultivated with ardour; but acknowledges that in each he met with obfcurities, and that in every quarter truth efcaped from his refearches. He therefore fat down to inveftigate the nature of truth, and the proper method of attaining to it in every department of refearch; and the refult of his labours was a kind of *novum organum*, by which he feems to have expected that Bacon's work would be buried in oblivion; and to this important volume he gave the title of *Concerning Truth; or, Thoughts on the Means of attaining Truth in all the Branches of Human Knowledge*. This volume was meant as nothing more than the introduction to a greater work, in which he propofed to inveftigate what is *certain* in knowledge and what *doubtful*, and then to ftrike the balance of the account.

He was prevented, however, from completing his plan, which he regrets exceedingly; for, as he affirms, with *becoming modefty*, his work would certainly have amended its readers! But the French government happened to think otherwife; his aim, which, he fays, was to lead mankind to reflect on their rights, was perceived, and he was accufed to the minifter as a feditious writer. The career of genius was ftopped by the dread of the Baftile; and he was obliged to take refuge in London. There it was his wifh to create *a univerfal confederation of the friends of liberty and truth*, and to eftablifh a *centre of correfpondence and union* with the learned and the politicians of Europe. This dark defign, however, was fruftrated by the treachery, as it would appear, of his affociates, who had bound themfelves, he fays, by the moft *facred oaths*, to affift him, and had offered to fign articles *even with their own blood*.

Finding himfelf unable to proceed directly to the object which he had in view, he refolved to *enlighten his* countrymen gradually, and to begin with exciting their love and admiration of the Englifh conftitution. That conftitution, which he had inveftigated on the fpot, appeared to him a model for thofe focieties which were defirous of changing their form of government. It was but little known, he fays, in France (the work of *De Lolme* being at that time only in the hands of the learned);

ed);

Briffot.

ed); and to make it known was to make it beloved, was to render it defired. But the French minifters ftood upon their guard, and it became neceffary to *deceive* them. He refolved therefore to bring forward a journal written actually in London, and profeffing to contain only a *defcription of the fciences and arts of England*, whilft the greater part of it was to be occupied in reality by an inveftigation of the *Englifh conftitution*.

After many difficulties, the miniftry granted a privilege for this journal, being publifhed in London, to be reprinted in Paris; and it firft appeared in 1784. "In the twelve numbers which have been publifhed (fays the author), the friends of liberty muft have perceived, that if, on the one fide, I endeavoured to inculcate more juft ideas than had hitherto been entertained concerning this celebrated ifland; fo, on the other, I refolutely made my advances toward that important end which has perpetually prefided over all my labours, *the univerfal emancipation of men*."

His affairs calling him at this time to Paris, he was arrefted and conveyed to the Baftile on the 12th of July 1784. In this conduct of the government we cannot perceive any thing very tyrannical or arbitrary, fince he confeffes, that, in the 16th page of the firft number of his Journal, he had fuffered the *fecret and favourite aim*, which always guided his pen, to become difcernible. He was, however, difcharged from prifon on the 5th of September, and returned with increafed zeal to his former employments.

"This perfecution (fays he), far from extinguifhing the ardour of my wifhes to inculcate the principles of freedom, ferved only to inflame it the more." Accordingly, in 1785, he publifhed two letters to the Emperor Jofeph II. *concerning the right of emigration, and the right of people to revolt*. The firft of thefe letters, which, though well known in Germany, were in France fuppreffed by the *police*, was occafioned by what the author calls the ridiculous and barbarous edict againft emigration; and the fecond by the punifhment of *Horiah* the chief of the *Walachian* infurgents. In this laft letter he lays it down as a maxim, that all people under fuch a government as that of the *Walachians*, have from nature a facred *right* to revolt, a right which they can and ought to exercife. In the fame fpirit he brought out, in 1786, his Philofophical Letters on the Hiftory of England, in 2 vols, and A Critical Examination of the Travels of the Marquis de Chatelleux in North America.

The French revolution appearing to him extremely diftant, notwithftanding all his efforts to haften it, he refolved to leave France for the purpofe of fettling in America. His project received the approbation of feveral, whofe fentiments were congenial with his own. But as it was thought imprudent to tranfport numerous families to a country fo far off, without thoroughly knowing it, Briffot was engaged to proceed thither, to examine the different places, to obferve the inhabitants, and to difcover where and in what manner the eftablifhment they had propofed might be moft advantageoufly fixed. He had fome time before inftituted a fociety at Paris for accomplifhing the abolition of the negro trade, and for foftening the condition of the flaves. At the period of his departure, this fociety confifted of a confiderable number of diftinguifhed members, and he was commiffioned to carry the firft fruits of their labours to America. His ftay there, however, was not fo long as he was defirous of making it. In the beginning of 1789 he was recalled by the news of the French revolution, which he conceived might probably produce a change in his own meafures and in thofe of his friends. This idea, added to other circumftances, accelerated his return. The fire had blazed forth in his native country. "Hope (fays he) animated every heart; the moft diftinguifhed champions had engaged in the conteft; I too became defirous to break a lance, and I publifhed my *Plan of Conduct for the Deputies of the People*."

Briffot, Brown.

This, and other works of a fimilar kind, of which he loudly boafts the merits, raifed him high in the favour of the republican part of the nation, and he became prefident of his diftrict; where he acted, according to his own account, with great uprightnefs in the municipality, in the firft committee of inquiries, and as an elector. At laft he became a member, firft of the *National Affembly*, and, after its diffolution, of the *Sanguinary Convention*; and by fome means or other got to be the leader of a party called fometimes the *Girondifts*, and fometimes the *Briffotines*. From that period the principal events of his life were involved with the public tranfactions of the nation, of which we have given an account in the *Encyclopædia* under the title REVOLUTION (fee that article, n° 101—182.) The Girondift faction was denounced by the Mountain, and Briffot fuffered by the guillotine on the 30th of November 1793. He fell indeed by a very unjuft fentence; but his fall was the natural confequence of that anarchical tyranny under which no man had contributed more than he to fubject his native country.

BROWN (Dr John), author of the *Elementa Medicinæ*, &c. was born in the village of Dunfe, or, as fome fay, Lintlaws, in the county of Berwick, in the year 1735-6. His parents were of mean condition, but much refpected in the neighbourhood for the integrity of their lives. His father gained his livelihood in the humble capacity of a day-labourer; while his mother contributed her fhare towards the fupport of the family by the profits arifing from a milch cow.

Such were the perfons who, in an obfcure part of the country, gave birth to a fon deftined, at a future period, to make a diftinguifhed figure in the republic of letters; and from whom originated a fyftem of the animal economy, which, whatever be its real merits, has undoubtedly produced a confiderable revolution in the practice of medicine.

At the age of three or four years, young Brown was put to a reading fchool in Dunfe, which he himfelf commemorates as the place rather of his education than of his nativity. Here, under the tuition of an old woman, he very early began to exhibit marks of that ftrength of mind for which he was afterwards fo eminently diftinguifhed. In the fhort period of a year he became able to read with facility any part of the Bible, and acquired over his clafs-fellows that fuperiority which he ever after maintained both at fchool and college.

It was almoft immediately after his entrance into this fchool, that his infatiable defire of reading commenced; and fo unremitting was his application, that he is faid never to have been found, even at thofe hours which children much more advanced in life devote to amufement, without a book in his hand.

While he was making this rapid progrefs in the rudiments

Brown.

diments of literature, he ſuffered what muſt have appeared to be a very heavy loſs in the death of his father; but his mother ſoon afterwards married a worthy man of the ſame name, whoſe care and attention ſupplied the place of a father to her ſon. This man being a weaver, deſigned to educate his ſon-in-law to the ſame buſineſs, and began to inſtruct him in his art when he was about nine years of age: but the taſte which young Brown had already acquired for letters, made him look with diſguſt on the inſipid employment of a weaver. His ſtep-father was no tyrant, and his mother was affectionate. They were both proud of the talents which at ſo early a period of life had appeared in their ſon, and they felt no inclination to ſtruggle with the invincible averſion which he expreſſed to the buſineſs for which they intended him.

Another circumſtance, however, contributed in no ſmall degree to make them recal their original reſolution. They were both of that ſect of religioniſts which in Scotland are called Seceders (ſee SECEDERS, *Encycl.)*; and it was ſuggeſted to them by ſome perſons of their own perſuaſion, who had remarked the uncommon abilities of the boy, that he might one day prove an able ſupport and promoter of their tenets as a preacher. He was accordingly, much to his ſatisfaction, taken away from the buſineſs to which he had conceived ſuch a diſtaſte, and ſent to the grammar-ſchool of Dunſe, which was taught at that time by a gentleman of the name of Cruickſhank, eminent for his grammatical knowledge. Here he appears to have ſpent ſome years with uncommon advantage and happineſs; during which he was eſteemed by all the country round as a kind of prodigy. Like Johnſon, and many other men of the higheſt celebrity, he united in the ſame perſon uncommon powers of mind, with no leſs ſtrength of body, as indeed his appearance indicated; and in his youth he enſured his own perſonal importance among his ſchool-fellows, by excelling them not leſs in athletic exerciſes than in the taſks preſcribed by their maſter. He was particularly fond, when a boy, of practiſing the pugiliſtic art; and indeed until the laſt period of his life he was obſerved by his friends always to view an exhibition of that kind with peculiar reliſh. He alſo prided himſelf much in being a ſtout walker; and mentions his having in one day accompliſhed, when but fifteen years of age, a journey of fifty miles between Berwick-upon-Tweed and Morpeth in Northumberland. When farther advanced in life, he travelled on foot from four in the afternoon of one day to two in the afternoon of next day, with the ſhort interval of one hour's reſt! But as one of his biographers very juſtly obſerves, "we have ſeen that he could make a more rational uſe of his ſtrength than merely to ſtake it againſt time and ſpace *."

Dr Beddoes.

His early years while at ſchool were marked by the moſt rigid attachment to his ſect. So ſtrict indeed were his religious ſentiments, if a boy of ten or eleven can be ſaid to have any ſentiments deſerving to be called religious, that he would have conceived the holding of any communion with the eſtabliſhed church as a kind of profanation. An event, however, happened, ſome time between the eleventh and thirteenth years of his age, which produced a total and unexpected revolution in his religious opinions. At a meeting of the provincial ſynod of Merſe and Tiviotdale, he was prevailed upon, though not without manifeſting much reluctance, to accompany a party of his ſchool-fellows to the pariſh church of Dunſe. The conſequence of this tranſgreſſion, as he had dreaded, was an immediate ſummons to appear before the ſeſſion of the Seceding congregation; to which, through pride, not chooſing to attend, in order to preclude a formal expulſion, he voluntarily abjured their tenets, and openly avowed his apoſtacy to the eſtabliſhment.

All changes in religion which are not the conſequence of candid inveſtigation are dangerous. He who leaves one ſect he knows not why, will quickly abandon, with as little reaſon, that to which in a fit of paſſion he had haſtily joined himſelf. From the moment of his quitting the communion of the Seceders, Brown's religious ardour ſuffered a gradual abatement; and though, to pleaſe his mother, he continued to proſecute his ſtudies with a view to the office of a clergyman in the church of Scotland, his opinions became daily more and more lax, and his life of courſe leſs and leſs regular. It was, however, a conſiderable time before he admitted, in their full extent, thoſe principles of irreligion which he afterwards avowed; for upon his firſt peruſing the Eſſays of Mr Hume, though his own zeal was then much cooled, he expreſſed great indignation at their dangerous tendency.

At the age of twelve years he had been employed by Mr Cruickſhank as a kind of uſher in the ſchool of Dunſe; and that gentleman having declared that his knowledge of the Latin language was equal to his own, his fame as a ſcholar was ſo ſpread over the country, that at the age of thirteen he was intruſted with the education of a gentleman's ſon in the neighbourhood, when he quitted the ſchool and his beloved maſter. In his new ſituation, however, he remained not long. Dr Beddoes conjectures, that to the ſtiffneſs of pedantry he added the ſourneſs of a bigot, and was therefore a diſagreeable inmate of the family. That a boy of thirteen, proud of his talents, and prouder of his learning, ſhould have the ſtiffneſs of a pedant, is indeed extremely probable; it was the natural conſequence of the praiſe with which he had been honoured by Mr Cruickſhank: but there is reaſon to believe that of his original bigotry few traces now remained. The real cauſe of his diſmiſſion from the family, we are aſſured, was his pride; and as it muſt have been the pride of parts, it confirms the firſt part of Dr Beddoes's conjecture.

It ſeems he was much diſpleaſed that, when company were at dinner, he was not deſired to remain after the cloth was removed; and yet if he was then only thirteen years of age, it is not eaſy to conceive for what purpoſe he ſhould have ſtaid. He could not poſſibly know much of the world, or of any thing likely to employ the converſation of country gentlemen; and we cannot help thinking, that the maſter of the houſe would have treated his gueſts with rudeneſs, had he detained among them a raw boy to liſten to every unguarded expreſſion which might eſcape them over their wine. It would appear, however, that he was not unwilling to give the tutor of his ſon an opportunity of diſplaying his abilities, when ſuch ſubjects were introduced as he knew him to have ſtudied; for a diſpute having ariſen, one day after Brown had retired to his own room, concerning the decrees of Providence, he ſent to requeſt his opinions on that abſtruſe ſubject. By the

the messenger Brown returned a verbal answer, that "the decrees of Providence are very unjust, for having made blockheads lairds."

Mr Cruickshank had some time before requested him to return to the situation which he had formerly held in the school of Dunse; and we cannot wonder that, immediately after making this insolent answer, he found it convenient to comply with his request. He was now about fifteen, and he continued in the school till the 20th year of his age; during which time, from the constant habit of teaching the Latin and Greek languages, he acquired a wonderful facility in reading both these languages, and in writing the former, though he wrote not with taste.

About this time it occurred to him that he might turn his classical acquirements to more account, by becoming a private teacher of languages in Edinburgh. To that city he accordingly repaired, where, while he obtained a livelihood as a teacher, he proposed at the same time to pursue his theological studies at the university. But an accident happened to him here which made him altogether change the plan he had come upon; and the death of his mother, after a residence of some time in Edinburgh, absolved him, as he thought, from the promise which he had made to her of appearing one day in the pulpit. Shortly after an unsuccessful competition for one of the chairs then vacant in the high-school, an application was made to a friend of his for a proper person to turn a medical thesis into Latin. Brown was recommended. He was limited to a certain time; within which it appeared scarce practicable to perform the task. He accomplished it, however, and in such a style of grammatical correctness and purity as far exceeded the general run of such productions. On this being remarked to him by his friends, he observed, "that he now knew his strength, and was ambitious of riding in his carriage as a physician." He therefore determined to apply himself with ardour to the study of medicine, to which this accidental circumstance alone directed his attention. Accordingly, at the commencement of the next winter session, he addressed a Latin letter to each of the medical professors, and by them was presented with tickets of admittance to their several classes.

From such a favourable beginning, being of a very sanguine disposition, he conceived the most flattering expectations of his future success; and indeed for some time he seems to have lived in affluent circumstances. His attainments were so various, and in such request in Edinburgh, that as a single man he could scarcely fail to gain a competent living; for during the last five years of his residence under Mr Cruickshank, to a thorough acquaintance with ancient history, he had added a very considerable knowledge of mathematics; in which, among other branches of science, he never had any objection to give instructions. In the acquisition of that variety of knowledge which he possessed, he was greatly assisted by a most tenacious memory; to the retentiveness of which an old school-fellow bears testimony, by affirming, that "after once reading over the lesson, consisting of two octavo pages in Latin, he would lay aside the book, and prelect the whole over without mistaking a single word."

Brown, already in easy circumstances for an individual, saw, or thought he saw, in the establishment of a boarding-house for students a resource which would enable him to maintain a family; and in expectation of realising this prospect, he married, in 1765, the daughter of a respectable tradesman in Edinburgh. The distinguished attention at that time paid him by Dr Cullen, in whose family he had become a necessary person, contributed in all probability to strengthen his hopes that his house would be filled with proper boarders through the Doctor's recommendation. His success in this way for some time answered his most sanguine expectations; and his circumstances at one period were so flourishing, that he is said to have kept a one-horse chaise.

It was, perhaps, the greatest misfortune that could have befallen Brown, that he possessed, in a high degree, those talents which make a man's company sought after by the gay and the dissipated: He was capable of "setting the table in a roar." We need not therefore wonder at his frequently neglecting more necessary pursuits to enjoy the conviviality of the numerous friends who courted his company; or that drinking and dissipation became habitual to him. He was as deficient in point of prudence as he excelled in genius. His house was filled with respectable boarders; but as he lived too splendidly for an income at best but precarious, he became gradually involved in debt, and his affairs were still more embarrassed by the burden of a numerous family. Soon after he began to be involved in these difficulties, he suffered an additional loss in being deprived of the patronage of Dr Cullen, in consequence of a disagreement that had taken place between them. This enmity, which had for some time before secretly subsisted, probably from mutual jealousy, was at length excited into an open rupture; first, by Dr Cullen's not exerting his interest in procuring for Brown the theoretical chair of medicine, then vacant in consequence either of the death or resignation of Dr Alexander Monro Drummond; and, secondly, by his rejecting, some time after, Brown's petition for admittance into the Edinburgh Philosophical Society.

In 1776 Brown was elected president of the Medical Society; and the same honour was again conferred on him in 1780. He was led on, in the gradual manner he himself describes in his masterly preface to the *Elementa Medicinæ*, to the discovery of his new doctrine; which, on dropping all correspondence with his former friend and benefactor, he now, for the first time, began to illustrate in a course of public lectures; and in these he displayed equal ingenuity and philosophical profundity. Much about the time of which we now speak, he published the first edition of the *Elementa Medicinæ*; a work which certainly proves its author to have been a man of uncommon genius and originality of thought. The circumstances in which this work was composed reflect great honour on his abilities. He never retired to his study; but, totally absorbed in his own ideas, wrote with the greatest tranquillity amidst the noise of ten children, occasionally settling their childish differences.

In the year 1779, though he had studied medicine ten or twelve years at the university of Edinburgh, he was prevailed upon by his friends to take a degree at St Andrews, where he gave a conspicuous proof of his facility in Latin composition. He wrote a thesis, or inaugural dissertation, in the tavern while the cloth was laying for dinner; and one of his companions, who was singing

Brown.

singing beside him, having uttered a false note, or sung out of time, Mr Brown, in the middle of his writing, stopped to shew him how the song ought to be sung, and then instantly proceeded in his thesis.

His family having now become so numerous as to render keeping a boarding-house inconvenient, he had already for some time given it up, and depended for support entirely on his practice as a physician and his public lectures. At this time the disputes between the Cullenians and the Brunonians (as the young men now styled themselves) were carried on with such acrimony on both sides, in the different societies, that it was not unusual for them to terminate in duels; and there exists at this day, on the records of the Medical Society, a law which it was thought expedient to enact, by which a member who challenges another for any thing said in public debate incurs the penalty of expulsion.

Observing the students of medicine frequently to seek initiation into the mysteries of free-masonry, Dr Brown thought their youthful curiosity afforded him a chance of proselytes. In 1784, he instituted a meeting of that fraternity, and intitled it *the Lodge of the Roman Eagle*. The business was conducted in the Latin language, which he spoke with the same fluency as Scotch; and he displayed much ingenuity in turning into Latin all the terms used in masonry.

As the terms on which he lived with his brethren of the faculty were such that he obstinately avoided meeting them even in consultation, we may conclude that his own private practice was but limited. His friends affirmed, perhaps without sufficient proof, that cabals were formed against him, and every advantage taken of the errors he was led to commit by his own imprudence. After a long series of struggles, therefore, hoping to meet with that encouragement among the English of which he had been disappointed in his own country, he put in practice a plan upon which he had long meditated, and removed in 1786 with part of his family to London. Immediately on his arrival, an incident befel him, which Dr Beddoes says he has heard the late Mr Murray, bookseller in Fleet-street, relate as a proof of his simplicity. The peculiarity of his appearance as he moved along (a short square figure, with an air of dignity, in a black suit, which heightened the scarlet of his cheeks and nose) fixed the attention of some *gentlemen* in the street. They addressed him in the dialect of his country. His heart, heavy as it must have been, from the precariousness of his situation, and distance from his accustomed haunts, expanded at these agreeable sounds. A conversation ensued; and the parties, by common consent, adjourned to a tavern. Here the stranger was kindly welcomed to town; and, after the glass had circulated for a time, something was proposed by way of sober amusement—a game at cards, or whatever the Doctor might prefer. The Doctor had been too civilly treated to demur; but his purse was scantily furnished, and it was necessary to quit his new friends in search of a supply. Mr Murray was the person to whom he had recourse: the reader will not wonder that his interference should have spoiled the adventure.

A London sharper, of another denomination, afterwards tried to make advantage by the Doctor. This was an ingenious speculator in public medicines. He thought a composition of the most powerful stimulants might have a run, under the title of *Dr Brown's exciting pill*; and, for the privilege of his name, offered him a sum in hand by no means contemptible, as well as a share of the contingent profits. Poor Brown, needy as he was, spurned at the proposal.

After this period, his life affords little variety of incident. Like Avicenna, his time seems to have been spent between his literary pursuits and his pleasures. A splendid manner of living, without an income to support it, had become habitual to him: The consequence was, that, from inability to discharge certain debts he had contracted, he was thrown into the king's bench prison; from which, however, he was, not long afterwards, released by the exertions of a few firm friends, particularly Mr Maddison of Charing-cross, a gentleman universally respected for his well-known benevolence. As a proof of the activity he was still capable of exerting, it will be sufficient to mention, that he accomplished the translation of his *Elementa*, with the addition of the supplementary notes, within 23 days, having been informed that a translation of the same was about to be published by another person.

Shortly before his death, the ambassador of the king of Prussia, in the name of his master, made Dr Brown an offer of a settlement in the court of Berlin; during the negociation of which he was unexpectedly cut off by an apoplexy early in the morning of the 7th of October 1788, the day succeeding that on which he had delivered to a company of thirteen gentlemen the greater part of the introductory lecture to his second course. At his death, he was between 52 and 53 years of age. His remains were interred in the church-yard of St James's Picadilly; and the only monument left behind him to transmit his name to posterity is his own works; which, when personal prejudice no longer shall prevail against their ingenious author, cannot fail to procure him all that deserved celebrity which they have already, in part, obtained in the different countries of Europe.

In 1787, he published his "Observations," without his name, which he afterwards, however, refers to in the Elements as his own. The "Enquiry," said to be written by Dr Jones, and which was composed in as short a time as the generality of men would transcribe a work of its extent, we can affirm, from undoubted authority, to be his production.

This sketch of the life of the unfortunate Dr Brown would be of very little value if not followed by a view of his system; but to give a complete view of that system would far exceed the limits within which, in a work like this, such articles must be confined. We trust, therefore, that our readers will be satisfied with an abstract; and as we are neither the partisans nor opponents of the Doctor, and not very partial to any medical *system* whatever, we shall content ourselves with inserting, in this place, the view which Dr Beddoes has given of Dr Brown's fundamental propositions in the valuable observations which he has prefixed to his edition of the Elements of Medicine.

"The varied structure of organized beings (says Dr Beddoes), it is the business of anatomy to explain. Consciousness, assisted by common observation, will distinguish animated from inanimate bodies with precision more than sufficient for all the ends of medicine. The cause of gravitation has been left unexplored by all prudent

Brown.

dent philoſophers; and Brown, avoiding all uſeleſs diſquiſition concerning the cauſe of vitality, confines himſelf to the phenomena which this great moving principle in nature may be obſerved to produce. His moſt general propoſitions are eaſy of comprehenſion.

" 1. To every animated being is allotted a certain portion only of the quality or principle on which the phenomena of life depend. This principle is denominated *excitability*.

" 2. The excitability varies in different animals, and in the ſame animal at different times. As it is more intenſe, the animal is more vivacious or more ſuſceptible of the action of exciting powers.

" 3. Exciting powers may be referred to two claſſes. 1. External; as heat, food, wine, poiſons, contagions, the blood, ſecreted fluids, and air. 2. Internal; as the functions of the body itſelf, muſcular exertion, thinking, emotion, and paſſion.

" 4. Life is a forced ſtate; if the exciting powers are withdrawn, death enſues as certainly as when the excitability is gone.

" 5. The excitement may be too great, too ſmall, or in juſt meaſure.

" 6. By too great excitement, weakneſs is induced, becauſe the excitability becomes defective; this is *indirect debility*: when the exciting powers and ſtimulants are withheld, weakneſs is induced; and this is *direct debility*. Here the excitability is in exceſs.

" 7. Every power that acts on the living frame is ſtimulant, or produces excitement by expending excitability. Thus, although a perſon accuſtomed to animal food may grow weak if he lives upon vegetables, ſtill the vegetable diet can only be conſidered as producing an effect, the ſame in kind with animals, though inferior in degree. Whatever powers, therefore, we imagine, and however they vary from ſuch as are habitually applied to produce due excitement, they can only weaken the ſyſtem by urging it into too much motion, or ſuffering it to ſink into langour.

" 8. Excitability is ſeated in the medullary portion of the nerves, and in the muſcles. As ſoon as it is anywhere affected, it is immediately affected everywhere; nor is the excitement ever increaſed in a part, while it is generally diminiſhed in the ſyſtem; in other words, different parts can never be in oppoſite ſtates of excitement.

" I have already ſpoken of an illuſtration, drawn up by Mr Chriſtie from a familiar operation, to facilitate the conception of Brown's fundamental poſitions. I introduce it here as more likely to anſwer its purpoſe than if ſeparately placed at the end of my preliminary obſervations. ' Suppoſe a fire to be made in a grate, filled with a kind of fuel not very combuſtible, and which could only be kept burning by means of a machine containing ſeveral tubes, placed before it, and conſtantly pouring ſtreams of air into it. Suppoſe alſo a pipe to be fixed in the back of the chimney, through which a conſtant ſupply of freſh fuel was gradually let down into the grate, to repair the waſte occaſioned by the flame, kept up by the air machine.

' The grate will repreſent the human frame; the fuel in it, the matter of life—the excitability of Dr Brown, and the ſenſorial power of Dr Darwin; the tube behind, ſupplying freſh fuel, will denote the power of all living ſyſtems, conſtantly to regenerate or reproduce excitability; while the air machine, of ſeveral tubes, denotes the various ſtimuli applied to the excitability of the body; and the flame drawn forth in conſequence of that application repreſents life, the product of the exciting powers acting upon the excitability.

' As Dr Brown has defined life to be *a forced ſtate*, it is fitly repreſented by a flame forcibly drawn forth from fuel little diſpoſed to combuſtion, by the conſtant application of ſtreams of air poured into it from the different tubes of a machine. If ſome of theſe tubes are ſuppoſed to convey pure or dephlogiſticated air, they will denote the higheſt claſs of exciting powers, opium, muſk, camphor, ſpirits, wine, tobacco, &c. the diffuſible ſtimuli of Dr Brown, which bring forth for a time a greater quantity of life than uſual, as the blowing in of pure air into a fire will temporarily draw forth an uncommon quantity of flame. If others of the tubes be ſuppoſed to convey common or atmoſpheric air, they will repreſent the ordinary exciting powers, or ſtimuli, applied to the human frame, ſuch as heat, light, air, food, drink, &c. while ſuch as convey impure and inflammable air may be uſed to denote what have formerly been termed ſedative powers, ſuch as poiſons, contagious miaſmata, foul air, &c.

' The reader will now probably be at no loſs to underſtand the ſeeming paradox of the Brunonian ſyſtem; that food, drink, and all the powers applied to the body, though they ſupport life, yet conſume it; for he will ſee that the application of theſe powers, though it brings forth life, yet at the ſame time it waſtes the excitability or matter of life, juſt as the air blown into the fire brings forth more flame, but waſtes the fuel or matter of fire. This is conformable to the common ſaying, " the more a ſpark is blown, the brighter it burns, and the ſooner it is ſpent." A Roman poet has given us, without intending it, an excellent illuſtration of the Brunonian ſyſtem, when he ſays,

" *Balnea, vina, Venus, conſumunt corpora noſtra;*
" *Sed vitam faciunt balnea, vina, Venus.*

" Wine, warmth, and love, our vigour drain;
" Yet wine, warmth, love, our life ſuſtain."

Or to tranſlate it more literally,

" Baths, women, wine, exhauſt our frame;
" But life itſelf is drawn from them."

' Equally eaſy will it be to illuſtrate the two kinds of debility, termed *direct* and *indirect*, which, according to Brown, are the cauſe of all diſeaſes. If the quantity of ſtimulus or exciting power is proportioned to the quantity of excitability, that is, if no more excitement is drawn forth than is equal to the quantity of excitability produced, the human frame will be in a ſtate of health, juſt as the fire will be in a vigorous ſtate when no more air is blown in than is ſufficient to conſume the freſh ſupply of fuel conſtantly poured down by the tube behind. If a ſufficient quantity of ſtimulus is not applied, or air not blown in, the excitability in the man, and the fuel in the fire, will accumulate, producing direct debility; for the man will become weak, and the fire low. Carried to a certain degree, they will occaſion death to the firſt, and extinction to the laſt. If, again, an over proportion of ſtimulus be applied, or too much air blown in, the excitability will ſoon be waſted, and the matter of fuel almoſt ſpent. Hence will

Brown.

will arise indirect debility, producing the same weakness in the man, and lowness in the fire, as before, and equally terminating, when carried to a certain degree, in death and extinction.

'As all the diseases of the body, according to Dr Brown, are occasioned by direct or indirect debility, in consequence of too much or too little stimuli, so all the defects of the fire must arise from direct or indirect lowness, in consequence of too much or too little air blown into it. As Brown taught that one debility was never to be cured by another, but both by the more judicious application of stimuli, so will be found the case in treating the defects of the fire. If the fire has become low, or the man weak, by the want of the needful quantity of stimulus, more must be applied, but very gently at first, and increased by degrees, lest a strong stimulus applied to the accumulated excitability should produce death; as in the case of a limb benumbed with cold (that is, weakened by the accumulation of its excitability in consequence of the abstraction of the usual stimulus of heat), and suddenly held to the fire, which we know from experience is in danger of mortification; or as in the case of the fire becoming very low by the accumulation of the matter of fuel, when the feeble flame, assailed by a sudden and strong blast of air, would be overpowered and put out, instead of being nourished and increased. Again, if the man or the fire have been rendered indirectly weak, by the application of too much stimulus, we are not suddenly to withdraw the whole, or even a great quantity of the exciting powers or air, for then the weakened life and diminished flame might sink entirely; but we are by little and little to diminish the overplus of stimulus, so as to enable the excitability, or matter of fuel, gradually to recover its proper proportion. Thus a man who has injured his constitution by the abuse of spirituous liquors is not suddenly to be reduced to water alone, as is the practice of some physicians, but he is to be treated as the judicious Dr Pitcairn of Edinburgh is said to have treated a Highland chieftian, who applied to him for advice in this situation. The Doctor gave him no medicines, and only exacted a promise of him, that he would every day put in as much wax into the wooden *queich*, out of which he drank his whisky, as would receive the impression of his arms. The wax thus gradually accumulating, diminished daily the quantity of the whisky, till the whole *queich* was filled with wax; and the chieftain was thus gradually, and without injury to his constitution, cured of the habit of drinking spirits.

'These analogies might be pursued farther; but my object is solely to furnish some general ideas, to prepare the reader for entering more easily into the Brunonian theory, which I think he will be enabled to do after perusing what I have said. The great excellence of that theory, as applied, not only to the practice of physic, but to the general conduct of the health, is, that it impresses on the mind a sense of the impropriety and danger of going from one extreme to another. The human frame is capable of enduring great varieties, if time be given it to accommodate itself to different states. All the mischief is done in the transition from one state to another. In a state of low excitement, we are not rashly to induce a state of high excitement; nor when elevated to the latter, are we suddenly to descend to the former, but step by step, and as one who from the top of a high tower descends to the ground. From hasty and violent changes the human frame always suffers; its particles are torn asunder, its organs injured, the vital principle impaired, and disease, often death, is the inevitable consequence.

Brown, Bruce.

'I have only to add, that though in this illustration of the Brunonian system (written several years ago), I have spoken of a tube constantly pouring in fresh fuel, because I could not otherwise convey to the reader a familiar idea of the power possessed by all living systems, to renew their excitability when exhausted; yet it may be proper to inform the student, that Dr Brown supposed every living system to have received at the beginning its determinate portion of excitability; and, therefore, although he spoke of the exhaustion, augmentation, and even renewal of excitability, I do not think it was his intention to induce his pupils to think of it as a kind of fluid substance existing in the animal, and subject to the law by which such substances are governed. According to him, excitability was an unknown *somewhat*, subject to peculiar laws of its own, and whose different states we were obliged to describe (though inaccurately) by terms borrowed from the qualities of material substances.'

"The Brunonian system has frequently been charged with promoting intemperance. The objection is serious; but the view already given of its principles shews it to be groundless. No writer had insisted so much upon the dependence of life on external causes, or so strongly stated the inevitable consequences of excess. And there are no means of promoting morality upon which we can rely, except the knowledge of the true relations between man and other beings or bodies. For by this knowledge we are directly led to shun what is hurtful, and pursue what is salutary. And in what else does moral conduct, as far it regards the individual, consist? It may be said that the author's life disproves the justness of this representation: his life, however, only shews the superior power of other causes, and of bad habits in particular; and I am ready to acknowledge the little efficacy of instruction when bad habits are formed. Its great use consists in preventing their formation; for which reason popular instruction in medicine would contribute more to the happiness of the human species, than the complete knowledge of every thing which is attempted to be taught in education, as it is conducted at present. But though the principles of the system in question did not correct the propensities of its inventor, it does not follow that they tend to produce the same propensities in others."

BRUCE (James, Esq; F. R. S.), the celebrated Abyssinian traveller, was born, 1730, at Kinnaird house, in the parish of Larbert and county of Stirling. His descent by both parents was ancient and honourable; and of that descent he was, perhaps, too proud. His grandfather was —— Hay, Esq; of Woodcockdale, in the county of Linlithgow, who, marrying Miss Bruce, the heiress of Kinnaird, gave the name of *Bruce* to all his descendants.

Perhaps this change of name may have taken place in obedience to the deed by which the estate of Kinnaird was settled on Mrs Hay's children; but it is a change which, in a country like Scotland, where antiquity of descent is highly valued, any man would voluntarily have adopted, who had married the heiress of such

Bruce.

ſuch a family. The Bruces of Kinnaird had been in poſſeſſion of that eſtate for three centuries: they were deſcended from a younger ſon of Robert de Bruce, the competitor with Baliol for the crown of Scotland. It would readily occur, that the knowledge of ſuch a deſcent would be beſt preſerved by continuing the name of their great anceſtor; and we have reaſon to believe, that the ſubject of this memoir was not much delighted when put in mind, as he frequently was, that, though the heir of the line, he was not the *male* heir of that branch of the illuſtrious family.

As he was allied to royalty by his father and grandmother, through his mother he was related to ſome of the moſt reſpectable families in the kingdom. She was the daughter of James Graham, Eſq; of Airth, dean of the faculty of advocates, and judge of the high court of admiralty in Scotland, by Marion, daughter of James Hamilton Eſq; of Pencaitland; and to a man of our traveller's turn of mind, there can be no doubt but that it muſt have afforded much ſatisfaction to think, that no family ranks higher in Scotland than thoſe of Bruce, Graham, and Hamilton. In him, however, it was weakneſs to be proud, if indeed he was proud, of family; for the talents beſtowed upon him by nature, or, to ſpeak more properly, by nature's God, would have made him great though he had been born on a dunghill. He would indeed have been, in all probability, much greater than he was, had he not been in poſſeſſion of the phantom of birth to gratify much of his ambition; for the facility with which he maſtered every ſtudy in which he engaged, would have carried him quickly to the top of the moſt honourable profeſſion.

Mr Bruce was inſtructed in grammatical learning at the ſchool of Harrow on the Hill, in the county of Middleſex, where he gave the moſt unequivocal proofs of genius, and acquired a very conſiderable knowledge of the Greek and Latin languages. It was cuſtomary with him to perform, not only his own exerciſes, but alſo the exerciſes of ſuch of his companions as were not equal to the taſk themſelves. Among theſe was his maternal uncle, who was frequently indebted to his aſſiſtance, and, on one occaſion, produced a copy of verſes of his compoſition, which excited, not only the applauſe, but the admiration of their maſter. Mr Graham, who was but a few months older than Mr Bruce, had, for ſome tranſgreſſion (we know not what), been puniſhed, as boys in the great ſchools in England are often puniſhed, by having a taſk ſet him, which he ſoon found himſelf unable to perform. His nephew deſired him to be under no uneaſineſs, promiſing to furniſh him with the verſes before the time at which they were to be given in. He was as good as his word; but the maſter of the ſchool ſoon diſcovering that they were not the performance of Mr Graham, exclaimed, that the author of theſe verſes, whoever he was, might apply to himſelf the words of Horace,

—— *Sublimi feriam ſidera vertice.*

While Mr Bruce was at Harrow, and for a year or two after he had left it, he was of a very delicate frame, and appeared to his friends to be threatened with a conſumption. The truth is, that he was uncommonly tall for his age, and felt all the feebleneſs of joints and other bodily weakneſſes to which overgrown boys are generally ſubject. His father intended him for the profeſſion of the law; and, upon his return from Harrow, he was entered into the univerſity of Edinburgh, where he went through a regular courſe of ſtudy to fit him for being enrolled in the body of advocates: but for ſome reaſon, which we do not perfectly know, he relinquiſhed the ſtudy of law for the purſuits of trade; and, going to London, entered into partnerſhip with a wine merchant of the name of Allen, whoſe daughter he married.

That lady falling into a bad ſtate of health, Mr Bruce took her abroad, in hopes that travelling would be attended with beneficial effects; but in theſe he was diſappointed, as ſhe died within a year after her marriage. He was induced, in order to diſpel his grief, to continue his travels; during which his father dying (at Edinburgh, 4th May 1758), the inheritance of his anceſtors devolved upon him, and he returned to Britain. Some of his ſubſequent tranſactions ſhall now be related in his own words.

"Every one will remember that period, ſo glorious to Britain, the latter end of the miniſtry of the late earl of Chatham. I was then returned from a tour through the greateſt part of Europe, particularly through the whole of Spain and Portugal, between whom there was then the appearance of an approaching war.

"I was about to retire to a ſmall patrimony I had received from my anceſtors, in order to embrace a life of ſtudy and reflection, nothing more active appearing within my power, when chance threw me unexpectedly into a very ſhort and very deſultory converſation with Lord Chatham.

"It was a few days after this that Mr Wood, then under-ſecretary of ſtate, my zealous and ſincere friend, informed me that Lord Chatham intended to employ me upon a particular ſervice; that, however, I might go down for a few weeks to my own country to ſettle my affairs, but, by all means, to be ready upon a call. Nothing could be more flattering to me than ſuch an offer, when ſo young; to be thought worthy by Lord Chatham of any employment, was doubly a preference. No time was loſt on my ſide; but juſt after receiving orders to return to London, his lordſhip had gone to Bath, and reſigned his office.

"This diſappointment, which was the more ſenſible to me that it was the firſt I had met with in public life, was promiſed to be made up to me by Lord Egremont and Mr George Grenville. The former had been long my friend; but unhappily he was then far gone in a lethargic indiſpoſition, which threatened, and did very ſoon put a period to his exiſtence. With Lord Egremont's death my expectations vaniſhed. Further particulars are unneceſſary; but I hope that, at leaſt in part, they remain in that breaſt where they naturally ought to be, and where I ſhall ever think, not to be long forgotten, is to be rewarded.

"Seven or eight months were paſſed in an expenſive and fruitleſs attendance in London, when Lord Halifax was pleaſed, not only to propoſe, but to plan for me a journey of conſiderable importance, and which was to take up ſeveral years. His lordſhip ſaid, that nothing could be more ignoble than, at ſuch a time of life, at the height of my reading, health, and activity, I ſhould, as it were, turn peaſant, and voluntarily bury myſelf in obſcurity and idleneſs; that though war was now drawing faſt to an end, full as honourable a competition remained

Bruce.

mained among men of ſpirit, which ſhould acquit themſelves beſt in the dangerous line of uſeful adventure and diſcovery.

" He obſerved, that the coaſt of Barbary, which might be ſaid to be juſt at our door, was yet but partially explored by Dr Shaw, who had only illuſtrated (very judiciouſly indeed) the geographical labours of Sanſon; that neither Dr Shaw nor Sanſon had been, or pretended to be, capable of giving the public any detail of the large and magnificent remains of ruined architecture, which they both vouch to have ſeen in great quantities, and of exquiſite elegance and perfection, all over the country. Such had not been their ſtudy, yet ſuch was really the taſte that was required in the preſent times. He wiſhed, therefore, that I ſhould be the firſt, in the reign juſt now beginning, to ſet an example of making large additions to the royal collection; and he pledged himſelf to be my ſupport and patron, and to make good to me, upon this additional merit, the promiſes which had been held forth to me by former miniſters for other ſervices.

" The diſcovery of the ſource of the Nile was alſo a ſubject of theſe converſations, but it was always mentioned to me with a kind of diffidence, as if to be expected from a more experienced traveller. Whether this was but another way of exciting me to the attempt I ſhall not ſay; but my heart, in that inſtant, did me juſtice to ſuggeſt, that this too was either to be atchieved by me, or to remain as it had done for theſe laſt 2000 years, a defiance to all travellers, and an opprobrium to geography.

" Fortune ſeemed to enter into this ſcheme. At the very inſtant, Mr Aſpinwall, very cruelly and ignominiouſly treated by the dey of Algiers, had reſigned his conſulſhip, and Mr Ford a merchant, formerly the dey's acquaintance, was named in his place. Mr Ford was appointed, and, dying a few days after, the conſulſhip became vacant. Lord Halifax preſſed me to accept of this as containing all ſorts of conveniences for making the propoſed expedition.

" This favourable event finally determined me. I had all my life applied unweariedly, perhaps with more love than talent, to drawing, the practice of mathematics, and eſpecially that part neceſſary to aſtronomy. The tranſit of Venus was at hand. It was certainly known that it would be viſible once at Algiers, and there was great reaſon to expect it might be twice. I had furniſhed myſelf with a large apparatus of inſtruments, the completeſt of their kind, for the obſervation. In the choice of theſe, I had been aſſiſted by my friend Admiral Campbell, and Mr Ruſſel ſecretary to the Turkey Company: every other neceſſary had been provided in proportion. It was a pleaſure now to know that it was not from a rock or a wood, but from my own houſe at Algiers, I could deliberately take meaſures to place myſelf in the liſt of men of ſcience of all nations, who were then preparing for the ſame ſcientific purpoſe.

" Thus prepared, I ſet out for Italy, through France; and though it was in time of war, and ſome ſtrong objections had been made to particular paſſports, ſolicited by our government from the French ſecretary of ſtate, Monſieur de Choiſeul moſt obligingly waved all ſuch exceptions with regard to me, and moſt politely aſſured me, in a letter accompanying my paſſport, that thoſe difficulties did not in any ſhape regard me, but that I was perfectly at liberty to paſs through, or remain in, France with thoſe that accompanied me, without limiting their number, as ſhort or as long a time as ſhould be agreeable to me.

" On my arrival at Rome, I received orders to proceed to Naples, there to await his majeſty's further commands. Sir Charles Saunders, then with a fleet before Cadiz, had orders to viſit Malta before he returned to England. It was ſaid that the grand-maſter of that order had behaved ſo improperly to Mr Harvey (afterwards Lord Briſtol) in the beginning of the war, and ſo partially and unjuſtly between the two nations in the courſe of it, that an explanation on our part was become neceſſary. The grand-maſter no ſooner heard of my arrival at Naples, than, gueſſing the errand, he ſent off Chevalier Mazzini to London, where he at once made his peace and his compliments to his majeſty upon his acceſſion to the throne.

" Nothing remained now but to take poſſeſſion of my conſulſhip. I returned, without loſs of time, to Rome, and from thence to Leghorn, where, having embarked on board the Montreal man of war, I proceeded to Algiers.

" While at Naples, I received from ſlaves, redeemed from the province of Conſtantine, accounts of magnificent ruins they had ſeen while traverſing that country with their maſter the Bey. I ſaw the abſolute neceſſity there was for aſſiſtance, without which it was impoſſible for any one man, however diligent and qualified, to do any thing but bewilder himſelf. All my endeavours, however, had hitherto been unſucceſsful to perſuade any Italian to put himſelf wilfully into the hands of a people conſtantly looked upon by them in no better light than pirates. At laſt Mr Lumiſden, by accident, heard of a young man who was then ſtudying architecture at Rome, a native of Bologna, whoſe name was Luigi Balugani. I can appeal to Mr Lumiſden as to the extent of this perſon's practice and knowledge, and that he knew very little when firſt ſent to me. In the twenty months which he ſtaid with me at Algiers, by aſſiduous application to proper ſubjects under my inſtruction, he became a very conſiderable help to me, and was the only one that ever I made uſe of, or that attended me for a moment, or ever touched one repreſentation of architecture in any part of my journey."

Our traveller, when in Spain, had endeavoured to find acceſs to that immenſe collection of Arabic manuſcripts which were periſhing in the duſt of the eſcurial; but in vain. " All my ſucceſs (ſays he) in Europe terminated in the acquiſition of thoſe few printed Arabic books that I had found in Holland; and theſe were rather biographers than general hiſtorians, and contained little in point of general information. The ſtudy of theſe, however, and of Maracci's Koran, had made me a very tolerable Arab; a great field was opening before me in Africa to complete a collection of manuſcripts, an opportunity which I did not neglect.

" After a year ſpent at Algiers, conſtant converſation with the natives while abroad, and with my manuſcripts within doors, had qualified me to appear in any part of the continent without the help of an interpreter. Ludolf had aſſured his readers, that the knowledge of any oriental language would ſoon enable them to acquire the Ethiopic; and I needed only the ſame number of books to have made my knowledge of that language

Bruce.

guage go hand in hand with my attainments in the Arabic. My immediate prospect of setting out on my journey to the inland parts of Africa had made me double my diligence; night and day there was no relaxation from these studies, although the acquiring any single language had never been with me either an object of time or difficulty."

At Algiers Mr Bruce was detained longer than he expected, in consequence of a dispute with the Dey concerning Mediterranean passes. This being adjusted, he proceeded to Mahon, and from Mahon to Carthage. He next visited Tunis and Tripoli, and travelled over the interior parts of these states. At Bengazi, a small town on the Mediterranean, he suffered shipwreck, and with extreme difficulty saved his life, though with the loss of all his baggage. He afterwards sailed to the isles of Rhodes and Cyprus, and proceeding to Asia Minor, travelled through a considerable part of Syria and Palestine, visiting Hassia, Latikea, Aleppo, and Tripoli; near which last city he was again in imminent danger of perishing in a river. The ruins of Palmyra and Baalbec were next carefully surveyed and sketched by him; and his drawings of these places are deposited in the king's library at Kew; "the most magnificent present in that line," to use his own words, "ever made by a subject to his sovereign."

It is much to be regretted that Mr Bruce published no particular account of these various journeys; from the nature of the places visited, and the abilities of the man, much curious and useful information might have been expected. Some manuscript accounts of different parts of them are said to have been left by him, but whether in such a state as to be fit for publication, we have not learned.

In these various travels some years were passed; and Mr Bruce now prepared for the grand expedition, the accomplishment of which had ever been nearest his heart, the discovery of the sources of the Nile. In the prosecution of that dangerous object, he left Sidon on the 15th of June 1768, and arrived at Alexandria on the 20th of that month. He proceeded from thence to Cairo, where he continued to the 12th of December following, when he embarked on the Nile; and in a very extraordinary boat, called a *canja*, of which he says the main-sail yard was about 200 feet in length, he sailed up that river as far as Syene, visiting in the course of his voyage the ruins of Thebes, and the place where Memphis once stood, now known by the name of *Metrahenny*. Leaving Kenne on the Nile, 16th February 1769, he crossed the desert of the Thebaid to Cosseir on the Red Sea, and arrived at Jidda on the 3d of May. In Arabia Felix he remained, not without making several excursions, till the 3d of September, when he sailed from Loheia, and arrived on the 19th at Masuah, where he was detained near two months by the treachery and avarice of the Naybe of that place. It was not till the 15th of November that he was allowed to quit Arkeeko, near Masua; and he arrived on the 15th of February 1770 at Gondar, the capital of Abyssinia, where he ingratiated himself with the most considerable persons of both sexes belonging to the court. This he accomplished by being a physician in the city, a soldier in the field, a courtier everywhere, demeaning himself as conscious that he was not unworthy of being a companion to the first of their nobility, and the king's guest, which is there a character, as it was with eastern nations of old, to which a certain sort of consideration is due. "To this I may add (says he), that, being in the prime of life, of no ungracious figure, having an accidental knack, which is not a trifle, of putting on the dress, and speaking the language easily and gracefully, I cultivated, with the utmost assiduity, the friendship of the fair sex, by the most modest and respectful distant attendance and obsequiousness in public, abating just as much of that in private as suited their humours and inclination;" and jealousy being a passion unknown in Abyssinia, he thus acquired from the ladies great support at court.

Several months were employed in attendance on the king, and in an unsuccessful expedition round the lake of Dambea. Towards the end of October Mr Bruce set out for the sources of the Nile; at which long desired spot he arrived on the 14th of November; and his feelings on the accomplishment of his wishes cannot better be expressed than in his own words:

"It is easier to guess than to describe the situation of my mind at that moment; standing in that spot which had baffled the genius, industry, and inquiry, of ancients and moderns for the course of near 3000 years. Kings had attempted this discovery at the head of armies, and each expedition was distinguished from the last only by the difference of the numbers which had perished, and agreed alone in the disappointment which had uniformly, and without exception, followed them all. Fame, riches, and honour, had been held out for a series of ages to every individual of those myriads those princes commanded, without having produced one man capable of gratifying the curiosity of his sovereign, or wiping off this stain upon the enterprise and abilities of mankind, or adding this desideratum for the encouragement of geography. Though a mere private Briton, I triumphed here in my own mind over kings and their armies; and every comparison was leading nearer and nearer to the presumption, when the place itself where I stood, the object of my vain glory, suggested what depressed my short-lived triumphs."

If these triumphs were short-lived, they were equally ill-founded: for if the source of the Nile was seen by Mr Bruce, there can be no doubt of its having been likewise seen by the Portuguese jesuits. Of this we have elsewhere brought forward sufficient proof; and the candid reader, who shall take the trouble to compare the extract printed at the bottom of this page (A), with our traveller's account of these coy fountains, as it stands

(A) "In the eastern part of this kingdom, on the declivity of a mountain, whose descent is so easy that it seems a beautiful plain, is that source of the Nile which has been sought after at so much expence of labour, and about which such a variety of conjectures hath been formed without success. This spring, or rather these two springs, are two holes, each about two feet diameter, a stone's cast distant from each other. The one is about five feet and an half in depth, at least we could not get our plummet farther, perhaps because it was stopped by roots, ſtands in his own book or in our article NILE (*Encycl.*), will be convinced that it was ridiculous in Mr Bruce, and is equally ridiculous in his friends, to pretend that he *diſcovered* what had baffled the genius of inquiry for the courſe of near 3000 years.

It was not, however, the conſciouſneſs of having been anticipated by the jeſuits (for theſe he without ceremony calls a ſet of liars), but the proſpect of danger to be encountered on his return to Europe, that caſt ſuch a damp on his preſent enjoyment. "I was but a few minutes (ſays he) arrived at the ſource of the Nile, through numberleſs dangers and ſufferings, the leaſt of which would have overwhelmed me, but for the continual goodneſs and protection of Providence; I was, however, but then half through my journey, and all thoſe dangers which I had already paſſed awaited me again on my return. I found a deſpondency gaining ground faſt upon me, which blaſted the crown of laurels I had too raſhly woven for myſelf."

When he returned to reſt the night of that diſcovery, repoſe was ſought for in vain. "Melancholy reflections upon my preſent ſtate, the doubtfulneſs of my return in ſafety, were I permitted to make the attempt, and the fears that even this would be refuſed, according to the rule obſerved in Abyſſinia with all travellers who have once entered the kingdom; the conſciouſneſs of the pain that I was then occaſioning to many worthy individuals, expecting daily that information concerning my ſituation which it was not in my power to give them: ſome other thoughts, perhaps ſtill nearer the heart than thoſe, crowded upon my mind, and forbade all approach of ſleep.

"I was, at that very moment, in poſſeſſion of what had for many years been the principal object of my ambition and wiſhes; indifference which, from the uſual infirmity of human nature, follows, at leaſt for a time, complete enjoyment, had taken place of it. The marſh, and the fountains, upon compariſon with the riſe of many of our rivers, became now a trifling object in my ſight. I remembered that magnificent ſcene in my own native country, where the Tweed, Clyde, and Annan, riſe in one hill; three rivers I now thought not inferior to the Nile in beauty, preferable to it in the cultivation of thoſe countries through which they flow; ſuperior, vaſtly ſuperior, to it in the virtues and qualities of the inhabitants, and in the beauty of its flocks, crowding its paſtures in peace, without fear or violence from man or beaſt. I had ſeen the riſe of the Rhine and Rhone, and the more magnificent ſources of the Soane; I began, in my ſorrow, to treat the inquiry about the ſource of the Nile as a violent effort of a diſtempered fancy.

> 'What's Hecuba to him, or he to Hecuba,
> 'That he ſhould weep for her?'

Grief and deſpondency now rolling upon me like a torrent, relaxed, not refreſhed, by unquiet and imperfect ſleep, I ſtarted from my bed in the utmoſt agony; I went to the door of my tent, every thing was ſtill; the Nile, at whoſe head I ſtood, was not capable either to promote or to interrupt my ſlumbers, but the coolneſs and ſerenity of the night braced my nerves, and chaſed away thoſe phantoms that while in bed had oppreſſed and tormented me.

"It was true that numerous dangers, hardſhips, and ſorrows, had beſet me through this half of my excurſion; but it was ſtill as true, that another Guide, more powerful than my own courage, health, or underſtanding, if any of them can be called man's own, had uniformly protected me in all that tedious half. I found my confidence not abated, that ſtill the ſame Guide was able to conduct me to my wiſhed-for home. I immediately reſumed my former fortitude, conſidered the Nile as indeed no more than riſing from ſprings as all other rivers do, but widely differing in this, that it was the palm for 3000 years held out to all the nations of the world as a *detur digniſſimo*, which in my cool hours I had thought was worth the attempting at the riſk of my life, which I had long either reſolved to loſe, or lay this diſcovery a trophy in which I could have no competitor, for the honour of my country, at the feet of my ſovereign, whoſe ſervant I was."

How unworthy is this ranting reflection of the greatneſs of mind which Mr Bruce on other occaſions unqueſtionably diſplayed! Had he indeed been the firſt European who diſcovered thoſe pitiful holes from which the Nile is ſaid to flow, his merit would not have conſiſted in travelling from Gondar to the village Geeſh, and viewing the fountains which are at that village the objects of idolatrous adoration, but in the addreſs with which he contrived to make himſelf the favourite of all the factions which agitated a barbarous and almoſt inhuman nation. In managing thoſe factions, he was indeed great; but he ſeems to have valued himſelf more upon looking at three ſprings, of which it is far from being certain that they are the ſources of the Nile (ſee NILE in this *Suppl.*), and of which two had certainly been examined more than a century before he was born, by different miſſionaries from the kingdom of Portugal! This, however, he calls the object of his wiſhes; and

roots, for the whole place is full of trees: of the other, which is ſomewhat leſs, with a line of ten feet, we could find no bottom, and were aſſured by the inhabitants that none ever had been found. It is believed here that theſe ſprings are the vents of a great ſubterraneous lake; and they have this circumſtance to favour their opinion, that the ground is always moiſt, and ſo ſoft that the water boils up under foot as one walks upon it. Such is the ground round about theſe fountains. At a little diſtance to the ſouth is a village named *Guix* (the *Geeſh* of Mr Bruce), through which the way lies to the top of the mountain, whence the traveller diſcovers a vaſt extent of land, which appears like a deep valley, though the mountain riſes ſo imperceptibly, that thoſe who go up or down it are ſcarce ſenſible of any declivity."—*Johnſon's Tranſlation of Father Lobo's Voyage to Abyſſinia*, Chap. X.

The only difference between Lobo's and Bruce's account of theſe fountains worthy of notice is, that the former found but *two*, while the latter found *three* holes; but Bruce ſays expreſsly, that the holes are partly artificial; and Lobo's deſcription of them indicates the ſame thing. It is therefore not improbable that there may now be four or five holes.

Bruce.

and having now accompliſhed it, he bent his thoughts on his return to his native country.

He arrived at Gondar on the 19th November 1770; but found, after repeated ſolicitations, that it was by no means an eaſy taſk to obtain permiſſion to quit Abyſſinia. A civil war in the mean time breaking out (no uncommon occurrence in that barbarous country), ſeveral engagements took place between the king's forces and the troops of the rebels, particularly three actions at a place called Serbraxos on the 19th, 20th, and 23d of May 1771. In each of them Mr Bruce acted a conſiderable part; and for his valiant conduct in the ſecond received, as a reward from the king, a chain of gold, of 184 links, each link weighing $3\frac{1}{11}$ dwts. or ſomewhat more than $2\frac{1}{4}$ lbs. troy in all. At Gondar, after theſe engagements, he again preferred the moſt earneſt entreaties to be allowed to return home, entreaties which were long reſiſted; but his health at laſt giving way, from the anxiety of his mind, the king conſented to his departure, on condition of his engaging by oath (B) to return to him in the event of his recovery, with as many of his kindred as he could engage to accompany him.

After a reſidence of nearly two years in that wretched country, Mr Bruce left Gondar on the 16th of December 1771, taking the dangerous way of the deſert of Nubia, in place of the more eaſy road of Maſuah, by which he entered Abyſſinia. He was induced to take this route from his knowledge and former experience of the cruel and ſavage temper of the Naybe of Maſuah. Arriving at Teawa the 21ſt March 1772, he had the misfortune to find the Shekh Fidele of Atbara, the counterpart of the Naybe of Maſuah in every bad quality: by his intrepidity and prudence, however, and by making good uſe of his foreknowledge of an eclipſe of the moon, which happened on the 17th of April, he was permitted to depart next day, and he arrived at Sennaar on the 29th of the ſame month.

Mr Bruce was detained upwards of four months at that miſerable and inhoſpitable place; the inhabitants of which he deſcribes in theſe expreſſive words: "War and treaſon ſeem to be the only employment of theſe horrid people, whom heaven has ſeparated by almoſt impaſſable deſerts from the reſt of mankind, confining them to an accurſed ſpot, ſeemingly to give them an earneſt in time of the only other worſe which he has reſerved to them for an eternal hereafter." This delay was occaſioned by the villany of thoſe who had undertaken to ſupply him with money; but at laſt, by diſpoſing of 178 links of his gold chain, the well-earned trophy of Serbraxos, he was enabled to make preparation for his dangerous journey through the deſerts of Nubia.

He left Sennaar on the 5th of September, and arrived on the 3d of October at Chendi, which he quitted on the 20th, and travelled through the deſert of Gooz, to which village he came on the 26th of October. On the 9th of November he left Gooz, and entered upon the moſt dreadful and dangerous part of his journey; the perils attending which he has related with a power of pencil not unworthy of the greateſt maſters. All his camels having periſhed, Mr Bruce was under the neceſſity of abandoning his baggage in the deſert, and with the greateſt difficulty reached Aſſouan upon the Nile on the 29th of November.

Bruce.

After ſome days reſt, having procured freſh camels, he returned into the deſert, and recovered his baggage, among which is particularly to be remarked a quadrant (of three feet radius) ſupplied by Louis XV. from the Military Academy at Marſeilles; by means of which noble inſtrument, now depoſited in the Muſeum at Kinnaird, Mr Bruce was enabled with preciſion and accuracy to fix the relative ſituations of the ſeveral remote places he viſited.

On the 10th of January 1773, after more than four years abſence, he arrived at Cairo, where, by his manly and generous behaviour, he ſo won the heart of Mahomet Bey, that he obtained a firman, permitting the commanders of Engliſh veſſels belonging to Bombay and Bengal to bring their ſhips and merchandiſe to Suez, a place far preferable in all reſpects to Jidda, to which they were formerly confined. Of this permiſſion, which no European nation could ever before acquire, many Engliſh veſſels have ſince availed themſelves; and it has proved peculiarly uſeful both in public and private diſpatches. Such was the worthy concluſion of his memorable journey through the deſert; a journey which, after many hardſhips and dangers, terminated in obtaining this great national benefit.

At Cairo Mr Bruce's earthly career had nearly been concluded by a diſorder in his leg, occaſioned by a worm in the fleſh. This accident kept him five weeks in extreme agony; and his health was not re-eſtabliſhed till a twelvemonth afterwards, at the baths of Porretta in Italy. On his return to Europe, Mr Bruce was received with all the admiration due to ſo exalted a character. After paſſing ſome conſiderable time in France, particularly at Montbard, with his friend the Comte de Buffon, by whom he was received with much hoſpitality, and is mentioned with great applauſe, he at laſt reviſited his native country, from which he had been upwards of twelve years abſent.

It was now expected that he would take the earlieſt opportunity of giving to the world a narrative of his travels, in which the public curioſity could not but be deeply intereſted. But ſeveral circumſtances contributed to delay the publication; and what theſe were will be beſt related in his own words:

"My friends at home gave me up for dead; and as my death muſt have happened in circumſtances difficult to have been proved, my property became as it were a *hæreditas jacens*, without an owner, abandoned in common to thoſe whoſe original title extended no further than temporary poſſeſſion.

"A number of law-ſuits were the inevitable conſequences of this upon my return. To theſe diſagreeable avocations, which took up much time, were added others ſtill more unfortunate. The relentleſs ague, caught at Bengazi,

(B) With regard to this oath, Mr Bruce ſays, that he hopes the difficulty of performing it extinguiſhed the ſin of breaking it; and that, at any rate, it being merely perſonal, his engagement to return ceaſed with the death of the king, of which he received intelligence during his ſtay at Sennaar.

Bruce.

Bengazi, maintained its ground, at times, for a ſpace of more than 16 years, though every remedy had been uſed, but in vain; and what was worſt of all, a lingering diſtemper had ſeriouſly threatened the life of a moſt near relation (his ſecond wife), which, after nine years conſtant alarm, where every duty bound me to attention and attendance, conducted her at laſt, in very early life, to her grave."

Amidſt the anxiety and the diſtreſs thus occaſioned, Mr Bruce was by no means neglectful of his private affairs. He conſiderably improved his landed property, encloſing and cultivating the waſte grounds, and he highly embelliſhed his paternal ſeat, making many additions to the houſe, one in particular of a noble muſeum, filled with the moſt precious ſtores of oriental literature, large collections of drawings made, and curious articles obtained, during his far extended peregrinations. An excellent ſtratum of coal at Kinnaird drew much of his attention: he erected ſteam engines of the moſt approved conſtruction, and placed his coalery on ſuch a footing that, at the period of his deceaſe, it produced about 2000l. a-year.

The termination of ſome law-ſuits, and of other buſineſs, which had occupied much of his time, having at length afforded leiſure to Mr Bruce to put his materials in order, his greatly deſired and long expected work made its appearance in 1790, in five large quarto volumes, embelliſhed with plates and charts. It is unneceſſary, and might be tedious, to enter at preſent into any critic or analyſis of this celebrated work. It is univerſally allowed to be replete with much curious and uſeful information; and to abound in narratives which at once excite our admiration and intereſt our feelings. The very ſingular and extraordinary picture which it gives of Abyſſinian manners, ſtartled the belief of ſome; but theſe manners, though ſtrange in the ſight of an European, are little more than might be expected in ſuch a barbarous country; and had an enlightened philoſopher viſited Scotland in the times of our earlieſt monarchs, he might perhaps have witneſſed and related ſcenes, different indeed from what Mr Bruce ſaw in Abyſſinia, but which to us would have ſeemed equally ſtrange.

A more ſerious objection to the truth of Mr Bruce's narrative was ſtarted by an anonymous, but able, critic *, in an Edinburgh newſpaper, ſoon after the publication, from the account of two aſtronomical phenomena, which *could not poſſibly have happened*, as Mr Bruce aſſerts. The firſt of theſe is the appearance of the new moon at Furſhout, during Mr Bruce's ſtay in that place, which he mentions to have been from 25th December 1768 to the 7th of January 1769; and on a particular day in that interval aſſerts, that the new moon was ſeen by a fakir, and was found by the ephemerides to be three days old; whereas it is certain that the moon changed on the 8th of January 1769. The other phenomenon appears equally impoſſible. At Teawa Mr Bruce ſays he terrified the Shekh by foretelling that an eclipſe of the moon was to take place at four afternoon of the 17th of April 1772; that accordingly, ſoon after that hour, he ſaw the eclipſe was begun; and when the ſhadow was half over, told the Shekh that in a little time the moon would be totally darkened. Now, by calculation, it is certain that at Teawa this eclipſe muſt have begun at 36 minutes paſt four, and the moon have been totally covered at 33 minutes paſt five; while the ſun ſet there a few minutes paſt ſix, before which time the moon, then in oppoſition, could not have riſen: ſo that as the moon roſe totally eclipſed, Mr Bruce could not ſee the ſhadow half over the diſk, nor point it out to the Shekh. To theſe objections, which appear unſurmountable, Mr Bruce made no reply, though in converſation he ſaid he would do it in the ſecond edition of his book.

* Suppoſed to be Dr Rotheram, profeſſor of natural philoſophy in the univerſity of St Andrew's.

Theſe are miſtakes which can hardly be accounted for by attributing them to the inaccuracy of his notes, or indeed to any cauſe which we are inclined to name; and perhaps he has fallen into a miſtake of the ſame kind in his account of the enormous main-ſail yard of the *canja*, in which he ſailed up the river Nile. To every man who has but dipped into the ſcience of mechanics, it is known that a beam of wood 200 feet in length, muſt be of proportional thickneſs, or it would fall in pieces by its own weight. This thickneſs muſt be greatly increaſed, to enable it to bear the ſtrain occaſioned by a prodigious ſail filled with wind; and thoſe only who have been at the Nile, and have ſeen the canjas, can ſay, whether theſe veſſels, or indeed any veſſels which can be employed on that river, would not be overſet by yards,

——To equal which, the talleſt pine
Hewn on Norwegian hills, to be the maſt
Of ſome great admiral, were but a wand.

The language of the work is in general harſh and unpoliſhed, though ſometimes animated. Too great a diſplay of vanity runs through the whole, and the apparent facility with which the traveller gained the moſt familiar acceſs to the courts, and even to the harams of the ſovereigns of the countries through which he paſſed, is apt to create in readers ſome doubts of the accuracy of the narration. Yet there appears upon the whole ſuch an air of manly veracity, and circumſtances are mentioned with a minuteneſs ſo unlike deceit, that theſe doubts are overcome by the general impreſſion of truth, which the whole detail irreſiſtibly faſtens upon the mind. The character of Ras Michael has often ſtruck us, as containing very ſtrong internal evidence of its having been taken from nature; for it is ſuch a character, at once extraordinary and conſiſtent, as neither Mr Bruce, nor perhaps any writer ſince Shakeſpeare, had genius to feign.

The firſt impreſſion of the book being almoſt diſpoſed of, Mr Bruce had ſtipulated with an eminent bookſeller in London for a ſecond edition to be publiſhed, we think in octavo; and he was buſy in preparing that edition for the preſs when death removed him from this tranſitory ſtage. On the 26th of April 1794 he entertained ſome company at Kinnaird-houſe with his uſual hoſpitality and elegance. About eight o'clock in the evening, when his gueſts were ready to depart, he was handing one of the ladies down ſtairs, when, having reached the ſeventh or eighth ſtep from the bottom, his foot ſlipped, and he fell down headlong. He was taken up ſpeechleſs; his face, particularly the forehead and temples, being ſeverely cut and bruiſed, and the bones of his hands broken. He continued in a ſtate of apparent inſenſibility for eight or nine hours, and expired on Sunday the 27th, in the 64th year of his age.

Mr Bruce's ſecond wife, whom he married on the

Bruce.

20th May 1776, was Mary, eldest daughter of Thomas Dundas, Esq; of Carron-hall, by Lady Janet Maitland, daughter of Charles sixth Earl of Lauderdale. By that lady, who, after a severe and lingering indisposition, died in 1784, he had three children, of whom one son and one daughter survive him.

Mr Bruce's person was large, his height exceeding six feet, his bulk being in proportion to his height; and at the period when he entered on his dangerous expedition, he was equally remarkable for strength and for agility. To those who never beheld him, the engraved medallion in the title pages of the first and third volumes of his Travels will convey some idea of his features. He excelled in all manly accomplishments, being trained to exercise and fatigue of every kind. He was a hardy, practised, and indefatigable swimmer; and his long residence among the Arabs had given him a more than ordinary facility in managing the horse. In the use of fire-arms he was so unerring, that in innumerable instances he never failed to hit the mark; and his dexterity in handling the spear and lance on horseback was also uncommonly great. He was master of most languages; and was so well skilled in oriental literature, that he revised the New Testament in the Ethiopic, Samaritan, Hebrew, and Syriac, making many useful notes and remarks on difficult passages. He had applied from early youth to mathematics, drawing, and astronomy, and had acquired some knowledge of physic and surgery. His memory was astonishingly retentive, and his mind vigorous. He was dexterous in negociation, a master of public business, and animated with the warmest zeal for the glory of his king and country. Such, at least, is *his own* representation of his character; and though an impartial judge would probably make considerable abatement for the natural bias of a man drawing his own portrait, yet it cannot be denied, that in personal accomplishments Mr Bruce equalled, if not exceeded, most of his contemporaries.

Thus accomplished, he could not but be eminently fitted for an attempt so full of difficulty and danger as what he called the discovery of the sources of the Nile: no one who peruses his account of the expedition, can fail to pay an unfeigned tribute of admiration to his intrepidity, manliness, and uncommon dexterity, in extricating himself out of situations the most dangerous and alarming, in the course of his long and hazardous journey; not to mention his conduct during his residence in Abyssinia, his behaviour at Masuah, Teawa, and Sennaar, evinces the uncommon vigour of his mind: but it was chiefly during his passage through the Nubian desert, that his fortitude, courage, and prudence, appeared to the greatest advantage. Of his learning and sagacity, his delineation of the course of Solomon's fleet from Tarshish to Ophir, his account of the cause of the inundations of the Nile, and his comprehensive view of the Abyssinian history, afford ample proofs. It must indeed be confessed, that in his account of the inundations of the Nile, as well as in his delineation of the course of Solomon's fleet, he has not the merit of originality; but on both these occasions he has stated the hypothesis which he maintains with greater clearness, and supported it with more plausible arguments, than any other author whose writings have fallen into our hands; and it was surely to his honour, that as soon as he learned that his hypothesis respecting Ophir and Tarshish had been controverted by Dr Doig of Stirling, he earnestly courted the acquaintance of that eminent scholar.

Bruce, Buck-wheat,

After his return to his own country, he resided mostly at Kinnaird; and till he became corpulent, spent much of his time in the various sports of the field, in which he engaged with great ardour. Though studious in youth, and at all times a stranger to intemperance and dissipation, he read but little in his later years; and seemed to find his chief pleasure in conversation, especially the conversation of well-informed ladies. In his friendships he sometimes appeared to be capricious, attaching himself to men in whose heads and hearts no other person could perceive a charm for a mind like his. Though in his own dealings he was always just and honourable, he was too ready to apprehend unfairness in others, and to express such apprehensions with undue warmth. To strangers he was often arrogant, and sometimes insolent; but in his own family he was an affectionate husband, a kind father, an agreeable entertainer, and to his servants a master perhaps too indulgent. In conversation, as well as in his writings, he embraced every opportunity of expressing a deep and lively sense of the care of a superintending Providence, without which he was convinced that there could be no safety in human strength or human foresight. His belief of the Christian religion rested on the surest grounds; and such was his veneration for the sacred writings, that for some years before his death they seemed to occupy all the time which he gave to study. He read no sermons, however elegant; and dissuaded others from such reading. "Read the Bible (said he), and you will soon perceive the emptiness of the most applauded sermons."

BUCK-WHEAT, a species of POLYGANUM (see that article *Encycl.*), was first introduced into Europe about the end of the 15th or the beginning of the 16th century. According to some botanists, who lived at that period, its native country is the northern parts of Asia, whence it was brought to Germany and France, where, about the year 1587, it was the common food of the poor.

A new species of this grain, or, to speak perhaps more properly, a variety of this species, has been for some time known under the name of *Siberian* buck-wheat, which appears to have considerable advantages over the former. It was sent from Tartary to St Petersburgh by the German botanists, who travelled thro' that country in the beginning of the present century; and it has thence been dispersed over all Europe. Linnæus received the first seeds of it in 1737 from Garber the botanist, and described the plant in his *Hortus Cliffertionus*. After this it was mentioned by Ammann in 1739: but it must have been earlier known in Germany; for in 1733 it was growing in the garden of Dr Ehrhart at Memmingen. In Siberia this plant sows itself for four or five years by the grains that drop; but at the end of that period the land becomes so full of tares that it is choked, and must be sown afresh. Even in the economical gardens of Germany, it is propagated in the same manner; and in that country it is in some places found growing wild, though it is nowhere cultivated in the neighbourhood. It is not, however, indigenous, otherwise Ehrhart might have raised it from German seed, which it seems he could not find in 1733. See

Bulam. See much curious information concerning this plant in Professor Beckmann's *Hiſtory of Inventions and Diſcoveries*.

BULAM, or Bulama, as it is more uſually called, forms part of the Archipelago, or cluſter of iſlands, lying on the weſtern or windward coaſt of Africa, and known by the name of the *Biſſaos* or *Biſſagos*, which are ſuppoſed to have been celebrated by the ancients under the appellation of the *Heſperides*. It is ſituated at the mouth of the Rio Grande, in 11° N. Lat. and 15° W. Long. from the meridian of London; and is between ſeventeen and eighteen leagues long, and from four to five broad.

This iſland has become an intereſting object to the inhabitants of Great Britain, in conſequence of its having been purchaſed in the year 1792 by a ſociety inſtituted for the ſame humane purpoſes with thoſe which gave riſe to the Sierra-Leona company (see Sierra-*Leona*, Encycl.) The Bulam aſſociation was formed towards the latter end of the year 1791; and they were induced to pitch upon that iſland as the moſt eligible tract for their intended colony, in conſequence of the flattering deſcription given of its climate, ſoil, and harbours, by M. Brue, formerly director-general of the French African companies.

The gentlemen originally appointed as truſtees for managing the concerns of the aſſociation at home were, *Paul Le Meſurier*, M. P.; *James Kirkpatrick*, Eſq; *George Hartwell*, Eſq; *Moſes Ximenes*, Eſq; *Sir John Riggs Miller*, Bart. and *David Scott*, Eſq. M. P.; and for eſtabliſhing the colony, and conducting the affairs of the ſociety abroad, the following gentlemen were nominated, viz. *Meſſrs H. H. Dalrymple*, *John Young*, *Sir William Halton*, Bart. *John King*, *Philip Beaver*, *Peter Clutterbuck*, *Nicholas Bayly*, *Francis Brodie*, *Charles Drake*, *John Paiba*, *Richard Hancorne*, *Robert Dobbins*, and *Iſaac Ximenes*.

A ſum of L. 9000 being quickly ſubſcribed for the eſtabliſhment of the intended colony, this committee ſailed from Spithead in three ſhips on the 11th of April 1792; and landing in due time at Bulama, they purchaſed that iſland from the kings of Canabac, who claimed it as their property. They purchaſed likewiſe from the kings of Ghinala the neighbouring iſland Arcas, and the adjacent land on the continent; and theſe ſeveral purchaſes being taken poſſeſſion of in the uſual form, a body of ſettlers, conſiſting of 49 men, 13 women, and 25 children, were left at Bulama under the ſuperintendence of Mr Beaver, with a temporary ſupply of proviſions, ſtores, plantation-tools, and merchandiſe, for trading with the neighbouring natives. It is from the diſpatches of theſe ſettlers, after having lived ſome time in Bulama, that the following account of the iſland was drawn up by Mr Johanſen.

"The climate, on the whole, may be deemed ſalubrious, and will become more ſo in proportion to the increaſe of cultivation. The mornings and evenings are temperate and pleaſant; the middle of the day is hot, but the fine ſea breeze which then ſets in tends greatly to cool and refreſh the air. The heat of the ſun is not either ſo exceſſive or intolerable as has been generally ſuppoſed: indeed nature has moſt admirably adapted our mechanical and phyſical qualities to the exigencies of different regions; and man, who is the inhabitant of every climate, may, in ſome meaſure, render himſelf indigenous to every ſoil. Here the only danger ariſes from too ſudden an expoſure to the operation of the vertical rays of the ſun, or an exceſs of labour; both of which the firſt ſettlers ought moſt ſtudiouſly to avoid.

"It appears from Mr Beaver's obſervations at noon, between the 20th of July 1792, and the 28th of April 1793, that the thermometer, when loweſt, was at 74; the medium heat 85; and that it never exceeded 96, except at one time when it roſe to 100, during a calm that occurred in the interval between the north-eaſt breeze in the morning and the ſouth-weſt in the evening of the 19th of February 1793. The difference between the heat of noon and that of the morning and evening is from 20 to 30 degrees. On the 23d of October 1792, hail of the ſize of a pin's head fell during two minutes, although not a cloud was to be ſeen during this phenomenon. The mercury in the thermometer then ſtood at 85; the wind was at north-eaſt in the morning and ſouth-weſt in the evening.

"Immediately after ſun-ſet a dew conſtantly begins to fall, which induces ſome to light a fire in their houſes; they at the ſame time put on warmer clothing. There is little or no twilight; and night and day are nearly equal: the earth has therefore time to cool during twelve hours abſence of the ſun.

"None of thoſe terrible and deſtructive hurricanes ſo frequently experienced in the Weſt Indies are to be met with here. The *tornadoes*, which ariſe chiefly from the eaſtern point of the compaſs, are but of ſhort duration, ſeldom laſting above an hour, and may be readily foreſeen ſome time previouſly to their commencement. They occur at the beginning and cloſe of the wet ſeaſon, and are highly beneficial, as they purify the air, and diſpel the noxious vapours with which it would otherwiſe abound.

"The rains ſet in about the latter end of May or the beginning of June, and diſcontinue in October or November. They do not fall every day, for there is often a conſiderable interval of clear weather, during which the atmoſphere is beautifully ſerene; the ſhowers in the firſt and laſt month occur but ſeldom, and are far from being violent; while, on the other hand, they ſometimes reſemble torrents, more eſpecially towards the middle of the ſeaſon. During the whole of this period, Europeans ſhould, if poſſible, confine themſelves to their habitations, as the rains prove injurious to health, more eſpecially if thoſe expoſed to them neglect to wipe their bodies dry, and to change their clothes immediately on their return home. It is deemed prudent alſo not to dig the earth until the expiration of a month after the return of fair weather, as this is conſidered to be unhealthy.

"During the continuance of the dry ſeaſon, a dew falls during the night, in ſufficient quantity to anſwer all the purpoſes of vegetation.

"Every ſtranger is generally here, as well as in the Weſt Indies, ſubject to a fever or *ſeaſoning* on his arrival. This is not infectious; it proceeds perhaps from an increaſed perſpiration and a ſudden extenſion of the pores of the human body, in conſequence of the heat, by which means it is rendered more liable to imbibe the abundant exhalations that ariſe from the animal, vegetable, and mineral kingdoms; but even this, ſlight as it is, might doubtleſs be avoided by means of a proper regimen, and a ſhort ſecluſion from the full action of the

Bulam.

the open air, more especially at noon, and during the evening, until the climate has been rendered familiar.

" Bulama is admirably adapted for all the purposes of an extensive commerce, being not only happily situated at the mouth of the Rio Grande, but in the vicinity of several other navigable rivers; so that a trade with the internal parts of Africa is thereby greatly facilitated. The landing is remarkably easy and safe, there being no surge; the ebb and flow is regular, and there is an increase of 16 feet of water at spring tide. The bay opposite the Great Bulama is adorned with a number of islands, covered with trees, and forms a most excellent harbour, sufficiently capacious to contain the whole navy of Great Britain, which might ride there in safety. The settlement in general is well supplied with water. A number of springs have been lately discovered in different places; and besides a draw-well in the fort, which was erected for the defence of the colony, there is a small stream, which runs into Elewsis Bay, near the new settlement called Hesper Elewsis: this is admirably situated for the supply of shipping.

" The island is beautifully surrounded, and interspersed with woods: lofty fruit and forest trees, mostly free from underwood and brambles, form a verdant belt, in some places two or three miles broad, which entirely encircles it, in such a manner as to represent a plantation artificially formed around a park. Within this the fields are regularly divided by trees, so as to resemble the hedge-rows in England. The beach has in some places the appearance of gravel walks; it is fringed with mangrove trees, which forming a line with the high-water mark, dip their branches into the sea, and thus afford nourishment to the oysters that often adhere to their extremities.

" Several parts of Bulama have been occasionally cultivated by the neighbouring blacks, though they did not constantly reside on it.

" The land in general rises gradually towards the middle of the island, where the highest spot is from 60 to 100 feet above the level of the sea. The small hill on which the fort is situated is nearly of the same altitude.

" The soil is abundantly rich and deep; stones do not here impede the labours of the farmer; and indeed none have hitherto been discovered, but a small sort, resembling pieces of ore, which are to be met with on the shore. There are many *savannahs* or natural meadows, so extensive that the eye can scarcely descry their boundaries. These are admirably adapted for the rearing of stock and feeding of cattle of every kind.

" Cotton, indigo, rice, and coffee, grow spontaneously on this coast; the sugar-cane is indigenous to many parts of Africa, and might be cultivated here by the labour of freemen, in equal perfection, and to much greater advantage, than in the exhausted islands of the West Indies. All kinds of tropical productions, such as pine-apples, limes, oranges, grapes, plums, cassada, guava, Indian wheat, the papaw, water-melon, musk-melon, the pumpkin, tamarind, banana, and numbers of other delicious fruits, also flourish here. The adjoining territories produce many valuable sorts of spices, gums, and materials for dyeing: all of which it is but fair to suppose, might be readily cultivated in a kindred climate and a congenial soil.

Bulam.

" The neighbouring seas abound with a variety of fish, highly agreeable to the palate. The lion, tyger, jackall, &c. are natives of the continent; but in Bulama no animals have been discovered, the wolf, some buffaloes, a few elephants, and a species of the deer, excepted.

" The woods abound with doves, guinea-fowls, and a variety of birds, celebrated for the beauty of their plumage.

" The natives of this part of Africa, like all savages, are entirely under the dominion of their passions: hence the violence of their attachment to their friends, and the excess of their resentment against their enemies. Their notions of property are very obscure and confused: they have no idea of any right arising from occupancy or improvement. What they want, they either receive or take wherever they may happen to meet with it, and they permit others to do the same. They have been taught by experience that the Europeans will not agree to this: against them therefore they employ every artifice that it is in the power of cunning to suggest.

" The colonists need not fear any attack on the part of the negroes, provided their own conduct be just and peaceable: for Mr Beaver, who was indeed admirably calculated by nature and habit for the station he occupied, could ensure both safety and respect when the settlers under him were reduced to four white men, although the neighbouring nations knew that he was in possession of commodities, for the acquisition of which many of them had become day-labourers. He often kept from twenty to forty gromittos, or black cultivators in pay, at that very period, at about four or five bars (A) each per month. These are easy to be procured, to almost any number that can possibly be wanted.

" Until a sufficient quantity of stock and provisions can be raised in the company's settlements, the adjacent islands will furnish abundance of cattle, hogs, fowls, &c. at a very cheap rate. A horse may be purchased at Goree for 1l. 10s. a bullock may be had from 12s. to 18s. sterling: provisions of all kinds are equally reasonable. Honey is also to be procured in great plenty, and bees-wax may be rendered an advantageous object of commercial speculation.

" In short, the acquisition of Bulama, Arcas, and the adjacent territories, presents the fairest opportunity of furnishing Europe with many valuable articles that have hitherto been brought from more remote countries, with much greater hazard, and at an increased expence. The intercourse with England is easy, safe, and expeditious; for the voyage may be performed in the space of three or four weeks: and by the terms of the first subscription, a settler on Bulama might purchase 500 acres of land for L. 30 Sterling; by the terms of the second, which we suppose are the terms at present, he might purchase on the islands of Bulama and Arcas, or on that part of the adjacent coast which was ceded to the society by the kings of Ghinala, 200 acres for L. 50 sterling.

" The

(A) A bar is about the value of three shillings and sixpence.

"The colonization of Africa opens a noble and extensive field to nations and to individuals. To people those fertile territories, despoiled of their inhabitants by the slave-trade; to rear the productions of the climes between the tropics, by the assistance of free men; to give ample scope to the industry and exertions of those who may be inclined to remove from Great Britain; and to extend the commerce and the manufactures of our native country—these are subjects which have excited the attention of the Bulama association, and now claim the assistance of the ingenious, the support of the rich, and the concurrence and good wishes of all."

BUNTING, is a bird which has been described under its generic name EMBERIZA (*Encycl.*); but there is one species, the *orange shouldered bunting* of Latham, of which M. Vaillant relates some particulars certainly not unworthy of notice in this place.

"The female of this beautiful bird (says he) has the simple colours of the sky-lark, and a short horizontal tail, like that of almost all other birds: the male, on the contrary, is wholly black except at the shoulder of the wing, where there is a large red patch; and his tail is long, ample, and vertical, like that of the common cock. But this brilliant plumage and fine vertical tail subsist only during the season of love, which continues six months. This period over, he lays aside his splendid habiliments, and assumes the more modest dress of his mate. The most extraordinary circumstance is, that the vertical tail also changes to a horizontal one, and the male so exactly resembles the female, that it is not possible to distinguish them from each other.

"The female has her turn. When she reaches a certain age, and has lost the faculty of propagating the species, she clothes herself for the remainder of her days in the garb which the male had temporarily assumed; her tail, like his at that period, grows long, and, like his also, from horizontal becomes vertical.

"The birds of this species associate together, live in a sort of republic, and build their nests near to each other. The society usually consists of about fourscore females; but, whether by a particular law of nature, more females are produced than males, or for any other reason of which I am ignorant, there are never more than twelve or fifteen males to this number of females, who have them in common."

According to our author, this transmutation is by no means confined to this particular species of bunting. Many females of the feathered creation, when they grow so old as to cease laying eggs, assume the more splendid colours of the male, which they retain during the remainder of their lives. This fact is strikingly perceptible in those species in which the male and female very much differ in colour, as the golden pheasant of China, for instance. In some species, and those not a few, the male alone regularly changes his colour, and assumes once in a year the plumage of the female; so that at a certain period all the birds of that species appear females. "I have in my possession (says our author) specimens of more than fifty of those changing species, in all their transitions from one hue to another; and the change is sometimes so great, that a person would suppose himself to see individuals totally different. A closet-naturalist, for instance, shewed me four birds as so many different species, and even as not belonging to the same genus, with which I was well acquainted, and which I knew to be the same bird, only of different ages."

Such changes as these, could they be proved to take place occasionally among domestic fowls, would in some measure account for strange stories of cocks laying eggs, which we have heard related by persons whose general veracity was never questioned.

BURKE (Edmund), was born in the city of Dublin on the 1st of January 1730. His father was an attorney of considerable knowledge in his profession, and of extensive practice; and the family from which he sprung was ancient and honourable. He received the rudiments of his classical education under Abraham Shackleton, a Quaker, who kept a private school or academy, as it has been called, at Bellytore, near Carlow, and is said to have been a very skilful and successful teacher.

Under the tuition of this master, Burke devoted himself with great ardour, industry, and perseverance, to his studies; and manifested, even from his boyish days, a distinguished superiority over his contemporaries. He was the pride of his preceptor, who prognosticated every thing great from his genius, and who was, in return, treated by his illustrious pupil, for forty years, with respect and gratitude.

From school Burke was sent to Trinity-college, Dublin, where it was asserted by Goldsmith and others his contemporaries, that he displayed no particular eminence in the performance of his exercises. Like Swift, he despised the logic of the schools; and like him too, he devoted his time and his talents to more useful pursuits. Johnson, though proud of being an Oxonian, did not much employ himself in academical exercises; and Dryden and Milton, who studied at Cambridge, were neither of them ambitious of college distinctions. Let not, however, the example of a Burke, a Johnson, a Dryden, or a Milton, seduce into by-paths the ordinary student; for though great genius either finds or makes its own way, common minds must be content to pursue the beaten track. Shakespeare, with very little learning, was the greatest dramatic poet that ever wrote; but how absurd would it be to infer from this fact, that every illiterate man may excel in dramatic poetry?

Whilst at college Burke applied himself with sufficient diligence to those branches of mathematical and physical science which are most subservient to the purposes of life; and though he neglected the syllogistic logic of Aristotle, he cultivated the method of induction pointed out by Bacon. Pneumatology, likewise, and ethics, occupied a considerable portion of his attention; and whilst attending to the acquisition of knowledge, he did not neglect the means of communicating it. He studied rhetoric and the art of composition, as well as logic, physics, history, and moral philosophy; and had at an early period of his life, says Dr Bisset, planned a confutation of the metaphysical theories of Berkeley and Hume.

For such a task as this, we do not think that nature intended him. Through the ever-active mind of Burke ideas seem to have flowed with too great rapidity to permit him to give that patient attention to minute distinctions, without which it is vain to attempt a confutation of the subtleties of Berkeley and Hume. The ablest antagonist of these two philosophers was remarkable for patient thinking, and even *apparent* slowness of apprehension;

apprehension; and we have not a doubt, but that if he had possessed the rapidity of thought which characterised Burke, his confutation of Hume and Berkeley would have been far from conclusive. It might have been equal to the *Essay on the Nature and Immutability of Truth*, but would not have been what we find it in *The Inquiry into the Human Mind on the Principles of Common Sense*, and in *The Essays on the Intellectual and Active Powers of Man*.

A task much better suited to Burke's talents than the writing of metaphysical disquisitions on the substratum of body, presented itself to him in the year 1749, and a task which was likewise more immediately useful. At that period one Lucas, a democratic apothecary, wrote a number of very daring papers against government, and acquired by them as great popularity at Dublin as Mr Wilkes afterwards obtained by his North Briton in London. Burke, though a boy, perceived, almost intuitively, the pernicious tendency of such levelling doctrines, and resolved to counteract it. He wrote several essays in the style of Lucas, imitating it so exactly as to deceive the public; pursuing his principles to consequences necessarily resulting from them, and shewing at the same time their absurdity and their danger. Thus was his first literary effort, like his last, calculated to guard his country against anarchical innovations.

Whilst employed in treasuring up knowledge, which at a future period was to command the admiration of listening senates, he did not neglect the means necessary to render himself agreeable in the varied intercourse of private life. To the learning of a scholar he added the manners of a gentleman. His company was sought among the gay and the fashionable, for his pleasing conversation and easy deportment; as much as among the learned, for the force and brilliancy of his genius, and the extent and depth of his knowledge. But though the object of very general regard in his native country, he had hardly any prospect of obtaining in it an independent settlement. He therefore applied, some time after the publication of his letters exposing the doctrines of Lucas, for the professorship of logic, which had then become vacant in the university of Glasgow: but whether that application was made too late, or that the university was unwilling to receive a stranger, certain it is that the vacant chair was filled by another, and that Burke was disappointed of an office in which he was eminently qualified to excel. For many years very little attention has been paid in the universities of Scotland, perhaps even too little, to the Aristotelian logic; and the professors, instead of employing their time in the analysing of syllogisms, deliver lectures on rhetoric and the principles of composition—lectures which no man was more capable of giving than the unsuccessful candidate for the professorship in Glasgow.

Disappointment of early views has frequently been the means of future advancement. Had Johnson become master of the Staffordshire school, talents might have been consumed in the tuition of boys which Providence formed for the instruction of men; and had Burke obtained the professorship of logic in Glasgow, he would have been the most eloquent lecturer in that university, instead of the most brilliant speaker in the British senate: but whether his talents might not have been as usefully employed in the university as in the senate, may perhaps be a question, though there can be no question whether they would have invested himself with an equal blaze of splendour.

Disappointed in Glasgow, he went to London, where he immediately entered himself of the Temple; and as there is reason to believe that he was in straitened circumstances, he submitted to the drudgery of regularly writing for daily, weekly, and monthly publications, essays on general literature and particular politics. The profits arising from such writings were at first small; but they were so necessary to their author, that the intense application which they required gradually impaired his health, till at last a dangerous illness ensued, when he resorted for medical advice to Dr Nugent, a physician whose skill in his profession was equalled only by the benevolence of his heart. The Doctor, considering that the noise, and various disturbances incidental to chambers, must retard the recovery of his patient, furnished him with apartments in his own house, where the attention of every member of the family contributed more than medicines to the restoration of his health. It was during this period that the amiable manners of Miss Nugent, the Doctor's daughter, made a deep impression on the heart of Burke; and as she could not be insensible to such merit as his, they felt for each other a mutual attachment, and were married soon after his recovery.

Hitherto his mental powers and acquirements were known in their full extent only to his friends and more intimate companions; but they were now made public in his first acknowledged work, intitled, *A Vindication of Natural Society*. The object of this performance was to expose the dangerous tendency of Lord Bolingbroke's philosophy. By the admirers of that nobleman, his principles were deemed inimical only to revealed religion and national churches, which they would have been glad to see overturned, provided our civil establishment had been preserved; and to the civil establishment they perceived no danger in the writings of the author of *The Patriot King*. Mr Burke thought very differently; and endeavoured to convince them, that if his Lordship's philosophy should become general, it would ultimately destroy their rank, their consequence, and their property, and involve the church and state in one common ruin. In his ironical attack upon artificial society, he makes use of the same common place mode of unfair reasoning which his noble antagonist had employed against religion and religious establishments. He argues, from the incidental abuses of political society, that political society must itself be evil; he goes over every form of civil polity, pointing out its defects in the most forcible language; and, in perfect imitation of the sceptical philosophy, he pulls them all down, one after another, without proposing any thing in their stead. So complete is the irony, that to many not acquainted with such disquisitions, he would appear to be seriously inveighing against civil government; and we have actually heard some of the advocates for modern innovation mention this work as a proof how different Mr Burke's opinions in politics once were from what they appear to have been when he wrote his *Reflections on the French Revolution*.

The truth, however, is, that there is no inconsistency between *The Vindication of Natural Society* and the latest publications of its illustrious author. At the period

Burke.

riod when that work was published, infidelity had infected only the higher orders of men, and such of the lower as had got the rudiments of a liberal education. Of these we believe a single individual was not then to be found, who supposed that society could subsist both without government and without religion; and therefore while they laboured to overturn the church, and to prove that Christianity itself is an imposture, they all pretended to be zealously attached to our civil government as established in king, lords, and commons. Except the clergy of the established church, there was no order of men whom they indiscriminately reviled. Hence it was that not Burke only, but Warburton, and almost every other opponent of Lord Bolingbroke, began their defences of revelation, by shewing the indissoluble connection between our civil and ecclesiastical establishments; and all the difference was, that he did, through the medium of the most refined irony, the very same thing which they had done by serious reasoning.

Soon after his *Vindication of Natural Society*, Burke published *A Philosophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful*; a work which soon made its author universally known and admired, and which has been studied by every English reader of taste. It is therefore needless for us to hazard any opinion either of its general merit or its particular defects. In one of the literary journals of that day, Mr Murphy urged objections against some of its fundamental principles, which, in our opinion, it would be very difficult to answer; whilst Johnson, who was certainly a severe judge, considered it as a model of philosophical criticism. "We have (said he) an example of true criticism in Burke's Essay on the Sublime and Beautiful. There is no great merit in shewing how many plays have ghosts in them, or how this ghost is better than that; you must shew how terror is impressed on the mind."

In consequence of this manifestation of Burke's intellectual powers, his acquaintance was courted by men of distinguished talents, and, among others, by Johnson and Sir Joshua Reynolds. The literary club which has been mentioned (*Encycl.*) in the life of Johnson, was instituted for their entertainment and instruction, and consisted at first of Johnson, Burke, Reynolds, Goldsmith, Dr Nugent, Mr Topham, Beauclerk, Sir John Hawkins, Mr Chamier, and Mr Bennet Langton, who were all men of letters and general information, though far above the rest stood Burke and Johnson. Of Burke indeed Johnson declared, upon all occasions, that he was the greatest man living; whilst Burke, on a very solemn occasion, said of Johnson, "He has made a chasm, which not only nothing can fill up, but which nothing has a tendency to fill up. Johnson is dead. Let us go to the next best—There is nobody—No man can be said to put you in mind of Johnson." Nor was the opinion which these two illustrious men held of each other's powers peculiar to themselves alone: all the members of the club observed, that in colloquial talents they were nearly matched, and that Johnson never discoursed with such animation and energy as when his powers were called forth by those of Burke.

Some years before the institution of this club, Burke, who had devoted much of his time to the study of history and politics, proposed to Mr Dodsley, an eminent bookseller, a plan of an Annual Register of the civil, political, and literary transactions of the times; and the proposal being acceded to, the work was begun and carried on for many years, either by Burke himself, or under his immediate inspection. It bears indeed internal marks of his genius, his learning, and his candour, being by much the most elegant and impartial periodical history which has perhaps appeared in any age or nation. Even when the heat of opposition made him, in his speeches, sometimes misrepresent the conduct of administration, the Annual Register, under his management, continued to render justice to all parties.

He still continued to write occasionally political essays for other publications than the Annual Register; and some of these essays in the *Public Advertiser* having attracted the notice of the Marquis of Rockingham, that nobleman sought the acquaintance of their author. It was in the year 1765 that the first interview took place between them; and the Marquis, who was then at the head of the treasury, offering to make Burke his own secretary, the offer was readily accepted. On this occasion he gave a remarkable proof of disinterestedness and delicate integrity. Through the influence of Mr Hamilton, known by the appellation of *Single Speech* Hamilton, and long suspected to be the author of *Junius's Letters*, he had some time before obtained a pension of L.300 a-year on the Irish establishment; but this pension he now thought it incumbent upon him to resign, because he had connected himself with a party opposite in many things to the party whose measures were supported by his friend.

During the Rockingham administration he was chosen member of Parliament for the borough of Wendover in the county of Bucks; and he prepared himself for becoming a public speaker, by studying, still more closely than he had yet done, history, poetry, and philosophy; and by storing his mind with facts, images, reasonings, and sentiments. He paid great attention likewise to parliamentary usage; and was at much pains to become acquainted with old records, patents, and precedents, so as to render himself complete master of the business of office. That he might communicate without embarrassment the knowledge which he had thus laboriously acquired, he frequented, with many other men of eminence, the Robin Hood Society, where he practised the replies and contentions of eloquence; and to acquire a graceful action, with the proper management of his voice, he was a very diligent observer of Garrick in Drury-Lane theatre. He procured his seat in 1765, and in the ensuing session delivered his maiden speech; which was such a display of eloquence as excited the admiration of the House, and drew very high praise from its most distinguished member Mr Pitt, afterwards Earl of Chatham.

The principal objects which engaged the attention of the Rockingham administration were the ferments in America, which was then in a state little short of rebellion, on account of the famous stamp-act. Parliament was divided in opinion respecting that measure. Whilst Mr Grenville and his party (under whose auspices the stamp-act had passed into a law) were for enforcing obedience to it by coercive measures, Mr Pitt and his followers denied that the parliament of Great Britain had a right to tax the Americans; and the marquis of Rockingham, who was hardly able to carry any measure in opposition to both these parties, had to consider,

Burke.

ſider, on this occaſion, whoſe ſentiments he would adopt. By the advice, it is ſaid, of Mr Burke, he choſe a middle courſe between the two oppoſite extremes. To gratify the Americans, he repealed the ſtamp-act; and to vindicate the honour of Britain, he got a law paſſed declaratory of her right to legiſlate for America in taxation as in every other caſe.

This meaſure, whoever was its author, was certainly not the offspring either of wiſdom or vigour. If the mother-country had a right to legiſlate in all caſes for America, obedience to the ſtamp-act ſhould certainly have been enforced; and the miniſtry which relinquiſhed an acknowledged right, to gratify the factious diſpoſition of diſtant colonies, was obviouſly unfit to guide the helm of a great empire. Lord Rockingham and his friends were accordingly diſmiſſed from office; and a new adminiſtration was formed under the auſpices of Mr Pitt, now created earl of Chatham.

Burke, in the mean time, wrote in defence of the party with which he was connected; and aſſumed great credit to it for compoſing the diſtractions of the Britiſh empire by the repeal of the American ſtamp-act, whilſt the conſtitutional ſuperiority of Great Britain was preſerved by the act for ſecuring the dependence of the colonies. After defending his friends, he proceeds to attack thoſe who had ſucceeded them in office. Of Lord Chatham he ſays—"He has once more deigned to take the reins of government into his own hand, and will, no doubt, drive with his wonted ſpeed, and raiſe a deal of duſt around him. His horſes are all matched to his mind; but as ſome of them are young and ſkittiſh, it is ſaid he has adopted the new contrivance lately exhibited by Sir Francis Delaval on Weſtminſter bridge: whenever they begin to ſnort and toſs up their heads, he touches the ſpring, throws them looſe, and away they go, leaving his lordſhip ſafe and ſnug, and as much at his eaſe as if he ſat on a woolpack."

The letter, of which this is an extract, was printed in the Public Advertiſer; and is ſaid to have contributed, in no ſmall degree, to leſſen the popularity of the illuſtrious ſtateſman againſt whom it was written. The miniſtry, indeed, which he had formed, conſiſted of very heterogeneous materials, and was not heartily approved of by the nation. It therefore ſoon fell in pieces by its own diſcord, and Lord Chatham retired in diſguſt.

The parliament being diſſolved in 1768, Burke was re-elected for Wendover, and took his ſeat, when the houſe met, in November. The duke of Grafton was now prime miniſter, and was oppoſed by two powerful parties in parliament; that of the marquis of Rockingham, and that of which Mr Grenville was conſidered as the leader. Theſe two parties, however, differed widely between themſelves. Mr Grenville had publiſhed a pamphlet, intitled, *The Preſent State of the Nation;* in which he very ably vindicated his own meaſures, and of courſe condemned the meaſures of thoſe who had ſucceeded him; and Burke replied to him, with greater eloquence, but perhaps with leſs of argument, in a tract, intitled, *Obſervations on the Preſent State of the Nation*, in which he makes a very high panegyric on his own patron, and the connections of the party, and animadverts with cutting ſeverity on their ſucceſſors in office.

About this period commenced the national frenzy which was excited by the expulſion of Wilkes from the houſe of commons, *for having printed and publiſhed a ſeditious libel, and three obſcene and impious libels.* In the controverſy to which this tranſaction gave riſe, Burke and Johnſon took oppoſite ſides. Johnſon, in his *Falſe Alarm*, contends, with great ability, that the expulſion of a member from the houſe of commons for the commiſſion of a crime, amounts to a diſqualification of that member from ſitting in the parliament from which he is expelled; whilſt Burke, though he diſapproved of the conduct of Wilkes as much as his friend, laboured to prove, that nothing but an act of the legiſlature can diſqualify any perſon from ſitting in parliament who is regularly choſen, by a majority of electors, to fill a vacant ſeat. It does not appear that this difference of opinion produced the ſmalleſt abatement of mutual regard between him and Johnſon. They both attended the weekly club, and were as much pleaſed with each other as formerly.

The proceedings of the Grafton adminiſtration, reſpecting Wilkes and other ſubjects, gave riſe to the celebrated *Letters of Junius.* That thoſe compoſitions were, in clearneſs, neatneſs, and preciſion of ſtyle, infinitely ſuperior to perhaps every other ſeries of newſpaper invectives, has never been controverted; and that they diſplay a vaſt extent of hiſtorical and political information, is known to all who are not themſelves ſtrangers to the hiſtory of this kingdom. Unclaimed by any author, and ſuperior to the productions of moſt authors, they have been given to Burke, to his brother Richard, a man likewiſe of very bright talents, to Mr Hamilton, and to Lord George Germaine. We ſhould hardly heſitate to adopt the opinion of thoſe who aſcribe them to Burke, had he not diſavowed them to his friend Johnſon. "I ſhould have believed Burke to be Junius (ſaid Johnſon), becauſe I know no man but Burke who is capable of writing theſe letters; but Burke *ſpontaneouſly* denied it to me. The caſe would have been different had I *aſked* him if he was the author. A man may think he has a right to deny when ſo queſtioned as to an anonymous publication." The difference between the ſtyle of theſe letters and that of Burke's acknowledged writings, would have had no weight with us; becauſe ſuch was his command of language, that he could aſſume, and occaſionally did aſſume, any ſtyle which he choſe to imitate. He had already ſo cloſely imitated the very different ſtyles of Lucas and Bolingbroke as to deceive the public; and what was to hinder him from imitating the ſtyle of Lord George Germaine, which certainly has a ſtrong reſemblance to that of Junius? We think, however, with Johnſon, that his *ſpontaneous diſavowal* of theſe letters ought to be held as ſufficient proof that he was not their author.

Burke had now gotten a very pleaſant villa near Beaconsfield in Buckinghamſhire; and being one of the freeholders of the county, he drew up a petition to the king, complaining of the conduct of the houſe of commons reſpecting the Middleſex election, and praying for a diſſolution of the parliament. The petition, though explicit and firm, was temperate and decorous, and as unlike to one on the ſame ſubject from the livery of London, as the principles of a moderate Whig are to thoſe of a turbulent democrate.

About

Burke.

About this period he stated very clearly his own political principles in a pamphlet intitled, "Thoughts on the Causes of the Present Discontents;" and his plan for removing these discontents had not a grain of democracy in its composition. He proposed to place the government in the hands of an open aristocracy of talents, virtue, property, and rank, combined together on avowed principles, and supported by the approbation and confidence of the people; and the aristocracy which he thought fittest for this great trust, was a combination of those Whig families which had most powerfully supported the revolution and consequent establishments. He expressed, in strong terms, his disapprobation of any change in the constitution and duration of parliament; and declared himself as averse from an administration which should have no other support than popular favour, as from one brought forward merely by the influence of the court.

In this plan there is not that wisdom or liberality which might have been expected from a man of Burke's cultivated mind and extensive reading. The Whigs, when in power, had been as venal as the Tories; and the imprisonment of Lord Oxford, the banishment of Atterbury bishop of Rochester, and the resolution of the house of commons to sit for seven years, when it had been chosen by its constituents for no more than three, were certainly greater violations of the constitution than the disqualification of Wilkes, or any other measure that had been carried by the court during the administrations of Grenville and the duke of Grafton. Burke shewed himself in this publication to be indeed no republican; but every sentence of it breathed the spirit of party.

Lord North was now prime minister; and in order to tranquillize America, he proposed, in the beginning of his administration, to repeal the obnoxious laws of his predecessors in office, and to reserve the duty on tea merely to maintain the authority of parliament. The consequences of this conduct we have detailed elsewhere (see Britain, *Encycl.*); and they are too well known to all our readers. The part which Burke acted during his administration will not, in our opinion, admit of any plausible defence. It was not indeed the part of a democrate, but of a man determined to oppose every measure of those in power. In the beginning of the contest, he certainly displayed more wisdom and patriotism than the minister; for, without entering directly into the question, Whether the mother-country had or had not a right to tax the colonies? he contented himself with warning the house against dangerous innovations. "The Americans (said he) have been very serviceable to Britain under the old system: do not, therefore, let us enter rashly upon new measures. Our commercial interests have been hitherto greatly promoted by our friendly intercourse with the colonies; do not let us endanger possession for contingency; do not let us substitute untried theories for a system experimentally ascertained to be useful."

This was undoubtedly sound reasoning, and everyway becoming a lover of his country: but his continued opposition to government, after all Europe had leagued against Great Britain, was a conduct which will admit of no vindication, and for which the only possible apology must be found in that ardour of temper which made his friend Hamilton say, on another occasion, "Whatever opinion Burke, from any motive, supports, so ductile is his imagination, that he soon conceives it to be right." In his most violent opposition, however, though his expressions were often extravagant and indecent, he never for a moment gave his support to the metaphysical doctrine of the *imprescriptible rights of man*, or to the actual innovations which some meant to introduce on the basis of that doctrine. His upright mind was indeed sufficiently guarded against these novelties by what he had observed in France during the year 1772. Whilst he remained in that country, his literary and political eminence made him courted by all the anti-monarchical and infidel philosophers of the time; and in the religious scepticism and political theories of Voltaire, Helvetius, Rousseau, and D'Alembert, he saw, even at that period, the probable overthrow of religion and government. His sentiments on this subject he took occasion, immediately on his return, to communicate to the house of commons; and to point out the conspiracy of atheism to the watchful policy of every government. He professed that he was not over-fond of calling in the aid of the secular arm to suppress doctrines and opinions; but he recommended a grand alliance among all believers against those ministers of rebellious darkness, who were endeavouring to shake all the works of God established in beauty and in order.

The American war proving unsuccessful, though Great Britain never made a more glorious stand, Lord North and his friends retired from office; and, in February 1782, a new ministry was formed, at the head of which was placed the marquis of Rockingham; Lord Shelburne and Mr Fox were the secretaries of state; and Mr Burke, who was appointed pay-master to the forces, exulted, rather childishly, in the house of commons, on the happiness which was to accrue, both to the king and to the people, from the able and upright conduct of the new ministers. The time in which the greater part of them continued in office was too short to permit them to do either much good or much evil.

On the 1st of July the marquis of Rockingham died; and the earl of Shelburne being placed at the head of the treasury, Fox and Burke resigned in disgust, and, to the astonishment of the nation, formed the famous coalition with Lord North, whose measures they had so long, and so vehemently opposed. In the coalition of North and Burke there would have been nothing wonderful. In the intercourse of private life, these two statesmen had always met on terms of friendship and mutual regard; they had the same ideas of the excellence of the constitution, and the same aversion to innovation under the name of reform; even their studies and amusements were very similar, being both men of taste and classical learning; and though Burke opposed the taxation of America by the British parliament, his opposition proceeded rather from motives of prudence and expediency than from any settled conviction that the measure was unconstitutional. But the political enmity of Fox and North had proceeded, not only to personal abuse, but to professions of mutual abhorrence; and perhaps there was hardly an unprejudiced person in the kingdom who entertained not suspicions, that the unexpected union of such enemies was cemented by a principle less pure than patriotism.

Mr Pitt was now chancellor of the exchequer; and when he announced to the house of commons the peace

Burke. which was concluded in January 1783, he found the terms on which it had been made severely condemned by North, Fox, Burke, and all their friends. The censure passed on it by Lord North and his followers was perfectly consistent with their former conduct, and with the opinions which they had uniformly maintained; but it was with no good grace that Fox and Burke, who had offered an unconditional peace to the Dutch, and so frequently proposed to recognize the independence of America, condemned the peace which had been concluded by Lord Shelburne. On this, as on many other occasions, they acted, not as enlightened politicians, but as the rancorous leaders of a party.

In consequence of a vote of censure passed by the commons, the ministers resigned their employments, and were succeeded by the duke of Portland, Lord North, Mr Fox, Mr Burke, and their friends. Burke had his former employment of paymaster to the forces; Lord North and Mr Fox were secretaries of state, and the duke of Portland was first lord of the treasury. To many persons this ministry had the appearance of greater strength than any that had governed the kingdom since the time of Sir Robert Walpole; but its duration was not longer than that of the preceding. On the 18th of November, Mr Fox introduced his famous India-bill, into the merits of which it is foreign from our purpose to enter: suffice it to say, that after being strongly supported by Burke, and ably opposed by Pitt and Dundas, it passed the house of commons by a very great majority; but was lost in the house of peers, and viewed by the king in such a light, that he determined on an entire change of administration.

Mr Pitt was now placed at the head of the treasury, where he has remained ever since (1800), notwithstanding the violent and powerful opposition which he met with at first from North and Fox and their coalesced friends: the voice of the nation has been on his side; and that voice will always drown the bellowings of patriotism.

The principal events in which Burke signalized himself, since the year 1784, were the trial of Hastings, the deliberations of the house on the proposed regency during the lamented illness of the king, and the French revolution; and on each of these occasions he displayed talents which astonished the nation. He has, indeed, been severely blamed for the pertinacity with which he prosecuted Mr Hastings, and his conduct has been attributed to very unworthy motives; but of this there is neither proof nor probability. The temperament of his mind was such, that, into whatever measure he entered, he entered with a degree of ardour of which cooler heads can hardly form a conception. Burke was but one member of a committee which found, or thought it found, evidences of the guilt of Hastings; and, in forming his opinion, it is little likely that he should have been biassed by interest or resentment, whose delicate sense of rectitude would not permit him to retain a pension when he could no longer support the party of that friend who had obtained it for him.

When the establishment of a regency was thought necessary, he took the part, as it was called, of the Prince of Wales, in opposition to the plan proposed by Lord Thurlow and the minister; and we doubt not but he was actuated by the purest principles: but the language which he used in the house was vehement, and some of his expressions were highly indecent. Our regard for his memory makes us wish to forget them. Burke.

Soon after the recovery of the king, the attention of Burke was attracted to the most momentous event of modern times;—an event which has convulsed all Europe, and of which, from the very first, his sagacity foresaw the consequences. Many of his friends in Parliament, as well as numbers of wise and good men out of it, augured, from the meeting of the states-general of France, great benefit to that nation, of which the government was considered as despotic and oppressive; and some were sanguine enough to prognosticate a new and happy order of things to all the nations connected with France, when its government should become more free. Burke thought very differently: He was well acquainted with the genius of the French people, and with the principles of those philosophers, as they called themselves, by whom a total revolution in church and state had long been projected; and from the commencement of their career in the constituent assembly, when they established, as the foundation of all legal government, the metaphysical doctrine of *the rights of man*, he predicted that torrent of anarchy and irreligion which they have since attempted to pour over all Europe. Fox and some of the other leading men in opposition affected to consider this as a vain fear; and a coolness took place between them and Burke, though they still acted together in Parliament. At last, perceiving the French doctrines of liberty and equality, and atheism, spreading through this nation, not only among those who had talents for such disquisitions, but in clubs and societies, of which the members could be no judges of metaphysical reasonings, he expressed his apprehension of the consequences in the house of commons. This brought on a violent altercation between him and Fox, who was supported by Sheridan; and a rupture took place between these old friends which was never healed. He no more attended the meetings of the opposition members; and in 1790 he published his celebrated *Reflections on the French Revolution.*

By the friends of government this work was admired as the most seasonable, as well as one of the ablest, defences of the British constitution that ever was written; whilst Fox and his friends, with the great body of English dissenters, though they admitted it to be the offspring of uncommon genius, affected to consider it as declamatory rather than argumentative, and as inconsistent with the principles which its author had hitherto uniformly maintained. Many answers were written to it; of which the most conspicuous were *Vindiciæ Gallicæ* by Mr Mac Intosh, and *The Rights of Man* by Thomas Paine. To these Burke deigned not to make a direct reply. He vindicated his general principles, as well as some of his particular reasonings, in *A Letter to a Member of the National Assembly*; and he very completely evinced the consistency of his principles in his *Appeal from the New to the Old Whigs.*

Of this great work, for great it undoubtedly is, the merits as well as the demerits have been much exaggerated; and some have made it a question, Whether it has on the whole been productive of good or harm? By the enemies of the author, it is represented as having given rise to the spirit of discontent, by exciting such writers as Paine and his adherents, who, but for the provocation given by *The Reflections*, might have remained

Burke.

remained in silence and obscurity. This was from the first a very improbable supposition; for the spirit of democracy has at all times been restless: but since the appearance of Professor Robison's *Proofs of a Conspiracy*, and Barruel's *History of Jacobinism*, it must be known to every reader to be a supposition contrary to fact. The conspirators were busy long before Burke wrote his *Reflections;* and the friends of order and religion are his debtors, for having so forcibly roused them from their slumber, and put them on their guard. With respect to composition, it is certainly neither so energetic nor so argumentative as the political tracts of Johnson, to which some have affected to consider it as superior: but it is more poetical, gives scope for a greater display of the knowledge of human nature; and, being written on a more interesting subject, it has had a much greater number of readers than those unrivalled pieces of political controversy.

Burke being now associated with Mr Pitt, continued to write from time to time memorials and remarks on the state of France, and the alliance that was formed against the new order of things in that distracted country, of which some have been published since his death; and having resolved to quit the bustle of public life as soon as the trial of Mr Hastings should be concluded, he vacated his seat when that gentleman was acquitted, and retired to his villa at Beaconsfield, where, on the 2d of August 1794, he met with a heavy domestic loss in the death of his only son. In the beginning of the same year he had lost his brother Richard, whom he tenderly loved: but though this reiterated stroke of death deeply affected him, it never relaxed the vigour of his mind, nor lessened the interest which he took in the public weal.

In this retreat, while he was labouring for the good of all around him, he was disturbed by a very unprovoked attack upon his character by some distinguished speakers in the house of Peers. Soon after the death of his son the king was graciously pleased to bestow a pension on him and Mrs Burke; and this those noble lords were pleased to represent as the reward of what they termed the change of his principles and the desertion of his friends. The injustice of this charge must be obvious to every impartial mind, since the pension was given after he had retired from parliament, and could not by his eloquence either support the ministry or gall the opposition. He was not a man to submit tamely to such an insult. He published a letter on the occasion, addressed to a noble lord (Earl Fitzwilliam), in which he repels the attack on his character, and retaliates on those by whom it was made, in terms of such eloquent and keen sarcasm, as will be read with admiration as long as the language of the letter shall be understood.

Burke having employed every effort which benevolence and wisdom could devise to stimulate civilized governments to unite in opposition to the impiety and anarchy of France, laboured likewise in private to relieve those who had suffered exile and proscription from the direful system. Through his influence a school was established in his neighbourhood for the education of those whose parents, for their adherence to principle, were rendered unable to afford to their children useful instruction; and that school, which on his deathbed he recommended to Mr Pitt, continues to flourish under his powerful protection.

Burke, Burnet.

When the appearance of melioration in the principles and government of France induced our sovereign to make overtures of peace to the French directory, Burke resumed his pen; and in a series of letters, intitled, *Thoughts on the Prospect of a Regicide Peace*, displayed a force of genius which is certainly not surpassed, and perhaps not equalled, even in his far-famed *Reflections on the French Revolution.* This was his last work, and was considered by himself as in its nature testamentary.

From the beginning of June 1797 his health rapidly declined; but his understanding exerted itself with undiminished force and uncontracted range; and his dispositions retained all their amiable sweetness. On the 7th of July, when the French revolution was mentioned, he spoke with pleasure of the conscious rectitude of his own intentions in what he had done and written respecting it; entreated those about him to believe, that if any unguarded expression of his on the subject had offended any of his former friends, no offence was by him intended; and he declared his unfeigned forgiveness of all who had on account of his writings, or for any other cause, endeavoured to do him an injury. On the day following he desired to be carried to another room; and whilst one of his friends, assisted by some servants, was complying with his request, Mr Burke faintly uttering, "God bless you," fell back and expired in the 68th year of his age.

From this detail, we trust that our readers are already sufficiently acquainted with his general character. In genius, variety of knowledge, and readiness of expression, Johnson alone of all his contemporaries could be considered as his rival; and, like that great man, he took every opportunity, especially during his last illness, to declare his unshaken belief of the Christian religion, his veneration for sincere Christians of all persuasions, and his own preference of the church of England. On the worship of that church he had indeed through the whole of his life been a regular and devout attendant; and the tears which the poor, in the neighbourhood of his villa, shed at his funeral, gave sufficient evidence that his faith had been productive of charity. In his public conduct, the irritability of his temper, and the ardour of his imagination, sometimes hurried him into the excesses of a mere party-man; but we believe that his great religious and political principles never varied. He has himself characterised his public conduct in the conclusion of his Reflections on the French Revolution, when he says, that "they come from one who has been no tool of power, no flatterer of greatness, and who in his last acts does not wish to belie the tenor of his life; from one who wishes to preserve consistency, but who would preserve consistency by varying his means to secure the unity of his end; and when the equipoise of the vessel in which he sails may be endangered by overloading it upon one side, is desirous of carrying the small weight of his reasons to that which may preserve the equipoise."

BURNET (James, Esq;), better known by the title of *Lord Monboddo*, descended from an ancient family in the county of Mearns in Scotland. He was the eldest son of Arthur Burnet, Esq; of Monboddo, where he was born in the year 1714. After passing through the usual course of school education, he prosecuted his studies at the universities of Aberdeen, Edinburgh, and

Leyden,

Burnet. Leyden, with distinguished reputation. He was admitted an advocate in 1737; and on the 12th of February 1767, he was raised to the bench, by the title of Lord Monboddo, in the room of Lord Milton, appointed a judge the 4th of June 1742, and who had succeeded Sir John Lauder of Fountainhall, admitted November 1. 1689; so that he was only the third judge in succession since the revolution.

Before his promotion to the bench, he had married Miss Farquharson, a very amiable woman, by whom he had a son and two daughters; whom, without regarding the difference of climate, he reared as the children of ancient Greece were reared.

From early youth Lord Monboddo's application to literary and juridical studies was severely diligent. Between classical literature and the law of Scotland, there exists a strong connection, arising from the adoption of the forms and maxims of the civil law of the Romans, by the ancient legislators and judges of Scotland. Accordingly, while Mr Burnet rose into reputation as a lawyer, he at the same time improved into profound erudition that knowledge of the Greek and Roman authors which he had acquired at school and the university; and his partiality to the Greek language could not fail to be strengthened by his frequent conversations with Dr Blackwell, the celebrated professor of that language in the Marischal College and University of Aberdeen.

His favourite studies, however, were not suffered to interfere with his duty as a judge. In his native county, his integrity as *Sheriff* will be long remembered; and during the whole time that he was a Lord of Session, he discharged the duties of his high office with an assiduity, a patience, a clear intelligence, and inflexible rectitude, which did honour to the court of which he was a judge. Like others, he was liable to error; but neither the awe of power, the blandishments of flattery, nor even compassion for distress, could turn Lord Monboddo aside from what he believed to be the course of justice.

Several of the judges of the court of session were at that period ambitious of shining among philosophers and men of taste; and Lord Kames's *Elements of Criticism* is a work which will be long read, and always admired. It was not, however, admired by Lord Monboddo; and he determined to vindicate the superiority of the ancients over the moderns, as well in philosophy as in belles lettres. With this view he published, in 1773, the first volume of his Origin and Progress of Language; which was perused with mingled sentiments of respect and indignation. It was better received in England than in his own country; and notwithstanding the ridicule brought upon him by his belief in the existence of *mermen*, and *men with tails*, the author felt himself sufficiently encouraged to complete his plan in five volumes.

Having, as he thought, vindicated *Grecian literature*, he was induced to undertake another great work in defence of *Grecian philosophy*, against the still more arrogant claims, as he deemed them, of Bacon and Newton, with their followers. With this view, he published, at different times, and in six volumes 4to, a work intitled *Ancient Metaphysics*, fraught, it must be confessed, with much erudition, much good sense, and, strange as the combination may seem, with much absurdity. In the preface to the first volume, he declares open war against all modern writers of philosophy, except Mr Harris, who was an adorer of the ancients like himself, Mr Baxter, and Dr Cudworth. He acknowledges Baxter's book on the Immateriality of the Soul to be a truly valuable work; and says of Cudworth's *Intellectual System*, that he agrees with it throughout. There is indeed such a coincidence of notions in the *Intellectual System* and the *Ancient Metaphysics*, that an ill-natured critic might be tempted to suspect, that every thing valuable in the latter was borrowed from the former. Burnet.

The Ancient Metaphysics had few admirers in Scotland; but it procured for its author, from a scholar of Oxford, we think Mr Huntingford, the title of αλλος Αριστοτελης. His Lordship continued to cultivate what he called *Greek philosophy*, and to attend his judicial duties, with indefatigable diligence till within a few days of his death, which happened at his house in Edinburgh, on the 26th of May 1799, at the advanced age of 85.

His private life was spent in the practice of all the social virtues, and in the enjoyment of much domestic felicity. Although rigidly temperate in his habits of life, he, however, delighted much in the convivial society of his friends; and among these he could number almost all the most eminent of those who were distinguished in Scotland for virtue, literature, or genuine elegance of conversation and manners. His son, a very promising boy, in whose education he took great delight, was snatched away from his affections by a premature death. But when it was too late for sorrow and anxiety to avail, the afflicted father stifled the emotions of nature in his breast, and wound up the energies of his soul to the firmest tone of stoical fortitude. He was, in like manner, bereaved of his excellent lady, the object of his dearest tenderness; and he endured the loss with a similar firmness, fitted to do honour either to philosophy or to religion. In addition to his office as a judge in the court of session, an offer was made to him of a seat in the court of justiciary. But though the emoluments of the office would have made a convenient addition to his income, he refused to accept it, lest its business should too much detach him from the pursuit of his favourite studies.

The vacations of the court of session afforded him sufficient leisure to retire every year, in spring and in autumn, to the country; and he used then to dress in a style of simplicity, as if he had been only a plain farmer; and to live among the people upon his estate with all the kind familiarity and attention of an aged father among his grown-up children. Although the estate, from the old leases, did not afford an income of more three or four hundred pounds a-year, he would never raise the rents upon his old tenants, nor displace an old tenant, for the sake of any augmentation of emolument offered by a richer or more enterprising stranger In imitation of the rural economy of some of the ancients, whom he chiefly admired, he accounted population the true wealth of an estate, and was desirous of no other improvement of his lands, than that of having the number of persons that should reside upon them, and be sustained by their produce, superior to that of the population of any equal portion of the lands of his neighbours.

It was at Monboddo that he had the pleasure of receiving Dr Samuel Johnson, with his friend James Boswell, at the time when these two gentlemen were upon

Burnet.

upon their well-known Tour through the Highlands of Scotland. Johnſon admired nothing in literature ſo much as the diſplay of a keen diſcrimination of human character, a juſt apprehenſion of the principles of moral action, and that vigorous common ſenſe which is the moſt happily applicable to the ordinary conduct of life. Monboddo delighted in the refinements, the ſubtleties, the abſtractions, the affectations, of literature; and, in compariſon with theſe, deſpiſed the groſſneſs of modern taſte and of common affairs. Johnſon thought learning and ſcience to be little valuable, except ſo far as they could be made ſubſervient to the purpoſes of living uſefully and happily with the world upon its own terms. Monboddo's favourite ſcience taught him to look down with contempt upon all ſublunary, and eſpecially upon all modern things; and to fit life to literature and philoſophy, not literature and philoſophy to life. James Boſwell, therefore, in carrying Johnſon to viſit Monboddo, probably thought of *pitting* them one againſt another, as two game cocks, and promiſed himſelf much ſport from the colloquial conteſt which he expected to enſue between them. But Monboddo was too hoſpitable and courteous to enter into keen contention with a ſtranger in his own houſe. There was much talk between them, but no angry controverſy, no exaſperation of that diſlike for each other's well-known peculiarities with which they had met. Johnſon, it is true, ſtill continued to think Lord Monboddo what he called *a prig* in literature; and Monboddo to cenſure Johnſon for allowing the moderns, in ſome things, to ſurpaſs the ancients.

Lord Monboddo uſed frequently to viſit London, to which he was allured by the opportunity that great metropolis affords of enjoying the converſation of a vaſt number of men of profound erudition. A journey to the capital became a favourite amuſement of his periods of vacation from the buſineſs of the court to which he belonged; and, for a time, he made this journey once a-year. A carriage, a vehicle that was not in common uſe among the ancients, he conſidered as an engine of effeminacy and ſloth, which it was diſgraceful for a man to make uſe of in travelling. To be dragged at the tail of a horſe, inſtead of mounting upon his back, ſeemed, in his eyes, to be a truly ludicrous degradation of the genuine dignity of human nature. In all his journeys, therefore, between Edinburgh and London, he was wont to ride on horſeback, with a ſingle ſervant attending him. He continued this practice, without finding it too fatiguing for his ſtrength, till he was upwards of eighty years of age. Within a few years of his death, on his return from a laſt viſit, which he made on purpoſe to take leave of all his old friends in London, he became exceedingly ill upon the road, and was unable to proceed; and had he not been overtaken by a Scotch friend, who prevailed upon him to travel the remainder of the way in a carriage, he might perhaps have actually periſhed by the way-ſide, or breathed his laſt in ſome dirty inn.

In London, his viſits were exceedingly acceptable to all his friends, whether of the literary or faſhionable world. He delighted to ſhew himſelf at court; and the king is ſaid to have taken a pleaſure in converſing with the old man with a diſtinguiſhing notice that could not but be very flattering to him. He uſed to mingle, with great ſatisfaction, with the learned and the ingenious, at the houſe of Mrs Montague. However, after the death of his friend Mr Harris, he found a very ſenſible diminution of the pleaſure he had been wont to enjoy in the ſociety of London.

A conſtitution of body, naturally framed to wear well and laſt long, was ſtrengthened to Lord Monboddo by exerciſe, guarded by temperance, and by a tenor of mind too firm to be deeply broken in upon by thoſe paſſions which conſume the principles of life. In the country he always uſed much the exerciſes of walking in the open air and of riding. The cold bath was a means of preſerving the health, to which he had recourſe in all ſeaſons, amid every ſeverity of the weather, and under every inconvenience of indiſpoſition or buſineſs, with a perſeverance invincible. He was accuſtomed, alike in winter and in ſummer, to riſe at a very early hour in the morning, and, without loſs of time, to betake himſelf to ſtudy or wholeſome exerciſe. It is ſaid that he even found the uſe of what he called the air bath, or the practice of occaſionally walking about, for ſome minutes, naked, in a room filled with freſh and cool air, to be highly ſalutary. In a word, if his peculiarities were ſtriking, his virtues, and learning, and talents, were equally ſtriking; and, taken altogether, he muſt be conſidered as a great and a good man.

Burns.

BURNS (Robert), was a native of Airſhire, one of the weſtern counties of Scotland. He was the ſon of humble parents; and his father paſſed through life in the condition of a hired labourer, or of a ſmall farmer. Even in this ſituation, however, it was not hard for him to ſend his children to the pariſh-ſchool, to receive the ordinary inſtruction in reading, writing, arithmetic, and the principles of religion. By this courſe of education young Robert profited to a degree that might have encouraged his friends to deſtine him to one of the liberal profeſſions, had not his father's poverty made it neceſſary to remove him from ſchool, as ſoon as he had grown up, to earn for himſelf the means of ſupport as a hired ploughboy or ſhepherd.

The expence of education in the pariſh-ſchools of Scotland is ſo ſmall, that hardly any parents who are able to labour want the means of giving to their children at leaſt ſuch education as young Burns received. From the ſpring labours of a ploughboy, from the ſummer employment of a ſhepherd, the peaſant-youth often returns for a few months, eagerly to purſue his education at the pariſh-ſchool.

It was ſo with Burns: he returned from labour to learning, and from learning went again to labour, till his mind began to open to the charms of taſte and knowledge; till he began to feel a paſſion for books, and for the ſubjects of books, which was to give a colour to the whole thread of his future life. On nature he ſoon began to gaze with new diſcernment and with new enthuſiaſm: his mind's eye opened to perceive affecting beauty and ſublimity, where, by the mere groſs peaſant, there was nought to be ſeen but water, earth, and ſky—but animals, plants, and ſoil.

What might perhaps firſt contribute to diſpoſe his mind to poetical efforts, is one particular in the devotional piety of the Scottiſh peaſantry; it is ſtill common for them to make their children get by heart the Pſalms of David, in that verſion of homely rhymes which is uſed in their churches. In the morning and in the evening of every day, or at leaſt on the evening of

Burns.

of every Saturday and Sunday, these Psalms are sung in solemn family-devotion, a chapter of the Bible is read, and extemporary prayer is fervently uttered. The whole books of the Sacred Scriptures are thus continually in the hands of almost every peasant. And it is impossible that there should not be occasionally some souls among them, awakened to the divine emotions of genius by that rich assemblage which those books present, of almost all that is interesting in incidents, or picturesque in imagery, or affectingly sublime or tender in sentiments and character. It is impossible that those rude rhymes, and the simple artless music with which they are accompanied, should not occasionally excite some ear to a fond perception of the melody of verse. That Burns had felt these impulses, will appear undeniably certain to whoever shall carefully peruse his *Cottar's Saturday's Night;* or shall remark, with nice observation, the various fragments of Scripture sentiment, of Scripture imagery, of Scripture language, which are scattered throughout his works.

Still more interesting to the young peasantry are those ancient ballads of love and war, of which a great number are, in the south of Scotland, yet popularly known, and often sung by the rustic maid or matron at her spinning-wheel. They are listened to with ravished ears by old and young. Their rude melody; that mingled curiosity and awe which are naturally excited by the very idea of their antiquity; the exquisitely tender and natural complaints sometimes poured forth in them; the gallant deeds of knightly heroism, which they sometimes celebrate; their wild tales of demons, ghosts, and fairies, in whose existence superstition alone has believed; the manners which they represent; the obsolete, yet picturesque and expressive, language in which they are often clothed—give them wonderful power to transport every imagination, and to agitate every heart. To the soul of Burns they were like a happy breeze touching the wires of an Æolian harp, and calling forth the most ravishing melody.

Beside all this, the Gentle Shepherd, and the other poems of Allan Ramsay, have long been highly popular in Scotland. They fell early into the hands of Burns; and while the fond applause which they received drew his emulation, they presented to him likewise treasures of phraseology and models of versification. He got acquainted at the same time with the poetry of Robert Ferguson, written chiefly in the Scottish dialect, and exhibiting many specimens of uncommon poetical excellence. The Seasons of Thomson too, the Grave of Blair, the far-famed Elegy of Gray, the Paradise Lost of Milton, perhaps the Minstrel of Beattie, were so commonly read, even among those with whom Burns would naturally associate, that poetical curiosity, although even less ardent than his, could in such circumstances have little difficulty in procuring them.

With such means to give his imagination a poetical bias, and to favour the culture of his taste and genius, Burns gradually became a poet. He was not, however, one of those forward children who, from a mistaken impulse, begin prematurely to write and to rhyme, and hence never attain to excellence. Conversing familiarly for a long while with the works of those poets who were known to him; contemplating the aspect of nature in a district which exhibits an uncommon assemblage of the beautiful and the ruggedly grand, of the cultivated and the wild; looking upon human life with an eye quick and keen, to remark as well the stronger and leading, as the nicer and subordinate, features of character; to discriminate the generous, the honourable, the manly, in conduct, from the ridiculous, the base, and the mean—he was distinguished among his fellows for extraordinary intelligence, good sense, and penetration, long before others, or perhaps even himself, suspected him to be capable of writing verses. His mind was mature, and well stored with such knowledge as lay within his search: he had made himself master of powers of language, superior to those of almost any former writer in the Scottish dialect, before he conceived the idea of surpassing Ramsay and Ferguson.

Burns.

Hitherto he had conversed intimately only with peasants on his own level; but having got admission into the fraternity of free masons, he had the fortune, whether good or bad, to attract in the lodges the notice of gentlemen better qualified than his more youthful companions to call forth the powers of his mind, and to show him that he was indeed a poet. A masonic song, a satirical epigram, a rhyming epistle to a friend, attempted with success, taught him to know his own powers, and gave him confidence to try tasks more arduous, and which should command still higher bursts of applause.

The annual celebration of the sacrament of the Lord's Supper, in the rural parishes of Scotland, has much in it of those old popish festivals, in which superstition, traffic, and amusement, used to be strangely intermingled. Burns saw, and seized in it one of the happiest of all subjects, to afford scope for the display of that strong and piercing sagacity by which he could almost intuitively distinguish the reasonable from the absurd, and the becocoming from the ridiculous; of that picturesque power of fancy, which enabled him to represent scenes, and persons, and groupes, and looks, attitude, and gestures, in a manner almost as lively and impressive, even in words, as if all the artifices and energies of the pencil had been employed; of that knowledge which he had necessarily acquired of the manners, passions, and prejudices of the rustics around him, of whatever was ridiculous, no less than of whatever was affectingly beautiful in rural life.

A thousand prejudices of Popish, and perhaps too of ruder Pagan superstition, have from time immemorial been connected in the minds of the Scottish peasantry, with the annual recurrence of the Eve of the Festival of all the Saints or Halloween. These were all intimately known to Burns, and had made a powerful impression upon his imagination and feelings. He chose them for the subject of a poem, and produced a piece which is almost to frenzy the delight of those who are best acquainted with its subject; and which will not fail to preserve the memory of the prejudices and usages which it describes, when they shall perhaps have ceased to give one merry evening in the year to the cottage fireside.

The simple joys, the honest love, the sincere friendship, the ardent devotion of the cottage; whatever in the more solemn part of the rustic's life is humble and artless, without being mean or unseemly—or tender and dignified, without aspiring to stilted grandeur—or to unnatural, buskined pathos, had deeply impressed the imagination

Burns.

imagination of the rising poet; had, in some sort, wrought itself into the very texture of the fibres of his soul. He tried to express in verse what he most tenderly felt, what he most enthusiastically imagined; and produced the *Cottar's Saturday Night*.

These pieces, the true effusions of genius, informed by reading and observation, and prompted by its own native ardour, as well as by friendly applause, were soon handed about among the most discerning of Burns's acquaintance; and were by every new reader perused, and reperused, with an eagerness of delight and approbation which would not suffer their author long to withhold them from the press. A subscription was proposed, was earnestly promoted by some gentlemen, who were glad to interest themselves in behalf of such signal poetical merit; was soon crowded with the names of a considerable number of the inhabitants of Airshire, who in the proffered purchase sought not less to gratify their own passion for Scottish poesy, than to encourage the wonderful ploughman. At Kilmarnock were the poems of Burns for the first time printed. The whole edition was quickly distributed over the country.

It is hardly possible to express with what eager admiration and delight they were everywhere received.—They eminently possessed all those qualities which the most invariably contribute to render any literary work quickly and permanently popular. They were written in a phraseology, of which all the powers were universally felt; and which being at once antique, familiar, and now rarely written, was hence fitted to serve all the dignified and picturesque uses of poetry, without making it unintelligible. The imagery, the sentiments, were at once faithfully natural, and irresistibly impressive and interesting. Those topics of satire and scandal in which the rustic delights; that humorous imitation of character, and that witty association of ideas familiar and striking, yet not naturally allied to one another, which has force to shake his sides with laughter; those fancies of superstition, at which he still wonders and trembles; those affecting sentiments and images of true religion, which are at once dear and awful to his heart—were all represented by Burns with all a poet's magic power. Old and young, high and low, grave and gay, learned or ignorant, all were alike delighted, agitated, transported.

In the mean time, some few copies of these fascinating poems found their way to Edinburgh; and having been read to Dr Blacklock, they obtained his warmest approbation. In the beginning of the winter 1786-7 Burns went to Edinburgh, where he was received by Dr Blacklock with the most flattering kindness, and introduced to every man of generosity and taste among that good man's friends. Multitudes now vied with each other in patronizing the rustic poet. Those who possessed at once true taste and ardent philanthropy were soon earnestly united in his praise: they who were disposed to favour any good thing belonging to Scotland, purely because it was Scottish, gladly joined the cry; those who had hearts and understanding to be charmed, without knowing why, when they saw their native customs, manners, and language, made the subjects and the materials of poesy, could not suppress that voice of feeling which struggled to declare itself for Burns: for the dissipated, the licentious, the malignant wits, and the freethinkers, he was so unfortunate as to have satire, and obscenity, and ridicule of things sacred, sufficient to captivate their fancies; even for the pious he had passages in which the inspired language of devotion might seem to come mended from his pen.

Thus did Burns, ere he had been many weeks in Edinburgh, find himself the object of universal curiosity, favour, admiration, and fondness. He was sought after, courted with attentions the most respectful and assiduous, feasted, flattered, caressed, treated by all ranks as the first boast of his country, whom it was scarcely possible to honour and reward to a degree equal to his merits. In comparison with the general favour which now promised to more than crown his most sanguine hopes, it could hardly be called praise at all which he had obtained in Airshire.

In this posture of our poet's affairs a new edition of his poems was earnestly called for. He sold the copyright for one hundred pounds; but his friends at the same time suggested, and actively promoted, a subscription for an edition, to be published for the benefit of the author, ere the bookseller's right should commence. Those gentlemen who had formerly entertained the public of Edinburgh with the periodical publication of the papers of the *Mirror*, having again combined their talents in producing the *Lounger*, were at this time about to conclude this last series of papers; yet before the Lounger relinquished his pen, he dedicated a number to a commendatory criticism of the poems of the Airshire bard.

The subscription-papers were rapidly filled; and it was supposed that the poet might derive from the subscription and the sale of his copy-right a clear profit of at least 700 pounds.

The conversation of even the most eminent authors is often found to be so unequal to the fame of their writings, that he who reads with admiration can listen with none but sentiments of the most profound contempt. But the conversation of Burns was, in comparison with the formal and exterior circumstances of his education, perhaps even more wonderful than his poetry. He affected no soft air or graceful motions of politeness, which might have ill accorded with the rustic plainness of his native manners. Conscious superiority of mind taught him to associate with the great, the learned, and the gay, without being overawed into any such bashfulness as might have made him confused in thought, or hesitating in elocution. He possessed withal an extraordinary share of plain common sense or mother-wit, which prevented him from obtruding upon persons, of whatever rank with whom he was admitted to converse, any of those effusions of vanity, envy, or self-conceit, in which authors are exceedingly apt to indulge, who have lived remote from the general practice of life, and whose minds have been almost exclusively confined to contemplate their own studies and their own works. In conversation he displayed a sort of intuitive quickness and rectitude of judgment upon every subject that arose. The sensibility of his heart, and the vivacity of his fancy, gave a rich colouring to whatever reasoning he was disposed to advance; and his language in conversation was not at all less happy than in his writings. For these reasons, those who had met and conversed with him once, were pleased to meet and to converse with him again and again.

For some time he conversed only with the virtuous, the

Burns.

the learned, and the wife; and the purity of his morals remained uncontaminated. But, alas! he fell, as others have fallen in fimilar circumftances. He fuffered himfelf to be furrounded by a race of miferable beings, who were proud to tell that they had been in company with Burns, and had feen Burns as loofe and as foolifh as themfelves. He was not yet irrecoverably loft to temperance and moderation; but he was already almoft too much captivated with their wanton revels, to be ever more won back to a faithful attachment to their more fober charms. He now alfo began to contract fomething of new arrogance in converfation. Accuftomed to be among his favourite affociates what is vulgarly but expreffively called *the cock of the company*, he could fcarcely refrain from indulging in fimilar freedom and dictatorial decifion of talk, even in the prefence of perfons who could lefs patiently endure his prefumption.

The fubfcription-edition of his poems, in the mean time, appeared; and although not enlarged beyond that which came from the Kilmarnock prefs by any new pieces of eminent merit, did not fail to give entire fatisfaction to the fubfcribers. He was now to clofe accounts with his bookfeller and his printer, to retire to the country with his profits in his pocket, and to fix upon a plan for his future life. He talked loudly of independence of fpirit and fimplicity of manners, and boafted his refolution to return to the plough; yet ftill he lingered in Edinburgh, week after week, and month after month, perhaps expecting that one or other of his noble patrons might procure him fome permanent and competent annual income, which fhould fet him above all neceffity of future exertions to earn for himfelf the means of fubfiftence; perhaps unconfcioufly reluctant to quit the pleafures of that voluptuous town-life to which he had for fome time too willingly accuftomed himfelf. An accidental diflocation or fracture of an arm or a leg confining him for fome weeks to his apartment, left him during this time leifure for ferious reflection; and he determined to retire from the town without longer delay. None of all his patrons interpofed to divert him from his purpofe of returning to the plough, by the offer of any fmall penfion, or any finecure place of moderate emolument, fuch as might have given him competence without withdrawing him from his poetical ftudies. It feemed to be forgotten that a ploughman thus exalted into a man of letters was unfitted for his former toils, without being regularly qualified to enter the career of any new profeffion; and that it became incumbent upon thofe patrons who had called him from the plough, not merely to make him their companion in the hour of riot, not fimply to fill his purfe with gold for a few tranfient expences, but to fecure him as far as was poffible from being ever overwhelmed in diftrefs in confequence of the favour which they had fhown him, and of the habits of life into which they had feduced him. Perhaps indeed the fame delufion of fancy betrayed both Burns and his patrons into the miftaken idea, that, after all which had paffed, it was ftill poffible for him to return in cheerful content to the homely joys and fimple toils of undiffipated rural life.

In this temper of Burns's mind, in this ftate of his fortune, a farm and the excife were the objects upon which his choice ultimately fixed for future employment and fupport. By the furgeon who attended him during his illnefs, he was recommended with effect to the commiffioners of excife; and Patrick Millar, Efq. of Dalfwinton, deceived, like Burns himfelf and Burns's other friends, into an idea that the poet and exciseman might yet be refpectable and happy as a farmer, generoufly propofed to eftablifh him in a farm, upon conditions of leafe which prudence and induftry might eafily render exceedingly advantageous. Burns eagerly accepted the offers of this benevolent patron. Two of the poet's friends from Airfhire were invited to furvey that farm in Dumfriesfhire which Mr Millar offered. A leafe was granted to the poetical farmer at that annual rent which his own friends declared that the due cultivation of his farm might eafily enable him to pay. What yet remained of the profits of his publication was laid out in the purchafe of farm-ftock; and Mr Millar might, for fome fhort time, pleafe himfelf with the perfuafion that he had approved himfelf the liberal patron of genius; had acquired a good tenant upon his eftate; and had placed a deferving man in the very fituation in which alone he himfelf defired to be placed, in order to be happy to his wifhes.

Burns, with his Jane, whom he now married, took up their refidence upon his farm. The neighbouring farmers and gentlemen, pleafed to obtain for an inmate among them the poet by whofe works they had been delighted, kindly fought his company, and invited him to their houfes. He found an inexpreffible charm in fitting down befide his wife, at his own firefide; in wandering over his own grounds; in once more putting his hand to the fpade and the plough; in forming his enclofures, and managing his cattle. For fome months he felt almoft all that felicity which fancy had taught him to expect in his new fituation. He had been for a time idle; but his mufcles were not yet unbraced for rural toil. He now feemed to find a joy in being the hufband of the miftrefs of his affections, in feeing himfelf the father of her children, fuch as might promife to attach him for ever to that modeft, humble, and domeftic life, in which alone he could hope to be permanently happy. Even his engagements in the fervice of the excife did not, at the very firft, threaten neceffarily to debafe him by affociation with the mean, the grofs, and the profligate, to contaminate the poet, or to ruin the farmer.

But it could not be: it was not poffible for Burns now to affume that fobernefs of fancy and paffions, that fedatenefs of feeling, thofe habits of earneft attention to grofs and vulgar cares, without which fuccefs in his new fituation was not to be expected. A thoufand difficulties were to be encountered and overcome, much money was to be expended, much weary toil was to be exercifed, before his farm could be brought into a ftate of cultivation in which its produce might enrich the occupier. This was not a profpect encouraging to a man who had never loved labour, and who was at this time certainly not at all difpofed to enter into agriculture with the enthufiafm of a projector. The bufinefs of the excife too, as he began to be more and more employed in it, diftracted his mind from the care of his farm, led him into grofs and vulgar fociety, and expofed him to many unavoidable temptations to drunken excefs, fuch as he had no longer fufficient fortitude to refift. Amidft the anxieties, diftractions, and feducements which thus arofe to him, home became infenfibly lefs and lefs pleafing

Burns.

fing; even the endearments of his Jane's affection began to lofe their hold on his heart; he became every day lefs and lefs unwilling to forget in riot thofe gathering forrows which he knew not to fubdue.

Mr Millar and fome others of his friends would gladly have exerted an influence over his mind which might have preferved him in this fituation of his affairs, equally from defpondency and from diffipation; but Burns's temper fpurned all controul from his fuperiors in fortune. He refented, as an arrogant encroachment upon his independence, that tenor of conduct by which Mr Millar wifhed to turn him from diffolute conviviality, to that fteady attention to the bufinefs of his farm, without which it was impoffible to thrive in it. His croffes and difappointments drove him every day more and more into diffipation; and this diffipation tended to enhance whatever was difagreeable and perplexing in the ftate of his affairs. He funk, by degrees, into the boon companion of mere excifemen; and almoft every drunken fellow, who was willing to fpend his money lavifhly in the alehoufe, could eafily command the company of Burns. The care of his farm was thus neglected; wafte and loffes wholly confumed his little capital; he refigned his leafe into the hands of his landlord; and retired, with his family, to the town of Dumfries, determining to depend entirely for the means of future fupport upon his income as an excife-officer.

Yet during this unfortunate period of his life, which paffed between his departure from Edinburgh to fettle in Dumfriesfhire, and his leaving the country, in order to take up his refidence in the town of Dumfries, the energy and activity of his intellectual powers appeared to have been not at all impaired. In a collection of Scottifh fongs, which were publifhed (the words with the mufic) by Mr Johnfon, engraver in Edinburgh, in 4 vols 8vo, Burns, in many inftances, accommodated new verfes to the old tunes with admirable felicity and fkill. He affifted in the temporary inftitution of a fmall fubfcription library, for the ufe of a number of the well-difpofed peafants in his neighbourhood. He readily aided, and by his knowledge of genuine Scottifh phrafeology and manners greatly enlightened, the antiquarian refearches of the late ingenious Captain Grofe. He ftill carried on an epiftolary correfpondence, fometimes gay, fportive, humorous, but always enlivened by bright flafhes of genius, with a number of his old friends, and on a very wide diverfity of topics. At times, as it fhould feem from his writings of this period, he reflected, with inexpreffible heart-bitternefs, on the high hopes from which he had fallen; on the errors of moral conduct into which he had been hurried by the ardour of his foul, and in fome meafure by the very generofity of his nature; on the difgrace and wretchednefs into which he faw himfelf rapidly finking; on the forrow with which his mifconduct oppreffed the heart of his Jane; on the want and deftitute mifery in which it feemed probable that he muft leave her and their infants; nor amidft thefe agonizing reflections did he fail to look, with an indignation half invidious, half contemptuous, on thofe who, with moral habits not more excellent than his, with powers of intellect far inferior, yet bafked in the fun-fhine of fortune, and were loaded with the wealth and honours of the world, while his follies could not obtain pardon, nor his wants an honourable fupply. His wit became from this time more gloomily farcaftic; and his converfation and writings began to affume fomething of a tone of mifanthropical malignity, by which they had not been before, in any eminent degree, diftinguifhed. But with all thefe failings, he was ftill that exalted mind which had raifed itfelf above the depreffion of its original condition: with all the energy of the lion, pawing to fet free his hinder limbs from the yet encumbering earth, he ftill appeared *not lefs than archangel ruined!*

Burns.

His morals were not mended by his removal from the country. In Dumfries his diffipation became ftill more deeply habitual; he was here more expofed than in the country to be folicited to fhare the riot of the diffolute and the idle: foolifh young men flocked eagerly about him, and from time to time preffed him to drink with them, that they might enjoy his wicked wit. The Caledonian Club, too, and the Dumfriesfhire and Galloway Hunt, had occafional meetings in Dumfries after Burns went to refide there, and the poet was of courfe invited to fhare their conviviality, and hefitated not to accept the invitation.

In the intervals between his different fits of intemperance, he fuffered ftill the keeneft anguifh of remorfe, and horribly afflictive forefight. His Jane ftill behaved with a degree of maternal and conjugal tendernefs and prudence, which made him feel more bitterly the evil of his mifconduct, although they could not reclaim him. At laft crippled, emaciated, having the very power of animation wafted by difeafe, quite broken-hearted by the fenfe of his errors, and of the hopelefs miferies in which he faw himfelf and his family depreffed; with his foul ftill tremblingly alive to the fenfe of fhame, and to the love of virtue; yet even in the laft feeblenefs, and amid the laft agonies of expiring life, yielding readily to any temptation that offered the femblance of intemperate enjoyment, he died at Dumfries, in the fummer of 1796, while he was yet three or four years under the age of forty, furnifhing a melancholy proof of the danger of *fuddenly* elevating even the greateft mind above its original level.

After his death, it quickly appeared that his failings had not effaced from the minds of his more refpectable acquaintance either the regard which had once been won by his focial qualities, or the reverence due to his intellectual talents. The circumftances of want in which he left his family were noticed by the gentlemen of Dumfries with earneft commiferation. His funeral was celebrated by the care of his friends with a decent folemnity, and with a numerous attendance of mourners, fufficiently honourable to his memory. Several copies of verfes were inferted in different newfpapers upon the occafion of his death. A contribution, by fubfcription, was propofed, for the purpofe of raifing a fmall fund, for the decent fupport of his widow, and the education of his infant children.

From the preceding detail of the particulars of this poet's life, the reader will naturally and juftly infer him to have been an honeft, proud, warm-hearted man; of high paffions and found underftanding, and a vigorous and excurfive imagination. He was never known to defcend to any act of deliberate meannefs. In Dumfries he retained many refpectable friends even to the laft; and it may be doubted whether any poet of the prefent age has exercifed a greater power over the minds of his readers. Burns has not failed to command

Burram-pooter, Butter.

one remarkable ſort of homage, ſuch as is never paid but to great original genius; a crowd of poetaſters ſtarted up to imitate him, by writing verſes as he had done in the Scottiſh dialect; but, *O imitatores! ſervum pecus!* To write rugged rhimes, in antiquated phraſe, is not to imitate the poetry of Burns.

BURRAMPOOTER. See Sandpu, *Encycl.*

BUTTER is a ſubſtance ſo well known, that it is needleſs to give here any definition of it; but as it is, in this country at leaſt, ſo general an article of food, that the proper methods of making and curing it have engaged the attention of ſome of our ableſt writers on agriculture, in addition to what has been ſaid on theſe ſubjects under the titles Butter and Dairy (*Encycl.*) our readers will probably be pleaſed with the following method of curing it, which is practiſed by ſome farmers in the pariſh of Udney, in the county of Aberdeen, and gives to their butter a great ſuperiority above that of their neighbours.

Take two parts of the beſt common ſalt, one part of ſugar, and one part of ſaltpetre; beat them up together, and blend the whole completely. Take one ounce of this compoſition for every 16 ounces of butter, work it well into the maſs, and cloſe it up for uſe.

Dr James Anderſon, from whoſe View of the Agriculture of the County of Aberdeen this receipt is taken, ſays, that he knows of no ſimple improvement in economics greater than this is, when compared with the uſual mode of curing butter by means of common ſalt alone. "I have ſeen (continues he) the experiment fairly made, of one part of the butter made at one time being thus cured, and the other part cured with ſalt alone: the difference was inconceivable. I ſhould ſuppoſe that, in any open market, the one would ſell for 30 *per cent.* more than the other. The butter cured with the mixture appears of a rich marrowy conſiſtence and fine colour, and never acquires a brittle hardneſs nor taſtes ſalt; the other is comparatively hard and brittle, approaching more nearly to the appearance of tallow, and is much ſalter to the taſte. I have ate butter cured with the above compoſition that had been kept three years, and it was as ſweet as at firſt; but it muſt be noted, that butter thus cured requires to ſtand three weeks or a month before it is begun to be uſed. If it be ſooner opened, the ſalts are not ſufficiently blended with it; and ſometimes the coolneſs of the nitre will then be perceived, which totally diſappears afterwards."

Butter.

The following obſervations reſpecting the proper method of keeping both milk and butter are by the ſame author, and we truſt may prove uſeful. Speaking ſtill of the county of Aberdeen, he ſays, "The pernicious practice of keeping milk in leaden veſſels, and ſalting butter in ſtone jars, begins to gain ground among ſome of the fine ladies in this county, as well as elſewhere, from an idea of cleanlineſs. The fact is, it is juſt the reverſe of cleanlineſs; for in the hands of a careful perſon nothing can be more cleanly than wooden diſhes, but under the management of a ſlattern they diſcover the ſecret which ſtone diſhes indeed do not.

"In return, theſe latter communicate to the butter and the milk, which has been kept in them, a poiſonous quality, which inevitably proves deſtructive to the human conſtitution. To the prevalence of this practice I have no doubt we muſt attribute the frequency of palſies, which begin to prevail ſo much in this kingdom; for the well known effect of the poiſon of lead is bodily debility, palſy—death!"

BYSAK, the firſt month of the Bengal year, beginning in April.

C.

Caffres.

CAFFRES, the inhabitants of Caffraria, are generally confounded with the Hottentots; but, according to M. Vaillant, there is a conſiderable difference between the manners, cuſtoms, and even appearance of theſe two nations.

The Caffres, ſays he, are generally taller than the Hottentots, more robuſt, more fierce, and much bolder. Their figure is likewiſe more agreeable, and their countenances have not that narrowneſs at the bottom, nor their cheeks thoſe prominences, which are ſo diſagreeable among the Hottentots. A round figure, a noſe not too flat, a broad forehead, and large eyes, give them an open and lively air; and if prejudice can overlook the colour of the ſkin, there are ſome Caffre women who, even in Europe, would be accounted pretty. Theſe people do not make their faces ridiculous, by pulling out their eye-brows like the Hottentots; they tattoo themſelves much, and particularly their bodies; their hair, which is frizzled very much, is never greaſed, but their bodies are liberally anointed, merely with a view to preſerve their vigour and agility.

Caffres.

The men generally beſtow more attention on their dreſs than the women, and are remarkably fond of beads and copper rings. The women wear hardly any of the ornaments in which the other ſavages in Africa take ſuch delight. They do not even wear copper bracelets; but their ſmall aprons, which are ſtill ſhorter than thoſe of the Hottentots, are bordered with a few rows of glaſs beads; and in this all their luxury conſiſts. It would appear that the Caffres are not ſo chaſte as the Hottentots, becauſe the men do not uſe a jackal to vail what nature teaches other men, even ſavages, to conceal. A ſmall cowl, which covers only the glans, inſtead of diſplaying modeſty, ſeems to announce the greateſt indecency. This ſmall covering adheres to a thong, which is faſtened round their girdles, merely that

Caffres. that it may not be loft; for a Caffre, if he be not afraid of being hurt or ftung by infects, cares very little whether his cowl be in its place or not. Our author faw one Caffre who, inftead of a cowl, wore a cafe made of wood, and ornamented with fculpture. This was a new and ridiculous fafhion, which he had borrowed from a nation of black people who lived at a great diftance from Caffraria.

In the hot feafon the Caffres go always naked, and retain nothing but their ornaments. In cold weather they wear kroffes made of calves or oxen hides, which reach down to the ground; but whatever the weather be, both fexes go bare-headed, except that they fometimes, though rarely, fix a plume of feathers in their hair.

The Caffre huts are more fpacious and higher than thofe of the Hottentots, and have alfo a more regular form. The frames of them are conftructed of wooden work, well put together, and very folid, being intended to laft for a long time: for the Caffres, applying to agriculture, which the free Hottentots do not, remain fixed to one fpot, unlefs fomething unexpected interrupt their repofe.

A more perceptible induftry, an acquaintance with fome of the moft neceffary arts of life, a little knowledge of agriculture, and a few religious dogmas, feem to announce that the Caffres approach much nearer to civilization than the Hottentots. They entertain a tolerably exalted idea of the Supreme Being and his power; they believe that the good will be rewarded, and the wicked punifhed, in a future ftate; but they have no notion of creation, which indeed was not admitted by the fages of Greece and Rome. They practife circumcifion, but can give no account of its origin among them, or of the purpofe for which the practice is continued.

Polygamy is ufed among the Caffres; and on the death of a father the male children and their mothers fhare the fucceffion among them. The girls remain with their mothers without property of any kind until they can procure hufbands. One very fingular cuftom of the Caffres is, that they do not, in general, inter their dead, but tranfport them from the kraal to an open ditch, which is common to the whole horde. At this ditch favage animals feed at their leifure on the multitude of carcafes which are heaped together. Funeral honours are due only to kings and the chiefs of each horde, whofe bodies are covered with a heap of ftones collected into the form of a dome.

This nation is governed by a general, chief, or king, whofe power is very limited. He appoints, however, the fubordinate chiefs over the different hordes, and through them communicates his directions or orders. The arms of the Caffre are a *club*, two feet and a half in length, and where thickeft three inches in diameter, and a plain lance or *affagey*. He defpifes poifoned arrows, which are fo much ufed by fome of the neighbouring nations; and with his two fimple weapons feeks always to meet his enemy face to face in the field. The Hottentot, on the contrary, concealed under a rock or behind a bufh, deals out deftruction, without being expofed to danger. The one is a perfidious tyger, which rufhes treacheroufly on his prey; the other is a generous lion, which, having given warning of his approach, makes his attack boldly, and perifhes if he prevail not againft his antagonift.

Calculus. CALCULUS, in mathematics, denotes a certain way of performing inveftigations and refolutions, which occur on many occafions, particularly in mechanical philofophy. Thus we fay, the *antecedental* calculus, the *algebraical* calculus, the *arithmetical* calculus, the *differential* calculus, the *exponential* calculus, the *fluxional* calculus, and the *integral* calculus. Of by much the greater part of thefe calculi fome account has been given in the Encyclopædia Britannica; but there is one of them, of which no notice has been taken in that work. It is,

The Antecedental CALCULUS, a geometrical method of reafoning, without any confideration of motion or velocity, applicable to every purpofe to which the much celebrated doctrine of fluxions of the illuftrious Newton has been, or can be, applied. This method was invented by James Glenie, Efq; "in which (he fays) every expreffion is truly and ftrictly geometrical, is founded on principles frequently made ufe of by the ancient geometers, principles admitted into the very firft elements of geometry, and repeatedly ufed by EUCLID himfelf. As it is a branch of general geometrical proportion, or univerfal comparifon, and is derived from an examination of the antecedents of ratios, having given confequents and a given ftandard of comparifon in the various degrees of augmentation and diminution they undergo by compofition and decompofition, I have called it the antecedental calculus. As it is purely geometrical, and perfectly fcientific, I have, fince it firft occurred to me in 1779, always made ufe of it inftead of the fluxionary and differential calculi, which are merely arithmetical. Its principles are totally unconnected with the ideas of motion and time, which, ftrictly fpeaking, are foreign to pure geometry and abftract fcience, though, in mixed mathematics and natural philofophy, they are equally applicable to every inveftigation, involving the confideration of either with the two numerical methods juft mentioned. And as many fuch inveftigations require compofitions and decompofitions of ratios, extending greatly beyond the triplicate and fubtriplicate, this calculus in all of them furnifhes every expreffion in a ftrictly geometrical form. The ftandards of comparifon in it may be any magnitudes whatever, and are of courfe indefinite and innumerable; and the confequents of the ratios, compounded or decompounded, may be either equal or unequal, homogeneous or heterogeneous. In the fluxionary and differential methods, on the other hand, 1, or unit, is not only the ftandard of comparifon, but alfo the confequent of every ratio compounded or decompounded."

This method is deduced immediately from Mr Glenie's Treatife on the Doctrine of Univerfal Comparifon or General Proportion: And as the limits of the prefent work will not allow us to enter upon this fubject, we therefore refer our readers to the two above mentioned treatifes, and to the fourth volume of the Tranfactions of the Royal Society of Edinburgh.

We confefs, however, that we do not expect fuch great advantage from the employment of this calculus as the very acute and ingenious author feems to promife from it. The mathematical world is truly indebted to him for the clear and difcriminating view that he has taken

taken of the doctrine of universal comparison, and we believe it to be perfectly accurate, and in some respects new. Notwithstanding the continual occupation of mathematicians with ratios and analogies, their particular objects commonly restricted their manner of conceiving ratio to some present modification of it. Hence it seems to have happened that their conceptions of it as a magnitude have not been uniform. But Mr Glenie, by avoiding every peculiarity, has at once attributed to it all the measurable affections of magnitude, addition or subtraction, multiplication or division, and ratio or proportion. He is perhaps the first who has roundly considered ratio or proportion as an affection of ratio; and it is chiefly by the employment of this undoubted affection of ratio that he has rendered the geometrical analysis so comprehensive.

But when we view this antecedental calculus, not as a method of expressing mathematical science, but as an art, as a calculus in short, and consider the means which it must employ, and the notation which must be used, we become less sanguine in our hopes of advantage from it. The notation cannot (we think) be more simple than that of the fluxionary method, justly called *arithmetical;* and if we insist on carrying clear conceptions along with us, we imagine that the arithmetical exposition of our symbols will generally be the simpler of the two. The *science* of the antecedental calculus seems to consist in the attainable perception of all the simple ratios, whether of *magnitudes* or *ratios*, or both, which concur to the formation of a compound and complicated ratio. Now this is equally, and more easily attainable in the fluxionary or other arithmetical method, when the consequent is a simple magnitude. When it is not, the same process is farther necessary in both methods, for getting rid of its complication.

We apprehend that it is a mistake that the geometrical method is more abstracted than the fluxionary, because the latter superadds to the notion of extension the notions of time and motion. These notions were introduced by the illustrious inventor *for the demonstration*, but never occupy the thoughts *in the use* of his propositions. These are *geometrical* truths, no matter how demonstrated; and when duly considered, involve nothing that is omitted in the antecedental calculus. We even presume to say, that the complication of thought, in the contemplation of the ratios of ratios, is greater than what will generally arise from the additional elements, time and motion.

We do not find that any of our most active mathematicians have availed themselves of the advantages of this calculus, nor do we know any specimen that has been exhibited of its eminent advantages in mathematical discussions. Should it prove more fertile in geometrical expressions of highly compounded or complicated quantities or relations, we should think it a mighty acquisition; being fully convinced that these afford to the memory or imagination an object (we may call it a sensible picture) which it can contemplate and remember with incomparably greater clearness and steadiness than any algebraical formula. We need only appeal to the geometrical expressions of many fluents, which are to be seen in Newton's lunar theory, in the physical tracts of Dr Matthew Stewart, and others who have shewn a partiality for this method.

It would be very presumptuous, however, for us to say, that the accurate geometer and metaphysician may not derive great advantages from prosecuting the very ingenious and recondite speculations of Mr Glenie, in his doctrine of universal comparison.

CALENDAR, in chronology. See *(Encycl.)* KALENDAR; and REVOLUTION, n° 184.

CALIPPIC PERIOD, in chronology, a period of 76 years, continually recurring; at every repetition of which, it was supposed by its inventor Calippus, an Athenian astronomer, that the mean and new full moons would always return to the same day and hour.

About a century before, the golden number, or cycle of 19 years, had been invented by Meton; which Calippus finding to contain 19 of Nabonassar's year, 4 days, and $\frac{1}{4}\frac{1}{7}\frac{1}{6}$, to avoid fractions he quadrupled it, and so produced his period of 76 years, or 4 times 19; after which he supposed all the lunations, &c. would regularly return to the same hour. But neither is this exact, as it brings them too late by a whole day in 225 years.

CALLAO, as it is called by its inhabitants, but more generally known to Europeans under the name of CAMPELLO, is a small island, which was visited by some of Lord Macartney's suite on their voyage to China. In consequence of that visit, we have the following description of it in Sir George Staunton's Account of the Embassy.

"It lies opposite to, and about eight miles to the eastward of, the mouth of a considerable river on the coast of Cochin-china, on the banks of which is situated the town of Fai-foo, a place of some note, not far from the harbour of Turon. The bearing of the highest peak of Callao from this harbour is about south-east, distance thirty miles. The extreme points of the island lie in latitude 15° 53′, and 15° 57′ north; the greatest length is from north-west to south-east, and is somewhat about five miles, and the mean breadth two miles. The only inhabited part is on the south-west coast, on a slip of ground rising gently to the east, and contained between the bottom of a semilunar bay and the mountains on each side of it. Those mountains, at a distance, appear as if they formed two distinct islands. The southern mountain is the highest, and is about 1500 feet. The lower grounds contain about 200 acres. This small but enchanting spot is beautifully diversified with neat houses, temples, clumps of trees, small hillocks swelling from the plain, and richly decorated with shrubbery and trees of various kinds; among which the elegant areca, rising like a Corinthian column, is eminently conspicuous. A rill of clear water, oozing from the mountains, is contrived to be carried along the upper ridges of the vale, from whence it is occasionally conveyed through sluices, for the purpose of watering the rice grounds, and appeared, though then in the dry season, fully sufficient for every purpose for which it could be wanted.

"The houses, in general, were clean and decent; a few were built with stone, and covered with tiles. One, probably the mansion of the chief person of the island, was enclosed by a stone wall, and the appoach to it was through a gateway between two stone pillars. The house was divided into a number of apartments, of which the arrangement did not seem to want either taste or convenience. This building stood at the head of the principal village, which consisted of about thirty habitations

habitations built of wood, chiefly the bamboo. Behind the village, and on the ſide of the hill, was a cave, acceſſible only by one way, through an irregular range of rocks. Within the cave, but near its mouth, was a ſmall temple, commanding a view of the whole vale. Several other temples were diſperſed over the plain, all of which were open in front, with a colonnade before them of round wooden pillars, painted red and varniſhed. The number of houſes on the iſland ſcarcely exceeded ſixty. Behind every houſe, not immediately in the principal village, were encloſures of ſugar-canes, tobacco, and other vegetables, growing in great luxuriance. The mountains were covered with verdure, and ſeemed well calculated for rearing goats, of which the iſland produced a few.

"Beſide the principal bay, there were ſeveral ſandy inlets, with ſmall patches of level ground behind them. Boats might eaſily land in any of theſe inlets; but a communication between them by land appeared to be exceedingly difficult, if not entirely prevented, by the ſteep and rugged ridges which ſeparated them from each other. On this account very ſlight works, and an eſtabliſhment of a few men only, would be requiſite for the defence of the iſland, a great part of its coaſt being impregnably fortified by nature. The depth of water in the bay and road was ſufficient for ſhips of any burden, and there was perfect ſhelter from every wind except the ſouth-weſt, to which quarter it was directly open. The ſhort diſtance, however, from the continent in that direction would always prevent the ſea from riſing high, though it might not be ſufficiently near to break the force of the wind."

The inhabitants of this iſland are ſo exceedingly ſhy and afraid of ſtrangers, that upon the approach of the Engliſh veſſel, they all, except a very few, retired on board their galleys. When the Britiſh landed, therefore, they found the doors of all the houſes open, with ſeveral domeſtic animals feeding before them, but neither man, woman, nor child within. After ſome time, however, a perſon was perceived lurking among the neighbouring trees, who, finding he was obſerved, came forward with reluctance and evident marks of fear. While he was yet at ſome diſtance, he fell upon his knees, and touched the ground with his forehead ſeveral times. On approaching to him, it was noticed that the firſt joint of every one of his fingers and toes was wanting, and as if twiſted off by violence: it was poſſible that he might have thus been treated by way of puniſhment for ſome crime, and that he was conſidered as the fitteſt perſon to be expoſed to the ſuppoſed danger of watching the movements of the ſtrangers coming aſhore. In a little time ſome others, hidden in the thickets, finding that no miſchief was ſuffered by the firſt, ventured out. None of them could underſtand the Chineſe interpreter; and not being able to read or write, there was no converſing with them by the medium of the Chineſe characters. Recourſe was had to hieroglyphics, and rude figures were drawn of the articles which were propoſed to be purchaſed; and this method ſucceeded tolerably well; poultry and fruits were brought for ſale, for which high prices were given, purpoſely to conciliate the good will of thoſe iſlanders. The few that were found grew ſoon familiar; and one old man preſſingly invited the ſtrangers to his houſe, ſituated upon an eminence, at a little diſtance. On arriving there, he introduced them to his wife, an old woman, who, after recovering from her aſtoniſhment at the ſight of figures ſo different from thoſe ſhe had ever been accuſtomed to behold, laid, in a neat manner, before them ſome fruits, ſugar, cakes, and water. On departing from the houſe, this decent and hoſpitable couple made ſigns to teſtify their deſire of ſeeing them again."

The poſſeſſion of this iſland would be of ſuch importance to any European nation who wiſhed to trade ſecurely with TUNG-QUIN and COCHIN CHINA, that it is ſaid the French had formerly ſome thoughts of purchaſing it. Sir George Staunton, however, is of opinion, that the want of ſhelter in the ſouth-weſt monſoon would render it of little value, without a further ſettlement near it upon the main land of Cochin-china: and he thinks, that if a ſolid eſtabliſhment there could be productive of advantage to any European nation, it would neceſſarily be ſo to Great Britain; becauſe, beſide the opening which it would make for the ſale of Britiſh manufactures among the people of the country, the Britiſh poſſeſſions in Hindoſtan would be ſure of a very conſiderable demand for their productions.

CAMEL, in navigation, is a machine which has been deſcribed with ſufficient accuracy in the Encyclopædia; but the following account of its invention, given by Profeſſor Beckmann, is perhaps not unworthy of a place in this Supplement.

"In the Zuyder-Zee, oppoſite to the mouth of the river Y, about ſix miles from the city of Amſterdam, there are two ſand banks, between which is a paſſage called the *Pampus*, which is ſufficiently deep for ſmall ſhips, but not for ſuch as are large or heavy laden. In 1672 the Dutch contrived, however, to carry their numerous fleet through this paſſage, by means of large empty cheſts faſtened to the bottom of each ſhip; and this contrivance gave riſe to the invention of the *camel*." In the Encyclopædia Britannica its invention is given to the famous De Wit; in the German Cyclopædia to Meyer a Dutch engineer of very conſiderable eminence; but the Dutch writers, almoſt unanimouſly, aſcribe the invention of the camel to a citizen of Amſterdam, who calls himſelf Meeuves Meindertſoon Bakker. "Some make the year of the invention to have been 1688, and others 1690. Much has been ſaid of the utility of this invention; but however beneficial it may be, we have reaſon to ſuppoſe that ſuch heavy veſſels as ſhips of war cannot be raiſed up, in ſo violent a manner, without ſuſtaining injury. A ſure proof of this is the well known circumſtance mentioned by Muſchenbroek (*Introductio ad Philoſoph. Natur.*), that the ports of a ſhip which had been raiſed by the camel could not afterwards be ſhut cloſely."

CAMELEON, one of the conſtellations of the ſouthern hemiſphere, near the ſouth pole, and inviſible in our latitude. There are 10 ſtars marked in this conſtellation in Sharp's catalogue.

CAMELOPARDALUS, a new conſtellation of the northern hemiſphere, formed by Hevelius, conſiſting of 32 ſtars, firſt obſerved by him. It is ſituated between Cepheus, Caſſiopeia, Perſeus, the Two Bears, and Draco; and it contains 58 ſtars in the Britiſh catalogue.

CAMELLIA, in botany (ſee *Encycl.*), is a plant which the Chineſe call *Cha-wha*, or flower of tea, on account of the reſemblance of the one to the other, and becauſe

Campbell. becauſe its petals are ſometimes mixed among the teas to increaſe their fragrance. Sir George Staunton, who calls it *Camellia Seſanqua*, ſaw it flouriſhing on the ſides and very high tops of mountains, where the ſoil conſiſted of little more than fragments of ſtone, crumbled into a ſort of coarſe earth by the joint action of the ſun and rain. It yields, he ſays, a nut, from which is expreſſed an eſculent oil, equal to the beſt which comes from Florence. On this account, it is cultivated in vaſt abundance; and is particularly valuable from the facility of its culture in ſituations fit for little elſe.

CAMPBELL (George, D. D.), ſo juſtly admired for his metaphyſical acuteneſs and various erudition, was, in 1719, born at Aberdeen, where his father, the reverend Colin Campbell, was one of the miniſters of the eſtabliſhed church. He was educated in his native city; and, after paſſing through the uſual courſe of academical learning, he ſtudied divinity under the Rev. J. Chalmers, profeſſor of divinity in Mariſchal College.—He was, in 1749, an unſucceſsful candidate for the church of Fordown, though his competitor Mr Forbes was a man of very ſlender abilities, and ſuppoſed to be attached to the conſtitution and liturgy of the church of England. It might indeed be that attachment which contributed principally to procure him the living in preference to Mr Campbell.

The living of Fordown is in the gift of the crown; and it has generally been a rule with his majeſty's miniſters, to give ſuch livings, when they become vacant, to thoſe candidates who are favoured by the majority of land-owners in the pariſh. At the era of 1749, the land-owners in ſome of the northern and middle counties of Scotland were more generally attached to the conſtitution of the church of England than to that of their own eſtabliſhment; and ſuch was certainly the caſe in the pariſh of Fordown.

But whatever was the cauſe of Mr Campbell's failure, he failed by a very ſmall number, and was not long without an eſtabliſhment. In 1750, he was preſented, by Sir Thomas Burnet of Leys, to the living of Banchary Ternan, on the Dee, about twenty miles weſt from Aberdeen. From this he was tranſlated, or, as the Scotch eccleſiaſtical phraſe is, *tranſported* to Aberdeen in 1756, and nominated one of the city miniſters, in the room of Mr John Biſſet deceaſed, a puritan of the old ſchool, whoſe ſtrictneſs and peculiarities are yet remembered by many in that place.

In 1759, on the deceaſe of principal Pollock, he was choſen principal of the Mariſchal college, and ſucceeded to the divinity chair in 1771, on Dr Alexander Gerard being tranſlated to the profeſſorſhip of divinity in King's college. Before his ſettling in Aberdeen, he married Miſs Grace Farquharſon, daughter of Mr Farquharſon of Whitehouſe, by whom he had no iſſue. This amiable woman died about a year before him. They were an eminent pattern of conjugal affection.

From this time he enjoyed a remarkable ſhare of good health and ſpirits. He had, all his life, a rooted averſion to medicine. He got the better of every ailment by a total and rigorous abſtinence from all kind of ſuſtenance whatever; and it was not till he was attacked by an alarming illneſs, about two years before his death, that he was perſuaded by his friends to call in medical aid. What nature could do, ſhe had all along performed well; but her day was over, and ſomething of art became neceſſary. Then, for the firſt time, he owned the utility of medical men, and declared his recantation of the very mean opinion he had formerly entertained of them and their art. A few months before his death, he reſigned his offices of principal, profeſſor of divinity, and one of the city miniſters, and was in all ſucceeded by Dr W. L. Brown, late of Utrecht, a man of diſtinguiſhed abilities. Dr Campbell retained all his faculties entire to the laſt, and died on the 6th of April 1796, in the 77th year of his age. His character has been ſo juſtly drawn by his ſucceſſor, that we ſhall give it to our readers in his words, adding only a circumſtance or two, which we have reaſon to think will contribute to endear his memory to every liberal and enlightened mind.

"Dr Campbell, as a public teacher, was long admired for the clearneſs and copiouſneſs with which he illuſtrated the great doctrines and precepts of religion, and the ſtrength and energy with which he enforced them. Intimately perſuaded of the truth and infinite conſequence of what relevation teaches, he was ſtrongly deſirous of carrying the ſame conviction to the minds of his hearers, and delivered his diſcourſes with that zeal which flows from ſtrong impreſſions, and that power of perſuaſion which is the reſult of ſincerity of heart, combined with clearneſs of underſtanding. He was ſatisfied, that the more the pure dictates of the goſpel were ſtudied, the more they would approve themſelves to the mind, and bring forth, in the affections and conduct, all the peaceable fruits of righteouſneſs. The unadulterated dictates of Chriſtianity, he was, therefore, only ſtudious to recommend and inculcate, and knew perfectly to diſcriminate them from the inventions and traditions of men. His chief ſtudy ever was, to direct belief to the great objects of practice; and, without theſe, he viewed the moſt orthodox profeſſion as "a ſounding braſs, and a tinkling cymbal." But, beſides the character of a preacher of righteouſneſs, he had alſo that of a teacher of the ſcience of divinity to ſuſtain. How admirably he diſcharged this duty, and with what effect he conveyed the ſoundeſt and moſt profitable inſtruction to the minds of his ſcholars, let thoſe declare who are now in various congregations of this country, communicating to their fellow Chriſtians the fruits of their ſtudies under ſo able and judicious a teacher. Diſcarding all attachment to human ſyſtems, merely conſidered as ſuch, he tied his faith to the Word of God alone, poſſeſſed the happieſt talent in inveſtigating its meaning, and communicated to his hearers the reſult of his own inquiries, with a preciſion and perſpicuity which brought light out of obſcurity, and rendered clear and ſimple what appeared intricate and perplexed. He expoſed, without reſerve, the corruptions which ignorance, craft, and hypocriſy, had introduced into religion, and applied his talent for ridicule to the beſt of all purpoſes, to hold up to contempt the abſurdities with which the pureſt and ſublimeſt truths had been loaded.

"Placed at the head of a public ſeminary of learning, he felt all the importance of ſuch a ſituation, and uniformly directed his influence to public utility. His enlarged and enlightened mind juſtly appreciated the extenſive conſequence of the education of youth. He anticipated all the effects reſulting to the great community of mankind, from numbers of young men iſſuing, Campbell. in regular ſucceſſion, from the univerſity over which he preſided, and occupying the different departments of ſocial life.

"His benevolent heart delighted to repreſent to itſelf the ſtudents under his direction uſefully and honourably diſcharging the reſpective duties of their different profeſſions; and ſome of them, perhaps, filling the moſt diſtinguiſhed ſtations of civil ſociety. With theſe proſpects before him, he conſtantly directed his public conduct to their attainment. He never ſuffered his judgment to be warped by prejudice or partiality, or his heart to be ſeduced by paſſion or private intereſt. Thoſe mean and ignoble motives by which many are actuated in the diſcharge of important truſts, approached not his mind. A certain honourable pride, if pride it may be called, diffuſed an uniform dignity over the whole of his behaviour. He felt the man degraded by the perverſion of public character. His underſtanding alſo clearly ſhewed him even perſonal advantage attached to ſuch principles and practice, as he adopted from a ſenſe of obligation, and thoſe elevated conceptions of real worth which were ſo congenial to his ſoul. He ſaw, he experienced, eſteem, reſpect, and influence, following in the train of integrity and beneficence; but contempt, diſgrace, averſion, and complete inſignificance, cloſely linked to corruption and ſelfiſhneſs. Little minds are ſeduced and overpowered by ſelfiſh conſiderations, becauſe they have not the capacity to look beyond the preſent advantage, and to extend to the miſery that ſtands on the other ſide of it. The ſame circumſtance that betrays the perverſity of their hearts, alſo evinces the weakneſs of their judgments.

"His reputation as a writer is as extenſive as the preſent intercourſe of letters; not confined to his own country, but ſpread through every civilized nation. In his literary purſuits, he aimed not, as is very often the caſe, with men of diſtinguiſhed literary abilities, merely at eſtabliſhing his own celebrity, or increaſing his fortune; but had chiefly at heart the defence of the great cauſe of Religion, or the elucidation of her dictates.

"At an early period he entered the liſts as a champion for Chriſtianity againſt one of its acuteſt opponents. He not only triumphantly refuted his arguments, but even conciliated his reſpect by the handſome and dexterous manner in which his defence was conducted. While he refuted the infidel, he ſpared the man, and exhibited the uncommon ſpectacle of a polemical writer poſſeſſing all the moderation of a Chriſtian. But while he defended Chriſtianity againſt its enemies, he was deſirous of contributing his endeavours to increaſe, among its profeſſors, the knowledge of the ſacred writings. Accordingly, in the latter part of his life, he favoured the world with a work, the fruit of copious erudition, of unwearied application, for almoſt thirty years, and of a clear and comprehenſive judgment. We have only to regret, that the other writings of the New Teſtament have not been elucidated by the ſame pen that tranſlated the Goſpels. Nor were his literary merits confined to theology, and the ſtudies more immediately connected with it. Philoſophy, and the fine arts, are alſo indebted to his genius and labours; and in him the polite ſcholar was eminently joined to the deep and liberal divine.

"Political principles will always be much affected by general character. This was alſo the caſe with Dr Campbell. In politics, he maintained that moderation which is the ſureſt criterion of truth and rectitude, and was equally diſtant from thoſe extremes into which men are ſo apt to run on great political queſtions. He cheriſhed that patriotiſm which conſiſts in wiſhing, and endeavouring to promote the greateſt happineſs of his country, and is always ſubordinate to univerſal benevolence. Firmly attached to the Britiſh conſtitution, he was animated with that genuine love of liberty which it inſpires and invigorates. He was equally averſe to deſpotiſm and to popular anarchy; the two evils into which political parties are ſo frequently hurried, to the deſtruction of all that is valuable in government. Party-ſpirit, of whatever deſcription, he conſidered as having an unhappy tendency to pervert, to the moſt pernicious purpoſes, the beſt principles of the human mind, and to clothe the moſt iniquitous actions with the moſt ſpecious appearances. Although tenacious of thoſe ſentiments, whether in religion or politics, which he was convinced to be rational and juſt, he never ſuffered mere difference of opinion to impair his good-will, to obſtruct his good offices, or to cloud the cheerfulneſs of converſation. His own converſation was enlivened by a vein of the moſt agreable pleaſantry."

So far was he from being influenced by jealouſy, or any portion of that corporation-ſpirit which ſometimes incites men of undoubted abilities to detract from the merit of every writer who fills not a ſtation as conſpicuous as their own, that he was loud in his praiſes of thoſe, whom men of meaner minds would have looked upon with diſguſt, as upon preſumptuous rivals. This generoſity was fully experienced by the writer of the article Miracle, in the Encyclopædia Britannica, who, though he had preſumed to treat the ſubject differently from Dr Campbell, received from him ſuch a teſtimony of approbation of what he had done, as he will hardly look for from any other man in ſimilar circumſtances.

Among his other qualities, which ſo much endeared him to all who had the honour of his acquaintance, Dr Campbell poſſeſſed an uncommon facility of paſſing from the graveſt to the moſt airy ſubjects, and from the livelieſt to the graveſt, without degrading the one or diminiſhing the pleaſure of the other. The infirmities of age abated not the cheerfulneſs of his temper, nor did even the perſuaſion of approaching diſſolution impair his ſerenity.

We cannot conclude this ſhort ſketch better than with a liſt of his works, in the order in which they were publiſhed. In 1752, he publiſhed a Sermon, preached before the Synod of Aberdeen.

1761. A Diſſertation on Miracles, againſt Mr Hume. This treatiſe is well known to the learned world. He obtained, and deſervedly obtained, a very high reputation, not only from the able manner in which he handled the ſubject, but from the liberal ſtyle in which he addreſſed his antagoniſt. It was ſpeedily tranſlated into French, German, and Dutch.

1771. A Sermon before the Society for Propagating Chriſtian Knowledge, Edinburgh.

——— ——— before the Synod of Aberdeen.

1776. The Philoſophy of Rhetoric, 2 vols 8vo. A work which diſcovers a clearneſs of diſcernment, and accuracy of obſervation, which juſtly entitled him to be ranked among the moſt judicious critics. He entered on this inquiry as early as 1750, when a part of the

Camphor.

work was composed. The laws of elegant composition and criticism are laid down with great perspicuity: but the most valuable part of the work is undoubtedly the *theory of evidence*, to which we know nothing superior, perhaps nothing equal, on the subject, in our own or any other language. His philosophy, in general, is the philosophy of Dr Reid; and where he differs from that acute reasoner respecting *abstraction*, and some other objects of metaphysical disquisition, we think it impossible to refuse him the pre-eminence in every thing but style.

1777. A Sermon on the King's Fast-day, on Allegiance, first printed in 4to, and afterwards, at the expence of government, six thousand copies were printed in 12mo, enlarged with notes, and sent to America, when the unhappy struggle had, however, put on appearances which prevented the effect hoped for from this sermon.

1780. An Address to the People of Scotland on the Alarms which have been raised by what is called the Popish Bill. This is a powerful dissuasive from bigotry, and every species of religious persecution.

1793. His *Magnum Opus*. The translation of the Gospels, with Preliminary Dissertations, 2 vols 4to.

1800. Lectures on Ecclesiastical History, a posthumous work, in 2 vols 8vo; which, in the opinion of most people, should have been suppressed.

CAMPHOR, or Camphire, (see *Encycl.*), is, in China, obtained by boiling the branches, twigs, and leaves, of the *Laurus-Camphora* in water, upon the surface of which it is found swimming in the form of an oil, or adhering, in a glutinous form, to a wooden rod, with which the boiling matter is constantly stirred. The glutinous mass is then mixed with clay and lime, and put into an earthen vessel, with another of the same size properly luted over it; the lower vessel being placed over a slow fire, the camphor gradually sublimes through the clay and lime, and adheres to the sides of the upper vessel, forming a cake of a shape corresponding to the cavity which received it. It is, however, less pure and much weaker than what is discovered in a solid state among the fibres of the trunk, as turpentine is found in different sorts of pines. In the great, but ill-peopled, island of Borneo, and also in Japan, the camphor tree is felled for the sole purpose of finding this costly drug in substance among the splinters of the trunk, in the same manner as other trees are felled in Louisiana merely for collecting the fruit they bear upon their summits. The Borneo, or Japan camphor, is pure, and so very strong, as readily to communicate much of its odour and its virtues to other inspissated oils, which thus pass for real camphor; and this adulterated drug is sold by Chinese artists at a vastly lower price than they gave themselves for the genuine substance from Borneo or Japan.

Sir George Staunton, from whom we have this account, does not inform us whether the camphor-tree of China, if felled and torn into splinters, would not produce as large quantities of the drug, and equally pure, as the trees of Borneo and Japan; but he assures us, that in China it is never so torn, being there a large and valuable timber-tree. "It is used (says he) in the best buildings of every kind, as well as for masts of vessels, and bears too high a price to allow of any part, except the branches, being cut up for the sake of the drug."

Canals.

CANALS of Communication may be of such advantage in a commercial or agricultural country, that every attempt to render them more convenient, and less expensive in the construction, is intitled to public notice. In the Encyclopædia, an account, sufficiently perspicuous, is given of the common canals with locks; but in many cases it is very difficult to provide a sufficient quantity of water for the consumption of a canal where many boats are to pass. Different attempts have therefore been made, by ingenious men, to save water in the passing of boats or lighters from one lock of a canal to another; and, among these, perhaps none is more deserving of public favour than the following, by the late Mr James Playfair of Russel-street, architect. We shall state his invention in his own words.

"The nature and principle of this manner of saving water consist in letting the water which has served to raise or fall a boat or barge from the lock, pass into reservoirs or cisterns, whose apertures of communication with the lock are upon different levels, and which may be placed or constructed at the side or sides of the lock with which they communicate, or in any other contiguous situation that circumstances may render eligible; which apertures may be opened or shut at pleasure, so that the water may pass from the lock to each reservoir of the canal, or from each reservoir to the lock, in the following manner: The water which fills the lock, when a boat is to ascend or descend, instead of being passed immediately into the lower part of the canal, is let pass into these cisterns or reservoirs, upon different levels; then, their communications with the lock being shut, they remain full until another vessel is wanted to pass; then, again, the cisterns are emptied into the lock, which is thereby nearly filled, so that only the remainder which is not filled is supplied from the higher part of the canal. Each of these cisterns must have a surface not less than that of the lock, and must contain half as much water as is meant to be expended for the passing of each vessel. The cistern the most elevated is placed twice its own depth (measuring by the aperture, or communicating opening of the cisterns) under the level of the water in the higher part of the canal. The second cistern is placed once its own depth under the first, and so on are the others to the lowest; which last is placed once its own depth above the level of the water in the lower part of the canal. The apertures of the intermediate cisterns, whatever their number may be, must all be equally divided into different levels; the surface of the water in the one being always on the level of the bottom of the aperture of the cistern which is immediately above. As an example of the manner and rule for constructing these cisterns, suppose that a lock is to be constructed twelve feet deep, that is, that the vessel may ascend or descend twelve feet in passing. Suppose the lock sixty feet long and six feet wide, the quantity of water required to fill the lock, and to pass a boat, is 4320 cubic feet; and suppose that, in calculating the quantity of water that can be procured for supplying the canal, after allowing for waste, it is found (according to the number of boats that may be expected to pass) that there will not be above 800 cubic feet for each; then it will be necessary to save five-sixths of the whole quantity that in the common case would be necessary: to do which ten cisterns must be made (the mode of placing which is expressed

preſſed in the drawing, fig. 1. Plate VII.), each of which muſt be one foot deep, or deeper at pleaſure, and each muſt have a ſurface of 360 feet ſquare, equal to the ſurface of the lock. The bottom of the aperture of the loweſt ciſtern muſt be placed one foot above the level of the water in the lower part of the canal, or eleven feet under the level of the high water; the ſecond ciſtern muſt be two feet above the level of the low water; the third three feet, and ſo on of the others; the bottom of the tenth, or uppermoſt ciſtern, being ten feet above the low water, and two feet lower than the high water; and, as each ciſtern muſt be twelve inches in depth, the ſurface of the water in the higher ciſtern will be one foot under the level of the water in the upper part of the canal. The ciſterns being thus conſtructed, when the lock is full, and the boat to be let down, the communications between the lock and the ciſterns, which until then have all been ſhut, are to be opened in the following manner: firſt, the communication with the higher ciſtern is opened, which, being at bottom two feet under the level of the water in the lock, is filled to the depth of one foot, the water in the lock deſcending one foot alſo at the ſame time; that communication is then ſhut, and the communication between the lock and the ſecond ciſtern is opened; one foot more of the water then paſſes into that ciſtern from the lock, and fills it; the opening is then ſhut: the ſame is done with the third, fourth, fifth, ſixth, ſeventh, eighth, ninth, and tenth, ciſterns, one by one, until they are all filled; and when the tenth, or lowermoſt ciſtern, is filled, there remains but two feet depth of water in the lock. The communication between the lock and the lower part of the canal is then opened, and the laſt two feet depth of water is emptied into the lower part of the canal. By this means, it is evident that, inſtead of twelve feet depth of water being let deſcend into the lower part of the canal, there is only two feet depth that deſcends, or one-ſixth of the whole; therefore, inſtead of 4320 cubic feet being uſed, there are only 720 cubic feet uſed: the remainder of the water in the ciſterns being uſed as follows: When another boat is to mount, the ſluices being then ſhut, and the boat in the lock, the tenth or lowermoſt ciſtern is emptied into the lock, which it fills one foot; the communication being then ſhut, the next loweſt ciſtern, or the ninth, is emptied into the lock, which is thereby filled another foot; and ſo, in like manner, all the other ciſterns are emptied one after another, until the higher ciſtern being emptied, which fills the tenth foot of water in the lock, there remains but two feet of water to fill, which is done from the upper part of the canal by opening the higher ſluice to paſs the boat; by that means, the ſame quantity of water deſcends from the upper part of the canal into the lock, that in the other caſe deſcended from the lock into the lower part of the canal; ſo that, in both caſes, the ſame quantity of water is ſaved, that is, five-ſixths of what would be neceſſary were there no ciſterns. Suppoſe again that, upon the ſame canal, and immediately after the twelve feet lock, it would be advantageous to conſtruct one of eighteen feet; then, in order not to uſe any greater quantity of water, it will be neceſſary to have ſixteen ciſterns, upon different levels, communicating with the lock in the ſame manner. Should, again, a lock of only ſix feet be wanted, after that of eighteen, then it will only be neceſſary to have four ciſterns on different levels, and ſo of any other height of lock. The rule is this: For finding the number and ſize of the ciſterns, each ciſtern being the ſame in ſuperficies with the lock, its depth muſt be ſuch as to contain one half the quantity of water meant to be uſed in the paſſing of one boat. The depth of the lock, divided by the depth neceſſary for ſuch a ciſtern, will give, in all caſes, the whole number of ciſterns, and two more: deduct the number two, therefore, from the number which you find by dividing the depth of the lock by the depth of one ciſtern, and you have always the number of ciſterns required; which are to be placed upon different levels, according to the rule already given. The above is the principle and manner of uſing the lock, for ſaving water in canals, and for enabling engineers to conſtruct locks of different depths upon the ſame canal, without uſing more water for the deep locks than for the ſhallow ones. With regard to the manner of diſpoſing the ciſterns, the circumſtances of the ground, the declivity, &c. will be the beſt guide for the engineer."

But ſuppoſing a ſufficiency of water, or admitting that this method of Mr Playfair's of ſaving it, where defective, is adequate to his fondeſt expectations, ſtill, in paſſing numerous locks, where the riſe is conſiderable, the interruption is ſo great, that it has often been wiſhed that an eligible method of lowering and elevating boats could be deviſed, without the aſſiſtance of water-locks. Though this is evidently at firſt view practicable, and ſeveral different modes of doing it have been ſuggeſted, ſome of which have actually been carried into effect, yet all of them have been found to be attended with ſuch inconvenience as to render an improvement in this reſpect ſtill neceſſary.

In China, where water-carriage is more generally practiſed than in any kingdom of Europe, boats are raiſed and lowered from one canal into another, by ſliding them along an inclined plane: but the contrivances for effecting that purpoſe are ſo awkward, and ſuch a number of hands are required, that it has in general been deemed inexpedient to reſort to that mode of practice in Europe. Several devices, that diſcover conſiderable ingenuity, however, have been publiſhed, with a view to facilitate this operation; either by rendering the motion up the inclined plane more equable, or producing a power ſufficient to move theſe great weights. But none of them have yet been ſo ſimple in their conſtruction as could be wiſhed, nor have they afforded ſatisfaction in practice. For the greater part of them, likewiſe, patents have been granted; ſo that whatever be their value, no engineer could avail himſelf of them without previouſly purchaſing a licence from the patentee.

The following contrivance for this purpoſe is the invention of James Anderſon, LL. D. whoſe knowledge of economics is well known, and of whoſe public ſpirit there cannot be a doubt. Inſtead of applying for a patent, to ſecure to himſelf the fruits of his ingenuity, he publiſhed, for the good of his countrymen in general, his device, in the View of the Agriculture of the County of Aberdeen, which he drew up for the conſideration of the board of agriculture. He introduces it to public notice with juſtly obſerving, that it poſſeſſes at leaſt the merit of ſimplicity, in as high a degree, perhaps,

haps, as could be wished; and, "in the opinion (says he) of very good judges of matters of this sort, to whom the plan has been shewn, it has been deemed fully adequate to the purpose of raising and lowering boats of a moderate size, that is, of 20 tons, or downwards; and it is the opinion of most men with whom I have conversed, who are best acquainted with the inland navigations, that a boat of from 10 to 15 tons is better than those of a larger size. When several are wanted to be sent at once, they may be affixed to one another, as many as the towing-horse can conveniently draw. Were boats of this size adopted, and were all the boats on one canal to be of the same dimensions, it would prove a great convenience to a country in a state of beginning improvements; because the expence of such a boat would be so trifling, that every farmer could have one for himself, and might of course make use of it when he pleased by the aid of his own horse, without being obliged to have any dependence on the time that might suit the convenience of his neighbour; and if two or more boats were going from the same neighbourhood, one horse could serve the whole.

"You are to suppose that fig. 2. (Plate VII.) represents a bird's-eye view of this simple apparatus, as seen from above. A is supposed to be the upper reach of the canal, and B the lower reach, with the apparatus between the two. This consists of three divisions; the middle one, extending from C to D, is a solid piece of masonry, raised from a firm foundation below the level of the bottom of the second reach: this is again divided into five parts, viz. *d d d*, where the wall rises only to the height of the water in the upper reach, and *e e*, two pillars, raised high enough to support the pivots of a wheel or pulley *g*, placed in the position there marked.

"The second division *h* consists of a wooden coffer, of the same depth nearly as the water in the upper reach, and of a size exactly fitted to contain one of the boats. This communicates directly with the upper reach, and being upon the same plane with it, and so connected with it as to be water-tight, it is evident, from inspection, that nothing can be more easy than to float a boat into this coffer from the upper reach; the part of the wheel that projects over it being at a sufficient height above it, so as to occasion no sort of interruption.

"Third division. At *i* is represented another coffer, precisely of the same dimensions with the first. But here two sluices, which were open in the former, and only represented by dotted lines, are supposed to be shut, so as to cut off all communication between the water in the canal and that in the coffer. As it was impossible to represent this part of the apparatus on so small a scale, for the sake of illustration it is represented more at large in fig. 5. where A, as before, represents the upper reach of the canal, and *h* one of the coffers. The sluice *k* goes into two cheeks of wood, joined to the masonry of the dam of the canal, so as to fit perfectly close; and the sluice *f* fits equally close into cheeks made in the side of the coffer for that purpose; between these two sluices is a small space *o*. The coffer, and this division *o*, are to be supposed full of water, and it will be easy to see that these sluices may be let down or drawn up at pleasure with much facility.

"Fig. 6. represents a perpendicular section of these parts in the same direction as in fig. 5. and in which the same letters represent the same parts.

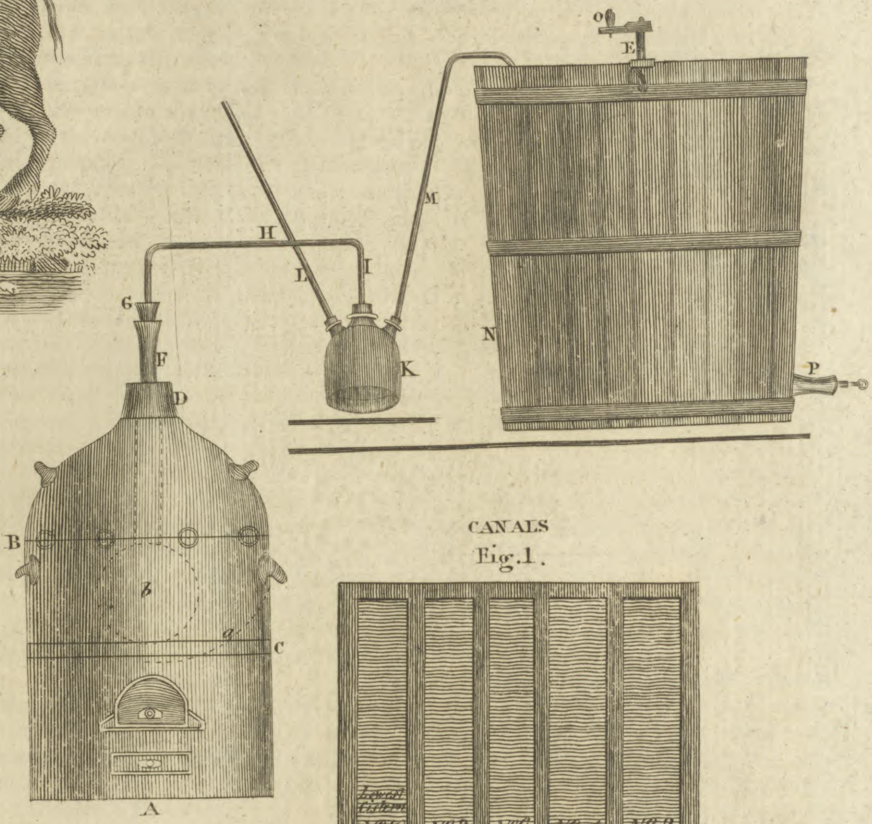
"Things being thus arranged, you are to suppose the coffer *h* to be suspended, by means of a chain passed over the pulley, and balanced by a weight that is sufficient to counterpoise it, suspended at the opposite end of the chain. Suppose, then, that the counterpoise be made somewhat lighter than the coffer with its contents, and that the line *m n* (fig. 6.) represents a division between the solid sides of the dam of separation, which terminates the upper reach and the wooden coffer, which had been closed only by the pressure of its own weight (being pushed a very little from A towards B, beyond its precise perpendicular swing), and that the joining all round is covered with lists of cloth put upon it for that purpose; it is evident that, so long as the coffer is suspended to this height, the joining must be water-tight; but no sooner is it lowered down a little than this joining opens, the water in the small division *o* is allowed to run out, and an entire separation is made between the fixed dam and this moveable coffer, which may be lowered down at pleasure without losing any part of the water it contained.

"Suppose the coffer now perfectly detached, turn to fig. 3. which represents a perpendicular section of this apparatus, in the direction of the dotted line *p p* (fig. 2.) In fig. 3. *h* represents an end view of the coffer, indicated by the same letter as in fig. 2. suspended by its chain, and now perfectly detached from all other objects, and balanced by a counterpoise *i*, which is another coffer exactly of the same size, as low down as the level of the lower reach. From inspection only, it is evident, that in proportion as the one of these weights rises, the other must descend. For the present, then, suppose that the coffer *h* is by some means rendered more weighty than *i*, it is plain it will descend while the other rises; and they will thus continue till *h* comes down to the level of the lower reach, and *i* rises to the level of the higher one.

"Fig. 4. represents a section in the direction AB (fig. 2.), in which the coffer *i* (seen in both situations) is supposed to have been gradually raised from the level of the lower reach B, to that of the higher A, where it now remains stationary; while the coffer *h* (which is concealed behind the masonry) has descended in the mean time to the level of the lower reach, where it closes by means of the juncture *r s*, fig. 6. (which juncture is covered with lists of cloth, as before explained, at *m n*, and is of course become water-tight), when, by lifting the sluice *t*, and the corresponding sluice at the end of the canal, a perfect communication by water is established between them. If, then, instead of water only, this coffer had contained a boat, floated into it from the upper reach, and then lowered down, it is very plain that when these sluices were removed, after it had reached the level of the lower reach, that boat might have been floated out of the coffer with as much facility as it was let into it above. Here then we have a boat taken from the higher into the lower canal; and, by reversing this movement, it is very obvious that it might be, with equal ease, raised from the lower into the higher one. It now only remains that I should explain by what means the equilibrium between these

LARGE SNOUTED BOAR

BLEACHING



CANALS

Fig. 1.

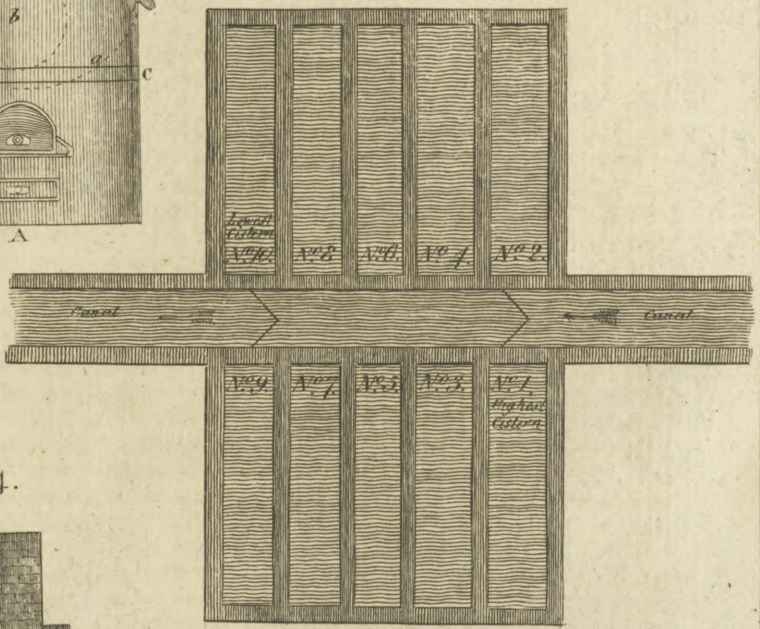


Fig. 2.

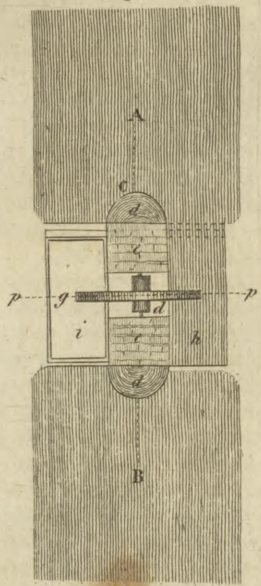

Fig. 3.

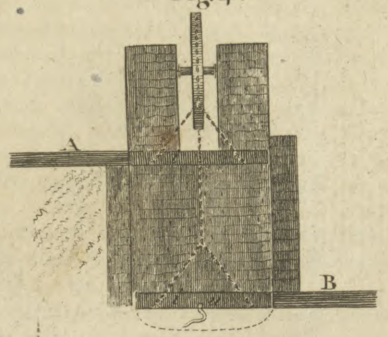

Fig. 5.

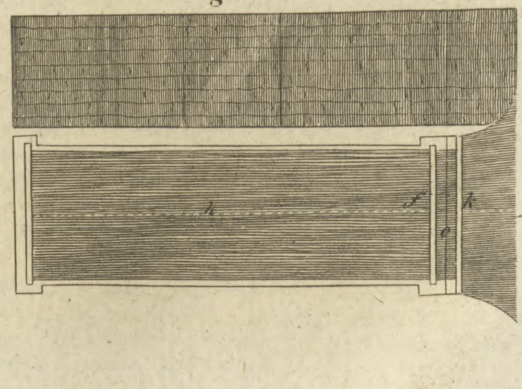

Fig. 6.

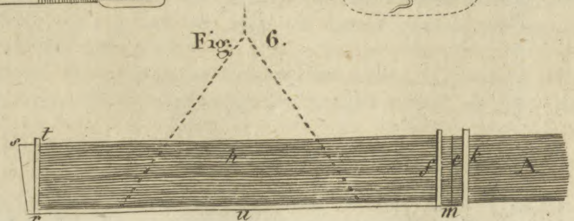

these counterbalancing weights can be deſtroyed at pleaſure, and the motion of courſe produced.

"It is very evident, that if the two correſponding coffers be preciſely of the ſame dimenſions, their weight will be exactly the ſame when they are both filled to the ſame depth of water. It is equally plain, that ſhould a boat be floated into either or both of them, whatever its dimenſions or weight may be, ſo that it can be contained afloat in the coffer, the weight of the coffer and its contents will continue preciſely the ſame as when it was filled with water only: hence, then, ſuppoſing one boat is to be lowered, or one to be raiſed at a time, or ſuppoſing one to be raiſed and another lowered at the ſame time—they remain perfectly in equilibrium in either place, till it is your pleaſure to deſtroy that equilibrium. Suppoſe, then, for the preſent, that both coffers are loaded with a boat in each, the double ſluices both above and below cloſed; and ſuppoſe alſo that a ſtop-cock *u*, in the under edge of the ſide of the lower coffer (fig. 4. and 6.), is opened, ſome of the water which ſerved to float the boat in the coffer will flow out of it, and conſequently that coffer will become lighter than the higher one; the upper coffer will of courſe deſcend, while the other mounts upwards. When a gentle motion has been thus communicated, it may be prevented from accelerating, merely by turning the ſtop-cock ſo as to prevent the loſs of more water, and thus one coffer will continue to aſcend, and the other to deſcend, till they have aſſumed their ſtations reſpectively; when, in conſequence of a ſtop below, and another above, they are rendered ſtationary at the level of the reſpective canals (A).

"Preciſely the ſame effect will be produced when the coffers are filled entirely with water.

"It is unneceſſary to add more to this explanation, except to obſerve that the ſpace for the coffer to deſcend into muſt be deeper than the bottom of the lower canal, in order to allow a free deſcent for the coffer to the requiſite depth; and of courſe it will be neceſſary to have a ſmall conduit to allow the water to get out of it. Two or three inches free, below the bottom of the canal, is all that would be neceſſary.

"Where the height is inconſiderable, there will be no occaſion for providing any counterpoiſe for the chain, as that will give only a ſmall addition to the weight of the undermoſt coffer, ſo as to make it preponderate, in circumſtances where the two coffers would otherwiſe be in perfect equilibrium: but, where the height is conſiderable, there will be a neceſſity for providing ſuch a counterpoiſe; as, without it, the chain, by becoming more weighty every foot it deſcended, would tend to deſtroy the equilibrium too much, and accelerate the motion to an inconvenient degree. To guard againſt this inconvenience, let a chain of the ſame weight, per foot, be appended at the bottom of each coffer, of ſuch a length as to reach within a few yards of the ground where the coffer is at its greateſt height (ſee fig. 3.); it will act with its whole weight upon the higheſt coffer while in this poſition; but, as that gradually deſcended, the chain would reach the ground, and, being there ſupported, its weight would be diminiſhed in proportion to its deſcent; while the weight of the chain on the oppoſite ſide would be augmented in the ſame proportion, ſo as to counterpoiſe each other exactly, in every ſituation, until the uppermoſt chain was raiſed from the ground. After which it would increaſe its weight no more; and, of courſe, would then give the under coffer that preponderance which is neceſſary for preſerving the machine ſteady. The under coffer, when it reached its loweſt poſition, would touch the bottom on its edges, which would then ſupport it, and keep every thing in the ſame poſition, till it was made lighter for the purpoſe of aſcending.

"What conſtitutes one particular excellence of the apparatus here propoſed is, that it is not only unlimited as to the extent of the riſe or depreſſion of which it is ſuſceptible (for it would not require the expenditure of one drop more water to lower it one hundred feet than one foot); but it would alſo be eaſy ſo to augment the number of pulleys at any one place as to admit of two, three, four, or any greater number of boats being lowered or elevated at the ſame time; ſo that let the ſucceſſion of boats on ſuch a canal be nearly as rapid as that of carriages upon a highway, none of them need be delayed one moment to wait an opportunity of paſſing: a thing that is totally impracticable where water-locks are employed; for the intercourſe, on every canal conſtructed with water-locks, is neceſſarily limited to a certain degree, beyond which it is impoſſible to force it.

"For example: ſuppoſe a hundred boats are following each other, in ſuch a rapid ſucceſſion as to be only half a minute behind each other: By the apparatus here propoſed, they would all be elevated preciſely as they came; in the other, let it be ſuppoſed that the lock is ſo well conſtructed as that it takes no more than five minutes to cloſe and open it; that is, ten minutes in the whole to each boat (for the lock, being once filled, muſt be again emptied before it can receive another in the ſame direction): at this rate, ſix boats only could be paſſed in an hour, and of courſe it would take ſixteen hours and forty minutes to paſs the whole hundred; and as the laſt boat would reach the lock in the ſpace of fifty minutes after the firſt, it would be detained fifteen hours and fifty minutes before its turn would come to be raiſed. This is an immenſe detention; but if a ſucceſſion of boats, at the ſame rate, were to follow continually, they never could paſs at all. In ſhort, in a canal conſtructed with water-locks, not more than ſix boats, on an average, can be paſſed in an hour, ſo that beyond that extent all commerce muſt be ſtopped; but, of the plan here propoſed, ſixty, or ſix hundred, might be paſſed in an hour if neceſſary, ſo as to occaſion no ſort of interruption whatever. Theſe are advantages of a very important nature, and ought not to be overlooked in a commercial country.

"This apparatus might be employed for innumerable other uſes as a moving power, which it would be foreign to our preſent purpoſe here to ſpecify. Nor does its power admit of any limitation, but that of the ſtrength of the chain, and of the coffers which are to ſupport the weights. All the other parts admit of being

(A) "It does not ſeem neceſſary to adopt any other contrivance than the above for regulating the motions; but if it ſhould be found neceſſary, it would be eaſy to put a ratch-wheel on the ſame axle."

being made so immoveably firm as to be capable of supporting almost any assignable weight.

"I will not enlarge on the benefits that may be derived from this very simple apparatus: its cheapness, when compared with any other mode of raising and lowering vessels that has ever yet been practised, is very obvious; the waste of water it would occasion is next to nothing; and when it is considered that a boat might be raised or lowered fifty feet nearly with the same ease as five, it is evident that the interruptions which arise from frequent locks would be avoided, and an immense saving be made in the original expence of the canal, and in the annual repairs.

"It is also evident that an apparatus, on the same principle, might be easily applied for raising coals or metals from a great depth in mines, wherever a very small stream of water could be commanded, and where the mine was level-free."

CANARY-bird, of which a description is given in the Encyclopædia, was not known in Europe till towards the end of the 15th century. Even in 1555, Bellon, who about that time described all the birds then known, does not so much as mention it. When it was first brought from the Canary Islands, it was so dear that it could be purchased only by people of fortune, who were often imposed upon. It was called the *sugar-bird*, because it was said to be fond of the sugar-cane, and could eat sugar in great abundance. This is rather a singular circumstance, sugar being to many fowls a poison. Experiments have shewn that a pigeon, to which four drams of sugar was given, died in four hours; and that a duck, which had swallowed five drams, did not live seven hours.

In the middle of the last century canary-birds began to be bred in Europe; and to this the following circumstance, related by Olina, seems to have given occasion: "A vessel which, among other commodities, was carrying a number of canary birds to Leghorn, was wrecked on the coast of Italy; and these birds being thus set at liberty, flew to the nearest land, which was the island of Elba, where they found the climate so favourable, that they multiplied, and perhaps would have become domesticated, had they not been caught in snares; for it appears that the breed of them there has been long destroyed. Olina says that the breed soon degenerated; but it is probable that by much the greater part of these canary-birds were males, which coupling with birds of the island, produced mules, such as are described by Gesner and other naturalists."

"Various treatises have been published in different languages, on the manner of breeding these birds, and many people have made it a trade, by which they have acquired considerable gain. It does no discredit to the industry of the Tyrolians, that they have carried it to the greatest extent. At Ymst there is a company, who, after the breeding season is over, send out persons to different parts of Germany and Switzerland to purchase birds from those who breed them. Each person brings with him commonly from three to four hundred, which are afterwards carried for sale, not only through every part of Germany, but also to England, Russia, and even Constantinople. About sixteen hundred are brought every year to England; where the dealers in them, notwithstanding the considerable expence they are at, and after carrying them about on their backs, perhaps a hundred miles, sell them for five shillings a piece. This trade, hitherto neglected, is now carried on in Schwartzwalde; and at present there is a citizen at Gottingen who takes with him every year to England several canary-birds and bulfinches (*loxia pyrrhula*), with the produce of which he purchases such small wares as he has occasion for."—*Professor Beckmann's History of Inventions and Discoveries.*

Canary-Seed. See Phalaris, *Encycl.*—Professor Beckmann doubts whether the plant which bears the canary-seed be the *phalaris* of the ancients, because that name seems to have been given by Pliny to more than one species of grass. He thinks it very probable, however, that the plant, which the modern botanists call *phalaris*, was first brought from the Canary Islands to Spain, where it began to be cultivated, as well as in the south of France, as soon as canary-birds came into general esteem. At present it is cultivated in various places, and forms no inconsiderable branch of trade, particularly in the island of Sicily, where it is called *Scagliuola* or *Scaghiola*. Were it not that the grains are not easily freed from the husks, this plant might be cultivated for the food of man, for its seeds yield a good kind of meal. The phalaris has by several writers been confounded with *argol* or the *lichen rocolla* of Linnæus; but they are very different plants. See *Lichen Rocolla* in this Supplement.

CANDLE, a thing so universally known as to need no particular description. Its use, however, is so great, that every information tending to its improvement must, we should think, be acceptable to our readers. Of the common method of making candles, whether of wax or of tallow, a sufficient account has been given in the Encyclopædia; but candles of every kind are far from being yet brought to that degree of perfection of which they seem susceptible. Thus, for example, the light of a candle, which is so exceedingly brilliant when first snuffed, is very speedily diminished to one half, and is usually not more than one-fifth or one-sixth, before the uneasiness of the eye induces us to snuff it. Hence it follows, that if candles could be made so as not to require snuffing, the average quantity of light afforded by the same quantity of combustible matter would be more than doubled. It may likewise be worthy of inquiry, since the cost and duration of candles are easily ascertainable, whether more or less light is obtained at the same expence during a given time, by burning a number of small candles instead of one of greater thickness.

To determine this last point, a method must be found of measuring the comparative intensities of light, for which see Photometer in this Supplement. With respect to the desideratum first mentioned, we have some very ingenious observations and well-contrived experiments by Mr Nicholson, in the second number of his valuable Journal, which we shall here insert nearly in the words of their author.

In every process of combustion the free access of air is of the utmost consequence. When a candle has a very slender wick, the flame is small and of a brilliant white colour; if the wick be large, the combustion is less perfect, and the flame brown; and a wick still larger, not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatilized matter, which does not become ignited till it has ascended towards the point. When the wick is either

Candle.

either very large or very long, part of this matter escapes combustion, and shews itself in the form of coal or smoke. The same things take place in the burning of a lamp; but when the wick of a lamp is once adjusted as to its length, the flame continues nearly in the same state for a much longer time than the flame of a candle.

"Upon comparing a candle with a lamp (says Mr Nicholson), two very remarkable particulars are immediately seen. In the first place, the tallow itself, which remains in the unfused state, affords a cup or cavity to hold that portion of melted tallow which is ready to flow into the lighted part of the wick. In the second place, the combustion, instead of being confined, as in the lamp, to a certain determinate portion of the fibrous matter, is carried, by a slow succession, through the whole length. Hence arises the greater necessity for frequent snuffing the candle; and hence also the station of the freezing point of the fat oil becomes of great consequence. For it has been shewn, that the brilliancy of the flame depends very much on the diameter of the wick being as small as possible; and this requisite will be most attainable in candles formed of a material that requires a higher degree of heat to fuse it. The wick of a tallow candle must be made thicker in proportion to the greater fusibility of the material, which would otherwise melt the sides of the cup, and run over in streams. The flame will therefore be yellow, smoky, and obscure, excepting for a short time immediately after snuffing. Tallow melts at the 92d degree of Fahrenheit's thermometer; spermaceti at the 133d degree; the fatty matter formed of flesh, after long immersion in water, melts at 127 degrees; the *pela* of the Chinese at 145 degrees; bees-wax at 142 degrees; and bleached wax at 155 degrees. Two of these materials are well known in the fabrication of candles. Wax in particular does not afford so brilliant a flame as tallow; but, on account of its less fusibility, the wick can be made smaller, which not only affords the advantage of a clear perfect flame, but from its flexibility it is disposed to turn on one side, and come in contact with the external air, which completely burns the extremity of the wick to white ashes, and thus performs the office of snuffing. We see therefore that the important object to society of rendering tallow candles equal to those of wax, does not at all depend on the combustibility of the respective materials, but upon a mechanical advantage in the cup, which is afforded by the inferior degree of fusibility in the wax; and that, to obtain this valuable object, one of the following effects must be produced: Either the tallow must be burned in a lamp, to avoid the gradual progression of the flame along the wick; or some means must be devised to enable the candle to snuff itself, as the wax candle does; or, lastly, the tallow itself must be rendered less fusible by some chemical process. I have no great reason to boast of success in the endeavour to effect these; but my hope is, that the facts and observations here presented may considerably abridge the labour of others in the same pursuit.

"The makers of thermometers and other small articles with the blow-pipe and lamp, give the preference to tallow instead of oil, because its combustion is more complete, and does not blacken the glass. In this operation the heat of the lamp melts the tallow which is occasionally brought into its vicinity by the workman. But for the usual purposes of illumination, it cannot be supposed that a person can attend to supply the combustible matter. Considerable difficulties arise in the project for affording this gradual supply as it may be wanted. A cylindrical piece of tallow was inserted into a metallic tube, the upper aperture of which was partly closed by a ring, and the central part occupied by a metallic piece nearly resembling that part of the common lamp which carries the wick. In this apparatus the piece last described was intended to answer the same purpose, and was provided with a short wick. The cylinder of tallow was supported beneath in such a manner that the metallic tube and other part of this lamp were left to rest with their whole weight upon the tallow at the ring or contraction of the upper aperture. In this situation the lamp was lighted. It burned for some time with a very bright clear flame, which, when compared with that of a candle, possessed the advantage of uniform intensity, and was much superior to the ordinary flame of a lamp in its colour, and the perfect absence of smell. After some minutes it began to decay, and very soon afterwards went out. Upon examination, it was found that the metallic piece which carried the wick had fused a sufficient quantity of tallow for the supply during the combustion; that part of this tallow had flowed beneath the ring, and to other remote parts of the apparatus, beyond the influence of the flame; in consequence of which, the tube and the cylinder of tallow were fastened together, and the expected progression of supply prevented. It seems probable that, in every lamp for burning consistent oils, the material ought to be so disposed that it may descend to the flame upon the principle of the fountain reservoir. I shall not here state the obstacles which present themselves in the prospect of this construction, but shall dismiss the subject by remarking, that a contrivance of this nature would be of the greatest public utility.

"The wick of a candle being surrounded by the flame, is nearly in the situation of a body exposed to destructive distillation in a close vessel. After losing its volatile products, the carbonaceous residue retains its figure, until, by the descent of the flame, the external air can have access to its upper extremity. But, in this case, the requisite combustion, which might snuff it, is not effected: for the portion of oil emitted by the long wick is not only too large to be perfectly burned, but also carries off much of the heat of the flame while it assumes the elastic state. By this diminished combustion and increased efflux of half-decomposed oil, a portion of coal or soot is deposited on the upper part of the wick, which gradually accumulates, and at length assumes the appearance of a fungus. The candle does not then give more than one-tenth of the light emitted in its best state. Hence it is that a candle of tallow cannot spontaneously snuff itself. It was not probable that the addition of a substance containing vital air or oxygen would supply that principle at the precise period of time required; but as experiment is the test of every probability of this nature, I soaked a wick of cotton in a solution of nitre, then dried it, and made a candle. When this came to be lighted, nothing remarkable happened for a short time; at the expiration of which a decrepitation followed at the lower extremity of the flame, which completely divided the wick, where

Candle.

where the blackened part commences. The whole of the matter in combuſtion therefore fell off, and the candle was of courſe inſtantly extinguiſhed. Whether this would have happened in all proportions of the ſalt or conſtructions of the candle, I did not try, becauſe the ſmell of azot was ſufficiently ſtrong and unpleaſant to forbid the uſe of nitre in the purſuit. From various conſiderations, I am diſpoſed to think that the ſpontaneous ſnuffing of candles made of tallow, or other fuſible materials, will ſcarcely be effected but by the diſcovery of ſome material for the wick which ſhall be voluminous enough to abſorb the tallow, and at the ſame time ſufficiently flexible to bend on one ſide.

"The moſt promiſing ſpeculation reſpecting this moſt uſeful article, ſeems to direct itſelf to the cup which contains the melted tallow. The imperfection of this part has already been noticed, namely, that it breaks down by fuſion, and ſuffers its fluid contents to eſcape. The Chineſe have a kind of candle about half an inch in diameter, which, in the harbour of Canton, is called a *lobchock;* but whether the name be Chineſe, or the corruption of ſome European word, I am ignorant. The wick is of cotton, wrapped round a ſmall ſtick or match of the bamboo cane. The body of the candle is white tallow; but the external part, to the thickneſs of perhaps one thirtieth of an inch, conſiſts of a waxy matter coloured red. This covering gives a conſiderable degree of ſolidity to the candle, and prevents its guttering, becauſe leſs fuſible than the tallow itſelf. I did not obſerve that the ſtick in the middle was either advantageous or the contrary; and as I now write from the recollection of this object at ſo remote a period as 25 years ago, I can only conjecture that it might be of advantage in throwing up a leſs quantity of oil into the flame than would have been conveyed by a wick of cotton ſufficiently ſtout to have occupied its place unſupported in the axis of the candle.

"Many years ago I made a candle in imitation of the lobchock. The expedient to which I had recourſe conſiſted in adapting the wick in the uſual pewter mould: wax was then poured in, and immediately afterwards poured out: the film of wax which adhered to the inner ſurface of the mould ſoon became cool, and the candle was completed by filling the mould with tallow. When it was drawn out, it was found to be cracked longitudinally on its ſurface, which I attributed to the contraction of the wax, by cooling, being greater than that of the tallow. At preſent I think it equally probable that the cracking might have been occaſioned by too ſudden cooling of the wax before the tallow was poured in; but other avocations prevented the experiments from being varied and repeated. It is probable that the Chineſe external coating may not be formed of pure hard bleached wax.

"But the moſt deciſive remedy for the imperfection of this cheapeſt, and in other reſpects beſt, material for candles, would undoubtedly be to diminiſh its fuſibility. Various ſubſtances may be combined with tallow, either in the direct or indirect method. In the latter way, by the decompoſition of ſoap, a number of experiments were made by Berthollet, of which an account is inſerted in the memoirs of the Academy at Paris for the year 1780, and copied into the 26th volume of the *Journal de Phyſique.* None of theſe point directly to the preſent object; beſides which, it is probable that the ſoap made uſe of by that eminent chemiſt was formed not of tallow, but oil. I am not aware of any regular ſeries of experiments concerning the mutual action of fat oils and other chemical agents, more eſpecially ſuch as may be directed to this important object of diminiſhing its ſolubility; for which reaſon I ſhall mention a few experiments made with this view.

"1. Tallow was melted in a ſmall ſilver veſſel. Solid tallow ſinks in the fluid, and diſſolves without any remarkable appearance. 2. Gum ſandarach in tears was not diſſolved, but emitted bubbles, ſwelled up, became brown, emitted fumes, and became criſp or friable. No ſolution nor improvement of the tallow. 3. Shell-lac ſwelled up with bubbles, and was more perfectly fuſed than the gum ſandarach in the former experiment. When the tallow was poured off, it was thought to congeal rather more ſpeedily. The lac did not appear to be altered. 4. Benzoin bubbled without much ſwelling, was fuſed, and emitted fumes of an agreeable ſmell, though not reſembling the flowers of benzoin. A ſlight or partial ſolution ſeemed to take place. The benzoin was ſofter and of a darker colour than before, and the tallow leſs conſiſtent. 5. Common reſin unites very readily with melted tallow, and forms a more fuſible compound than the tallow itſelf. 6. Camphor melts eaſily in tallow, without altering its appearance. When the tallow is near boiling, camphoric fumes fly off. The compound appeared more fuſible than tallow. 7. The acid or flowers of benzoin diſſolves in great quantities without any ebullition or commotion. Much ſmoke ariſes from the compound, which does not ſmell like the acid of benzoin. Tallow alone does not fume at a low heat, though it emits a ſmell ſomething like that of oil olive. When the proportion of the acid was conſiderable, ſmall needled cryſtals appeared as the temperature diminiſhed. The appearances of ſeparation are different according to the quantity of acid. The compound has the hardneſs and conſiſtence of firm ſoap, and is partially tranſparent. 8. Vitriolated tartar, nitre, white ſugar, cream of tartar, cryſtallized borax, and the ſalt ſold in the markets under the name of ſalt of lemons, but which is ſuppoſed to be the eſſential ſalt of ſorrel, or vegetable alkali ſuperſaturated with acid of ſugar, were reſpectively tried without any obvious mutual action or change of properties in the tallow. 9. Calcined magneſia rendered tallow opaque and turbid, but did not ſeem to diſſolve. Its effect reſembled that of lime.

"It is propoſed to try the oxygenated acetous acid, or radical vinegar; the acid of ants, of ſugar, of borax, of galls, the tanning principle, the ſerous and gelatinous animal matter, the fecula of vegetables, vegetable gluten, bird-lime, and other principles, either by direct or indirect application. The object, in a commercial point of view, is intitled to an extenſive and aſſiduous inveſtigation. Chemiſts in general ſuppoſe the hardneſs or leſs fuſibility of wax to ariſe from oxygen; and to this object it may perhaps be advantageous to direct a certain portion of the inquiry. The metallic ſalts and calces are the combinations from which this principle is moſt commonly obtained; but the combinations of theſe with fat oils have hitherto afforded little promiſe of the improvement here ſought. The ſubject is, however, ſo little known, that experiments of the looſeſt and moſt conjectural kind are by no means to be deſpiſed."

Thus

Thus far Mr Nicholson: but it is probable that many of the advantages which he proposes by these mixtures might be obtained merely by purifying the tallow, and keeping it in that state for a long time exposed to the air before it be formed into candles. It is certain that tallow is rendered more difficult of fusion by age; and this is the sole reason that old candles are less apt to run, and therefore more valuable than such as have been lately made.

CANONGOES, in Bengal, are the registers of land and hereditary expounders of the usages of the country. They have their officers and deputies everywhere; they are not liable to removal; and all papers attested by them are received as authentic and decisive in all disputes relative to lands and their boundaries. See *Sir Charles Rouse Boughton's Dissertation on the Landed Property of Bengal.*

CAOUTCHOUC, Elastic Gum, or *Indian Rubber*, is a substance of which a pretty full account has been given in the Encyclopædia. It has there been likewise observed how useful it might be, if we could form it into catheters and other flexible instruments, by dissolving it in a menstruum less expensive, or at least more easily attained, than ether. Since that article was published, we have seen an account of such a menstruum in the *Annales de Chimie*, by M. Grossart (Chirly); and of the expence of that menstruum, or the difficulty of procuring it, no complaint will be made, when it is known to be nothing more than very hot water.

The author was led to this discovery by some experiments made with ether on caoutchouc; of which he gives the following account:

" It appeared, even in my first experiments, that I was attempting too much, and giving myself useless trouble, in searching for a manner of completely dissolving the elastic gum, so that it might be again made up in new forms. I then thought that it would be easier to find out a method, as it were, of soldering it, and of not acting upon it more than might be necessary to cause its softened parts to reunite. Experience has shewn me, that a strong pressure made upon two pieces of caoutchouc (when brought to that state of softness) and continued until they are entirely dry, caused them to contract so strong an adhesion, that the piece, being pulled out till it broke, often broke, not at the united part, but by the side of it.

" By means of ether I immediately succeeded in making these tubes. The method which appears to me to succeed the best is, to cut a bottle circularly in a spiral slip of a few lines in breadth. It is very easy to cut a bottle in such a manner as to form a single long slip, and thus unnecessary joinings are avoided.

" The whole slip is to be plunged into ether until it is sufficiently softened, which comes to pass sooner or later according to the quality of the vitriolic ether that is employed. Half an hour frequently suffices; but I have already observed, that there is a great diversity in the manner in which different sorts of vitriolic ether act, and of which the cause is not yet, so far as I know, determined.

" The slip being taken out, one of the extremities is to be taken hold of and rolled, first upon itself at the bottom of the tube, pressing it; then the rolling is to be continued, mounting spirally along the mould, and taking care to lay over and compress with the hand every edge, one against the other, so that there may not be any vacant space, and that all the edges may join exactly. The whole then is to be bound hard with a tape of an inch in width, taking care to turn it the same way with the slip of elastic gum. The tape is to be tied up with packthread, so that, by every turn of the packthread joining another, an equal pressure is given to every part: it is then left to dry, and the tube is made.

" The bandage is to be taken off with great care, that none of the outward surfaces, which may have been lodged within the hollows of the tape (of which the caoutchouc takes the exact impression), may be pulled away. I advise the application of a tape before packthread, because, especially in the thinner tubes, we should run the risk of cutting the caoutchouc if the packthread were applied immediately upon it.

" It is easy to take off the tube of elastic gum which has been formed upon a solid mould of one piece: if the mould be made rather conic, it may be made to slide off by the smaller end; at the worst, it is easily accomplished by plunging it into hot water; for it is softened by the heat, and is distended: without this precaution it would be sometimes difficult to draw it off when dry, because, having been applied upon the mould whilst it had its volume augmented by the interposition of the ether, the parts of the caoutchouc are drawn nearer each other by the evaporation of the interposed bodies.

" The great affinity between these two bodies is seen by the length of time that the odour of the ether remains, notwithstanding the great volatility of the latter, and that the apparent dryness of the tube seems to shew that there is none remaining; nevertheless, after a certain time, the odour disappears entirely. One of those tubes, which was made with ether after the method here described, does not retain the least trace of the solvent. It is needless to say that it is easy to make tubes as thin or as thick as may be judged proper.

" Although the process that I am now describing is but very little expensive, yet I have tried to employ other solvents in lieu of ether, because it is not to be had in every place, and requires particular care in its preservation. I have employed, with some success, the essential oils of lavender and of turpentine: both of them speedily dilate the caoutchouc, and are of no great price. The disagreeable smell of the oil of turpentine becomes, perhaps, in process of time, less disagreeable than that of lavender. This last is dearer: but the difference is not so great as it appears at first; for we may make some advantage of the oil of lavender that is employed by the following operation: Upon plunging into alcohol the elastic tube prepared with the oil of lavender, the alcohol charges itself with the oil, and forms a very good lavender water; the same as would be made by an immediate mixture of oil of lavender with spirit of wine. Immersion in this liquor also serves to hasten the drying of the caoutchouc instruments thus made by means of essential oils. I have made tubes with the oils of turpentine and of lavender; both are much slower in evaporating than ether. The oil of turpentine particularly appeared to me always to have a kind of stickiness, and I know not as yet that we have any means whereby to get speedily rid of its smell.

" Nevertheless there is a solvent which has not that incon-

Caoutchouc.

inconvenience; it is cheaper, and may eaſily be procured by every one: this ſolvent is *water*. I conceive it will appear ſtrange to mention water as a ſolvent of elaſtic gum, that liquid having been always ſuppoſed to have no action upon it. I myſelf reſiſted the idea; but reflecting that ether, by being ſaturated with water, is the better enabled to act on caoutchouc, and that this gum when plunged into boiling water becomes more tranſparent at the edges, I preſumed that this effect was not due ſimply to the dilatation of its volume by the heat. I thought that, at that temperature, ſome action might take place, and that a long-continued ebullition might produce more ſenſible effects. I was not diſappointed in my expectations, and one of thoſe tubes was prepared without any other ſolvent than water and heat. I proceeded in the ſame manner as with ether: the elaſtic gum dilates but very little in boiling water; it becomes whitiſh, but recovers its colour again by drying it in the air and light. It is ſufficiently prepared for uſe when it has been a quarter of an hour in boiling water: by this time its edges are ſometimes tranſparent. It is to be turned ſpirally round the mould, in the manner we deſcribed before, and replunged frequently into the boiling water during the time that is employed in forming the tube, to the end that the edges may be diſpoſed to unite together. When the whole is bound with packthread, it is to be kept ſome hours in boiling water; after which it is to be dried, ſtill keeping on the binding.

"If we wiſh to be more certain that the connection is perfect, the ſpiral may be doubled; but we muſt always avoid placing the exterior ſurfaces of the ſlips one upon the other, as thoſe ſurfaces are the parts which moſt reſiſt the action of ſolvents. This precaution is leſs neceſſary when ether is employed, on account of its great action upon the caoutchouc.

"It might be feared that the action of water upon caoutchouc would deprive us of the advantages which might otherwiſe be expected; but theſe fears will be removed, if we conſider that the affinities differ according to the temperatures; that it is only at a very high temperature that water exerciſes any ſenſible action upon caoutchouc. I can affirm, that at 120° of Reaumur's thermometer (302° of Fahrenheit) this affinity is not ſuch as that the water can give a liquid form to caoutchouc; and it does not appear that we have any thing to fear in practice from a combination between theſe two bodies, which, though it really is a true ſolution, does not take place in any ſenſible degree but at a high temperature. It is therefore at preſent eaſy to make of caoutchouc whatever inſtruments it may be advantageous to have of a flexible, ſupple, and elaſtic ſubſtance, which is impermeable to water at the temperature of our atmoſphere, and reſiſts the action of acids as well as that of moſt other ſolvents. As to the durability of theſe inſtruments, few ſubſtances promiſe more than this, becauſe it may be ſoldered afreſh in a damaged part. Any woven ſubſtance may be covered with it; it is only required that the ſubſtance ſhould be of a nature not to be acted upon during the preparation, either by ether or by boiling water; for theſe two agents are thoſe which appear to me to merit the preference. Artiſts will frequently find an advantage in employing ether, as it requires leſs time; ſo that a perſon may make, in a ſingle day, any tube he may have occaſion for. The expence of ether is very little, ſince it is needful only to diſpoſe the caoutchouc to adhere; and being brought into that ſtate, the caoutchouc may be kept in a veſſel perfectly well cloſed. It would alſo diminiſh the expence of the ether if, inſtead of waſhing it with a large quantity of water, there ſhould be added to it only as much water as it can take up."

Cap.

CAP and BUTTON, are two ſmall iſlands, or rather rocks, lying in longitude 105° 48′ 30″ eaſt; and in latitude, the former 5° 58′ 30″, the latter 5° 49′ ſouth. They were viſited by ſome of the perſons attending Lord Macartney on his embaſſy to China; and are thus deſcribed by Sir George Staunton.

"At a little diſtance they might be miſtaken for the remains of old caſtles, mouldering into heaps of ruins, with tall trees already growing upon the tops; but at a nearer view, they betrayed evident marks of a volcanic origin. Exploſions from ſubterraneous fires, produce, for the moſt part, hills of a regular ſhape, and terminating in truncated cones; but when from a ſubaqueous volcano eruptions are thrown up above the ſurface of the ſea, the materials, falling back into the water, are more irregularly diſperſed, and generally leave the ſides of the new creation naked and miſhapen, as in the inſtance of AMSTERDAM, and of thoſe ſmaller ſpots called, from ſome reſemblance in ſhape, the Cap and Button.

"In the Cap were found two caverns, running horizontally into the ſide of the rock; and in theſe were a number of thoſe birds neſts ſo much prized by the Chineſe epicures. They ſeemed to be compoſed of fine filaments cemented together by a tranſparent viſcous matter, not unlike what is left by the foam of the ſea upon ſtones alternately covered by the tide, or thoſe gelatinous animal ſubſtances found floating on every coaſt. The neſts adhere to each other, and to the ſides of the cavern, moſtly in rows, without any break or interruption. The birds that build theſe neſts are ſmall grey ſwallows, with bellies of a dirty white. They were flying about in conſiderable numbers; but they were ſo ſmall, and their flight ſo quick, that they eſcaped the ſhot fired at them. The ſame neſts are ſaid alſo to be found in deep caverns, at the foot of the higheſt mountains in the middle of Java, and at a diſtance from the ſea, from which the birds, it is thought, derive no materials, either for their food or the conſtruction of their neſts; as it does not appear probable they ſhould fly, in ſearch of either, over the intermediate mountains, which are very high, or againſt the boiſterous winds prevailing thereabouts. They feed on inſects, which they find hovering over ſtagnated pools between the mountains, and for catching which their wide opening beaks are particularly adapted. They prepare their neſts from the beſt remnants of their food. Their greateſt enemy is the kite, who often intercepts them in their paſſage to and from the caverns, which are generally ſurrounded with rocks of grey limeſtone or white marble. The neſts are placed in horizontal rows at different depths, from 50 to 500 feet. The colour and value of the neſts depend on the quantity and quality of the inſects caught, and perhaps alſo on the ſituation where they are built. Their value is chiefly determined by the uniform fineneſs and delicacy of their texture; thoſe that are white and tranſparent being moſt eſteemed, and fetching often in China their weight in ſilver.

Cap.

These nests are a considerable object of traffic among the Javanese, and many are employed in it from their infancy. The birds having spent near two months in preparing their nests, lay each two eggs, which are hatched in about fifteen days. When the young birds become fledged, it is thought time to seize upon their nests, which is done regularly thrice a-year, and is effected by means of ladders of bamboo and reeds, by which the people descend into the cavern; but when it is very deep, rope ladders are preferred. This operation is attended with much danger; and several break their necks in the attempt. The inhabitants of the mountains generally employed in it begin always by sacrificing a buffalo; which custom is constantly observed by the Javanese on the eve of every extraordinary enterprise. They also pronounce some prayers, anoint themselves with sweet-scented oil, and smoke the entrance of the cavern with gum-benjamin. Near some of those caverns a tutelar goddess is worshipped, whose priest burns incense, and lays his protecting hands on every person preparing to descend into the cavern. A flambeau is carefully prepared at the same time, with a gum which exudes from a tree growing in the vicinity, and is not easily extinguished by fixed air or subterraneous vapours. The swallow which builds those nests is described as not having its tail feathers marked with white spots, which is a character attributed to it by Linnæus; and it is possible that there are two species or varieties of the swallow, whose nests are alike valuable." CARP. See Cyprinus, both in the *Encycl.* and in this *Supplement*.

CARPENTRY,

1 Definition.

THE art of framing timber for the purposes of architecture, machinery, and, in general, for all considerable structures.

It is not intended in this article to give a full account of carpentry as a *mechanical* art, or to describe the various ways of executing its different works, suited to the variety of materials employed, the processes which must be followed for fashioning and framing them for our purposes, and the tools which must be used, and the manner in which they must be handled: This would be an occupation for volumes; and though of great importance, must be entirely omitted here. Our only aim at present will be to deduce, from the principles and laws of mechanics, and the knowledge which experience and judicious inferences from it have given us concerning the strength of timber, in relation to the strain laid on it, such maxims of construction as will unite economy with strength and efficacy.

This object is to be attained by a knowledge, 1st, of the strength of our materials, and of the absolute strain that is to be laid on them; 2dly, of the modifications of this strain, by the place and direction in which it is exerted, and the changes that can be made by a proper disposition of the parts of our structure; and, 3dly, having disposed every piece in such a manner as to derive the utmost advantage from its relative strength, we must know how to form the joints and other connections in such a manner as to secure the advantages derived from this disposition.

2 An important branch of mechanical science

This is, evidently, a branch of mechanical science, which makes carpentry a *liberal* art, constitutes part of the learning of the Engineer, and distinguishes him from the workman. Its importance in all times and states of civil society is manifest and great. In the present condition of these kingdoms, raised, by the active ingenuity and energy of our countrymen, to a pitch of prosperity and influence unequalled in the history of the world, a condition which consists chiefly in the superiority of our manufactures, attained by prodigious multiplication of engines of every description, and for every species of labour, the Science (so to term it) of carpentry is of immense consequence. We regret therefore exceedingly, that none of our celebrated artists have done honour to themselves and their country, by digesting into a body of consecutive doctrines the results of their great experience, so as to form a system from which their pupils might derive the first principles of their education. The many volumes called Complete Instructors, Manuals, Jewels, &c. take a much humbler flight, and content themselves with instructing the mere workman, or sometimes give the master-builder a few approved forms of roofs and other framings, with the rules for drawing them on paper; and from thence forming the working draughts which must guide the saw and the chissel of the workman. Hardly any of them offer any thing that can be called a principle, applicable to many particular cases, with the rules for this adaptation. We are indebted for the greatest part of our knowledge of this subject to the labours of literary men, chiefly foreigners, who have published in the memoirs of the learned academies dissertations on different parts of what may be termed the *science of carpentry*. It is singular that the members of the Royal Society of London, and even of that established and supported by the patriotism of these days for the encouragement of the arts, have contributed so little to the public instruction in this respect. We observe of late some beginnings of this kind, such as the last part of

3 Principally indebted to foreigners for a knowledge of this subject.

Nicholson's CARPENTERS AND JOINERS ASSISTANT, published by J. Taylor, Holborn, 1797. And it is with pleasure that we can say, that we were told by the editor, that this work was prompted in a great measure by what has been delivered in the *Encyclopædia Britannica* in the articles ROOF and *STRENGTH of Materials*. It abounds more in important and new observations than any book of the kind that we are acquainted with. We again call on such as have given a scientific attention to this subject, and pray that they would render a meritorious service to their country by imparting the result of their researches. The very limited nature of this work does not allow us to treat the subject in detail; and we must confine our observations to the fundamental and leading propositions.

4 Theory, founded on what.

The theory (so to term it) of carpentry is founded on two distinct portions of mechanical science, namely, a knowledge of the strains to which framings of timber are exposed, and a knowledge of their *relative* strength.

We shall therefore attempt to bring into one point of view the propositions of mechanical science that are more immediately applicable to the art of carpentry, and are to be found in various articles of our work, particularly ROOF and *STRENGTH of Materials*. From these propositions we hope to deduce such principles as shall enable an attentive reader to comprehend distinctly what is to be aimed at in framing timber, and how to attain this object with certainty: and we shall illustrate and confirm our principles by examples of pieces of carpentry which are acknowledged to be excellent in their kind.

5 Composition and resolution of forces

The most important proposition of general mechanics to the carpenter is that which exhibits the composition and resolution of forces; and we beg our practical readers to endeavour to form very distinct conceptions of it, and to make it very familiar to their mind. When accommodated to their chief purposes, it may be thus expressed:

Plate VIII.

1. If a body, or any part of a body, be at once pressed in the two directions AB, AC (fig. 1.), and if the intensity or force of those pressures be in the proportion of these two lines, the body is affected in the same manner as if it were pressed by a single force acting in the direction AD, which is the diagonal of the parallelogram ABDC formed by the two lines, and whose intensity has the same proportion to the intensity of each of the other two that AD has to AB or AC.

Such of our readers as have *studied* the laws of motion, know that this is fully demonstrated. We refer them to the article MECHANICS, n° 5, &c. where it is treated at some length. Such as wish for a very accurate view of this proposition, will do well to read the demonstration given by D. Bernoulli, in the first volume of the *Comment. Petropol.* and the improvement of this demonstration by D'Alembert in his *Opuscles*, and in the *Comment. Taurinens.* The practitioner in carpentry will get more useful confidence in the doctrine, if he will shut his book, and verify the theoretical demonstrations by actual experiments. They are remarkably easy and convincing. Therefore it is our request that the artist, who is not so habitually acquainted with the subject, do not proceed further till he has made it quite familiar to his thoughts. Nothing is so conducive to this as the actual experiment; and since this only requires the trifling expence of two small pulleys and a few yards of whipcord, we hope that none of our practical readers will omit it: They will thank us for this injunction.

6 Illustrated by experiment.

2. Let the threads A *d*, AF *b*, and AE *c* (fig. 2.), have the weights *d*, *b*, and *c*, appended to them, and let two of the threads be laid over the pulleys F and E. By this apparatus the knot A will be drawn in the directions AB, AC, and AK. If the sum of the weights *b* and *c* be greater than the single weight *d*, the assemblage will of itself settle in a certain determined form; if you pull the knot A out of its place, it will always return to it again, and will rest in no other position. For example, if the three weights are equal, the threads will always make equal angles, of 120 degrees each, round the knot. If one of the weights be three pounds, another four, and the third five, the angle opposite to the thread stretched by five pounds will always be square, &c. When the knot A is thus in equilibrio, we must infer, that the action of the weight *d*, in the direction A *d*, is in direct opposition to the combined action of *b*, in the direction AB, and of *c*, in the direction AC. Therefore, if we produce *d* A to any point D, and take AD to represent the magnitude of the force, or pressure exerted by the weight *d*, the pressures exerted on A by the weights *b* and *c*, in the directions AB, AC, are in fact equivalent to a pressure acting in the direction AD, whose intensity we have represented by AD. If we now measure off by a scale on AF and AE the lines AB and AC, having the same proportions to AD that the weights *b* and *c* have to the weight *d*, and if we draw DB and DC, we shall find DC to be equal and parallel to AB, and DB equal and parallel to AC; so that AD is the diagonal of a parallelogram ABDC. We shall find this always to be the case, whatever are the weights made use of; only we must take care that the weight which we cause to act without the intervention of a pulley be less than the sum of the other two: if any one of the weights exceeds the sum of the other two, it will prevail, and drag them along with it.

Now, since we know that the weight *d* would just balance an equal weight *g*, pulling directly upwards by the intervention of the pulley G; and since we see that it just balances the weights *b* and *c*, acting in the directions AB, AC, we must infer, that the knot A is affected in the same manner by those two weights, or by the single weight *g*; and therefore that *two pressures, acting in the directions, and with the intensities*, AB, AC, *are equivalent to a single pressure having the direction and proportion of* AD. In like manner, the pressures AB, AK, are equivalent to AH, which is equal and opposite to AC. Also AK and AC are equivalent to AI, which is equal and opposite to AB.

We shall consider this combination of pressures a little more particularly. 7 Considered more particularly.

Suppose an upright beam BA (fig. 3.) pushed in the direction of its length by a load B, and abutting on the ends of two beams AC, AD, which are firmly resisted at their extreme points C and D, which rest on two blocks, but are nowise joined to them: these two beams can resist no way but in the directions CA, DA; and therefore the pressures which they sustain from the beam BA are in the directions AC, AD. We wish to know how much each sustains? Produce BA to E, taking

taking AE from a ſcale of equal parts, to repreſent the number of tons or pounds by which BA is preſſed. Draw EF and EG parallel to AD and AC; then AF, meaſured on the ſame ſcale, will give us the number of pounds by which AC is ſtrained or cruſhed, and AG will give the ſtrain on AD.

It deſerves particular remark here, that the length of AC or AD has no influence on the ſtrain, ariſing from the thruſt of BA, while the directions remain the ſame. The effects, however, of this ſtrain are modified by the length of the piece on which it is exerted. This ſtrain compreſſes the beam, and will therefore compreſs a beam of double length twice as much. This may change the form of the aſſemblage. If AC, for example, be very much ſhorter than AD, it will be much leſs compreſſed: The line CA will turn about the centre C, while DA will hardly change its poſition; and the angle CAD will grow more open, the point A ſinking down. The artiſt will find it of great conſequence to pay a very minute attention to this circumſtance, and to be able to ſee clearly the change of ſhape which neceſſarily reſults from theſe mutual ſtrains. He will ſee in this the cauſe of failure in many very great works.—By thus changing ſhape, ſtrains are often produced in places where there were none before, and frequently of the very worſt kind, tending to break the beams acroſs.

The dotted lines of this figure ſhew another poſition of the beam AD′. This makes a prodigious change, not only in the ſtrain on AD′, but alſo in that on AC. Both of them are much increaſed; AG is almoſt doubled, and AF is four times greater than before. This addition was made to the figure, to ſhew what enormous ſtrains may be produced by a very moderate force AE, when it is exerted on a very obtuſe angle.

The 4th and 5th figures will aſſiſt the moſt uninſtructed reader in conceiving how the very ſame ſtrains AF, AG, are laid on theſe beams, by a weight ſimply hanging from a billet reſting on A, preſſing hard on AD, and alſo leaning a little on AC; or by an upright piece AE, joggled on the two beams AC, AD, and performing the office of an ordinary king-poſt. The reader will thus learn to call off his attention from the means by which the ſtrains are produced, and learn to conſider them abſtractedly, merely as ſtrains, in whatever ſituation he finds them, and from whatever cauſe they ariſe.

We preſume that every reader will perceive, that the proportions of theſe ſtrains will be preciſely the ſame if every thing be inverted, and each beam be drawn or pulled in the oppoſite direction. In the ſame way that we have ſubſtituted a rope and weight in fig. 4. or a king-poſt in fig. 5. for the loaded beam BA of fig. 3. we might have ſubſtituted the framing of fig. 6. which is a very uſual practice. In this framing, the batten DA is ſtretched by a force AG, and the piece AC is compreſſed by a force AF. It is evident that we may employ a rope, or an iron rod hooked on at D, in place of the batten DA, and the ſtrains will be the ſame as before.

This ſeemingly ſimple matter is ſtill full of inſtruction; and we hope that the well-informed reader will pardon us, though we dwell a little longer on it for the ſake of the young artiſt.

By changing the form of this framing, as in fig. 7. we produce the ſame ſtrains as in the diſpoſition repreſented by the dotted lines in fig. 3. The ſtrains on both the battens AD, AC, are now greatly increaſed.

The ſame conſequences reſult from an improper change of the poſition of AC. If it is placed as in fig. 8. the ſtrains on both are vaſtly increaſed. In ſhort, the rule is general; that the more open we make the angle againſt which the puſh is exerted, the greater are the ſtrains which are brought on the ſtruts or ties which form the ſides of the angle.

The reader may not readily conceive the piece AC of fig. 8. as ſuſtaining a compreſſion; for the weight B appears to hang from AC as much as from AD. But his doubts will be removed by conſidering whether he could employ a rope in place of AC. He cannot: But AD may be exchanged for a rope. AC is therefore a ſtrut and not a tie.

In fig. 9. AD is again a ſtrut, butting on the block D, and AC is a tie: and the batten AC may be replaced by a rope. While AD is compreſſed by the force AG, AC is ſtretched by the force AF.

If we give AC the poſition repreſented by the dotted lines, the compreſſion of AD is now AG′, and the force ſtretching AC′ is now AF′; both much greater than they were before. This diſpoſition is analogous to fig. 8. and to the dotted lines in fig. 3. Nor will the young artiſt have any doubts of AC′ being on the ſtretch, if he conſider whether AD can be replaced by a rope. It cannot, but AC′ may; and it is therefore not compreſſed, but ſtretched.

In fig. 10. all the three pieces, AC, AD, and AB, are ties on the ſtretch. This is the complete inverſion of fig. 3.; and the dotted poſition of AC induces the ſame changes in the forces AF′, AG′, as in fig. 3.

Thus have we gone over all the varieties which can happen in the bearings of three pieces on one point. All calculations about the ſtrength of carpentry are reduced to this caſe: for when more ties or braces meet in a point (a thing that rarely happens), we reduce them to three, by ſubſtituting for any two the force which reſults from their combination, and then combining this with another; and ſo on.

The young artiſt muſt be particularly careful not to miſtake the kind of ſtrain that is exerted on any piece of the framing, and ſuppoſe a piece to be a brace which is really a tie. It is very eaſy to avoid all miſtakes in this matter by the following rule, which has no exception.

8
Rule for diſtinguiſhing the caſes of compreſſion and extenſion.

Take notice of the direction in which the piece acts from which the ſtrain proceeds. Draw a line in that direction *from* the point on which the ſtrain is exerted; and let its length (meaſured on ſome ſcale of equal parts) expreſs the magnitude of this action in pounds, hundreds, or tons. From its *remote* extremity draw lines parallel to the pieces on which the ſtrain is exerted. The line parallel to one piece will neceſſarily cut the other, or its direction produced: If it cut the piece itſelf, that piece is compreſſed by the ſtrain, and it is performing the office of a ſtrut or brace: if it cut its direction produced, the piece is ſtretched, and it is a tie. In ſhort, the ſtrains on the pieces AC, AD, are to be eſtimated in the direction of the points F and G *from* the ſtrained point A. Thus, in fig. 3. the upright piece BA, loaded with the weight B, preſſes the point A in the direction AE: ſo does the rope AB in the other figures, or the batten AB in fig. 5.

In

In general, if the ſtraining piece is within the angle formed by the pieces which are ſtrained, the ſtrains which they ſuſtain are of the oppoſite kind to that which it exerts. If it be puſhing, they are drawing; but if it be within the angle formed by their directions produced, the ſtrains which they ſuſtain are of the ſame kind. All the three are either drawing or preſſing. If the ſtraining piece lie within the angle formed by one piece and the produced direction of the other, its own ſtrain, whether compreſſion or extenſion, is of the ſame kind with that of the moſt remote of the other two, and oppoſite to that of the neareſt. Thus, in fig. 9. where AB is drawing, the remote piece AC is alſo drawing, while AD is puſhing or reſiſting compreſſion.

In all that has been ſaid on this ſubject, we have not ſpoken of any joints. In the calculations with which we are occupied at preſent, the reſiſtance of joints has no ſhare; and we muſt not ſuppoſe that they exert any force which tends to prevent the angles from changing. The joints are ſuppoſed perfectly flexible, or to be like compaſs joints; the pin of which only keeps the pieces together when one or more of the pieces draws or pulls. The carpenter muſt always ſuppoſe them all compaſs joints when he calculates the thruſts and draughts of the different pieces of his frames. The ſtrains on joints, and their power to produce or balance them, are of a different kind, and require a very different examination.

9 General expreſſion of the magnitude of the ſtrain.

Seeing that the angles which the pieces make with each other are of ſuch importance to the magnitude and the proportion of the excited ſtrains, it is proper to find out ſome way of readily and compendiouſly conceiving and expreſſing this analogy.

In general, the ſtrain on any piece is proportional to the ſtraining force. This is evident.

Secondly, the ſtrain on any piece AC is proportional to the ſine of the angle, which the ſtraining force makes with the other piece directly, and to the ſine of the angle which the pieces make with each other inverſely.

For it is plain, that the three preſſures AE, AF, and AG, which are exerted at the point A, are in the proportion of the lines AE, AF, and FE (becauſe FE is equal to AG). But becauſe the ſides of a triangle are proportional to the ſines of the oppoſite angles, the ſtrains are proportional to the ſines of the angles AFE, AEF, and FAE. But the ſine of AFE is the ſame with the ſine of the angle CAD, which the two pieces AC and AD make with each other; and the ſine of AEF is the ſame with the ſine of EAD, which the ſtraining piece BA makes with the piece AC. Therefore we have this analogy, Sin. CAD : Sin. EAD = AE : AF, and $AF = AE \times \frac{\text{Sin. EAD}}{\text{Sin. CAD}}$.—Now the ſines of angles are moſt conveniently conceived as decimal fractions of the radius, which is conſidered as unity. Thus, *Sin.* 30° is the ſame thing with 0,5, or $\frac{1}{2}$; and ſo of others. Therefore, to have the ſtrain on AC, ariſing from any load AE acting in the direction AE, multiply AE by the ſine of EAD, and divide the product by the ſine of CAD.

This rule ſhews how great the ſtrains muſt be when the angle CAD becomes very open, approaching to 180 degrees. But when the angle CAD becomes very ſmall, its ſine (which is our diviſor) is alſo very ſmall; and we ſhould expect a very great quotient in this caſe alſo. But we muſt obſerve, that in this caſe the ſine of EAD is alſo very ſmall; and this is our multiplier. In ſuch a caſe, the quotient cannot exceed unity.

But it is unneceſſary to conſider the calculation by the tables of ſines more particularly. The angles are ſeldom known any otherwiſe but by drawing the figure of the frame of carpentry. In this caſe, we can always obtain the meaſures of the ſtrains from the ſame ſcale, with equal accuracy, by drawing the parallelogram AFCG.

10 Strains propagated to the points of ſupport.

Hitherto we have conſidered the ſtrains excited at A only as they affect the pieces on which they are exerted. But the pieces, in order to ſuſtain, or be ſubject to, any ſtrain, muſt be ſupported at their ends C and D; and we may conſider them as mere intermediums, by which theſe ſtrains are made to act on thoſe points of ſupport: Therefore AF and AG are alſo meaſures of the forces which preſs or pull at C and D. Thus we learn the ſupports which muſt be found for theſe points. Theſe may be infinitely various. We ſhall attend only to ſuch as ſomehow depend on the framing itſelf.

11 Action of a ſtraining beam.

Such a ſtructure as fig. 11. very frequently occurs, where a beam BA is ſtrongly preſſed to the end of another beam AD, which is prevented from yielding, both becauſe it lies on another beam HD, and becauſe its end D is hindered from ſliding backwards. It is indifferent from what this preſſure ariſes: we have repreſented it as owing to a weight hung on at B, while B is withheld from yielding by a rod or rope hooked to the wall. The beam AD may be ſuppoſed at full liberty to exert all its preſſure on D, as if it were ſupported on rollers lodged in the beam HD; but the loaded beam BA preſſes both on the beam AD and on HD. We wiſh only to know what ſtrain is borne by AD?

All bodies act on each other in the direction perpendicular to their touching ſurfaces; therefore the ſupport given by HD is in a direction perpendicular to it. We may therefore ſupply its place at A by a beam AC, perpendicular to HD, and firmly ſupported at C. In this caſe, therefore, we may take AE, as before, to repreſent the preſſure exerted by the loaded beam, and draw EG perpendicular to AD, and EF parallel to it, meeting the perpendicular AC in F. Then AG is the ſtrain compreſſing AD, and AF is the preſſure on the beam HD.

12 The form of the abutting joint of no great importance.

It may be thought, that ſince we aſſume as a principle that the mutual preſſures of ſolid bodies are exerted perpendicular to their touching ſurfaces, this balance of preſſures, in framings of timbers, depends on the directions of their butting joints: but it does not, as will readily appear by conſidering the preſent caſe. Let the joint or abutment of the two pieces BA, AD be mitred, in the uſual manner, in the direction *f* A *f'*. Therefore, if A *e* be drawn perdendicular to A *f*, it will be the direction of the actual preſſure exerted by the loaded beam BA on the beam AD. But the reaction of AD, in the oppoſite direction A *t*, will not balance the preſſure of BA; becauſe it is not in the direction preciſely oppoſite. BA will therefore ſlide along the joint, and preſs on the beam HD. AE repreſents the load on the mitre joint A. Draw E *e* perpendicular to A*e*, and E *f* parallel to it. The preſſure AE will be balanced by the reactions *e* A and *f* A: or, the preſſure AE produces the preſſures A *e* and A *f*; of of which A f muſt be reſiſted by the beam HD, and A e by the beam AD. The preſſure A f not being perpendicular to HD, cannot be fully reſiſted by it; becauſe (by our aſſumed principle) it reacts only in a direction perpendicular to its ſurface. Therefore draw fp, fi parallel to HD, and perpendicular to it. The preſſure A f will be reſiſted by HD with the force p A; but there is required another force i A, to prevent the beam BA from ſlipping outwards. This muſt be furniſhed by the reaction of the beam DA.—In like manner, the other force A e cannot be fully reſiſted by the beam AD, or rather by the prop D, acting by the intervention of the beam; for the action of that prop is exerted through the beam in the direction DA. The beam AD, therefore, is preſſed to the beam HD by the force A e, as well as by A f. To find what this preſſure on HD is, draw $e\,g$ perpendicular to HD, and $e\,o$ parallel to it, cutting EG in r. The forces g A and o A will reſiſt, and balance A e.

Thus we ſee, that the two forces A e and A f, which are equivalent to AE, are equivalent alſo to A p, A i, A o, and A g. But becauſe A f and e E are equal and parallel, and E r and $f\,i$ are alſo parallel, as alſo $e\,r$ and $f\,p$, it is evident, that $i\,f$ is equal to r E, or to o F, and i A is equal to $r\,e$, or to G g. Therefore the four forces A g, A o, A p, A i, are equal to AG and AF. Therefore AG is the compreſſion of the beam AD, or the force preſſing it on D, and AF is the force preſſing it on the beam HD. The proportion of theſe preſſures, therefore, is not affected by the form of the joint.

This remark is important; for many carpenters think the form and direction of the butting joint of great importance; and even the theoriſt, by not proſecuting the general principle through *all* its conſequences, may be led into an error. The form of the joint is of no importance, in as far as it affects the ſtrains in the direction of the beams; but it is often of great conſequence, in reſpect to its own firmneſs, and the effect it may have in bruiſing the piece on which it acts, or being crippled by it.

13 Origin of the ſtrain on a tie-beam.

The ſame compreſſion of AB, and the ſame thruſt on the point D by the intervention of AD, will obtain, in whatever way the original preſſure on the end A is produced. Thus ſuppoſing that a cord is made faſt at A, and pulled in the direction AE, and with the ſame force, the beam AD will be equally compreſſed, and the prop D muſt react with the ſame force.

But it often happens that the obliquity of the preſſure on AD, inſtead of compreſſing it, ſtretches it; and we deſire to know what tenſion it ſuſtains? Of this we have a familiar example in a common roof. Let the two rafters AC, AD (fig. 12.), preſs on the tie-beam DC. We may ſuppoſe the whole weight to preſs vertically on the ridge A, as if a weight B were hung on there. We may repreſent this weight by the portion A b of the vertical or plumb line, intercepted between the ridge and the beam. Then drawing $b\,f$ and $b\,g$ parallel to AD and AC, A g and A f will repreſent the preſſures on AC and AD. Produce AC till CH be equal to A f. The point C is forced out in this direction, and with a force repreſented by this line. As this force is not perpendicularly acroſs the beam, it evidently ſtretches it; and this extending force muſt be withſtood by an equal force pulling it in the oppoſite direction. This muſt ariſe from a ſimilar oblique thruſt of the oppoſite rafter on the other end D. We concern ourſelves only with this extenſion at preſent; but we ſee that the coheſion of the beam does nothing but ſupply the balance to the extending forces. It muſt ſtill be ſupported externally, that it *may reſiſt*, and, by reſiſting obliquely, be ſtretched. The points C and D are ſupported on the walls, which they preſs in the directions CK and DO, parallel to A b. If we draw HK parallel to DC, and HI parallel to CK (that is, to A b), meeting DC produced in I, it follows from the compoſition of forces, that the point C would be ſupported by the two forces KC and IC. In like manner, making DN = A g, and completing the parallelogram DMNO, the point D would be ſupported by the forces OD and MD. If we draw $g\,o$ and $f\,k$ parallel to DC, it is plain that they are equal to NO and CK, while A o and A k are equal to DO and CK, and A b is equal to the ſum of DO and CK (becauſe it is equal to A o + A k). The weight of the roof is equal to its vertical preſſure on the walls.

Thus we ſee, that while a preſſure on A, in the direction A b, produces the ſtrains A f and A g, on the pieces AC and AD, it alſo excites a ſtrain CI or DM in the piece DC. And this completes the mechaniſm of a frame; for all derive their efficacy from the triangles of which they are compoſed, as will appear more clearly as we proceed.

14 External action of a frame.

But there is more to be learned from this. The conſideration of the ſtrains on the two pieces AD and AC, by the action of a force at A, only ſhewed them as the means of propagating the ſame ſtrains in their own direction to the points of ſupport. But, by adding the ſtrains exerted in DC, we ſee that the frame becomes an intermedium, by which exertions may be made on other bodies, in certain directions and proportions; ſo that this frame may become part of a more complicated one, and, as it were, an element of its conſtitution. It is worth while to aſcertain the proportion of the preſſures CK and DO, which are thus exerted on the walls. The ſimilarity of triangles gives the following analogies:

$$\text{DO} : \text{DM} = \text{A}b : b\text{D}$$
$$\text{CI, or DM} : \text{CK} = \text{C}b : \text{A}b$$
$$\text{Therefore DO} : \text{CK} = \text{C}b : b\text{D}.$$

Or, *the preſſures on the points* C *and* D, *in the direction of the ſtraining force* A b, *are reciprocally proportional to the portions of* DC *intercepted by* A b.

Alſo, ſince A b is = DO + CK, we have

$\text{A}b : \text{CK} = \text{C}b + b\text{D}$ (or CD) : bD, and

$\text{A}b : \text{DO} = \text{CD} : b\text{C}$.

In general, any two of the three parallel forces A b, DO, CK, are to each other in the reciprocal proportion of the parts of CD, intercepted between their directions and the direction of the third.

And this explains a ſtill more important office of the frame ADC. If one of the points, ſuch as D, be ſupported, an external power acting at A, in the direction A b, and with an intenſity which may be meaſured by A b, may be ſet in equilibrio, with another acting at C, in the direction CL, oppoſite to CK or A b, and with an intenſity repreſented by CK: for ſince the preſſure CH is partly withſtood by the force IC, or the firmneſs of the beam DC ſupported at D, the force KC will complete the balance. When we do not attend to the ſupport at D, we conceive the force A b to be balanced by by KC, or KC to be balanced by A *b*. And, in like manner, we may neglect the ſupport or force acting at A, and conſider the force DO as balanced by CK.

15 It becomes a lever. Thus our frame becomes a lever, and we are able to trace the interior mechanical procedure which gives it its efficacy: it is by the intervention of the forces of coheſion, which connect the points to which the external forces are applied with the ſupported point or fulcrum, and with each other.

Theſe ſtrains or preſſures A *b*, DO, and CK, not being in the directions of the beams, may be called *tranſverſe*. We ſee that by their means a frame of carpentry may be conſidered as a ſolid body: but the example which brought this to our view is too limited for explaining the efficacy which may be given to ſuch conſtructions. We ſhall therefore give a general propoſition, which will more diſtinctly explain the procedure of nature, and enable us to trace the ſtrains as they are propagated through all the parts of the moſt complicated framing, finally producing the exertion of its moſt diſtant points.

16 General propoſition. We preſume that the reader is now pretty well habituated to the conception of the ſtrains as they are propagated along the lines joining the points of a frame, and we ſhall therefore employ a very ſimple figure.

Let the ſtrong lines ACBD (fig. 13.) repreſent a frame of carpentry. Suppoſe that it is pulled at the point A by a force acting in the direction AE, but that it reſts on a fixed point C, and that the other extreme point B is held back by a power which reſiſts in the direction BF: It is required to determine the proportion of the ſtrains excited in its different parts, the proportion of the external preſſures at A and B, and the preſſure which is produced on the obſtacle or fulcrum C?

It is evident that each of the external forces at A and B tend one way, or to one ſide of the frame, and that each would cauſe it to turn round C if the other did not prevent it; and that if, notwithſtanding their action, it is turned neither way, the forces in actual exertion are in equilibrio by the intervention of the frame. It is no leſs evident that theſe forces concur in preſſing the frame on the prop C. Therefore, if the piece CD were away, and if the joints C and D be perfectly flexible, the pieces CA, CB would be turned round the prop C, and the pieces AD, DB would alſo turn with them, and the whole frame change its form. This ſhews, by the way, and we deſire it to be carefully kept in mind, that the firmneſs or ſtiffneſs of framing depends entirely on the triangles bounded by beams which are contained in it. An open quadrilateral may always change its ſhape, the ſides revolving round the angles. A quadrilateral may have an infinity of forms, without any change of its ſides, by merely puſhing two oppoſite angles towards each other, or drawing them aſunder. But when the three ſides of a triangle are determined, its ſhape is alſo invariably determined; and if two angles be held faſt, the third cannot be moved. It is thus that, by inſerting the bar CD, the figure becomes unchangeable; and any attempt to change it by applying a force to an angle A, immediately excites forces of attraction or repulſion between the particles of the ſtuff which form its ſides. Thus it happens, in the preſent inſtance, that a change of ſhape is prevented by the bar CD. The power at A preſſes its end againſt the prop; and in doing this it puts the bar AD on the ſtretch, and alſo the bar DB. Their places might therefore be ſupplied by cords or metal wires. Hence it is evident that DC is compreſſed, as is alſo AC: and, for the ſame reaſon, CB is alſo in a ſtate of compreſſion; for either A or B may be conſidered as the point that is impelled or withheld. Therefore DA and DB are ſtretched, and are reſiſting with attractive forces. DC and CB are compreſſed, and are reſiſting with repulſive forces. DB is alſo acting with repulſive forces, being compreſſed in like manner: and thus the ſupport of the prop, combined with the firmneſs of DC, puts the frame ADBC into the condition of the two frames in fig. 8. and fig. 9. Therefore the external force at A is really in equilibrio with an attracting force acting in the direction AD, and a repulſive force acting in the direction AK. And ſince all the connecting forces are mutual and equal, the point D is pulled or drawn in the direction DA. The condition of the point B is ſimilar to that of A, and D is alſo drawn in the direction DB. Thus the point D, being urged by the forces in the directions DA and DB, preſſes the beam DC on the prop, and the prop reſiſts in the oppoſite direction. Therefore the line DC is the diagonal of the parallelogram, whoſe ſides have the proportion of the forces which connect D with A and B. This is the principle on which the reſt of our inveſtigation proceeds. We may take DC as the repreſentation and meaſure of their joint effect. Therefore draw CH, CG, parallel to DA, DB. Draw HL, GO, parallel to CA, CB, cutting AE, BF in L and O, and cutting DA, DB in I and M. Complete the parallelograms ILKA, MONB. Then DG and AI are the equal and oppoſite forces which connect A and D; for GD = CH, = AI. In like manner DH and BM are the forces which connect D and B.

The external force at A is in immediate equilibrio with the combined forces, connecting A with D and with C. AI is one of them: Therefore AK is the other; and AL is the compound force with which the external force at A is in immediate equilibrium. This external force is therefore equal and oppoſite to AL. In like manner, the external force at B is equal and oppoſite to BO; and AL is to BO as the external force at A to the external force at B. The prop C reſiſts with forces equal to thoſe which are propagated to it from the points D, A, and C. Therefore it reſiſts with forces CH, CG, equal and oppoſite to DG, DH; and it reſiſts the compreſſions KA, NB, with equal and oppoſite forces C *k*, C *n*. Draw *k l*, *n o* parallel to AD, BD, and draw C *l* Q, C *o* P: It is plain that *k* CH *l* is a parallelogram equal to KAIL, and that C *l* is equal to AL. In like manner C *o* is equal to BO. Now the forces C *k*, CH, exerted by the prop, compoſe the force C *l*; and C *n*, CG compoſe the force C *o*. Theſe two forces C *l*, C *o* are equal and parallel to AL and BO; and therefore they are equal and oppoſite to the external forces acting at A and B. But they are (primitively) equal and oppoſite to the preſſures (or at leaſt the compounds of the preſſures) exerted on the prop, by the forces propagated to C from A, D, and B. Therefore the preſſures exerted on the prop are the ſame as if the external forces were applied there in the ſame directions as they are applied to A and B. Now if we make CV, CZ equal to C *l* and C *o*, and

and complete the parallelogram CVYZ; it is plain that the force YC is in equilibrio with lC and oC. Therefore the pressures at A, C, and B, are such as would balance if applied to one point.

Lastly, in order to determine their proportions, draw CS and CR perpendicular to DA and DB. Also draw Ad, Bf perpendicular to CQ and CP; and draw Cg, Ci perpendicular to AE, BF.

The triangles CPR and BPf are similar, having a common angle P, and a right angle at R and f.

In like manner the triangles CQS and AQd are similar. Also the triangles CHR, CGS are similar, by reason of the equal angles at H and G, and the right angles at R and S. Hence we obtain the following analogies:

$$Co : CP = On : PB, = CG : PB$$
$$CP : CR = \quad PB : fB$$
$$CR : CS = \quad CH : CG$$
$$CS : CQ = \quad Ad : AQ$$
$$CQ : Cl = AQ : Kl, = AQ : CH.$$

Therefore, by equality,

$$Co : Cl = \quad Ad : fB$$
$$\text{or } BO : AL = \quad Cg : Ci.$$

That is, the external forces are reciprocally proportional to the perpendiculars drawn from the prop on the lines of their direction (A).

17 Extensive consequences. This proposition (sufficiently general for our purpose) is fertile in consequences, and furnishes many useful instructions to the artist. The strains LA, OB, CY, that are excited, occur, in many, we may say in all, framings of carpentry, whether for edifices or engines, and are the sources of their efficacy. It is also evident, that the doctrine of the transverse strength of timber is contained in this proposition; for every piece of timber may be considered as an assemblage of parts, connected by forces which act in the direction of the lines which join the strained points on the matter which lies between those points, and also act on the rest of the matter, exciting those lateral forces which produce the inflexibility of the whole. See STRENGTH *of Materials*, Encycl.

Thus it appears that this proposition contains the principles which direct the artist to frame the most powerful levers; to secure uprights by shores or braces, or by ties and ropes; to secure scaffoldings for the erection of spires, and many other most delicate problems of his art. He also learns, from this proposition, how to ascertain the strains that are produced, without his intention, by pieces which he intended for other offices, and which, by their transverse action, put his work in hazard. In short, this proposition is the key to the science of his art.

We would now counsel the artist, after he has made the tracing of the strains and thrusts through the various parts of a frame familiar to his mind, and even amused himself with some complicated fancy framings, to read over with care the articles STRENGTH *of Materials* and ROOF in the *Encyclopædia Britannica*. He will now conceive its doctrines much more clearly than when he was considering them as abstract theories. The mutual action of the woody fibres will now be easily comprehended, and his confidence in the results will be greatly increased.

There is a proposition (n° 19. in the article ROOF) which has been called in question by several very intelligent persons; and they say that Belidor has demonstrated, in his SCIENCE DES INGENIEURS, that a beam firmly fixed at both ends is not twice as strong as when simply lying on the props, and that its strength is increased only in the proportion of 2 to 3; and they support this determination by a list of experiments recited by Belidor, which agree *precisely* with it. Belidor also says that Pitot had the same result in his experiments. These are respectable authorities: but Belidor's reasoning is any thing but demonstration; and his experiments are described in such an imperfect manner, that we cannot build much on them. It is not said in what manner the battens were secured at the ends, any farther than that it was by *chevalets*. If by this word is meant a tressle, we cannot conceive how they were employed; but we see it sometimes used for a wedge or key. If the battens were wedged in the holes, their resistance to fracture may be made what we please: they may be loose, and therefore resist little more than when simply laid on the props. They may be (and probably were) wedged very fast, and bruised or crippled. 18 Decision of a disputed and very important question.

Our proposition mentioned distinctly the security given to the ends of the beams. They were mortised into remote posts. Our *precise* meaning was, that they were simply kept from rising by these mortises, but at full liberty to bend up between E and I, and between G

(A) The learned reader will perceive, that this analogy is precisely the same with that of forces which are in equilibrio by the intervention of a lever. In fact, this whole frame of carpentry is nothing else than a *built* or *framed lever* in equilibrio. It is acting in the same manner as a solid, which occupies the whole figure compressed in the frame, or as a body of any size and shape whatever that will admit the three points of application A, C, and B. It is always in equilibrio in the case first stated; because the pressure *produced* at B by a force applied to A is always such as balances it. The reader may also perceive, in this proposition, the analysis or tracing of those internal mechanical forces which are indispensably requisite for the functions of a lever. The mechanicians have been extremely puzzled to find a legitimate demonstration of the equilibrium of a lever ever since the days of Archimedes. Mr Vince has the honour of first demonstrating, most ingeniously, the principle assumed by Archimedes, but without sufficient ground, for *his* demonstration: but Mr Vince's demonstration is only a putting the mind into that perplexed state which makes it acknowledge the proposition, but without a clear perception of its truth. The difficulty has proceeded from the abstract notion of a lever, conceiving it as a mathematical line—inflexible, without reflecting how it is inflexible—for the very source of this indispensable quality furnishes the mechanical connection between the remote pressures and the fulcrum; and this supplies the demonstration (without the least difficulty) of the desperate case of a straight lever urged by parallel forces. See ROTATION, n° 11. *Encycl.*

G and K. Our assertion was not made from theory alone (although we think the reasoning incontrovertible), but was agreeable to numerous experiments made in those precise circumstances. Had we mortised the beams firmly into two very stout posts, which could not be drawn nearer to each other by bending, the beam would have borne a *much* greater weight, as we have verified by experiment. We hope that the following mode of conceiving this case will remove all doubts.

Let LM be a long beam (fig. 14.) divided into six equal parts, in the points D, B, A, C, E. Let it be firmly supported at L, B, C, M. Let it be cut through at A, and have compass-joints at B and C. Let FB, GC be two equal uprights, resting on B and C, but without any connection. Let AH be a similar and equal piece, to be occasionally applied at the seam A. Now let a thread or wire AGE be extended over the piece GC, and made fast at A, G, and E. Let the same thing be done on the other side of A. If a weight be now laid on at A, the wires AFD, AGE will be strained, and may be broken. In the instant of fracture we may suppose their strains to be represented by A *f* and A *g*. Complete the parallelogram, and A *a* is the magnitude of the weight. It is plain that nothing is concerned here but the cohesion of the wires; for the beam is sawed through at A, and its parts are perfectly moveable round B and C.

Instead of this process apply the piece AH below A, and keep it there by straining the same wire BHC over it. Now lay on a weight. It must press down the ends of BA and CA, and cause the piece AH to strain the wire BHC. In the instant of fracture of *the same* wire, its resistance H *b* and H *c* must be equal to A *f* and A *g*, and the weight *b* H which breaks them must be equal to A *a*.

Lastly, employ all the three pieces FB, AH, GC, with the same wire attached as before. There can be no doubt but that the weight which breaks all the four wires must be $= a\text{ A} + b$, or twice A *a*.

The reader cannot but see that the wires perform the very same office with the fibres of an entire beam LM held fast in the four holes D, B, C, and E, of some upright posts.

In the experiments for verifying this, by breaking slender bars of fine deal, we get complete demonstration, by measuring the curvatures produced in the parts of the beam thus held down, and comparing them with the curvature of a beam simply laid on the props B and C: and there are many curious inferences to be made from these observations, but we have not room for them in this place.

19 The best manner of framing purlins.

We may observe, by the way, that we learn from this case, that purlins are able to carry twice the load when notched into the rafters that they carry when mortised into them, which is the most usual manner of framing them. So would the binding joists of floors; but this would double the thickness of the flooring. But this method should be followed in every possible case, such as breast summers, lintels over several pillars, &c. These should never be cut off and mortised into the sides of every upright; numberless cases will occur which shew the importance of the maxim.

We must here remark, that the proportion of the spaces BC and CM, or BC and LB, has a very sensible effect on the strength of the beam BC; but we have not yet satisfied our minds as to the *rationale* of this effect. It is undoubtedly connected with the serpentine form of the curve of the beam before fracture. This should be attended to in the construction of the springs of carriages. These are frequently supported at a middle point (and it is an excellent practice), and there is a certain proportion which will give the easiest motion to the body of the carriage. We also think that it is connected with that deviation from the best theory observable in Buffon's experiments on various lengths of the same scantling. The force of the beams diminished much more than in the inverse proportion of their lengths.

20 Ties are in general better than struts.

We have seen that it depends entirely on the position of the pieces in respect of their points of ultimate support, and of the direction of the external force which produces the strains, whether any particular piece is in a state of extension or of compression. The knowledge of this circumstance may greatly influence us in the choice of the construction. In many cases we may substitute slender iron rods for massive beams, when the piece is to act the part of a tie. But we must not invert this disposition; for when a piece of timber acts as a strut, and is in a state of compression, it is next to certain that it is not equally compressible in its opposite sides through the whole length of the piece, and that the compressing force on the abutting joint is not acting in the most equable manner all over the joint. A very trifling inequality in either of these circumstances (especially in the first) will compress the beam more on one side than on the other. This cannot be without the beam's bending, and becoming concave on that side on which it is most compressed. When this happens, the frame is in danger of being crushed, and soon going to ruin. It is therefore indispensably necessary to make use of beams in all cases where struts are required of considerable length, rather than of metal rods of slender dimensions, unless in situations where we can effectually prevent their bending, as in trussing a girder internally, where a cast iron strut may be firmly cased in it, so as not to bend in the smallest degree. In cases where the pressures are enormous, as in the very oblique struts of a centre or arch frame, we must be particularly cautious to do nothing which can facilitate the compression of either side. No mortises should be cut near to one side; no lateral pressure, even the slightest, should be allowed to touch it. We have seen a pillar of fir 12 inches long and one inch in section, when loaded with three tons, snap in an instant when pressed on one side by 16 pounds, while another bore $4\frac{1}{2}$ tons without hurt, because it was inclosed (loosely) in a stout pipe of iron.

In such cases of enormous compression, it is of great importance that the compressing force bear equally on the whole abutting surfaces. The German carpenters are accustomed to put a plate of lead over the joint. This prevents, in some measure, the penetration of the end fibres. Mr Perronet, the celebrated French architect, formed his abutments into arches of circles, the centre of which was the remote end of the strut. By this contrivance the unavoidable change of form of the triangle made no partial bearing of either angle of the abutment. This always has a tendency to splinter off the heel of the beam where it presses strongest. It is a very judicious practice.

When circumstances allow it, we should rather employ

ploy ties than ſtruts for ſecuring a beam againſt lateral ſtrains. When an upright pillar, ſuch as a flag-ſtaff, a maſt, or the uprights of a very tall ſcaffolding, are to be ſhored up, the dependence is more certain on thoſe braces that are ſtretched by the ſtrain than on thoſe which are compreſſed. The ſcaffolding of the iron bridge near Sunderland had ſome ties very judiciouſly diſpoſed, and others with leſs judgment.

We ſhould proceed to conſider the tranſverſe ſtrains as they affect the various parts of a frame of carpentry; but we have very little to add to what has been ſaid already in the article *Strength of Materials* (Encycl.), and in the article Roof. What we ſhall add in this article will find a place in our occaſional remarks on different works. It may, however, be of uſe to recal to the reader's memory the following propoſitions.

21 General theorems concerning the relative ſtrength of beams.

1. When a beam AB (fig. 15.) is firmly fixed at the end A, and a ſtraining force acts perpendicularly to its length at any point B, the ſtrain occaſioned at any ſection C between B and A is proportional to CB, and may therefore be repreſented by the product $W \times CB$; that is, by the product of the number of tons, pounds, &c. which meaſure the ſtraining force, and the number of feet, inches, &c. contained in CB. As the loads on a beam are eaſily conceived, we ſhall ſubſtitute this for any other ſtraining force.

2. If the ſtrain or load is uniformly diſtributed along any part of the beam lying beyond C (that is, further from A), the ſtrain at C is the ſame as if the load were all collected at the middle point of that part; for that point is the centre of gravity of the load.

3. The ſtrain on any ſection D of a beam AB (fig. 16.) reſting freely on two props A and B, is $w \times \frac{AD \times DB}{AB}$ (ſee Roof, n° 19. and *Strength of Materials*, n° 92, &c. *Encycl.*) Therefore,

4. The ſtrain on the middle point, by a force applied there, is one fourth of the ſtrain which the ſame force would produce, if applied to one end of a beam of the ſame length, having the other end fixed.

5. The ſtrain on any ſection C of a beam, reſting on two props A and B, occaſioned by a force applied perpendicularly to another point D, is proportional to the rectangle of the exterior ſegments, or is equal to $w \times \frac{AC \times DB}{AB}$. Therefore

The ſtrain at C occaſioned by the preſſure on D, is the ſame with the ſtrain at D occaſioned by the ſame preſſure on C.

6. The ſtrain on any ſection D, occaſioned by a load uniformly diffuſed over any part EF, is the ſame as if the two parts ED, DF of the load were collected at their middle points *e* and *f*. Therefore

The ſtrain on any part D, occaſioned by a load uniformly diſtributed over the whole beam, is one-half of the ſtrain that is produced when the ſame load is laid on at D; and

The ſtrain on the middle point C, occaſioned by a load uniformly diſtributed over the whole beam, is the ſame which half that load would produce if laid on at C.

7. A beam ſupported at both ends on two props B and C (fig. 14.) will carry twice as much when the ends beyond the props are kept from riſing, as it will carry when it reſts looſely on the props.

8. Laſtly, the tranſverſe ſtrain on any ſection, occaſioned by a force applied obliquely, is diminiſhed in the proportion of the ſine of the angle which the direction of the force makes with the beam. Thus, if it be inclined to it in an angle of thirty degrees, the ſtrain is one half of the ſtrain occaſioned by the ſame force acting perpendicularly.

On the other hand, the relative strength of a beam, or its power in any particular ſection to reſiſt any tranſverſe ſtrain, is proportional to the abſolute coheſion of the ſection directly, to the diſtance of its centre of effort from the axis of fracture directly, and to the diſtance from the ſtrained point inverſely.

Thus in a rectangular ſection of the beam, of which b is the breadth, d the depth (that is, the dimenſion in the direction of the ſtraining force), meaſured in inches, and f the number of pounds which one ſquare inch will juſt ſupport without being torn aſunder, we muſt have $f \times b \times d^2$, proportional to $w \times CB$ (fig. 15.) Or, $f \times b \times d^2$, multiplied by ſome number m, depending on the nature of the timber, muſt be equal to $w \times CB$. Or, in the caſe of the ſection C of fig. 16. that is ſtrained by the force w applied at D, we muſt have $m \times f b d^2 = w \times \frac{AC \times DB}{AB}$. Thus if the beam is of ſound oak, m is very nearly $= \frac{1}{9}$ (ſee *Strength of Materials*, n° 116. Encycl.) Therefore we have $\frac{f b d^2}{9} = w \times \frac{AC \times CB}{AB}$.

Hence we can tell the preciſe force w which any ſection C can juſt reſiſt when that force is applied in any way whatever. For the above-mentioned formula gives $w = \frac{f b d^2}{9 CB}$, for the caſe repreſented by fig. 15. But the caſe repreſented in fig. 16. having the ſtraining force applied at D, gives the ſtrain at C $(= w) = f \times \frac{b d^2 \times AB}{9 AC \times CB}$.

Example. Let an oak beam, four inches ſquare, reſt freely on the props A and B, ſeven feet apart, or 84 inches. What weight will it juſt ſupport at its middle point C, on the ſuppoſition that a ſquare inch rod will juſt carry 16,000 pounds, pulling it aſunder?

The formula becomes $w = \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 42}$, or $w = \frac{86016000}{15876}$, $= 5418$ pounds. This is very near what was employed in Buffon's experiment, which was 5312.

Had the ſtraining force acted on a point D, half way between C and B, the force ſufficient to break the beam at C would be $= \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 21} = 10836$ lbs.

Had the beam been found red fir, we muſt have taken $f = 10{,}000$ nearly, and m nearly 8; for although fir be leſs coheſive than oak in the proportion of 5 to 8 nearly, it is leſs compreſſible, and its axis of fracture is therefore nearer to the concave ſide.

22 Of joints.

Having conſidered at ſufficient length the ſtrains of different kinds which ariſe from the form of the parts of a frame of carpentry, and the direction of the external forces which act on it, whether conſidered as impelling or as ſupporting its different parts, we muſt now proceed to consider the means by which this form is to be secured, and the connections by which those strains are excited and communicated.

The joinings practised in carpentry are almost infinitely various, and each has advantages which make it preferable in some circumstances. Many varieties are employed merely to please the eye. We do not concern ourselves with these: Nor shall we consider those which are only employed in connecting small works, and can never appear on a great scale: yet even in some of these, the skill of the carpenter may be discovered by his choice; for in all cases it is wise to make every, even the smallest, part of his work as strong as the materials will admit. He will be particularly attentive to the changes which will necessarily happen by the shrinking of timber as it dries, and will consider what dimensions of his framings will be affected by this, and what will not; and will then dispose the pieces which are less essential to the strength of the whole, in such a manner that their tendency to shrink shall be in the same direction with the shrinking of the whole framing. If he do otherwise, the seams will widen, and parts will be split asunder. He will dispose his boardings in such a manner as to contribute to the stiffness of the whole, avoiding at the same time the giving them positions which will produce lateral strains on truss beams which bear great pressures; recollecting, that although a single board has little force, yet many united have a great deal, and may frequently perform the office of very powerful struts.

Our limits confine us to the joinings which are most essential for connecting the parts of a single piece of a frame when it cannot be formed of one beam, either for want of the necessary thickness or length; and the joints for connecting the different sides of a trussed frame.

23
Of building up beams.

Much ingenuity and contrivance has been bestowed on the manner of building up a great beam of many thicknesses, and many singular methods are practised as great nostrums by different artists: but when we consider the manner in which the cohesion of the fibres performs its office, we will clearly see that the simplest are equally effectual with the most refined, and that they are less apt to lead us into false notions of the strength of the assemblage.

24
Building up a girder or lever.

25
Joggling preferable to scarfing.

Thus, were it required to build up a beam for a great lever or a girder, so that it may act nearly as a beam of the same size of one log—it may either be done by plain joggling, as in fig. 17. A, or by scarfing, as in fig. 17. B or C. If it is to act as a lever, having the gudgeon on the lower side at C, we believe that most artists will prefer the form B and C; at least this has been the case with nine-tenths of those to whom we have proposed the question. The best informed only hesitated; but the ordinary artists were all confident in its superiority; and we found their views of the matter very coincident. They consider the upper piece as grasping the lower in its hooks; and several imagined that, by driving the one very tight on the other, the beam would be stronger than an entire log: but if we attend carefully to the internal procedure in the loaded lever, we shall find the upper one clearly the strongest. If they are formed of equal logs, the upper one is thicker than the other by the depth of the joggling or scarfing, which we suppose to be the same in both; consequently, if the cohesion of the fibres in the intervals is able to bring the uppermost filaments into full action, the form A is stronger than B, in the proportion of the greater distance of the upper filaments from the axis of the fracture: this may be greater than the difference of the thickness, if the wood is very compressible. If the gudgeon be in the middle, the effect, both of the joggles and the scarfings, is considerably diminished; and if it is on the upper side, the scarfings act in a very different way. In this situation, if the loads on the arms are also applied to the upper side, the joggled beam is still more superior to the scarfed one. This will be best understood by resolving it in imagination into a trussed frame. But when a gudgeon is thus put on that side of the lever which grows convex by the strain, it is usual to connect it with the rest by a powerful strap, which embraces the beam, and causes the opposite point to become the resisting point. This greatly changes the internal actions of the filaments, and, in some measure, brings it into the same state as the first, with the gudgeon below. Were it possible to have the gudgeon on the upper side, and to bring the whole into action without a strap, it would be the strongest of all; because, in general, the resistance to compression is greater than to extension. In every situation the joggled beam has the advantage; and it is the easiest executed.

We may frequently gain a considerable accession of strength by this building up of a beam; especially if the part which is stretched by the strain be of oak, and the other part be fir. Fir being so much superior to oak as a pillar (if Musschenbroek's experiments may be confided in), and oak so much preferable as a tie, this construction seems to unite both advantages. But we shall see much better methods of making powerful levers, girders, &c. by trussing.

Observe that the efficacy of both methods depends entirely on the difficulty of causing the piece between the cross joints to slide along the timber to which it adheres. Therefore, if this be moderate, it is wrong to make the notches deep; for as soon as they are so deep that their ends have a force sufficient to push the slice along the line of junction, nothing is gained by making them deeper; and this requires a greater expenditure of timber.

Scarfings are frequently made oblique, as in fig. 18. but we imagine that this is a bad practice. It begins to yield at the point, where the wood is crippled and splintered off, or at least bruised out a little: as the pressure increases, this part, by squeezing broader, causes the solid parts rise to a little upwards, and gives them some tendency, not only to push their antagonists along the base, but even to tear them up a little. For similar reasons, we disapprove of the favourite practice of many artists, to make the angles of their scarfings acute, as in fig. 19. This often causes the two pieces to tear each other up. The abutments should always be perpendicular to the directions of the pressures. Lest it should be forgotten in its proper place, we may extend this injunction also to the abutments of different pieces of a frame, and recommend it to the artist even to attend to the shrinking of the timbers by drying. When two timbers abut obliquely, the joint should be most full

full at the obtuſe angle of the end; becauſe, by drying, that angle grows more obtuſe, and the beam would then be in danger of ſplintering off at the acute angle.

26 We muſt not wedge too hard. It is evident that the niceſt work is indiſpenſably neceſſary in building up a beam. The parts muſt abut on each other completely, and the ſmalleſt play or void takes away the whole efficacy. It is uſual to give the butting joints a ſmall taper to one ſide of the beam, ſo that they may require moderate blows of a maul to force them in, and the joints may be perfectly cloſe when the external ſurfaces are even on each ſide of the beam. But we muſt not exceed in the leaſt degree; for a very taper wedge has great force; and if we have driven the pieces together by very heavy blows, we leave the whole in a ſtate of violent ſtrain, and the abutments are perhaps ready to ſplinter off by a ſmall addition of preſſure. This is like too ſevere a proof for artillery; which, though not ſufficient to burſt the pieces, has weakened them to ſuch a degree, that the ſtrain of ordinary ſervice is ſufficient to complete the fracture. The *workman* is tempted to exceed in this, becauſe it ſmooths off and conceals all uneven ſeams; but he muſt be watched. It is not unuſual to leave ſome abutments open enough to admit a thin wedge reaching through the beam. Nor is this a bad practice, if the wedge is of materials which is not compreſſed by the driving or the ſtrain of ſervice. Iron would be preferable for this purpoſe, and for the joggles, were it not that by its too great hardneſs it cripples the fibres of timber to ſome diſtance. In conſequence of this, it often happens that, in beams which are ſubjected to deſultory and ſudden ſtrains (as in the levers of reciprocating engines), the joggles or wedges widen the holes, and work themſelves looſe: Therefore ſkilful engineers never admit them, and indeed as few bolts as poſſible, for the ſame reaſon: but when reſiſting a ſteady or dead pull, they are not ſo improper, and are frequently uſed.

Beams are built up not only to increaſe their dimenſions in the direction of the ſtrain (which we have hitherto called their depth), but alſo to increaſe their breadth or the dimenſions perpendicular to the ſtrain. We ſometimes double the breadth of a girder which is thought too weak for its load, and where we muſt not increaſe the thickneſs of the flooring. The maſt of
27 Building of maſts. a great ſhip of war muſt be made bigger athwartſhip, as well as fore and aft. This is one of the niceſt problems of the art; and profeſſional men are by no means agreed in their opinions about it. We do not preſume to decide; and ſhall content ourſelves with exhibiting the different methods.

The moſt obvious and natural method is that ſhewn in fig. 20. It is plain that (independent of the connection of croſs bolts, which are uſed in them all when the beams are ſquare) the piece C cannot bend in the
28 Method uſed in the French Navy. direction of the plane of the figure without bending the piece D along with it. This method is much uſed in the French navy; but it is undoubtedly imperfect. Hardly any two great trees are of equal quality, and ſwell and ſhrink alike. If C ſhrinks more than D, the feather of C becomes looſe in the groove wrought in D to receive it; and when the beam bends, the parts can ſlide on each other like the plates of a coach ſpring; and if the bending is in the direction *e f*, there is nothing to hinder this ſliding but the bolts, which ſoon work themſelves looſe in the bolt-holes.

Fig. 21. exhibits another method. The two halves 29 Another method.
of the beam are tabled into each other in the ſame manner as in fig. 17. It is plain that this will not be affected by the unequal ſwelling or ſhrinking, becauſe this is inſenſible in the direction of the fibres; but when bent in the direction *a b*, the beam is weaker than fig. 20. bent in the direction *e f*. Each half of fig. 20. has, in every part of its length, a thickneſs greater than half the thickneſs of the beam. It is the contrary in the alternate portions of the halves of fig. 21. When one of them is bent in the direction AB, it is plain that it drags the other with it by means of the croſs butments of its tables, and there can be no longitudinal ſliding. But unleſs the work is accurately executed, and each hollow completely filled up by the table of the other piece, there will be a lateral ſlide along the croſs joints ſufficient to compenſate for the curvature; and this will hinder the one from compreſſing or ſtretching the other in conformity to this curvature.

The imperfection of this method is ſo obvious, that 30 Its imperfection.
it has ſeldom been practiſed: but it has been combined with the other, as is repreſented in fig. 22. where the beams are divided along the middle, and the tables in each half are alternate, and alternate alſo with the tables of the other half. Thus 1, 3, 4, are prominent, and 5, 2, 6, are depreſſed. This conſtruction evidently puts a ſtop to both ſides, and obliges every part of both pieces to move together. *a b* and *c d* ſhow ſections of the built-up beam correſponding to AB and CD.

No more is intended in this practice by any intelligent artiſt, than the cauſing the two pieces to act together in all their parts, although the ſtrains may be unequally diſtributed on them. Thus, in a built-up girder, the binding joints are frequently mortiſed into very different parts of the two ſides. But many ſeem to aim at making the beam ſtronger than if it were of one piece; and this inconſiderate project has given riſe to many whimſical modes of tabling and ſcarfing, which we need not regard.

The practice in the Britiſh dock-yards is ſomewhat 31 Britiſh method;
different from any of theſe methods. The pieces are tabled as in fig 22. but the tables are not thin parallelopipeds, but thin priſms. The two outward joints or viſible ſeams are ſtraight lines, and the table n° 1. riſes gradually to its greateſt thickneſs in the axis. In like manner, the hollow 5 for receiving the oppoſite table, ſinks gradually from the edge to its greateſt depth in the axis. Fig. 23. repreſents a ſection of a round piece of timber built up in this way, where the full line EFGH is the ſection correſponding to AB of fig. 22. and the dotted line EGFH is the ſection correſponding to CD.

This conſtruction, by making the external ſeam ſtraight, leaves no lodgment for water, and looks much fairer to the eye: but it appears to us that it does not give ſuch firm hold when the maſt is bent in the direction EH. The exterior parts are moſt ſtretched and moſt compreſſed by this bending; but there is hardly any abutment in the exterior parts of theſe tables. In the very axis, where the abutment is the firmeſt, there is little or no difference of extenſion and compreſſion.

But this conſtruction has an advantage, which we imagine much more than compenſates for theſe imperfections,

fections, at leaft in the particular cafe of a round maft: it will draw together by hooping incomparably better than any of the others. If the cavity be made fomewhat too fhallow for the prominence of the tables, and if this be done uniformly along the whole length, it will make a fomewhat open feam; and this opening can be regulated with the utmoft exactnefs from end to end by the plane. The heart of thofe vaft trunks is very fenfibly fofter than the exterior circles: Therefore, when the whole is hooped, and the hoops hard driven, and at confiderable intervals between each fpell —we are confident that all may be compreffed till the feam difappears; and then the whole makes one piece, *much* ftronger than if it were an original log of that fize; becaufe the middle has become, by compreffion, as folid as the cruft, which was naturally firmer, and refifted farther compreffion. We verified this beyond a doubt, by hooping a built ftick of a timber which has this inequality of firmnefs in a remarkable degree, and it was nearly twice as ftrong as another of the fame fize.

Our maftmakers are not without their fancies and whims; and the manner in which our mafts and yards are generally built up, is not near fo fimple as fig. 22.: but it confifts of the fame effential parts, acting in the very fame manner, and derives all its efficacy from the principles which are here employed.

32 Attended with peculiar advantages.

This conftruction is particularly fuited to the fituation and office of a fhip's maft. It has no bolts; or, at leaft, none of any magnitude, or that make very important parts of its conftruction. The moft violent ftrains perhaps that it is expofed to, is that of twifting, when the lower yards are clofe braced up by the force of many men acting by a long lever. This form refifts a twift with peculiar energy: it is therefore an excellent method for building up a great fhaft for a mill. The way in which they are ufually built up is by reducing a central log to a polygonal prifm, and then filling it up to the intended fize by *planting* pieces of timber along its fides, either fpiking them down, or cocking them into it by a feather, or joggling them by flips of hard wood funk into the central log and into the flips. *N. B.* Joggles of elm are fometimes ufed in the middle of the large tables of mafts; and when funk into the firm wood near the furface, they muft contribute much to the ftrength. But it is very neceffary to employ wood not much harder than the pine; otherwife it will foon enlarge its bed, and become loofe; for the timber of thefe large trunks is very foft.

The moft general reafon for piecing a beam is to increafe its length. This is frequently neceffary, in order to procure tie-beams for very wide roofs. Two pieces muft be fcarfed together.—Numberlefs are the modes of doing this; and almoft every mafter carpenter has his favourite noftrum. Some of them are very ingenious: But here, as in other cafes, the moft fimple are commonly the ftrongeft. We do not imagine that any, the moft ingenious, is equally ftrong with a tie confifting of two pieces of the fame fcantling laid over each other for a certain length, and firmly bolted together. We acknowledge that this will appear an artlefs and clumfy tie-beam; but we only fay that it will be ftronger than any that is more artificially made up of the fame thicknefs of timber. This, we imagine, will appear fufficiently certain.

33 Various methods of fcarfing.

The fimpleft and moft obvious fcarfing (after the one now mentioned) is that reprefented in fig. 24. n° 1. and 2. If confidered merely as two pieces of wood joined, it is plain that, as a tie, it has but half the ftrength of an entire piece, fuppofing that the bolts (which are the only connections) are faft in their holes. N° 2. requires a bolt in the middle of the fcarf to give it that ftrength; and, in every other part, is weaker on one fide or the other.

But the bolts are very apt to bend by the violent ftrain, and require to be ftrengthened by uniting their ends by iron plates; in which cafe it is no longer a wooden tie. The form of n° 1. is better adapted to the office of a pillar than n° 2.; efpecially if its ends be formed in the manner fhewn in the elevation n° 3. By the fally given to the ends, the fcarf refifts an effort to bend it in that direction. Befides, the form of n° 2. is unfuitable for a poft; becaufe the pieces, by fliding on each other by the preffure, are apt to fplinter off the tongue which confines their extremity.

Fig. 25. and 26. exhibit the moft approved form of a fcarf, whether for a tie or for a poft. The key reprefented in the middle is not effentially neceffary; the two pieces might fimply meet fquare there. This form, without a key, needs no bolts (although they ftrengthen it greatly); but, if worked very true and clofe, and with fquare abutments, will hold together, and will refift bending in any direction. But the key is an ingenious and a very great improvement, and will force the parts together with perfect tightnefs. The fame precaution muft be obferved that we mentioned on another occafion, not to produce a conftant internal ftrain on the parts by overdriving the key. The form of fig. 25. is by far the beft; becaufe the triangle of 26. is much eafier fplintered off by the ftrain, or by the key, than the fquare wood of 25. It is far preferable for a poft, for the reafon given when fpeaking of fig. 24. n° 1. and n° 2. Both may be formed with a fally at the ends equal to the breadth of the key. In this fhape, fig. 25. is vaftly well fuited for joining the parts of the long corner pofts of fpires and other wooden towers. Fig. 25. n° 2. differs from n° 1. only by having three keys. The principle and the longitudinal ftrength are the fame. The long fcarf of n° 2. tightened by the three keys, enables it to refift a bending much better.

None of thefe fcarfed tie-beams can have more than one-third of the ftrength of an entire piece, unlefs with the affiftance of iron plates; for if the key be made thinner than one-third, it has lefs than one-third of the fibres to pull by.

We are confident, therefore, that when the heads of the bolts are connected by plates, the fimple form of fig. 24. n° 1. is ftronger than thofe more ingenious fcarfings. It may be ftrengthened againft lateral bending by a little tongue, or by a fally; but it cannot have both.

The ftrongeft of all methods of piecing a tie-beam would be to fet the parts end to end, and grafp them between other pieces on each fide, as in fig. 27. This is what the fhip-carpenter calls *fifhing* a beam; and is a frequent practice for occafional repairs. Mr Perronet ufed it for the tie-beams or ftretchers, by which he connected the oppofite feet of a centre, which was yielding to its load, and had pufhed afide one of the piers above four inches. Six of thefe not only withftood a ftrain of 1800 tons, but, by wedging behind them, he brought

34 Fifhing a beam.

brought the feet of the truſs 2$\frac{1}{2}$ inches nearer. The ſtretchers were 14 inches by 11 of ſound oak, and could have withſtood three times that ſtrain. Mr Perronet, fearing that the great length of the bolts employed to connect the beams of theſe ſtretchers would expoſe them to the riſk of bending, ſcarfed the two ſide pieces into the middle piece. The ſcarfing was of the triangular kind *(Trait de Jupiter)*, and only an inch deep, each face being two feet long, and the bolt paſſed through cloſe to the angle.

In piecing the pump rods, and other wooden ſtretchers of great engines, no dependence is had on ſcarfing; and the engineer connects every thing by iron ſtraps. We doubt the propriety of this, at leaſt in caſes where the bulk of the wooden connection is not inconvenient. Theſe obſervations muſt ſuffice for the methods employed for connecting the parts of a beam; and we now proceed to conſider what are more uſually called the
35 joints of a piece of carpentry.

Square joints.

Where the beams ſtand ſquare with each other, and the ſtrains are alſo ſquare with the beams, and in the plane of the frame, the common mortiſe and tenon is the moſt perfect junction. A pin is generally put through both, in order to keep the pieces united, in oppoſition to any force which tends to part them. Every carpenter knows how to bore the hole for this pin, ſo that it ſhall draw the tenon tight into the mortiſe, and cauſe the ſhoulder to butt cloſe, and make neat work; and he knows the riſk of tearing out the bit of the tenon beyond the pin, if he draw it too much. We may juſt obſerve, that ſquare holes and pins are much preferable to round ones for this purpoſe, bringing more of the wood into action, with leſs tendency to ſplit it. The ſhip carpenters have an ingenious method of making long wooden bolts, which do not paſs completely through, take a very faſt hold, though not nicely fitted to their holes, which they muſt
36 not be, leſt they ſhould be crippled in driving. They
Foxtail wedging.
call it *foxtail wedging*. They ſtick into the point of the bolt a very thin wedge of hard wood, ſo as to project a proper diſtance; when this reaches the bottom of the hole by driving the bolt, it ſplits the end of it, and ſqueezes it hard to the ſide. This may be practiſed with advantage in carpentry. If the ends of the mortiſe are widened inwards, and a thin wedge be put into the end of the tenon, it will have the ſame effect, and make the joint equal to a dovetail. But this riſks the ſplitting the piece beyond the ſhoulder of the tenon, which would be unſightly. This may be avoided as follows: Let the tenon T, fig. 28. have two *very* thin wedges *a* and *c* ſtuck in near its angles, projecting equally; at a very ſmall diſtance within theſe, put in two ſhorter ones *b*, *d*, and more within theſe if neceſſary. In driving this tenon, the wedges *a* and *c* will take firſt, and ſplit off a thin ſlice, which will eaſily bend without breaking. The wedges *b*, *d*, will act next, and have a ſimilar effect, and the others in ſucceſſion. The thickneſs of all the wedges taken together muſt be equal to the enlargement of the mortiſe toward the bottom.

When the ſtrain is tranſverſe to the plane of the two beams, the principles laid down in n° 85, 86. of the article *Strength of Materials*, will direct the artiſt in placing his mortiſe. Thus the mortiſe in a girder for receiving the tenon of a binding joiſt of a floor ſhould be as near the upper ſide as poſſible, becauſe the girder becomes concave on that ſide by the ſtrain. But as this expoſes the tenon of the binding joiſt to the riſk of being torn off, we are obliged to mortiſe farther down. The form (fig. 29.) generally given to this joint is extremely judicious. The ſloping part *a b* gives a very firm ſupport to the additional bearing *e d*, without much weakening of the girder. This form ſhould be copied in every caſe where the ſtrain has a ſimilar direction.

The joint that moſt of all demands the careful atten- 37
Oblique mortiſe and tenon.
tion of the artiſt, is that which connects the ends of beams, one of which puſhes the other very obliquely, putting it into a ſtate of extenſion. The moſt familiar inſtance of this is the foot of a rafter preſſing on the tie-beam, and thereby *drawing* it away from the other wall. When the direction is very oblique (in which caſe the extending ſtrain is the greateſt), it is difficult to give the foot of the rafter ſuch a hold of the tie-beam as to bring many of its fibres into the proper action. There would be little difficulty if we could allow the end of the tie-beam to project to a ſmall diſtance beyond the foot of the rafter: but, indeed, the dimenſions which are given to tie-beams, for other reaſons, are always ſufficient to give enough of abutment when judiciouſly employed. Unfortunately this joint is much expoſed to failure by the effects of the weather. It is much expoſed, and frequently periſhes by rot, or becomes ſo ſoft and friable that a very ſmall force is ſufficient, either for pulling the filaments out of the tie-beam, or for cruſhing them together. We are therefore obliged to ſecure it with particular attention, and to avail ourſelves of every circumſtance of conſtruction.

One is naturally diſpoſed to give the rafter a deep hold by a long tenon; but it has been frequently obſerved in old roofs that ſuch tenons break off. Frequently they are obſerved to tear up the wood that is above them, and puſh their way through the end of the tie-beam. This, in all probability, ariſes from the firſt ſagging of the roof, by the compreſſion of the rafters and of the head of the king-poſt. The head of the rafter deſcends, the angle with the tie-beam is diminiſhed by the rafter revolving round its ſtep in the tie-beam. By this motion the heel or inner angle of the rafter becomes a fulcrum to a very long and powerful lever much loaded. The tenon is the other arm, very ſhort, and being ſtill freſh, it is therefore very powerful. It therefore forces up the wood that is above it, tearing it out from between the cheeks of the mortiſe, and then puſhes it along. Carpenters have therefore given up long tenons, and give to the toe of the tenon a ſhape which abuts firmly, in the direction of the thruſt, on the ſolid bottom of the mortiſe, which is well ſupported on the under ſide by the wall-plate. This form has the farther advantage of having no tendency to tear up the end of the mortiſe. This form is repreſented in fig. 30. The tenon has a ſmall portion *a b* cut perpendicular to the ſurface of the tie-beam, and the reſt *b c* is perpendicular to the rafter.

But if the tenon is not ſufficiently ſtrong (and it is not ſo ſtrong as the rafter, which is thought not to be ſtronger than is neceſſary), it will be cruſhed, and then the rafter will ſlide out along the ſurface of the beam. It is therefore neceſſary to call in the aſſiſtance of the whole

whole rafter. It is in this distribution of the strain among the various abutting parts that the varieties of joints and their merits chiefly consist. It would be endless to describe every nostrum, and we shall only mention a few that are most generally approved of.

38 Most approved forms.

The aim in fig. 31. is to make the abutments exactly perpendicular to the thrusts. It does this very precisely; and the share which the tenon and the shoulder have of the whole may be what we please, by the portion of the beam that we notch down. If the wall-plate lie duly before the heel of the rafter, there is no risk of straining the tie across or breaking it, because the thrust is made direct to that point where the beam is supported. The action is the same as against the joggle on the head or foot of a king-post. We have no doubt but that this is a very effectual joint. It is not, however, much practised. It is said that the sloping seam at the shoulder lodges water; but the great reason seems to be a secret notion that it weakens the tie-beam. If we consider the direction in which it acts as a tie, we must acknowledge that this form takes the best method for bringing the whole of it into action.

Fig. 32. exhibits a form that is more general, but certainly worse. What part of the thrust that is not borne by the tenon acts obliquely on the joint of the shoulder, and gives the whole a tendency to rise up and slide outward.

The shoulder joint is sometimes formed like the dotted line *a b c d e f g* of fig. 32. This is much more agreeable to the true principle, and would be a very perfect method, were it not that the intervals *b d* and *d f* are so short that the little wooden triangles *b c d*, *d e f*, will be easily pushed off their bases *b d*, *d f*.

Fig. 33. seems to have the most general approbation. It is the joint recommended by Price (page 7.), and copied into all books of carpentry as the *true joint* for a rafter foot. The visible shoulder-joint is flush with the upper surface of the tie-beam. The angle of the tenon at the tie nearly bisects the obtuse angle formed by the rafter and the beam, and is therefore somewhat oblique to the thrust. The inner shoulder *a c* is nearly perpendicular to *b d*. The lower angle of the tenon is cut off horizontally as at *e d*. Fig. 34. is a section of the beam and rafter foot, shewing the different shoulders.

We do not perceive the peculiar merit of this joint. The effect of the three oblique abutments *a b*, *a c*, *e d*, is undoubtedly to make the whole bear on the outer end of the mortise, and there is no other part of the tie-beam that makes immediate resistance. Its only advantage over a tenon extending in the direction of the thrust is, that it will not tear up the wood above it. Had the inner shoulder had the form *e c i*, having its face *i c* perpendicular, it would certainly have acted more powerfully in stretching many filaments of the tie-beam, and would have had much less tendency to force out the end of the mortise. The little bit *c i* would have prevented the sliding upwards along *e c*. At any rate, the joint *a b* being flush with the beam, prevents any sensible abutment on the shoulder *a c*.

Fig. 33. n° 2. is a simpler, and in our opinion a preferable, joint. We observe it practised by the most eminent carpenters for all oblique thrusts; but it surely employs less of the cohesion of the tie-beam than might be used without weakening it, at least when it is supported on the other side by the wall-plate.

Fig. 33. n° 3. is also much practised by the first carpenters.

Fig. 35. is proposed by Mr Nicholson (page 65.) as preferable to fig. 33. n° 3. because the abutment of the inner part is better supported. This is certainly the case; but it supposes the whole rafter to go to the bottom of the socket, and the beam to be thicker than the rafter. Some may think that this will weaken the beam too much, when it is no broader than the rafter is thick; in which case they think that it requires a deeper socket than Nicholson has given it. Perhaps the advantages of Nicholson's construction may be had by a joint like fig. 35. n° 2.

39 Circumstances to be attended to.

Whatever is the form of these butting joints, great care should be taken that all parts bear alike, and the artist will attend to the magnitude of the different surfaces. In the general compression, the greater surfaces will be less compressed, and the smaller will therefore change most. When all has settled, every part should be *equally* close. Because great logs are moved with difficulty, it is very troublesome to try the joint frequently to see how the parts fit; therefore we must expect less accuracy in the interior parts. This should make us prefer those joints whose efficacy depends chiefly on the visible joint.

It appears from all that we have said on this subject, that a very small part of the cohesion of the tie-beam is sufficient for withstanding the horizontal thrust of a roof, even though very low pitched. If therefore no other use is made of the tie-beam, one much slenderer may be used, and blocks may be firmly fixed to the ends, on which the rafters might abut, as they do on the joggles on the head and foot of a king-post. Although a tie-beam has commonly floors or ceilings to carry, and sometimes the workshops and store-rooms of a theatre, and therefore requires a great scantling, yet there frequently occur in machines and engines very oblique stretchers, which have no other office, and are generally made of dimensions quite inadequate to their situation, often containing ten times the necessary quantity of timber. It is therefore of importance to ascertain the most perfect manner of executing such a joint. We have directed the attention to the principles that are really concerned in the effect. In all hazardous cases, the carpenter calls in the assistance of iron straps; and they are frequently necessary, even in roofs, notwithstanding this superabundant strength of the tie-beam. But this is generally owing to bad construction of the wooden joint, or to the failure of it by time. Straps will be considered in their place.

There needs but little to be said of the joints at a joggle worked out of solid timber; they are not near so difficult as the last. When the size of a log will allow the joggle to receive the whole breadth of the abutting brace, it ought certainly to be made with a square shoulder; or, which is still better, an arch of a circle, having the other end of the brace for its centre. Indeed this in general will not sensibly differ from a straight line perpendicular to the brace. By this circular form, the settling of the roof makes no change in the abutment; but when there is not sufficient stuff for this, we must avoid bevel joints at the shoulders, because these always tend to make the brace slide off. The brace in fig. 36. must not be joined as at *a*, but as at *b*, or some equivalent manner. Observe the joints at the

the head of the main posts of Drury Line theatre, fig. D.

40 Butting joints.

When the very oblique action of one side of a frame of carpentry does not extend but compress the piece on which it abuts (as in fig. 11.), there is no difficulty in the joint. Indeed a joining is unnecessary, and it is enough that the pieces abut on each other; and we have only to take care that the mutual pressure be equally borne by all the parts, and that it do not produce lateral pressures, which may cause one of the pieces to slide on the butting joint. A very slight mortise and tenon is sufficient at the joggle of a king-post with a rafter or straining beam. It is best, in general, to make the butting plain, bisecting the angle formed by the sides, or else perpendicular to one of the pieces. In fig. 36. n° 2. where the straining beam *a b* cannot slip away from the pressure, the joint *a* is preferable to *b*, or indeed to any uneven joint, which never fails to produce very unequal pressures on the different parts, by which some are crippled, others are splintered off, &c.

41 Directions for placing iron straps.

When it is necessary to employ iron straps for strengthening a joint, a considerable attention is necessary, that we may place them properly. The first thing to be determined is the direction of the strain. This is learned by the observations in the beginning of this article. We must then resolve this strain into a strain parallel to each piece, and another perpendicular to it. Then the strap which is to be made fast to any of the pieces must be so fixed, that it shall resist in the direction parallel to the piece. Frequently this cannot be done; but we must come as near to it as we can. In such cases we must suppose that the assemblage yields a little to the pressures which act on it. We must examine what change of shape a small yielding will produce. We must now see how this will affect the iron strap which we have already supposed attached to the joint in some manner that we thought suitable. This settling will perhaps draw the pieces away from it, leaving it loose and unserviceable (this frequently happens to the plates which are put to secure the obtuse angles of butting timbers, when their bolts are at some distance from the angles, especially when these plates are laid on the inside of the angles); or it may cause it to compress the pieces harder than before; in which case it is answering our intention. But it may be producing cross strains, which may break them; or it may be crippling them. We can hardly give any general rules; but the reader will do well to read what is written in n° 36. and 41. of the article Roof, *Encycl.* In n° 36. he will see the nature of the strap or stirrup, by which the king-post carries the tie-beam. The strap that we observe most generally ill placed is that which connects the foot of the rafter with the beam. It only binds down the rafter, but does not act against its horizontal thrust. It should be placed farther back on the beam, with a bolt through it, which will allow it to turn round. It should embrace the rafter almost horizontally near the foot, and should be notched square with the back of the rafter. Such a construction is represented in fig. 37. By moving round the eye-bolt, it follows the rafter, and cannot pinch and cripple it, which it always does in its ordinary form. We are of opinion that straps which have eye-bolts in the very angles, and allow all motion round them, are of all the most perfect. A branched strap, such as may at once bind the king-post and the two braces which butt on its foot, will be more serviceable if it have a joint. When a roof warps, those branched straps frequently break the tenons, by affording a fulcrum in one of their bolts. An attentive and judicious artist will consider how the beams will act on such occasions, and will avoid giving rise to these great strains by levers.—A skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art, and subject to imperfections in workmanship which he cannot discern nor amend. We must refer the reader to Nicholson's Carpenter and Joiner's Assistant for a more particular account of the various forms of stirrups, screwed rods, and other iron work for carrying tie-beams, &c.

As for those that are necessary for the turning joints of great engines constructed of timber, they make no part of the art of carpentry.

After having attempted to give a systematic view of the principles of framing carpentry, we shall conclude, by giving some examples which will illustrate and confirm the foregoing principles. 42 Examples of different pieces of carpentry.

Fig. 38. is the roof of the chapel of the Royal Hospital at Greenwich, constructed by Mr S. Wyatt. 43 Roof of Greenwich chapel.

	Inches Scantling.
AA, Is the tie-beam, 57 feet long, spanning 51 feet clear - - - - -	14 by 12
CC, Qneen-posts - - - - -	9×12
D, Braces - - - - - -	9×7
E, Truss beam - - - - -	10×7
F, Straining piece - - - - -	6×7
G, Principal rafters - - - -	10×7
H, A cambered beam for the platform -	9.7
B, An iron string, supporting the tie-beam	2×2

The trusses are 7 feet apart, and the whole is covered with lead, the boarding being supported by horizontal ledgers *h*, *h*, of 6 by 4 inches.

This is a beautiful roof, and contains less timber than most of its dimensions. The parts are all disposed with great judgment. Perhaps the iron rod is unnecessary; but it adds great stiffness to the whole.

The iron straps at the rafter feet would have had more effect if not so oblique. Those at the head of the posts are very effective.

We may observe, however, that the joints between the straining beam and its braces are not of the best kind, and tend to bruise both the straining beam and the truss beam above it.

Fig. 39. the roof of St Paul's, Covent Garden, constructed by Mr Wapshot in 1796. 44 St Paul's, Covent Garden.

AA, Tie-beam spanning 50 feet 2 inches	16.12
B, Queen-post - - - - -	9×8
C, Truss beam - - - . - -	10×8

FF, Principal brace (at bottom) - -	10×8½
HH, Principal rafter (at bottom) -	10×8½
gg, Studs supporting the rafter - -	8×8

This roof far excels the original one put up by Inigo Jones. One of its trusses contains 198 feet of timber. One of the old roof had 273, but had many inactive timbers, and others ill disposed. (*N. B.* The figure which we gave of it in the article Roof, copied from Price,

Price, is very erroneous). The internal truſs FCF is admirably contrived for ſupporting the exterior rafters, without any preſſure on the far projecting ends of the tie-beam. The former roof had bent them greatly, ſo as to appear ungraceful.

We think that the camber (ſix inches) of the tie-beam is rather hurtful; becauſe, by ſettling, the beam lengthens; and this muſt be accompanied by a *conſiderable* ſinking of the roof. This will appear by calculation.

45 Birmingham theatre.

Fig. 40. the roof of Birmingham theatre, conſtructed by Mr Geo. Saunders. The ſpan is 80 feet clear, and the truſſes are 10 feet apart.

L, Principal braces - - -	9 and 6×9
M, Common ditto - - - -	6×9
N, Purlins - - - - -	7×5
Q, Straining ſill - - - -	5½×9

This roof is a fine ſpecimen of Britiſh carpentry, and is one of the boldeſt and lighteſt roofs in Europe. The ſtraining ſill Q gives a firm abutment to the principal braces, and the ſpace between the poſts is 19½ feet wide, affording roomy workſhips for the carpenters and other workmen connected with a theatre. The contrivance for taking double hold of the wall, which is very thin, is excellent. There is alſo added a beam (marked R), bolted down to the tie-beams. The intention of this was to prevent the total failure of ſo bold a truſſing, if any of the tie-beams ſhould fail at the end by rot.

46 Drury Lane theatre.

Akin to this roof is fig. 41. the roof of Drury Lane theatre, 80 feet 3 inches in the clear, and the truſſes 15 feet apart, conſtructed by Mr Edward Grey Saunders.

A, Beams - - - - -	10 by 7
B, Rafters - - - - -	7×7
C, King-poſts - - - -	12×7
D, Struts - - - - -	5×7
E, Purlins - - - - -	9×5
G, Pole plates - - - -	5×5
I, Common rafters - - - -	5×4
K, Tie-beam to the main truſs - -	15×12
L, Poſts to ditto - - - -	15×12
M, Principal braces to ditto -	14 and 12×12
N, Struts - - - - -	8×12
P, Straining beams - - - -	12×12

The main beams are truſſed in the middle ſpace with oak truſſes 5 inches ſquare. This was neceſſary for its width of 32 feet, occupied by the carpenters, painters, &c. The great ſpace between the truſſes affords good ſtore-rooms, dreſſing-rooms, &c.

It is probable that this roof has not its equal in the world for lightneſs, ſtiffneſs, and ſtrength. The main truſs is ſo judiciouſly framed, that each of them will ſafely bear a load of near 300 tons; ſo it is not likely that they will ever be quarter loaded. The diviſion of the whole into three parts makes the exterior roofings very light. The ſtrains are admirably kept from the walls, and the walls are even firmly bound together by the roof. They alſo take off the dead weight from the main truſs one-third.

The intelligent reader will perceive that all theſe roofs are on one principle, depending on a truſs of three pieces and a ſtraight tie-beam. This is indeed the great principle of a truſs, and is a ſtep beyond the roof with two rafters and a king poſt. It admits of much greater variety of forms, and of greater extent. We may ſee that even the middle part may be carried to any ſpace, and yet be flat at top; for the truſs beam may be ſupported in the middle by an inverted king-poſt (of timber, not iron), carried by iron or wooden ties from its extremities: And the ſame ties may carry the horizontal tie-beam K; for till K be torn aſunder, or M, M, and P be crippled, nothing can fail. 47 Remarks.

The roof of St Martin's church in the Fields is conſtructed on good principles, and every piece properly diſpoſed. But although its ſpan does not exceed 40 feet from column to column, it contains more timber in a truſs than there is in one of Drury-Lane theatre. The roof of the chapel at Greenwich, that of St Paul's, Covent Garden, that of Birmingham, and that of Drury Lane theatres, form a ſeries gradually more perfect. Such ſpecimens afford excellent leſſons to the artiſts. We therefore account them a uſeful preſent to the public.

There is a very ingenious project offered to the public by Mr Nicholſon (*Carpenter's Aſſiſtant*, p. 68.) He propoſes iron rods for king-poſts, queen-poſts, and all other ſituations where beams perform the office of ties. This is in proſecution of the notions which we publiſhed in the article Roof of the *Encycl.* (ſee nº 36, 37.) He receives the feet of the braces and ſtruts in a ſocket very well connected with the foot of his iron king-poſt; and he ſecures the feet of his queen-poſts from being puſhed inwards, by interpoſing a ſtraining ſill. He does not even mortiſe the foot of his principal rafter into the end of the tie-beam, but ſets it in a ſocket like a ſhoe, at the end of an iron bar, which is bolted into the tie-beam a good way back. All the parts are formed and diſpoſed with the preciſion of a perſon thoroughly acquainted with the ſubject; and we have not the ſmalleſt doubt of the ſucceſs of the project, and the complete ſecurity and durability of his roofs, and we expect to ſee many of them executed. We abound in iron, but we muſt ſend abroad for building timber. This is therefore a valuable project; at the ſame time, however, let us not over-rate its value. Iron is but about 12 times ſtronger than red fir, and is more than 12 times heavier; nor is it cheaper, weight for weight, or ſtrength for ſtrength. 48 Project by Mr Nicholſon.

Our illuſtrations and examples have been chiefly taken from roofs, becauſe they are the moſt familiar inſtances of the difficult problems of the art. We could have wiſhed for more room even on this ſubject. The conſtruction of dome roofs has been (we think) miſtaken, and the difficulty is much leſs than is imagined. We mean in reſpect of ſtrength; for we grant that the obliquity of the joints, and a general intricacy, increaſes the trouble of workmanſhip exceedingly. Another opportunity may perhaps occur for conſidering this ſubject.

49 Wooden bridges. Wooden bridges form another claſs equally difficult and important; but our limits are already overpaſſed, and will not admit them. The principle on which they ſhould all be conſtructed, without exception, is that of a truſs, avoiding all lateral bearings on any of the timbers. In the application of this principle, we muſt farther remark, that the angles of our truſs ſhould be as acute as poſſible; therefore we ſhould make it of as few and as long pieces as we can, taking care to prevent the bending of the truſs beams by bridles, which embrace them, but without preſſing them to either ſide. When the truſs conſiſts of many pieces, the angles are very obtuſe; and the thruſts increaſe nearly in the duplicate proportion of the number of angles. The proper maxims will readily occur to the artiſt who conſiders with attention the ſpecimens of centres or coombs, which we ſhall give in the article CENTRE.

50 Framing of great levers. With reſpect to the frames of carpentry which occur in engines and great machines, the varieties are ſuch that it would require a volume to treat of them properly. The principles are already laid down; and if the reader be really intereſted in the ſtudy, he will engage in it with ſeriouſneſs, and cannot fail of being inſtructed. We recommend to his conſideration, as a ſpecimen of what may be done in this way, the working beam of Hornblower's ſteam-engine (ſee *STEAM-Engine*, n° 84. *Encycl.*) When the beam muſt act by chains hung from the upper end of arch heads, the framing there given ſeems very ſcientifically conſtructed; at the ſame time, we think that a ſtrap of wrought iron, reaching the whole length of the upper bar (ſee the figure), would be vaſtly preferable to thoſe partial plates which the engineer has put there, for the bolts will ſoon work looſe.

But when arches are not neceſſary, the form employed by Mr Watt is vaſtly preferable, both for ſimplicity and for ſtrength. It conſiſts of a ſimple beam AB (fig. 42.), having the gudgeon C on the upper ſide. The two piſton-rods are attached to wrought iron joints A and B. Two ſtrong ſtruts DC, EC reſt on the upper ſide of the gudgeon, and carry an iron ſtring ADEB, conſiſting of three pieces, connected with the ſtruts by proper joints of wrought iron. A more minute deſcription is not needed for a clear conception of the principle. No part of this is expoſed to a croſs ſtrain; even the beam AB might be ſawed through at the middle. The iron ſtring is the only part which is ſtretched; for AC, DC, EC, BC, are all in a ſtate of compreſſion. We have made the angles equal, that all may be as great as poſſible, and the preſſure on the ſtruts and ſtrings a minimum. Mr Watt makes them much lower, as A *d e* B, or A δ ε B. But this is for economy, becauſe the ſtrength is almoſt inſuperable. It might be made with wooden ſtrings; but the workmanſhip of the joints would more than compenſate the cheapneſs of the materials.

WE offer this article to the public with deference, and we hope for an indulgent reception of our eſſay on a ſubject which is in a manner new, and would require much ſtudy. We have beſtowed our chief attention on the ſtrength of the conſtruction, becauſe it is here that perſons of the profeſſion have the moſt ſcanty information. We beg them not to conſider our obſervations as too refined, and that they will ſtudy them with care. One principle runs through the whole; and when that is clearly conceived and familiar to the mind, we venture to ſay that the practitioner will find it of eaſy application, and that he will improve every performance by a continual reference to it. 51 Concluſion.

If this attempt to inſtruct our moſt valuable and much eſteemed artiſts ſhall appear to meet with their approbation, it may encourage us to engage in the ſerious taſk of compoſing a ſyſtem on the ſubject. But this is a great work, and will require much time and liberal contribution of knowledge from the eminent carpenters who do honour to this country by their works.

Caſcabel || Caſſini. CASCABEL, the knob or button of metal behind the breech of a cannon, as a kind of handle by which to elevate and direct the piece; to which ſome add the fillet and ogees as far as the baſe-ring.

CASEMATE, or CAZEMATE, in fortification, a kind of vault or arch of ſtone-work, in that part of the flank of a baſtion next the curtain; ſerving as a battery to defend the face of the oppoſite baſtion, and the moat or ditch.

It is now ſeldom uſed, becauſe the batteries of the enemy are apt to bury the artillery of the caſemate in the ruins of the vault; beſide, the great ſmoke made by the diſcharge of the cannon renders it intolerable to the men. So that, inſtead of the ancient covered caſemates, later engineers have contrived open ones, only guarded by a parapet, &c.

CASEMATE is alſo uſed for a well with ſeveral ſubterraneous branches, dug in the paſſage of the baſtion, till the miner is heard at work, and air given to the mine.

CASSINI (James), a celebrated French aſtronomer, was born at Paris February 18. 1677, being the younger ſon of Johannes Dominicus Caſſini, of whom ſome account has been given in the *Encyclopædia*.

After his firſt ſtudies in his father's houſe, in which it is not to be ſuppoſed that mathematics and aſtronomy would be neglected, he was ſent to ſtudy philoſophy at the Mazarine college, where the celebrated Varignon was then profeſſor of mathematics. From the aſſiſtance of this eminent young man Caſſini profited ſo well, that at 15 years of age he ſupported a mathematical theſis with great honour. At the age of 17 he was admitted a member of the Academy of Sciences; and the ſame year he accompanied his father in a journey to Italy, where he aſſiſted him in the verification of the meridian at Bologna and other meaſurements. On his return he performed ſimilar operations in a journey into Holland, where he diſcovered ſome errors in the meaſure of the earth by Snell, the reſult of which was communicated to the Academy in 1702. He made alſo a viſit to England in 1696, where he was made a member of the Royal Society. In 1712 he ſucceeded his father as aſtronomer royal at the obſervatory of Paris. In 1717 he gave to the Academy his reſearches on the diſtance of the fixed ſtars; in which he ſhewed that the whole annual orbit, of near 200 millions of miles diameter, is but as a point in compariſon of that diſtance. The ſame year he communicated Caſſini.

Caſſini. municated alſo his diſcoveries concerning the inclination of the orbits of the ſatellites in general, and eſpecially of thoſe of Saturn's ſatellites and ring. In 1725 he undertook to determine the cauſe of the moon's libration, by which ſhe ſhews ſometimes a little towards one ſide, and ſometimes a little on the other, of that half which is commonly behind or hid from our view.

In 1732 an important queſtion in aſtronomy exerciſed the ingenuity of our author. His father had determined, by his obſervations, that the planet Venus revolved about her axis in the ſpace of 23 hours; and M. Bianchini had publiſhed a work in 1729, in which he ſettled the period of the ſame revolution at 24 days 8 hours. From an examination of Bianchini's obſervations which were upon the ſpots in Venus, he diſcovered that he had intermitted his obſervations for the ſpace of three hours, from which cauſe he had probably miſtaken new ſpots for the old ones, and ſo had been led into the miſtake. The probability is, that both had fallen into ſome miſtake, or that they had proceeded on very different principles; for otherwiſe ſuch different reſults are wholly unaccountable. Dr Herſchel ſeems ſatisfied that the period of the revolution is leſs than Bianchini has made; but he does not ſay what it is, or that it is not much greater than it was ſuppoſed by Caſſini. Our author, after he had convicted Bianchini, as he thought, of error, determined the nature and quantity of the acceleration of the motion of Jupiter at half a ſecond per year, and of that of the retardation of Saturn at two minutes per year; that theſe quantities would go on increaſing for 2000 years, and then would decreaſe again. In 1740 he publiſhed his Aſtronomical Tables, and his Elements of Aſtronomy; very extenſive and accurate works.

Although aſtronomy was the principal object of our author's conſideration, he did not confine himſelf abſolutely to that branch, but made occaſional excurſions into other fields. We owe alſo to him, for example, Experiments on Electricity, or the Light produced by Bodies by Friction; Experiments on the Recoil of Firearms; Reſearches on the Riſe of the Mercury in the Barometer at different Heights above the Level of the Sea; Reflections on the perfecting of Burning-glaſſes; and other Memoirs.

The French Academy had properly judged, that one of its moſt important objects was the meaſurement of the earth. In 1669 Picard meaſured a little more than a degree of latitude to the north of Paris; but as that extent appeared too ſmall from which to conclude the whole circumference with ſufficient accuracy, it was reſolved to continue that meaſurement on the meridian of Paris to the north and the ſouth, through the whole extent of the country. Accordingly, in 1683, the late M. de la Hire continued that on the north ſide of Paris, and the older Caſſini that on the ſouth ſide. The latter was aſſiſted in 1700 in the continuation of this operation by his ſon our author. The ſame work was farther continued by the ſame academicians; and, finally, the part left unfiniſhed by De la Hire in the north was finiſhed in 1718 by our author, with the late Maraldi, and De la Hire the younger.

Theſe operations produced a conſiderable degree of preciſion. It appeared alſo, from this meaſured extent of ſix degrees, that the degrees were of different lengths in different parts of the meridian; and in ſuch ſort that our author concluded, in the volume publiſhed for 1718, that they decreaſed more and more towards the pole, and that therefore the figure of the earth was that of an oblong ſpheroid, or having its axis longer than the equatorial diameter. He alſo meaſured the perpendicular to the ſame meridian, and compared the meaſured diſtance with the differences of longitude as before determined by the eclipſes of Jupiter's ſatellites: whence he concluded that the length of the degrees of longitude was ſmaller than it would be on a ſphere, and that therefore again the figure of the earth was an oblong ſpheroid, contrary to the determination of Newton by the theory of gravity. Though Newton was of all men the moſt averſe from controverſy, the other mathematicians in Britain did not tamely ſubmit to concluſions in direct oppoſition to the fundamental doctrine of a philoſopher of whoſe talents the nation was juſtly proud. The conſequence was, that the French government ſent two different ſets of meaſurers, the one to meaſure a degree at the equator, the other at the polar circle; and the compariſon of the whole determined the figure to be an oblate ſpheroid, contrary to Caſſini's determination.

After a long and laborious life, James Caſſini died in April 1756, in conſequence of a fall, and was ſucceeded in the Academy and Obſervatory by the ſubject of the following article. He publiſhed, A Treatiſe on the Magnitude and Figure of the Earth; as alſo, The Elements or Theory of the Planets, with Tables; beſide an infinite number of papers in the Memoirs of the Academy, from the year 1699 to 1755.

Cassini de Thury (Ceſar François), a celebrated French aſtronomer, director of the obſervatory, penſioner aſtronomer, and member of moſt of the learned ſocieties of Europe, was born at Paris June 17. 1714, being the ſecond ſon of James Caſſini, the ſubject of the preceding memoir, whoſe occupations and talents he inherited and ſupported with great honour. He received his firſt leſſons in aſtronomy and mathematics from MM. Maraldi and Camus; and made ſuch a rapid progreſs, that when he was not more than ten years of age he calculated the phaſes of a total eclipſe of the ſun. At the age of eighteen he accompanied his father in his two journeys undertaken for drawing the perpendicular to the obſervatory meridian from Straſbourg to Breſt. From that time a general chart of France was deviſed; for which purpoſe it was neceſſary to traverſe the country by ſeveral lines parallel and perpendicular to the meridian of Paris, and our author was charged with the conduct of this buſineſs; in which he was ſo ſcrupulous as to meaſure again what had been meaſured by his father. This great work was publiſhed in 1740, with a chart ſhewing the new meridian of Paris, by two different ſeries of triangles, paſſing along the ſea coaſts to Bayonne, traverſing the frontiers of Spain to the Mediterranean and Antibes, and thence along the eaſtern limits of France to Dunkirk, with parallel and perpendicular lines deſcribed at the diſtance of 6000 toiſes from one another, from ſide to ſide of the country.

A tour which, in 1741, our author made in Flanders, in the train of the king, gave riſe, at his majeſty's inſtance, to the chart of France; relative to which Caſſini publiſhed different works, as well as a great number of the ſheets of the chart itſelf. In 1761 he undertook an expedition into Germany, for the purpoſe of continuing to Vienna the perpendicular of the Pa-

ris

Cassini || Catalogues of Books.

ris meridian; to unite the triangles of the chart of France with the points taken in Germany; to prepare the means of extending into that country the same plan as in France; and thus to establish successively for all Europe a most useful uniformity.—Our author was at Vienna the 6th of June 1761, the day of the transit of the planet Venus over the sun, of which he observed as much as the state of the weather would permit him to do, and published the account of it in his *Voyage en Allemagne*.

Finally, M. Cassini, always meditating the perfection of his grand design, profited of the peace of 1783 to propose the joining of certain points taken upon the English coast with those which had been determined on the coast of France, and thus to connect the general chart of the latter with that of the British isles, like as he had before united it with those of Flanders and Germany. The proposal was favourably received by the English government, and presently carried into effect under the direction of the Royal Society, the execution being committed to the late General Roy. See the life of that general in this *Supplement*.

Between the years 1735 and 1770, M. Cassini published, in the volumes of Memoirs of the French Academy, a prodigious number of pieces, consisting chiefly of astronomical observations and questions; among which are observable, researches concerning the parallax of the sun, the moon, Mars, and Venus; on astronomical refractions, and the effect caused in their quantity and laws by the weather; numerous observations on the obliquity of the ecliptic, and on the law of its variations. In short, he cultivated astronomy for fifty years, the most important for that science that ever elapsed for the magnitude and variety of objects, in which he commonly sustained a principal share.

M. Cassini was of a very strong and vigorous constitution, which carried him through the many laborious operations in geography and astronomy which he conducted. An habitual retention of urine, however, rendered the last twelve years of his life very painful and distressing, till it was at length terminated by the smallpox the 4th of September 1784, in the 71st year of his age. He was succeeded in the academy, and as director of the observatory, by his only son John-Dominic Cassini, the fourth in order of direct descent who has filled that honourable station.

CASTRAMETATION, the art or act of encamping an army.

CATACAUSTICS, or Catacaustic Curves, in the higher geometry, are the species of caustic curves formed by reflection.

CATACOUSTICS, or Cataphonics, is the science of reflected sounds; or that part of acoustics which treats of the properties of echoes.

CATALOGUES of Books, is a subject of which a very curious history has been given to the world by Professor Beckmann. In the Encyclopædia mention has been made of some of the most valuable catalogues, their defects pointed out, and rules given for making them more perfect; but nothing has there been said of their origin, or of the uses which might be made of the oldest catalogues.

Catalogues of Books.

According to the Professor, George Willer, whom some improperly call Viller, and others Walter, a bookseller at Augsburg, who kept a very large shop, and frequented the Franckfort fairs, first fell upon the plan of causing to be printed, before every fair, a catalogue of all the new books, in which the size and printers names were marked. Le Mire, better known under the name of Miræus, says that catalogues were first printed in the year 1554; but Labbe (A), Reimann (B), and Heumann (C), who took their information from Le Mire, make the year erroneously to be 1564. Willer's catalogues were printed till the year 1592 by Nicol. Bassæus, printer at Franckfort. Other booksellers, however, must have soon published catalogues of the like kind, though that of Willer continued a long time to be the principal.

In all these catalogues, which are in quarto and not paged, the following order is observed. The Latin books occupy the first place, beginning with the Protestant theological works, perhaps because Willer was a Lutheran; then come the Catholic; and after these, books of jurisprudence, medicine, philosophy, poetry, and music. The second place is assigned to German books, which are arranged in the same manner.

The booksellers of Leipsic soon perceived the advantage of catalogues, and began not only to reprint those of Franckfort, but also to enlarge them with many books which had not been brought to the fairs in that city. Our author had for some time in his custody, *Catalogus universalis pro nundinis Francofurtensibus vernalibus, de anno* 1600; or, A catalogue of all the books on sale in Book-street, Franckfort, and also of the books published at Leipsic, which have not been brought to Franckfort, with the permission of his highness the elector of Saxony, to those new works which have appeared at Leipsic. Printed at Leipsic by Abraham Lamberg, and to be had at his shop. On the September catalogue of the same year, it is said that it is printed from the Franckfort copy with additions. He found an Imperial privilege for the first time on the Franckfort September catalogue of 1616: *Cum gratia et privilegio speciali s. caes. maj. Prostat apud J. Krugerum Augustanum.*

Reimmann says, that after Willer's death the catalogue was published by the Leipsic bookseller Henning Grosse, and by his son and grandson. The council of Franckfort caused several regulations to be issued respecting catalogues; an account of which may be seen in D. Orth's *Treatise on the Imperial Fairs at Franckfort*. After the business of bookselling was drawn from Franckfort to Leipsic, occasioned principally by the restrictions to which it was subjected at the former by the censors, no more catalogues were printed there; and the shops in Book-street were gradually converted into taverns (D).

" In the 16th century there were few libraries; and these, which did not contain many books, were in monasteries,

(A) Labbe, Bibliotheca Bibliothecarum. Lipsiæ, 1682, 12mo, p. 112.
(B) Einleitung in die *Historiam Literariam*, i. p. 203.
(C) Conspectus Reip. Litter. c. vi. § 2. p. 316.
(D) Joh. Adolph. Stock, Frankfurter Chronik, p. 77.

naſteries, and conſiſted principally of theological, philoſophical, and hiſtorical works, with a few, however, on juriſprudence and medicine; while thoſe which treated of agriculture, manufactures, and trade, were thought unworthy of the notice of the learned, or of being preſerved in large collections. The number of theſe works was, nevertheleſs, far from being inconſiderable; and at any rate, many of them would have been of great uſe, as they would have ſerved to illuſtrate the inſtructive hiſtory of the arts. Catalogues which might have given occaſion to inquiries after books, that may be ſtill ſomewhere preſerved, have ſuffered the fate of tomb-ſtones, which, being waſted and crumbled to pieces by the deſtroying hand of time, become no longer legible. A complete ſeries of them perhaps is nowhere to be found, at leaſt I do not remember (ſays the Profeſſor) to have ever ſeen one in any library."

This loſs, however, he thinks, might be in ſome meaſure ſupplied by the catalogues of Cleſs and Draudius; who, by the deſire of ſome bookſellers, collected together all the catalogues which had been publiſhed at the different fairs in different years. The work of Cleſs has the following title: *Unius ſæculi ejuſque virorum litteratorum monumentis tum florentiſſimi, tum fertiliſſimi, ab anno* 1500 *ad* 1602 *nundinarum autumnalium incluſive, elenchus conſummatiſſimus—deſumtus partim ex ſingularum nundinarum catalogis, partim ex bibliothecis.* Auctore Joanne Cleſſio, Wineccenſi, Hannoio, philoſopho ac medico.—By the editor's preface, it appears that the firſt edition was publiſhed in 1592. The order is almoſt the ſame as that obſerved by Willer in his catalogues.

The work of Draudius, which was printed in ſeveral quarto volumes for the firſt time in 1611, and afterwards in 1625, is far larger, more complete, and more methodical. Our author, however, confeſſes, that he never ſaw a perfect copy of either edition. This catalogue conſiſts of three parts; of which the firſt has the title of *Bibliotheca claſſica, ſive Catalogus officinalis, in quo ſinguli ſingularum facultatum ac profeſſionum libri, qui in quavis fere lingua extant—recenſentur; uſque ad annum* 1624 *incluſive.* Auctore M. Georgio Draudio.—It contains Latin works on theology, juriſprudence, medicine, hiſtory, geography, and politics. The copy in the library of the univerſity of Gottingen ends at page 1304, which has, however, a catch-word, that ſeems to indicate a deficiency.—The ſecond part is intitled, *Bibliotheca claſſica ſive Catalogus officinalis, in quo philoſophici artiumque adeo humaniorum, poetici etiam et muſici libri uſque ad annum* 1624 *continentur.* This part, containing Latin books alſo, begins at page 1298, and ends with page 1654, which is followed by an index of all the authors mentioned.—A ſmaller volume, of 302 pages, without an index, has for title, *Bibliotheca exotica, ſive Catalogus officinalis librorum peregrinis linguis uſualibus ſcriptorum.* And a third part, forming 759 pages, beſides an index of the authors, is called, *Bibliotheca librorum Germanicorum claſſica;* that is, A catalogue of all the books printed in the German language till the year 1625.

We have reaſon to believe that there are other editions of this catalogue than thoſe mentioned by Profeſſor Beckmann; and it might become ſome prince or great man, for it is not a work for a bookſeller, to compare all the editions together, and publiſh a new one more correct than any that is at preſent extant. This indeed would be an expenſive and not an eaſy taſk; for our author obſerves, that all the oldeſt catalogues had the ſame faults as thoſe of later date, and that theſe faults have been copied by Draudius. Many books are mentioned which were never printed, and many titles, names, and dates, are given incorrectly; but Draudius nevertheleſs is well worth the attention of any one who may be inclined to employ his time and ingenuity on the hiſtory of literature; and his work certainly was of uſe to Haller when he compoſed his *Bibliotheca.*

Catalogues of the Stars, have uſually been diſpoſed, either as collected into certain figures called *conſtellations*, or according to their right aſcenſions, that is, the order of their paſſing over the meridian.

Of the principal catalogues, according to the firſt of theſe forms, an account has been given in the *Encyclopædia.* The firſt catalogue, we believe, that was printed in the new or ſecond form, according to the order of the right aſcenſions, is that of De la Caille, given in his Ephemerides for the ten years between 1755 and 1765, and printed in 1755. It contains the right aſcenſions and declinations of 307 ſtars, adapted to the beginning of the year 1750. In 1757 De la Caille publiſhed his *Aſtronomiæ Fundamenta*, containing a catalogue of the right aſcenſions and declinations of 398 ſtars, likewiſe adapted to the beginning of 1750. And in 1763, the year after his death, was publiſhed the *Cœlum Auſtrale Stelliferum* of the ſame author; containing a catalogue of the places of 1942 ſtars, all ſituated to the ſouthward of the tropic of Capricorn, and obſerved by him while he was at the Cape of Good Hope in 1751 and 1752; their places being alſo adapted to the beginning of 1750. In the ſame year was publiſhed his Ephemerides for the ten years between 1765 and 1775; in the introduction to which are given the places of 515 zodiacal ſtars, all deduced from the obſervations of the ſame author; the places adapted to the beginning of the year 1765.

In the Nautical Almanac for 1773, is given a catalogue of 387 ſtars, in right aſcenſion, declination, longitude, and latitude, derived from the obſervations of the late celebrated Dr Bradley, and adjuſted to the beginning of the year 1760. This ſmall catalogue, and the reſults of about 1200 obſervations of the moon, are all that the public have yet ſeen of the multiplied labours of this moſt accurate and indefatigable obſerver, although he has now (1798) been dead upwards of 38 years.

In 1775 was publiſhed a thin volume, intitled *Opera Inedita*, containing ſeveral papers of the late Tobias Mayer, and among them a catalogue of the right aſcenſions and declinations of 998 ſtars, which may be occulted by the moon and planets; the places being adapted to the beginning of the year 1756.

At the end of the firſt volume of "Aſtronomical Obſervations made at the Royal Obſervatory at Greenwich," publiſhed in 1776, Dr Maſkelyne, the preſent aſtronomer royal, has given a catalogue of the places of 34 principal ſtars, in right aſcenſion and north polar diſtance, adapted to the beginning of the year 1770.

Theſe being the reſult of ſeveral years repeated obſervations, made with the utmoſt care and the beſt inſtruments, it may be preſumed are exceedingly accurate.

In 1782, M. Bode of Berlin publiſhed a very extenſive catalogue of 5058 of the fixed ſtars, collected from

Catalogues of the Stars.

from the obſervations of Flamſteed, Bradley, Hevelius, Mayer, De la Caille, Meſſier, Monnier, D'Arquier, and other aſtronomers; all adapted to the beginning of the year 1780; and accompanied with a celeſtial atlas or ſet of maps of the conſtellations, engraved in a moſt delicate and beautiful manner.

To theſe may be added Dr Herſchel's catalogue of double ſtars, printed in the Phil. Tranſ. for 1782 and 1783; Meſſier's nebulæ and cluſters of ſtars, publiſhed in the *Connoiſſance des Temps* for 1784; and Herſchel's catalogue of the ſame kind, given in the Phil. Tranſ. for 1786.

In 1789 Mr Francis Wollaſton publiſhed "A Specimen of a General Aſtronomical Catalogue, in Zones of North-polar Diſtance, and adapted to January 1. 1790." Theſe ſtars are collected from all the catalogues before-mentioned, from that of Hevelius downwards. This work contains five diſtinct catalogues; viz. Dr Maſkelyne's new catalogue of 36 principal ſtars; a general catalogue of all the ſtars, in zones of north-polar diſtance; an index to the general catalogue; a catalogue of all the ſtars, in the order in which they paſs the meridian; and a catalogue of zodiacal ſtars, in longitude and latitude.

Finally, in 1792, Dr Zach publiſhed at Gotha, *Tabulæ Motuum Solis*; to which is annexed a new catalogue of the principal fixed ſtars, from his own obſervations made in the years 1787, 1788, 1789, 1790. This catalogue contains the right aſcenſions and declinations of 381 principal ſtars, adapted to the beginning of the year 1800.—*Hutton's Mathematical Dictionary.*

Beſides theſe two methods of forming *catalogues* of the ſtars, Dr Herſchel has conceived a new one, in which the comparative brightneſs of the ſtars is accurately expreſſed. It is long ſince aſtronomers were firſt led to arrange the ſtars in claſſes of different magnitudes by their various degrees of brilliancy or luſtre. Brightneſs and ſize have at all times been conſidered as ſynonymous terms; ſo that the brighteſt ſtars have been referred to the claſs comprehending thoſe of the firſt magnitude; and as the ſubſequent orders of ſtars have been ſuppoſed to decreaſe in luſtre, their magnitude has been determined in the ſame decreaſing progreſſion: but the want of ſome fixed and ſatisfactory ſtandard of luſtre has been the ſource of conſiderable confuſion and uncertainty in ſettling the relative magnitudes of the ſtars. A ſtar marked 1. 2m. is ſuppoſed to be between the firſt and ſecond magnitude; but 2. 1m. intimates that the ſtar is nearly of the ſecond magnitude, and that it partakes ſomewhat of the luſtre of a ſtar of the firſt order. Such ſubdiviſions may be of ſome uſe in aſcertaining ſtars of the firſt, ſecond, and third claſſes; but the expreſſions 5m, 5.6m, 6.5m, 6m, muſt be very vague and indefinite. Dr Herſchel obſerves that he has found them ſo in fact; and he therefore conſiders this method of pointing out the different luſtre of ſtars as a reference to an imaginary ſtandard. If any dependence could be placed on this method of magnitudes, "it would follow, that no leſs than eleven ſtars in the conſtellation of the Lion, namely, β σ π ξ A *b* *c* *d* 54, 48, 72, had all undergone a change in their luſtre ſince Flamſteed's time: For if the idea of magnitudes had been a clear one, our author, who marked β 1.2m. and γ 2m. ought to be underſtood to mean that β is larger than γ; but we now find that actually γ is larger than β. Every one of the eleven ſtars (ſays Dr Herſchel) which I have pointed out may be reduced to the ſame contradiction."

The author has pointed out the inſtances of the inſufficiency of this method, and of the uncertain concluſions that are deduced from it, in determining the comparative brightneſs of ſtars found not only in Mr Flamſteed's catalogue, but alſo in the catalogues of other aſtronomers. It is ſufficiently apparent that the preſent method of expreſſing the brightneſs of the ſtars is very defective. Dr Herſchel therefore propoſes a different mode, that is more preciſe and ſatisfactory.

"I place each ſtar (he ſays), inſtead of giving its magnitude, into a ſhort ſeries, conſtructed upon the order of brightneſs of the neareſt proper ſtars. For inſtance, to expreſs the luſtre of D, I ſay CDE. By this ſhort notation, inſtead of referring the ſtar D to an imaginary uncertain ſtandard, I refer it to a preciſe and determined exiſting one. C is a ſtar that has a greater luſtre than D, and E is another of leſs brightneſs than D. Both C and E are neighbouring ſtars, choſen in ſuch a manner that I may ſee them at the ſame time with D, and therefore may be able to compare them properly. The luſtre of C is in the ſame manner aſcertained by BCD; that of B by ABC; and alſo the brightneſs of E by DEF; and that of F by EFG.

"That this is the moſt natural, as well as the moſt effectual way to expreſs the brightneſs of a ſtar, and by that means to detect any change that may happen in its luſtre, will appear, when we conſider what is requiſite to aſcertain ſuch a change. We can certainly not wiſh for a more deciſive evidence, than to be aſſured, by actual inſpection, that a certain ſtar is now no longer more or leſs bright than ſuch other ſtars to which it has been formerly compared; provided we are at the ſame time aſſured that thoſe other ſtars remain ſtill in their former unaltered luſtre. But if the ſtar D will no longer ſtand in its former order CDE, it muſt have undergone a change; and if that order is now to be expreſſed by CED, the ſtar has loſt ſome part of its luſtre; if, on the contrary, it ought now to be denoted by DCE, its brightneſs muſt have had ſome addition. Then, if we ſhould doubt the ſtability of C and E, we have recourſe to the orders BCD and DEF, which expreſs their luſtre; or even to ABC and EFG, which continue the ſeries both ways. Now having before us the ſeries BCDEF, or if neceſſary even the more extended one ABCDEFG, it will be impoſſible to miſtake a change of brightneſs in D, when every member of the ſeries is found in its proper order except D."

In the author's journal or catalogue, in which the order of the luſtre of the ſtars is fixed, each ſtar bears its own proper name or number, *e. g.* "the brightneſs of the ſtar δ Leonis may be expreſſed by β δ ϵ Leonis, or better by 94—68—17 Leonis; theſe being the numbers which the three above ſtars bear in the Britiſh catalogue of fixed ſtars."

This method of arrangement occurred to Dr Herſchel ſo early as the year 1782; but he was diverted from the regular purſuit of it by a variety of other aſtronomical engagements. After many trials, he propoſed, in the Tranſactions of the Royal Society of London for 1796, the plan which appeared to him the moſt eligible. It is as follows:—Inſtead of denoting particular ſtars by letters, he makes uſe of numbers; and in his choice of the ſtars which are to expreſs the luſtre

of

Catalogues of the Stars.

of any particular one, he directs his firſt view to perfect equality.* When two ſtars ſeem to be ſimilar both in brightneſs and magnitude, he puts down their numbers together, ſeparated merely by a point, as 30.24 Leonis; but if two ſtars, which at firſt ſeemed alike in their luſtre, appeared on a longer inſpection to be different, and the preference ſhould be always decidedly in favour of the ſame ſtar, he ſeparates theſe ſtars by a comma, thus, 41,94 Leonis. This order muſt not be varied; nor can three ſuch ſtars, as 20, 40, 39, Libræ, admit of a different arrangement. If the ſtate of the heavens ſhould be ſuch as to require a different order in theſe numbers, we may certainly infer that a change has taken place in the luſtre of one or more of them. When two ſtars differ very little in brightneſs, but ſo that the preference of the one to the other is indiſputable, the numbers that expreſs them are ſeparated by a ſhort line, as 17—70 Leonis, or 68—17—70 Leonis. When two ſtars differ ſo much in brightneſs, that one or two other ſtars might be interpoſed between them, and ſtill leave ſufficient room for diſtinction, they are diſtinguiſhed by a line and comma, thus, —, or by two lines, as 32— —41 Leonis. A greater difference than this is denoted by a broken line, thus — — —29 Bootis. On the whole, the author obſerves, the marks and diſtinctions which he has adopted cannot poſſibly be miſtaken; "a point denoting equality of luſtre; a comma indicating the leaſt perceptible difference; a ſhort line to mark a decided but ſmall ſuperiority; a line and comma, or double line, to expreſs a conſiderable and ſtriking exceſs of brightneſs; and a broken line to mark any other ſuperiority which is to be looked upon as of no uſe in eſtimations that are intended for the purpoſe of directing changes."

The difficulties that attend this arrangement are not diſguiſed; but the importance and utility of it more than compenſate for the labour which it muſt neceſſarily require. By a method of this kind, many diſcoveries of changeable and periodical ſtars might probably have been made, which have eſcaped the moſt diligent and accurate obſervers. We might then, as the author ſuggeſts, be enabled to reſolve a problem in which we are all immediately concerned.

"Who, for inſtance, would not wiſh to know what degree of permanency we ought to aſcribe to the luſtre of our ſun? Not only the ſtability of our climates, but the very exiſtence of the whole animal and vegetable creation itſelf, is involved in the queſtion. Where can we hope to receive information upon this ſubject but from aſtronomical obſervations? If it be allowed to admit the ſimilarity of ſtars with our ſun as a point eſtabliſhed, how neceſſary will it be to take notice of the fate of our neighbouring *ſuns*, in order to gueſs at that of our own? That *ſtar*, which among the multitude we have dignified by the name of *ſun*, to-morrow may ſlowly begin to undergo a gradual decay of brightneſs, like β Leonis, α Ceti, α Draconis, δ Urſæ majoris, and many other diminiſhing ſtars that will be mentioned in my catalogues. It may ſuddenly increaſe, like the wonderful ſtar in the back of Caſſiopea's chair, and the no leſs remarkable one in the foot of Serpentarius; or gradually come on like β Geminorum, β Ceti, ζ Sagittarii, and many other increaſing ſtars, for which I alſo refer to my catalogues; and, laſtly, it may turn into a periodical one of 25 days duration, as Algol is one of three days, δ Cephei of five, β Lyræ of ſix, η Antinoi of ſeven days, and as many others as are of various periods."

Having thus explained the general principle on which this catalogue is formed, as we find it in the author's firſt memoir on the ſubject, we muſt refer the reader to the Doctor's own account for its particular arrangement; obſerving only that the catalogue ſubjoined comprehends nine conſtellations, which are arranged in alphabetical order, with the comparative brightneſs of the ſtars accurately ſtated. In a ſubſequent paper, publiſhed in the ſame volume, he has completely verified the utility of his method by experience, and ſhewn that there is no permanent change of luſtre in the ſtars. In the notes to his firſt catalogue he mentioned α Herculis as a periodical ſtar. By a ſeries of obſervations on this ſtar, compared with κ Ophiuchi, which was moſt conveniently ſituated for his purpoſe, he has been able not only to confirm this opinion, but to aſcertain its period. His obſervations are arranged in a table, by means of which he determines that this ſtar had gone through four ſucceſſive changes in an interval of 241 days; and therefore the duration of its period muſt be about 60 days and a quarter. This fact concurs with other circumſtances in evincing the rotatory motion of the ſtars on their axes. "Dark ſpots, or large portions of the ſurface, leſs luminous than the reſt, turned alternately in certain directions, either towards or from us, will account for all the phenomena of periodical changes in the luſtre of the ſtars, ſo ſatisfactorily, that we certainly need not look out for any other cauſe." If it be alledged that the periods in the change of luſtre of ſome ſtars, ſuch as Algol, β Lyræ, δ Cephei, and η Antinoi, are ſhort, being only 3, 5, 6, and 7 days reſpectively; while thoſe of *o* Ceti, and of the changeable ſtar in Hydra, and that in the neck of the Swan, are long, amounting to 331, 394, and 497 days; and that we cannot aſcribe phenomena ſo different in their duration to the ſame cauſe—it may be anſwered to this objection, that the force of it is founded on our limited acquaintance with the ſtate of the heavens. To the 7 ſtars, the periodical changes of which were before known, we may now add α Herculis, which performs a revolution of its changes in 60 days.

"The ſtep from the rotation of α Herculis to that of *o* Ceti is far leſs conſiderable than that from the period of Algol to the rotation of α Herculis; and thus a link in the chain is now ſupplied, which removes the objection that aroſe from the vacancy." The rotation of the fifth ſatellite of Saturn is proved by the change obſervable in its light; and "this variation of light, owing to the alternate expoſition of a more or leſs bright hemiſphere of this periodical ſatellite, plainly indicates that the ſimilar phenomenon of a changeable ſtar ariſes from the various luſtre of the different parts of its ſurface, ſucceſſively turned to us by its rotatory motion."

Beſides, we perceive a greater ſimilarity between the ſun and the ſtars, by means of the ſpots that muſt be admitted to exiſt on their ſurfaces, as well as on that of the ſun.

Dr Herſchel farther obſerves, that the ſtars, beſides a rotatory motion on their axes, may have other movements; "ſuch as nutations or changes in the inclination of their axes; which, added to bodies much flattened by quick rotatory motions, or ſurrounded by rings like Saturn, will eaſily account for many new phenomena

Catenaria, Catharine.

na that may then offer themſelves to our extended views." To this paper is likewiſe ſubjoined a catalogue of nine conſtellations; and the author promiſes to give the whole of them in ſucceſſive ſhort catalogues on the ſame plan.

CATENARIA, or CATENARY CURVE. See *Encycl.* and ARCH in this *Supplement*.

CATHARINE II. Empreſs of all the Ruſſias, acted ſo conſpicuous a part on the theatre of the world; poſſeſſed ſuch uncommon powers of mind, highly cultivated by ſcience and literature; and was ſuch a patroneſs of ſcience and literature in others—that it cannot be deemed foreign from a work of this nature to give ſome account of the principal events of her more private life.

SOPHIA AUGUSTA FREDERICA, who, upon her marriage to the grandſon of Peter the great, aſſumed the name CATHARINA ALEXIEVNA, was born at *Stettin* on the 2d of May 1729. Her father was Chriſtian Auguſtus, prince of Anhalt Zerbſt Dornburg, at that time major-general in the Pruſſian ſervice, commander in chief of the regiments of infantry, and governor of the town and fortreſs of Stettin. Her mother, who was born princeſs of Holſtein Eutin, was a woman of great parts and beauty, of nearly the ſame age with the prince-royal of Pruſſia, afterwards Frederic the Great, with whom ſhe kept up a regular correſpondence, and who afterwards contributed to the aggrandiſement of her daughter. This accompliſhed princeſs took upon herſelf the care of educating the young Sophia, whom ſhe brought up in the ſimpleſt manner, and would not ſuffer to exhibit the leaſt ſymptoms of that pride to which ſhe had ſome propenſity from her earlieſt childhood. The conſequence of this ſalutary reſtraint was, that good humour, intelligence, and ſpirit, were even then the ſtriking features of her youthful character. Being naturally addicted to reading, to reflection, to learning, and to employment, ſhe was taught the French and other faſhionable languages; and was inſtructed to read ſuch books chiefly as might make her acquainted with hiſtory and with the principles of ſcience; whilſt the doctrines of the Lutheran religion were carefully explained to her by a divine, who little thought how ſoon his illuſtrious pupil would embrace another faith.

The Empreſs Elizabeth, who then ſwayed the ſceptre of Ruſſia, had in early life been promiſed in marriage to the young prince of Holſtein Eutin, brother to the princeſs of Anhalt Zerbſt; but at the inſtant when the marriage was about to be celebrated, the prince fell ſick and died. Elizabeth, who loved him to exceſs, became inconſolable, and in the bitterneſs of her grief made a vow of celibacy. This vow, though ſenſual, and even laſcivious, ſhe kept ſo far as never publicly to acknowledge any man as a huſband; and upon her aſcending the throne of her anceſtors, ſhe called her nephew the Duke of Holſtein Gottorp to her court, where he was ſolemnly proclaimed, when fourteen years of age, Grand Duke, with the title of Imperial Highneſs, and declared ſucceſſor to the Empreſs Elizabeth. To ſecure the ſucceſſion in the family of Peter the Great, the Empreſs was very deſirous to have her nephew married; and the princeſs of Anhalt Zerbſt, not ignorant of the tender remembrance which ſhe ſtill preſerved for her brother, conceived the idea of placing, by means of it, her daughter on the throne of Ruſſia. She communicated her plan to the king of Pruſſia, who not only applauded it, but lent her his aſſiſtance to carry it into execution.

Full of ambitious hopes, therefore, the princeſs repaired with her daughter to St Peterſburg, where ſhe was received with friendſhip by Elizabeth, and where the young Sophia ſoon made a conſiderable impreſſion on the mind of the Grand Duke. As Peter was well made, of a good figure, and, though uneducated, not deſtitute of natural talents, the attachment became reciprocal; and the princeſs of Zerbſt, throwing herſelf at the feet of the empreſs, aſſured her, that the two lovers were attached to each other by a paſſion unconquerable; and, calling to her mind the love which ſhe had herſelf borne to the prince of Holſtein, conjured her to promote the happineſs of that prince's niece. The ſtratagem ſucceeded. The choice of Elizabeth was next day announced to the council and to the foreign miniſters; and preparations were made for celebrating the marriage with a magnificence worthy of the heir of the throne of the Ruſſias. In the mean time the Grand Duke was ſeized with the ſmall-pox, from which, tho' he recovered, it was with ſuch a change of features, as rendered him, from being comely, almoſt hideous, and converted the love of the young princeſs of Anhalt, if indeed ſhe ever felt for him that paſſion, into horror and diſguſt. She was not, however, of a diſpoſition to let a disfigured countenance frighten her from a throne. She embraced the Greek religion, changed her name from Sophia Auguſta Frederica to CATHARINA ALEXIEVNA, and with the entire approbation of Elizabeth was married to her nephew the Grand Duke.

For ſome time this ill-matched pair lived together, though without love, yet on terms apparently decent; but a mutual diſlike gradually took place between them, which the courtiers quickly diſcovered, and were at pains to foment into hatred. Peter was now ugly, and his mind was uninformed. Catharine, if not a beauty, was at leaſt a lovely woman, and highly accompliſhed. She could find no entertainment in his converſation, and he felt himſelf degraded by her ſuperiority. A faction was formed at court, headed by the great chancellor Beſtucheff, to exclude the Grand Duke from the throne, and to place Catharine at the head of affairs; and to accompliſh this end, every art was employed to fill the feeble mind of the empreſs with jealouſies of her nephew, and with a contempt of his character. He was repreſented at one time as extremely ambitious, and capable of the moſt daring enterpriſes, to get immediate poſſeſſion of the throne; and at another, as a wretch given up to drunkenneſs and to every unprincely vice.

The conſequence of the firſt of theſe accuſations was, that he was kept at a diſtance from his aunt, and a ſtranger to public affairs; and being wholly unemployed, that time which his education had not fitted him to fill up with reading, reflection, and rational converſation, hung ſo heavy on his mind, that it was no difficult matter for thoſe diſſipated young men, who were placed about him for that very purpoſe, to initiate him in the habits of drunkenneſs, and the other mean practices to which it was pretended he had long been devoted. In ſuch a ſchool, it was no wonder that he became a proficient in grovelling diſſipation; or that, being unpoliſhed, and even of rude manners, he choſe for his companions ſome of the loweſt of the people.

Catharine, in the mean time, languiſhed for that happineſs

Catharine. pinefs which fhe could not find in the fociety of her hufband. She was fond of pleafure; but it was that comparatively refined pleafure which fhe had enjoyed at the court of Berlin. She loved balls, mufic, and elegant converfation, and could take no fhare in the drunken revels of Peter. Among the young men with whom he was furrounded, his chamberlain Soltikoff was particularly remarked for the elegance of his tafte and the graces of his perfon; and though yet fcarcely more than a boy in years, he was faid to have obtained the favours of feveral ladies of the court. Succefs had made him confident and ambitious; and his ambition prompted him to afpire at making a conqueft even of the Grand Duchefs. By ftudying her tafte, and contriving to amufe her, he was at laft fuccefsful; and obtained from her Imperial Highnefs every favour which he could wifh: but he enjoyed not his fortune with moderation, and his enemies contrived to get him placed in an honourable office at a diftance from the court. He was commiffioned to repair to Stockholm, with the title of Envoy Extraordinary, to notify to the king of Sweden the birth of Paul Petrovitch, of whom the Grand Duchefs had juft been delivered *. The prefumptuous Soltikoff, proud of the employment, fet off with hafte to Sweden, and left it with equal fpeed. But fcarcely had he quitted Stockholm, on the wings of love and ambition, when he was ftopped on the road by a courier, who put into his hands an order for him to go immediately to Hamburg, and there to refide in the quality of minifter plenipotentiary from the court of Ruffia.

* Oct. 1. 1754.

Catharine for fome time preferved her attachment to the exiled chamberlain; but all at once the prefence of a ftranger, whom fortune had brought to the court of Ruffia, made her forget the lover whom fhe no longer faw. This perfon was Staniflaus Poniatowfky, the late king of Poland, who firft made his appearance at St Peterfburg in the train of the Britifh ambaffador, and very quickly gained the affections of the Grand Duchefs. In carrying on this intrigue, the lovers were not fo cautious as to deceive the eyes of the envious courtiers, who reported to the emprefs not only all that they faw, but whatever they fufpected. Elizabeth was incenfed, and commanded Poniatowfky to quit without delay the dominions of Ruffia. The accomplifhed Pole obeyed; but foon returned clothed with a character which made him in fome degree independent of the emprefs.

The Count de Bruhl, then prime minifter to the king of Poland, faw of what importance it was to his mafter to have a powerful intereft at the court of Ruffia. He was likewife no ftranger to the paffion which the Grand Duchefs entertained for Poniatowfky; and having got that nobleman decorated with the order of the White Eagle, he fent him back to St Peterfburgh in the quality of minifter plenipotentiary from the republic and king of Poland. Nor was this all that Bruhl did for the two lovers. Being informed by the chancellor Beftucheff, that the Grand Duke and Grand Duchefs were languifhing in a penury unworthy of their rank, he remitted to Poniatowfky 6000 ducats, to be employed, in fuch a manner as he might judge beft, for fecuring the favour of the prince and his confort. The ambaffador profited by thefe counfels and benefactions. He was already fure of the Grand Duchefs's heart, and he very quickly gained the favour of her hufband. He talked Englifh and German with him; drank, fmoked, abufed the French, and extolled the king of Pruffia with unlimited praife.

The Grand Duchefs was fo blinded by her paffion, that fhe was never without Poniatowfky in her company. She devoted to him the whole of her time; and fhe made this intimacy fo little a fecret, that public report was loud to her prejudice. In the mean time fhe was delivered of the Princefs Anne†, who lived only fifteen months. The Grand Duke was the only perfon about court who feemed to know nothing of what was paffing. His whole time was occupied in copying, with fervile affectation, the air, the manners, the tone of the king of Pruffia; and in dreffing a little army at Oranianbaum in the Pruffian uniform. His eyes, however, were at laft opened. Some of the courtiers, from hatred to the chancellor, who countenanced the intrigue between the Grand Duchefs and the Polifh ambaffador, roufed his jealoufy in order to deftroy their enemy. They fucceeded. He forbade his wife to be feen with Poniatowfky, and prevailed with the emprefs to deprive the chancellor of his office, and to banifh him to an eftate which he had 120 verfts beyond Mofcow.

† February 1758.

Catharine had now to fupport at once the averfion of her hufband, the indignation of the emprefs, the infulting difdain of a court, which a few days before was lavifh of its affiduities and fmiles; and what afflicted her moft of all, the dread of lofing for ever her favourite Poniatowfky. Her courage, however, did not forfake her. Poniatowfky was indeed recalled, and left Ruffia, after fuffering fome deferved indignities from the Grand Duke, who about this time formed a connection with one of the daughters of the Senator Vorontzoff, brother to the new chancellor. This lady, Elizabeth Romanovna Vorontzoff, was elder fifter to the Princefs Dafhkoff, who acted fo confpicuous a part in the revolution which fet the crown on the head of Catharine. She was beautiful, but vain; and poffeffed not either the wit or the underftanding of her fifter.

In the mean time the health of the emprefs vifibly declining, Catharine was very defirous of being reconciled to her: but the irritated fovereign would liften to no accommodation, except on terms too humiliating for the haughty fpirit of the Grand Duchefs. Catharine, therefore, abfented herfelf from court, and afked permiffion to retire into Germany. This, as fhe had forefeen, was refufed. Elizabeth was too fond of the young Paul Petrovitch to permit the departure of his mother, and thereby expofe him to the danger of being at fome future period declared illegitimate. She took the Grand Duchefs again into favour; and it is thought, that had fhe lived a little longer than fhe did, fhe would have excluded Peter from the throne, and declared Paul her immediate fucceffor.

Whilft the emprefs was meditating the aggrandifement of the young prince and his mother, the Grand Duke had conceived a plan for degrading them both. He had refolved, at the moment his aunt fhould clofe her eyes, to affemble his troops, to get himfelf proclaimed emperor, to repudiate the Grand Duchefs, to declare the young Paul Petrovitch illegitimate, and publicly to marry his miftrefs Elizabeth Romanovna Vorontzoff. We have fhewn elfewhere (fee Russia, n° 72. *Encycl.*) how this plan, when almoft ready to be carried into execution, was betrayed to Catharine, who, ever fince her caballing with the Chancellor Beftucheff, had refolved, Catharine. resolved, by some means or other, to snatch the sceptre from the feeble hand of her husband. At present, we believe she was not acquainted with it; and though she had, she could not now have turned it to her advantage, as her party, ever since the disgrace of Bestucheff, was without a leader of any abilities.

Amid these distractions, caused by the prospect of the death of the empress, and the known hatred of the Grand Duke and Duchess to each other, Count Panin, preceptor to the young prince, devoted himself entirely to Catharine. He wished to see her possessed of all the power of the empire; but he was afraid to proceed to the extremity to which she proposed to go, and to deprive Peter of the name of Emperor. He contrived therefore to procure an apparent reconciliation between the Grand Duke and his consort, as well as between him and his aunt Elizabeth; and he had almost persuaded the silly prince not to assume the sovereign power on the death of the empress, till he should be solemnly invested with it by a decree of the senate. Could he obtain this point, he knew that the power of Peter would be limited, and the authority secured to his wife and his son. He was, however, disappointed. Catharine herself disapproved of this plan, and concurred with the real friends of her husband in advising him "to conform to established custom in assuming the reins of empire."

He had hardly received this advice when word was brought him that the Empress Elizabeth was dead (A); and the courtiers pressed in crowds about him. He accosted them with dignity, received the oaths of the officers of his guard, and seemed at once to have laid aside his weakness. In an hour he got on horseback, traversed the streets of St Petersburgh, and distributed money among the multitude and the soldiers. He had been so treated by his aunt, that he could not possibly be grieved at her death; but in paying the last duties to her remains, he betrayed no indecent elation. The first actions of his reign were prudent and patriotic, and such as would have done honour to a greater prince. He appeared to be reconciled to his wife, in whose company he spent much of his time; he recalled from prison and banishment 17,000 persons, some of them of rank and of great talents, who had been the victims of Elizabeth's jealous timidity; he permitted the nobility to bear arms or not at their own discretion, freeing them at the same time from the extreme servitude under which they had been held by his immediate predecessors; and he abolished *the secret committee*, an infamous inquisitorial tribunal, which ever since the reign of the father of Peter the Great had been the chief engine of Russian despotism.

He neglected, however, one thing; which, among the people over whom he was appointed to reign, would have contributed more to the security of his throne than all the wise and beneficent edicts which he had published. He made no preparations to be crowned at Moscow. Instead of complying with this ancient ceremony, and humouring the prejudices of his superstitious subjects, he thought of nothing but of war with Denmark, and of a personal interview with the king of Prussia in Germany. His admiration of that great monarch hurried him indeed into the most extravagant follies. Not contented with giving him peace, and entering into an offensive and defensive alliance with him, he had the meanness to solicit a commission in his army, and to accept of the rank of major-general. Of this title he seemed more vain than of that of Emperor of all the Russias. He constantly wore the Prussian uniform; introduced among his troops the Prussian discipline, which, though better than their own, was disagreeable, because it was new, and much more because it was German; and he raised his uncle, a man of no military talents, and a foreigner, to the dignity of generalissimo of the Russian armies; giving him at the same time the particular command of the horse-guards, a body of men which had never before been under any command but that of the supreme head of the empire. Nor did his infatuated predilection for Germany, a country abhorred by the Russians, stop even here: He disbanded the noble guards which had placed Elizabeth on the throne, dismissed the horse-guards from the service which they performed at court, and substituted his Holstein guards in their place.

Whilst he was thus alienating from himself the affections of the army, he contrived to disgust another order of men, whose attachment he should have laboured above all things to retain. He was at pains to shew his preference of the Lutheran faith and worship to the doctrines and ceremonies of the Greek church; he attempted to make some alterations in the dress of the monks; he annexed great part of the possessions of the church to the domains of the crown; and he banished the archbishop of Novogorod, who opposed these innovations; and found himself obliged suddenly to recal him.

He had now returned to his former courses. He shut himself up for whole days with his mistress and drunken companions; he compelled the nobility and ladies of the court to sit in company with buffoons and comedians; he insulted every foreign minister but the ministers of Great Britain and Prussia; and he made no secret of his intention to repudiate the empress, declare Paul Petrovitch illegitimate, and marry the Countess Vorontzoff. Convinced, however, as it would seem, that he could not be a father, he resolved to adopt Prince Ivan, the descendant of the elder brother of Peter the Great, whom Elizabeth had dethroned and confined in prison; to declare him his successor; and to unite him in marriage with the young princess of Holstein Beck, who was then at St Petersburgh, and whom he cherished as his daughter.

This inconsistent and weak conduct of the emperor turned the attention of all orders of men to the empress, who made it her sole employment to gain those hearts which he was losing. Instructed from her infancy in the arts of dissimulation, it was not difficult for her to affect, in the sight of the multitude, sentiments the most foreign to her mind. The pupil of the French philosophers put on the air of a bigot to the most superstitious ceremonies of the Greek religion, and treated the ministers of that religion with the profoundest reverence. And whilst her husband was getting drunk

(A) Christmas-day 1761 according to the Russian calendar, or the 5th of January 1762 according to ours.

Catharine. amidst a rabble of buffoons, and disgusting every person of decency who approached him, she kept her court with a mixture of dignity and affability, which attracted to her all who, by capacity, courage, or reputation, were capable of serving her.

Correct, however, as her public conduct appeared, her private life was not less licentious than formerly. While yet Grand Duchess, she had formed a very tender connection with Gregory Orloff, a man of mean birth, and of no education, but possessed at once of personal beauty and the most daring courage. He had an inferior commission in the artillery, while his two brothers were common soldiers in the regiments of guards. The intrigue which she carried on with him was known only to one of her women named Catharine Ivanovna; nor did Orloff himself for some time suspect the rank of the lady who so lavishly conferred upon him her favours in secret. At last, finding him intrepid and discreet, she discovered herself, unveiled to him all her ambitious designs, and easily prevailed with him and his brothers to enter with zeal into her conspiracy against the emperor. Orloff likewise gained over Bibikoff his friend, a Lieutenant Passick, with other officers; and by their means easily seduced some regiments of the guards. The Princess Dashkoff was strongly attached to Catharine, we believe, from worthy motives, and had frequent meetings with Orloff on the business of the conspiracy, without suspecting that he was so much as known to the empress. Count Panin, too, and the Hetman of the Kosacks, were determined to tumble Peter from the throne; but they were not inclined to go all the lengths proposed by Catharine and her two favourites. Hoping to enjoy the actual power of the empire themselves, they were for declaring Paul Petrovitch emperor in the room of his father, and conferring upon his mother the name and authority only of regent; while the princess and Orloff, knowing the sentiments and wishes of the empress, were resolved to vest her with sovereign power, or to perish themselves in the hazardous attempt.

In the mean time the anniversary of the patron saints of Russia was at hand, when Peter had determined, at the conclusion of the festival, to divorce the empress, shut her up in prison, declare her son illegitimate, and publicly marry his mistress. As they who plan a conspiracy are always more vigilant than those against whom it is directed, the friends of Catharine were carefully informed of all that passed about the emperor, whilst he was kept in total ignorance of their proceedings. It was therefore necessary for them to unite in the same plan, and to carry it quickly into execution; for delay or divisions would involve them all in one common ruin. The empress contrived to bring over the Hetman entirely to her views; and the Princess Dashkoff, by the sacrifice, it has been said, of her charms, found little difficulty in reconciling Count Panin to the same measures. They now agreed to seize the Tzar on his arrival at Peterhoff, an Imperial palace on the shore of the Gulf of Cronstedt, where he proposed to celebrate the approaching festival; and they were waiting impatiently for the moment of action, when all at once their plot was discovered.

Passick, who has been mentioned among the conspirators, had gained the soldiers of the company of guards in which he was a lieutenant; but one of them, who thought that his captain was in the secret, asked that officer one evening, When they were to take up arms against the emperor? The captain, surprised, had recourse to dissimulation, and easily drew from the soldier all that he knew of the conspiracy. It was nine o'clock at night. Passick was put under arrest; but found means to slip into the hands of a man who had been placed as a spy over him by the Princess Dashkoff, a scrap of paper containing these words, "Proceed to execution this instant, or we are undone." The man was desired to carry it to the Hetman, by whom he would be handsomely rewarded; but he hurried with it to the princess, who instantly communicated the intelligence to the other conspirators. She herself put on man's apparel, and hastened to the place where she was accustomed to meet Orloff and his friends; where she found them, as impatient as herself to carry their plot into immediate execution.

During this awful crisis the empress was at Peterhoff, at the distance of 25 versts from St Petersburgh; and one of the brothers of Gregory Orloff, named Alexius, undertook to find her out, whilst he himself, with his other brother and Bibikoff his friend, repaired to the barracks for the purpose of instructing the soldiers of their party how to act on the first signal. Alexius Orloff carried with him a short note from the Princess Dashkoff, but neglected to deliver it; and the empress, being suddenly roused from a sound sleep, was much alarmed, when she saw at the side of her bed a soldier of whom she knew nothing. Her alarm was increased when the stranger said, "Your majesty has not a moment to lose; get ready to follow me;" and instantly disappeared. She rose, however, and calling her woman Ivanovna, they disguised themselves in such a manner that they could not be known by the sentinels about the palace; and the soldier returning, they hurried with him to a coach which was waiting at the garden gate. Orloff took the reins, but drove with such fury that the horses soon fell down; and they were obliged to travel part of the way on foot. They had not, however, gone far, when they met a light country cart; and she who was aspiring to the throne of the greatest empire in the world, was glad to enter the capital of that empire in this humble vehicle.

It was seven in the morning when she arrived in St Petersburgh: and to the soldiers, who gathered about her in great numbers, she said, that "her danger had driven her to the necessity of coming to ask their assistance; that the Tzar had intended, that very night, to put her and her son to death; and that she had so great confidence in their dispositions, as to put herself entirely into their hands." They immediately shouted, "Long live the empress!" And the chaplain of one of the regiments fetching a crucifix, received their oaths of fidelity.

The troops, however, were not unanimous in this revolt. Though Gregory Orloff was treasurer of the artillery, and well enough beloved by the soldiers, that corps refused to follow him until he should produce the orders of Villebois their general: and that officer, withheld either by fidelity to the emperor or by fear, presumed to speak to Catharine of the obstacles which yet remained for her to surmount; adding, that she ought to have foreseen them. She haughtily replied, that "she had not sent for him to ask what she ought to have foreseen, Catharine. foreseen, but to know how he intended to act." "To obey your Majesty," returned Villebois; and putting himself at the head of his regiment, he immediately joined the conspirators. So ripe indeed were the minds of all men for this revolt, that in the space of two hours the empress found herself surrounded by 2000 warriors, together with great part of the inhabitants of Petersburgh: and with that numerous train of attendants she repaired to the church of Kasan, where the archbishop of Novogorod, setting the Imperial crown on her head, proclaimed her sovereign of all the Russias, declaring, at the same time, Paul Petrovitch her successor.

Matters had now proceeded by much too far to admit of any compromise between Catharine and her husband: but had the infatuated Tzar put his affairs wholly into the hands of Marshal Munich, that intrepid veteran would have tumbled the empress from her throne almost as quickly as she had got possession of it. He acted, however, a very different part. Upon receiving intelligence of what had been done at St Petersburgh, he asked indeed the Marshal's advice, but suffered himself to be guided by his mistress and timid companions. Through their terrors and his own irresolution opportunities were lost which could never be recovered; for though his Holstein guards, with tears in their eyes, swore that they were all ready to sacrifice their lives in his service, and though the old Marshal offered to lead them against the rebels, saying to the emperor, "I will go before you, and their swords shall not reach you till they have pierced my body," he was persuaded to treat with the empress, to acknowledge his misconduct, and to offer to share with her the sovereign power. At last he was weak enough to abandon his troops, and to surrender at discretion to his consort; whose creatures hurried him from Oranienbaum to Peterhoff, stripped him of all his clothes, and, after leaving him for some time in his shirt, a butt to the outrages of an insolent soldiery, threw over him an old morning-gown, and shut him up alone, with a guard at the door of his wretched apartment. On the 29th of June, O. S.* 1762, Count Panin was sent to him by the empress; and after a long conference, prevailed with him to write and sign a solemn resignation of his crown, and a declaration of his utter incapacity to govern so great an empire.

* July 10.

The revolution was now complete, and Peter seemed to enjoy some composure of mind; but in the evening he was carried a prisoner to Ropscha, a small Imperial palace, at the distance of 20 versts from Peterhoff, where he was murdered on the 17th of July, just one week after his deposition. Of the manner of his death different accounts have been given. By some he is said to have been poisoned; by others, to have been strangled by one of the Orloffs; and a few have thought that he perished by the same means as Edward II. of England. Whether the empress was accessory to his death is not known; though it is certain, that so far from making any inquiry after his murderers, she affected to believe that he had died naturally of the *piles!*

The first care of Catharine was to reward those who had been the principal actors in the revolt. Panin was made prime minister; the Orloffs received the title of Count; and the favourite Gregory was appointed lieutenant-general of the Russian armies, and knight of the order of St Alexander Nesky, the second order of the empire. Several officers of the guards were promoted, of whom 24 received considerable estates; and among the soldiers, whom she treated with the greatest affability, brandy and beer were liberally distributed. The Chancellor Bestucheff, who had been the most inveterate enemy of Peter, was recalled from his exile, restored to his rank of field-marshal, and had an annual pension settled upon him of 20.000 rubles. To the friends of the emperor she behaved with great moderation. Prince George, whom he had constituted Duke of Courland, was indeed obliged to renounce his title; but the administration of Holstein was committed to him, and he ever after served the empress with zeal and fidelity.

The news of the revolution was soon spread over Europe; and none of the sovereigns, though they knew by what steps Catharine had mounted the throne, hesitated for a moment to acknowledge her title. She was not, however, at perfect ease in her own mind; nor was her right recognised by all her subjects. Though she published manifestoes, setting forth the intentions of the late emperor towards her and her son, which made resistance necessary; though in these papers she attributed her elevation to the wishes of her people and the providence of God; and though she called upon all who were sincerely attached to the orthodox faith of the Greek church, to consider the sudden death of Peter as the judgment of heaven in favour of the revolution—yet in the distant provinces no exultations were heard; both soldiers and peasants observed a gloomy silence. Even at Moscow, so great was the disaffection to Catharine's government, that it was some time before she could venture to go to that city to be crowned; and she found in it at last so cold a reception, that she very quickly returned to St Petersburgh.

Nor was this the only cause of her uneasiness. The connection between Orloff and her became visible, and gave just offence to her other friends. The princess of Dashkoff first perceived it; and when she presumed to expostulate with the empress on the meanness and imprudence of her passion, she was banished from the court to Moscow. Count Panin and the Hetman saw with indignation that they had dethroned the grandson of Peter the Great, to aggrandise a rude and low-born upstart. Cabals and conspiracies were entered into by high and low, both against Catharine and against her favourite; and it required all her abilities and firmness to preserve at once her throne and her lover. On one occasion she hoped to obtain from the Princess Dashkoff sufficient proof that Panin and the Hetman of the Kosacks were concerned in a plot which had just been discovered; and with this view she wrote to her a letter of four pages, filled with the most tender epithets and the most magnificent promises, conjuring her in the name of their long-standing friendship, to reveal what she knew of the recent conspiracies. With becoming magnanimity, the princess replied, "Madam, I have heard nothing; but if I had heard any thing, I should take good care how I spoke of it. What is it you require of me? That I should expire upon a scaffold? I am ready to mount it."

Catharine, despairing of conquering such a spirit, attempted to attach to her those whom she dared not to punish. Some of the inferior conspirators were banished to Siberia, while Panin and the Hetman, whom she most dreaded, received additional marks of her favour. In the mean time, to gain the affections of the people. at

Catharine. at large, ſhe paid the utmoſt attention to the adminiſtration of juſtice; formed magnificent eſtabliſhments for the education of the youth of both ſexes; founded hoſpitals for orphans, for the ſick, and for lying-in women; invited foreigners of all nations, poſſeſſed of any merit, to ſettle in different parts of her vaſt territories; increaſed the naval force of the empire; and gave ſuch encouragement to the cultivation of every elegant and uſeful art, that in the ſhort ſpace of a year and a half from her acceſſion to the throne, the national improvement of Ruſſia was viſible.

In the good fortune and glory of Catharine, no one rejoiced more ſincerely than Count Poniatowſky. He approached towards the confines of Ruſſia, and wrote to her in the tendereſt ſtyle of congratulation, requeſting permiſſion to pay his reſpects to her in the capital of her empire. It is not improbable that he flattered himſelf with the hopes that ſhe would give him her hand in marriage, and thus raiſe him to the throne of the Tzars; but ſhe had promiſed to the Empreſs Elizabeth, that ſhe would never again ſee the count; and to that promiſe ſhe at preſent adhered. She wrote to him, however, in the moſt affectionate terms; and tho' ſhe gave him no encouragement to repair to St Peterſburgh, ſhe aſſured him that ſhe had other proſpects in view for his aggrandiſement, and that he might depend upon her perpetual friendſhip: and ſhe ſoon appeared to be as good as her word. On the death of Auguſtus III. ſhe raiſed her former favourite to the throne of Poland, in oppoſition to the wiſhes of the courts of Vienna and Verſailles, as well as of a great majority of the Poliſh nobles. She defeated the intrigues of the two foreign courts by more ſkilfully conducted intrigues of her own; and by pouring her armies into the republic, ſhe ſo completely overawed the nuncios, that Poniatowſky was choſen by the unanimous ſuffrages of the diet which met for the election of a ſovereign; and, on the 7th of September 1764, was proclaimed King of Poland and Grand Duke of Lithuania, by the name of Staniſlaus Auguſtus.

Whilſt ſhe was thus diſpoſing of foreign kingdoms, ſhe was kept under perpetual dread of being tumbled from the throne of her own vaſt empire. Her want of title to that throne was now ſeen by all ranks of her ſubjects: the good qualities of Peter the third were remembered, and his failings and faults forgotten. His fate was univerſally lamented; and, except the conſpirators, who may be ſaid to have embrued their hands in his blood, there was hardly a Ruſſian who did not regret that the ſovereignty had paſſed from the ancient family of the Tzars to a foreigner, allied only by marriage to the blood royal. Even the conſpirators themſelves had loſt much of their regard for Catharine. The princeſs of Daſhkoff was a ſecond time baniſhed to Moſcow; and, to magnify her own importance, ſhe ſpoke freely of the means by which the empreſs, whom ſhe accuſed of ingratitude, had been raiſed to the throne. The inhabitants of Moſcow, who never favoured the uſurpation, were thus made ripe for a revolt. At St Peterſburgh, Count Panin felt himſelf uneaſy under the predominant influence of the favourite, and tried in vain to divert Catharine's affections to a new object. She received a few ſecret viſits from a handſome young man, and then appointed him to a lucrative and honourable employment in ſome diſtant province of the empire; when Orloff recovered his former aſcendency, which through his own careleſſneſs he had nearly loſt. In this ſtate of the public mind, conſpiracies were very frequent; and as the general object of them was to place on the throne Prince Ivan, who was again languiſhing in the dungeon from which Peter had taken him, the empreſs had given to his guard an order, ſigned by her own hand, to put that unfortunate prince to death, ſhould any attempt be made to liberate him from his priſon. An attempt was made by a very inferior officer, as ſome have ſuppoſed, by the inſtructions of Catharine, and her bloody order was inſtantly obeyed. The aſſaſſins were rewarded, and promoted in the army; but the officer who attempted to reſcue the prince was condemned to death, and ſuffered unexpectedly the ſentence of the law. The brothers and ſiſters of Ivan, who had been kept in a priſon different from his, were ſent to Denmark; and, to provide them with neceſſaries ſuitable to their rank, the empreſs made them a preſent of 200,000 rubles, and paid annually, to the maintenance of their dignity, a penſion of thirty thouſand.

The throne of Catharine was now firmly eſtabliſhed, by the death or renunciation of every perſon who was deſcended of the imperial family; and ſhe had leiſure to turn her thoughts to the aggrandiſement of the empire. It was ſoon ſeen that this was the object which ſhe had in view when ſhe raiſed Count Poniatowſky to the throne of Poland, and that ſhe was not actuated on that occaſion by any remains of her former attachment. We have elſewhere ſhewn (ſee Poland, *Encycl.* n° 98—115) under what pretences ſhe invaded the kingdom of him who had formerly been one of her moſt favoured lovers, and by what means ſhe annexed great part of it to the territories of Ruſſia. But it is not through her wars that in this article we mean to trace her character: It is not as a ſovereign and heroine that her life is entitled to a place in a general repoſitory of arts, ſciences, and miſcellaneous literature, but as a patroneſs of art and of ſcience, and as the legiſlatrix of a vaſt empire, who employed all her talents and all her power for the civilization of a great part of the human race.

Under the article Russia (*Encycl.*), we have mentioned the famous *code of laws for a great empire*, and the propoſed *convention of deputies from all the claſſes*, which Catharine and the Princeſs Daſhkoff ſo artfully employed as means to bring about the revolution which ſeated the former on the throne. The ſtates actually met in the ancient capital of the empire, and the ſovereign's inſtructions for framing a new code of laws was read amidſt reiterated burſts of applauſe. All preſent extolled the ſagacity, the wiſdom, the humanity of the empreſs; but fear and flattery had a greater ſhare in theſe exclamations than any juſt knowledge of the ſubject. The deputies of the Samoides alone had the courage to ſpeak freely. One of them ſtood up, and, in the name of himſelf and his brethren, ſaid, "We are a ſimple and honeſt people. We quietly tend our reindeer. We are in no want of a new code; but make laws for the Ruſſians, our neighbours, that may put a ſtop to their depredations." The following ſittings did not paſs ſo quietly. A debate about the liberation of the boors was carried on with ſuch warmth, that fatal conſequences were to be apprehended; and the deputies were diſmiſſed to their reſpective provinces in the

Catharine. the manner which we have elsewhere related. Previous, however, to the dissolution of this assembly, the members were required to signalize the meeting by some conspicuous act of gratitude; and, by a general acclamation, the titles of GREAT, WISE, PRUDENT, and MOTHER OF THE COUNTRY, were decreed to the empress. With assumed modesty she accepted only of the last, "as the most benign and glorious recompence for her labours and solicitudes in behalf of a people whom she loved."

For that people she did indeed labour, and labour most usefully. She introduced into the administration of justice the greatest reformation of which the half-civilized state of Russia would perhaps admit. She spared neither trouble nor expence to diffuse over the empire the light of science, and the benefits of useful and elegant arts; and she protected, as far as she could, the poor from the oppressions of the rich. About the middle of 1767, she conceived the idea of sending several learned men to travel through the interior of her vast dominions, to determine the geographical position of the principal places, to mark their temperature, and to examine into the nature of their soil, their vegetable and mineral productions, and the manners of the people by whom they were inhabited. To this employment she appointed Pallas, Gmelin, Euler, and many others of the highest eminence in the republic of letters; from whose journals of these interesting travels large additions have been made to the general stock of useful knowledge. This survey of the empire, and the maps made from it, had Catharine done nothing else, would alone have been sufficient to render her name immortal. Well convinced in her own mind, that it is not so much by the power of arms, as by precedence in science, that nations obtain a conspicuous place in the annals of the world, with a laudable zeal she encouraged artists and scholars of all denominations. She granted new privileges to the two academies of sciences and the arts; encouraged such of the youth as had behaved well in these national institutes, to travel for farther improvement over Europe, by bestowing upon them, for three years, large pensions to defray their expence; and, to remove as much as possible the Russian prejudice against all kinds of learning, she granted patents of nobility to those who, during their education, had conducted themselves with propriety, and become proficients in any branch of useful or elegant knowledge. Still farther to encourage the fine arts in her dominions, she assigned an annual sum of 5000 rubles for the translation of foreign literary works into the Russian language.

In the year 1768, the small-pox raged at St Petersburgh, and proved fatal to vast numbers of all ranks and of every age. The empress was desirous to introduce the practice of inoculation among her subjects; and resolved to set the example by having herself and her son inoculated, With this view, she applied for a physician from England: and Dr Thomas Dimsdale of Hertford being recommended to her, he repaired with his son to the capital of Russia, where he inoculated first the empress, then the grand duke, and afterwards many of the nobility. The experiment proving successful, he was created a baron of the empire, appointed actual counsellor of state, and physician to her imperial majesty, with a pension of L. 500 sterling a-year, to be paid him in England, besides L. 10,000 which he immediately received. So popular was the empress at this period, that, by a decree of the senate, the anniversary of her recovery from the small-pox was enjoined to be celebrated as a religious festival; and it has ever since been observed as such. Catharine.

She was now engaged in war with the Turks of which a sufficient account for a work of this nature has been given under the title TURKEY *(Encycl)*; but there was one transaction of her and her friends, of which no mention was made in that article, though it is of importance to him who would form a just estimate of her personal character.

We have noticed the sensuality of the empress Elizabeth. She bore three children to the grand veneur Alexey Gregorievitch Razumoffsky, to whom, indeed, she is said to have been clandestinely married. Of these children the youngest was a girl, brought up under the name of Princess Tarrakanoff. Prince Radzivil, who has been mentioned in the article POLAND *(Encycl.)*, irritated at Catharine's cruelties to his countrymen, conceived the project of placing the young princess on the throne of her ancestors; and, having gained over the persons to whom her education was intrusted, he carried her off to Rome as a place of safety. Catharine, in return, seized his large estates; and he and the princess were reduced to extreme poverty. Radzivil repaired to Poland in order to learn what could be done to forward his great enterprise; and scarcely had he arrived there when an offer was made to restore to him his possessions, upon condition of his carrying his ward to St Petersburgh. This he refused: but had the baseness to promise, that he would give himself no farther concern about the daughter of Elizabeth; and he was put in possession of all his estates.

By the instructions of the empress, Alexius Orloff, who nominally commanded the Russian fleet at the Dardanelles, repaired to Rome, got access to young Tarrakanoff, and found means to persuade her that all Russia was ready to revolt from Catharine, and place her on the throne of her mother. To convince her of his sincerity, he pretended to feel for her the tenderest and most respectful passion; and the unsuspicious lady was induced to accept of him as a husband. The ruffian who had assassinated the grandson of Peter the Great, did not hesitate to seduce and betray his grand daughter. Under pretence of having the marriage ceremony performed according to the rites of the Greek church, he suborned some subaltern villains to personate priests and lawyers; thus combining profanation with imposture against the unprotected and too confident Tarrakanoff.

Having been treated for some days, both at Rome and at Leghorn, with all the respect due to a sovereign, the unsuspecting princess expressed a wish to go on board a Russian ship of war. This was just what Orloff wanted. Attended by a numerous and obsequious train, she was rowed from the shore in a boat with magnificent ensigns, hoisted upon the deck of the ship in a splendid chair, and immediately handcuffed. In vain did she throw herself at the feet of her pretended husband, and conjure him by every thing tender which had passed between them. She was carried down into the hold; the next day the vessel sailed for St Petersburgh; where, upon her arrival, the princess was shut up in the fortress; and what became of her since was never

Catharine. never known. Such were the means which Catharine ſcrupled not to employ in order to get rid of all pretenders to her throne.

Soon after this ſervice rendered to her by Alexius Orloff, ſhe diſmiſſed his brother Gregory from her favour, and connected herſelf with Vaſſiltchikoff, a ſub-lieutenant of the guards. The former favourite had indeed become inſolent, and, as Catharine thought, ungrateful. He aſpired to nothing leſs than the throne. From love to himſelf, and to a ſon which ſhe had born to him, ſhe offered to enter into a ſecret marriage; but with this propoſal the proud prince (A) was not ſatisfied, and hoped that his refuſal would impel her to receive him publicly as her huſband and partner in power. He was miſtaken. She diveſted him of all his employments; but gave him a penſion of 150,000 rubles, a handſome ſervice of plate, and an eſtate with 6000 peaſants upon it; and, thus enriched, he ſet out upon a journey through various parts of Europe. He returned, however, much ſooner than was expected; the new favourite was handſomely rewarded, and ſent to a diſtance; Orloff was reſtored to all his offices, and his baleful influence was again felt.

He attempted to perſuade the empreſs to diſmiſs Panin from the court; but the grand duke interpoſed in behalf of his old preceptor; and, for once, Catharine liſtened to the entreaties of her ſon. When a dreadful rebellion, under a Koſak of the name of Pugetſhoff, who pretended to be Peter III. eſcaped from his aſſaſſins, was ſhaking the throne to its foundation—the influence of Orloff was ſuch as to prevent the empreſs, for ſome time, from employing her ableſt general againſt the rebels, becauſe that general was Panin, brother to the miniſter. Danger, however, at laſt prevailed over the favourite: Panin was ſent againſt Pugetſhoff; the rebellion was cruſhed; and Catharine found leiſure to give ſomething like a legal conſtitution to the empire. In that work, the laws and regulations eſtabliſhed for the government of the various provinces, and for the equitable adminiſtration of juſtice through the whole of her vaſt dominions, evinces the greateſt wiſdom and ſagacity in their author, as well as a proper regard to the practicable liberties and rights of men. In the capital, ſhe eſtabliſhed the moſt perfect police, by which the internal tranquillity of a great city was, perhaps, ever maintained; and whilſt her private conduct was far from correct, ſhe was acting in the capacity of ſovereign, ſo as to deſerve, indeed, the appellation of *Mother of her people.*

To follow her through all her wars and intrigues with foreign courts, would ſwell this article to the ſize of a volume. Such a narrative, too, belongs rather to the hiſtory of Ruſſia than to the memoirs of Catharine; in which it is the buſineſs of the biographer to develop the private character of the woman, rather than to detail the exploits of the ſovereign. Her partition of Poland, and afterwards the annihilation of it as an independent republic; her encroachments on the territories of the grand ſignior; her formation of the armed neutrality; the influence which ſhe maintained over the courts of Sweden and Denmark; and the art with which ſhe threw the weight of Ruſſia ſometimes into the ſcale of Auſtria, and ſometimes into that of Pruſſia, Catharine. juſt as the intereſts of her own dominions required the one or the other to preponderate—ſhew how admirably ſhe was qualified to guide the helm of a great empire in all its tranſactions with foreign ſtates. We ſpeak not of the equity of her proceedings; for it muſt be confeſſed, that equity formed no barrier againſt her ambition; and that ſhe never failed to ſubjugate thoſe whom ſhe pretended to take under her protection. Her ruling paſſion was to enlarge her own territories, already ſo very extenſive; and, for the attainment of that object, ſhe contrived the moſt judicious plans, which ſhe executed with vigour. In this part of her conduct, however, ſhe has been equalled by other monarchs; but in the zeal and the wiſdom with which ſhe endeavoured to introduce among her half-ſavage ſubjects the bleſſings of knowledge and induſtry, ſhe ſtands unrivalled, except, perhaps, by her predeceſſor Peter the Great. Of this we need bring no other proof, in addition to what has been already ſtated, than that ſhe founded in St Peterſburgh alone thirty-one ſeminaries, where 6800 children of both ſexes were educated at the annual expence to the government of 754,335 rubles. She ſuperintended herſelf the education of her grandchildren, and wrote for them books of inſtruction. If it be true, that "every man acquainted with the common principles of human action, will look with veneration on the writer who is at one time combating Locke, and at another making a catechiſm for children in their fourth year;" with what veneration ſhould we look upon the empreſs of Ruſſia, could we forget the means by which ſhe obtained that elevation from which ſhe frequently deſcended for a ſimilar employment: This ſhe did, not for her own deſcendants alone, but alſo for the children of others; of whom ſhe had always a great number in her apartments, who ſhared in the inſtruction given to her grandchildren, and whoſe careſſes ſhe returned with extreme complaiſance.

Her greateſt weakneſs was ſurely that groſs paſſion which her panegyriſts have dignified with the name of love; but to ſuch an appellation it had no claim, if love be any thing more than a ſexual appetite. Beſides Gregory Orloff, ſhe had not fewer than ten favourites after the death of her huſband; and of theſe ſhe ſeems to have felt a refined affection for none but Lanſkoi, a young Pole of a very ancient family, and of elegant manners, and the famous Potemkin, to whom ſhe is ſaid ſecretly to have given her hand, and who preſerved her friendſhip, if not her affection, to the end of his life. To Lanſkoi, whoſe education had been much neglected, ſhe condeſcended to become preceptrix; and, as he made great progreſs in the acquiſition of uſeful knowledge, ſhe admired in him her own creation. Potemkin, though not amiable, deſerved her favour for the fidelity and abilities with which he ſerved her, both in the council and in the field; and in him, when ſhe had ceaſed to look on him with the eyes of love, ſhe reſpected the intriguing politician and intrepid commander, who had formed plans for driving the Turks out of Europe, and ſetting her on the throne of Byzantium. Her other favourites had nothing to recommend

(A) She had ſome time before obtained for him a patent, creating him a prince of the Roman empire.

Catharine.

mend them but masculine beauty and corporeal strength. One of them, however, thought it necessary to have a library in the grand house, of which the empress, upon receiving him into favour, had made him a present; and desired the principal bookseller to fill his shelves. The man asked him what books he would please to have. "You understand that better than I (replied the favourite); that is your business. You know the proper assortments; I have destined a large room to receive them. Let there be large books at the bottom, and smaller and smaller up to the top; that is the way they stand in the empress's library!" In the conversation of such men the cultivated mind of Catharine could enjoy no interchange of sentiments.

We know not whether that more than Asiatic magnificence, which she displayed on every public occasion, should be considered as an instance of weakness or of wisdom. If she delighted in balls, and masquerades, and sumptuous entertainments, and dress loaded with jewels, and every kind of splendid ornament, for their own sakes, she betrayed a weakness unworthy of that sovereign who held in her hand the balance of Europe, and at whose nod the greatest powers of Asia trembled: but if she introduced such splendor into her court merely to divert the attention of the Russians from the means by which she got possession of the throne, and to ween them from their own savage and slovenly manners; even this may perhaps be considered as one of her most masterly strokes in politics.

Her ambition was boundless; but, if such a phrase may be allowed, it was not always true ambition. When the French republic had established itself on the ruins of monarchy, and was propagating new theories of government through all Europe, true ambition would surely have led the autocratrix of the north to unite her forces with those of the coalesced powers, in order to crush the horrid hydra, before its anarchical principles could be introduced among her own barbarous subjects. Such would certainly have been the advice of her favourite Potemkin, who longed to lead a Russian army into France, even before the murder of the unfortunate Lewis. That general, however, had died in October 1791; and when Britain, Austria, and Prussia, were leagued against the new republic, Catharine looked coolly on, in hopes, it is probable, of availing herself of their weakness, when exhausted by a long and bloody war. She gave refuge, indeed, in her dominions to many emigrants from France, and sent a squadron of ships to co-operate with the navy of England: but in this last measure she regarded merely her own immediate interest; for her crazy ships were repaired by British carpenters at the expence of the British government, and her officers had an opportunity of learning the evolutions of the British navy. She had likewise other prospects in view when she lent to the allies this slender aid. She meditated a new war with Turkey; and, depending upon meeting with no opposition, if she should not receive assistance from England and Austria, she flattered herself with accomplishing her darling project of driving the Ottomans out of Europe, and of reigning in Constantinople. But she was disappointed. On the morning of the 9th of November 1796, she was seized with what her principal physician judged a fit of apoplexy; and, at 10 o'clock in the evening of the following day, expired, in the 68th year of her age, leaving behind her the character of one of the greatest sovereigns that ever swayed a sceptre.

Cauda, Cause.

After this long detail of the incidents of her life, it is needless to inform the reader that Catharine II. had no religion, and, of course, no principles of morality, which could induce her in every instance to do to others as she would have them do to her. She was a professed disciple of the French philosophers; by some of whom she was ridiculed, and by others cheated. The incense which she paid to the genius of Voltaire did not hinder him from frequently breaking his jests upon the autocratrix of Russia and her successive favourites; and Diderot, whom she caressed, sold to her an immense library, when he possessed hardly a book, and was obliged to ransack Germany and France for volumes to enable him to fulfil his bargain. Such is the friendship, and such the gratitude, which subsists among the amiable pupils of nature, and the philanthropic advocates for the rights of man.

CAUDA *Capricorni*, a fixed star of the fourth magnitude, in the tail of Capricorn; called also, by the Arabs, *Dineb Algedi*; and γ by Bayer.

CAUDA *Ceti*, a fixed star of the third magnitude; called also, by the Arabs, *Dined Kaetos*; marked β by Bayer.

CAUDA *Cygni*, a fixed star of the second magnitude, in the Swan's tail; called by the Arabs *Dineb Adigege*, or *Eldegiagich*; and marked α by Bayer.

CAUDA *Delphini*, a fixed star of the third magnitude, in the tail of the Dolphin; marked ϵ by Bayer.

CAUDA *Draconis*, or Dragon's tail, the moon's southern or descending node.

CAUDA *Leonis*, a fixed star of the first magnitude, in the Lion's tail; called also, by the Arabs, *Dineb Eleced*; and marked β by Bayer. It is called also *Lucida Cauda*.

CAUDA *Ursæ Minoris*, a fixed star of the third magnitude, at the end of the Lesser Bear's tail; called also the *Pole Star*, and, by the Arabs, *Alrukabah*; and marked α by Bayer.

CAUSE has been defined, we think, with accuracy in the Encyclopædia, and the doctrine stated which we believe to be true. Objections however have been made to that doctrine, of which we have endeavoured to remove some, under the title ACTION, in this Supplement; and the doctrine itself has been well illustrated (at least such is our opinion) in the supplementary article ASTRONOMY. We have, therefore, very little to add here on the subject of causes, though it is the most important subject which can employ the mind of man. What is the relation between a physical cause and that which is termed its effect—between heat, for instance, and the fusion of metals? Is it a *necessary connection*, or only a *conjunction*, discovered by experience to be *constant?*

If by *necessary* connection be meant that kind of connection of which the contrary cannot be conceived, we do not think that the connection of any physical cause with its effect can be called necessary. We see no difficulty in conceiving, that fire, instead of fusing gold, might fix mercury. This *may* indeed be impossible; and

Cause, Center. and we might perhaps see the impossibility, did we as completely know the nature of fire and of metals, as we know the relations of pure geometry. We know that the three angles of a plain triangle cannot possibly be either greater or less than two right angles; for in this comparison nothing is hid from our mental view. We do not, however, perceive the impossibility of mercury being fixed, as clay is hardened, by heat; for of *heat*, and mercury, and clay, we know very little, and that little is the offspring of experience.

But if the connection between cause and effect be not *necessary*, are we not deprived of the means of demonstrating the great fundamental truth of religion? We have nowhere said, that the connection between cause and effect is not necessary; but only, that we do not perceive the necessary connection between what are called *physical* causes and their effects. That every event is, and must be, brought about by *some cause* or some *agency*, we hold to be a self-evident truth, which no man can deny who understands the terms in which it is expressed; but what or where the agency is, we can very seldom, if ever, know, except when we think of our own voluntary actions. When a change is observed, we cannot doubt of its being produced by something: either the thing changed is animated, and has produced the change by its own agency, just as we move our heads and legs by an act of volition; or if it be inanimated, and of itself incapable of agency, the change has been produced by something external, denominated a *cause*. But all external causes, which are not likewise agents, in the proper sense of the word, may be traced, we think, as effects up to some agency; and therefore, in our opinion, there is no real, ultimate, efficient cause but mind, or that which is endued with power. In proof of this doctrine, if it need any proof, we can only refer to what has been said elsewhere on our notions of *power* and of *physical causes*. See (*Encycl.*) METAPHYSICS, n° 109, &c.—PHILOSOPHY and PHYSICS, *passim*—and (*Suppl.*) ACTION and ASTRONOMY.

1 Definition. CENTER, or CENTRE, a word borrowed from the French name *ceintre* or *cintre*, given to the frame of timber, by which the brick or stone of arched vaulting is supported during its erection, and from which it receives its form and curvature.

2 Purpose of this article. It is not our intention to describe the variety of constructions which may be adopted in easy situations, where the arches are of small extent, and where sufficient foundation can be had in every part of it for supporting the frame. In such cases, the frequency of the props which we can set up dispenses with much care; and a frame of very slight timbers, connected together in an ordinary way, will suffice for carrying the weight, and for keeping it in exact shape. But when the arches have a wide span, and consequently a very great weight, and when we cannot set up intermediate pillars, either for want of a foundation in the soft bottom of a river, or because the arch is turned between two lofty piers, as in the dome of a stately cathedral—we are then obliged to rest every thing on the piers themselves; and the framing which is to support our arch before the keystone is set, must itself be an arch, depending on the mutual abutment of its beams. One should think that this view of the construction of a centre would offer itself at the first, naturally derived from the erection it was to assist: but it has not been so. When intermediate pillars were not employed, it was usual to frame the mould for the arch with little attention to any thing but its shape, and then to cross it and recross it in all directions with other pieces of timber, till it was thought so bound together that it could be lifted in any position, and, when loaded with any weight, could not change its shape. The frame was then raised in a lump, like any solid body of the same shape, and set in its place. This is the way still practised by many country artists, who, having no clear principles to guide them, do not stop till they have made a load of timber almost equal to the weight which it is to carry.

Center. But this artless method, besides leading the employer into great expence, is frequently fatal to the undertaker, from the unskilfulness of the construction. The beams which connect its extremities are made also to support the middle by means of posts which rest on them. They are therefore exposed to a transverse or cross strain, which they are not able to bear. Their number must therefore be increased, and this increases the load. Some of these cross strains are derived from beams which are pressed very obliquely, and therefore exert a prodigious thrust on their supports. The beams are also greatly weakened by the mortises which are cut in them to receive the tenons of the crossing beams: and thus the whole is exceedingly weak, in proportion to what the same quantity of timber may be made by a proper disposition of its parts.

The principles from which we are to derive this disposition are the general mechanical principles of carpentry, of which we have given some account in that article. These furnish one general rule: When we would give the utmost strength possible to a frame of carpentry, every piece should be so disposed that it is subject to no strain but what either pushes or draws it in the direction of its length: and, if we would be indebted to timber alone for the force or strength of the centre, we must rest all on the first of these strains; for when the straining force tends to *draw* a beam out of its place, it must be held there by a mortise and tenon, which possesses but a very trifling force, or by iron straps and bolts. Cases occur where it may be very difficult to make every strain a thrust, and the best artists admit of ties; and indeed where we can admit a tie-beam connecting the two feet of our frame, we need seek no better security. But this may sometimes be very inconvenient. When it is the arch of a bridge that we are to support, such a tie-beam would totally stop the passage of small craft up and down the river. It would often be in the water, and thus exposed to the most fatal accidents by freshes, &c. Interrupted ties, therefore, must be employed, whose joint or meetings must be supported by something analogous to the king-posts of roofs. When this is judiciously done, the security is abundantly good. But great judgment is necessary, and a very scrupulous attention to the disposition of the pieces. It is by no means an easy matter to discern whether a beam, which makes a part of our centre, is in a state of compression or in a state of extension. In some works of the most eminent carpenters even of this day, we see pieces considered as struts (and considerable dependence had on them in this capacity), while they are certainly performing the office of tie-beams, and should be secured acccordingly. This was the case in the boldest centre (we think) that has been

3 General principles of construction.

Center.

been executed in Europe, that of the bridge of Orleans, by Mr Hupeau. Yet it is evidently of great consequence not to be mistaken in this point; for when we are mistaken, and the piece is stretched which we imagine to be compressed, we not only are deprived of some support that we expected, but the expected support has become an additional load.

4 How to distinguish a strut from a tie.

To ascertain this point, we may suppose the piers to yield a little to the pressure of the archstones on the centre frames. The feet, therefore, fly outwards, and the shape is altered by the sinking of the crown. We must draw our frame anew for this new state of things, and must notice what pieces must be made longer than before. All such pieces have been acting the part of tie-beams.

But a centre has still another office to sustain; it must keep the arch in its form; that is, while the load on the centre is continually increasing, as the masons lay on more courses of arch stones, the frame must not yield and go out of shape, sinking under the weight on the haunches, and rising in the crown, which is not yet carrying any load. The frame must not be supple; and must derive its stiffness, not from the closeness and strength of its joints, which are quite insignificant when set in competition with such immense strains, but from struts or ties, properly disposed, which hinder any of the angles from changing its amplitude.

5 How to secure stiffness and strength.

It is obvious, from all that has been said, that the strength and stiffness of the whole must be found in the triangles into which this frame of carpentry may be resolved. We have seen that the strains which one piece produces on two others, with which it meets in one point, depends on the angles of their intersection; and that it is greater as an obtuse angle is more obtuse, or an acute angle more acute. And this suggests to us the general maxim, "to avoid as much as possible all very obtuse angles." Acute angles, which are not necessarily accompanied by obtuse ones, are not so hurtful; because the strain here can never exceed the straining force; whereas, in the case of an obtuse angle, it may surpass it in any degree.

Such are the general rules on this subject. Although something of the mutual abutment of timbers, and the support derived from it, has been long perceived, and employed by the carpenters in roofing, and also (doubtless) in the forming of centres, yet it is a matter of historical fact, that no general and distinct views had been taken of it till about the beginning of this century, or a little earlier. Fontana has preserved the figure of the frames on which the arches of St Peter's at Rome were turned. The one employed for the dome is constructed with very little skill; and those for the arches of the nave and transepts, though incomparably superior, and of considerable simplicity and strength, are yet far inferior to others which have been employed in later times. It is much to be regretted that no trace remains of the forms employed by the great architect and consummate mechanician Sir Christopher Wren. We should doubtless have seen in them every thing that science and great sagacity could suggest. We are told, indeed, that his centering for the dome of St Paul's was a wonder of its kind; begun in the air at the height of 160 feet from the ground, and without making use of even a projecting corniche whereon to rest it.

6 The earliest theory, on scientific principles,

The earliest theory of the kind that we have met with, that is proposed on scientific principles, and with the express purpose of serving as a lesson, are two centres by Mr Pitot of the Academy of Sciences, about the beginning of this century. As they have considerable merit (greatly resembling those employed by Michael Angelo in the nave of St Peter's), and afford some good maxims, we shall give a short account of them. We crave the excuse of the artists if we should employ their terms of art somewhat aukwardly, not being very familiarly acquainted with them. Indeed, we observe very great differences, and even ambiguity, in the terms employed.

What we shall describe under the name of a *centre* is (properly speaking) only one frame, truss, or rib, of a centre. They are set up in vertical planes, parallel to each other, at the distance of 5, 6, 7, or 8 feet, like the trusses or main couples of a roof. Bridging joists are laid across them.—In smaller works these are laid sparingly, but of considerable scantling, and are boarded over; but for great arches, a bridging joist is laid for every course of archstones, with blockings between to keep them at their proper distances. The stones are not laid immediately on these joists, but beams of soft wood are laid along each joist, on which the stone is laid. These beams are afterwards cut out with the chissel, in order to separate the centre from the ring of stones, which must now support each other by their mutual abutment.

7 Illustrated. Plate XIV.

The centre is distinguishable into two parts, ALLB (fig. 1.) and LDL, which are pretty independent of each other, or at least act separately. The horizontal STRETCHER LL cuts the semicircle ADB half way between the spring and the crown of the arch; the arches AL, LD, being 45° each. This stretcher is divided in the same proportion in the points G and H; that is, GH is one half of LL, and LG, HL are each one-fourth of LL nearly. Each end is supported by two STRUTS EI, GI, which rest below on a SOLE or BED properly supported. The interval between the heads of the struts GI, HK is filled up by the STRAINING BEAM GH, abutting in a proper manner on the struts (see CARPENTRY, *Supplement*). The extremities L, L, are united in like manner by butting joints, with the heads of the outer struts. The ARCH MOULDS AP, BP, are connected with the struts by cross pieces PQ, which we shall call BRIDLES, which come inwards on each side of the struts (being double), and are bolted to them. This may be called the lower part of the frame. The upper part consists of the king post DR, supported on each side by the two struts or braces ML, ON, mortised into the post, and also mortised into the stretcher, at the points L, N, where it is supported by the struts below. The arches LD, LD are connected with the struts by the bridles PQ, in the same manner as below.

8 Propriety of this arrangement.

There is a great propriety in many parts of this arrangement. The lower parts or haunches of the arch press very lightly on the centres. Each archstone is lying on an inclined plane, and tends to slide down only with its relative weight; that is, its weight is to its tendency to slide down the joint as radius to the sine of elevation of the joint. Now it is only by this tendency to slide down the joint that they press on the centering, which in every part of the arch is perpendicular to the joint: But the pressure on the joint, arising from this cause, is much less than this, by reason of the friction of the

the joints. A block of dry freeſtone will not ſlide down at all; and therefore will not preſs on the centering, if the joint be not elevated 35 degrees at leaſt. But the archſtones are not laid in this manner, by ſliding them down along the joint, but are laid on the centres, and ſlide down *their* ſlope, till they touch the blocks on which they are to reſt; ſo that, in laying the archſtones, we are by no means allowed to make the great deduction from their weight juſt now mentioned, and which Mr Couplet preſcribes (Mem. Acad. Sciences, 1729). But there is another cauſe which diminiſhes the preſſure on the centres; each block ſlides down the planks on which it is laid, and preſſes on the block below it, in the direction of the tangent to the arch. This preſſure is tranſmitted through this block, in the ſame direction, to the next, and through it to the third, &c. In this manner it is plain that, as the arch advances, there is a tangential preſſure on the lower archſtones, which diminiſhes their preſſure on the frame, and, if ſufficiently great, might even puſh them away from it. Mr Couplet has given an analyſis of this preſſure, and ſhews, that in a ſemicircular arch of uniform thickneſs none of the arch ſtones below 30° preſs on the frames. But he (without ſaying ſo) calculates on the ſuppoſition that the blocks deſcend along the circumference of this frame in the ſame manner as if it were perfectly ſmooth. As this is far from being the caſe, and as the obſtructions are to the laſt degree various and irregular, it is quite uſeleſs to inſtitute any calculation on the ſubject. A little reflection will convince the reader, that in this caſe the obſtruction ariſing from friction *muſt* be taken into account, and that it *muſt not* be taken into account in eſtimating the preſſure of each ſucceſſive courſe of ſtones as they are laid. It is enough that we ſee that the preſſure of the lower courſes of archſtones on the frame is diminiſhed. Mr Couplet ſays, that the whole preſſure of a ſemicircular arch is but $\frac{4}{9}$ths of its weight; but it is much greater, for the reaſon juſt now given. We have tried, with a well made wooden model (of which the circumference was rubbed with black lead to render it more ſlippery), whether *any* part of the wooden blocks repreſenting the archſtones were detached from the frame by the tangential preſſure of the ſuperior blocks; but we could not ſay confidently that any were ſo detached. We perceived that all kept hold of a thin ſlip of Chineſe paper (alſo rubbed with black lead) between them and the frame, ſo that a ſenſible force was required to pull it out. From a combination of circumſtances, which would be tedious to relate, we believe that the centres carry more than two-thirds of the weight of the arch before the keyſtone is ſet. In elliptical and lower pitched circular arches, the proportion is ſtill greater.

9 By a centre of M. Pitot's.

It ſeems reaſonable enough, therefore, to diſpoſe the framing in the manner propoſed by Pitot, directing the main ſupport to the upper maſs of the arch, which preſſes moſt on the frame. We ſhall derive another advantage from this conſtruction, which has not occurred to Mr Pitot.

There is an evident propriety in the manner in which he has diſtributed the ſupports of the upper part. The ſtruts which carry the king poſt ſpring from thoſe points of the ſtretcher where it reſts on the ſtruts below: thus the ſtretcher, on which all depends, bears no tranſverſe ſtrains. It is ſtretched by the ſtrut above it, and it is compreſſed in a ſmall degree between the ſtruts below it, at leaſt by the outer ones. Mr Pitot propoſes the ſtraining beam GH as a lateral ſupport to the ſtretcher, which may therefore be of two pieces: but although it *does* augment its ſtrength, it does not ſeem neceſſary for it. The ſtretcher is abundantly carried by the ſtrap, which may and ſhould ſuſpend it from the king poſt. The great uſe of the ſtraining piece is to give a firm abutment to the inner ſtruts, without allowing any lateral ſtrain on the ſtretcher. *N. B.* Great care muſt be taken to make the hold ſufficiently firm and extenſive between the ſtretcher and the upper ſtruts, ſo that its coheſion to reſiſt the thruſts from theſe ſtruts may be much employed.

The only imperfection that we find in this ſrame is the lateral ſtrains which are brought upon the upper ſtruts by the bridles, which certainly tranſmit to them part of the weight of the archſtones on the curves. The ſpace between the curves and ML ſhould alſo have been truſſed. Mr Pitot's form is, however, extremely ſtiff; and the cauſing the middle bridle to reach down to the ſtretcher, ſeems to ſecure the upper ſtruts from all riſk of bending.

This centre gives a very diſtinct view of the offices of all the parts, and makes therefore a proper introduction to the general ſubject. It is the ſimpleſt that can be in its principle, becauſe all the eſſential parts are ſubjected to one kind of ſtrain. The ſtretcher LL is the only exception, and its extenſion is rather a collateral circumſtance than a ſtep in the general ſupport. 10

The ſtrength of this frame.

The examination of the ſtrength of the frame is extremely eaſy. Mr Pitot gives it for an arch of 60 feet ſpan, and ſuppoſes the archſtones 7 feet long, which is a monſtrous thickneſs for ſo ſmall an arch; 4 feet is an abundant allowance, but we ſhall abide by his conſtruction. He gives the following ſcantlings of the parts:

The ring or circumference conſiſts of pieces of oak 12 inches broad and 6 thick.

The ſtretcher LL is 12 inches ſquare.

The ſtraining piece GH is alſo 12 by 12.

The lower ſtruts 10 by 8.

The king poſt 12 by 12.

The upper ſtruts 10 by 6.

The bridles 20 by 8.

Theſe dimenſions are French, which is about $\frac{1}{17}$th larger than ours, and the ſuperficial dimenſions (by which the ſection and the abſolute ſtrength is meaſured) is almoſt $\frac{1}{8}$th larger than ours. The cubic foot, by which the ſtones are meaſured, exceeds ours nearly $\frac{1}{5}$th. The pound is deficient about $\frac{1}{13}$th. But ſince very nice calculation is neither eaſy nor neceſſary on this ſubject, it is needleſs to depart from the French meaſures, which would occaſion many fractional parts and a troubleſome reduction.

The arch is ſuppoſed to be built of ſtone which weighed 160 pounds per foot. Mr Pitot, by a computation (in which he has committed a miſtake), ſays, that only $\frac{11}{14}$ths of this weight is carried by the frame. We believe, however, that this is nearer the truth than Mr Couplet's aſſumption of $\frac{4}{9}$ths already mentioned.

Mr Pitot farther aſſumes, that a ſquare inch of ſound oak will carry 8640 pounds. By his language we ſhould imagine that it will not carry much more: but this is very far below the ſtrength of any Britiſh oak that we have tried; ſo far, indeed, that we rather imagine

Center. gine that he means that this load may be laid on it with perfect security for any time. But to compensate for knots and other accidental imperfections, he assumes 7200 as the measure of its absolute force.

He computes the load on each frame to be 707520 pounds, which he reduces to $\frac{11}{14}$ths, or 555908 pounds.

The absolute force of each of the lower struts is 576000 (at 7200 per inch), and that of the curves 518400. Mr Pitot, considering that the curves are kept from bending outwards by the arch stones which press on them, thinks that they may be considered as acting precisely as the outer struts EI. We have no objection to this supposition.

11 Computed. With these data we may compute the load which the lower truss can safely bear by the rule delivered in the article CARPENTRY. We therefore proceed as follows:

Measure off by a scale of equal parts as, at, each 576000, and add tv 518400. Complete the parallelogram $avxs$, and draw the vertical xc, meeting the horizontal line aC in c. Make cb equal to ca. Join xb, and complete the parallelogram $axby$. It is evident that the diagonal xy will represent the load which these pieces can carry; for the line av is the united force of the curve AP and the strut IE, and as is the strength of IG. These two are equivalent to ax. xb is, in like manner, equivalent to the support on the other side, and xy is the load which will just balance the two supports ax and bx.

When xy is measured on the same scale, it will be found = 2850000 pounds. This is more than five times the load which actually lies on the frame. It is therefore vastly stronger than is necessary. Half of each of the linear dimensions would have been quite sufficient, and the struts needed only to be 5 inches by 4. Even this would have carried twice the weight, and would have borne the load really laid on it with perfect safety.

We proceed to measure the strength of the upper part. The force of each strut is 432000, and that of the curve is 518400; therefore, having drawn Mv parallel to the strut ON, make Mv = 432000, and Ms = 432000 + 518400. Complete the parallelogram Msrv. Draw the horizontal line rk, cutting the vertical MC in k, and make ky = Mk. It is plain, from what was done for the lower part, that My will measure the load which can be carried by the upper part. This will be found = 1160000. This is also greatly superior to the load; but not in so great a proportion as the other part. The chief part of the load lies on the upper part; but the chief reason of the difference is the greater obliquity of the upper struts. This shortens the diagonal My of the parallelogram of forces. Mr Pitot should have adverted to this; and instead of making the upper struts more slender than the lower, he should have made them stouter.

The strain on the stretcher LL is not calculated. It is measured by $r'k'$, when My is the load actually lying on the upper part. Less than the sixth part of the cohesion of the stretcher is more than sufficient for the horizontal thrust; and there is no difficulty of making the foot joints of the struts abundantly strong for the purpose. Center.

The reader will perceive that the computation just now given does not state the proportions of the strains *actually exerted* on the different pieces, but the load on the whole, on the supposition that each piece is subjected to a strain proportioned to its strength. The other calculation is much more complicated, but is not necessary here.

This centre has a very palpable defect. If the piers should yield to the load, and the feet of the centre fly out, the lower part will exert a very considerable strain on the stretcher, tending to break it across between N and L, and on the other side. HKF of the lower part is firmly bound together, and cannot change its shape, and will therefore act like a lever, turning round the point F. It will draw the strut HK away from its abutment with GH, and the stretcher will be strained across at the place between H and F, where it is bolted with the bridle. This may be resisted in some degree by an iron strap uniting ON and HK; but there will still be a want of proportional strength. Indeed, in an arch of such height (a semicircle), there is but little risk of this yielding of the piers; but it is an imperfection.

The centre (fig. 2.) is constructed on the same principle precisely for an elliptical arch (A). The calculation of its strength is nearly the same also; only the two upper struts of a side being parallel, the parallelogram Msrv (of fig. 1.) is not needed, and in its stead we measure off on ON a line to represent twice its strength. This comes in place of Mr' of fig. 1.—*N. B.* The calculation proceeds on the supposition that the short straining piece MM makes but one firm body with the king post. Mr Pitot employed this piece (we presume) to separate the heads of the struts, that their obliquity might be lessened thereby: and this is a good thought; for when the angle formed by the struts on each side is very open, the strain on them becomes very great. 12 A centre on the same principles for an elliptical arch.

The stretcher of this frame is scarfed in the middle. Suppose this joint to yield a little, there is a danger of the lower strut ON losing its hold, and ceasing to join in the support: for when the crown sinks by the lengthening of the stretcher, the triangle ORN of fig. 2. will be more distorted than the space above it, and ON will be loosened. But this will not be the case when the sinking of the crown arises from the mere compression of the struts. Nor will it happen at all in the centre, fig. 1. On the contrary, the strut ON will abutt more firmly by the yielding of the foot of ML.

The figure of this arch of Mr Pitot's consists of three arches of circles, each of 60 degrees. As it is elegant, it will not be unacceptable to the artist to have a construction for this purpose.

Make BY = CD, and CZ = $\frac{1}{4}$CY. Describe the semicircle ZÆY, and make ZS = ZÆ. S is the centre of the side arches, each of 60 degrees. The centre T of the 13 How to construct such an arch.

(A) It is the middle arch of the bridge at Lille Adam, of which Mr Pitot had the direction. It is of 80 feet span, and rises 31 feet.

Center. the arch, which unites these two, is at the angle of an equilateral triangle STS.

This construction of Mr Pitot's makes a handsome oval, and very near an ellipsis, but lies a little without it. We shall add another of our own, which coincides with the ellipse in eight points, and furnishes the artist, by the way, a rule for drawing an infinite variety of ovals.

Let AB, DE (fig. 2. N° 2.) be the axes of an ellipse, C the centre, and F, *f* the two foci. Make C*b* = CD, and describe a circle AD*be* passing through the three given points A, D, and *b*. It may be demonstrated, that if from any point P of the arch AD be drawn a chord PD, and if a line PR*r* be drawn, making the angle DPR = PDC, and meeting the two axes in the points R and *r*, then R and *r* will be the centres of circles, which will form a quarter APD of an oval, which has AB and DE for its two axes.

We want an oval which shall coincide as much as possible with an ellipsis? The most likely method for this is to find the very point P where the ellipsis cuts the circle AD*be*. The easiest way for the artist is to describe an arch of a circle *am*, having AB for its radius, and the remote focus *f* for its centre. Then set one foot of the compasses on any point P, and try whether the distance PF from the nearest focus F is exactly equal to its distance P*m* from that circle. Shifting the foot of the compasses from one point of the arch to another, will soon discover the point. This being found, draw PD, make the angle DP*r* = PD*r*, and R and *r* are the centres wanted. Then make C*s* = CR, and we get the centres for the other side.

The geometer will not relish this mechanical construction. He may therefore proceed as follows: Draw D*d* parallel to AB, cutting the circle in *d*. Draw *ed*, cutting AC in N. Draw CG parallel to A*e*, and make the angle CG*i* = AD*e*. Bisect CN in O, and join O*i*. Make OM, OM′ = O*i*, and draw MP, M′P′ perpendicular to AB. These ordinates will cut the circle AD*be* in the points P and P′, where it is cut by the ellipse. We leave the demonstration as a geometrical exercise for the dilettante.

14 Centre for the nave of St Peter's.

We said, that this centering of Mr Pitot's resembled in principle the one employed by Michael Angelo for the nave and transepts of St Peter's church at Rome. Fontana, who has preserved this, ascribes the construction of it to one of the name of San Gallo. A sketch of it is given in fig. 3. It is, however, so much superior, and so different in principle, from that employed for the cupola, that we cannot think it the invention of the same person. It is, like Pitot's, not only divisible, but really divided into two parts, of which the upper carries by much the greatest part of the load. The pieces are judiciously disposed, and every important beam is amply secured against all transverse strains. Its only fault is a great profusion of strength. The innermost polygon *aghb* is quite superfluous, because no strain can force in the struts which rest on the angles. Should the piers yield outwards, this polygon will be loose, and can do no service. Nor is the triangle *gib* of any use, if the king-post above it be strapped to the tie-beam and straining sill. Perhaps the inventor considered the king-post as a pillar, and wished to secure the tie-beam against its cross strain. This centering, however, must be allowed to be very well composed; and we expect that the well-informed reader will join us in preferring it to Mr Pitot's, both for simplicity of principle, for scientific propriety, and for strength.

There is one considerable advantage which may be derived from the actual division of the truss into two parts. If the tie-beam LL, instead of resting on the stretcher EF, had rested on a row of chocks formed like double wedges, placed above each other, head to point, the upper part of the centering might be struck independent of the lower, and this might be done gradually, beginning at the outer ends of the stretcher. By this procedure, the joints of the arch-stones will close on the haunches, and will almost relieve the lower centering, so that all can be pulled out together. Thus may the arch settle and consolidate in perfect safety, without any chance of breaking the bond of the mortar in any part; an accident which frequently happens in great arches. This procedure is peculiarly advisable for low pitched or elliptical arches. But this will be more clearly seen afterwards, when we treat of the internal movements of an arch of masonry.

This may suffice for an account of the more simple construction of trussed centres; and we proceed to such as have a much greater complication of principle. We shall take for examples some constructed by Mr Perronet, a very celebrated French architect.

15 Perronet's maxim of construction.

Mr Perronet's general maxim of construction is to make the truss consist of several courses of separate trusses, independent (as he thinks) of each other, and thus to employ the joint support of them all. In this construction it is not intended to make use of one truss, or part of one truss, to support another, as in the former set, and as is practised in the roofs of St Paul's church, Covent Garden, and in Drury Lane theatre. Each truss spans over the whole distance of the piers, and would stand alone (having, however, a tottering equilibrium). It consists of a number of struts, set end to end, and forming a polygon. These trusses are so arranged, that the angles of one are in the middle of the sides of the next, as when a polygon is inscribed in a circle, and another (of the same number of sides) is circumscribed by lines which touch the circle in the angles of the inscribed polygon. By this construction the angles of the alternate trusses lie in lines pointing towards the centre of the curve. King-posts are therefore placed in this direction between the adjoining beams of the trusses. These king-posts consist of two beams, one on each side of the truss, and embrace the truss-beams between them, meeting in the middle of their thickness. The abutting beams are mortised, half into each half of the post. The other beam, which makes the base of the triangle, passes through the post, and a strong bolt is driven through the joint, and secured by a key or a nut. In this manner is the whole united; and it is expected, that when the load is laid on the uppermost truss, it will all butt together, forcing down the king-posts, and therefore pressing them on the beams of all the inferior trusses, causing them also to abutt on each other, and thus bear a share of the load. Mr Perronet does not assume the invention to himself; but says that it was invented and practised by Mr Mansard de Sagonne at the great bridge of Moulins. It is much more ancient, and is the work of the celebrated physician and architect Perrault; as may be seen in the collection of machines and inventions of that gentleman published after

ter his death, and alſo in the great collection of inventions approved of by the Academy of Sciences. It is this which we propoſe to examine.

16 Centering employed for the bridge of Cravant,

Fig 4. repreſents the centering employed for the bridge of Cravant. The arches are elliptical, of 60 feet ſpan and 20 feet riſe. The archſtones are four feet thick, and weigh 176 pounds per foot. The truſs-beams were from 15 to 18 feet long, and their ſection was 9 inches by 8. Each half of the king poſts was about 7 feet long, and its ſection 9 inches by 8. The whole was of oak. The five truſſes were $5\frac{1}{2}$ feet aſunder. The whole weight of the arch was 1350000 lbs. which we may call 600 tons (it is 558). This is about 112 tons for each truſs. We muſt allow near 90 tons of this really to preſs the truſs. A great part of this preſſure is borne by the four beams which make the feet of the truſs, coupled in pairs on each ſide. The diagonal of the parallelogram of forces drawn for theſe beams is, to one of the ſides, in the proportion of 360 to 285. Therefore ſay, as 360 to 285; ſo is 90 to $71\frac{1}{4}$ tons, the thruſt on each foot. The ſection of each is 144 inches. We may with the utmoſt ſafety lay three tons on every inch for ever. This amounts to 432 tons, which is more than ſix times the ſtrain really preſſing the foot beams in the direction of their length; nay, the upper truſs alone is able to carry much more than its load. The abſolute ſtrength of its foot-beam is 216 tons. It is much more advantageouſly placed; for the diagonal of the parallelogram of forces correſponding to its poſition is to the ſide as 438 to 285. This gives $58\frac{6}{10}$ tons for the ſtrain on each foot; which is not much above the fourth part of what it is able to carry for ever. No doubt can therefore be entertained of the ſuperabundant ſtrength of this centering. We ſee that the upper row of ſtruts is quite ſufficient, and all that is wanted is to procure ſtiffneſs for it; for it muſt be carefully kept in mind, that this upper row is not like an equilibrated arch. It will be very unequally loaded as the work advances. The haunches of the frame will be preſſed down, and the joints at the crown raiſed up. This muſt be reſiſted.

Here then we may gather, by the way, a uſeful leſſon. Let the outer row of ſtruts be appropriated to the carriage of the load, and let the reſt be employed for giving ſtiffneſs. For this purpoſe let the outer row have abundant ſtrength. The advantages of this method are conſiderable. The poſition of the beams of the exterior row is more advantageous, when (as in this example) the whole is made to reſt on a narrow foot; for this obliges us to make the laſt angle, at leaſt of the lower row, more open, which increaſes the ſtrain on the ſtrut; beſides, it is next to impoſſible to diſtribute the compreſſing thruſts among the different rows of the truſs beams; and a beam which, during one period of the maſon work, is acting the part of a ſtrut, in another period is bearing no ſtrain but its own weight, and in another it is ſtretched as a tie. A third advantage is, that, in a caſe like this, where all reſts on a narrow foot, and the lower row of beams are bearing a great part of the thruſt, the horizontal thruſt on the pier is very great, and may puſh it aſide. This is the moſt ruinous accident that can happen. An inch or two of yielding will cauſe the crown of the arch to ſink prodigiouſly, and will inſtantly derange all the bearings of the abutting beams: but when the lower beams already act as ties, and are quite adequate to their office, we render the frame perfectly ſtiff or unchangeable in its form, and take away the horizontal thruſt from the piers *entirely*. This advantage is the more valuable, becauſe the very circumſtance which obliges us to reſt all on a narrow foot, places this foot on the very top of the pier, and makes the horizontal thruſt the more dangerous.

But, to proceed in our examination of the centering of Cravant bridge, let us ſuppoſe that the king poſts are removed, and that the beams are joined by compaſs joints. If the pier ſhall yield in the ſmalleſt degree, both rows of ſtruts muſt ſink; and ſince the angles (at leaſt the outermoſt) of the lower row are more open than thoſe of the upper row, the crown of the lower row will ſink more than that of the upper.

The angles of the alternate rows muſt therefore ſeparate a little. Now reſtore the king poſts; they prevent this ſeparation. Therefore *they are ſtretched*; therefore the beams of the lower row are alſo ſtretched; conſequently they no longer butt on their mortiſes, and muſt be held in their places by bolts. Thus it appears that, in this kind of ſagging, the original diſtribution of the load among the different rows of beams is changed, and the upper row becomes loaded beyond our expectation.

If the ſagging of the whole truſs proceed only from the compreſſion of the timbers, the caſe is different, and we *may* preſerve the original diſtribution of mutual abutment more accurately. But in this caſe the ſtiffneſs of the frame ariſes chiefly from croſs ſtrains. Suppoſe that the frame is loaded with archſtones on each ſide up to the poſts HC, *h c*; the angles E and *e* are preſſed down, and the beams EOF, *e o* F puſh up the point F. This cannot riſe without bending the beams EOF, *e o* F; becauſe O and *o* are held down by the double king poſts, which graſp the beams between them. There is therefore a croſs ſtrain on the beams. Obſerve alſo, that the triangle EHF does not preſerve its ſhape by the connection of its joints; for although the ſtrut beams are mortiſed into the king poſt, they are in very ſhallow mortiſes, rather for ſteadying them than for holding them together. Mr Perronet did not even pin them, thinking that their abutment was very great. The triangle is kept in ſhape by the baſe EF, which is firmly bolted into the middle poſt at O. Had theſe interſections not been ſtrongly bolted, we imagine that the centres of ſome of Mr Perronet's bridges would have yielded much more than they did; yet ſome of them yielded to a degree that our artiſts would have thought very dangerous. Mr Perronet was obliged to load the crown of the centering with very great weights, increaſing them as the work advanced, to prevent the frames from going out of ſhape: in one arch of 120 feet he laid on 45 tons. Notwithſtanding this imperfection, which is perhaps unavoidable, this mode of framing is undoubtedly very judicious, and perhaps the beſt which can be employed without depending on iron-work.

17 For the bridge of Nogent,

Fig. 5. repreſents another, conſtructed by Perronet for an arch of 90 feet ſpan and 28 feet riſe. The truſſes were 7 feet apart, and the arch was $4\frac{1}{2}$ thick; ſo that the unreduced load on each frame was very nearly 235 tons. The ſcantling of the ſtruts was 15 by 12 inches. The principle is the ſame as that of the former. The chief difference is, that in this centre the outer truſs-beam of the lower row is not coupled with the middle row,

Center. row, but kept nearly parallel to the outer beam of the upper row. This adds greatly to the ſtrength of the foot, and takes off much of the horizontal thruſt from the pier.

Mr Perronet has ſhewn great judgment in cauſing the polygon of the inner row of truſs beams gradually to approach the polygon of the outer row. By this diſpoſition, the angles of the inner polygon are more acute than thoſe of the outer. A little attention will ſhew, that the general ſagging of all the polygons will keep the abutments of the lower one nearer, or exactly, to their original quantity. We muſt indeed except the foot beam. It is ſtill too oblique; and, inſtead of converging to the foot of the upper row, it ſhould have diverged from it. Had this been done, this centre is almoſt perfect in its kind. As it is, it is at leaſt ſix times ſtronger than was abſolutely neceſſary. We ſhall have occaſion to refer to this figure on another occaſion.

18 St Maxence, This maxim is better exemplified by Mr Perronet in the centering of the bridge of St Maxence, exhibited in fig. 5. n° 2. than in that of Nogent, fig. 5. n° 1. But we think that a horizontal truſs-beam *a b* ſhould have been inſerted (in a ſubordinate manner) between the king-poſts next the crown on each ſide. This would prevent the crown from riſing while the haunches only are loaded, without impairing the fine abutments of *c d*, *c d*, when the arch is nearly completed. This is an excellent centering, but is not likely to be of much uſe in theſe kingdoms; becauſe the arch itſelf will be conſidered as ungraceful and ugly, looking like a huge lintel. Perronet ſays, that he preferred it to the ellipſe, becauſe it was lighter on the piers, which were thin. But the failure of one arch muſt be immediately followed by the ruin of all. We know much better methods of lightening the piers.

19 Neuilly, and Fig. 6. repreſents the centering of the bridge of Neuilly, near Paris, alſo by Perronet. The arch has 120 feet ſpan, and 30 feet riſe, and is 5 feet thick. The frames are 6 feet apart, and each carries an abſolute (that is, not reduced to $\frac{1}{14}$ or to $\frac{4}{7}$) load of 350 tons. The ſtrut beams are 17 by 14 inches in ſcantling. The king poſts are of 15 by 9 each half; and the horizontal bridles, which bind the different frames together in five places, are alſo 15 by 9 each half. There are eight other horizontal binders of 9 inches ſquare.

This is one of the moſt remarkable arches in the world; not altogether on account of its width (for there are ſeveral much wider), but for the flatneſs at the crown; for about 26 feet on each ſide of the middle it was intended to be a portion of a circle of 150 feet radius. An arch (ſemicircular) of 300 feet ſpan might therefore be eaſily conſtructed, and would be much ſtronger than this, becauſe its horizontal thruſt at the crown would be vaſtly greater, and would keep it more firmly united.

The bolts of this centre are differently placed from thoſe of the former; and the change is judicious. Mr Perronet had doubtleſs found by this time, that the ſtiffneſs of his framing depended on the tranſverſe ſtrength of the beams; and therefore he was careful not to weaken them by the bolts. But notwithſtanding all his care, the framing ſunk upwards of 13 inches before the keyſtones were laid; and during the progreſs of the work, the crown roſe and ſunk, by various ſteps, as the loading was extended along it. When 20 courſes were laid on each ſide, and about 16 tons laid on the crown of each frame, it ſunk about an inch. When 46 courſes were laid, and the crown loaded with 50 tons, it ſunk about half an inch more. It continued ſinking as the work advanced; and when the keyſtone was ſet it had ſunk $13\frac{1}{4}$ inches. But this ſinking was not general; on the contrary, the frame had riſen greatly at the very haunches, ſo as to open the upper part of the joints, many of which gaped an inch; and this opening of the joints gradually extended from the haunches towards the crown, in the neighbourhood of which they opened on the under ſide. This evidently aroſe from a want of ſtiffneſs in the frame. But theſe joints cloſed again when the centres were ſtruck, as will be mentioned afterwards.

We have taken particular notice of the movements and twiſting of this centre, becauſe we think that they indicate a deficiency, not only of ſtiffneſs, but of abutment among the truſs beams. The whole has been too flexible, becauſe the angles are too obtuſe: This ariſes from their multiplicity. When the intercepted arches have ſo little curvature, the power of the load to preſs it inward increaſes very faſt. When the intercepted arch is reduced to one half, this power is more than doubled; and it is alſo doubled when the radius of curvature is doubled. The king-poſts ſhould have been farther apart near the crown, ſo that the quantity of arch between them ſhould compenſate for its diminiſhed curvature.

The power of withſtanding any given inequality of load would therefore have been greater, had the centre conſiſted of fewer pieces, and their angles of meeting been proportionally more acute. The greateſt improvement would have been, to place the foot of the lower tier of truſs-beams on the very foot of the pier, and to have alſo ſeparated it at the head from the reſt with a longer king-poſt, and thus to have made the diſtances of the beams on the king-poſts increaſe gradually from the crown to the ſpring. This would have made all the angles of abutment more acute, and would have produced a greater preſſure on all the lower tiers when the frame ſagged.

Fig. 7. repreſents the centering of the bridge of Orleans. The arch has 100 feet ſpan, and riſes 30, and the arch-ſtones are 6 feet long. It is the conſtruction of Mr Hupeau, the firſt architect of the bridge. It is the boldeſt work of the kind that we have ſeen, and is conſtructed on clear principles. The main abutments are few in number. Becauſe the beams of the outer polygon are long, they are very well ſupported by ſtraining beams in the middle; and the ſtruts or braces which ſupport and butt on them, are made to reſt on points carried entirely by *ties*. The inventor, however, ſeems to have thought that the angles of the inner polygon were ſupported by mutual compreſſion, as in the outer polygon. But it is plain that the whole inner polygon may be formed of iron rods. Not but that both polygons *may* be in a ſtate of compreſſion (this is very poſſible); but the ſmalleſt ſagging of the frame will change the proportions of the preſſures at the angles of the two polygons. The preſſures on the exterior angles will increaſe, and thoſe on the lower or interior angles will diminiſh moſt rapidly; ſo that the abutments in the lower polygon will be next to nothing. 20 Orleans.

Center.

thing. Such points could bear very little preſſure from the braces which ſupport the middle of the long bearings of the upper beams, and their preſſures muſt be borne chiefly by the joints ſupported by the king-poſts. The king-poſts would then be in a ſtate of extenſion. It is difficult, however, to decide what is the preciſe ſtate of the preſſure at theſe interior angles.

21 Inſtructive hiſtory of this centre.

The hiſtory of the erection of this bridge will throw much light on this point, and is very inſtructive. Mr Hupeau died before any of the arches were carried farther than a very few of the firſt courſes. Mr Perronet ſucceeded to the charge, and finiſhed the bridge. As the work advanced, the crown of the frame roſe very much. It was loaded; and it ſunk as remarkably. This ſhewed that the lower polygon was giving very little aid. Mr Perronet then thought the frame too weak, and inſerted the long beam DE, making the diagonal of the quadrangle, and very nearly in the direction of the lower beam *a b*, but falling rather below this line. He now found the frame abundantly ſtrong. It is evident that the truſs is now changed exceedingly, and conſiſts of only the two long ſides, and the ſhort ſtraining beam lying horizontally between their heads. The whole centering conſiſts now of one great truſs *a* E *e b*, and its long ſides *a* E, *e b*, are truſſed up at B and *f*. Had this ſimple idea been made the principle of the conſtruction, it would have been excellent. The angle *a* DE might have been about 176°, and the polygon D *c h g* employed only for giving a ſlight ſupport to this great angle, ſo as not to allow it to exceed 180°. But Mr Perronet found, that the joint *c*, at the foot of the poſt E *c*, was about to *draw looſe*, and he was obliged to bolt long pieces of timber on each ſide of the joint, embracing both beams. Theſe were evidently acting the ſame part as iron ſtraps would have done; a complete proof that, whatever may have been the original preſſures, there was no abutment now at the point *c*, and that the beams that met there were not in a ſtate of compreſſion, but were on the ſtretch. Mr Perronet ſays that he put theſe cheeks to the joints *to ſtiffen* them. But this was not their office; becauſe the adjoining beams were not ſtruts, but ties, as we have now proved.

We may therefore conclude, that the outer polygon, with the aſſiſtance of the pieces *a b*, DE, were carrying the whole load. We do not know the diſtance between the frames; but ſuppoſing them ſeven feet apart, and the arch 6 feet thick, and weighing 170 pounds per foot, we learn the load. The beams were 16 inches ſquare. If we now calculate what they would bear at the ſame very moderate rate allowed to the other centres, we find that the beams AB and *a b* are not loaded to one-ſixth of their ſtrength.

We have given this centre as a fine example of what carpentry is able to perform, and becauſe, by its ſimplicity, it is a ſort of text on which the intelligent artiſt may make many comments. We may ſee plainly that, if the lower polygon had been formed of iron rods, firmly bolted into the feet of the king-poſts, it would have maintained its ſhape completely. The ſervice done by the beam DE was not ſo much an increaſe of abutment as a diſcharge of the weight and of the *pull* at the joint *c*. Therefore, in caſes where the feet of the truſs are *neceſſarily* confined to a very narrow ſpace, we ſhould be careful to make the upper polygon ſufficient to carry the whole load (ſay by doubling its beams), and we may then make the lower polygon of ſlender dimenſions, provided we ſecure the joints on the king-poſts by iron ſtraps which embrace a conſiderable portion of the tie on each ſide of the joint.

Center.

22 All theſe centres good in their kind.

We are far from thinking that theſe centres are of the beſt kind that could be employed in their ſituation; but they are excellent in their kind: and a careful ſtudy of them will teach the artiſt much of his profeſſion. When we have a clear conception of the ſtate of ſtrain in which the parts of a frame really are, we know what ſhould be done in order to draw all the advantage poſſible from our materials. We have ſaid in another place, that where we can give our joints ſufficient connection (as by ſtraps and bolts, or by cheeks or fiſhes), it is better to uſe ties than ſtruts, becauſe ties never bend.

We do not approve of Mr Perronet's practice of giving his truſſes ſuch narrow feet. By bringing the foot of the lower polygon farther down, we greatly diminiſh all the ſtrains, and throw more load on the lower polygon: and we do not ſee any of Mr Perronet's centres where this might not have been done. He ſeems to affect a great ſpan, to ſhew the wonders of his art; but our object is to teach how to make the beſt centre of a given quantity of materials; and how to make the moſt perfect centre, when we are not limited in this reſpect, nor in the extent of our fixed points.

23 Excellence of the centre employed for Blackfriars bridge.

We ſhall conclude this ſeries of examples with one where no ſuch affectation takes place. This is the centering of the bridge at Blackfriars, London. The ſpan of the arch is 100 feet, and its height from the ſpring is about 43. The drawing fig. 8. is ſufficiently minute to convey a diſtinct notion of the whole conſtruction. We need not be very particular in our obſervations, after what has been ſaid on the general principles of conſtruction. The leading maxim, in the preſent example, ſeems to be, *that every part of the arch ſhall be ſupported by a ſimple truſs of two legs reſting, one on each pier*. H, H, &c. are called APRON PIECES, to ſtrengthen the exterior joints and to make the RING as ſtiff in itſelf as poſſible. From the ends of this apron-piece proceed the two legs of each truſs. Theſe legs are 12 inches ſquare: They are not of an entire piece, but of ſeveral, meeting in firm abutment. Some of their meetings are ſecured by the double king-poſts, which graſp them firmly between them, and are held together by bolts. At other interſections, the beams appear halved into each other; a practice which cannot but weaken them much, and would endanger their breaking by croſs ſtrains, if it were poſſible for the frame to change its ſhape. But the great breadth of this frame is an effectual ſtop to any ſuch change. The fact was, that *no ſinking or twiſting whatever* was obſerved during the progreſs of the maſon work. Three points in a ſtraight line were marked on purpoſe for this obſervation, and were obſerved every day The arch was more than ſix feet thick; and yet the ſinking of the crown, before ſetting the key-ſtones, did not amount to one inch.

The centre employs about one-third more timber than Perronet's great centre in proportion to the ſpan of the arch; but the circumference increaſes in a greater proportion than this, becauſe it is more elevated. In every way of making a compariſon of the dimenſions, Mr Mylne's arch employs more timber; but it

Center.

it is *beyond all comparison* ſtronger. The great elevation is partly the reaſon of this. But the diſpoſition of the timbers is alſo much more advantageous, and may be copied even in the low pitched arches of Neuilly. The ſimple truſs, reaching from pier to pier for the middle point of the arch, gives the ſtrong ſupport where it is moſt of all wanted; and in the lateral points H, although one leg of the truſs is very oblique, the other compenſates for it by its upright poſition.

The chief peculiarity of this centre is to be ſeen in its baſe. This demands a more particular attention: but we muſt firſt make ſome obſervations on the condition of an arch, as it reſts on the centering after the keyſtones are all ſet, and on the gradual transference of the preſſure from the boards of the centering to the joints of the archſtones.

24 Obſervations on the ſtate of an arch as it reſts on the centering.

While all the archſtones lie on the centering, the lower courſes are alſo leaning pretty ſtrongly on each other. But the mortar is hardly compreſſed in the joints; and leaſt of all in the joints near the crown. Suppoſe the arch to be catenarian, or of any other ſhape that is perfectly equilibrated: When the centering is gradually withdrawn, all the archſtones follow it. Their wedge-like form makes this impoſſible, without the middle ones ſqueezing the lateral ones aſide. This compreſſes the mortar between them. As the ſtones thus come nearer to each other, thoſe near the crown muſt deſcend more than thoſe near the haunches, before every ſtone has leſſened its diſtance from the next by the ſame quantity; for example, by the hundredth part of an inch. This circumſtance alone muſt cauſe a ſinking in the crown, and a change of ſhape. But the joints near the crown are *already* more open than thoſe near the haunches. This produces a ſtill greater change of form before all is ſettled. Some maſons endeavour to remedy, or at leaſt to diminiſh, this, by uſing no mortar in the joints near the crown. They lay the ſtones dry, and even force them together by wedges and blocks laid between the ſtones on oppoſite ſides of the crown: They afterwards pour in fine cement. This appears a good practice. Perronet rejects it, becauſe the wedging ſometimes breaks the ſtones. We ſhould not think this any great harm; becauſe the fracture will make them cloſe where they would otherwiſe lie hollow. But, after all our care, there is ſtill a ſinking of the crown of the arch. By gradually withdrawing the centering, the joints cloſe, the archſtones begin to butt on each other, and to force aſide the lateral courſes. This abutment gradually increaſing, the preſſure on the haunches of the centering is gradually diminiſhed by the mutual abutment, and ceaſes entirely in that courſe, which is the loweſt that formerly preſſed it: it then ceaſes in the courſe above, and then in the third, and ſo on. And, in this manner, not only the centering quits the arch, gradually, from the bottom to the top, *by its own retiring from it*, but the arch alſo quits the centering *by changing its ſhape*. If the centering were now puſhed up again, it would touch the arch firſt at the crown; and it muſt *lift up* that part gradually before it come again in contact with the haunches. It is evident, therefore, that an arch, built on a centre of a ſhape perfectly ſuited to equilibration, will not be in equilibrio when the centering is removed. It is therefore neceſſary to form the centering in ſuch a manner (by raiſing the crown), that it ſhall *leave* the arch of a proper form. This is a very delicate taſk, requiring a previous knowledge of the enſuing change of form. This cannot be aſcertained by the help of any theory we are acquainted with.

But, ſuppoſe this attained, there is another difficulty: While the work advances, the centering is warped by the load laid on it, and continually increaſing on each ſide. The firſt preſſure on the centering forces down the haunches, and raiſes the crown. The arch is therefore leſs curved at the haunches than is intended: the joints, however, accommodate themſelves to this form, and are cloſe, and filled with mortar. When the maſons approach the middle of the arch, the frame ſinks there, and riſes up at the haunches. This opens all the joints in that place on the *upper* ſide. By the time that the keyſtones are ſet, this warping has gone farther; and joints are opened on the *under* ſide near the crown. It is true we are here ſpeaking rather of an extreme caſe, when the centering is *very* flexible; but this occurred to Mr Perronet in the two great bridges of Neuilly and of Mantz. In this laſt one, the crown ſunk above a foot before the key was ſet, and the joints at the haunches opened above an inch *above*, while ſome nearer the crown opened near a quarter of an inch *below*.

25 A delicate buſineſs to ſtrike the centering.

In this condition of things, it is a delicate buſineſs to ſtrike the centering. Were it removed in an inſtant, all would probably come down; for the archſtones are not yet abutting on each other, and the joints in the middle are open below. Mr Perronet's method appears to us to be very judicious. He began to detach the centering at the very bottom, on each ſide equally, where the preſſure on the centering is very ſlight. He cut away the blocks which were immediately under each archſtone. He proceeded gradually upwards in this way with ſome ſpeed, till all was detached that had been put out of ſhape by the bending of the centering. This being no longer ſupported, ſunk inward, till it was ſtopped by the abutment which it found on the archſtones near the crown, which were ſtill reſting on their blocks. During part of this proceſs, the open joints opened ſtill more, and looked alarming. This was owing to the removal of the load from the haunches of the centering. This allowed the crown to ſink ſtill more, by forcing out the arch ſtones at the haunches. He now pauſed ſome days; and during this time the two haunches, now hanging in the air, gradually preſſed in toward the centering, their outer joints cloſing in the meanwhile. The haunches were now preſſing pretty hard on the archſtones nearer the crown. He then proceeded more ſlowly, deſtroying the blocks and bridgings of theſe upper archſtones. As ſoon as he deſtroyed the ſupport of one, it immediately yielded to the preſſure of the haunch; and if the joint between it and the one adjoining toward the crown happened to be open, whether on the under or the upper ſide, it immediately cloſed on it. But in proceeding thus, he found every ſtone ſink a little while it cloſed on its neighbour; and this was like to produce a ragged ſoffet, which is a deformity. He therefore did not allow them to ſink ſo much. In the places of the blocks and bridgings which he had cut away, he ſet ſmall billets, ſtanding on their ends, between the centering and the archſtones. Theſe allowed the pendulous arch to puſh toward the crown without ſenſibly deſcending; for the billets were puſhed out of the perpendicular, and ſome of them tumbled down. Proceeding

Center. ing in this way, he advanced to the very next courſe to the keyſtone on each ſide, the joints cloſing all the way as he advanced. The laſt job was very troubleſome; we mean the detaching the three uppermoſt courſes from the centering: for the whole elaſticity of the centering was now trying to unbend, and preſſing hard againſt them. He found that they were lifted up; for the joints beyond them, which had cloſed completely, now opened again below; but this job was finiſhed in one day, and the centre ſprung up two or three inches, and the whole arch ſunk about ſix inches. This was an anxious time; for he dreaded the great momentum of ſuch a vaſt maſs of matter. It was hard to ſay where it would ſtop. He had the pleaſure to ſee that it ſtopped very ſoon, ſettling ſlowly as the mortar was compreſſed, and after one or two days ſettling no more. This ſettling was very conſiderable both in the bridge at Neuilly and in that at Mautz. In the former, the ſinking during the work amounted to 13 inches. It ſunk ſix inches more when the blocks and bridgings were taken out, and $1\frac{1}{2}$ when the little ſtandards were deſtroyed, and $1\frac{1}{4}$ more next day; ſo that the whole ſinking of the *pendulous* arch was $9\frac{1}{2}$ inches, beſides what it had ſunk by the bending and compreſſion of the centering.

The crown of the centering was an arch of a circle deſcribed with a radius of 150 feet; but by the ſinking of the arch its ſhape was conſiderably changed, and about 60 feet of it formed an arch of a circle whoſe radius was 244 feet. Hence Mr Perronet infers, that a ſemicircle of 500 feet ſpan may be erected. It would no doubt be ſtronger than this arch, becauſe its greater horizontal thruſt would keep the ſtones firmer together. The ſinking of the arches at Mantz was not quite ſo great, but every thing proceeded in the ſame way. It amounted in all to $20\frac{1}{2}$ inches, of which 12 inches were owing to the compreſſion and bending of the centering.

26 The foregoing obſervations exemplified.

In fig. 5. n° 1. may be obſerved an indication of this procedure of the maſonry. There may be noticed a horizontal line *a c*, and a diagonal *a b*. Theſe are ſuppoſed to be drawn on the maſonry as it would have ſtood had the frames not yielded during the building. The dotted line A*b′ c′* ſhews the ſhape which it took by the ſinking of the centering. The dotted line on the other ſide was actually drawn on the maſonry when the keyſtone was ſet; and the wavy black line on the ſame ſide ſhews the form which the dotted line took by the ſtriking of the centering. The undulated part of this line cuts its former poſition a little below the middle, going without it below, and falling within it above. This ſhews very diſtinctly the movement of the whole maſonry, diſtinguiſhing the parts that were forced out and the parts which ſunk inward.

We preſume that the practical reader will think this account of the internal movements of a ſtupendous arch very inſtructive and uſeful. As Mr Perronet obſerved it to be uniformly the ſame in ſeveral very large arches which he erected, we may conclude that it is the general proceſs of nature. We by no means have the confidence in the durability or ſolidity of his arches which he prudently profeſſes to have. We have converſed with ſome very experienced maſons, who have alſo erected very great arches, and in very difficult ſituations, which have given univerſal ſatisfaction; and we have found them uniformly of opinion, that an arch which has ſettled to ſuch a proportion of its curvature as to change the radius from 150 to 244 feet, is in a very hazardous ſituation. They think the hazard the greater, becauſe the ſpan of the arch is ſo great in proportion to its weight (as they expreſs it very emphatically) or its height. The weight, ſay they, of the haunches is too ſmall for forcing together the keyſtones, which have ſcarcely any wedge-like form to keep them from ſliding down. This is very good reaſoning, and expreſſes very familiar notions. The mechanician would ſay, that the horizontal thruſt at the crown is too ſmall. When we queſtioned them about the propriety of Mr Perronet's method of removing the centering, they unanimouſly approved of its general principle, but ſaid that it was very tickliſh indeed in the execution. The caſes which he narrates were new to them. They ſhould have almoſt deſpaired of ſucceſs with arches which had gone ſo much out of ſhape by the bending of the centres; becauſe, ſaid they, the ſlope of the centering, to a great diſtance from the crown, was ſo little, that the archſtones could not ſlide outwards along it, to cloſe even the under ſide of the joints which had opened above the haunches; ſo that *all* the archſtones were at too great a diſtance from each other; and a great and *general* ſubſiding of the whole was neceſſary for bringing them even to touch each other. They had *never* obſerved ſuch bendings of the centerings which they had employed, having never allowed themſelves to contract the feet of their truſſes into ſuch narrow ſpaces. They obſerved, that nothing but lighters with their maſts down can paſs under the truſſes, and that the ſides muſt be ſo protected by advanced works from the accidental ſhock of a loaded boat, that there cannot be left room for more than one. They added, that the bridges of communication, neceſſary for the expeditious conducting of the work, made all this ſuppoſed roomineſs uſeleſs: beſides, the buſineſs can hardly be ſo urgent and crowded anywhere, as to make the paſſage through every arch indiſpenſably neceſſary. Nor was the inconvenience of this obſtruction greatly complained of during the erection of Weſtminſter or Blackfriars bridges. Nothing ſhould come in competition with the *undoubted* ſolidity of the centering and the future arch; and all boaſting diſplay of talent and ingenuity by an engineer, in the exhibition of the wonders of his art, is miſplaced here.

Theſe appeared to us good reaſons for preferring the more cautious, and incomparably more ſecure, conſtruction of Mr Mylne, in which the breadth given to each baſe of the truſſes permitted a much more effective diſpoſition of the abutting timbers, and alſo enabled the engineer to make it incomparably ſtiffer; ſo that no change need be apprehended in the joints which have already cloſed, and in which the mortar has already taken its ſet, and commenced an union that never can be reſtored if it be once broken in the ſmalleſt degree, no not even by greater compreſſion.

Here we beg leave to mention our notions of the connection that is formed by mortar compoſed of lime or gypſum. We conſider it as conſiſting chiefly, if not ſolely, in a cryſtallization of the lime or gypſum and water. As much water is taken up as is neceſſary for the formation of the cryſtals during their gradual converſion into mild calcareous earth or alabaſter, and the reſt evaporates. When the free acceſs of air is abſolutely 27 The connection that is formed by mortar of lime, &c.

Center.

lutely prevented, the cryſtallization never proceeds to that ſtate, even although the mortar becomes extremely dry and hard. We had an opportunity of obſerving this accidentally, when paſſing through Maeſtricht in 1770, while they were cutting up a maſſy revetment of a part of the fortifications more than 300 years old. The mortar between the bricks was harder than the bricks (which were Dutch clinkers, ſuch as are now uſed only for the greateſt loads); but when mixed with water it made it lime water, ſeemingly as ſtrrong as if freſh lime had been uſed. We obſerved the ſame thing in one ſmall part of a huge maſs of ancient Roman work near Romney in Kent; but the reſt, and all the *very old* mortar that we have ſeen, was in a mild ſtate, and was generally much harder than what produced any lime-water. Now when the mortar in the joints has begun its firſt cryſtallization, and is allowed to remain in perfect reſt, we are confident that the ſubſequent cryſtals, whether of lime, or of calcareous earth, or of gypſum, will be much larger and ſtronger than can ever be produced if they are once broken; and the farther that this cryſtallization has been carried, that is, the harder that the mortar has become, leſs of it remains to take any new cryſtallization. Why ſhould it be otherwiſe here than in every other cryſtallization that we are acquainted with?

28 Neceſſity of keeping the joints in their firſt ſtate.

We think therefore that it is of great conſequence to keep the joints in their *firſt* ſtate if poſſible; and that the ſtrength (as far as it depends on the mortar) is greatly diminiſhed by their opening; eſpecially when the mortar has acquired conſiderable hardneſs, which it will do in a month or ſix weeks, if it be good. The cohesion given by mortar is indeed a mere trifle, when oppoſed to a force which tends to open the joints, acting, as it generally does, with the tranſverſe force of a lever: but in ſituations where the overload on any particular archſtones tends to puſh them down through between their neighbours, like wedges, the coheſion of the mortar is then of very great conſequence.

We muſt make another obſervation. Mr Perronet's ingenious proceſs tended very effectually to cloſe the joints. It doing this, the forces which he brought into action had little to oppoſe them; but as ſoon as they were cloſed, the contact of the parts formerly open oppoſed an obſtruction incomparably greater, and immediately balanced a force which was but juſt able to turn the ſtone gently about the two edges in which it touched the adjoining ſtones. This is an important remark, though ſeemingly very trifling; and we wiſh the practitioner to have a very clear conception of it; but it would take a multitude of words to explain it. It is worth an experiment. Form a little arch of wooden blocks; and form one of theſe ſo, that when they are all reſting on the centering, it may be open at the outer joint—Remove the centering—Then preſs on the arch at ſome diſtance from the open joint.—You will find that a very ſmall preſſure will make the arch bend till that joint cloſes.—Preſs a little harder, and the arch will bend more, and the next joint will open.—Thus you will find that, by preſſing alternately on each ſide of the open joint, that ſtone can eaſily be made to flap over to either ſide; and that immediately after this is done the reſiſtance increaſes greatly. This ſhews clearly, that a very moderate force, judiciouſly employed, will cloſe the joints, but will not preſs the parts ſtrongly together. The joints therefore are *cloſed*, but *no more than cloſed*, and are hanging only by the edges by which they were hanging while the joints were open. The arch, therefore, though apparently cloſe and firm, is but looſe and tottering. Mr Perronet ſays, that his arches were firm, becauſe hardly a ſtone was obſerved to chip or ſplinter off at the edges by the ſettlement. But he had done every thing to prevent this, by digging out the mortar from between the headers, to the depth of two inches, with ſaws made on purpoſe. But we are well informed, that before the year 1791 (twenty years after the erection) the arches at Neuilly had ſunk very ſenſibly, and that very large ſplinters had flewn off in ſeveral places. It could not be otherwiſe. The original conſtruction was too bold; we may ſay needleſsly and oſtentatiouſly bold. A very gentle ſlope of the roadway, which would not have ſlackened the mad gallop of a ducal carriage, nor ſenſibly checked the laborious pull of a loaded waggon, and a proper difference in the ſize of the arches, would have made this wonderful bridge incomparably ſtronger and alſo much more elegant and pleaſing to the eye. Indeed, it is far from being as handſome as it might have been. The ellipſe is a moſt pleaſing figure to every beholder; but this is concealed as much as poſſible, and it is attempted to give the whole the appearance of a tremendous lintel. It has the oppreſſive look of danger. It will not be of long duration. The bridge at Mantz is ſtill more exceptionable, becauſe its piers are tall and ſlender. If any one of the arches fails, the reſt muſt fall in a moment. An arch of Blackfriars Bridge might be blown up without diſturbing its neighbours.

29 Mr Perronet's conſtructions too bold.

30 A bad method of ſtriking the centre.

Mr Perronet mentions another mode of ſtriking the centering, which he ſays is very uſual in France. Every ſecond bridging is cut out. Some time after, every ſecond of the remainder; after this, every ſecond of the remainder; and ſo on, till all are removed. This is never practiſed in this country, and is certainly a very bad method. It leaves the arch hanging by a number of diſtant points; and it is wonderful that any arch can bear this treatment.

31 The common method in Britain.

Our architects have generally proceeded with extreme caution. Wherever they could, they ſupported the centering by intermediate pillars, even when it was a truſſed centre, having a tie-beam reaching from ſide to ſide. The centre was made to reſt, not immediately on theſe pillars, but on pieces of timber formed like acute wedges, placed in pairs, one above the other, and having the point of the one on the thick end of the other. Theſe wedges were well ſoaped and rubbed with black lead, to make them ſlippery. When the centres are to be ſtruck, men are ſtationed at each pair of the wedges with heavy malls. They are directed to ſtrike together on the oppoſite wedges. By this operation, the whole centering deſcends together; or, when any part of the arch is obſerved to have opened its joints on the upper ſide, the wedges below that part are ſlackened. The framing may perhaps bend a little, and allow that part to ſubſide. If any part of the arch is obſerved to open its joints on the under ſide, the wedges below that part are allowed to ſtand after the reſt have been ſlackened. By this proceſs, the whole comes down gradually, and as ſlowly as we pleaſe, and the defects of every part of the arch may be attended to. Indeed the caution and moderation of our builders have commonly been ſuch, that few

Center.

few defects have been allowed to shew themselves. We are but little acquainted with joints opening to the extent of two inches, and in such a case would probably lift every stone of the arch again (B). We have not employed trussed centerings so much perhaps as we should have done; nor do we see their advantage (speaking as mere builders) over centres supported all over, and unchangeable in their form. Such centres must bend a little, and require loading on the middle to keep them in shape. Their compression and their elasticity, are very troublesome in the striking of the centres in Mr Perronet's manner. The elasticity is indeed of use when the centres are struck in the way now described.

These observations on the management of the internal movements of a great arch will enable the reader to appreciate all the merit of Mr Mylne's very ingenious construction. We proceed therefore to complete our description.

The gradual enlargement of the base of the piers of Blackfriars bridge enabled the architect to place a series of five posts *c*, *c*, *c*, *c*, *c*, one on each stap of the pier; the ingenious contexture of which made it like one solid block of stone (see ARCH, *Supplement*). These struts

32 The excellence of Mr Mylne's method.

were gradually more and more oblique, till the outer one formed an obtuse angle with the lowest side of the interior polygon of the truss. On the top of these posts was laid a sloping SEAT or beam D of stout oak, the upper part of which was formed like a zig-zag scarfing. The posts were not perpendicular to the under side of the seat. The angles next the pier were somewhat obtuse. Short pieces of wood were placed between the heads of the posts (but not mortised into them), to prevent them from slipping back. Each face of the scarf was covered with a thick and smooth plate of copper. The feet of the truss were mortised into a similar piece F, which may be called the SOLE of the truss, having its lower side notched in the same manner with the upper side of D, and like it covered with copper. Between these two lay the STRIKING WEDGE E, the faces of which corresponded exactly with the slant faces of the seat and the sole. The wedge was so placed, that the corresponding faces touched each other for about half of their length. A block of wood was put in at the broad end or base of this wedge, to keep it from slipping back during the laying the arch-stones. Its outer end E was bound with iron, and had an iron bolt several inches long driven into it. The head of this bolt was broad enough to cover the whole wood of the wedge within the iron ferule.

We presume that the reader, by this time, foresees the use of this wedge. It is to be driven in between the sole and the seat (having first taken out the block at the base of the wedge). As it advances into the wider spaces, the whole truss must descend, and be freed from the arch; but it will require prodigious blows to drive it back. Mr Mylne did not think so, founding his expectation on what he saw in the launching of great ships, which slide very easily on a slope of 10 or 12 degrees. He rather feared, that taking out the block behind would allow the wedge to be pushed back at once, so that the descent of the truss would be too rapid. However, to be certain of the operation, he had prepared an abundant force in a very ingenious manner. A heavy beam of oak, armed at the end with iron, was suspended from two points of the centre like a battering ram, to be used in the same manner. Nothing could be more simple in its structure, more powerful in its operation, or more easy in its management. Accordingly the success was to his wish. The wedge did not slip back of itself; and very moderate blows of the ram drove it back with the greatest ease. The whole operation was over in a very few minutes. The spectators had suspected, that the space allowed for the recess of the wedge was not sufficient for the settlement of the arch; but the architect trusted to the precautions he had taken in its construction. The reader, by turning to the article ARCH in this *Supplement*, will see that there was only the arch LY which could be expected to settle: accordingly, the recess of the wedge was found to be much more than was necessary. However, had this not been the case, it was only necessary to take out the pieces between the posts below the seat, and then to drive back the heads of the struts; but this was not needed (we believe) in any of the arches. We are well assured that none of the arches sunk an inch and a half. The great arch of 100 feet span did not sink one inch at the crown. It could hardly be perceived whether the arch quitted the centering gradually or not, so small had been the changes of shape.

33 The great superiority of the centering used by him.

We have no hesitation in saying, that (if we except some waste of great timber by uncommon joggling) the whole of this performance is the most perfect of any that has come to our knowledge. We doubt not but that several have equalled it, or may have excelled it; but we do not know of them: and we think that the bringing forward such performances is no less serviceable to the public, than it is honourable to the inventor. Nor do we suppose that any views of interest can be so powerful as to prevent an ingenious architect from communicating to the public such honourable specimens of his own talents. We should be happy to communicate more of this kind; for we consider it as a very important article of practical mechanics, and think that it is of consequence to the nation that it should be very generally understood. In every corner of the country bridges are to be built—we have everywhere good *masons*, who are fully able to execute any practicable project, but too little acquainted with principle to invent, or to accommodate even what they know to local circumstances, and are very apt to be duped by appearances of ingenuity, or misled by erroneous notions of the strains which are excited. We profess more science, and

(B) The writer of this article can only say, that, after much inquiry, he has no information of any arch being received from the builder as sufficient that had suffered half the change of shape mentioned by Mr Perronet. The arch of Dublin bridge, built by an excellent, but a very private, mason, Mr Steeven, is 105 feet wide, with only 22 feet of rise. It was erected (but not on a trussed centering) without changing one full inch in its elevation; and when the centering was removed, it sunk only $1\frac{1}{4}$th inches, and about half an inch more when the parapets were added and the bridge completely finished.

and to treat the ſubject with the aſſiſtance of accurate principles: But while we are certain that every circumſtance is ſuſceptible of the moſt accurate determination, we muſt acknowledge that we have by no means attained an accurate knowledge of all the ſtrains which are produced and excited in a frame of carpentry, which is ſettling and changing its ſhape, even though it be not very complicated; far leſs are we poſſeſſed of a clear view of what happens in a maſs of maſonry in ſimilar conditions. Therefore, though we ſpeak with the ſtrong belief of our being right, we ſpeak with a ſenſe of our fallibility, and with great deference to the judgment of eminent and experienced architects and engineers. We ſhould conſider their free and candid criticiſms as the higheſt favour; and we even ſolicit them, with aſſurances of thanks, and that we will take ſome opportunity, before the cloſe of this work, to acknowledge and correct our miſtakes. We even preſume to hope, that the liberal-minded artiſt will be pleaſed with this opportunity which we give him of increaſing the national ſtock of knowledge. Let mutual jealouſy and rivalſhip reign in the breaſts, and prompt the exertions, of our reſtleſs neighbours on the continent—let them think that the dignity of man conſiſts in perpetual warfare, in which every individual feels himſelf indebted only to himſelf, freed from all the ſweet ties of domeſtic partiality, of friendſhip, and of patriotic attachment. We hope that the hearts of Britons will long continue to be warmed and *fortified* by the thoughts of mutual aſſiſtance, mutual co-operation, mutual attachment, and a patriotic preference of their countrymen to all other men. While theſe ſentiments are regulated by unſhaken honeſty, by candour, and by Chriſtian charity, we ſhall be ſecured from the *errors* of partial attachments, and yet enjoy all the pleaſures of unſophiſticated nature. Families will ſtill be bound together by the affectionate ties of blood; and the whole frame of Britiſh ſociety will be in harmony with the bonds which connect the members of each family, by their endleſs croſſings and intermixings. In this ſtate, the ſtate of ſocial nature, the man of talents will not lock up all the fruits of his exertions in his own breaſt, but will feel a pleaſure in imparting them to a ſociety that is dear to him, and on which he depends for all his beſt enjoyments. Nothing will hold the good man back when this is in his power, but the virtuous uſe which he can make of his ſuperiority in the diſcharge of his own little circle of duties. This is all that is required of true patriotiſm; and it is not too much to be expected from Britons, who feel a pleaſure in viewing their country as the great ſchool of the arts, under the patronage of a ſovereign who has done more for their improvement than all the other princes of Europe, and who (we are well aſſured) is now meditating a plan which muſt be highly gratifying to every eminent profeſſor of the arts.

34 The ſubject of this article connected with the conſtruction of wooden bridges.

THE ſubject which we have been conſidering is very cloſely connected with the conſtruction of wooden bridges. Theſe are not always conſtructed on the ſole principles of equilibrium, by means of mutual abutment. They are ſtiff frames of carpentry, where, by a proper diſpoſition, beams are put into a ſtate of extenſion, as well as of compreſſion, ſo as to ſtand in place of ſolid bodies as big as the ſpaces which the beams encloſe; and thus we are enabled to couple two, three, or four of theſe together, and ſet them in abutment with each other like mighty arch-ſtones. We ſhall cloſe this article, therefore, with two or three ſpecimens of wooden bridges, diſpoſed in a ſeries of progreſſive compoſition, ſo as to ſerve as a ſort of introduction to the art in general, and furniſh a principle which will enable the intelligent and cautious artiſt to puſh it with confidence as far as it can go.

The general problem is this. Suppoſe that a bridge is to be thrown over the ſpace AB (fig. 9.), and that this is too wide for the ſtrength of the ſize of timber which is at our command; how may this beam AB be ſupported with ſufficient effect? There are but two ways in which the middle point C (where the greateſt ſtrain is) can be ſupported: 1. It may be ſuſpended by two ropes, iron rods, or wooden ties, DC, EC, made faſt to two firm points, D, E, above it; or it may reſt on the ridge of two rafters *d*C, *e*C, which reſt on two firm points *d*, *e*, below it 2. It may be ſupported by connecting it with a point ſo ſupported; and this connection may be formed, either by ſuſpending it from this point, or by a poſt reſting on it. Thus it may hang, by means of a rod or a king-poſt FC, from the ridge F of two rafters AF, BF; or it may reſt on the ſtrut C*f*, whoſe lower extremity *f* is carried by the ropes, rods, or wooden ties A*f*, B*f*. Plate XVII.

Whichſoever of theſe methods we employ, it follows, from the principles of carpentry, that the ſupport given to the point C is ſo much the more powerful, as we make the angle DCE, or *d*C*e*, or the equivalent angles AFB, or A*f*B, more acute.

Each of theſe methods may be ſuppoſed equally ſtrong. Our choice will depend chiefly on the facility of finding the proper points of ſupport D, E, *d*, *e*; except in the ſecond caſe, where we require no fixed points but A and B. The ſimple forms of the firſt caſe require a great extent of figure. Very rarely can we ſuſpend it from points ſituated as D and E. It is even ſeldom that we have depth enough of bank to allow the ſupport of the rafters *d*C, *e*C; but we can always find room for the ſimple truſs AFB. This therefore is the moſt uſually practiſed.

35 The uſual and ſimpleſt method of conſtructing ſuch bridges.

In the conſtruction, we muſt follow the maxims and directions preſcribed in the article CARPENTRY of this volume, and the article ROOF of the *Encycl.* The beams FA, FB muſt be mortiſed into AB, in the firmeſt manner, and there ſecured with ſtraps and bolts; and the middle muſt hang by a ſtrap attached to the king-poſt FC, or to the iron rod that is uſed for a king-poſt. No mortiſing in the point C muſt be employed; it is unneceſſary, and it is hurtful, becauſe it weakens the beam, and becauſe it lodges water, and ſoon decays by rot. The beſt practice is not to ſuſpend the beam immediately by this ſtrap, but to let it reſt, as in fig. 10. on a beam C, which croſſes the bridge below, and has its other end ſupported in the ſame manner by the other truſs.

It is evident that the length of the king-poſt has no effect on the ſupport of C. We may therefore contract every thing, and preſerve the ſame ſtrength of ſupport, by finding two points *a* and *b* (fig. 11.) in the banks, at a moderate diſtance below A and B, and ſetting up the rafters *a*F, *b*F, and ſuſpending C from the ſhortened king-poſt. In this conſtruction, when the beam AB reſts on a croſs bearer, as is drawn here, the

ſtruts

Center.

ftruts a F, b F are kept clear of it. No connection between them is neceffary, and it may be hurtful, by inducing crofs ftrains on both. It will, however, greatly increafe the ftiffnefs of the whole. This conftruction may fafely be loaded with ten times the weight that AB can carry alone.

36 An improvement of that method.

Suppofe this done, and that the fcantling of AB is too weak for carrying the weight which may be brought on the parts AC, CB. We may now trufs up each half, as in fig. 12. and then the whole will form a handfome bridge, of the fimpleft conftruction poffible. The interfections of the fecondary braces with thofe of the main trufs will form a hand-rail of agreeable figure.

We are not confined to the employment of an entire piece AB, nor to a rectilineal form. We may frame the bridge as in fig. 13. and in this form we diffuade from allowing any connection with the middle points of the main braces. This conftruction alfo may be followed till each beam AC and CB is loaded to ten times what it can fafely bear without the fecondary truffing.

37 Another method.

There is another way by which a bridge of one beam may be fupported beyond the power of the firft and fimpleft conftruction. This is reprefented in fig. 14. and fig. 15. The trufs beam FG fhould occupy one-third of AB. The advantage of this conftruction is very confiderable. The great elevation of the braces (which is a principal element of the ftrength) is preferved, and the braces are greatly fhortened.

This method may be pufhed ftill farther, as in fig. 16.

38 Thefe methods combined.

And all thefe methods may be combined, by joining the conftructions of fig. 14. and fig. 15. with that of fig. 16.

In all of them there is much room for the difplay of fkill, in the proper adjuftment of the fcantling of the timber, and the obliquity of the braces to the lengths of the different bearings. A very oblique ftrut, or a flender one, will fuffice for a fmall load, and may often give an opportunity to increafe the general ftrength; while the great timbers and upright fupports are referved for the main preffures. Nothing will improve the compofition fo much as reflecting progreffively, and in the order of thefe examples, on the whole. This alone can preferve the great principle in its fimplicity and full energy.

39 The elements of all that can be done in this art.

Thefe conftructions are the elements of all that can be done in the art of building wooden bridges, and are to be found more or lefs obvioufly and diftinctly in all attempts of this kind. We may affert, that the more obvioufly they appear, the more perfect the bridge will be. It is aftonifhing to what extent the principle may be carried. We have feen a bridge of 42 feet fpan formed of two oak truffes, the biggeft timber of which did not exceed fix inches fquare, bearing with perfect fteadinefs and fafety a waggon loaded with more than two tons, drawn by four ftout horfes. It was framed as fig. 16. nearly, with the addition of the dotted lines, and was near thirty years old; protected, however, from the weather by a wooden roof, as many bridges in Germany are.

We recollect another in the neighbourhood of Stettin, which feemed conftructed with great judgment and fpirit. It had a carrriage road in the middle about 20 feet (we think) wide, and on each fide a foot-way about five feet wide. The fpan was not lefs than 60 feet, and the greateft fcantling did not appear to exceed 10 inches by 6.

This bridge confifted of four truffes, two of which formed the outfide of the bridge, and the other two made the feparation between the carriage road and the two foot ways. We noticed the conftruction of the truffes very particularly, and found it fimilar to the laft, except in the middle divifion of the upper trufs, which, being very long, was double truffed, as in fig. 17.

The reader will find in that volume of Leupold's *Theatrum Machinarum*, which he calls *Theatrum Pontificum*, many fpecimens of wooden bridges, which are very frequent in the champain parts of Germany. They are not, in general, models of mechanic art; but the reflecting reader, who confiders them *carefully*, will pick up here and there fubordinate hints, which are ingenious, and may fometimes be ufeful.

What we have now exhibited are not to be confidered as models of conftruction, but as elementary examples and leffons, for leading the reader fyftematically into a thorough conception of the fubject. 40

A wonderful bridge in Switzerland.

We cannot quit the fubject without taking notice of a very wonderful bridge at Wittengen in Switzerland, flightly defcribed by Mr Coxe (*Travels*, vol. I. 132.) It is of a conftruction more fimple ftill than the bridges we have been defcribing. The fpan is 230 feet, and it rifes only 25. The fketch (fig. 18.) will make it fufficiently intelligible. ABC is one of two great arches, approaching to a catenarian fhape, built up of feven courfes of folid logs of oak, in lengths of 12 or 14 feet, and 16 inches or more in thicknefs. Thefe are all picked of a natural fhape, fuited to the intended curve; fo that the wood is nowhere cut acrofs the grain to trim it into fhape. Thefe logs are laid above each other, fo that their abutting joints are alternate, like thofe of a brick wall; and it is indeed a wooden wall, fimply built up, by laying the pieces upon each other, taking care to make the abutting joints as clofe as poffible. They are not faftened together by pins or bolts, or by fcarfings of any kind. They are, however, held together by iron ftraps, which furround them, at the diftance of five feet from each other, where they are faftened by bolts and keys.

Thefe two arches having been erected (by the help, we prefume, of pillars, or a centering of fome kind), and well butted againft the rock on each fide, were freed from their fupports, and allowed to fettle. They are fo placed, that the intended road abc interfects them about the middle of their height. The roadway is fupported by crofs joifts, which reft on a long horizontal fummer beam. This is connected with the arches on each fide by uprights bolted into them. The whole is covered with a roof, which projects over the arches on each fide to defend them from the weather. Three of the fpaces between thefe uprights have ftruts or braces, which give the upper work a fort of truffing in that part.

This conftruction is fimple and artlefs; and appears, by the attempt to trufs the ends, to be the performance of a perfon ignorant of principle, who has taken the whole notion from a ftone arch. It is, however, of a ftrength much more than adequate to any load that can be laid on it. Mr Coxe fays, but does not explain how, that it is fo contrived that any part of it can be repair-

ed

ed independent of the reft. It was the laft work of one Ulrich Grubenhamm of Tuffen, in the canton of Appenzel, a carpenter without education, but celebrated for feveral works of the fame kind; particularly the bridge over the Rhine at Schafhanfen, confifting of two arches, one of 172 and the other of 193 feet fpan, both refting on a fmall rock near the middle of the river.

While writing this article, we got an account of a wooden bridge, erected in North America, in which this fimple notion of Grubenhamm's is mightily improved. The fpan of the arch was faid to exceed 250 feet, and its rife exceedingly fmall. The defcription we got is very general, but fufficient, we think, to make it perfectly intelligible.

41 Another in North America.

In fig. 19. DD, EE, FF, are fuppofed to be three beams of the arch. They confift of logs of timber of fmall lengths, fuppofe of 10 or 12 feet, fuch as can be found of a curvature fuited to its place in the arch without trimming it acrofs the grain. Each beam is double, confifting of two logs applied to each other, fide to fide, and *breaking joint*, as the workmen term it. They are kept together by wedges and keys driven through them at fhort intervals, as at K, L, &c.

The manner of joining and ftrongly binding the two fide pieces of each beam is fhewn in fig. 20. The mortife *a i c b* and *d c i o*, which is cut in each half beam, is confiderably longer on the outfide than on the infide, where the two mortifes meet. Two keys, BB and CC, are formed, each with a notch *b c d*, or *a i o*, on its fide; which notch fits one end of the mortife. The inner fide of the key is ftraight, but fo formed, that when both keys are in their places, they leave a fpace between them wider at one end than the other. A wedge AA, having the fame taper as the fpace juft mentioned, is put into it and driven hard. It is evident that this muft hold the two logs firmly together.

This is a way of uniting timber not mentioned in the article Carpentry; and it has fome peculiarities worthy of notice. In the firft place, it may be employed fo as to produce a very ftrong lateral connection, and would then co-operate finely with the other artificial methods of fcarfing and tabling that we defcribed in the article referred to. But it requires nice attention to fome circumftances of conftruction to fecure this effect. If the joints are accurately formed to each other, as if the whole had been one piece divided by an infinitely thin faw, this manner of joining will *keep* them all in their places. But no driving of the wedge AA will make them firmer, or caufe one piece to prefs hard on the other. If the abutment of two parts of the half beam is already clofe, it will remain fo; but if open in the fmalleft degree, driving of the wedge will not make it tighter. In this refpect, therefore, it is not fo proper as the forms defcribed in Carpentry.

In order that the method now defcribed may have the effect of *drawing* the halves of the beams together, and of keeping them hard fqueezed on each other, the joints muft be made fo as not to correfpond exactly. The prominent angle *a i o* (fig. 21.), formed by the ends of the two half mortifes, muft be made a little more obtufe than the angle *a f o* of the notch of the key which this prominence is intended to fill up. Moreover, the oppofite fide *e t* of this key fhould not be quite ftraight, but a very little convex. With thefe precautions, it is eafy to fee that, by driving the wedge AA, we caufe the notch *a f o* to take hold, firft at the two points *a* and *o*, and then, by continuing to drive the wedge, the fides *a f*, *o f*, of the notch gradually comprefs the wood of the half beams, and prefs them on each other. By continuing to drive the wedge, the mutual compreffion of the key and the beam fqueezes all together, and the fpace *a f o i* is completely filled up. We may fee, from this procefs, that the mutual compreffion and drawing together of the timber will be greater in proportion as we make the angle *a i o* more prominent, and its correfponding angle *a f o* more deep; always taking care that the key fhall be thick enough not to break in the narrow part.

This adjuftment of the keys to the mortife is neceffary on another account. Suppofing the joints to fit each other exactly before driving the wedge, and that the whole fhrinks a little by drying—by this the angle *a i o* will become more prominent, and the angle *a f o* will become more fhallow; the joint will open at *a* and *o*, and the mutual compreffure will be at an end.

We may alfo obferve, that this method will not give any additional firmnefs to the abutments of the different lengths employed to piece out the arch-beam; in which refpect it differs materially from the other modes of joining timber.

Having fhewn how each beam is pieced together, we muft now fhew how a number of them are united, fo as to compofe an arch of any thicknefs. This is done in the very fame way. The beams have other mortifes worked out of their inner fides, half out of each half of the beam. The ends of the mortifes are formed in the fame way with thofe already defcribed. Long keys BB, CC, (fig. 19.) are made to fit them properly, the notches being placed fo as to keep the beams at a proper diftance from each other. It is now plain that driving in a long wedge AA will bind all together.

In this manner may an arch be extended to any fpan, and made of any thicknefs of arching. The bridge over Portfmouth river in North America was more than 250 feet in length, and confifted of feveral parallel arches of beams. The inventor (we think that his name is Bludget) faid that he found the ftrength fo great, that he could with perfect confidence make one of four times the fpan.

We admire the ingenuity of this conftruction, and think it very effectual for bringing the timbers into firm and uniform abutment; but we imagine that it requires equilibration, becaufe it is extremely flexible. There is nothing to keep it from bending, by an inequality of load, but the tranfverfe ftrength of the beams. The keys and wedges can have very little power to prevent this bending. The diftance between the beams will alfo contribute little or nothing to the ftiffnefs; nay, we imagine that a great diftance between them will make the frame more flexible. Could the beams be placed fo near each other that they could be fomehow joggled on each other, the whole would be ftiffer; but at prefent they will bend like the plates of a coach-fpring. But nothing hinders us from adding diagonal pieces to this conftruction, which will give it any degree of ftiffnefs, and will enable it to bear any inequality of loading. When completed in this manner, we imagine that it will be at leaft equal to any conftruction that has yet been thought of. One advantage it poffeffes that is very precious: Any piece that fails

may be taken out, and replaced by another, without disturbing the rest, and without the smallest risk. On the whole, we think it a very valuable addition to British carpentry. The method here practised, both for joining the parts of one beam and for framing the different beams together, suggests the most firm and light constructions for dome-roofs that can be conceived; incomparably superior to any that have yet been erected. The whole may be framed, without a nail or a spike, into one net-like shell that cannot even be pulled in pieces. We may perhaps consider this in another article; at present we return to the consideration of trussed bridges.

42 Bridges combined by simple addition or by composition.

When the width of the river exceeds what is thought practicable by a single truss, we must then combine, either by simple addition, or by composition, different trusses together. We compose a bridge by simple addition when we make a frame of carpentry of an unchangeable and proper shape, to serve as one of the archstones of a bridge of masonry. This may easily be comprehended by looking at fig. 22. Each of the frames A, B, C, D, must be considered as a separate body, and all are supported by their mutual abutment. The nature of the thing is not changed, although we suppose that the rails of the frame B, instead of being mortised into an upright *b′ b′*, unconnected with the frame C, is mortised into the upright *c c* of that frame, the direction and intensity of the mutual pressures of the two frames are the same in both cases; accordingly this is a very common form of small wooden bridges. It is usual, indeed, to put diagonal battens into each: but we believe that this is more frequently done to please the eye than to produce an unalterable shape of each frame.

To an unskilful carpenter this bridge does not seem essentially different from the centering of Mr Hupeau for the bridge of Orleans; and indeed, in many cases, it requires reflection, and sometimes very minute reflection, to distinguish between a construction which is only an addition of frame to frame till the width be covered, from a construction where one frame works on the adjoining one transversely, pushing it in one part, and drawing it in another. The ready way for an unlettered artist to form a just notion of this point, is to examine whether he may saw through the connecting piece *b′ b′* from one end to the other, and make them two separate frames. Whenever this cannot be done without that part opening, it is a construction by composition. Some of the beams are on the stretch; and iron straps, extending along both pieces, are necessary for securing the joint. The bridge is no longer a piece of masonry, but a performance of pure carpentry, depending on principles peculiar to that art. Equilibration is necessary in the first construction; but, in the second, any inequality of loading is made ineffectual for hurting the edifice, by means of the stretch that is made to operate on some other piece. We are of opinion, that this most simple employment of the distinguishing principle of carpentry, by which the beams are made to act as ties, will give the most perfect construction of a wide bridge. One polygon alone should contain the whole of the abutments; and one other polygon should consist entirely of ties; and the beams which form the radii, connecting the angles of the two polygons, complete the whole. By confining the attention to these two simple objects, the abutments of the outer polygon, and the joints of the inner one, may be formed in the most simple and efficient manner, without any collateral connections and dependencies, which divide the attention, increase the complication, and commonly produce unexpected and hurtful strains. It was for this reason that we have so frequently recommended the centering of the bridge of Orleans. Its office will be completely performed by a truss of the form of fig. 23.; where the polygon ABCDEF, consisting of two layers of beams (if one is not sufficient), contains the whole abutments, and the other A *b c d e* F is nothing but an iron rod. In this construction, the obtuseness of the angles of the lower polygon is rather an advantage. The braces G *c*, G *d*, which are wanted for trussing the middle of the outer beams, will effectually secure the angles of the exterior polygon against all risk of change. The reader must perceive that we have now terminated in the construction of the Norman roof. We indeed think it the best general form, when some moderate declivity is not an insuperable objection. When this is the case, we recommend the general plan of the centering of the bridge of Orleans. We would make the bridge (we speak of a great bridge) consist of four trusses; two to serve as the outsides of the bridge, and two inner trusses, separating the carriage-way from the foot-paths. The road should follow the course of the lower polygon, and the main truss should form the rails. It might look strange; but we are here speaking of strength; and evident, but not unwieldy, strength, once it becomes familiar, is the surest source of beauty in all works of this kind.

43 How to distinguish bridges formed according to these different methods.

44 The best general form of a wooden bridge.

Centre of Friction, is that point in the base of a body on which it revolves; into which, if the whole surface of the base, and the mass of the body, were collected, and made to revolve about the centre of the base of the given body, the angular velocity destroyed by its friction would be equal to the angular velocity destroyed in the given body by its friction in the same time. See Friction in this Supplement.

Centre of Gyration, is that point in which, if the whole mass be collected, the same angular velocity will be generated in the same time, by a given force acting at any place, as in the body or system itself. This point differs from the centre of oscillation, in as much as in this latter case the motion of the body is produced by the gravity of its own particles; but, in the case of the centre of gyration, the body is put in motion by some other force acting at one place only.

Centre of Oscillation, is that point in the axis or line of suspension of a vibrating body, or system of bodies, in which, if the whole matter or weight be collected, the vibrations will still be performed in the same time, and with the same angular velocity, as before. Hence, in a compound pendulum, its distance from the point of suspension is equal to the length of a simple pendulum whose oscillations are isochronal with those of the compound one.

Centre of Pressure, of a fluid against a plane, is that point against which a force being applied equal and contrary to the whole pressure, it will just sustain it, so as that the body pressed on will not incline to either side.—This is the same as the centre of percussion, supposing the axis of motion to be at the intersection of this plane with the surface of the fluid; and the centre of of pressure upon a plane parallel to the horizon, or upon any plane where the pressure is uniform, is the same as the centre of gravity of that plane.

CENTROBARICO, the same as centre of gravity.

CENTROBARIC METHOD, is a method of determining the quantity of a surface or solid, by means of the generating line or plane and its centre of gravity. The doctrine is chiefly comprised in this theorem:

Every figure, whether superficial or solid, generated by the motion of a line or plane, is equal to the product of the generating magnitude and the path of its centre of gravity, or the line which its centre of gravity describes.

CERUSE, or WHITE-LEAD, is a substance so much used in painting, and for other purposes, that numerous modes have been employed for the preparation of it. Of the most common of these, a sufficient account has been given in the Encyclopædia (see CERUSE, and the same word CHEMISTRY-*Index);* but Lord Dundonald has discovered a more expeditious and facile method than any of them, which becomes the more useful, as the substance with which it is effected has been hitherto rejected by the chemical world as a *caput mortuum*.

His lordship directs common lead to be reduced to a calx, but not too fine, and to have a proportion of five-sixth parts thereof, intimately mixed with muriat, or solution of potass. In this state, he directs it to be frequently stirred, in order to have the new surfaces of the mixture exposed to the carbonic acid of atmospheric air; as his lordship observes, that the effects of the carbonic acid on the alkali existing in the present state of the mixture is essentially necessary, in order to effect the intended purpose. In this state it is to be frequently sprinkled with water, and, after the calx has been long enough immersed with the muriat to be sufficiently operated upon, the muriat is to be levigated by common water from the calx, and to be concentrated by evaporation, in order to be made use of at a future period with other calx. The calx is to be afterwards ground, levigated, and dried for use.

For this discovery, his lordship obtained a patent on the 18th of August 1797; and the success which has attended the former patents of this scientific nobleman leads us to conclude, that the present discovery is entitled to the attention of the public.

CHAMBERS (Sir William), the celebrated architect, was descended of the ancient family of Chalmers in Scotland, barons of Tartas in France. His grandfather suffered considerably in his fortune by supplying Charles XII. of Sweden with money, &c. which that monarch repaid in base coin. Sir William's father resided several years in Sweden to recover his claims; and there Sir William was born, and, at eighteen years of age, appointed supercargo to the Swedish East India company. From a voyage which he made to China, he brought home the Asiatic style of ornament, in tents, temples, mosques, and pagodas. These ornaments (through the interest of Lord Bute) he was enabled to apply in the gardens at Kew. Patronised by the princess dowager and the king, Mr Chambers had much of the fashionable business of the day. Under Burke's reform, he was appointed surveyor general of the board of works. Somerset-house was worth to him at least L. 2000 a-year. His *Chef d'œuvres* are his staircases, particularly those at Lord Besborough's, Lord Gower's, and the Royal and Antiquarian Societies. The terrace behind Somerset-house is a bold effort of conception. His designs for interior arrangements were excellent. His Treatise on Civil Architecture alone will immortalize his name. In private life, Sir William was hospitable, kind, and amiable. His son married Miss Rodney; Mr Cotton, Mr Iunis, and Mr Harward, married his beautiful daughters. Having been abstemious in his youth, Sir William's constitution did not begin to break till he was seventy years of age. For the last three years, he was kept alive by wine and oxygenated air; and died on the 5th of March 1796. His celebrity will be lasting in the works which he has left; and as he was equally skilled in the theory and practice of the arts which he professed, his precepts are as valuable as his works. At his death, he was fellow of the Royal and Antiquarian Societies, treasurer of the Royal Academy, surveyor-general of the board of works, and knight of the Swedish order of the Polar Star.

CHAMFER, or CHAMFERET, an ornament in architecture, consisting of half a scotia; being a kind of small furrow or gutter on a column.

UNIVERSAL CHARACTERS, could they be introduced, would contribute so much to the diffusion of useful knowledge, that every attempt to make such a scheme simple and practicable is at least intitled to notice. Accordingly, in the *Encyclopædia Britannica*, under the word CHARACTER, a short account is given of the principal plans of universal characters which had then fallen under our observation; but since that article was published, a new method of writing, by which the various nations of the earth may communicate their sentiments to each other, has been proposed by *Thomas Northmore*, Esq; of Queen-street, Mayfair. It bears some resemblance to that which we have given from the *Journal Literaire*, 1720, but it is not the same; and of the two, Mr Northmore's is perhaps the most ingenious. The ground-work of the superstructure differs not indeed from that of the journalist, being this in both, "That if the same numerical *figure* be made to represent the *same word* in the various languages upon earth, an universal character is immediately obtained." The only objection which the author or his friends saw to such a plan, originates in the diversity of idioms; but, as he truly observes, every schoolboy has this difficulty to encounter as often as he construes Terence.

Such then was Mr Northmore's original plan: but he soon perceived that it was capable of considerable improvement; for, instead of using a figure for *every* word, it will be necessary to apply one only to every *useful* word; and we all know how few words are absolutely necessary to the communication of our thoughts. Even these may be much abbreviated by the adoption of certain *uniform fixed* signs (not amounting to above 20), for the various cases, numbers, genders, degrees of comparison, of nouns, tenses, and moods of verbs, &c. All words of negation, too, may be expressed by a prefixed sign. A few instances will best explain the author's meaning.

Suppose the number 5 to represent the word *see*.
6 — — *a man*,
7 — — *happy*,
8 — — *never*,
9 — — *I*.

"I

"I would then (ſays he) expreſs the tenſes, genders, caſes, &c. *in all languages*, in ſome ſuch *uniform* manner as following:

(1)	5	=	*preſent tenſe*,	—	ſee,
(2)	$\cdot 5$	=	*perfect tenſe*,	—	ſaw,
(3)	$:5$	=	*perfect participle*,	—	ſeen,
(4)	$5:$	=	*preſent participle*,	—	ſeeing,
(5)	$5\cdot$	=	*future*,	— —	will ſee,
(6)	$\underline{5}$	=	*ſubſtantive*,	—	ſight,
(7)	$\underline{\underline{5}}$	=	*perſonal ſubſtantive*,	—	ſpectator,
(8)	6	=	*nominative caſe*,	—	a man,
(9)	$\ddot{6}$	=	*genitive*,	— —	of a man,
(10)	$\dddot{6}$	=	*dative*,	— —	to a man,
(11)	$\overset{\frown}{6}$	=	*feminine*,	— —	a woman,
(12)	$+6$	=	*plural*,	— —	men,
(13)	7	=	*poſitive*,	— —	happy,
(14)	$\hat{7}$	=	*comparative*,	—	happier,
(15)	$\hat{\hat{7}}$	=	*ſuperlative*,	—	happieſt,
	$\underline{7}$	=	as above, No. 6.	—	happineſs,
(16)	-7	=	*negation*,	— —	unhappy.

"From the above ſpecimen, I ſhould find no difficulty in comprehending the following ſentence, though it were written in the language of the Hottentots:

$9, 8, .5, -\hat{7}, \overset{\frown}{6}$. *I never ſaw a more unhappy woman.*

"Thoſe languages which do not uſe the pronoun prefixed to the verb, as the Greek and Roman, &c. may apply it, in a ſmall character, ſimply to denominate the perſon; thus, inſtead of 9, 8, .5, *I never ſaw;* they may write, 8, $_9.5$, which will ſignify that the verb is in the firſt perſon, and will ſtill have the ſame meaning."

Our author ſeems confident that, according to this ſcheme of an univerſal character, about 20 ſigns, and leſs than 10,000 *choſen* words (ſynonyms being ſet aſide), would anſwer all the ends propoſed; and that foreigners, by referring to their numerical dictionary, would eaſily comprehend each other. He proceeds next to ſhew how appropriate ſounds may be given to his ſigns, and an univerſal *living language* formed from the univerſal *characters*.

To attain this end, he propoſes to diſtinguiſh the ten numerals by ten monoſyllabic names of eaſy pronunciation, and ſuch as may run without difficulty into one another. To illuſtrate his ſcheme, however, he calls them, for the preſent, by their common Engliſh names; but would pronounce each number made uſe of by uttering ſeparately its component parts, after the manner of accountants. Thus let the number 6943 repreſent the word *horſe*, he would not, in the univerſal language, call a horſe *ſix thouſand nine hundred and forty-three*, but *ſix*, *nine*, *four*, *three*, and ſo on for all the words of a ſentence, making the proper ſtop at the end of each. In the ſame manner, a diſtinct appellation muſt be appropriated to each of the prefixed ſigns, to be pronounced immediately after the numeral to which it is an appendage. Thus if *plu* be the appellation or the ſign of the plural number, *ſix, nine, four, three, plu* will be *horſes*.

"Thus (ſays our author), I hope it is evident that about 30 or 40 diſtinct ſyllables are ſufficient for the above purpoſe; but I am much miſtaken if *eleven* only will not anſwer the ſame end. This is to be done by ſubſtituting the firſt 20 or 30 numerals for the ſigns, and ſaying, as in algebra, that a term is in the power of ſuch a number, which may be expreſſed by the ſimple word *under*. *Ex. gr.* Let 6943 repreſent the word *horſe;* and ſuppoſe four to be the ſign of the plural number, I would write the word thus, $\overset{4}{6943}$; and pronounce it, ſix, nine, four, three, in the power of or *under* four. By theſe means eleven diſtinct appellations would be ſufficient, and time and uſe would much abbreviate the pronunciation."

To refuſe the praiſe of ingenuity to this contrivance for an univerſal language would be very unjuſt; but elocution in this manner would be ſo very tedious, that ſurely the author himſelf, when he thinks more coolly on the ſubject, will perceive, that in the living ſpeech its defects would more than balance its advantages. A *pangraph*, as he calls his univerſal character, would indeed be uſeful, and is certainly practicable; a *panleg* (if we may form ſuch a word) would not be very uſeful, unleſs it were much more perfect than it could be made according to the plan before us.

CHAUSETRAPPES. See *Crow's Feet*, Encycl.

CHEMIN des Ronds, in fortification, the way of the rounds, or a ſpace between the rampart and the low parapet under it, for the rounds to go about it.

CHEMISTRY,

1 Definition. IS a ſcience, the object of which is to aſcertain the ingredients that enter into the compoſition of bodies, to examine the nature of theſe ingredients, the manner in which they combine, and the properties reſulting from their combination.

As an art, it has been in ſome meaſure coeval with the human race; for many of the moſt important branches of manufactures could not have been conducted without at leaſt ſome knowledge of chemical combinations. As a ſcience, it can hardly be dated farther back than the middle of the 17th century; but ſince that time it has advanced with a rapidity altogether unprecedented in the annals of philoſophy. Newton laid its foundation; and ſince his days an almoſt incredible number of the moſt diſtinguiſhed names in Europe have enliſted under its banners. So rapid has this progreſs been, that though the article CHEMISTRY in the *Encyclopædia Britannica* was written only about ten years ago, the language and reaſoning of chemiſtry have been ſo greatly improved, and the number of facts have accumulated ſo much, that we find ourſelves under the neceſſity of tracing over again the very elements of the ſcience.

2 Importance of chemiſtry. Indeed, if we conſider the importance of chemiſtry, we ſhall not be ſo much ſurpriſed at the ardour with which it has been cultivated. As a ſcience, it is intimately connected with all the phenomena of nature; the cauſes of rain, ſnow, hail, dew, wind, earthquakes: even the changes of the ſeaſons can never be explored with any chance of ſucceſs while we are ignorant of chemiſtry; and the vegetation of plants, and ſome of the moſt important functions of animals, have received all their illuſtration from the ſame ſource. No ſtudy can give us more exalted ideas of the wiſdom and goodneſs of the Great Firſt Cauſe than this, which ſhews us everywhere the moſt aſtoniſhing effects produced by the moſt ſimple though adequate means, and diſplays to our view the great care which has everywhere been taken to ſecure the comfort and happineſs of every living creature. As an art, it is intimately connected with all our manufactures: The glaſs-blower, the potter, the ſmith, and every other worker in metals, the tanner, the ſoap-maker, the dyer, the bleacher, are really practical chemiſts; and the moſt eſſential improvements have been introduced into all theſe arts by the progreſs which chemiſtry has made as a ſcience. Agriculture can only be improved rationally and certainly by calling in the aſſiſtance of chemiſtry; and the advantages which medicine has derived from the ſame ſource are too obvious to be pointed out.

It is evident from the definition of chemiſtry that it muſt conſiſt in a hiſtory of the ſimple ſubſtances which enter into the compoſition of bodies, in an inveſtigation of the manner in which theſe ſubſtances combine, and in a deſcription of the properties of the compounds which they form. And this is the arrangement which we mean to purſue; reſerving to ourſelves, however, the liberty of deviating a little from it, whenever it may appear neceſſary for the ſake of perſpicuity. All our claſſifications are in fact artificial; nature does not know them, and will not ſubmit to them. They are uſeful, however, as they enable us to learn a ſcience ſooner, and to remember it better; but if we mean to derive theſe advantages from them, we muſt renounce a rigid adherence to arbitrary definitions, which nature diſclaims. 3 Arrangement.

We ſhall begin by an account of the ſimpleſt bodies, and proceed gradually to thoſe which are more compound. By *ſimple bodies*, we do not mean what the ancient philoſophers called the *elements of bodies*, but merely ſubſtances which have not yet been decompounded. Very poſſibly the bodies which we reckon ſimple may be real compounds; but till this has actually been proved, we have no right to ſuppoſe it. Were we acquainted with all the elements of bodies, and with all the combinations of which theſe elements are capable, the ſcience of chemiſtry would be as perfect as poſſible; but at preſent this is very far from being the caſe.

We ſhall divide this article into four parts. The *firſt* part ſhall treat of thoſe bodies which are at preſent conſidered as ſimple; the *ſecond*, of thoſe bodies which are formed by the union of two ſimple bodies, and which, for want of a better word we ſhall call *compound bodies;* the *third*, of thoſe bodies which are formed by the union of two compound bodies; and the *fourth*, of bodies ſuch as they are preſented to us by nature in the mineral, vegetable, and animal kingdoms.

PART I. OF SIMPLE BODIES.

4 Claſſes of ſimple bodies. ALL the bodies which are at preſent reckoned ſimple, becauſe they have never been decompounded, may be reduced into ſix claſſes.

1. Oxygen,
2. Simple combuſtibles,
3. Metals,
4. Earths,
5. Caloric,
6. Light.

Theſe ſhall form the ſubjects of the ſix following chapters.

CHAP. I. *Of* OXYGEN.

Plate XVIII. TAKE a quantity of nitre, or ſaltpetre, as it is alſo called, and put it into a gun-barrel A (fig. 1.), the touch-hole of which has been previouſly cloſed up with metal. This barrel is to be bent in ſuch a manner, that while the cloſe end, in which the nitre lies, is put into the fire E, the open end may be plunged below the ſurface of the water, with which the veſſel B is filled. At the ſame time, the glaſs jar D, previouſly filled with water, is placed on the ſupport C, lying at the bottom of the veſſel of water B, ſo as to be exactly over the open end of the gun-barrel A. As ſoon as the nitre becomes hot, it emits a quantity of air, which iſſuing from the end of the gun-barrel, aſcends to the top of the glaſs jar D, and gradually diſplaces all the water. The glaſs jar D then appears to be empty, but is in fact filled with air. It may then be removed in the following 5 Method of procuring oxygen.

ing

ing manner: Slide it away a little from the gun-barrel and the ſupport, and then dipping any flat diſh into the water below it, raiſe it on it, and bear it away. The diſh muſt be allowed to retain a quantity of water in it, (ſee fig. 2.) Another jar may then be filled with air in the ſame manner; and this proceſs may be continued either till the nitre ceaſes to give out air, or till as many jarfuls have been obtained as are required. This method of obtaining and confining air was firſt invented by Dr Mayow, and afterwards much improved by Dr Hales. All the airs obtained by this or any other proceſs, or, to ſpeak more properly, all the airs differing from the air of the atmoſphere, have, in order to diſtinguiſh them from it, been called *gaſes*, and this name we ſhall afterwards employ.

6 Diſcovered by Prieſtley and Scheele.

The gas which we have obtained by the above proceſs was diſcovered by Dr Prieſtley on the 1ſt of Auguſt 1774, and called by him *dephlogiſticated air*. Mr Scheele of Sweden diſcovered it in 1775, without any previous knowledge of what Dr Prieſtley had done: he gave it the name of *empyreal air*. Condorcet, ſo conſpicuous during the French revolution, gave it firſt the name of *vital air*; and Mr Lavoiſier afterwards called it *oxygen gas*; a name which is now generally received, and which we ſhall adopt.

Oxygen gas may be obtained likewiſe by the following proceſs:

7 Another method.

D (in fig. 3.) repreſents a wooden trough, the inſide of which is lined with lead or tinned copper. AB is a ſhelf running along the inſide of it, about three inches from the top. C is the cavity of the trough, which ought to be a foot deep. It is to be filled with water at leaſt an inch above the ſhelf AB. In the body of the trough, which may be called the ciſtern, the jars deſtined to hold gas are to be filled with water, and then to be lifted, and placed inverted upon the ſhelf at B, with their edges a little over it. This trough, which was invented by Dr Prieſtley, has been called by the French chemiſts the *pneumato-chemical*, or ſimply *pneumatic* apparatus, and is extremely uſeful in all experiments in which gaſes are concerned. Into the glaſs veſſel E put a quantity of the black oxide (A) of manganeſe in powder, and pour over it as much of that liquid which in commerce is called *oil of vitriol*, and in chemiſtry *ſulphuric acid*, as will ſomewhat more than cover it. Then inſert into the mouth of the veſſel the glaſs tube F, ſo cloſely that no air can eſcape except through the tube. This may be done by covering the joining with a paſte made of wheat-flour and water, or any other *lute*, as ſubſtances uſed for ſimilar purpoſes are called. The end of the tube C is then to be plunged into the pneumatic apparatus D, and the jar G, previouſly filled with water, to be placed over it on the ſhelf. The whole apparatus being fixed in that ſituation, the glaſs veſſel E is to be heated by means of a lamp or a candle. A great quantity of oxygen gas ruſhes along the tub F, and fills the jar G. As ſoon as the jar is filled, it may be ſlid to another part of the ſhelf, and other jars ſubſtituted in its place, till as much gas has been obtained as is wanted.

8 Properties of oxygen.

1. Oxygen gas is colourleſs, and inviſible like common air. Like it too, it is elaſtic, and capable of indefinite expanſion and compreſſion.

9 Supports flame,

2. If a lighted taper be let down into a jar of oxgen gas, it burns with ſuch ſplendor that the eye can ſcarcely bear the glare of light, and at the ſame time time produces a much greater heat than when burning in common air. It is well known that a candle put into a well cloſed jar, filled with common air, is extinguiſhed in a few ſeconds. This is the caſe alſo with a candle encloſed in oxygen gas; but it burns much longer in an equal quantity of that gas than of common air.

10 And life.

3. It was proved long ago by Boyle, that animals cannot live without air, and by Mayow that they cannot breathe the ſame air for any length of time without ſuffocation. Dr Prieſtley and ſeveral other philoſophers have ſhewn us, that animals live much longer in the ſame quantity of oxygen gas than of common air. Count Morozzo placed a number of ſparrows, one after another, in a glaſs bell filled with common air, and inverted over water.

	H.	M.
The firſt ſparrow lived - -	3	0
The ſecond - - - - -	0	3
The third - - - - -	0	1

He filled the ſame glaſs with oxygen gas, and repeated the experiment.

	H.	M.
The firſt ſparrow lived - -	5	23
The ſecond - - - - -	2	10
The third - - - - -	1	30
The fourth - - - - -	1	10
The fifth - - - - -	0	30
The ſixth - - - - -	0	47
The ſeventh - - - - -	0	27
The eighth - - - - -	0	30
The ninth - - - - -	0	22
The tenth - - - - -	0	21

He then put in two together; the one died in 20 minutes, but the other lived an hour longer.

11 Exiſts in the atmoſphere.

4. Atmoſpherical air contains about 27 parts in the hundred of oxygen gas. This was firſt diſcovered by Scheele. It has been proved by a great number of experiments, that no ſubſtance will burn in common air previouſly deprived of all the oxygen gas which it contained; but combuſtibles burn with great ſplendor in oxygen gas, or in other gaſes to which oxygen gas has been added. Oxygen gas then is abſolutely neceſſary for combuſtion.

5. It has been proved alſo, by many experiments, that no breathing animal can live for a moment in any air or gas which does not contain oxygen mixed with it. Oxygen gas then is abſolutely neceſſary for reſpiration.

6. When ſubſtances are burnt in oxygen gas, or in any other gas containing oxygen, if the air be examined after the combuſtion, a great part of the oxygen will be found to have diſappeared. If charcoal, for inſtance, be burnt in oxygen gas, there will be found, inſtead of part of the oxygen, another very different gas, known by the name of carbonic acid gas. Exactly the ſame thing takes place when air is reſpired by animals; part of the oxygen gas diſappears, and its place is occupied by ſubſtances poſſeſſed of very different properties. Oxygen gas

(A) This ſubſtance ſhall be afterwards deſcribed. It is now very well known in Britain, as it is in common uſe with bleachers and ſeveral other manufacturers.

Oxygen.

gas then undergoes some change during combustion, as well as the bodies which have been burnt; and the same observation applies also to respiration (B).

12 Its specific gravity.

7. The specific gravity of oxygen gas, as determined by Mr Kirwan *, is 0,00135, that of water being 1,0000, as is always the case when specific gravity is mentioned absolutely. It is therefore 740 times lighter than the same bulk of water. Its weight to atmospherical air is as 1103 to 1000: 116 cubic inches of oxygen gas weigh 39,03 grains troy, 116 cubic inches of common air, 35,38 grains.

* On *Phlogiston*, sect. i.

13 *Affinity* explained.

8. Oxygen is capable of combining with a great number of bodies, and forming compounds. As the combination of bodies is of the utmost importance in chemistry, before proceeding farther we shall attempt to explain it. When common salt is thrown into a vessel of pure water, it melts, and very soon spreads itself through the whole of the liquid, as any one may convince himself by the taste. In this case the salt is combined with the water, and cannot afterwards be separated by filtration or any other method merely mechanical. It may, however, by a very simple process: Pour into the solution a quantity of spirit of wine, and the whole of the salt instantly falls to the bottom.

Why did the salt dissolve in water, and why did it fall to the bottom on pouring in spirit of wine? These questions were first answered by Sir Isaac Newton. There is a certain attraction between the particles of common salt and those of water, which causes them to unite together whenever they are presented to one another. There is an attraction also between the particles of water and of spirit of wine, which equally disposes them to unite, and this attraction is greater than that between the water and salt; the water therefore leaves the salt to unite with the spirit of wine, and the salt being now unsupported, falls to the ground by its gravity. This power, which disposes the particles of different bodies to unite, was called by Newton *attraction*, by Bergman, *elective attraction*, and by many of the German and French chemists, *affinity*; and this last term we shall employ, because the other two are rather general. All substances which are capable of combining together are said to have an *affinity for* (C) each other: those substances, on the contrary, which do not unite, are said to have *no affinity* for each other. Thus there is no affinity between water and oil. It appears from the instance of the common salt and spirit of wine, that substances differ in the degree of their affinity for other substances, since the spirit of wine displaced the salt and united with the water. Spirit of wine therefore has a stronger affinity for water than common salt has.

In 1719 Geoffroi invented a method of representing the different degrees of affinities in tables, which he called *tables of affinity*. His method consisted in placing the substances whose affinities were to be ascertained at the top of a column, and the substances with which it united below it, each in the order of its affinity; the substance which had the strongest affinity next it, and that which had the weakest farthest distant, and so of the rest. According to this method, the affinity of water for spirit of wine and common salt would be marked as follows:

WATER,

Sirit of wine,
Common salt.

This method has been universally adopted, and has contributed very much to the rapid progress of chemistry.

We shall proceed therefore to give a table of the affinities of oxygen. 14 Affinities of oxygen.

OXYGEN,

Carbon,
Zinc,
Iron,
Manganese,
Hydrogen,
Azot,
Sulphur,
Phosphorus,
Cobalt,
Nickel,
Lead,
Tin,
Phosphorous acid,
Copper,
Bismuth,
Antimony,
Mercury,
Silver,
Arsenic,
Sulphurous acid,
Oil,
Nitrous gas,
Gold,
White oxide of arsenic,
Muriatic acid,
Oxide of tin,

White

(B) Mayow had in the last century made considerable progress towards the discovery of oxygen gas. He knew that only a part of the air supported combustion: This part he called *particulæ igneo-aereæ*. He knew that this part was contained in nitre: "Pars nitri aerea nihil aliud quam particulæ ejus igneo-aereæ est." He adds, "At non est estimandum pabulum igneo-aereum ipsum aerem esse, sed tantum partem ejus majus activam subtilemque. Quippe lucerna vitro inclusa expirat cum tamen copia aeris satis ampla in eodem continetur." He knew also that it was this part of the air which was useful in respiration. After mentioning several experiments to prove this, he adds, "Ex dictis certo constat animalia respirando particulas quasdam vitales easque elasticas ab aere haurire." See his *Tractatus quinque Medico-Physici*, p. 12. and 106.—He knew also that this part of the air was necessary to combustion: "Et tamen certo constat, particulas nitro-aereas non minus quam sulphureas ad ignem conflandum necessareas esse." *Ibid*, p. 26.

(C) We are not certain that the phrase *affinity for* is warranted by classical authority; we have ventured, however, to use it, because, as the word *affinity* in this article signifies a species of attraction, we thought it would be more perspicuous to put after it the preposition *for*, which usually follows the word *attraction*, than *to* or *with*, which come after *affinity* when used in its ordinary acceptation.

Sulphur.

White oxide of lead?
Nitrous acid,
White oxide of manganese,
Water.

The reason of this order will appear when we treat of these various substances.

Chap. II. *Of* Simple Combustible Bodies.

15 Five simple combustibles.

By *combustibles*, we mean substances capable of combustion; and by *simple combustibles*, bodies of that nature which have not yet been decompounded. These are only five in number, Sulphur, Phosphorus, Carbon, Hydrogen, and Azot. Were we to adhere strictly to our definition indeed, we should add all the metals; for they are also combustible, and have not yet been decompounded: But for the reasons formerly given, we shall venture to deviate a little from strict logic, and consider them afterwards as a distinct class of substances.

Sect. I. *Of Sulphur.*

Sulphur, distinguished also in English by the name of *brimstone*, was known in the earliest ages. As it is found native in many parts of the world, it could not fail very soon to attract the attention of mankind. It was used by the ancients in medicine, and its fumes were employed in bleaching wool*.

* Pliny. lib. xxxv. c. 15.

16 Properties of sulphur.

Sulphur is a hard brittle substance, commonly of a yellow colour, without any smell, and of a weak though perceptible taste.

It is a non-conductor of electricity, and of course becomes electric by friction.

If a considerable piece of sulphur be exposed to a sudden though gentle heat, by holding it in the hand, for instance, it breaks to pieces with a crackling noise†.

† Fourcroy.

Its specific gravity is 1,990.

When heated to the temperature of 185° of Fahrenheit, it melts and becomes very fluid. If the temperature be still farther increased, the fluidity diminishes; but when the sulphur is then carried from the fire and allowed to cool, it becomes as fluid as ever before it congeals‡.

‡ Dr Black.

17 Flowers of sulphur.

When sulphur is heated to the temperature of 170°, it rises up in the form of a fine powder, which may be easily collected in a proper vessel. This powder is called *flowers of sulphur*. When substances fly off in this manner on the application of a moderate heat, they are called *volatile*; and the process itself, by which they are raised, is called *volatilization*.

Sulphur undergoes no change by being allowed to remain exposed to the open air.

When thrown into water, it does not melt, as common salt does, but falls to the bottom, and remains there unchanged; it is therefore *insoluble* in water. If, however, it be poured, while in a state of fusion, into water, it assumes a red colour, and retains such a degree of softness, that it may be kneaded between the fingers; but it loses this property in a few days§.

§ Fourcroy.

18 Sulphur capable of crystallizing.

There are a great many bodies which, after being dissolved in water or melted by heat, are capable of assuming certain regular figures. If a quantity of common salt, for instance, be dissolved in water, and that fluid, by the application of a moderate heat, be made to fly off in the form of steam; or, in other words, if the water be slowly *evaporated*, the salt will fall to the bottom of the vessel in cubes. These regular figures are called *crystals*. Now sulphur is capable of crystallizing. If it be melted, and as soon as its surface begins to congeal, the liquid sulphur beneath be poured out, the internal cavity will exhibit long needle-shaped crystals of an octahedral figure. This method of crystallizing sulphur was contrived by Rouelle.

19 Converted by combustion into an acid.

When sulphur is heated to the temperature of 302° in the open air, it takes fire spontaneously, and burns with a pale blue flame, and at the same time emits a great quantity of fumes of a very strong suffocating odour. When heated to the temperature of 570°, or a little higher, it burns with a bright white flame, and at the same time emits a vast quantity of fumes. If the heat be continued long enough, the sulphur burns all away without leaving any ashes or *residuum*. If the fumes be collected, they are found to consist entirely of *sulphuric acid*. By combustion, then, sulphur is converted into an acid. This fact was known several centuries ago, but no intelligible explanation was given of it till the time of Stahl. That chemist undertook the task; and founded on his experiments a theory so exceedingly ingenious, and supported by such a vast number of facts, that it was in a very short time adopted with admiration by all the philosophic world, and contributed not a little to raise chemistry to that rank among the sciences from which the ridiculous pretensions of the early chemists had excluded it.

20 Stahl's explanation of this.

According to Stahl, there is only one substance in nature capable of combustion, which therefore he called Phlogiston; and all those bodies which can be set on fire contain less or more of it. Combustion is merely the separation of this substance. Those bodies which contain none of it are of course incombustible. All combustibles, except those which consist of pure phlogiston (if there be any such), are composed of an incombustbile body and phlogiston united together. During combustion the phlogiston flies off, and the incombustible body remains behind. Now when sulphur is burnt, the substance which remains is sulphuric acid, an incombustible body. Sulphur therefore is composed of sulphuric acid and phlogiston.

To establish this theory completely, it was necessary to shew that sulphur could be actually made by combining sulphuric acid and phlogiston; and this also Stahl undertook to perform. *Sulphat of potass* is a substance composed of sulphuric acid and potass (D), and *charcoal* is a combustible body, and therefore, according to the theory of Stahl, contains phlogiston: when burnt, it leaves a very inconsiderable residuum, and consequently contains hardly any thing else than phlogiston. He melted together in a crucible a mixture of *potass* and *sulphat of potass*, stirred into it one-fourth part by weight of pounded charcoal, covered the crucible with another inverted over it, and applied a strong heat to it. He then allowed it to cool, and examined its contents. The charcoal had disappeared, and there only remained in the crucible a mixture of potass and sulphur combined together,

(D) The nature of *potass* shall afterwards be explained. It is the *potash* well known in commerce in a state of purity.

Sulphur. together, and of a darker colour than usual, from the residuum of the charcoal. Now there were only three substances in the crucible at first, potass, sulphuric acid, and charcoal: two of these have disappeared, and *sulphur* has been found in their place. Sulphur then must have been formed by the combination of these two. But charcoal consists of phlogiston and a very small residuum, which is still found in the crucible. The sulphur then must have been formed by the combination of sulphuric acid and phlogiston. This simple and luminous explanation appeared so satisfactory, that the composition of sulphur was long considered as one of the best demonstrated truths in chemistry.

21 Unsatisfactory. There are two facts, however, which Stahl either did not know or did not sufficiently attend to, neither of which were accounted for by his theory. The first is, that sulphur will not burn if air be completely excluded; the second, that sulphuric acid is heavier than the sulphur from which it was produced.

To account for these, or facts similar to these, succeeding chemists refined upon the theory of Stahl, deprived his phlogiston of *gravity*, and even assigned it a principle of *levity*. Still, however, the necessity of the contact of air remained unexplained. At last Mr Lavoisier, who had already distinguished himself by the extensiveness of his views, the accuracy of his experiments, and the precision of his reasoning, undertook the examination of this subject, and his experiments were published in the Memoirs of the Academy of Sciences for

22 Real explanation by Lavoisier. 1777. He put a quantity of sulphur into a large glass vessel filled with air, which he inverted into another vessel containing mercury, and then set fire to the sulphur by means of a burning-glass. It emitted a blue flame, and gave out thick vapours, but was very soon extinguished, and could not be again kindled. There was, however, a little sulphuric acid formed, which was a good deal heavier than the sulphur which had disappeared; there was also a diminution in the air of the vessel proportional to this increase of weight. The sulphur, therefore, during its conversion into an acid, must have absorbed part of the air. He then put a quantity of sulphuret of iron, which consists of sulphur and iron combined together, into a glass vessel full of air, which he inverted over water (E). The quantity of air in the vessel continued diminishing for eighteen days, as was evident from the ascent of the water to occupy the space which it had left; but after that period no farther diminution took place. On examining the sulphuret, it was found somewhat heavier than when first introduced into the vessel, and the air of the vessel wanted precisely the same weight. Now this air had lost all its oxygen; all the oxygen of the air in the vessel must therefore have entered into the sulphuret. Part of the sulphur was converted into sulphuric acid; and as all the rest of the sulphuret was unchanged, the whole of the increase of weight must have been owing to something which had entered into that part of the sulphur which was converted into acid. This something we know was oxygen. Sulphuric acid therefore must be composed of sulphur and oxygen; for as the original weight of the whole contents of the vessel remained exactly the same, there was not the smallest reason to suppose that any substance had left the sulphur. Sulphur.

It is impossible, then, that sulphur can be composed of sulphuric acid and phlogiston, as Stahl supposed; since sulphur itself enters as a part into the composition of that acid. There must therefore have been some want of accuracy in the experiment by which Stahl proved the composition of sulphur, or at least some fallacy in his reasonings; for it is impossible that two contradictory facts can both be true. Upon examining the potass and sulphur produced by Stahl's experiment, we find them to be considerably lighter than the charcoal, sulphuric acid, and potass originally employed. Something therefore has made its escape during the application of the heat. And if the experiment be conducted in a close vessel, with a pneumatic apparatus attached to it, a quantity of gas will be obtained exactly equal to the weight which the substances operated on have lost; and this weight considerably exceeds that of all the charcoal employed. This gas is *carbonic acid gas*, which is composed of charcoal and oxygen, as will afterwards appear. We now perceive what passes in this experiment: Charcoal has a stronger affinity for oxygen at a high temperature than sulphur has. When charcoal therefore is presented to sulphuric acid in that temperature, the oxygen of the acid combines with it, they fly off in the form of carbonic acid gas, and the sulphur is left behind.

The combustion of sulphur, then, is nothing else than the act of its combination with oxygen; and, for any thing which we know to the contrary, it is a simple substance.

The affinities of sulphur, according to Bergman, are as follows: 23 Affinities of sulphur.

Lead,
Tin,
Silver,
Mercury,
Arsenic,
Antimony,
Iron,
Fixed alkalies,
Ammonia,
Barytes,
Lime,
Magnesia,
Phosphorus?
Oils,
Ether,
Alcohol.

Sect. II. *Of Phosphorus.*

Let a quantity of bones be burnt, or, as it is termed in chemistry, *calcined*, till they cease to smoke, or to give out any odour, and let them afterwards be reduced to a fine powder. Put this powder into a glass vessel, and pour sulphuric acid on it by little at a time, till farther additions do not cause any extrication of air bubbles (F). Dilute the mixture with a good deal of water, agitate it well, and keep it hot for some hours; then pass it through a filter. Evaporate the liquid slowly 24 Production of phosphorus.

(E) This experiment was first made by Scheele, but with a different view.

(F) The copious emission of air bubbles is called in chemistry *effervescence*.

Phosphorus slowly till a quantity of white powder falls to the bottom. This powder must be separated by filtration and thrown away. The evaporation is then to be resumed; and whenever any white powder appears, the filtration must be repeated in order to separate it. During the whole process, what remains on the filter must be washed with pure water, and this water added to the liquor. The evaporation is to be continued till all the moisture disappears, and nothing but a dry mass remains. Put this mass into a crucible, and keep it melted in the fire till it ceases to exhale sulphureous odours; then pour it out. When cold it assumes the appearance of a brittle glass. Pound this glass in a mortar, and mix it with one-third by weight of charcoal dust. Put this mixture into an earthen ware retort, and apply a receiver containing a little water. Put the retort into a sand bath, and increase the fire till it becomes red hot. A substance then passes into the receiver, which has the appearance of melted wax, and which congeals as it falls into the water of the receiver. This substance is *phosphorus*.

25 Its discovery.

It was discovered by Brandt, a chemist of Hamburgh, about the year 1667, while he was employed in attempting to extract from human urine a liquid capable of converting silver into gold *.

Kunkel, another German chemist, hearing of the discovery, was anxious to find out the process, and for that purpose associated himself with a friend of his named Kraft. But the latter procured the secret from the discoverer; and expecting by means of it to acquire a fortune, refused to give any information to his associate. Vexed at this treachery, Kunkel resolved to attempt the discovery himself; and though he knew only that phosphorus was obtained from urine, prosecuted the inquiry with so much zeal, that he succeeded, and has been deservedly considered as one of the discoverers †.

Boyle likewise discovered phosphorus. Leibnitz indeed affirms that Kraft taught Boyle the whole process, and Kraft declared the same thing to Stahl. But surely the assertion of a dealer in secrets, and one who had deceived his own friend, on which the whole of this story is founded, cannot be put in competition with the affirmation of a man like Boyle, who was one of the honestest men, as well as greatest philosophers, of his age; and he positively assures us that he made the discovery without being previously acquainted with the process ‡.

Gahn, a Swedish chemist, discovered, in 1769, that phosphorus was contained in bones ‖, and Scheele (G) very soon after invented a process for obtaining it from them. Phosphorus is now generally procured in that manner. The process described in the beginning of this section is that of the Dijon academicians: it differs from that of Scheele only in a single particular.

* Leibnitz, Melange de Berlin.

† Stahl's Three Hundred Experiments.

‡ Boyle Abridged by Shaw, iii. 174.

‖ Bergman's Notes on Scheffer.

26 Its properties.

Phosphorus, when pure, is of a clear, transparent, yellowish colour; but when kept some time in water, it becomes opaque, and then has a great resemblance to white wax. Its consistence is nearly that of wax: it may be cut with a knife or twisted to pieces with the fingers. It is insoluble in water. Its specific gravity is 1,714.

It melts at the temperature of 99° *, and even at 67° it gives out a white smoke, and is luminous in the dark; that is to say, it suffers a slow combustion: so that it can only be prevented from taking fire by keeping it in a very low temperature, or by allowing it to remain always plunged in water. If air be excluded, it evaporates at 219°, and boils at 554° †. When heated to 122° (H), it burns with a very bright flame, and gives out a great quantity of white smoke, which is luminous in the dark; at the same time it emits an odour which has some resemblance to that of garlic. It leaves no residuum; but when the white smoke is collected, it is found to be an *acid*. Stahl considered this acid as the muriatic (I). According to him, phosphorus was composed of muriatic acid and phlogiston, and the combustion of it was merely the separation of phlogiston. He even declared, that to make phosphorus, nothing more was necessary than to combine muriatic acid and phlogiston; and that this composition was as easily accomplished as that of sulphur itself ‡.

* Pelletier, Journal de Physique, xxxv. 380.

† Ibid. 381.

27 Converted by combustion

‡ Three Hundred Experiments.

These assertions gained implicit credit; and the composition and nature of phosphorus were considered as completely understood, till Margraf of Berlin published his experiments in the year 1743. That great man, one of those illustrious philosophers who have contributed so much to the rapid increase of the science, distinguished equally for the ingenuity of his experiments and the clearness of his reasoning, attempted to produce phosphorus by combining together phlogiston and muriatic acid; but though he varied his process a thousand ways, presented the acid in many different states, and employed a variety of substances to furnish phlogiston, all his attempts failed, and he was obliged to give up the combination as impracticable. On examining the acid produced during the combustion of phosphorus, he found that its properties were very different from those of muriatic acid. It was therefore a distinct substance. The name of *phosphoric acid* was given to it; and it was concluded that phosphorus was composed of this acid united to phlogiston.

28 Into phosphoric acid.

But it was observed in 1772 by Morveau §, that phosphoric acid was heavier than the phosphorus from which it was produced (K); and Boyle had long before shewn that phosphorus would not burn except when in contact with air. These facts were sufficient to prove the inaccuracy of the theory concerning the composition of phosphorus; but they remained themselves unaccounted for, till Lavoisier published those celebrated experiments, which threw so much light on the nature and composition of acids.

§ Digress. Academ. p. 253.

He exhausted a glass globe of air by means of an air-pump;

(G) Crell, in his life of Scheele, informs us that Scheele was himself the discoverer of the fact. This, he says, clearly appears from a printed letter of Scheele to Gahn, who was before looked upon as the discoverer. See *Crell's Annals*, English Transl. I. 17.

(H) Morveau, *Encycl. Method. Chimie*, art *Affinité*.—According to Nicholson at 160°. See his *Translation of Chaptal*.

(I) This acid shall be afterwards described.

(K) The same observation had been made by Margraf, but no attention was paid to it.

Phoſphorus.

pump; and after weighing it accurately, he filled it with oxygen gas, and introduced into it 100 grains of phoſphorus. The globe was furniſhed with a ſtop-cock, by which oxygen gas could be admitted at pleaſure. He ſet fire to the phoſphorus by means of a burning-glaſs. The combuſtion was extremely rapid, accompanied by a bright flame and much heat. Large quantities of white flakes attached themſelves to the inner ſurface of the globe, and rendered it opaque; and theſe at laſt became ſo abundant, that notwithſtanding the conſtant ſupply of oxygen gas, the phoſphorus was extinguiſhed. The globe, after being allowed to cool, was again weighed before it was opened. The quantity of oxygen employed during the experiment was aſcertained, and the phoſphorus, which ſtill remained unchanged, accurately weighed. The white flakes, which were nothing elſe than pure phoſphoric acid, were found exactly equal to the weights of the phoſphorus and oxygen, which had diſappeared during the proceſs.

29 Which is phoſphorus combined with oxygen.

Phoſphoric acid therefore muſt have been formed by the combination of theſe two bodies; for the abſolute weight of all the ſubſtances together was the ſame before and after the proceſs *. It is impoſſible then that phoſphorus can be compoſed of phoſphoric acid and phlogiſton, as phoſphorus itſelf enters into the compoſition of that acid (L).

* *Lavoiſier's Chemiſtry*, Part I. chap. v.

Thus the combuſtion of phoſphorus, like that of ſulphur, is nothing elſe than its combination with oxygen; for during the proceſs no new ſubſtance appears except the acid, accompanied indeed with much heat and light.

30 Phoſphorus combines with ſulphur.

Phoſphorus combines readily with ſulphur, as Margraf diſcovered during his experiments on phoſphorus. This combination was afterwards examined by Mr Pelletier. The two ſubſtances are capable of being mixed in different proportions. Seventy-two grains of phoſphorus and nine of ſulphur, when heated in about four ounces of water, melt with a gentle heat. The compound remains fluid till it be cooled down to 77°, and then becomes ſolid. Theſe ſubſtances were combined in the ſame manner in the following proportions:

72 Phoſphor. / 18 Sulphur	congeals at	59°
72 Phoſphor. / 36 Sulphur	at	50°
72 Phoſphor. / 72 Sulphur	at	41°
72 Phoſphor. / 216 Sulphur	at	99°

Phoſphorus and ſulphur may be combined alſo by melting them together without any water; but the combination takes place ſo rapidly, that they are apt to ruſh out of the veſſel if the heat be not exceedingly moderate †.

† *Pelletier, Jour. de Phyſ.* xxxv. 382.

Phoſphorus is capable of combining alſo with many other bodies: the compounds produced are called *phoſphurets*.

The affinities of phoſphorus have not yet been aſcertained.

Carbon.

Sect. III. *Of Carbon.*

If a piece of wood be put into a crucible, well covered with ſand, and kept red hot for ſome time, it is converted into a black ſhining brittle ſubſtance, without either taſte or ſmell, well known under the name of *charcoal*. This ſubſtance contains always mixed with it ſeveral earthy and ſaline particles. When freed from theſe impurities it is called *carbon*.

31 Properties of carbon.

Charcoal is inſoluble in water. It is not affected (provided that all air be excluded) by the moſt violent heat which can be applied, excepting only that it is rendered much harder.

New-made charcoal abſorbs moiſture with avidity. When heated to a certain temperature, it abſorbs air copiouſly. La Metherie plunged a piece of burning charcoal into mercury, in order to extinguiſh it, and introduced it immediately after into a glaſs veſſel filled with common air. The charcoal abſorbed four times its bulk of air. On plunging the charcoal in water, one-fifth of this air was diſengaged. This air, on being examined, was found to contain a much ſmaller quantity of oxygen than atmoſpherical air does. He extinguiſhed another piece of charcoal in the ſame manner, and then introduced it into a veſſel filled with oxygen gas. The quantity of oxygen gas abſorbed amounted to eight times the bulk of the charcoal; a fourth part of it was diſengaged on plunging the charcoal into water *. It appears from the experiments of Sennebier, that charcoal when expoſed to the atmoſphere abſorbs oxygen gas in preference to *azot* †, as the other portion of common air is called.

* *Jour. de Phyſ.* xxx. 309.

† *Ann. de Chim.* iv. 261.

When heated to the temperature of 370° ‡, it takes fire, and, provided it has been previouſly freed from the earths and ſalts which it generally contains, it burns without leaving any reſiduum. If this combuſtion be performed in cloſe veſſels filled with oxygen gas inſtead of common air, part of the charcoal and oxygen diſappear, and in their room is found a particular gas exactly equal to them in weight. This gas has the properties of an acid, and is therefore called *carbonic acid gas*. Mr Lavoiſier, to whom we are indebted for this diſcovery, aſcertained, by a number of very accurate experiments, that this gas was compoſed of about 28 parts of carbon and 72 of oxygen ‖.

‡ *Morveau, Encycl. Method.* art. *Affinité.*

32 Converted into an acid.

‖ *Mem. Acad.* 1781, p. 448.

33 Suſceptible of cryſtallization.

Carbon is ſuſceptible of cryſtallization. In that ſtate it is called *diamond*. The figure of the diamond varies conſiderably; but moſt commonly it is a hexagonal priſm terminated by a ſix-ſided pyramid. When pure it is colourleſs and tranſparent. Its ſpecific gravity is from 3,44 to 3,55. It is one of the hardeſt ſubſtances in nature; and as it is not affected by a conſiderable heat, it was for many ages conſidered as incombuſtible. Sir Iſaac Newton, obſerving that combuſtibles refracted light more powerfully than other bodies, and that the diamond poſſeſſed this property in great perfection, ſuſpected,

---

(L) The quantity of phoſphorus conſumed was 45 grains
The quantity of oxygen gas - - - 69,375

Weight of the phoſphoric acid produced 114,375
Phoſphoric acid therefore is compoſed of 100 parts phoſphorus and 154 oxygen.

Carbon.

pected, from that circumstance, that it was capable of combustion. This singular conjecture was verified in 1694 by the Florentine academicians, in the presence of Cosmo III. grand duke of Tuscany. By means of a burning-glass, they destroyed several diamonds. Francis I. emperor of Germany, afterwards witnessed the destruction of several more in the heat of a furnace. These experiments were repeated by Rouelle, Macquer, and D'Arcet; who proved that the diamond was not merely evaporated, but actually burnt, and that if air was excluded it underwent no change.

No attempt, however, was made to ascertain the product, till Lavoisier undertook a series of experiments for that purpose in 1772. He obtained *carbonic acid gas*. It might be concluded from these experiments, that the diamond contains carbon; but it was reserved for Mr Tennant to shew that it consisted entirely of that substance.

34 When it forms diamond.

Into a tube of gold, having one end closed and a glass tube adapted to the other to collect the product, that gentleman put $2\frac{1}{4}$ grains of diamonds and a quarter of an ounce of nitre (M). This tube was heated slowly; the consequence of which was, that great part of the nitric acid passed off before the diamond took fire, and by that means almost the whole of the carbonic acid formed during the combustion of the diamond remained in the potass, for which it has a strong affinity. To ascertain the quantity of this carbonic acid, he dissolved the potass in water, and added to the solution another salt composed of muriatic acid and lime. Muriatic acid has a stronger affinity for potass than for lime; it therefore combines with the potass, and at the same time the lime and carbonic acid unite and fall to the bottom of the vessel, because they are nearly insoluble in water. He decanted off the liquor, and put the lime which contained the carbonic acid gas into a glass globe, having a tube annexed to it. This globe and tube he then filled with mercury, and inverted into a vessel containing the same fluid. The lime by that means occupied the very top of the tube. It now remained to separate the carbonic acid from the lime, which may be done by mixing it with any acid, as almost every other acid has a stronger affinity for lime than carbonic acid has. Accordingly on introducing muriatic acid, 10,3 ounce measures of carbonic acid gas, or nearly 9,166 grains, were separated. But, according to the experiments of Lavoisier, this gas is composed of 72 parts of oxygen and 28 of carbon; 9,166 grains, therefore contain 2,56 grains of carbon, which is almost precisely the weight of the diamond consumed. It follows, therefore, that it was composed of pure carbon*. The difficulty of burning the diamond is owing entirely to its hardness. Messrs Morveau and Tennant rendered common charcoal so hard by exposing it for some time to a violent fire in close vessels, that it lost much of its natural tendency to combustion, and endured even a red heat without catching fire †.

* Phil. Transf. 1797. p. 123.

† Encycl. Method. Chimie, art. Acier.

Charcoal possesses a number of singular properties, which render it of considerable importance. It is incapable of putrefying or rotting like wood, and is not therefore liable to decay through age. This property has been long known. It was customary among the ancients to *char* the outside of those stakes which were to be driven into the ground or placed in water, in order to preserve the wood from spoiling. New-made charcoal, by being rolled up in cloths which have contracted a disagreeable odour, effectually destroys it. It takes away the bad taint from meat beginning to putrefy, by being boiled along with it. It is perhaps the best teeth powder known. Mr Lowitz of Petersburgh has shewn, that it may be used with advantage to purify a great variety of substances.

Carbon unites with a number of bodies, and forms with them compounds known by the name of *carburets*. 35 Carburets.

Its affinities have not yet been ascertained.

Sect. IV. *Of Hydrogen.*

Put into a glass vessel furnished with two mouths a quantity of fresh iron filings, quite free from rust. Lute into one of these mouths the end of a crooked glass tube. Insert the other end of this tube below a glass jar filled with water, and inverted into a pneumatic apparatus. Then pour upon the iron filings a quantity of sulphuric acid, diluted with twice its own weight of water, and close up the mouth of the vessel. Immediately the iron filings and acid effervesce with violence, a vast quantity of gas is produced, which rushes through the tube and fills the jar. This gas is called *hydrogen gas* (N). 36 Method of procuring hydrogen.

It was obtained by Dr Mayow and by Dr Hales from various substances, and had been known long before in mines under the name of the *fire damp*. Mr Cavendish * was the first who examined its properties with attention. They were afterwards more fully investigated by Priestley, Scheele, and Fontana.

* Phil. Transf. 1766.

Hydrogen, like *air*, is invisible and elastic, and capable of indefinite compression and dilatation. 37 Its properties.

Its specific gravity differs according to its purity, Kirwan found it 0,00010 †; Lavoisier 0,000094 ‡, or about twelve times lighter than common air.

† On Phlogiston sect. 1st.

‡ Lavoisier's Chemistry, Appendix.

All burning substances are immediately extinguished by being plunged into this gas. It is incapable, therefore, of supporting combustion.

Animals, when they are obliged to breathe it, die almost instantaneously. Scheele, indeed, found that he could breathe it for some time without inconvenience §; but Fontana, who repeated the experiment, discovered that this was owing to the quantity of common air contained in the lungs when he began to breathe; for on expiring as strongly as possible before drawing in the hydrogen gas, he could only make three respirations, and even these three produced extreme feebleness and oppression about the breast ‖.

§ Scheele on Fire.

‖ Jour de Phys. xv. 99.

If a phial be filled with hydrogen gas, and a lighted candle be brought to its mouth, the gas will take fire, and burn gradually till it is all consumed. If hydrogen

(M) Nitre is composed of potass and nitric acid; and nitric acid contains a great quantity of oxygen, which is easily separated by heat. Diamond, when mixed with nitre, burns at a much lower heat than by any other process.

(N) It was formerly called *inflammable air*, and by some chemists *phlogiston*.

Hydrogen.

gen and oxygen gas be mixed together and kindled, they burn inſtantaneouſly, and produce an exploſion like gunpowder. The ſame effect follows when a mixture of hydrogen gas and atmoſpherical air is kindled, but the exploſion is leſs violent. Hydrogen gas will not burn except in contact with oxygen gas, nor will it burn even in contact with oxygen gas, unleſs a red heat be applied to it. If 85 parts by weight of oxygen gas, and 15 of hydrogen gas, be mixed together, and ſet on fire in a cloſe veſſel, they diſappear, and in their place there is found a quantity of water exactly equal to them in weight. This water muſt be compoſed of theſe two gaſes; for it did not previouſly exiſt in the veſſel, and no other ſubſtance except the gaſes was introduced. Water then is compoſed of oxygen and hydrogen; and the combuſtion of hydrogen is nothing elſe but the act of its combination with oxygen (o).

38
Compoſition of water.

It had been ſuppoſed, in conſequence of the experiments of Dr Prieſtley and ſeveral other philoſophers, that when hydrogen gas was allowed to remain in contact with water, it was gradually decompoſed, and converted into another gas; but Mr de Morveau *, Mr Haſſenfratz †, and Mr Libes ‡, have ſhewn that it undergoes no change, provided ſufficient care be taken to exclude every other gas.

* *Encycl. Method. Chim.* i. 754.
† *Ann. de Chim.* i. 192.
‡ *Jour. de Phyſ.* xxxvi. 412.

39
Compounds of hydrogen gas.

Hydrogen gas diſſolves ſulphur, phoſphorus, and carbon. The compounds are called *ſulphurated*, *phoſphorated*, and *carbonated hydrogen gas*.

40
Sulphurated hydrogen gas.

1. Sulphurated hydrogen gas was firſt examined with attention by Scheele, who, together with Bergman, diſcovered many of its properties. Mr Kirwan likewiſe publiſhed a very valuable paper on the ſame ſubject. If equal parts of ſulphur and potaſs be melted together in a covered crucible, they combine together, and form a compound known by the name of *ſulphuret of potaſs*, but formerly called, from its red colour, *hepar ſulphuris*, or *liver of ſulphur*. When this ſubſtance is moiſtened with water, it gives out a quantity of ſulphurated hydrogen gas; hence this gas was at firſt called *hepatic gas*.

Mr Gengembre encloſed a bit of ſulphur in a glaſs veſſel filled with hydrogen gas, and melted the ſulphur by means of a burning-glaſs. A quantity of it diſappeared, and the hydrogen aſſumed all the properties of *hepatic gas*. Hence it follows that this gas is merely ſulphur diſſolved in hydrogen gas.

The eaſieſt method of obtaining it is to pour an acid, the muriatic for inſtance, on a quantity of the ſulphuret reduced to powder. An efferveſcence takes place, the gas is extricated, and may be collected by means of a pneumatic apparatus. The theory of this emiſſion is obvious. The ſulphur is gradually converted into ſulphuric acid, by decompoſing the water, which is always united with acids, and ſeizing its oxygen: the hydrogen of the water is thus ſet at liberty; it aſſumes the gaſeous form, and at the ſame time diſſolves part of the remaining ſulphur, for which it has a conſiderable affinity.

Hydrogen.

The ſpecific gravity of ſulphurated hydrogen gas is 0,00135*; it is to common air as 1106 to 1000.

* *Kirwan on Phlogiſton*, ſect. iii.

It has a very fetid odour, preciſely ſimilar to that emitted by rotten eggs, which indeed is owing to the emiſſion of the very ſame gas.

It is not more reſpirable than hydrogen gas. When ſet on fire, in contact with oxygen gas, it burns with a light blue flame, without exploding, and at the ſame time a quantity of ſulphur is depoſited. The combuſtion of this gas, then, is merely the union of its hydrogen, and perhaps part of its ſulphur, with oxygen.

This gas turns ſyrup of violets to a green colour †. It does not ſeem capable of exiſting in atmoſpherical air without decompoſition; for the moment it comes into contact with oxygen gas, ſulphur is depoſited ‡.

† *Fourcroy's Chemiſtry*, art. Sulphur
‡ *Bergman.*

41
Phoſphorated hydrogen gas.

2. Phoſphorated hydrogen gas was diſcovered by Mr Gengembre in 1783, and by Mr Kirwan ſome time after, before he became acquainted with the experiments of that gentleman. It may be procured by mixing phoſphorus with potaſs diſſolved in water, and applying a boiling heat to the ſolution. The phoſphorus is gradually converted into an acid by decompoſing the water, and uniting with its oxygen. The hydrogen aſſumes the form of a gas, and flies off after diſſolving a little of the phoſphorus. This gas may be collected by means of a pneumatic apparatus.

Phoſphorated hydrogen gas has a ſmell reſembling that of putrid fiſh. When mixed with oxygen gas or common air, it becomes luminous; and on the application of the ſmalleſt heat, it burns with aſtoniſhing rapidity §. The products are water and phoſphoric acid. The combuſtion of this gas therefore is nothing elſe than the union of its phoſphorus and hydrogen with oxygen, attended by an emiſſion of heat and light.

§ *Kirwan.*

Phoſphorated hydrogen gas may alſo be formed by introducing a bit of phoſphorus into a jar containing hydrogen gas: but care muſt be taken to make this gas as dry as poſſible; for its affinity with phoſphorus is weakened in proportion to its moiſture ‖.

‖ *Brugnatelli, Nicholſon's Journal*, i. 445.

42
Carbonated hydrogen gas.

3. Carbonated hydrogen gas ariſes ſpontaneouſly in hot weather from marſhes, but always mixed with ſeveral other gaſes. Several ſpecies of it have been lately diſcovered by the aſſociated Dutch chemiſts Bondt, Dieman, Van Trooſtwyck, and Lauwerenberg ¶. When 75 parts of ſulphuric acid and 25 of ſpirit of wine are mixed together, a gas is extricated which ſuffers no alteration from ſtanding over water. Its ſpecific gravity is 0,00111, or it is to common air as 909 to 1000. It has a fetid odour, and burns with a ſtrong compact flame. When paſſed through ſulphur it is converted into ſulphurated hydrogen gas, and at the ſame time a quantity of carbon is depoſited in the form of a fine powder; it muſt therefore be compoſed of carbon and hydrogen gas. When burnt, the product is carbonic acid

¶ *Ann. de Chim.* xxi. 48.

(o) The hiſtory of this great diſcovery, and the objections which have been made to it, we reſerve for the chapter which treats of *Water*, where they will be better underſtood than they could be at preſent. This ſubſtance was called *hydrogen* by the French chemiſts, becauſe it enters into the compoſition of water, from ὑδωρ *water*, and γινομαι *I am born*. Objections have been made to the propriety of the name, into which we ſhall not enter. It ought never to be forgotten that Newton had long before, with a ſagacity almoſt greater than human, conjectured, from its great refracting power, that water *contained a combuſtible ſubſtance*.

Hydrogen. acid gas and water *. By making ether (P) pass thro' a red hot glass tube, another carbonated hydrogen gas was formed, the specific gravity of which was 0,00086. Spirit of wine, passed in the same manner, afforded a gas, the specific gravity of which was 0,00053, and which burned with a paler flame than the other two. These gases were found to contain from 80 to 74 parts of carbon, and from 20 to 26 of hydrogen. The first species was found to contain most carbon, and the last to contain least †.

* Ibid.

† Ibid.

43 Affinities of these gases.

The affinity of hydrogen gas for these three combustibles is as follows:

Sulphur,
Carbon,
Phosphorus (Q).

Dr Austin found, that by repeatedly passing electric explosions through a small quantity of carbonated hydrogen gas, it was permanently dilated to more than twice its original bulk. He rightly concluded, that this remarkable expansion could only be owing to the evolution of hydrogen gas. On burning air thus expanded, he found that it required a greater quantity of oxygen than the same quantity of gas not dilated by electricity: An addition therefore had been made to the combustible matter; for the quantity of oxygen necessary to complete the combustion of any body, is always proportional to the quantity of that body. He concluded from these experiments, that he had decomposed the carbon which had been dissolved in the hydrogen gas; and that carbon was composed of hydrogen and azot (R), some of which was always found in the vessel after the dilated gas had been burnt by means of oxygen ‡. If this conclusion be fairly drawn, we must expunge *carbon* from the list of simple substances, and henceforth consider it as a compound.

44 Attempt to decompose carbon

‡ Phil. Transf. lxxx. 51.

45 Examined,

There was one circumstance which ought to have prevented Dr Austin from drawing this conclusion, at least till warranted by more decisive experiments. The quantity of combustible matter had been increased. Now, if the expansion of the carbonated hydrogen gas was owing merely to the decomposition of carbon, no such increase ought to have taken place, but rather the contrary; for the carbon, which was itself a combustible substance, was resolved into two ingredients, hydrogen and azot, only the first of which burnt on the addition of oxygen and the application of heat. Dr Austin's experiments have been lately repeated by Mr William Henry with a great deal of accuracy §. He found that the dilatation which Dr Austin describes actually took place, but that it could not be carried beyond a certain degree, a little more than twice the original bulk of the gas. Upon burning separately by means of oxygen, two equal portions of carbonated hydrogen gas, one of which had been expanded by electricity to double its original bulk, the other not, he found that each of them produced precisely the same quantity of *carbonic acid gas*. Both therefore contained the same quantity of carbon; consequently no carbon had been decompounded by the electric shocks.

§ Phil. Transf. 1797 part 2d.

Azot.

46 And found unsuccessful.

Mr Henry then suspected that the dilatation was owing to the water which every gas contains in a larger or smaller quantity. To ascertain this, he endeavoured to deprive the carbonated hydrogen gas of as much water as possible, by making it pass over very dry potass, which attracts water with avidity. Gas treated in this manner could only be expanded one-sixth of its bulk; but on admitting a drop or two of water, the expansion went on as usual. The substance decompounded by the electricity, then, was not the carbon, but the water in the carbonated hydrogen gas. Nor is it difficult to see in what manner this decomposition is effected. Carbon, at a high temperature, has a greater affinity for oxygen than hydrogen has; for if the steam of water be made to pass over red hot charcoal, it is decomposed, and carbonic acid and hydrogen gas are formed. The electric explosion supplies the proper temperature; the carbon unites with the oxygen of the water, and forms carbonic acid; and the hydrogen, thus set at liberty, occasions the dilatation. Carbonic acid gas is absorbed with avidity by water: and when water was admitted into 709 measures of gas thus dilated, 100 measures were absorbed; a proof that carbonic acid gas was actually present. As to the azot which Dr Austin found in his dilated gas, it evidently proceeded from the admission of some atmospheric air, about 73 parts of which in the 100 consist of this gas: for Dr Austin's gas had stood long over water; and Drs Priestley and Higgins have shewn that air in such a situation always becomes impregnated with azot.

47 Affinities of hydrogen.

The affinities of hydrogen have not yet been ascertained, but perhaps they are as follows:

Oxygen,
Carbon,
Azot.

Sect. V. *Of Azot.*

48 Method of procuring azot.

If a quantity of iron filings and sulphur, mixed together and moistened with water, be put into a glass vessel full of air, it will absorb all the oxygen in the course of a few days; but a considerable residuum of air still remains incapable of any farther diminution. This residuum has obtained the appellation of *azotic gas*.

It

(P) Ether is a very volatile and fragrant liquid, obtained by mixing spirit of wine and acids, and distilling. It shall be afterwards described.

(Q) Sulphur decomposes carbonated hydrogen gas; therefore its affinity is greater than that of carbon. The Dutch chemists melted phosphorus in carbonated hydrogen gas, but no change was produced; therefore the affinity of phosphorus is inferior to that of carbon.

(R) See next Section.—His theory was, that carbonated hydrogen gas was composed of hydrogen, and azot, and carbon of azot, and carbonated hydrogen gas, which comes nearly to the same thing with regard to the elements of carbon. It is singular enough, that though Dr Austin would not allow the presence of carbon in carbonated hydrogen gas, he actually decomposed it by melting sulphur in it: the sulphur combined with the hydrogen gas, and a quantity of carbon was precipitated. This experiment he relates without making any remarks upon it, and seems indeed not to have paid any attention to it.

Azot.

49 Discovery of azot.

It was discovered in 1772 by Dr Rutherford, now professor of botany in the university of Edinburgh (s). Scheele procured it by the above process as early as 1776, and proved that it was a distinct fluid. Mr Lavoisier afterwards proved the same thing, without any previous knowledge of Scheele's discoveries.

The air of the atmosphere contains about ,73 parts of azotic gas; almost all the rest is oxygen gas. The easiest method of procuring azotic gas is to put some sulphuret of potass into a glass vessel filled with air, and accurately closed, and then to apply heat to the sulphuret. All the oxygen is absorbed almost instantly. This method was first pointed out by Morveau*.

* Nicholson's Journal, i. 268.

Mr Kirwan examined the specific gravity of azotic gas obtained by Scheele's process; it was 0,00120: it is therefore somewhat lighter than the atmospheric air; it is to atmospheric air as 985 to 1000†.

† On Phlogiston § 1st.

50 Its properties.

It tinges delicate blue colours slightly with green‡. It is exceedingly noxious to animals; if they are obliged to respire it, they drop down dead almost instantly (T). No combustible will burn in it. This is the reason that a candle is extinguished in atmospherical air as soon as the oxygen near it is consumed. Mr Goettling, indeed, published, in 1794, that phosphorus shone, and was converted into phosphoric acid, in pure azotic gas. Were this the case, it would not be true that no combustible burns in this gas; for the conversion of phosphorus into an acid, and even its shining, is an actual though slow combustion. Mr Goettling's experiments were soon after repeated by Drs Scherer and Jaeger, who found that phosphorus does not shine in azotic gas when it is perfectly pure; and that therefore the gas on which Mr Goettling's experiments were made had contained a mixture of oxygen gas, owing principally to its having been only confined by water. These results were afterwards confirmed by Professor Lampadius and Professor Hildebrandt. It is therefore proved beyond a doubt, that phosphorus does not burn in azotic gas, and that whenever it appears to do so, there is always some oxygen gas present §.

‡ Fourcroy, Ann. de Chim. i. 45.

§ Nicholson's Journal, ii. 8.

Azotic gas is capable of dissolving phosphorus, as has been proved by the experiments of Fourcroy and Vauquelin.

It dissolves also a little carbon: for azotic gas obtained from animal substances, which contain a great deal of azot, when confined long in jars, deposites on the sides of them a black matter which has the properties of carbon *.

* Fourcroy, Ann. de Chim. i. 45.

These two solutions, the properties of which have not yet been accurately examined, are called *phosphorated and carbonated azotic gas.*

51 Production of nitric acid.

Azotic gas is capable of combustion. Take a glass tube, the diameter of which is about the sixth part of an inch; shut one of its ends with a cork, through the middle of which passes a small wire with a ball of metal at each end. Fill the tube with mercury, and then plunge its open end into a bason of that fluid. Throw up into the tube as much of a mixture, composed of 13 parts of azotic and 87 parts of oxygen gas, as will fill 3 inches. Through this gas make, by means of the wire in the cork, a number of electric explosions pass. The volume of gas gradually diminishes, and in its place there is found a quantity of *nitrous acid*. This acid, therefore, is composed of azot and oxygen: and these two substances are capable of combining, or, which is the same thing, azotic gas is capable of combustion in the temperature produced by electricity, which we know to be pretty high. The combustibility of azotic gas, and the nature of the product, was first discovered by Mr Cavendish, and communicated to the Royal Society on the 2d of June 1785 (U).

52 Attempts to decompose azot.

The affinities of azot are still unknown. It has never yet been decompounded, and must therefore, in the present state of our knowledge, be considered as a simple substance. Dr Priestley, who obtained azotic gas at a very early period of his experiments, considered it as a compound of oxygen gas and phlogiston, and for that reason gave it the name of *phlogisticated air*. According to the theory of Stahl, which was then universally prevalent, he considered combustion as merely the separation of phlogiston from the burning body. To this theory he made the following addition: Phlogiston is separated during combustion by means of chemical affinity: *Air* (that is, *oxygen gas)* has a strong affinity for phlogiston: Its presence is necessary during combustion, because it combines with the phlogiston as it separates from the combustible; and it even contributes by its affinity to produce that separation: The moment the air has combined with as much phlogiston as it can receive, or, to use a chemical term, the moment it is *saturated* with phlogiston, combustion necessarily stops, because no more phlogiston can leave the combus-

(s) See his thesis *De Aere Mephitico*, published in 1772.—" Sed aer salubris et purus respiratione animali non modo ex parte fit mephiticus sed et *aliam indolis suæ mutationem inde patitur*. Postquam enim omnis aer mephiticus (carbonic acid gas) ex eo, ope lixivii caustici secretus et abductus fuerit, *qui tamen restat* nullo modo salubrior inde evadit; nam quamvis nullam ex aqua calcis præcipitationem faciat haud minus quam antea *et flammam et vitam extinguit*. Page 17.

" Aer qui per carbones ignitos folle adactus fuit, atque deinde ab omni aere mephitico *(carbonic acid gas)* expurgatus, malignus tamen adhuc reperitur et omnino similis est ei qui respiratione inquinatur. Immo ab experimentis patet hanc solam esse aeris mutationem quæ inflammationi adscribi potest. Si enim accenditur materies quælibet quæ ex phlogisto et basi fixa atque simplici constat, *aer inde natus ne minimam aeris mephitici quantitatem in se continere videtur*. Sic aer in quo sulphur aut phosphorus urinæ combustus fuit, licet maxime malignus, calcem tamen ex aqua minime præcipitat. Interdum quidem si ex phosphoro natus fuerit, nubeculam aquæ calcis inducit sed tenuissimam, nec aeri mephitico attribuendam, sed potius acido illi quod in phosphoro inest, et quod, ut experimenta docuerunt, hoc singulari dote pollet." Page 19.

(T) Hence the name *azot*, given it by the French chemists, which signifies *destructive to life*, from α and ζωη.

(U) It is remarkable enough, that the acidity of nitric acid was ascribed by Mayow, in 1674, to the presence of oxygen. *Indoles caustica spiritus nitri* (says he) *a particulis ejus igneo-aereis provenit*. Tract. p. 19.

Azot.

combustible (v): Air saturated with phlogiston is azotic gas. This was a very ingenious theory, and, when Dr Priestley published it, exceedingly plausible. A great number of the most eminent chemists accordingly embraced it: But it was soon after discovered, that during combustion the quantity of air, instead of increasing, as it ought to have done, had phlogiston been added to it, actually diminished both in volume and weight. There was no proof, therefore, that during combustion any substance whatever combined with air, but rather the contrary. It was discovered also, that a quantity of air combined with the burning substance during combustion, as we have seen was the case with sulphur, phosphorus, carbon, and hydrogen; and that this air had the properties of oxygen gas. These discoveries entirely overthrew the evidence on which Dr Priestley's theory was founded: accordingly, as no attempt to decompound azot has succeeded, it has been given up by almost every chemist except Dr Priestley himself. Atmospheric air, as Scheele first proved, is composed of about 27 parts of oxygen and 73 of azotic gas. During combustion, the oxygen is abstracted and the azotic gas remains behind.

53 Unsuccessful.

La Metherie made an attempt to prove that azot was composed of oxygen and carbon (w). He took a bit of burning charcoal, extinguished it in mercury, and then plunged it while hot into oxygen gas. On being plunged into water, one fourth of the gas was disengaged, and part of it was found to consist of azotic gas. From this he concluded that he had formed azotic gas by combining oxygen and carbon: But it was proved by Mr Lavoisier, beyond the possibility of doubt, that oxygen and carbon form carbonic acid gas. They cannot then certainly form azot; for two contradictory facts cannot both be true. There must then have been something overlooked in the experiment. Indeed the experiment itself does not warrant the conclusion which De La Metherie drew from it. He did not ascertain whether the weight of the charcoal was diminished; and, besides, there was azot mixed with the oxygen gas which he employed, as he himself has informed us: And how was it possible for him to admit the charcoal into water without, at the same time, admitting some atmospherical air?

We have now described all the combustibles which are at present reckoned simple, except the metals. We have found, that during combustion all of them combine with oxygen; that no part of them is disengaged, no part of them lost: we have therefore concluded, that the combustion of these substances is nothing else but the act of their uniting with oxygen. We have seen, however, that none of them, except phosphorus, was capable of uniting with oxygen at the common temperature of the atmosphere; that, in order to produce the union, heat was necessary, and that the degree of this heat was different for each. Hydrogen required a red heat, and azot a still greater. We have seen, too, that during these combinations a quantity of heat and light escaped. Now, why is heat necessary for these combinations? and whence come the heat and the light which we perceive during the combustion of these bodies? These questions are of the highest importance, and can only be answered by a particular investigation of the nature and properties of heat and light. This investigation we shall attempt, as soon as we have described the *metals* and *earths*, which form the subject of the two following chapters.

Metals.

Chap. III. *Of* Metals.

54 Properties of metals.

Metals may be considered as the great instruments of all our improvements: Without them, many of the arts and sciences could hardly have existed. So sensible were the ancients of their great importance, that they raised those persons who first discovered the art of working them to the rank of deities. In chemistry, they have always filled a conspicuous station: at one period the whole science was confined to them; and it may be said to have owed its very existence to a rage for making and transmuting metals.

55 Lustre.

1. One of the most conspicuous properties of the metals is a particular brilliancy which they possess, and which has been called the *metallic lustre*. This proceeds from their reflecting much more light than any other body; a property which seems to depend partly on the closeness of their texture. This renders them peculiarly proper for mirrors, of which they always form the basis.

56 Opacity.

2. They are absolutely opaque, or impervious to light, even after they have been reduced to very thin plates. Silver leaf, for instance, $\frac{1}{160000}$ of an inch thick, does not permit the smallest ray of light to pass throught it. Gold, however, may be rendered transparent; for gold leaf, $\frac{1}{280000}$ of an inch thick, transmits light of a lively green colour *. And it is not improbable that all the other metals, as Sir Isaac Newton supposed, would become transparent, if they could be reduced to a sufficient degree of thinness. It is to this opacity that a part of the excellence of the metals, as mirrors, is owing; their brilliancy alone would not qualify them for that purpose.

* Nicholson's Notes on Fourcroy.

57 Fusibility.

3. They may be melted by the application of heat, and even then still retain their opacity. This property enables us to cast them in moulds, and then to give them any shape we please. In this manner many elegant iron utensils are formed.

58 Gravity.

4. Their specific gravity is greater than that of any other body hitherto discovered.

5. They are better conductors of electricity than any other body.

59 Malleability.

6. But one of their most important properties is *malleability*; by which is meant the capacity of being extended and flattened when struck with a hammer. This property enables us to give the metallic body any form we think proper, and thus renders it easy for us to

(v) This ingenious theory was first conceived by Dr Rutherford, as appears from the following passage of his thesis. "Ex iisdem etiam deducere licet quod aer ille malignus (azotic gas) componitur ex *aere atmospherico cum phlogisto unito et quasi saturato*. Atque idem confirmatur eo, quod aer qui metallorum calcinationi jam inserviit, et phlogiston ab iis abripuit, ejusdem plane sit indolis." *De aere Mephitico*, p. 20.

(w) Or rather of *hydrogen*, for he considered carbon itself as a compound.

Metals.

to convert them into the various inſtruments for which we have occaſion. All metals do not poſſeſs this property; but it is remarkable that almoſt all thoſe which were known to the ancients have it. Heat increaſes this property conſiderably.

60 Ductility.

7. Another property which is alſo wanting in many of the metals, is *ductility;* by which we mean the capacity of being drawn out into wire by being forced through holes of various diameters. This property has by ſome been called *tenacity;* and it doubtleſs depends upon the tenacity of the various metals.

61 Calcination

8. When expoſed to the action of heat and air, moſt of the metals loſe their luſtre, and are converted into earthy-like powders of different colours and properties, according to the metal and the degree of heat employed. Several of the metals even take fire when expoſed to a ſtrong enough heat; and after combuſtion the reſiduum is found to be the very ſame earthy-like ſubſtance. If any of theſe *calces*, as they are called, be mixed with charcoal-powder, and expoſed to a ſtrong heat in a proper veſſel, it is changed again to the metal from which it was produced. From theſe phenomena Stahl concluded, that metals were compoſed of *earth* and *phlogiſton*. He was of opinion that there was only one primitive earth, which not only formed the baſis of all thoſe ſubſtances known by the name of earths, but the baſis alſo of all the metals. He found, however, that it was impoſſible to combine any mere earth with phlogiſton; and concluded, therefore, with Beccher, that there was another principle beſides earth and phlogiſton, which entered into the compoſition of the metals. To this principle Beccher gave the name of *mercurial earth*, becauſe, according to him, it exiſted moſt abundantly in *mercury*. This principle was ſuppoſed to be very volatile, and therefore to fly off during calcination: and ſome chemiſts even affirmed that it might be obtained in the ſoot of thoſe chimneys under which metals have been calcined.

62 Stahl's theory of the compoſition of metals

63 Defective.

A ſtriking defect was ſoon perceived in this theory. The original metal may again be produced by heating its calx along with ſome other ſubſtance which contains phlogiſton: now, if the mercurial earth flies off during combuſtion, it cannot be neceſſary for the formation of complete metals, for they may be produced without it: if, on the contrary, it adheres always to the calx, there is no proof of its exiſtence at all. Chemiſts, in conſequence of theſe obſervations, found themſelves obliged to diſcard the mercurial principle altogether, and to conclude that metals were compoſed of earth only, united to phlogiſton. But if this be really the caſe, how comes it that theſe two ſubſtances cannot be united by art? Henkel was the firſt who attempted to ſolve this difficulty. According to him, earth and phlogiſton are ſubſtances of ſo oppoſite a nature, that it is exceedingly difficult, or rather it has been hitherto impoſſible, for us to commence their union; but after it has been once begun by nature, it is an eaſy matter to complete it. No calcination has hitherto deprived the metals of all their phlogiſton; ſome ſtill adheres to the calces. It is this remainder of phlogiſton which renders it ſo eaſy to reſtore them to their metallic ſtate.

64 Improved by Henkel.

Were the calcination to be continued long enough to deprive them altogether of phlogiſton, they would be reduced to the ſtate of other earths; and then it would be equally difficult to convert them into metals, or, to uſe a chemical term, to *reduce* them. Accordingly we find that the more completely a calx has been calcined, the more difficult is its reduction. This explanation was favourably received. But after the characteriſtic properties of the various *earths* had been aſcertained, and the calces of metals were accurately examined, it was perceived that the calces differed in many particulars from all the *earths*, and from one another. To call them all the ſame ſubſtance, then, was to go much farther than either experiment or obſervation would warrant, or, rather, it was to declare open war againſt both experiment and obſervation. It was concluded, therefore, that each of the metals was compoſed of a peculiar *earthy ſubſtance* combined with phlogiſton. For this great improvement in accuracy, chemiſtry is chiefly indebted to Bergman.

65 Farther improved.

66 Still imperfect.

But there were ſeveral phenomena of calcination which had all this time been unaccountably overlooked. The calces are all conſiderably heavier than the metals from which they are obtained. Boyle had obſerved this circumſtance, and had aſcribed it to a quantity of *fire* which, according to him, became fixed in the metal during the proceſs*. But ſucceeding chemiſts paid little attention to it, or to the action of air, till Mr Lavoiſier publiſhed his celebrated experiments on calcination, in the Memoirs of the Paris Academy for 1774. He put eight ounces of *tin* into a large glaſs retort, the point of which was drawn out into a very ſlender tube to admit of eaſy fuſion. This retort was heated ſlowly till the tin began to melt, and then ſealed hermetically. This heat was applied to expel ſome of the air from the retort; without which precaution it would have expanded and burſt the veſſel. The retort, which was capable of containing 250 cubic inches, was then weighed accurately, and placed again upon the fire. The tin ſoon melted, and a pellicle formed on its top, which was gradually converted into a grey powder, that ſunk by a little agitation to the bottom of the liquid metal: in ſhort, the tin was partly converted into a *calx*. This proceſs went on for three hours; after which the calcination ſtopped, and no farther change could be produced on the metal. The retort was then taken from the fire, and found to be preciſely of the ſame weight as before the operation. It is evident, then, that no new ſubſtance had been introduced, and that therefore the increaſed weight of calces cannot, as Boyle ſuppoſed, be owing to the fixation of fire (x).

* *Fire and flame weighed.*

67 Refuted by Lavoiſier.

When the point of the retort was broken, the air ruſhed in with a hiſſing noiſe, and the weight of the retort was increaſed by ten grains. Ten grains of air, therefore, muſt have entered, and, conſequently, preciſely that quantity muſt have diſappeared during the calcination. The metal and its calx being weighed, were found juſt ten grains heavier than before: therefore, the air which diſappeared was abſorbed by the metal: and as that part of the tin which remained in a metallic ſtate was unchanged, it is evident that this air

(x) This experiment had been performed by Boyle with the ſame ſucceſs. He had drawn a wrong concluſion from not attending to the ſtate of the air of the veſſel. *Shaw's Boyle*, II. 394.

Metals. air must have united with the calx. The increase of weight, then, which metals experience during calcination, is owing to their uniting with air (Y). But all the air in the vessel was not absorbed, and yet the calcination would not go on. It is not the whole, then, but some particular part of the air which unites with the calces of metals. By the subsequent discoveries of Priestley, Scheele, and Lavoisier himself, it was ascertained, that the residuum of the air, after calcination has been performed in it, is always pure azotic gas: It follows, therefore, that it is only the *oxygen* which combines with calces; and that a metallic calx is not a simple substance, but a compound. Mr Lavoisier observed, that the weight of the calx was always equal to that of the metal employed, together with that of the oxygen absorbed. It became a question then, Whether metals, during calcination, lost any substance, and consequently, whether they contained any phlogiston? Mr Lavoisier accordingly proposed this question; and he answered it himself by a number of accurate experiments and ingenious observations. Metals cannot be calcined excepting in contact with oxygen, and in proportion as they combine with it Consequently they not only absorb oxygen during their calcination, but that absorption is absolutely necessary to their assuming the form of a calx. If the calx of mercury be heated in a retort, to which a pneumatic apparatus is attached, to the temperature of 1200°, it is converted into pure mercury; and, at the same time, a quantity of oxygen separates from it in a gaseous form. As this process was performed in a close vessel, no new substance could enter: The calx of mercury, then, was reduced to a metallic state without phlogiston. The weights of the metal and the oxygen gas are together just equal to that of the calx; the calx of mercury, therefore, must be composed of mercury and oxygen; consequently there is no reason whatever to suppose that mercury contains phlogiston. Its calcination is merely the act of uniting it with oxygen (Z). The calces of lead, silver, and gold, may be decomposed exactly in the same manner; and Mr Van Marum, by means of his great electrical machine, decomposed also those of tin, zinc, and antimony, and resolved them into their respective metals and oxygen *. The same conclusions, therefore, must be drawn with respect to these metals. All the metallic calces may be decomposed by presenting to them substances which have a greater affinity for oxygen than they have. This is the reason that charcoal-powder is so efficacious in reducing them: and if they are mixed with it, and heated in a proper vessel, furnished with a pneumatic apparatus, it will be easy to discover what passes. During the reduction, a great deal of carbonic acid gas comes over, which, together with the metal, is equal to the weight of the calx and the charcoal: it must therefore contain all the ingredients; and we know that carbonic acid gas is composed of carbon and oxygen. During the process, then, the oxygen of the calx combined with charcoal and the metal remained behind. It cannot be doubted, therefore, that all the metallic calces are composed of the entire metals combined with oxygen; and that calcination, like combustion, is merely the act of this combination. All metals, then, in the present state of chemistry, must be considered as simple substances; for they have never yet been decompounded.

* Jour. de Phys. 1785.

68 Oxide and oxidation, what.

The words *calx* and *calcination* are evidently improper, as they convey false ideas; we shall therefore afterwards employ, instead of them, the words *oxide* and *oxidation*, which were invented by the French chemists. A metallic *oxide* signifies a metal united with oxygen; and *oxidation* implies the act of that union.

Metals are capable of uniting with oxygen in different proportions, and, consequently, of forming each of them different oxides. These are distinguished from one another by their colour. One of the oxides of iron, for instance, is of a green colour; it is therefore called the *green oxide;* the other, which is brown, is called the *brown oxide.*

69 Number of metals.

The metals at present amount to 21; only 11 of which were known before the year 1730. Their names are gold, silver, platinum, mercury, copper, iron, tin, lead, zinc, antimony, bismuth, arsenic, cobalt, nickel, manganese, tungsten, molybdenum, uranium, tellurium, titanium, chromum.

The first eight of these were formerly called *metals* by way of eminence, because they are possessed either of malleability or ductility, or of both properties together; the rest were called *semimetals*, because they are brittle. But this distinction is now pretty generally laid aside; and, as Bergman observes, it ought to be so altogether, as it is founded on a false hypothesis, and conveys very erroneous ideas to the mind. The first four

(Y) It is remarkable that John Rey, a physician of Perigord, had ascribed it to this very cause as far back as the year 1630: But his writings had excited little attention, and had sunk into oblivion, till after his opinion had been incontestibly proved by Lavoisier. Mayow also, in the year 1674, ascribed the increase of weight to the combination of metals with oxygen. *Quippe vix concipi potest* (says he), *unde augmentum illud antimonii (calcinati) nisi a particulis nitro-aereis igneisque inter calcinandum* FIXIS *procedat.* Tract. p 28. *Plane ut antimonii fixatio non tam a sulphuris ejus externi assumptione, quam particulis nitro-aereis, quibus flamma nitri abundat* EI INFIXIS *provenire videatur.* Ibid. p. 29.

(Z) This experiment was performed by Mr Bayen in 1774. This philosopher perceived, earlier than Lavoisier, that all metals did not contain phlogiston. "Ces experiences (says he) vont nous detromper. Je ne tiendrai plus le langage des disciples de Stahl, qui seront forcés de restreindre la doctrine sur le phlogistique, ou d'avouer que les precipités mercurials, dont je parle, ne sont pas des chaux metalliques, ou enfin qu'il y a des chaux qui peuvent se reduire sans le concours du phlogistique. Les experiences que j'ai faites me force de conclure que dans la chaux mercuriale dont je parle, le mercure doit son *etat calcaire, non à la perte du phlogistique* qu'il n'a pas essuyée, *mais a sa combinaison intime avec le fluide elastique*, dont le poids ajouté a celui du mercure est la seconde cause de l'augmentation de pesanteur qu'on observe dans les precipités que j'ai soumis a l'examen." *Jour. de Phys.* 1774, pages 288, 295. It was in consequence of hearing Bayen's paper read that Lavoisier was induced to turn his attention to the subject.

Gold.

four metals were formerly called *noble* or *perfect metals*, because their oxides are reducible by the mere application of heat; the next four were *imperfect metals*, because their oxides were thought not reducible without the addition of some combustible substance; but this distinction also is now very properly exploded.

Sect. I. *Of Gold.*

70 Properties of gold.

Gold seems to have been known from the very beginning of the world. Its properties and its scarcity have rendered it more valuable than any other metal.

It is of an orange red, or reddish yellow colour, and has no perceptible taste or smell.

No other substance can be compared with it in ductility and malleability. It may be beaten out into leaves so thin that one grain of gold will cover $56\frac{3}{4}$ square inches. These leaves are only $\frac{1}{282000}$ of an inch thick. But the gold leaf with which silver wire is covered has only $\frac{1}{12}$ of that thickness. An ounce of gold, upon silver wire, is capable of being extended more than 1300 miles in length.

Its tenacity is such, that a gold wire $\frac{1}{10}$ of an inch in diameter is capable of supporting a weight of 500 pounds without breaking *.

* *Macquer's Dict.*

Its hardness is 6 (A); its specific gravity 19,3. It melts at 32° of Wedgewood's pyrometer (B). When melted, it assumes a bright bluish green colour. It expands in the act of fusion, and consequently contracts while becoming solid more than most metals; a circumstance which renders it less proper for casting into moulds.

It requires a very violent heat to volatilize it; it is therefore, to use a chemical term, exceedingly *fixed*. Boyle and Kunkel kept it for some months in a glass-house furnace, and yet it underwent no change: nor did it lose any perceptible weight, after being exposed for some hours to the utmost heat of Mr Parker's lens †. Mr Lavoisier, however, observed, that a piece of silver, held over gold melted by a fire blown by oxygen gas, which produces a much greater heat than common air, was sensibly *gilt*: Part of the metal, then, must have been volatilized.

† *Kirwan's Miner.* i. 92.

After fusion, it is capable of assuming a crystalline form. Tillet and Mongez obtained it in short quadrangular pyramidal crystals.

71 Oxidation of gold.

It is capable of combining with oxygen, and forming an *oxide of gold*. There are two methods of producing this combination, *the application of heat*, and *solution in acids*. When it is exposed to a very violent heat in contact with air, gold absorbs oxygen. But the temperature must be very high; so high, indeed, that hardly any certain method of oxidating gold by heat is known, except by electricity. When the electric explosion is transmitted through gold leaf placed between two plates of glass, or when a strong charge is made to fall on a gilded surface—in both cases the metal is oxidated, and assumes a purple colour. It has been said also, that the same effect has been produced by a very violent fire; but few of the instances which have been adduced are well authenticated.

The other method of oxidating gold is much easier. For this purpose, equal parts of nitric and muriatic acids are mixed together (C) and poured upon gold; an effervescence takes place, the gold is gradually dissolved, and the liquid assumes a yellow colour. It is easy to see in what manner this solution is produced. No metal is soluble in acids till it has been reduced to the state of an oxide. There is a strong affinity between the oxide of gold and muriatic acid. The nitric acid furnishes oxygen to the gold, and the muriatic acid dissolves the oxide as it forms. When nitric acid is deprived of the greater part of its oxygen, it assumes a gaseous form, and is then called *nitrous gas*. It is the emission of this gas which causes the effervescence. The oxide of gold may be precipitated from the nitro-muriatic acid by pouring in a little potass dissolved in water, or, which is much better, a little lime; both of which have a stronger affinity for muriatic acid than the oxide has. This oxide is of a yellow colour.

It is probable that gold is capable of two different degrees of oxidation, and of forming two different oxides, *the yellow* and *the purple*: But neither the quantity of oxygen contained in these oxides, nor the differences between them, have been accurately ascertained. The oxides of gold may be decomposed in close vessels by the application of heat. The gold remains fixed, and the oxygen assumes the gaseous form. They may be decomposed, too, by all the substances which have a stronger affinity with oxygen than gold has. The affinities of the oxides of gold, according to Bergman *, are as follows:

* *Bergman on Elective Attractions, Opusc.* t. 3.

Muriatic acid,
Nitro-muriatic,
Nitric,
Sulphuric,
Arsenic,
Fluoric,

Tartarous,

(A) We have borrowed from Mr Kirwan the method of denoting the different degrees of hardness by figures, which we think a great improvement. These figures will be understood by Mr Kirwan's own explanation, which we here subjoin.

3, Denotes the hardness of chalk.
4, A superior hardness, but yet what yields to the nail.
5, What will not yield to the nail, but easily, and without grittiness, to the knife.
6, That which yields more difficultly to the knife.
7, That which scarcely yields to the knife.
8, That which cannot be scraped by a knife, but does not give fire with steel.
9, That which gives a few feeble sparks with steel.
10, That which gives plentiful lively sparks. *Kirwan's Mineralogy*, I. 38.

(B) According to the calculation of the Dijon academicians, it melts at 1298° Fahr.; according to Bergman, at 1301°.

(C) This mixture, from its property of dissolving gold, was formerly called *aqua regia* (for gold, among the alchymists, was the king of metals); it is now called *nitro-muriatic acid.*

Silver.

Tartarous,
Phoſphoric,
Sebacic,
Pruſſic,
Fixed alkali (D),
Ammonia.

Gold is not changed either by air or water. It does not ſeem capable of combining either with ſulphur or carbon. Mr Pelletier combined it with phoſphorus, by melting together in a crucible half an ounce of gold and an ounce of phoſphoric glaſs (E), ſurrounded with charcoal. The *phoſphuret of gold* thus produced was brittle, whiter than gold, and had a cryſtallized appearance. It was compoſed of 23 parts of gold and one of phoſphorus *. He formed the ſame compound by dropping ſmall pieces of phoſphorus into gold in fuſion †.

72 Phoſphuret of gold.

* *Ann. de Chim.* i. 71.
† *Ibid.* xiii. 104.

Gold is alſo capable of combining with moſt of the metals. Its affinities are placed, by Bergman, in the following order:

Mercury,
Copper,
Silver,
Lead,
Biſmuth,
Tin,
Antimony,
Iron,
Platinum,
Zinc,
Nickel,
Arſenic,
Cobalt,
Manganeſe,
Phoſphorus?
Sulphurets of alkalies.

Sect. II. *Of Silver.*

73 Properties of ſilver.

Silver appears to have been known almoſt as early as gold. It is a metal of a ſhining white colour, without either taſte or ſmell.

It is the moſt malleable and ductile of all metals except gold, and perhaps platinum. It can be reduced to leaves about $\frac{1}{160000}$ of an inch thick, and drawn into wire much finer than a human hair.

Its tenacity is ſuch, that a wire of ſilver, $\frac{1}{10}$th of an inch in diameter, is capable of ſuſtaining 270 pounds without breaking ‡.

Its hardneſs is 6,5 §. Its ſpecific gravity, before hammering, is 10,474; after hammering, 10,510‖: for it is remarkable that the ſpecific gravity of almoſt all the metals is increaſed by hammering.

It continues melted at 28° Wedgewood (F), but requires a greater heat to bring it to fuſion ¶.

‡ *Macquer's Dict.*
§ *Kirwan.*
‖ *Briſſon.*
¶ *Kirwan's Mineral.* ii. 107.

The experiments of the French academicians have proved that it may be volatilized, but that it requires a very violent heat.

When cooled ſlowly, it aſſumes a cryſtalline form. Tillet and Mongez obtained it in quadrangular pyramidal cryſtals, both inſulated and in groups.

74 Oxides of ſilver.

Silver may be combined with oxygen, and converted into an oxide by expoſure to a very violent heat. By this method Junker partly converted it into a *glaſs*; and Macquer, by expoſing it 20 times ſucceſſively to the heat of a porcelain furnace, obtained a *glaſs* (G) of an olive green colour *. The oxide of ſilver may alſo be formed by diſſolving the metal in an acid, and precipitating it from its ſolution by potaſs, lime, &c.: for, during its ſolution, the metal becomes oxidated. Little is known at preſent concerning the oxides of ſilver, nor whether there be more than two, the *black* and the *blue*. From the experiments of Wenzel and Bergman, it follows, that one oxide of ſilver is compoſed of about 90 parts of metal and 10 of oxygen †. The affinities of the oxides, according to Bergman, are as follows:

* *Macquer's Dict.*
† *Kirwan's Miner.* ii. 493.

Muriatic acid,
Sebacic,

75 Sulphuret of ſilver.

When ſilver is melted with ſulphur in a low red heat, it combines with it and forms *ſulphuret of ſilver*. It is very difficult to determine the proportion of the ingredients which enter into the compoſition of this ſubſtance, becauſe there is an affinity between ſilver and its ſulphuret, which diſpoſes them to combine together. The greateſt quantity of ſulphur which a given quantity of ſilver is capable of taking up is, according to Wenzel, $\frac{15}{100}$ ‡. Sulphuret of ſilver is of a black or very deep violet colour, brittle, and much more fuſible than ſilver. If ſufficient heat be applied, the ſulphur is volatilized, and the metal remains behind in a ſtate of purity.

‡ *Ibid.* 492.

76 Phoſphuret of ſilver.

If one ounce of ſilver, one ounce of phoſphoric glaſs, and two drams of charcoal, be mixed together, and heated in a crucible, *phoſphuret of ſilver* is formed. It is

(D) Have the alkalies any affinity for the yellow oxide? Is not their affinity confined to the purple oxide alone? And does not this oxide act as an acid?

(E) Phoſphoric acid evaporated to dryneſs, and then fuſed.

(F) According to the Dijon academicians, it melts at 1044° Fahr.; according to Bergman, at 1000°.

(G) Metallic oxides, after fuſion, are called *glaſs*, becauſe they acquire a good deal of reſemblance, in ſome particulars, to common glaſs.

Silver.

is of a white colour, and appears granulated, or as it were crystallized. It breaks under the hammer, but may be cut with a knife. It is composed of four parts of silver and one of phosphorus. Heat decomposes it by separating the phosphorus *. Pelletier has observed, that silver in fusion is capable of combining with more phosphorus than solid silver: for when phosphuret of silver is formed by projecting phosphorus into melted silver, after the crucible is taken from the fire a quantity of phosphorus is emitted the moment the metal congeals †.

* *Pelletier, Ann. de Chim.* i. 73.

† *Ibid.* xiii. 110.

Silver does not seem capable of combining with carbon.

77 Alloys of silver.

Silver is capable of combining with gold, and forming an *alloy* (H) composed of one part of silver and five of gold. That this is the proportion of the ingredients, was discovered by Homberg. He kept equal parts of gold and silver in gentle fusion for a quarter of an hour, and found, on breaking the crucible, two masses; the uppermost of which was pure silver, the undermost the whole gold combined with $\frac{1}{5}$th of silver. Silver, however, may be mixed with gold in almost any proportion. But there is a great difference between the mixture of two substances and their chemical combination. Metals which melt nearly at the same temperature may be mixed from that very circumstance in any proportion; but substances can combine chemically only in one proportion. This observation, which is certainly of importance, was first made, as far as we know, by Mr Keir ‡. The alloy of silver and gold is of a greenish colour; but its properties have not yet been accurately examined.

‡ *Translation of Macquer's Dict.* art. *Allay.*

78 Becomes tarnished by exposure.

Silver is not effected by water, nor by exposure to the air; but Mr Proust has remarked, that when long exposed in places frequented by men, as in churches, theatres, &c. it acquires a covering of a violet colour, which deprives it of its lustre and malleability. This covering, which forms a thin layer, can only be detached from the silver by bending it, or breaking it in pieces with a hammer It was examined by Mr Proust, and found to be *sulphuret of silver*. He accounts for this transition of the silver into a *sulphuret*, by supposing that a quantity of sulphur is constantly formed and exhaled by living bodies *.

* *Ann. de Chim.* i. 142.

79 Its affinities.

The affinities of silver, according to Bergman, are as follows:

Lead,
Copper,
Mercury,
Bismuth,
Tin,
Gold,
Antimony,
Iron,
Manganese,
Zinc,
Arsenic,
Nickel,
Platinum,
Sulphurets of alkalies,
Sulphur,
Phosphorus.

Sect. III. *Of Platinum.*

Platinum.

The metals hitherto described have been known to mankind from the earliest ages, and have been always in high estimation on account of their beauty, scarcity, ductility, and indestructibility. But platinum, though perhaps inferior to them in none of these qualities, and certainly far superior in others, was unknown, as a distinct metal, before the year 1752 (I).

80 Discovery of platinum.

It has been found only in America, in Choco in Peru, and in the mine of Santa Fe, near Carthagena. The workmen of these mines must no doubt have been early acquainted with it; but they seem to have paid very little attention to it. It was unknown in Europe till Mr Wood brought some of it from Jamaica in 1741. Soon after it was noticed by Don Antonio de Ulloa, a Spanish mathematician, who had accompanied the French academicians to Peru in their voyage to measure a degree of the meridian. In the year 1752 it was examined by Scheffer of Sweden, and discovered by him to be a new metal, approaching very much to the nature of gold, and therefore called by him *aurum album*,

(H) Metals combined together are called *alloys* or *allays*.

(I) Father Cortinovis, indeed, has attempted to prove that this metal was the *electrum* of the ancients. See the *Chemical Annals of Brugnatelli*, 1790. That the electrum of the ancients was a metal, and a very valuable one, is evident from many of the ancient writers, particularly Homer. The following lines of Claudian are alone sufficient to prove it:

Atria cinxit ebur, trabibus solidatur ahenis
Culmen et in celsas surgunt electra *columnas.* L. I. v. 164.

Pliny gives us an account of it in his Natural History. He informs us that it was a composition of silver and gold; and that by candle-light it shone with more splendor than silver. The ancients made cups, statues, and columns of it. Now, had it been our platinum, is it not rather extraordinary that no traces of a metal, which must have been pretty abundant, should be perceptible in any part of the old continent?

As the passage of Pliny contains the fullest account of electrum to be found in any ancient author, we shall give it in his own words, that every one may have it in his power to judge whether or not the description will apply to the platinum of the moderns.

"Omni auro inest argentum vario pondere.—Ubicunque quinta argenti portio est, *electrum* vocatur. Scrobes eæ reperiuntur in Canaliensi. Fit et cura electrum argento addito. Quod si quintam portionem excessit, incudibus non restitit. Et electro auctoritas, Homero teste, qui Menelai regiam auro, electro, argento, ebore fulgere tradit. Minervæ templum habet Lindos insulæ Rhodiorum in quo Helena sacravit calicem ex electro.—Electri natura est ad lucernarum lumina clarius argento splendere. Quod est nativum, et venena deprehendit. Namque discurrunt in calicibus arcus cœlestibus similes cum igneo stridore, et gemina ratione prædicunt."—*Lib.* xxxiii. *cap.* iv.

Platinum. *album, white gold.* Soon after it was examined by Lewis, Margraf, Macquer and Beaumé, Morveau, Bergman, and many other illustrious chemists.

81 Its properties. Platinum, when pure, is of a white colour like silver, but not so bright (K). It has no taste nor smell.

It is both ductile and malleable; but the precise degree has not yet been ascertained. It has been drawn into a wire of $\frac{1}{1940}$ of an inch in diameter. This wire admitted of being flattened, and had more strength than a wire of silver or gold of the same size *.

* *Withering.*

It is exceedingly difficult to fuse it. Macquer and Beaumé succeeded by means of a powerful burning-glass. It melts more easily when mixed with other substances. Its fixity is still greater than its infusibility. If the strongest fires cannot melt it, much less can they volatilize it.

Its hardness is 7,5 †. Its specific gravity, after being hammered, is 23,000; so that it is by far the heaviest body known.

† *Kirwan's Miner.* ii. 103.

Some of the experiments which have been made on platinum seem to prove that it may be oxidated by the application of a violent heat. The oxide of this metal may be easily formed by dissolving platinum in nitro-muriatic acid, and precipitating it by means of an earth or potass. The various oxides of platinum have never yet been examined with accuracy. The one at present best known possesses, as Mr Berthollet has proved, the properties of an acid.

The *sulphuret of platinum* is unknown.

82 Phosphuret of platinum. By mixing together an ounce of platinum, an ounce of phosphoric glass, and a dram of powdered charcoal, and applying a heat of about 32° Wedgewood, Mr Pelletier formed a *phosphuret of platinum* weighing more than an ounce. It was partly in the form of a button, and partly in cubic crystals. It was covered above by a blackish glass. It was of a silver white colour, very brittle, and hard enough to strike fire with steel. When exposed to a fire strong enough to melt it, the phosphorus was disengaged, and burnt on the surface ‡.

‡ *Ann. de Chim.* i. 71.

He found also, that when phosphorus was projected on red hot platinum, the metal instantly fused and formed a phosphuret. As heat expels the phosphorus, Mr Pelletier has proposed this as an easy method of purifying platinum §.

§ *Ibid.* xiii. 105.

Platinum does not seem capable of combining with carbon.

It is not in the least affected by the action of water or air.

83 Alloys of platinum. 1. When gold and platinum are exposed to a strong heat, they combine, and form an alloy of a much whiter colour, but nearly as ductile as gold. The proportions of the ingredients are not known. When $\frac{1}{47}$ only of the alloy is platinum, the gold is scarcely altered in colour.

2. Whether silver and platinum combine chemically has not yet been properly ascertained. When fused together (for which a very strong heat is necessary), they form a mixture, not so ductile as silver, but harder and less white. The two metals are separated by keeping them for some time in the state of fusion; the platinum sinking to the bottom from its weight. This circumstance would induce one to suppose that there is very little affinity between them.

Sect. IV. *Of Mercury.*

Mercury. Mercury, called also *quicksilver*, was known to the ancients, and seems to have been employed by them in gilding.

84 Properties of mercury. It is of a white colour, exactly like that of polished silver. It has no taste, but acquires a slight odour when rubbed between the hands.

Its specific gravity is 13,568 *.

* *Brisson.*

It differs from all other metals in always existing, at the common temperature of the atmosphere, in a state of fluidity. It freezes at -39° †; or, which is the same thing, it ceases to be a solid, and melts whenever it is placed in a temperature above -39°. It boils at the temperature of 600°.

† See *Macnab's Experiments, Phil. Trans.*

From the experiments made on frozen mercury in Russia, Hudson's Bay, and Britain, we know that this metal, when solid, is malleable; but the extreme difficulty of examining it in that state, on account of the lowness of the temperature, has rendered it hitherto impossible to ascertain the precise degree either of its malleability, ductility, or hardness.

85 It forms three oxides; Mercury is capable of combining with oxygen, and of forming *oxides*, differing from each other in the quantity of oxygen which they contain. The oxides of mercury, at present known, are the *black*, the *yellow*, and the *red*.

86 The black oxide, 1. When mercury is agitated for some time in contact with oxygen gas, or atmospheric air, it is partly converted into a greyish black powder, and at the same time part of the oxygen disappears. This is the *black* oxide of mercury. It is not known how much oxygen it contains, nor even whether the whole of the mercury which composes it be actually combined with oxygen.

87 Yellow oxide, 2. The best way of forming the yellow oxide is to dissolve mercury, either in boiling sulphuric acid or in cold nitric acid. During its solution, it deprives these acids of just as much oxygen as is necessary to convert it into a yellow oxide; and if potass or lime be afterwards added to the solution, it precipitates, and may be obtained pure by washing it with water. It is a bright yellow-coloured powder, which acts very powerfully as an emetic. From the observations of Bergman, it appears that it is composed of about 96,8 parts of mercury, and 3,2 of oxygen ‡.

‡ *Kirwan's Miner.* ii. 489.

88 And red oxide. 3. The *red oxide* of mercury may be prepared, either by distilling nitric acid off the metal repeatedly, or by keeping mercury for a long time exposed to a heat sufficient to evaporate it while it is in contact with air. When formed by the first process, it was formerly called *red precipitate;* when by the last, *precipitate per se.* It is a beautiful red powder, or rather small red crystals, which have some escharotic qualities. When prepared by the second process, the heat must not be much below 600° nor much above 800°, otherwise no union would take place;

(K) To this colour it owes its name. *Plata*, in Spanish, is *silver;* and *platina, little silver*, was the name first given to the metal. Bergman changed that name into *platinum*, that the Latin names of all the metals might have the same termination and gender. It was, however, first called *platinum* by Linnæus.

Mercury.

place; and it must be continued for some weeks. From the experiments of Mr Kirwan, it appears to contain 92,6 parts of mercury and 7,4 of oxygen*.

* Kirwan's Miner. ii. 489.

These oxides may be decomposed by the application of a heat amounting to 1200°. The oxygen flies off in the form of gas, and running mercury remains behind.

89 Their affinities.

The affinities of the oxides of mercury, according to Bergman, are as follows:

Sebacic acid,
Muriatic,
Oxalic,
Succinic,
Arsenic,
Phosphoric,
Sulphuric,
Benzoic (L)?
Saccholactic,
Tartarous,
Citric,
Sulphurous,
Nitric,
Fluoric,
Zoonic (M)?
Acetous,
Boracic,
Prussic,
Carbonic.

90 Black sulphuret of mercury.

When two parts of mercury and three parts of flowers of sulphur are triturated for some time together, or when equal parts of mercury and melted sulphur are mixed together—they combine, and form a black powder, formerly called *ethiops mineral*, and now *black sulphuret of mercury*.

91 Red sulphuret.

When 300 grains of mercury and 68 of sulphur, with a few drops of solution of potass to moisten them, are triturated for some time in a porcelain cup by means of a glass pestle, black oxide of mercury is produced. Add to this 160 grains of potass, dissolved in as much water. Heat the vessel containing the ingredients over the flame of a candle, and continue the trituration without interruption during the heating. In proportion as the liquid evaporates, add clear water from time to time, so that the oxide may be constantly covered to the depth of near an inch. The trituration must be continued about two hours; at the end of which time the mixture begins to change from its original black colour to a brown, which usually happens when a large part of the fluid is evaporated. It then passes very rapidly to a red. No more water is to be added; but the trituration is to be continued without interruption. When the mass has acquired the consistence of a gelly, the red colour becomes more and more bright, with an incredible degree of quickness. The instant the colour has acquired its utmost beauty, the heat must be withdrawn, otherwise the red passes to a dirty brown. This red powder is the red sulphuret of mercury, called formerly *cinnabar*, and, when reduced to a fine powder, *vermilion* (N). The process above described has been lately discovered by Mr Kirchoff, and is by far the simplest and cheapest mode of forming red sulphuret with which we are acquainted*. Count De Moussin Pouschin has discovered, that its passing to a brown colour may be prevented by taking it from the fire as soon as it has acquired a red colour, and placing it for two or three days in a gentle heat, taking care to add a few drops of water, and to agitate the mixture from time to time. During this exposure, the red colour gradually improves, and at last becomes excellent. He discovered also, that when this sulphuret is exposed to a strong heat, it becomes instantly brown, and then passes into a dark violet; when taken from the fire it passes instantly to a beautiful carmine red†.

* Nicholson's Journ. ii. 1.

† Ibid. p. 7.

The difference between these two sulphurets has never yet been ascertained. One would be apt to suspect at first that the black sulphuret consists of the real sulphuret of mercury combined with sulphur; the red, of the sulphuret of mercury combined with mercury, and that the real sulphuret of mercury was not yet accurately known. But it cannot be doubted that, during the formation of the *red sulphuret*, according to Kirchoff's process, there is an absorption of oxygen. The phenomena above described point out *that* almost incontestibly; and we observed, on attempting to repeat the experiment, that the black sulphuret, during its trituration, emitted sulphurated hydrogen gas. Perhaps, then, the mercury may be oxidated. We suspected at first that part of the sulphur might be converted into an acid; but on attempting an alteration of the process, in consequence of that supposition, we could not succeed.

The red sulphuret of mercury is found naturally in several parts of the world. It used to be prepared by forming a black sulphuret with three parts of sulphur and one of mercury, and then setting fire to it. Part of the sulphur is burnt, and there remains behind a violet-coloured body, which is powdered and put into a glass vessel, to the bottom of which a red heat is applied. A reddish brown substance sublimes, which is red *sulphuret of mercury*; but its colour is not nearly equal to that which is prepared by Kirchoff's process.

92 Phosphuret of mercury.

Mr Pelletier, after several unsuccessful attempts to form phosphuret of mercury, at last succeeded by distilling a mixture of red oxide of mercury and phosphorus. Part of the phosphorus combined with the oxygen of the oxide, and was converted into an acid; the rest combined with the mercury.

Phosphuret of mercury is of a black colour, of a pretty solid consistence, and capable of being cut with a knife. When exposed to the air, it exhaled vapours of phosphorus ‡.

‡ Ann. de Chim. xiii. 122.

Mercury does not seem capable of combining with carbon.

93 Its amalgams.

The combinations of mercury with the other metals are called *amalgams*.

1. The amalgam of gold forms very readily, because there is a very strong affinity between the two metals. If a bit of gold be dipped into mercury, its surface, by combining with mercury, becomes as white as silver. The

(L) Benzoat of mercury is decomposed by sulphuric acid. *Tromsdorf, Ann. de Chim.* xi. 316.

(M) Zoonic acid decomposes the acetite of mercury. *Berthollet.*

(N) The word *vermilion* is derived from the French word *vermeil*, which comes from *vermiculus* or *vermiculum*; names given in the middle ages to the *kermes* or *coccus ilicis*, well known as a red dye. *Vermilion* originally signified the red dye of the kermes. See *Beckmann's Hist. of Inventions*, ii. 180.

Mercury.

The easiest way of forming this amalgam is to throw small pieces of red hot gold into mercury. The proportions of the ingredients are not easily determined, because the amalgam has an affinity both for the gold and the mercury; in consequence of which they appear to combine in any proportion. Most probably it is composed of two parts of gold and one of mercury. The combination is formed most readily in these proportions; and if too much mercury be added, it may be separated by filtration. The amalgam is of a white colour, and of the consistence of butter*. This amalgam crystallizes in quadrangular prisms; which crystals, according to the Dijon academicians, are composed of six parts of mercury and one of gold. It is much used in gilding.

* Keir's Notes on Macquer's Dict art, Amalgam.

2. The amalgam of silver is made in the same manner. It forms dendritical crystals, which, according to the Dijon academicians, contain eight parts of mercury and one of silver. Gellert was the first who remarked that its specific gravity was greater than that of mercury, though that of silver be less.

3. Dr Lewis attempted to form an amalgam of platinum, but hardly succeeded after a labour which lasted for several weeks. Mr Morveau succeeded by means of heat †. But a much more expeditious method has been lately discovered by Count Moussin Pouschin. He took a dram of the orange-coloured salt, composed of *oxide of platinum and ammonia* (O), and triturated it with an equal weight of mercury in a mortar of chalcedony. In a few minutes the salt became brown, and afterwards acquired a greenish shade. The matter was reduced to a very fine powder. Another dram of mercury was added, and the trituration continued: The matter became grey. A third dram of mercury began to form an amalgam; and six drams made the amalgam perfect. The whole operation scarce lasted 20 minutes. Mercury was added till it amounted to nine times the weight of the salt, and yet the amalgam continued very tenacious. It was easily spread out under the pestle; it received the impression of the most delicate seals, and had a very close and brilliant grain. This amalgam is decomposed, and the mercury passes to the state of black oxide by the simple contact of several of the metals and a great number of animal matters. This effect even takes place on rubbing it between the fingers ‡.

† Ann. de Chim. xxiv. 205.

‡ Ibid.

94 Affinities.

The affinities of mercury, as ascertained by the experiments of Morveau (P), are as follows:

Gold,
Silver,
Tin,
Lead,
Bismuth,
Zinc,
Copper,
Antimony,
Arsenic (Q),
Iron.

Sect. V. *Of Copper.*

Copper.

Except gold and silver, copper seems to have been more early known than any other metal. In the first ages of the world, before the method of working iron was discovered, copper was a principal ingredient in all domestic utensils and instruments of war. Even during the Trojan war, as we learn from Homer, the combatants had no other armour but what was made of bronze, which is a mixture of *copper and tin*. The word *copper* is derived from the island of Cyprus, where it was first discovered, or at least wrought to any extent, by the Greeks.

95 Properties of copper.

Copper is of a pale red colour with a shade of yellow. Its taste is styptic and nauseous; and when rubbed it emits a disagreeable smell. It possesses a considerable degree of malleability, though less than silver. Its tenacity is such, that a wire of $\frac{1}{10}$ of an inch in diameter can sustain a weight of $299\frac{1}{4}$ pounds without breaking*.

Its hardness is 8 †. Its specific gravity, when not hammered, is 7,788; when wire-drawn, 8,878 ‡. The specific gravity of Japan copper is 9,000 §; that of Swedish copper, 9,3243 ‖.

It melts at 27° Wedgewood; according to the calculation of the Dijon academicians, at 1449° Fahrenheit. When allowed to cool slowly, it assumes a crystalline form. The Abbe Mongé, to whom we owe many valuable experiments on the crystallization of metals, informs us, that these crystals are quadrangular pyramids, frequently inserted into one another.

* Macquer's Dict.
† Kirwan's Miner ii. 127.
‡ Brisson.
§ Keir's Notes on Macquer's Dict.
‖ Bergman, ii. 263.

96 Brown oxide of copper.

When copper is heated red hot in contact with air, it is soon covered with a brown earthy crust, which may be easily separated by hammering or by plunging the metal into water. If the heat be continued, another scale of the same kind soon forms; and by continuing the process the whole metal may be converted into an earthy-like crust, which is merely a combination of copper and oxygen, and is therefore called *brown oxide of copper*. It is composed of about 84 parts of copper and 16 of oxygen *.

* Kirwan's Miner. ii. 487.

97 Blue and green oxides.

When copper is dissolved in sulphuric acid, and precipitated by means of lime, it falls in the form of a blue-coloured powder, which is the *blue oxide of copper*. If this oxide of copper be dried in the open air, it assumes a green colour, and is then called the *green oxide of copper*. This last oxide may also be produced by distilling a sufficient quantity of nitric acid off copper. Little satisfactory is yet known with respect to these oxides; it has not even been ascertained whether the blue and green be really two different oxides, or whether the difference in colour be owing to some other cause. It is probable, however, that the *green* oxide contains more oxygen than the blue; because the blue oxide assumes a green colour when exposed for some time to the open air, during which it may be supposed to absorb oxygen. An experiment of Fourcroy proves incontestibly, that the *brown* oxide contains less oxygen than the green. He converted the green oxide into the brown by applying heat; and during the distillation obtained oxygen gas †.

† Fourcroy iii. 101.

98 Their affinities.

The affinities of the oxides of copper, according to Bergman, are as follows:

Pyro-mucous acid ‡
Oxalic,
Tartarous,

‡ Schrickel.

(O) Ammonia is an alkali hereafter to be described. It is often called, in English, *hartshorn*.

(P) We shall have occasion to consider these celebrated experiments afterwards.

(Q) These two are added from Bergman. Bergman places *lead* before tin, and zinc before bismuth.

Tartarous,
Muriatic,
Sulphuric,
Saccholactic,
Nitric,
Sebacic,
Arsenic,
Phosphoric,
Succinic,
Fluoric,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Prussic,
Carbonic,
Fixed alkalies,
Ammonia,
Fixed oils.

When copper is long exposed to the air, its surface becomes covered over with a green crust, which is *green oxide of copper*. This oxidation never penetrates beyond the surface.

Copper is not attacked by water at the boiling temperature; but if cold water be allowed to remain long on its surface, the metal becomes partly oxidated.

99
Sulphuret of copper.

Sulphur mixes readily with copper. The combination may be formed by mixing the ingredients together and applying a pretty strong heat. *Sulphuret of copper* is brittle, softer than copper, of a black colour externally, and within of a leaden grey. It is composed, according to Kirwan's experiments, of 81 parts of copper and 19 of sulphur *.

* *Kirwan's Miner.* ii. 508.

100
Phosphuret of copper.

Mr Pelletier formed *phosphuret of copper* by melting together one ounce of copper, one ounce of phosphoric glass, and one dram of charcoal. It was of a white colour. On exposure to the air, it lost its lustre and became blackish †. Margraf was the first person that formed this phosphuret. His method was to distil phosphorus and brown oxide of copper together. It is formed most easily by projecting phosphorus into red hot copper. According to Pelletier, it contains 20 parts of phosphorus and 80 of copper ‡. This phosphuret is harder than iron: It is not ductile, and yet cannot easily be pulverised. Its specific gravity is 7,1220. It crystallizes in tetrahedral prisms §.

† *Ann. de Chim.* i. 74.

‡ *Ibid.* xiii. 3.

§ *Sage Journ. de Phys.* xxxviii. 468.

101
Alloys of copper

1. Copper combines readily with gold when the two metals are melted together. The compound is of a reddish colour, more fusible than gold, but less ductile. The proportions of the ingredients which form this alloy are not known; nor would it be easy to ascertain them, as the two metals are almost equally fusible. The current gold of this country is composed of 11 parts of gold and one part of copper.

2. The alloy of copper and silver is made as easily as that of gold, and the properties are equally unknown. It is harder and more sonorous than silver. The current silver coin of Britain is composed of 15 parts of silver and one of copper.

3. Platinum combines readily with copper. The alloy is much more fusible than platinum; it is ductile, hard, takes a fine polish, and is not liable to tarnish. This alloy has been employed with advantage for composing the mirrors of reflecting telescopes.

4. The amalgam of copper cannot be formed by simply mixing that metal with mercury, nor even by the application of heat; because the heat necessary to melt copper sublimes mercury. Dr Lewis has given us several processes for forming this amalgam. One of the simplest is to triturate mercury with a quantity of common salt and verdigrise; a substance composed of oxide of copper and vinegar. The theory of this process is not very obvious.

102
Its affinities

The affinities of copper are, according to Bergman, as follows:

Gold,
Silver,
Arsenic,
Iron,
Manganese,
Zinc,
Antimony,
Platinum,
Tin,
Lead,
Nickel,
Bismuth,
Cobalt,
Mercury,
Sulphuret of alkali,
Sulphur,
Phosphorus.

Sect. VI. *Of Iron.*

103
Discovery of iron.

Iron, the most abundant and most useful of all the metals, was neither known so early, nor wrought so easily, as gold, silver, and copper. For its discovery we must have recourse to the nations of the east, among whom, indeed, almost all the arts and sciences first sprung up. The writings of Moses (who was born about 1635 years before Christ) furnish us with the amplest proof at how early a period it was known in Egypt and Phœnicia. He mentions furnaces for working iron *, ores from which it was extracted †; and tells us that swords ‡, knives §, axes ||, and tools for cutting stones ¶, were then made of that metal. How many ages before the birth of Moses iron must have been discovered in these countries, we may perhaps conceive, if we reflect, that the knowledge of iron was brought over from Phrygia to Greece by the Dactyli *, who settled in Crete during the reign of Minos I. about 1431 years before Christ; yet during the Trojan war, which happened 200 years after that period, iron was in such high estimation, that Achilles proposed a ball of it as one of his prizes during the games which he celebrated in honour of Patroclus (R). At that period none of their weapons were formed of iron. Now if the Greeks in 200 years had made so little progress in an art which they learned from others, how long must it

Iron.

it have taken the Egyptians, Phrygians, Chalybes, or whatever nation firſt diſcovered the art of working iron, to have made that progreſs in it which we find they had done in the days of Moſes?

104
Its properties.

Iron, when freſh broken, is of a bluiſh grey colour. It has a ſtyptic taſte, and emits a ſmell when rubbed.

It is malleable and ductile in every temperature; and its malleability is increaſed in proportion as the temperature augments. Its tenacity is ſuch, that an iron wire $\frac{1}{10}$ of an inch in diameter ſuſtains a weight of 450 pounds without breaking *.

* *Macquer's Dict.*

Its hardneſs is ſuch, that it may be eaſily reduced to powder by the application of a file. Its ſpecific gravity is 7,788. It is infuſible in the ſtrongeſt heats hitherto produced.

It is attracted by the magnet or loadſtone, and is itſelf capable of becoming magnetic; but it retains this property only for a very ſhort time.

It is not hardened by being plunged into liquids while hot, nor ſoftened by being cooled ſlowly.

Iron combines with oxygen very readily. When kindled in oxygen gas, it burns with great rapidity and ſplendor, and is in this manner converted into an oxide. It is converted into an oxide alſo when ſurrounded by moiſt air, or when plunged in water; becauſe it has a ſtronger affinity for oxygen than hydrogen has, and is therefore capable of decompoſing water.

105
Forms two oxides.

Mr Prouſt has lately proved, that there are only two oxides of iron, the *green* and the *brown* or *red*, and that all the other ſuppoſed oxides are merely mixtures of theſe two in various proportions †.

The *green oxide* may be obtained by diſſolving iron in ſulphuric acid, and then precipitating it by potaſs. It is a light, green-coloured, earthy-like ſubſtance, compoſed, as Mr Lavoiſier has ſhewn, of 27 parts of oxygen, and 73 of iron ‡. When this oxide is expoſed to the air, it quickly abſorbs more oxygen, and is converted into a brown powder, which is the *brown oxide*. Mr Prouſt has proved that it contains 52 parts of iron and 48 of oxygen. This oxide is well known under the name of *ruſt of iron*, which is generally, however, or perhaps always, combined with carbonic acid gas.

† *Ann. de Chim.* xxiii. 85. and *Nicholſon's Journal*, i. 453.

‡ *Mem. Acad. Par.* 1782.

106
Their affinities.

The affinities of theſe oxides, according to Bergman, are as follows:

Gallic acid?
Oxalic acid,
Tartarous,
Camphoric §,
Sulphuric,
Saccholactic,
Muriatic,
Pyromucous ||,
Nitric,
Sebacic,
Phoſphoric,
Arſenic,
Fluoric,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic.

§ *La Grange.*

|| *Schrickel.*

107
Sulphuret.

Iron unites readily with ſulphur. Sulphuret of iron, formerly called *pyrites*, is found ready formed in many parts of the world. It is not eaſy to determine the proportions of its ingredients, becauſe it is capable of combining both with iron and ſulphur, and conſequently, if there happens to be any exceſs of either during its formation, it takes it up. Perhaps the proportions are not far from equal parts of ſulphur and of iron. It is of a pale yellow or browniſh colour, and is capable of aſſuming a cryſtalline form. Its ſpecific gravity is about 4,000. When placed upon the fire it precipitates; and at a red heat loſes its yellow colour, and becomes of an iron grey, excepting its ſurface, which is of a bright red. It melts at 102° Wedgewood in a covered crucible into a bluiſh ſlag, ſomewhat porous internally *. When expoſed to air and moiſture, the ſulphur, as happens in all ſulphurets, gradually abſorbs oxygen, and is converted into an acid.

* *Kirwan's Miner.* ii. 76.

If iron filings and ſulphur be mixed together, and formed into a paſte with water, the ſulphur decompoſes the water, and abſorbs oxygen ſo rapidly, that the mixture takes fire, even though it be buried under ground. This phenomenon was firſt diſcovered by Homberg; and it is conſidered as affording an explanation of the origin of volcanoes. The native ſulphuret of iron has been obſerved more than once to take fire on being ſuddenly moiſtened with water.

108
Phoſphuret,

Iron combines readily with phoſphorus, and forms *phoſphuret of iron*; to which Bergman, who firſt diſcovered it, gave the name of *ſiderum*.

There is a particular kind of iron, known by the name of *cold ſhort iron*, becauſe it is brittle when cold, though it be malleable when hot. Bergman was employed at Upſal in examining the cauſe of this property, while Meyer was occupied at Stetin with the ſame inveſtigation; and both of them diſcovered, nearly at the ſame time, that, by means of ſulphuric acid, a white powder could be ſeparated from this kind of iron, which by the uſual proceſs they converted into a metal of a dark ſteel grey, exceedingly brittle, and not very ſoluble in acids. Its ſpecific gravity was 6,700; it was not ſo fuſible as copper; and when combined with iron rendered it *cold ſhort*. Both of them concluded that this ſubſtance was a new metal; and Bergman gave it the name of *ſiderum*. But Klaproth ſoon after recollecting that the ſalt compoſed of phoſphoric acid and iron bore a great reſemblance to the white powder obtained from cold ſhort iron, ſuſpected the preſence of phoſphoric

Iron.

phosphoric acid in this new metal. To decide the point, he combined phosphoric acid and iron, and obtained, by heating it in a crucible along with charcoal powder (s), a substance exactly resembling the new metal. Meyer, when Klaproth communicated to him this discovery, informed him that he had already satisfied himself, by a more accurate examination, that siderum contained phosphoric acid. Soon after this Scheele actually decomposed the white powder obtained from cold short iron, and thereby demonstrated, that it was composed of phosphoric acid and iron. The siderum of Bergman, however, is composed of phosphorus and iron, the phosphoric acid being deprived of its oxygen during the *reduction*; or it is phosphuret of iron. It may be formed by fusing in a crucible an ounce of phosphoric glass, an ounce of iron, and half a dram of charcoal powder. It is very brittle, and appears white when broken. When exposed to a strong heat, it melts, and the phosphorus is dissipated *. It may be formed also by melting together equal parts of phosphoric glass and iron filings. Part of the iron combines with the oxygen of the phosphoric glass, and is vitrified; the rest forms the phosphuret, which sinks to the bottom of the crucible. It may be formed also by dropping small bits of phosphorus into iron filings heated red hot †. The proportions of the ingredients of this phospuret have not yet been determined.

* Pelletier, *Ann. de Chim.* i. 104.

† *Id. Ann. de Chim.* xiii. 113.

109 And carburet of iron.

Iron likewise combines with carbon, and forms a *carburet*. Carburet of iron has been long known and used in the arts under the names of *plumbago* and *black lead*. It is of a dark iron grey or blue colour, and has something of a metallic lustre. It has a greasy feel, and blackens the fingers, or any other substance to which it is applied. It is found in many parts of the world, especially in England, where it is manufactured into pencils. It is not affected by the most violent heat as long as air is excluded, nor is it in the least altered by simple exposure to the air, or to water. Its nature was first investigated by Scheele; who proved, by a very ingenious analysis, that it could be converted almost wholly into carbonic acid gas, and that the small residuum was iron. It follows from this analysis, that it is composed of carbon and iron; for the carbon, during its combustion, had been converted into carbonic acid gas. By the subsequent experiments of Pelletier and other French chemists, it has been shewn to consist nearly of nine parts of carbon to one of iron.

110 Varieties of iron.

There are a great many varieties of iron, which artists distinguish by particular names; but all of them may be reduced under one or other of the three following states: *Wrought iron* (or simply *iron*), *steel*, and *cast* or *raw iron*.

111 Wrought iron.

Wrought Iron is the substance which we have been hitherto describing. As it has never yet been decompounded, we consider it when pure as a simple body; but it has seldom or never been found without some small mixture of foreign substances. These substances are either some of the other metals, or oxygen, carbon, or phosphorus.

112 Steel.

Steel is distinguished from iron by the following properties.

It is so hard as to be unmalleable while cold, or at least it acquires this property by being immersed while ignited into a cold liquid: for this immersion, though it has no effect upon *iron*, adds greatly to the hardness of *steel*.

It is brittle, resists the file, cuts glass, affords sparks with flint, and retains the magnetic virtue for any length of time.

It loses this hardness by being ignited and cooled very slowly.

It melts at above 130° Wedgewood. It is malleable when red hot, but scarcely so when raised to a white heat.

It may be hammered out into much thinner plates than iron. It is more sonorous; and its specific gravity, when hammered, is greater than that of iron.

By being repeatedly ignited in an open vessel, and hammered, it becomes *wrought iron* *.

* Dr Pearson on Wootz, *Phil. Trans.*

113 Cast iron.

Cast Iron is distinguished by the following properties:

It is scarcely malleable at any temperature. It is generally so hard as to resist the file. It can neither be hardened nor softened as steel can by ignition and cooling. It is exceedingly brittle. It melts at 130° Wedgewood. It is more sonorous than steel †.

† *Ibid.*

Cast iron is converted into wrought iron by exposing it for a considerable time in a furnace to a heat sufficiently strong to melt it. During the process it is constantly stirred by a workman, that every part of it may be equally exposed to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the conversion is completed. The heaving is evidently produced by the emission of an elastic fluid ‡.

‡ Beddoes, *Phil. Trans.* 1791.

Wrought iron may be converted into steel by being kept for some hours in a strong red heat, surrounded with charcoal powder in a covered crucible. By this process, which is called *cementation*, the iron gains some weight.

114 Cause of these varieties.

These different kinds of iron have been long known, and the converting of them into each other has been practised in very remote ages. Many attempts have been made to explain the manner in which this conversion is accomplished. According to Pliny, steel owes its peculiar properties chiefly to the water into which it is plunged in order to be cooled §. Beccher supposed that fire was the only agent; that it entered into the iron, and converted it into steel. Reaumur was the first who attended accurately to the process; and his numerous experiments have certainly contributed to elucidate the subject. He supposed that iron was converted into steel by combining with saline and oily or sulphureous particles, and that these were introduced by the fire. But it was the analysis of Bergman, published in 1781, that first paved the way to the explanation of the nature of these different species of iron.

§ *Pliny*, l. xxxiv. 14.

By dissolving in diluted sulphuric acid 100 parts of cast iron, he obtained 40 ounce measures of hydrogen; from 100 parts of steel he obtained 48 ounce measures; and from 100 parts of wrought iron, 50 ounce measures. Now as the hydrogen is produced by the property which iron has of decomposing water and uniting with its oxygen, it is evident that the greater the quantity of hydrogen obtained,

(s) This process in chemistry is called *reduction*.

Iron.

tained, with the more oxygen does the iron combine. But the quantities of iron were equal; they ought therefore to have combined with equal quantities of oxygen. But it is evident, from the quantities of hydrogen obtained, that the caſt iron received leſs oxygen than either of the other two: caſt iron therefore muſt contain already ſome oxygen, ſince it requires leſs than the other two ſpecies in order to be ſaturated. Here then is one difference between caſt iron and the other two kinds; it contains oxygen. Steel, on the contrary, does not appear to contain any oxygen. The difference between the quantity of hydrogen produced during its ſolution and that of wrought iron, which contains no oxygen, is exceedingly ſmall, and it has been found to diminiſh in proportion to the purity of the ſteel.

From 100 parts of caſt iron Bergman obtained 2,2 of plumbago, or $\frac{1}{45}$; from 100 parts of ſteel, 0,5, or $\frac{1}{200}$; and from 100 parts of wrought iron, 0,12, or $\frac{1}{800}$. Now plumbago is compoſed of $\frac{9}{10}$ths of carbon; caſt iron therefore contains a conſiderable quantity of carbon, ſteel a ſmaller quantity, and wrought iron a very minute portion, which diminiſhes according to its purity, and would vaniſh altogether if iron could be obtained perfectly pure. Mr Grignon, in his notes on this analyſis, endeavoured to prove that plumbago was not eſſentially a part of caſt iron and ſteel, but that it was merely accidentally preſent. But Bergman, after conſidering his objections, wrote to Morveau on the 18th November 1783. "I will acknowledge my miſtake whenever Mr Grignon ſends me a ſingle bit of caſt iron or ſteel which does not contain plumbago; and I beg of you, my dear friend, to endeavour to diſcover ſome ſuch, and to ſend them to me; for if I am wrong, I wiſh to be undeceived as ſoon as poſſible *." This was almoſt the laſt action of the illuſtrious Bergman. He died a few months after at the age of 49, leaving behind him a moſt brilliant reputation, which no man ever more deſervedly acquired. His induſtry, his indefatigable, his aſtoniſhing induſtry, would alone have contributed much to eſtabliſh his name; his extenſive knowledge would alone have attracted the attention of philoſophers; his ingenuity, penetration, and accurate judgment, would alone have ſecured the applauſe; and his candour and love of truth procured him the confidence and the eſteem of the world.—But all theſe qualities were united in Bergman, and conſpired to form one of the greateſt men and nobleſt characters that ever adorned human nature.

* *Morveau, Encycl. Method. Chimie*, i. 448.

The experiments of Bergman were fully confirmed by thoſe of Morveau, Vandermonde, Monge, and Berthollet, who have likewiſe thrown a great deal of additional light on the ſubject. From all theſe experiments the following deductions may be made.

Wrought iron is a ſimple ſubſtance, and if perfectly pure would contain nothing but *iron*.

Steel is iron combined with carbon. The proportion of this laſt ingredient has not yet been aſcertained; Dr Pearſon fixes it at $\frac{1}{150}$th part at a medium. Steel, in conſequence of its compoſition, has been called by ſome chemiſts *carburet of iron;* but before aſſigning it that name, which has been alſo given to plumbago, it ought to be determined what are the proportions of carbon and iron which ſaturate each other. Is it the proportion in which theſe two ſubſtances exiſt in ſteel, or that which forms plumbago? In the firſt caſe, plumbago is carburet of iron combined with carbon; in the ſecond, ſteel is carburet combined with iron. Or is it ſome intermediate proportion? Till theſe points be determined, perhaps it would be better to continue the old names than to riſk the impoſing of falſe ones.

Caſt iron is iron contaminated with various foreign ſubſtances, the proportions of which vary according to circumſtances. Theſe ſubſtances are chiefly oxide of iron and carbon, and ſometimes ſilica (T).

Bergman found a quantity of manganeſe in the iron and ſteel which he examined; but it appears from the experiments of Vauquelin, that his method of determining the preſence of that metal was not accurate.

Mr Vauquelin * has lately analyſed four kinds of ſteel with great care, and contrived his proceſſes with much ingenuity. The reſult of his analyſis is as follows:

* *Jour. des Mines.* See *Nicholſon's Journal*, i. 200

115 Vauquelin's analyſis of ſteel.

Firſt ſteel, compoſed of	Carbon,	0,00789
	Silica,	0,00315
	Phoſphorus,	0,00345
	Iron,	0,98551
		1
Second ſteel, compoſed of	Carbon,	0,00683
	Silica,	0,00273
	Phoſphorus,	0,00827
	Iron,	0,98217
		1
Third ſteel, compoſed of	Carbon,	0,00789
	Silica,	0,00315
	Phoſphorus,	0,00791
	Iron,	0,98105
		1
Fourth ſteel, compoſed of	Carbon,	0,00631
	Silica,	0,00252
	Phoſphorus,	0,01520
	Iron,	0,97597
		1

It cannot be concluded from theſe experiments that all ſteel contains phoſphorus and ſilica; far leſs that theſe ſubſtances enter neceſſarily into the compoſition of ſteel. This *may* be the caſe, and former analyſes may not have been nice enough to detect it; but before it can be admitted, it muſt be ſhewn that theſe ſubſtances are always preſent in ſteel, and that it loſes its eſſential properties when deprived of them.

116 Alloys of iron.

Iron combines with moſt metals.

1\. The alloy of gold and iron is very hard, and might, according to Dr Lewis, who examined it, be employed with advantage in forming cutting inſtruments.

2\. That iron combines with ſilver is certain, but hardly any thing is known about the nature of the compound.

3\. Platinum is uſually found alloyed with iron. Dr Lewis did not ſucceed in his attempts to unite theſe metals

(T) An earth which ſhall be deſcribed in the next chapter.

Tin.

metals by fusion, but he melted together cast iron and platinum. The alloy was excessively hard, and possessed ductility.

4. There is very little affinity between iron and mercury; they cannot therefore be amalgamated by simple mixture, even with the assistance of heat. Vogel affirms that he has produced an amalgam of iron by the following process: Pound one part of iron filings and two parts of alum in a mortar to a fine powder; then pour in two or three parts of mercury, and triturate till the substances be thoroughly mixed. Pour on a little water, and continue the trituration for about an hour. If then no particles of iron can be distinguished, pour on a little more water to wash out the alum, and then dry the amalgam. If particles of iron be perceptible, the trituration must be continued till they disappear *.

5. Iron may be united to copper by fusion, but not without considerable difficulty. The alloy has been applied to no use.

117
Its affinities.

The affinities of iron, according to Bergman, are as follows:

Nickel,
Cobalt,
Manganese,
Arsenic,
Copper,
Gold,
Silver,
Tin,
Antimony,
Platinum,
Bismuth,
Lead,
Mercury,
Sulphuret of alkali,
Carbon?
Phosphorus?
Sulphur?

* Ann. de Chim. vi. 39.

Sect. VII. *Of Tin.*

The Phenicians were the first of those nations which make a figure in ancient history that were acquainted with *tin*. They procured it from Spain † and from Britain, with which nations they carried on a very lucrative commerce. At how early a period they imported this metal we may easily conceive, if we recollect that it was in common use in the time of Moses ‡.

118
Properties of tin:

Tin is of a greyish white colour: it has a strong disagreeable taste, and emits a peculiar smell when rubbed.

It is very malleable; tin-leaf, or *tinfoil* as it is called, is about $\frac{1}{1000}$th part of an inch thick, and it might be beat out into leaves as thin again if such were wanted for the purposes of art. Its ductility, however, is exceedingly imperfect; for a tin wire $\frac{1}{10}$th of an inch in diameter, is capable of supporting only 49 pounds without breaking §. It is very flexible, and produces a crackling noise when bended.

Its hardness is 6 ‖. Its specific gravity is 7,291; after hammering, 7,299 ¶.

It melts at the temperature 410°, according to Dr Lewis; according to the Dijon academicians, at 419°. When heated red hot in close vessels it sublimes. It crystallizes in the form of a rhomboidal prism *.

† Pliny, l. 4. c. 34. and l. 34. c. 47.

‡ Numbers, xxxi. 22.

§ Macquer's Dictionary.

‖ Kirwan's Miner. ii. 195.

¶ Brisson.

* Pajot, Jour. de Phys. xxxviii. 52.

119
Oxides,

Tin unites very readily with oxygen. When heated in contact with air, its surface soon becomes covered with a grey pellicle; when this is taken off, another appears soon after; and in this manner the whole metal may be converted into a dirty grey powder, which is the *grey oxide of tin*. It is composed, according to Fourcroy, of 90 parts of tin and 10 of oxygen.

When tin is heated red hot in contact with air, it takes fire *, and burns with a very lively white flame, and is gradually sublimed. If the sublimate be examined, it is found to consist of a white powder; it is the *white oxide of tin*. The white oxide is perhaps never obtained quite pure by this process; it seems always to contain a mixture of *grey oxide*: but it may be obtained pure by pouring nitric acid upon tin, and then drying it. That metal having a much stronger attraction for oxygen than azot has, decomposes the acid with the greatest rapidity, and assumes the appearance of a white powder, which is the *white oxide*. This oxide possesses many of the properties of an acid, and is therefore often called *stannic acid*. It seems to consist of about 77 parts of tin and 23 of oxygen †.

The affinities of the grey oxide of tin, according to Bergman, are as follows:

Pyromucous acid ‡,
Sebacic acid,
Tartaric,
Muriatic,
Sulphuric,
Oxalic,
Arsenic,
Phosphoric,
Nitric,
Succinic,
Fluoric,
Saccholactic,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Prussic.

* Geoffroy.

† Kirwan's Miner. ii. 488.

‡ Schrickel.

120
Sulphurets,

Tin combines readily with sulphur. This sulphuret may be formed by fusing the two ingredients together. It is brittle, heavier than tin, and not so fusible. It is of a bluish colour and lamellated structure, and is capable of crystallizing. According to Bergman, it is composed of 80 parts of tin and 20 of sulphur; according to Pelletier, of 85 parts of tin and 15 of sulphur §.

Sulphur likewise combines with the white oxide of tin, by mixing them together, and applying a gentle heat ‖. This compound has been called *aurum musivum*. It is a mass consisting of beautiful gold-coloured flakes, and is used as a paint. It is composed of about 40 parts of sulphur and 60 of white oxide of tin ¶. The process for making this substance was formerly very complicated. Pelletier first demonstrated its real composition, and was hence enabled to make many important improvements in the manner of manufacturing it *.

§ Ann. de Chim. xiii. 287.

‖ Pelletier, Ibid. p. 297.

¶ Ibid. 293.

* See his Memoire, Ann. de Chim. xiii. 280.

121
Phosphuret,

Phosphorus is easily combined with tin, by melting in a crucible equal parts of filings of tin and phosphoric glass. Tin has a greater affinity for oxygen than phosphorus has. Part of the metal therefore combines with the

Tin. the oxygen of the glaſs during the fuſion, and flies off in the ſtate of an oxide, and the reſt of the tin combines with the phoſphorus. The phoſphuret of tin may be cut with a knife; it extends under the hammer, but ſeparates in laminæ. When newly cut it has the colour of ſilver; its filings reſemble thoſe of lead. When theſe filings are thrown on burning coals, the phoſphorus takes fire. This phoſphuret may likewiſe be formed by dropping phoſphorus gradually into melted tin. According to Pelletier, to whoſe experiments we are indebted for the knowledge of all the phoſphurets, it is compoſed of about 85 parts of tin and 15 of phoſphorus*. Margraf alſo formed this phoſphuret, but he was ignorant of its compoſition.

* Ann. de Chim. xiii. 116.

122 Alloys. Tin does not ſeem capable of combining with carbon. It is capable of combining with moſt of the metals.

1. It mixes readily with gold by fuſion; but the proportions in which theſe metals combine chemically are ſtill unknown. When one part of tin and twelve of gold are melted together, the alloy is brittle, hard, and bad coloured. Twenty-four parts of gold and one of tin produce a pale coloured alloy, harder than gold, but poſſeſſed of conſiderable ductility. Gold alloyed with no more than $\frac{1}{17}$th of tin is ſcarcely altered in its properties, according to Mr Alchorne†; but Mr Tillet, who has lately examined this alloy, found, that whenever it was heated it broke into a number of pieces.

† Alchorne, Phil. Tranſ.

2. The alloy of ſilver and tin is hardly known. According to Gellert and ſucceeding chemiſts, it is exceedingly brittle.

3. The alloy of platinum and tin is very fuſible and brittle, at leaſt when theſe metals are mixed in equal proportions‡.

‡ Dr Lewis.

4. Mercury diſſolves tin very readily, by being poured on it when melted. This amalgam cryſtallizes in the form of cubes, according to Daubenton; but, according to Sage, in grey brilliant ſquare plates, thin towards the edges, and attached to each other ſo that the cavities between them are polygonal. It is compoſed of three parts of mercury and one of tin. The amalgam of tin is uſed to ſilver the backs of glaſs mirrors.

5. Tin unites very readily with copper, and forms alloys known by the names of *bronze* and *bell-metal*. The proportions of the ingredients cannot eaſily be aſſigned, perhaps becauſe the alloy has an affinity both for copper and tin. The ſpecific gravity of the alloy in all proportions is greater than the mean ſpecific gravity of the two metals ſeparately. When the quantity of tin is ſmall compared to that of the copper, $\frac{1}{10}$th for inſtance, the alloy is called *bronze*: it is brittle, yellow, and much heavier than copper; much more fuſible, and leſs liable to be altered by expoſure to the air. It was this alloy which the ancients uſed for ſharp-edged inſtruments before the method of working iron was brought to perfection. The χαλκος of the Greeks, and perhaps the *æs* of the Romans, was nothing elſe. Even their copper coins contain a mixture of tin §.

§ See Dizé's Analyſis, Jour. de Phyſ. 1790.

6. Tin ſeems capable of being united to iron by fuſion. That there is an affinity between theſe metals is evident from their adheſion when iron is dipt into melted tin. This is the method of making *tinplate*.

123 And affinities of tin. The affinities of tin, according to Bergman, are as follows:

Zinc,
Mercury,
Copper,
Antimony,
Gold,
Silver,
Lead,
Iron,
Manganeſe,
Nickel,
Arſenic,
Platinum,
Biſmuth,
Cobalt,
Sulphuret of alkali,
Oxygen?
Sulphur?
Phoſphorus?

Sect. VIII. *Of Lead.*

Lead. Lead appears to have been very early known. It is mentioned ſeveral times by Moſes. The ancients ſeem to have conſidered it as nearly related to tin.

Lead is of a bluiſh white colour, ſomewhat darker than tin. When newly melted it is very bright, but ſoon becomes tarniſhed by expoſure to the air. It has ſcarcely any taſte, but emits on friction a peculiar ſmell. 124 Properties of lead.

It is very malleable, and may be reduced to thin plates by the hammer; but its ductility is very imperfect: a wire of lead $\frac{1}{10}$th of an inch in diameter is only capable of ſupporting a weight of $29\frac{1}{4}$ pounds*.

* Macquer's Dictionary.

Its hardneſs is 5†; its ſpecific gravity is 11,3523‡. Its ſpecific gravity is not increaſed by hammering, neither does it become harder, as is the caſe with other metals: a proof that the hardneſs which metals aſſume under the hammer is in conſequence of an increaſe of denſity.

† Kirwan's Miner. ii. 202.

‡ Briſſon.

It melts, according to Dr Lewis, at 540° Fahrenheit; according to the Dijon academicians, at 549°. When expoſed to a violent heat it evaporates completely.

When cooled ſlowly, after being fuſed, it cryſtallizes. The Abbé Mongez obtained it in quadrangular pyramids, lying on one of their ſides. Each pyramid was compoſed as it were of three layers. Pajot obtained it in the form of a polyhedron with 32 ſides, formed by the concourſe of ſix quadrangular pyramids §.

§ Jour. de Phyſ. xxxviii. 53.

Lead ſtains paper or the fingers of a bluiſh black colour.

There is a ſtrong affinity between this metal and oxygen. When nitric acid is poured upon it, an efferveſcence enſues, owing to the decompoſition of the acid; the lead ſeizes oxygen from it, and is converted into a white powder, which may be obtained pure by evaporating it to dryneſs, and then waſhing it in pure water. This is the *white oxide of lead*. It is compoſed of about 95 parts of lead and five of oxygen ‖. The affinities of this oxide are, according to Bergman, as follows: 125 Its oxides.

‖ Kirwan's Miner. ii. 499.

Sulphuric acid,
Sebacic,
Saccholactic,
Oxalic,
Arſenic,
Tartarous,
Phoſphoric,
Muriatic,

Benzoic,

Lead.

Benzoic (υ)?
Sulphurous,
Suberic?
Zoonic? } (*v*)

Acetous,
Boracic,
Pruſſic,
Carbonic,
Fixed alkali.

When lead is expoſed to heat in contact with air, its ſurface is ſoon covered with a grey pellicle; when this is taken off, another ſoon forms: and in this manner the whole lead may ſoon be converted into a dirty grey powder, which ſeems to be the white oxide mixed with a little lead. When this powder is heated red hot, it aſſumes a deep yellow colour. This is the *yellow oxide* of lead, formerly called *maſſicot*. If the heat be continued, the colour is gradually changed to a beautiful red. This is the *red oxide of lead*, formerly called *minium*. It is compoſed, as Lavoiſier has ſhewn, of 88 parts of lead and 12 of oxygen *.

* *Mem. Par.* 1781.

The manner in which theſe changes are brought about is evident; the metal gradually abſorbs oxygen from the atmoſphere. This has been actually proved by experiment. Theſe oxides (if they really differ in the proportion of oxygen) reſemble acids in ſeveral of their properties. They are very eaſily converted into glaſs by fuſion. Scheele has ſhewn that there is alſo a *brown oxide of lead*, which contains more oxygen than any of the others.

126 Sulphuret,

Sulphur unites eaſily to lead by fuſion. The ſulphuret of lead is brittle, of a deep grey colour, and much leſs fuſible than lead. Theſe two ſubſtances are often found naturally combined; the compound is then called *galena*. Sulphuret of lead is compoſed, according to the experiments of Wenzel, of 868 parts of lead and 132 of ſulphur †.

† *Kirwan's Miner.* ii. 492.

127 Phoſphuret,

Phoſphuret of lead may be formed by mixing together equal parts of filings of lead and phoſphoric glaſs, and fuſing them in a crucible. It may be cut with a knife, but ſeparates into plates when hammered. It is of a white ſilver colour with a ſhade of blue, but it ſoon tarniſhes when expoſed to the air. This phoſphuret may alſo be formed by dropping phoſphorus into melted lead. It is compoſed of about 12 parts of phoſphorus and 88 of lead ‡.

‡ *Pelletier, Ann. de Chim.* xiii. 114.

128 Alloys, and

Lead combines with moſt of the other metals.

1. Little is known concerning the alloy of lead and gold. It is ſaid to be brittle.

2. The alloy of ſilver and lead is very fuſible, and neither elaſtic nor ſonorous.

3. Platinum and lead unite in a ſtrong heat: the alloy is brittle, of a purpliſh colour, and ſoon changes on expoſure to the air *.

* *Fourcroy.*

4. Mercury, when poured upon melted lead, diſſolves it readily. The amalgam is white and brilliant, and aſſumes a ſolid form. It is capable of cryſtallizing. The cryſtals are compoſed of one part of lead and one and a half of mercury †.

† *Dijon Academicians.*

5. Copper and lead combine eaſily by fuſion; but the alloy has not been applied to any uſe.

6. Iron does not unite with lead.

7. Lead and tin may be combined by fuſion. The alloy in the proportion of two parts of lead and one of tin is more ſoluble than either of the metals ſeparately. It is accordingly uſed by plumbers as a ſolder.

129 Affinities.

Lead, when taken internally, acts as a poiſon. Its affinities, according to Bergman, are as follows:

Gold,
Silver,
Copper,
Mercury,
Biſmuth,
Tin,
Antimony,
Platinum,
Arſenic,
Zinc,
Nickel,
Iron,
Sulphuret of alkali,
Sulphur,
Phoſphorus?

130 Names and marks given to the metals by the ancients.

The ancients gave to the ſeven metals laſt deſcribed (omitting *platinum*, which they did not know) the names of the planets, and denoted each of them by particular marks, which repreſented both the planet and the metal.

Gold was the	Sun, and repreſented by	☉.
Silver	the Moon,	☽.
Mercury	Mercury,	☿.
Copper	Venus,	♀.
Iron	Mars,	♂.
Tin	Jupiter,	♃.
Lead	Saturn,	♄.

It ſeems moſt probable that theſe names were firſt given to the planets; and that the ſeven metals, the only ones then known, were ſuppoſed to have ſome relation to the planets or to the gods that inhabited them, as the number of both happened to be the ſame. It appears from a paſſage in Origen, that theſe names firſt aroſe among the Perſians (w). Why each particular metal was denominated by a particular planet it is not eaſy to ſee. Many conjectures have been made, but ſcarcely any of them are ſatisfactory.

As

(υ) Benzoat of lead is decompoſed by muriatic acid. *Trommſdorf, Ann. de Chim.* xi. 317.

(*v*) Suberic acid decompoſes nitrat of lead. See *Jameſon's Mineralogy*, p. 166. Zoonic acid produces the ſame effect, as Berthollet has obſerved.

(v) Schrickel places it after the three mineral acids.

(w) *Contra Celſum*, lib. vi. 22.—" Celſus de quibuſdam Perſarum myſteriis ſermonem facit. Harum rerum, inquit, aliquod reperitur in Perſarum doctrina Mithraciſque eorum myſteriis veſtigium. In illis enim duæ cæleſtes converſiones, alia ſtellarum fixarum, errantium alia, et animæ per eas tranſitus quodam ſymbolo repræſentantur, quod hujuſmodi eſt. Scala altas portas habens, in ſumma autem octava porta. Prima portarum plumbea, altera ſtannea, Lead.

131 Origin of theſe marks according to the aſtrologers;

As to the characters by which theſe metals were expreſſed, aſtrologers ſeem to have conſidered them as the attributes of the deities of the ſame name. The circle in the earlieſt periods among the Egyptians was the ſymbol of divinity and perfection; and ſeems with great propriety to have been choſen by them as the character of the ſun, eſpecially as, when ſurrounded by ſmall ſtrokes projecting from its circumference, it may form ſome repreſentation of the emiſſion of rays. The ſemicircle is, in like manner, the image of the moon; the only one of the heavenly bodies that appears under that form to the naked eye. The character ♄ is ſuppoſed to repreſent the ſcythe of Saturn; ♃ the thunderbolts of Jupiter; ♂ the lance of Mars, together with his ſhield; ♀ the looking-glaſs of Venus; and ☿ the caduceus or wand of Mercury.

132 According to the alchymiſts.

The alchymiſts, however, give a very different account of theſe ſymbols. Gold was the moſt perfect metal, and was therefore denoted by a circle. Silver approached neareſt it; but as it was inferior, it was denoted only by a ſemicircle. In the character ☿ the adepts diſcovered gold with a ſilver colour. The croſs at the bottom expreſſed the preſence of a myſterious ſomething, without which mercury would be ſilver or gold. This ſomething is combined alſo with copper; the poſſible change of which into gold is expreſſed by the character ♀. The character ♂ declares the like honourable affinity alſo; though the ſemicircle is applied in a more concealed manner: for, according to the propereſt mode of writing, the point is wanting at the top, or the upright line ought only to touch the horizontal, and not to interſect it. Philoſophical gold is concealed in ſteel; and on this account it produces ſuch valuable medicines. Of tin, one half is ſilver, and the other conſiſts of the unknown ſomething; for this reaſon the croſs with the half moon appears in ♃. In lead this ſomething is predominant, and a ſimilitude is obſerved in it to ſilver. Hence in its character ♄ the croſs ſtands at the top, and the ſilver character is only ſuſpended on the right hand behind it.

133 Their real origin.

The fact, however, according to Profeſſor Beckmann, from whom moſt of the above remarks have been taken, ſeems to be, that theſe characters are mere abbreviations of the old names of the planets. "The character of Mars (he obſerves*), according to the oldeſt mode of repreſenting it, is evidently an abbreviation of the word Θουρος, under which the Greek mathematicians underſtood that deity; or, in other words, the firſt letter Θ, with the laſt letter ς placed above it. The character of Jupiter was originally the initial letter of Ζευς; and in the oldeſt manuſcripts of the mathematical and aſtrological works of Julius Firmicus, the capital Z only is uſed, to which the laſt letter ς was afterwards added at the bottom, to render the abbreviation more diſtinct. The ſuppoſed looking-glaſs of Venus is nothing elſe than the initial letter diſtorted a little of the word Φωσφορος, which was the name of that goddeſs. The imaginary ſcythe of Saturn has been gradually formed from the two firſt letters of his name Κρονος, which tranſcribers, for the ſake of diſpatch, made always more convenient for uſe, but at the ſame time leſs perceptible. To diſcover in the pretended caduceus of Mercury the initial letter of his Greek name Στιλβων, one needs only look at the abbreviations in the oldeſt manuſcripts, where they will find that the Σ was once written as C; they will remark alſo, that tranſcribers, to diſtinguiſh this abbreviation from the reſt ſtill more, placed the C thus ◠, and added under it the next letter τ. If thoſe to whom this deduction appears improbable will only take the trouble to look at other Greek abbreviations, they will find many that differ ſtill farther from the original letters they expreſs than the preſent character ☿ from the C and τ united. It is poſſible alſo that later tranſcribers, to whom the origin of this abbreviation was not known, may have endeavoured to give it a greater reſemblance to the caduceus of mercury. In ſhort, it cannot be denied that many other aſtronomical characters are real ſymbols, or a kind of proper hieroglyphics, that repreſent certain attributes or circumſtances, like the characters of Aries, Leo, and others quoted by Saumaiſe."

* *Hiſtory of Inventions, Engliſh tranſlation*, iii. 67.

Zinc.

Sect. IX. *Of Zinc.*

134 Diſcovery of zinc.

The ancients were acquainted with a mineral to which they gave the name of *Cadmea*, from Cadmus, who firſt taught the Greeks to uſe it. They knew that when melted with copper it formed braſs; and that when burnt, a white ſpongy kind of aſhes was volatiliſed, which they uſed in medicine*. This mineral contained a good deal of zinc; and yet there is no proof remaining that the ancients were acquainted with that metal (x). It is firſt mentioned in the writings of Albertus Magnus, who died in 1280: but whether he had ſeen it is not ſo clear, as he gives it the name of *marcaſite of gold*, which implies, one would think, that it had

* *Pliny*, l. 34. c. 2. and 10.

ſtannea, tertia ex ære, quarta ferrea, quinta ex ære mixto, ſexta argentea, ſeptima ex auro. Κλιμαξ ὑψιπυλος, επι δ' αιτη πυλη ογδοη. Ἡ πρωτη των πυλων μολιβδου, ἡ δευτερα κασσιτερου, ἡ τριτη χαλκου, ἡ τεταρτη σιδηρου, ἡ πεμπτη κερασου νομισματος, ἡ ἑκτη αργυρου, χρυσου δ' ἡ ἑβδομη. Primum aſſignant Saturno tarditatem illius ſideris plumbo indicantes: alteram Veneri, quam referunt, ut ipſi quidem putant, ſtanni ſplendor et mollities; tertiam Jovi, aheneam illam quidem et ſolidam: quartam Mercurio, quia Mercurius et ferrum, uterque operum omnium tolerantes, ad mercaturam utiles, laborum patientiſſimi. Marti quintam, inæqualem illam et variam propter mixturam. Sextam, quæ argentea eſt, lunæ; ſeptimam auream ſoli tribuunt, quia ſolis et lunæ colores hæc duo metalla referunt."

Borrichius ſuſpects, with a good deal of probability, that the names of the gods in this paſſage have been tranſpoſed by tranſcribers, either through ignorance or deſign. He arranges them as follows: "Secundam portam faciunt Jovis, comparantes ei ſtanni ſplendorem et mollitiem; tertiam Veneris æratam et ſolidam; quartam Martis, eſt enim laborum patiens, æque ac ferrum, celebratus hominibus; quintam Mercurii propter miſturam inæqualem ac variam, et quia negotiator eſt; ſextam Lunæ argenteam; ſeptimam Solis auream." *Ol. Borrichius de ortu et progreſſu chemiæ.* Hafniæ, 1668, 4to, p. 29.

(x) Grignon indeed ſays, that ſomething like it was diſcovered in the ruins of an ancient Roman city in Champagne; but the ſubſtance which he took for it was not examined with any accuracy. It is impoſſible, therefore to draw any inference whatever from his aſſertion. *Bulletin des fouilles d'une ville Romaine*, p. 11.

Zinc.

had a yellow colour (Y). The word *zinc* occurs first in the writings of Paracelsus, who died in 1541. He informs us very gravely, that it is a metal, and not a metal, and that it consists chiefly of the ashes of copper *. This metal has also been called *spelter*.

* See Vol. vi. of his Works in 4to.

Zinc has never been found in Europe in a state of purity, and it was long before a method was discovered of extracting it from its ore (Z). Henkel pointed out one in 1721, and Von Swab obtained it by distillation in 1742, and Margraf published a process in the Berlin Memoirs in 1746 †.

† Bergman, ii. 309.

135 Properties of zinc.

It is of a bluish white colour, somewhat lighter than lead. It has neither taste nor smell.

It has some degree of malleability; for by compression it may be reduced into thin plates ‡; but it cannot be drawn out into wire. It is more brittle when hot than when cold.

‡ Sage.

Its hardness is 6 §. Its specific gravity, when compressed, is 7,1908 ‖; in its usual state, 6,862 ¶. It melts at about 699° Fahrenheit *.

§ Kirwan's Miner. ii. 232

‖ Brisson.

¶ Kirwan, ibid.

When allowed to cool slowly, it crystallizes in small bundles of quadrangular prisms, disposed in all directions. If they are exposed to the air while hot, they assume a blue changeable colour †.

* Bergman.

† Mongez.

136 Its oxides,

When zinc is kept melted in contact with air, it becomes covered with a grey pellicle, which gradually assumes a yellowish tint. By removing this pellicle from time to time, the whole of the metal may be reduced into a grey powder. This is the *grey oxide of zinc*. This oxide is probably composed of about 85 parts of zinc and 15 of oxygen ‡. When zinc is violently heated, it burns with a bright white flame, and at the same time a quantity of very light white flakes are sublimed. These flakes are the *white oxide of zinc*, which contains a good deal more oxygen than the grey oxide (A).

‡ Morveau, Kirwan's Miner. ii. 489.

Zinc may also be oxidated by solution in acids, particularly the nitric acid. Whether the oxide obtained by precipitating zinc from its solution in that acid, or by distilling that acid off zinc, be really different from the white oxide, has not yet been properly ascertained; but one would be apt to suspect, from the experiments mentioned by Mr Kirwan, that it contained a good deal more oxygen *.

* Mineral. ii. 499.

The affinities of the oxides, or rather of the white oxide of zinc, are, according to Bergman, as follows:

Oxalic acid,
Sulphuric,
Pyromucous †,
Muriatic,
Saccholactic,
Nitric,
Sebacic,
Tartaric,
Phosphoric,
Citric,
Succinic,
Fluoric,
Arsenic,
Formic,
Lactic,
Acetous,
Boracic,
Prussic,
Carbonic,
Ammonia.

† Schrickel.

137 Sulphuret,

There is an affinity between sulphur and zinc, as is evident from these two substances being often found united; but it is very difficult to form the sulphuret of zinc artificially, on account of the rapid oxidation and consequent volatilization of the zinc. Morveau, however, succeeded in forming it.

138 Phosphurets,

Zinc may be combined with phosphorus, by dropping small bits of phosphorus into it while in a state of fusion. Pelletier, to whom we are indebted for the experiment, added also a little resin, to prevent the oxidation of the zinc. Phosphuret of zinc is of a white colour, a metallic splendor, but resembles lead more than zinc. It is somewhat malleable. When hammered or filed, it emits the odour of phosphorus. When exposed to a strong heat, it burns like zinc ‡.

‡ Ann. de Chim. xiii. 129.

Phosphorus

(Y) The passages in which he mentions it are as follows:—*De Mineral.* lib. ii. cap. 11. "Marchasita, sive marchasida ut quidam dicunt, est lapis in substantia, et habet multas species, quare colorem accipit cujuslibet metalli, et sic dicitur marchasita argentea et aurea, et sic dicitur aliis. Metallum tamen quod colorat eum non distillat ab ipso, sed evaporat in ignem, et sic relinquitur cinis inutilis, et hic lapis notus est apud alchimicos, et in multis locis veniuntur.

Lib. iii. cap. 10. "Æs autem invenitur in venis lapidis, et quod est apud locum qui dicitur Gofelaria est purissimum et optimum, et toti substantiæ lapidis incorporatum, ita quod totus lapis est sicut marchasita aurea, et profundatum est melius ex eo quod purius.

Lib. v. cap. 5. "Dicimus igitur quod marchasita duplicem habet in sui creatione substantiam, argenti vivi scilicet mortificati, et ad fixionem approximantis, et sulphuris adurentis. Ipsam habere sulphureitatem comperimus manifesta experientia. Nam cum sublimatur, ex illa emanat substantia sulphurea manifesta comburens. Et sine sublimatione similiter perpenditur illius sulphureitas.

"Nam si ponatur ad ignitionem, non suscipit illam priusquam inflammatione sulphuris inflammetur, et ardeat. Ipsam vero argenti vivi substantiam manifestatur habere sensibiliter. Nam albedinem præstat Veneri meri argenti, quemadmodum et ipsum argentum vivum, et colorem in ipsius sublimatione cælestium præstare, et luciditatem manifestam metallicam habere vidimus, quæ certum reddunt artificem Alchimiæ, illam has substantias continere in radice sua."

(Z) The real discoverer of this method appears to have been Dr Isaac Lawson. See *Pott*, III. Diss. 7. and *Watson's Chemical Essays*.

(A) Pott observed, that it was $\frac{1}{18}$th heavier than the zinc from which it was obtained; and Mr Boyle had long before ascertained the same fact.—*Shaw's Boyle*, II. 391, 394.

This oxide of zinc was well known to the ancients. Dioscorides describes the method of preparing it. The ancients called it *pompholyx*, the early chemists gave it the name of *lana philosophica*. Dioscorides compares it to wool, εριων τολυπαις αφομοιουνται, v. 85. p. 352.

Zinc.

Phoſphorus combines alſo with the oxide of zinc, a compound which Margraf had obtained during his experiments on phoſphorus. When 12 parts of oxide of zinc, 12 parts of phoſphoric glaſs, and two parts of charcoal powder, are diſtilled in an earthen ware retort, and a ſtrong heat applied, a metallic ſubſtance ſublimes of a ſilver-white colour, which, when broken, has a vitreous appearance. This, according to Pelletier, is phoſphuret of oxide of zinc. When heated by the blowpipe, the phoſphorus burns, and leaves behind a glaſs tranſparent while in fuſion, but opaque after cooling*.

* Pelletier, ibid. 128.

139 Carburet,

Zinc alſo combines with carbon, and forms carburet of zinc. The French chemiſts have ſhewn that zinc generally contains ſome carbon.

140 Alloys,

Zinc combines with moſt of the metals:

1. It mixes with gold in any proportion. The alloy is the whiter and the more brittle the greater quantity of zinc it contains. An alloy, conſiſting of equal parts of theſe metals, is very hard and white, receives a fine poliſh, and does not tarniſh readily. It has therefore been propoſed by Mr Malouin† as very proper for the ſpecula of teleſcopes. One part of zinc is ſaid to deſtroy the ductility of 100 parts of gold‡.

† Mem. Acad. Par. 1742.
‡ Keir's Macquer's Dictionary.

2. The alloy of ſilver and zinc is eaſily produced by fuſion. It is brittle.

3. Platinum combines very readily with zinc. The alloy is brittle, pretty hard, very fuſible, and of a bluiſh white colour, not ſo clear as that of zinc§.

§ Dr Lewis.

4. Zinc may be combined with mercury by fuſion. The amalgam is ſolid. It cryſtallizes when melted and cooled ſlowly into lamellated hexagonal figures, with cavities between them. They are compoſed of one part of zinc and two and a half of mercury‖. It is uſed to rub on electrical machines, in order to excite electricity.

‖ Elemens de Chim. Dijon, t. 3.

5. Zinc combines very readily with copper. This alloy, which is called *braſs*, was known to the ancients. They uſed an ore of zinc to form it, which they called *cadmia*. This alloy was very much valued by the ancients. Dr Watſon has proved that it was to braſs which they gave the name of *orichalcum*¶. Their *æs* was copper or rather bronze (B). Braſs is compoſed of about three parts of copper and one of zinc. It is of a beautiful yellow colour, more fuſible than copper, and not ſo apt to tarniſh. It is malleable, and ſo ductile that it may be drawn out into wire. When the alloy contains three parts of zinc and four of copper, it aſſumes a colour nearly the ſame with gold, but it is not ſo malleable as braſs. It is then called *pinchbeck*, *prince's metal*, or *Prince Rupert's metal*.

¶ Mancheſter Tranſ. vol. ii.

6. The alloy of iron and zinc has ſcarcely been examined: but Malouin has ſhewn that zinc may be uſed inſtead of tin to cover iron plates; a proof that there is an affinity between the two metals*.

* Mem. Par. 1742.

7. Tin and zinc combine eaſily. The alloy is harder than tin. This alloy is often the principal ingredient in the compound called *pewter*.

8. Mr Gmelin has ſucceeded in forming an alloy of zinc and lead by fuſion. He put ſome ſuet into the mixture, and covered the crucible, in order to prevent the evaporation of the zinc. When the zinc exceeded the lead very much, the alloy was malleable, and much harder than lead. A mixture of two parts of zinc and one of lead formed an alloy more ductile and harder than the laſt. A mixture of equal parts of zinc and lead formed an alloy differing little in ductility and colour from lead; but it was harder, and more ſuſceptible of poliſh, and much more ſonorous. When the mixture contained a ſmaller quantity of zinc, it ſtill approached nearer the ductility and colour of lead, but it continued harder, more ſonorous, and ſuſceptible of poliſh, till the proportions approached to one of zinc and 16 of lead, when the alloy differed from the laſt metal only in being ſomewhat harder†.

† Ann. de Chim. ix. 95.

141 And affinities.

The affinities of zinc, according to Bergman, are as follows:

Copper,
Antimony,
Tin,
Mercury,
Silver,
Gold,
Cobalt,
Arſenic,
Platinum,
Biſmuth,
Lead,
Nickel,
Iron.

SECT. X. *Of Antimony.*

Antimony.

THE ancients were acquainted with an oxide of antimony to which they gave the names of στιμμι and *ſtibium*. Pliny‡ informs us that it was found in ſilver ore; and we know that at preſent there are ſilver ores§ in which it is contained. It was uſed as an external application to ſore eyes; and Pliny gives us the method of preparing it‖. Galen ſuppoſes that the τετραγωνον of Hippocrates was a preparation of antimony; but this wants proof. It does not appear, however, that the ancients conſidered this ſubſtance as a metal, or that they knew antimony in a ſtate of purity (C). Who firſt extracted it from its ore we do not know; but Baſil Valentine, a chemiſt of the 16th century, is the firſt who deſcribes the proceſs.

‡ Pliny, l. xxxiii. c. 6.
§ Kirwan's Miner. ii. 110.
‖ Pliny, ibid.

142 Diſcovery of Antimony.

(B) The ancients do not ſeem to have known accurately the difference between copper, braſs, and bronze. Hence the confuſion obſervable in their names. They conſidered braſs as only a more valuable kind of copper, and therefore often uſed the word *æs* indifferently to denote either. It was not till a late period that mineralogiſts began to make the diſtinction. They called copper *æs cyprium*, and afterwards only *cyprium*, which in proceſs of time was converted into *cuprum*. When theſe changes took place is not known accurately. Pliny uſes *cyprium*, lib. xxxvi. c. 26. The word *cuprum* occurs firſt in Spartian, who lived about the year 290. He ſays in his life of Caracalla, *cancelli ex ære vel cupro*.

(C) Mr Roux indeed, who at the requeſt of Count Caylus analyſed an ancient mirror, found it compoſed of copper, lead, and antimony. This would go far to convince us that the ancients knew this metal, provided it could be proved that the mirror was *really* an ancient one; but this point appears to be extremely doubtful.

Antimony.

process. To him indeed we are indebted for our acquaintance with many of the properties of this metal.

Antimony is of a white colour, with a shade of grey. It has a sensible taste, but no smell *.

* Fourcroy.

143 Properties of antimony.

It is neither malleable nor ductile, but exceedingly brittle. Its specific gravity, according to Brisson, is 6,702; according to Bergman, 6,860. Its hardness is 6,5 †. It melts at 809° Fahrenheit ‡. If after this the heat be increased, the metal evaporates. On cooling it assumes the form of oblong crystals, perpendicular to the internal surface of the vessel in which it cools. It is to this crystallization that the laminated structure which antimony always assumes is owing.

† Kirwan's Miner. ii. 244.

‡ Bergman.

Neither air nor water have much effect on this metal.

144 Its oxides.

When antimony is beat to powder, and exposed for some time to a gentle heat, it absorbs oxygen, and is converted into a grey powder. This is the *grey oxide of antimony*. When this metal is kept for some time melted in contact with air, it sublimes in the form of a white powder, formerly called *snow* or *white flowers of antimony*. This is the *white oxide of antimony*. This oxide may be procured also by pouring nitric acid on antimony, and then evaporating to dryness. Antimony attracts the oxygen from the acid, and thus passes very rapidly into the state of an oxide. This oxide seems to consist of about 77 parts of antimony and 23 of oxygen §. The nature of these oxides has never yet been accurately inquired into. It is not even known at present whether the white oxide obtained by heat and that obtained by nitric acid contain the same quantity of oxygen. The experiments mentioned by Mr Kirwan make the contrary probable ‖; and yet these oxides have too many qualities in common to render these experiments conclusive. The white oxide of antimony is soluble in water ¶; and when fused, is converted into a transparent glass. The white oxide obtained by nitric acid seems to possess many of the properties of an acid.

§ Kirwan's Miner. ii. 489.

‖ Ibid.

¶ Rouelle.

The affinities of the grey oxide of antimony are, according to Bergman, as follows:

Sebacic acid,
Muriatic,
Benzoic (D)?
Oxalic,
Sulphuric,
Pyromucous *,
Nitric,
Tartarous,
Saccholactic,
Phosphoric,
Citric,
Succinic,
Fluoric,
Arsenic,
Formic,
Lactic,
Acetous,
Boracic,
Prussic,
Carbonic.

* Schrickel.

145 Sulphurets,

Sulphur combines readily with antimony. This compound is often found native: it was formerly called antimony, and the pure metal was then called *regulus of antimony*. Sulphuret of antimony is easily melted by a moderate heat: if the heat be continued, the sulphur sublimes, and at the same time the antimony absorbs oxygen, and is converted into a grey oxide. This sulphuret is composed of 74 parts of antimony and 26 of sulphur *.

* Bergman, iii. 167.

The grey oxide of antimony is also capable of combining with about $\frac{4}{100}$ of sulphur. This compound, by fusion, may be converted into glass. It was formerly used in medicine under the name of *glass of antimony*.

146 Phosphuret,

When equal parts of antimony and phosphoric glass are mixed together with a little charcoal powder, and melted in a crucible, phosphuret of antimony is produced. It is of a white colour, brittle, appears laminated when broken, and at the fracture there appear a number of small cubic facettes. When melted it emits a green flame, and then sublimes in the form of a white powder. Phosphuret of antimony may likewise be prepared by fusing equal parts of antimony and phosphoric glass, or by dropping phosphorus into melted antimony †.

† Pelletier, Ann. de Chim. xiii. 132.

Antimony is capable of combining with most of the metals

147 Alloys,

1. Gold may be alloyed with antimony by fusing them together. The antimony is afterwards separable by an intense heat. This alloy is little known, and has never been applied to any use.

2. The alloy of silver and antimony is brittle, and its specific gravity, as Gellert has observed, is greater than intermediate between the specific gravities of the two metals which enter into it.

3. Platinum easily combines with antimony. The alloy is brittle, and much lighter than platinum ‡. The antimony cannot afterwards be completely separated by heat.

‡ Dr Lewis.

4. Mercury does not easily combine with antimony. Mr Gellert succeeded in amalgamating this metal by putting it into hot mercury, and covering the whole with water.

5. Copper combines readily with antimony by fusion. The alloy is of a beautiful violet colour, and its specific gravity is greater than intermediate §.

§ Gellert.

6. Iron combines with antimony, and forms a brittle hard alloy, the specific gravity of which is less than intermediate. The magnetic quality of iron is much more diminished by being alloyed with antimony than with any other metal ‖.

‖ Id.

7. The alloy of tin and antimony is white and brittle; its specific gravity is less than intermediate ¶.

¶ Id.

8. When equal quantities of lead and antimony are fused, the alloy is porous and brittle: three parts of lead and one of antimony form a compact alloy, malleable, and much harder than lead: 12 parts of lead and one of antimony form an alloy very malleable, and a good deal harder than lead: 16 parts of lead and one of antimony form an alloy which does not differ from lead except in hardness *. This alloy forms printers types.

* Gmelin, Ann. de Chim. viii. 319.

9. Zinc and antimony form a brittle alloy, the specific gravity of which is less than intermediate †. The alloys of antimony are little known. Gellert is almost the only person who has examined them. It would require a great number of experiments to be able to fix the proportions of their ingredients.

† Gellert.

The

(D) Muriatic acid decomposes benzoat of antimony. *Trommsdorf, Ann. de Chim.* xi. 317.

The affinities of antimony are, according to Bergman, as follows:

Iron,
Copper,
Tin,
Lead,
Nickel,
Silver,
Bismuth,
Zinc,
Gold,
Platinum,
Mercury,
Arsenic,
Cobalt,
Sulphuret of arsenic,
Sulphur,
Phosphorus?

Sect. XI. *Of Bismuth.*

The ancients appear to have known nothing of bismuth, nor do we know who discovered it; but it is first mentioned by George Agricola, who was born about the end of the 15th century.

148 Properties of bismuth. Bismuth is of a yellowish or reddish white colour, and almost destitute both of taste and smell.

It is brittle. Its hardness is 6 *. Its specific gravity is 9,8227 †. It melts at 460° Fahrenheit ‡. When heated in close vessels, it sublimes. When allowed to cool slowly after fusion, it crystallizes.

* *Kirwan.* † *Brisson.* ‡ *Lewis.*

Bismuth is not altered by water. When exposed to the air it soon tarnishes.

149 Its oxides, When bismuth is kept fused in contact with air, it is gradually oxidated. When heated red hot, it emits a very faint blue flame, and its oxide evaporates in the form of a yellowish smoke. When this smoke is collected, it is found to consist of a brown-coloured powder. This is the *brown oxide of bismuth.* It is composed of about 94 parts of bismuth and 6 of oxygen §. Bismuth decomposes nitric acid with great rapidity, by attracting its oxygen. If the quantity of acid be considerable, it dissolves the oxide as it forms; but the greater part of it may be precipitated by diluting the acid with water. This precipitate, which is a white powder, is *white oxide of bismuth.* It is composed of about 84 parts bismuth and 16 of oxygen ‖.

§ *Kirwan's Miner.* ii. 489. ‖ *Ibid.*

The affinities of the oxides of bismuth are, according to Bergman, as follows:

Oxalic acid,
Arsenic,
Tartarous,
Phosphoric,
Sulphuric,
Sebacic,
Muriatic,
Benzoic (E)?
Nitric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Prussic,
Carbonic,
Ammonia.

Sulphur combines readily with bismuth by fusion. 150 Sulphuret, The sulphuret of bismuth is of a bluish grey colour, and crystallizes into beautiful tetrahedral needles. It is composed of 85 parts of bismuth and 15 of sulphur *.

* *Wenzel, Kirwan's Miner.* ii. 492.

There appears to be little affinity between bismuth and phosphorus. Mr Pelletier attempted to produce the phosphuret of bismuth by various methods without success. 151 Phosphuret, When he dropped phosphorus, however, into bismuth in fusion, he obtained a substance which did not apparently differ from bismuth, but which, when exposed to the blow-pipe, gave evident signs of containing phosphorus. Phosphuret of bismuth, according to Pelletier, is composed of about 96 parts of bismuth and four of phosphorus †.

† *Ann. de Chim.* xiii. 130.

Bismuth combines readily with most of the metals. 152 Alloys,

1. Equal parts of bismuth and gold form a brittle alloy, nearly of the same colour with bismuth ‡.
2. Equal parts of bismuth and silver form also a brittle alloy, but less so than the last. The specific gravity of both these is greater than intermediate §.
3. The alloy of bismuth and platinum is also very brittle. When exposed to the air it assumes a purple, violet, or blue colour. The bismuth may be separated by heat ‖.
4. Mercury dissolves bismuth very easily. The amalgam is more fluid than pure mercury, and has the property of dissolving lead and rendering it also fluid ¶. It is capable, however, of crystallizing. The crystals are either octahedrons, lamellated triangles, or hexagons. They are composed of one part of bismuth and two of mercury *.
5. The alloy of copper and bismuth is not so red as copper.
6. Nothing is known concerning the alloy of iron and bismuth.
7. Bismuth and tin unite readily. A small portion of bismuth increases the brightness, hardness, and sonorousness of tin: it often therefore enters into the composition of the compound called *pewter.* Equal parts of tin and bismuth form an alloy that melts at 280°: eight parts of tin and one of bismuth, melt at 390°: two parts of tin and one of bismuth, at 330° †.
8. The alloy of lead and bismuth is of a dark grey colour, a close grain, but very brittle.
9. Bismuth does not combine with zinc.
10. The alloy of antimony and bismuth is unknown.

‡ *Keir, Macquer's Dict.* § *Ibid.* ‖ *Dr Lewis.* ¶ *Cramer.* * *Chim. Dijon,* i. 3. † *Dr Lewis.*

Bismuth likewise enters into triple compounds with metals: Two parts of lead, three of tin, and five of bismuth, form an alloy which melts at the heat of boiling water, which is 212°.

153 And affinities. The affinities of bismuth, according to Bergman, are as follows:

Lead,
Silver,
Gold,
Mercury,

(E) Muriatic acid decomposes benzoat of bismuth.—*Trommsdorf, Ann. de Chim.* xi. 317.

Mercury,
Antimony,
Tin,
Copper,
Platinum,
Nickel,
Iron,
Sulphuret of alkali,
Sulphur,
Phosphorus ?

Sect XII. *Of Arsenic.*

The word *arsenic* (αρσενικον) occurs first in the works of Dioscorides, and of some other authors who wrote about the beginning of the Christian era. It denotes in their works the same substance which Aristotle had called σανδαραχη (F), and his disciple Theophrastus αρρενικον, which is a reddish coloured mineral, composed of arsenic and sulphur, used by the ancients in painting, and as a medicine.

The *white oxide of arsenic*, or what is known in commerce by the name of arsenic, is mentioned by Avicenna in the 11th century; but at what period the metal called *arsenic* was first extracted from that oxide is unknown. Paracelsus seems to have known it. It is mentioned by Schroeder in his Pharmacopœia published in 1649 *.

* *Bergman*, ii. 278.

153 Properties of arsenic.

Arsenic, when pure, is of a bluish white colour. It is exceedingly brittle. Its hardness is 7 †. Its specific gravity 8,310 ‡.

† *Kirwan's Miner.* ii. 254.
‡ *Bergman*, ii. 278.

When exposed to the temperature of 354° in close vessels it sublimes §, and crystallizes in regular tetrahedrons.

§ *Ibid.*

It is not much altered by water. Boiling water, however, is capable of dissolving, and retaining $\frac{1}{10000}$th of arsenic; but that part of the metal is no doubt reduced to the state of an oxide ||.

154 Its oxides,

|| *Habneman, Chim. Ann.* 1788, i. 182.

When arsenic is exposed to the open air, it very soon loses its lustre, and is gradually converted into a greyish black substance by combining with oxygen. This is called the *grey oxide of arsenic*.

When exposed to a moderate heat in contact with air, it sublimes in the form of a white powder, and at the same time emits a smell resembling garlic. If the heat be increased, it burns with an obscure bluish flame. This sublimate is *white oxide of arsenic*, which is composed of 93 parts of arsenic and 7 of oxygen ¶.

¶ *Kirwan's Miner.* ii. 490.

It is of a sharp acrid taste, which at last leaves an impression of sweetness, and is one of the most virulent poisons known. It has an alliacious smell. It is soluble in 80 parts of water at the temperature of 60°, and in 15 parts of boiling water *. When this solution is evaporated, the oxide crystallizes †. When heated to 283°, it sublimes: if heat be applied in close vessels, it becomes pellucid like glass, but when exposed to the air it soon recovers its former appearance. The specific gravity of this glass is 5,000; that of the white oxide, 3,706 ‡. This oxide is capable of combining with most of the metals, and in general renders them brittle. Its affinities, according to Bergman, are as follows:

* *Bergman*, ii. 278.
† *Brandt, Act. Upsal*, 1733.
‡ *Bergman*, ii. 278.

Muriatic acid,
Oxalic,
Sulphuric,
Nitric,
Sebacic,
Tartarous,
Phosphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Arsenic,
Acetous,
Prussic,
Ammonia,
Water,
Alcohol ?

Arsenic, or rather the white oxide of arsenic, is capable of combining with an additional dose of oxygen. The compound produced is *arsenic acid*, first discovered by Scheele, which contains 91 parts of arsenic and 9 of oxygen *.

* *Berthollet, Kirwan's Miner.* ii. 490.

Arsenic combines readily with sulphur. When heat is applied to a mixture of white oxide of arsenic and sulphur, the oxide is decomposed, part of the sulphur combines with its oxygen, and the remainder unites with the reduced metal. The sulphuret of arsenic produced by this process is of a yellow colour, and was formerly called *orpiment*. It is composed, according to Westrum, of 20 parts of arsenic and 80 of sulphur †. It is often found native. If a stronger heat be applied, so as to melt the sulphuret, it assumes a scarlet colour, and is much less volatile than formerly. This new compound was formerly called *realgar*. It is composed, according to Westrum, of 80 parts of arsenic and 20 of sulphur ‡. The difference therefore between it and orpiment is evident. During the fusion part of the sulphur without doubt sublimes. It might be called *red sulphuret of arsenic*.

155 Sulphuret,

† *Kirwan's Miner.* ii. 492.
‡ *Ibid.*

156 Phosphuret,

Arsenic combines readily with phosphorus. The phosphuret of arsenic may be formed by distilling equal parts of its ingredients over a moderate fire. It is black and brilliant, and ought to be preserved in water. It may be formed likewise by putting equal parts of phosphorus and arsenic into a sufficient quantity of water, and keeping the mixture moderately hot for some time §.

§ *Pelletier, Ann. de Chim.* xiii. 139.

Arsenic unites with most metals, and in general renders them more brittle and more fusible.

1. Melted gold takes up $\frac{1}{60}$th of arsenic ||. The alloy is brittle and pale.

|| *Bergman, ibid.*

2. Melted silver takes up $\frac{1}{14}$th of arsenic ¶. The alloy is brittle.

¶ *Ibid.*

157 Alloys,

3. The alloy of platinum and arsenic is brittle and very fusible. It was first formed by Scheffer. The arsenic may be separated by heat.

4. The amalgam of arsenic is composed of five parts of mercury and one of arsenic *.

* *Ibid.*

5. Copper takes up $\frac{5}{6}$ths of arsenic †. This alloy is white;

† *Ibid.*

(F) Pliny seems to make a distinction between sandaracha and arsenic. See Lib. xxxiv. c. 18.

Cobalt. white; and when the quantity of arsenic contained in it is small, both ductile and malleable *. It is called *white tombac*.

6. Iron is capable of combining with more than its own weight of arsenic †. This alloy is white, brittle, and capable of crystallizing. It is found native ‡.

7. The alloy of tin and arsenic is harder and more sonorous than tin, and has much resemblance externally to zinc. Tin often contains a small quantity of arsenic.

8. Lead takes up $\frac{1}{6}$th of arsenic §. The alloy is brittle and dark coloured.

9. Zinc takes up $\frac{1}{5}$th of arsenic, antimony $\frac{1}{8}$th, and bismuth $\frac{1}{15}$th ‖.

158 And affinities.

The affinities of arsenic, according to Bergman, are as follows:

Nickel,
Cobalt,
Copper,
Iron,
Silver,
Tin,
Gold,
Platinum,
Zinc,
Antimony,
Sulphuret of alkali,
Sulphur,
Phosphorus.

* Gellert.

† Bergman, Ann de Chim xiii. 139.

‡ Kirwan's Miner. ii. 256.

§ Bergman, Ibid.

‖ Ibid.

Sect. XIII. *Of Cobalt.*

A mineral called *cobalt* (G), of a grey colour, and very heavy, has been used in different parts of Europe since the 15th century to tinge glass of a blue colour. From this mineral Brandt obtained in 1733 a new metal, to which he gave the name of *cobalt* ¶.

159 Properties of cobalt.

Cobalt is of a white colour, inclining to a bluish or steel grey. When pure, it is somewhat malleable while red hot *. Its hardness is 8 †. Its specific gravity is 8,15 (H). It requires for fusion a heat at least as great as cast iron, which melts at 130° Wedgewood. No heat has been produced great enough to volatalize it ‡.

Cobalt, when pure, does not seem to be affected by air or water.

It is attracted by the magnet.

¶ Act. Upsal. 1733.

* Leonhardi.

† Kirwan's Miner. ii. 268.

‡ Bergman, iv.

160 Its oxides.

It is not oxidated by heat without very great difficulty; but it has the property of decomposing nitric acid, and of attracting oxygen by that means with great rapidity.

The *oxide of cobalt* is of so deep a blue as to appear black. The oxide procured by heat is composed of 88 parts of cobalt and 12 of oxygen; that by nitric acid contains about 77 parts of cobalt and 23 of oxygen *. Its affinities, according to Bergman, are as follows:

Oxalic acid,
Muriatic,
Sulphuric,
Tartarous,
Nitric,
Sebacic,
Phosphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Arsenic,
Boracic,
Prussic,
Carbonic,
Ammonia.

* Kirwan's Miner. ii. 268. 490.

161 Sulphuret,

The *sulphuret of cobalt* is not formed without difficulty. It is scarcely known.

162 Phosphuret,

Phosphuret of cobalt may be formed by heating the metal red hot, and then gradually dropping in small bits of phosphorus. It contains about $\frac{1}{15}$th of phosphorus. It is white and brittle, and when exposed to the air soon loses its metallic lustre. The phosphorus is separated by heat, and the cobalt is at the same time oxidated. This phosphuret is much more fusible than pure cobalt †.

163 Alloys,

The combinations of cobalt with other metals have been very little examined into.

1. The alloy of gold and cobalt is not known.

2. Cobalt does not combine with silver by fusion ‡; but, according to Gellert, the alloy of silver and cobalt *may* be formed: it is brittle and of a grey colour §.

3. The alloy of platinum and cobalt is unknown.

4. Mer-

† Pelletier, Ann. de Chim. xiii. 134.

‡ Bergman's Elect. Attract.

§ Metallur. Chim.

(G) The word *cobalt* seems to be derived from *cobalus*, which was the name of a spirit that, according to the superstitious notions of the times, haunted mines, destroyed the labours of the miners, and often gave them a great deal of unnecessary trouble. The miners probably gave this name to the mineral out of joke, because it thwarted them as much as the supposed spirit, by exciting false hopes, and rendering their labour often fruitless; for as it was not known at first to what use the mineral could be applied, it was thrown aside as useless. It was once customary in Germany to introduce into the church-service a prayer that God would preserve miners and their works from *kobalts* and spirits. See *Beckmann's History of Inventions*, II. 362.

Mathesius, in his tenth sermon, where he speaks of *cadmia fossilis* (probably cobalt ore), says, "Ye miners call it *kobolt*; the Germans call the black devil and the old devil's whores and hags, old and black *kobel*, which, by their witchcraft do injury to people and to their cattle."

Lehmann, Paw, Delaval, and several other philosophers, have supposed that *smalt* (oxide of cobalt melted with glass and pounded) was known to the ancients, and used to tinge the beautiful blue glass still visible in some of their works; but we learn from Gmelin, who analysed some of these pieces of glass, that they owed their *blue* colour, not to the presence of *cobalt* but of *iron*.

According to Lehmann, cobalt ore was first used to tinge glass blue by Christopher Schurer, a glass-maker at Platten, about the year 1540.

(H) *Berg.* II. 231. According to Brisson, 7,8119.

Nickel.

4. Mercury does not appear to amalgamate with cobalt.

5. The alloy of copper and cobalt is scarcely known.

6. The alloy of iron and cobalt is very hard, and not easily broken. Cobalt generally contains some iron, from which it is with great difficulty separated.

7. The alloy of tin and cobalt is of a light violet colour.

8. Cobalt does not combine with lead by fusion.

9. The alloy of zinc and cobalt is not formed without difficulty.

10. The alloy of antimony and cobalt is unknown.

11. Cobalt does not combine with bismuth by fusion *.

* *Baumé.*

12. Arsenic combines very readily with cobalt. The alloy is brittle, much more fusible, and more easily oxidated than pure cobalt †.

† *Bergman*, iv.

164
And affinities.

The affinities of cobalt are as follows:

Iron,
Nickel,
Arsenic,
Copper,
Gold,
Platinum,
Tin,
Antimony,
Zinc,
Sulphuret of alkali,
Sulphur,
Posphorus?

Sect. XIV. *Of Nickel.*

A heavy mineral of a red colour is met with in several parts of Germany, which bears a strong resemblance to an ore of copper; but none of that metal can be extracted from it: for this reason the Germans called it *kupfer nickel* (devil's copper). Hierne mentioned it in 1694. Cronstedt was the first chemist who examined it with accuracy. He concluded from his experiments, which were published in the Stockholm Transactions for 1751 and 1754, that it contained a new metal, to which he gave the name of *nickel*.

165
Discovery of nickel,

Some chemists, particularly Mr Sage, affirmed, that it contained no new metal, but merely a compound of various known metals, which could be separated from each other by the usual processes. These assertions induced Bergman to undertake a very laborious course of experiments, in order if possible to obtain *nickel* in a state of purity: for Cronstedt had not been able to separate a quantity of arsenic, cobalt, and iron, which adhered to it with much obstinacy. These experiments have been very fully detailed in the article Chemistry, in the *Encycl.* to which be beg leave to refer. Bergman has shewn, that nickel possesses peculiar properties, and that it can neither be reduced to any other metal, nor formed artificially by any combination of metals. It must therefore be considered as a peculiar metal. It may possibly be a compound, and so may likewise many other metals; but we must admit every thing to be a peculiar body which has peculiar properties, and we must admit every body to be simple till some proof be actually produced that it is a compound; otherwise we forsake the road of science, and get into the regions of fancy and romance.

Nickel is of a greyish white colour, and when less pure inclines a little to red.

166
Its properties,

It is both ductile and malleable. Its hardness is 8 *. Its specific gravity 9,000 †. It requires for fusion a temperature at least equal to 150° Wedgewood ‡.

* *Kirwan's Miner.* ii. 281.
† *Bergman*, ii. 231.
‡ *Ibid.*

It is powerfully attracted by the magnet, and is even possessed of the property of attracting iron. This induced Bergman to suppose that nickel, when purest, was still contaminated with about one-third of iron: but as this is the only proof of its containing iron, Klaproth, with reason, deems it an insufficient one, and considers attraction by the magnet as a property of nickel §.

§ *Ann. de Chim.* i. 170.

167
Oxides,

When exposed to a strong heat, nickel is oxidated slowly. Its oxide is of a *brown* colour; if impure, it is *greenish*. The oxide of nickel, according to Klaproth, is composed of 77 parts of nickel and 23 of oxygen ¶. Its affinities, according to Bergman, are as follows:

¶ *Kirwan's Miner.* ii. 490.

Oxalic acid,
Muriatic,
Sulphuric,
Tartarous,
Nitric,
Sebacic,
Phosphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Arsenic,
Boracic,
Prussic,
Carbonic,
Ammonia,
Potass?
Soda?

168
Sulphuret,

Cronstedt found that nickel combined readily with sulphur by fusion. The sulphuret which he obtained was yellow and hard, with small sparkling facets; but the nickel which he employed was impure.

169
Phosphuret,

Nickel combines very readily with phosphorus, either by fusing it along with phosphoric glass, or by dropping phosphorus into it while red hot. The phosphuret of nickel is of a white colour, and when broke exhibits the appearance of very slender prisms collected together. When heated, the phosphorus burns, and the metal is oxidated. It is composed of 83 parts of nickel and 17 of phosphorus *. The nickel, however, on which this experiment was made, was not pure.

* *Pelletier, Ann. de Chim.* xiii. 135.

170
Alloys,

Little is known concerning the alloys of nickel with other metals. Equal parts of silver and nickel form a white ductile alloy. Equal parts of copper and nickel form a red ductile alloy. The compounds which this metal forms with tin and zinc are brittle. It does not combine with mercury †. It has a very strong affinity for iron, cobalt, and arsenic, and is scarcely ever found except combined with some of them.

† *Bergman*, ii. 231.

171
And affinities.

Its affinities, according to Bergman, are as follows:

Iron,
Cobalt,
Arsenic,

Copper,

Manganese.

Copper,
Gold,
Tin,
Antimony,
Platinum,
Bismuth,
Lead,
Silver,
Zinc,
Sulphuret of alkali,
Sulphur,
Popsphorus ?

Sect. XV. *Of Manganese.*

[171] Discovery of manganese.

The dark grey mineral called *manganese*, in Latin *magnesia* (according to Boyle, from its resemblance to the *magnet)*, has been long known and used in making glass. A mine of it was discovered in England by Mr Boyle. It was long supposed to be an ore of iron; but Port and Cronstedt having demonstrated that it contained very little of that metal, the latter referred it in his Mineralogy to a distinct order of earths, which he called *terræ magnesiæ*. Bergman, from its specific gravity, and several other qualities, suspected that it was a metallic oxide: he accordingly made several attempts to reduce it, but without success; the whole mass either assuming the form of scoriæ, or yielding only small separate globules attracted by the magnet. This difficulty of fusion led him to suspect that the metal he was in quest of bore a strong analogy to platinum. In the mean time, Dr Gahn, who was making experiments on the same mineral, actually succeeded in reducing it by the following process: He lined a crucible with charcoal powder moistened with water, put into it some of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal powder, luted another crucible over it, and exposed the whole for about an hour to a very intense heat. At the bottom of the crucible was found a metallic button, or rather a number of small metallic globules, equal in weight to one-third of the mineral employed *. It is easy to see by what means this reduction was accomplished. The charcoal attracted the oxygen from the oxide, and the metal remained behind. This metal is called *manganese*.

* *Bergman*, ii. 211.

172 Its properties,

Manganese is of a greyish white colour. It is not malleable, and yet not so brittle as to be easily broken. Its hardness is 8 †. Its specific gravity is 7,000 ‡. Its fusion requires so great a heat, that it has been very seldom accomplished.

† *Kirwan's Miner.* ii. 288.

‡ *Hielm.*

When reduced to powder, it is attracted by the magnet.

173 Oxides,

When exposed to the air, it very soon tarnishes, and assumes a darker colour, till at last it becomes black and friable. This change is produced by the absorption of oxygen. It takes place much more rapidly if heat be applied to the metal. The substance thus obtained is the *black oxide of manganese*. This oxide is found in great abundance in nature, though scarcely ever in a state of purity. It is composed of 75 parts of manganese and 25 of oxygen §.

§ *Bergman*, ii. 225.

If a quantity of muriatic acid be poured upon this oxide, and heat applied, part of the acid combines with some of the oxygen of the oxide, and flies off in yellow fumes. The oxide is dissolved in the rest. If potash be added to this solution, a white powder is precipitated. This is the *white oxide of manganese*. It contains, according to Bergman, about 80 parts of manganese and 20 of oxygen. It soon attracts more oxygen when exposed to the air, and is converted into *black oxide*.

The affinities of the white oxide, according to Bergman, are as follows:

Oxalic acid,
Citric,
Phosphoric,
Tartarous,
Fluoric,
Muriatic,
Sulphuric,
Nitric,
Saccholactic,
Succinic,
Sebacic,
Tartaric,
Formic,
Lactic,
Acetous,
Prussic,
Carbonic.

The sulphuret of manganese is unknown.

174 Phosphuret,

Phosphorus may be combined with manganese by melting together equal parts of the metal and of phosphoric glass; or by dropping phosphorus upon red hot manganese. The phosphuret of manganese is of a white colour, brittle, granulated, disposed to crystallize, not altered by exposure to the air, and more fusible than manganese. When heated, the phosphorus burns and the metal becomes oxidated *.

* *Pelletier, Ann. de Chim.* xiii. 137.

175 Carburet,

Manganese combines readily with carbon by fusion (1).

176 Alloys,

Little is known concerning the alloys of manganese. It combines readily with copper. The compound, according to Bergman, is very malleable, its colour is red, and it sometimes becomes green by age. Gmelin made a number of experiments to see whether this alloy could be formed by fusing the black oxide of manganese along with copper. He partly succeeded, and proposed to substitute this alloy instead of the alloy of copper and arsenic, which is used in the arts †. We believe, however, that upon trial the new alloy has been found not to answer.

† *Ann. de Chim.* i. 303.

Manganese combines readily with iron; indeed it has scarcely ever been found quite free from some mixture of that metal. It combines also very easily with arsenic and tin, not easily with zinc, and not at all with mercury ‡.

‡ *Bergman*, ii. 211.

177 And affinities.

The affinities of manganese, according to Bergman, are as follows:

Copper,
Iron,
Gold,

Silver,

(1) *Bergman*, III. 379.—Sometimes manganese is very speedily oxidated by exposure to the air; sometimes scarcely altered by it, as Klaproth and Pelletier have observed. Mr Kirwan supposes that the manganese which is soon altered contains carbon, and that this is the cause of the difference. See *Miner.* II. 288.

Tungſten.

Silver,
Tin,
Sulphuret of alkali,
Phoſphorus ?
Carbon ?

The three metals, *cobalt*, *nickel*, and *manganeſe*, reſemble iron in ſeveral particulars: Like it, they are magnetic, very hard, and very difficult to fuſe: but they differ from it in ſpecific gravity, malleability, and in the properties of all their combinations with other ſubſtances; the oxides, for inſtance, of iron, cobalt, nickel, and manganeſe, poſſeſs very different qualities.

Sect. XVI. *Of Tungsten.*

178 Diſcovery of tungſten.

There is a mineral found in Sweden of an opaque white colour and great weight; from which laſt circumſtance it got the name of *tungsten*, or *ponderous ſtone*. Some mineralogiſts conſidered it as an ore of tin, others ſuppoſed that it contained iron. Scheele analyſed it in 1781, and found that it was compoſed of lime and a peculiar earthy-like ſubſtance, which he called from its properties *tungstic acid*. Bergman conjectured that the baſis of this acid was a metal; and this conjecture was ſoon after fully confirmed by the experiments of Meſſrs D'Elhuyart, who obtained the ſame ſubſtance from a mineral of a browniſh black colour, called by the Germans *wolfram*, which is ſometimes found in tin mines. This mineral they found to contain $\frac{65}{100}$ of tungſtic acid; the reſt of it conſiſted of manganeſe, iron, and tin. This acid ſubſtance they mixed with charcoal powder, and heated violently in a crucible. On opening the crucible after it had cooled, they found in it a button of metal, of a dark brown colour, which crumbled to powder between the fingers. On viewing it with a glaſs, they found it to conſiſt of a congeries of metallic globules, ſome of which were as large as a pin-head. The metal thus obtained is called *tungsten*. The manner in which it was produced is evident; tungſtic acid is compoſed of oxygen and tungſten: the oxygen combined with the carbon, and left the metal in a ſtate of purity.

179 Its Properties.

Tungſten is externally of a brown colour, internally of a ſteel grey *.

Its ſpecific gravity is 17,600 †. It is more infuſible than manganeſe ‡.

When heat is applied to tungſten it is converted into a yellow powder, compoſed of 80 parts of tungſten and 20 of oxygen §. This is the *yellow oxide of tungsten* or *tungstic acid*.

The ſulphuret of tungſten is of a bluiſh black colour, hard, and capable of cryſtallizing.

Phoſphorus is capable of combining with tungſten ||.

Of the alloys of tungſten we know nothing, except from the experiments of Elhuyarts, which have been tranſcribed into the article Chemistry in the *Encyclopædia*; to which, therefore, we beg leave to refer.

* Luyart. † Id. ‡ Id. § Id. || Pelletier, Ann. de Chim. xiii. 137.

Sect. XVII. *Of Molybdenum.*

180 Diſcovery of molybdenum.

The Greek word *molybdena*, and its Latin tranſlation *plumbago*, ſeem to have been employed by the ancients to denote various oxides of lead; but by the moderns they were applied indiſcriminately to all ſubſtances poſſeſſed of the following properties: Light, friable, and ſoft, of a dark colour and greaſy feel, and which leave a ſtain upon the fingers. Scheele firſt examined theſe minerals with attention. He found that two very different ſubſtances had been confounded together. To one of theſe, which is compoſed of carbon and iron, and which has been already deſcribed, he appropriated the word *plumbago*; the other he called *molybdena*.

Molybdenum.

Molydbena is compoſed of ſcaly particles adhering ſlightly to each other. Its colour is bluiſh, very much reſembling that of lead. Scheele analyſed it, and obtained ſulphur and a whitiſh powder, which poſſeſſed the properties of an acid, and which, therefore, he called *acid of molybdena*. Bergman firſt ſuſpected that the baſis of this acid was a metal. It was at the requeſt of Bergman and Scheele that Mr Hielm began the laborious courſe of experiments by which he ſucceeded in obtaining a metal from this acid. His method was to form it into a paſte with linſeed oil, and then to apply a very ſtrong heat. This proceſs he repeated ſeveral times ſucceſſively. Klaproth and Pelletier alſo attempted to reduce it, and with equal ſucceſs. The metal is *molybdenum* (K).

181 Its properties.

Molybdenum is externally of a whitiſh yellow colour, but its fracture is a whitiſh grey.

Hitherto it has only been procured in ſmall grains, agglutinated together in brittle maſſes.

Its ſpecific gravity is 7,500. It is almoſt infuſible in our fires.

When expoſed to a ſtrong heat, it is gradually converted into a whitiſh-coloured oxide *. When nitric acid is poured upon it, molybdenum attracts oxygen, and is converted into a *white oxide*, which poſſeſſes the properties of an acid †. This is the *molybdic acid*.

Molybdenum combines readily with ſulphur; and the compound has exactly the properties of molybdena, the ſubſtance which Scheele decompounded ‡. Molybdena is therefore *ſulphuret of molybdenum*. The reaſon that Scheele obtained from it molybdic acid was, that the metal combined with oxygen during his proceſs.

Molybdenum is alſo capable of combining with phoſphorus §.

Few of the alloys of this metal have been hitherto examined.

It ſeems capable of uniting with gold. The alloy is probably of a white colour ||.

It combines readily with platinum while in the ſtate of an oxide. The compound is fuſible. Its ſpecific gravity is 20,00 ¶.

The alloys of molybdenum with ſilver, iron, and copper, are metallic and friable; thoſe with lead and tin are powders which cannot be fuſed *.

* Pelletier, Journ. de Phyſ. 1785. † Ibid. ‡ Ibid. § Pelletier, Ann. de Chim. xiii. 137. || Ruprecht, Ann. de Chim. viii. 8. ¶ Hielm, Ann. de Chim. iv. 17. * Pelletier, Journal de Phyſique, Dec. 1785.

Sect. XVIII. *Of Uranium.*

182 Diſcovery of uranium.

There is a mineral found in the George Wagsfort mine at Johann-Georgenſtadt in Saxony, partly in a pure or unmixed ſtate, and partly ſtratified with other kinds of ſtones and earths. The firſt variety is of a blackiſh colour inclining to a dark iron grey, of a moderate ſplendor, a cloſe texture, and when broken preſents a ſomewhat uneven, and, in the ſmalleſt particles, a conchoidal ſurface. It is quite opaque, tolerably hard, and on being pounded yields a black powder. Its ſpecific gravity is about 7,500. The ſecond ſort is diſtinguiſhed

(K) This name was given it by Hielm.

Uranium. distinguished by a finer black colour, with here and there a reddish cast; by a stronger lustre, not unlike that of pitcoal; by an inferior hardness; and by a shade of green, which tinges its black colour when it is reduced to powder *.

* Klaproth, Crell's Journal, Eng. Transl. i. 126.

This fossil was called *pechblende*; and mineralogists, misled by the name (L), had taken it for an ore of zinc, till the celebrated Werner, convinced from its texture, hardness, and specific gravity, that it was not a *blende*, placed it among the ores of iron. Afterwards he suspected that it contained *tungsten*; and this conjecture was seemingly confirmed by the experiments of some German mineralogists, published in the Miners Journal †. But Klaproth, whose analyses always display the most consummate skill, joined with the most rigid accuracy, examined this mineral about the year 1789, and found that it consisted chiefly of sulphur combined with a peculiar metal, to which he gave the name of *uranium* (M).

† Ibid.

183 Its properties. Uranium is of a dark grey colour; internally it is somewhat inclined to brown ‡.

‡ Ibid. 233.

Its malleability is unknown. Its hardness is about 6. It requires a stronger heat for fusion than manganese. Indeed Klaproth only obtained it in very small conglutinated metallic grains, forming altogether a porous and spongy mass.—Its specific gravity is 6,440 §.

§ Ibid.

When exposed for some time to a red heat, it suffers no change. By means of nitric acid, however, it may be converted into a yellow powder. This is the *yellow oxide of uranium*. This oxide is found native mixed with the mineral above described. Its affinities have not yet been determined.

Uranium is capable of combining with sulphur. The mineral from which Mr Klaproth first obtained it is a native sulphuret of uranium.

Nothing is known concerning the alloys or affinities of uranium.

Sect. XIX. *Of Titanium.*

184 Discovery of titanium. There is a mineral found in Hungary which, from its external appearance, has been called *red shorl*; but Klaproth, who examined it about the year 1795, discovered that it consisted chiefly of a peculiar metal, to which he gave the name of *titanium*.

185 Its properties. Titanium is of a brownish red colour, and considerable lustre. It is brittle. Its hardness is 9; its specific gravity 4,18.

When exposed to a strong heat in a clay crucible, it suffered no alteration, except that its colour became browner; but in a coal crucible it lost its lustre and broke to pieces.

It is found naturally crystallized in right-angled quadrangular prisms, longitudinally furrowed, and about half an inch in length.

No acid had any effect in oxidating it; but when mixed with five times its weight of potass, and heated in a porcelain furnace, it melted, and formed when cold a dense greyish mass, the surface of which was crystallized. When dissolved in boiling water, it soon let fall a white powder, weighing about one-third more than the titanium employed. This is the *oxide of titanium*. Fifty grains of it were reduced by ignition to 38. While hot it was yellowish, but, like oxide of zinc, became white as it cooled. When heated on charcoal, it assumes first a *rosy red*, and afterwards a *slate blue* colour, and at last melts into an imperfect bead with a finely striated surface. Mr Klaproth did not succeed in reducing it to the metallic state.

Titanium does not seem to have any affinity for sulphur *.

* M'Gregor.

There was a substance discovered by Mr M'Gregor in the valley of Menachan in Cornwall, and hence called *menachanite*. Upon this substance Mr M'Gregor made a very interesting set of experiments, which were published in the Journal de Physique for 1791. He suspected it to contain a new metal. From its properties, Mr Kirwan conjectured that it was the same with titanium †; and this conjecture has been very lately confirmed by Mr Klaproth, who analysed menachanite, and found it to be an ore of that metal. 186 Menachanite.

† Mineral. ii. 331.

Sect. XX. *Of Tellurium.*

In the mountains of Fatzbay, near Zalethna in Transylvania, there is a mine called *Mariahilf*; the ore of which is wrought for the gold that it contains. Mr Muller of Reichenstein examined it in 1782, and suspected that it contained a new metal; and Bergman, to whom he had sent some of the ore, was of the same opinion: but the quantity of the mineral which these chemists had examined was too inconsiderable to enable them to decide with certainty. Klaproth analysed a larger quantity of it about the year 1797, and found that 1000 parts of it consisted of 72 parts of iron, 2,5 of gold, and 925,5 of a new metal, to which he has given the name of *tellurium* (N). 187 Discovery of tellurium.

Tellurium is of a white colour like tin, approaching somewhat to the grey colour of lead ‡. 188 Its properties.

‡ Klaproth, Philosophical Magazine, i. 78.

It is very brittle and friable. Its fracture is laminated. Its specific gravity is 6,115.

It is as easily melted as lead. When suffered to cool quietly and gradually, it readily assumes a crystallized surface §.

§ Muller.

When heated by the blowpipe upon charcoal, it burns with a very lively flame of a blue colour, inclining at the edges to green. It is so volatile as to rise entirely in a whitish grey smoke; at the same time it exhales a disagreeable odour like that of radishes. This smoke is the *white oxide* of tellurium, which may be formed also by dissolving the metal in nitro-muriatic acid, and pouring into the saturated solution a quantity of water: a white powder precipitates, which is the oxide ‖.

‖ Klaproth.

When this oxide is heated for some time in a retort, it melts, and appears, after cooling, of a yellow straw colour, having acquired a sort of radiated texture. When formed

(L) *Blende* is the name given to ores of zinc.

(M) From *Uranus* (Ουρανος), the name given by Mr Bode to the new planet discovered by Herschel; which name the German astronomers have adopted. Mr Klaproth called the metal at first *uranite*; but he afterwards changed that name for *uranium*.

(N) Mr Kirwan, in the new edition of his Mineralogy, which was published before Mr Klaproth's experiments were known, gives this metal the name of *Sylvanite*.—Tellurium exists in several other mines in the same mountains.

Tellurium.

formed into a paste with any fat oil, and distilled in a red heat, brilliant metallic drops are observed to cover the upper part of the retort, which at intervals fall to the bottom of the vessel, and are immediately replaced by others. After cooling, metallic fixed drops are found adhering to the sides and at the bottom of the vessel; the remainder of the metal is reduced. Its surface is brilliant and almost always crystallized. When this oxide is exposed to heat on charcoal, it is reduced with a rapidity that resembles detonation *.

* *Klaproth.*

Tellurium combines with sulphur. The sulphuret of this metal is of a grey colour and radiated structure. When placed on red hot charcoal, the metal burns as well as the sulphur with a blue flame.

Tellurium amalgamates with mercury by simple trituration†.—The other properties of this metal are unknown.

† *Muller.*

189 Chromum.

A NEW metal has lately been discovered by Vauquelin in the red lead ore of Siberia. It is grey, very hard, brittle, and easily crystallizes in small needles ‡. He has given it the name of *chromum* (o).

‡ *Nicholson's Journal*, ii. 146.

190 General table of the properties of the metals.

We have now described all the metals at present known. The following table will exhibit in one view their principal properties.

Metals.	Colour.	Hardness.	Specific gravity	Fusing Point.	Malleability.	Ductility	
Gold.	Yellow.	6	19,300	32 W. (P) 1298 F.	282000	500	
Silver.	White.	6½	10,510	28 W. 1044 F.	160000	270	
Platinum.	White.	7½	23,000	150 W.?		above 500	
Mercury.	White.		13,568	—39 F.			
Copper.	Red.	8	8,870	27 W. 1449 F.		299¼	
Iron.	Blue-grey.	9	7,788	150 W. 20577 F.		450	Magnetic.
Tin.	White.	6	7,299	410 F.	2000	49	
Lead.	Blue-white.	5	11,352	540 F.		29¼	
Zinc.	White.	6	7,190	700 F.		o	
Antimony.	Grey.	6½	6,860	700 F.	o	o	
Bismuth.	Yellow-white.	6	9,822	460 F.	o	o	
Arsenic.	White.	7	8,310	400 F. ?	o	o	
Cobalt.	White.	8	8,150	130 W. 17977 F.			Magnetic.
Nickel.	White.	8	9,000	150 W. 20577 F.			Magnetic.
Manganese.	White.	8	7,000	150 W. 20577 F.	o	o	Magnetic.
Tungsten.	Brown.	6	17,600		o	o	
Molybdenum	Grey.		7,500		o	o	
Uranium.	Grey.	6	6,440				
Titanium.	Red.	9	4,180		o	o	
Tellurium.	White.		6,115	540 F.	o	o	
Chromum.	Grey.				o	o	

(o) From χρωμα, because it possesses the property of giving colour to other bodies in a remarkable degree.

We

Tellurium.

191 Remarks on metallic oxides.

We have seen that all the metals are capable of combining with oxygen; that almost every one forms various oxides, containing different quantities of oxygen, and varying in colour and other properties according to the proportion of oxygen which they contain. No part of chemistry has more engaged the attention of philosophers than the metallic oxides; and yet such is the difficulty of the subject, that scarcely any part of chemistry is more imperfectly understood.

We neither know how many oxides every particular metal is capable of forming, nor the manner in which they are formed: neither have the differences between oxides of the same metallic base been inquired into; though there cannot be a doubt that they differ, not only in their affinities, but in many of their other properties. The *white oxide* of manganese, for instance, combines readily with acids, but the *black* is incapable of uniting with any.

Mr Proust, in a very valuable paper which he lately published concerning the oxides of iron *, hints that metals are only capable of two degrees of oxidation, or, which is the same thing, that only two different oxides can be produced from the same metal. We think he has proved this completely as far as iron is concerned; and probably the observation holds good with respect to many other metals. Arsenic, copper, tin, molybdenum, and perhaps even mercury, seem to be capable of only two degrees of oxidation; but it would require a very numerous and accurate set of experiments to be able to determine the matter, or even to form a probable conjecture. Analogy is certainly against the supposition; for it has been demonstrated that some substances at least are capable of combining with three different doses of oxygen (q), and why may not this be the case also with the metals?

* *Ann. de Chim.* xxiii. 85.—*Nicholson's Journ.* i. 453.

There is one observation, however, which we owe to Mr Proust, the truth of which cannot be doubted, and which is certainly of the highest importance—that metals are not capable of indefinite degrees of oxidation, but only of a certain number; and that every particular oxide consists of a determinate quantity of the metal and of oxygen chemically combined. Iron, for instance, is not capable, as has been supposed, of uniting with oxygen in all the intermediate degrees between $\frac{27}{100}$ and $\frac{48}{100}$, and consequently of forming 20 or 30 different oxides; it can only combine with precisely $\frac{27}{100}$ parts, or $\frac{48}{100}$ parts, and with no other proportions; and therefore is only capable of forming two oxides, the *green* and the *brown*. In like manner, every other metal combines with certain proportions of oxygen, and forms either two oxides or more according to its nature. To talk therefore of oxidating a metal indefinitely is not accurate, except it be intended to signify the combining of part of it with oxygen, while the rest remains in its natural state. If iron be oxidated at all, it must be combined with $\frac{27}{100}$ of oxygen; if it be oxidated more than this, it must be combined with $\frac{48}{100}$ of oxygen.

We beg leave to add another observation, which we consider as of no less importance, and which will serve in some measure to modify and explain what has been just now said. Oxygen is capable of uniting with metals, or with any other substance for which it has an affinity, only in *one* determinate proportion. Iron, for instance, and oxygen can only combine in the proportion of 73 parts of iron and 27 of oxygen. These two quantities saturate each other, and form a compound which is incapable of receiving into it any more oxygen or iron: this compound is the *green oxide of iron*. How comes it then, it will be asked, that there is another oxide of iron, the *brown oxide*, which contains 52 parts of iron and 48 of oxygen, proportions certainly very different from 73 and 27? We answer, there is an affinity between the green oxide of iron and oxygen; they are capable of combining together, and of saturating each other in the proportion of about 71,5 parts of green oxide and 28,5 of oxygen; and the compound which they form is the *brown oxide*, which of course contains 52 parts of iron and 48 of oxygen: But then it is not formed by the combination of these two substances directly, but by the combination of the green oxide and oxygen. In like manner, the arsenic acid is not composed of arsenic and oxygen combined directly, but of white oxide of arsenic combined with oxygen. The very same thing takes place in all the other metals. We cannot at present prove the truth of this observation in a satisfactory manner, because it would be necessary to draw our proofs from combinations which are yet undescribed; but we will have occasion to consider it afterwards.

Tellurium.

We have seen that all the metals hitherto tried are capable of combining with sulphur, except gold and titanium; that all of them on which the experiments have been made can be united with phosphorus; and that three of them, iron, zinc, and manganese, united with carbon; and perhaps many more of them may hereafter be found capable of assuming the form of carburets.

We have seen, too, that they are capable of uniting with one another and forming alloys. This was long reckoned peculiar to metals, and it is at present one of the best criterions for determining the metallic nature of any substance. Much is wanting to render the chemistry of alloys complete. Many of them have never been examined; and the proportions of almost all of them are unknown. Neither has any accurate method been yet discovered of determining the affinities of metals for each other. The order of affinities which we have given for each metal was determined by Bergman; but he acknowledged himself that he wanted the proper data to ensure accuracy.

Chap. IV. *Of* Earths.

The word *earth*, in common language, has two meanings; it sometimes signifies the *globe* which we inhabit, and sometimes the *mould* on which vegetables grow. Chemists have examined this mould, and have found that it consists of a variety of substances mixed together without order or regularity. The greatest part of it, however, as well as of the stones, which form apparently so large a proportion of the globe, consists of a small number of bodies, which have a variety of commmon properties.

(q) We shall see afterwards that azot is one of these.

Lime. perties. These bodies chemists have agreed to class together, and to denominate *earths*.

Every body which possesses the following properties is an *earth*:

192 Properties of earths.

1. Insoluble in water, or nearly so; or at least becoming insoluble when combined with carbonic acid.

2. Little or no taste or smell; at least when combined with carbonic acid.

3. Incombustible, and incapable while pure of being altered by the fire.

4. A specific gravity not exceeding 4,9.

5. When pure, capable of assuming the form of a white powder.

The earths at present known amount to ten; the names of which are, lime, magnesia, barytes, strontites, alumina, silica, jargonia, glucina, yttria, agustina.

Every one of the above characteristics is not perhaps rigorously applicable to each of these bodies; but all of them possess a sufficient number of common properties to render it useful to arrange them under one class.

Sect. I. *Of Lime.*

Lime has been known from the earliest ages. The ancients employed it in medicine; it was the chief ingredient in their mortar; and they used it as a manure to fertilize their fields.

193 Method of procuring lime.

It abounds in many parts of the world, or perhaps we should rather say, that there is no part of the world where it does not exist. It is found purest in limestones, and marbles and chalk. None of these substances, however, is, strictly speaking, lime; but they are all capable of becoming lime by a well-known process, by keeping them for some time in a white heat: this process is called *the burning of lime*; the product is denominated *quicklime*. This last substance is what we call *lime*.

194 Properties of lime.

Pure lime is of a white colour, moderately hard, but easily reduced to a powder.

It has a hot burning taste, and in some measure corrodes and destroys the texture of those animal bodies to which it is applied. It has no smell. Its specific gravity is 2,3 *.

If water be poured on newly burnt lime, it swells and falls to pieces, and is soon reduced to a very fine powder. In the mean time, so much heat is produced, that part of the water flies of in vapour. If the quantity of lime slacked (as this process is termed) be great, the heat produced is sufficient to set fire to combustibles. In this manner vessels loaded with lime have sometimes been burnt. When great quantities of lime are slacked in a dark place, not only heat, but light also is emitted, as Mr Pelletier has observed †. When slacked lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime; which water may be separated again by the application of a red heat; and by this process the lime becomes just what it was before being slacked ‡.

195 Lime-water.

Six hundred parts of water, at the temperature of 60°, dissolve about one part of lime; boiling hot water dissolves about double that quantity §. This solution is called *lime-water*. It is limpid, has an acrid taste, and changes vegetable blue colours to green. One ounce troy of lime-water contains about one grain of lime.

* *Kirwan's Miner.* i. 5.

† *Journ. de Phys.* t. 22

‡ *Dr Black.*

§ *Kirwan's Miner.* i. 5.

One thousand parts of lime are capable of absorbing, and retaining, at a heat of 600°, 228 parts of water *.

* *Lavoisier.*

Lime has never yet been obtained in the state of crystals.

It is incapable of being fused by the most violent heat that can be produced in furnaces, or even by the most powerful burning-glasses.

196 Sulphuret, and

Lime unites readily with sulphur, and forms *sulphuret of lime*. This compound may be obtained by mixing unslacked lime and flowers of sulphur together, and adding a little water. The heat produced by the slacking of the lime is sufficient to make the sulphur and the lime unite. This sulphuret is of a red colour. When water is poured on it, sulphurated hydrogen gas is emitted. The sulphur is gradually converted into sulphuric acid by uniting with the oxygen of the water, the hydrogen of which flies off in the form of gas, dissolving at the same time a part of the sulphur.

197 Phosphuret of lime.

It is capable also of combining with phosphorus.—The phosphuret of lime decomposes water by the assistance of a moderate heat, and gives out phosphurated hydrogen gas.

198 Cause of the difference between limestone and lime.

Limestone and chalk, though they are capable of being converted into lime by *burning*, possess hardly any of the properties of that active substance. They are tasteless, scarcely soluble in water, and do not perceptibly act on animal bodies. Now, to what are the new properties of lime owing? What alteration does it undergo in the fire?

It had been long known that limestone loses a good deal of weight by being burned or *calcined*. It was natural to suppose, therefore, that something was separated from it during calcination. Accordingly, Van Helmont, Ludovicus, and Macquer, made experiments in succession, in order to discover what that *something* was; and they concluded from them that it was *pure water*, which the lime recovered again when exposed to the atmosphere. As the new properties of lime could hardly be ascribed to this loss, but to some other cause, Stahl's opinion, like all the other chemical theories of that wonderful man, was generally acceded to. He supposed that the new properties which lime acquired by calcination, were owing entirely to the more minute division of its particles by the action of the fire. Boyle indeed had endeavoured to prove, that these properties were owing to the *fixation of fire* in the lime: a theory which was embraced by Newton and illustrated by Hales, and which Meyer new modelled, and explained with so much ingenuity and acuteness as to draw the attention of the most distinguished chemists. But while Meyer was thus employed in Germany, Dr Black, of Edinburgh, published those celebrated experiments which form so brilliant an era in the history of chemistry.

199 According to Stahl;

200 Explained by Dr Black.

He first ascertained that the quantity of water separated from limestone during its calcination was not nearly equal to the weight which it lost. He concluded in consequence that it must have lost something else than mere water. What this could be, he was at first at a loss to conceive; but recollecting that Dr Hales had proved, that limestone, during its solution in acids, emitted a great quantity of *air*, he conjectured that *this* might probably be what it lost during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture verified;

Lime.

verified; and that the *air* and *the water* which separated from the lime, were together precisely equal to the loss of weight which it had sustained. Lime therefore owes its new properties to the loss of *air;* and limestone differs from lime merely in being combined with a certain quantity of *air:* for he found that, by restoring again the same quantity of *air* to lime, it was converted into limestone. This air, because it existed in lime in a fixed state, he called *fixed air*. It was afterwards examined by Dr Priestley and other philosophers, found to possess peculiar properties, and to be that species of gas now known by the name of *carbonic acid gas*. Lime then is a simple substance, that is to say, it has never yet been decompounded; and limestone is composed of carbonic acid and lime. Heat separates the carbonic acid, and leaves the lime in a state of purity.

201 Affinities of lime.

The affinities of lime, according to Bergman, are as follows:

Oxalic acid,
Suberic (R)?
Sulphuric,
Tartarous,
Succinic,
Phosphoric,
Saccholactic,
Nitric,
Muriatic,
Sebacic,
Fluoric,
Arsenic,
Formic,
Lactic,
Citric,
Benzoic,
Sulphurous,
Acetous,
Boracic,
Nitrous,
Carbonic,
Prussic,
Sulphur,
Phosphorus,
Water,
Fixed oil.

Sect. II. *Of Magnesia.*

202 Discovery of magnesia.

About the beginning of the eighteenth century, a Roman canon exposed a white powder to sale at Rome as a cure for all diseases. This powder he called *magnesia alba*. He kept the manner of preparing it a profound secret; but in 1707 Valentini informed the public that it might be obtained by calcining the lixivium which remains after the preparation of nitre; and two years after, Slevogt discovered that it might be precipitated by potass from the mother ley (s) of common salt. This powder was generally supposed to be *lime*, till Frederic Hoffman observed that it formed very different combinations with other bodies *. But little was known concerning its nature till Dr Black published his celebrated experiments in 1755. Margraf published a dissertation on it in 1759, and Bergman another in 1775, in which he collected the observations of these two philosophers, and which he enriched also with many additions of his own.

Magnesia.

* Bergman, i. 365.

203 Method of procuring it.

As magnesia has never yet been found native in a state of purity, it may be prepared in the following manner: *Sulphat of magnesia*, a salt composed of this earth and sulphuric acid, exists in sea-water, and in many springs, particularly some about Epsom, from which circumstance it was formerly called *Epsom salt*. This salt is to be dissolved in water, and half its weight of potass added. The magnesia is immediately precipitated, because potass has a stronger affinity for sulphuric acid. It is then to be washed with a sufficient quantity of water, and dried.

204 Its properties.

Magnesia thus obtained is a very soft white powder, which has very little taste, and is totally destitute of smell. Its specific gravity is about 2,3 †.

It is soluble in about 7900 times its own weight of water at the temperature of 60° ‡.

† Kirwan's Miner. i. 8.

‡ Ibid.

Even when combined with carbonic acid (for which it has a strong affinity) it is capable of absorbing and retaining $1\frac{1}{4}$ times its own weight of water, without letting go a drop; but on exposure to the air, this water evaporates, though more slowly than it would from lime.

Magnesia has never yet been obtained in a crystallized form.

It tinges vegetable blues of an exceedingly slight green.

It is not melted by the strongest heat which it has been possible to apply; but Mr D'Arcet observed that, in a very high temperature, it became somewhat agglutinated.

When magnesia and sulphur are put into a vessel of water, and kept for some time exposed to a moderate heat, they combine, and form sulphuret of magnesia; which, according to Fourcroy, is capable of crystallizing.

The phosphuret of magnesia has never been examined.

Effect of heat on mixtures of lime and magnesia.

Equal parts of lime and magnesia mixed together, and exposed by Lavoisier to a very violent heat, did not melt; neither did they melt when Mr Kirwan placed them in the temperature of 150° Wedgewood. The following Table, drawn up by Mr Kirwan from his own experiments, shews the effect of heat on these two earths mixed together in different proportions.

Proportions.

(R) The affinity of this acid for lime is inferior to the oxalic, which decomposes the suberat of lime. *Jameson's Mineral. of Shetland and Arran*, p. 168.

(s) *The mother ley* is the liquid that remains after as much as possible of any salt has been obtained from it. Common salt, for instance, is obtained by evaporating sea-water. After as much salt has been extracted from a quantity of sea-water as will crystallize, there is still a portion of liquid remaining. This portion is the mother ley.

Magnesia.

Proportions.	Heat.	Effect.
80 Lime 20 Mag.	150° Wedg.	Went through the crucible.
75 Lime 25 Mag.	160	Went through the crucible.
66 Lime 33 Mag.		Went through the crucible.
20 Lime 80 Mag.	165	Did not melt.
33 Lime 66 Mag.	138	Did not melt.
30 Lime 10 Mag.	156	Melted into a fine greenish yellow glass; but the crucible was corroded throughout.

206 Affinities of magnesia. The affinities of magnesia, according to Bergman, are as follows:

Oxalic acid,
Phosphoric,
Sulphuric,
Fluoric,
Sebacic,
Arsenic,
Saccholactic,
Succinic,
Nitric,
Muriatic,
Tartarous,
Citric,
Formic,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Prussic,
Sulphur,
Phosphorus?
Water.

Sect. III. *Of Barytes.*

207 Discovery of barytes. A very heavy mineral is found in Sweden, Germany, and Britain, which Margraf considered as a compound of sulphuric acid and lime. But Scheele and Gahn analysed it in 1774, and found that it consisted of sulphuric acid combined with a peculiar species of earth. This analysis was soon after confirmed and extended by Bergman. The earth was at first called *terra ponderosa, heavy earth*, on account of the great specific gravity of the substance from which it was obtained. Morveau called it *barote* (from *βαρυς, heavy*), which Bergman changed into *barytes;* and this last term is now universally adopted.

Barytes. Barytes is generally found combined either with sulphuric or carbonic acid. From the first of these compounds, which is by far the most common, it may be obtained by the following process:

208 Method of obtaining it. Reduce the mineral to a powder and mix it with $2\frac{1}{2}$ its weight of carbonat of soda (T), previously deprived of all its water. Expose the mixture to a red heat for an hour and a half, avoiding fusion, and a double decomposition takes place; the sulphuric acid unites with the soda, while the carbonic acid combines with the barytes. Wash it in a sufficient quantity of water to dissolve the compound of sulphuric acid and soda, the carbonat of barytes, which is almost insoluble, remains behind. Lest it should be mixed with some other earths, which is generally the case, boil it for three hours in ten times its weight of distilled vinegar, the specific gravity of which is 1,033; by which the barytes will be dissolved, and likewise the lime and magnesia, if there happen to be any; but every other earth (U) remains untouched. Pour off the solution, and add to it sulphuric acid as long as any precipitate is formed. This precipitate consists of the whole barytes and the lime (if there be any) combined with sulphuric acid. Wash it in 50 times its weight of water, and all the lime will be dissolved. There will now remain nothing but barytes combined with sulphuric acid, which may be decomposed as before by carbonat of soda *. The carbonic acid may then be separated by applying a very violent heat †; or, what is better, nitric acid may be poured upon it, which will separate the carbonic acid and combine with the barytes; and then the nitric acid may be driven off by a moderate heat ‡.

* *Afsvelius, Ann. de Chim.* iii.
† *Hope, Edin. Trans.* iv. 36.
‡ *Fourcroy* and *Vauquelin, Ann. de Chim.* xxi. 276.

209 Its properties. Barytes thus obtained is a light, spongy, porous body, which may be very easily reduced to powder. It has a harsh and more caustic taste than lime; and when taken into the stomach, proves a most violent poison. It has no perceptible smell.

Its specific gravity has not yet been ascertained.

It imbibes water with a hissing noise, but, according to Dr Hope, without swelling or splitting as lime does §. However, when exposed to the air, as Fourcroy and Vauquelin inform us, it effloresces, cracks, bursts, swells up, heats, and becomes white, by absorbing moisture ‖.

§ *Edin. Trans. ibid.*
‖ *Ann. de Chim. ibid.* and *Nicholson's Journal*, i. 535.

Cold water dissolves about $\frac{1}{17}$th part of its weight of barytes, and boiling water more than half its weight. As the water cools, the barytes is deposited in crystals, the shape of which varies according to the rapidity with which they have been formed. When most regular, they are flat hexagonal prisms, having two broad sides, with two intervening narrow ones, and terminated at each end by a four-sided pyramid, which in some instances constitutes the larger part of the crystal. When formed slowly, they are distinct and large; but when the water is saturated with barytes, they are deposited rapidly, and are generally more slender and delicate. Then, too, they are attached to one another in such a manner as to assume a beautiful foliacious appearance, not unlike the leaf of a fern ¶.

¶ *Hope, ibid.*

These crystals are transparent and colourless, and appear to be composed of about 53 parts of water and 47 of

(T) Soda is an alkali, which shall be afterwards described. Carbonat of soda is soda combined with carbonic acid, the common state in which it is obtained; potass might also be used.

(U) Except strontites, which Pelletier has detected in this mineral.

Barytes. of barytes. When expofed to the heat of boiling water, they undergo the *watery fufion*, or, which is the fame thing, they melt without lofing any of the water which they contain. A ftronger heat makes the water fly off. When expofed to the air, they attract carbonic acid, and crumble into duft. They are foluble in $17\frac{1}{2}$ parts of water at the temperature of 60°; but boiling water diffolves any quantity whatever: the reafon of which is evident; at that temperature their own water of cryftallization is fufficient to keep them in folution *.

* *Id.*

Water faturated with barytes is called *barytic water*. It has the property of converting vegetable blues to a green.

When barytes is expofed to the blowpipe on a piece of charcoal, it fufes, bubbles up, and runs into globules, which quickly penetrate the charcoal †. This is probably in confequence of containing water; for Lavoifier found barytes not affected by the ftrongeft heat which he could produce.

† *Fourcroy* and *Vauquelin, ibid.*

210
Sulphuret of barytes.

Barytes combines readily with fulphur. The eafieft way of forming fulphuret of barytes is to mix eight parts of fulphat of barytes with one part of pounded charcoal, and to apply a ftrong heat. The charcoal combines with the oxygen of the fulphuric acid, and the compound flies off in the form of carbonic acid gas. There remains behind fulphur combined with barytes. Sulphuret of barytes is foluble in water: It is of a yellow colour. It is capable of cryftallizing; and then affumes a yellowifh white colour ‡.

‡ *Fourcroy.*

The phofphuret of barytes has not been examined.

No mixture of barytes and lime, nor of barytes and magnefia, is fufible in the ftrongeft heat which it has been poffible to apply §.

§ *Lavoifier, Acad. Par.* 1782.

211
Its affinities.

The affinities of barytes, according to Bergman, are as follows:

Sulphuric acid,
Oxalic,
Succinic,
Fluoric,
Phofphoric,
Saccholactic,
Suberic (v)?
Nitric,
Muriatic,
Sebacic,
Citric,
Tartarous,
Arfenic,
Fluoric,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Pruffic,
Sulphur,
Phofphorus,
Water,
Fixed oils.

Sect. IV. *Of Strontites.*

Strontites.

212
Difcovery of ftrontites.

About the year 1787, a mineral was brought to Edinburgh, by a dealer in foffils, from the lead mine of Strontian in Argylefhire, where it is found imbedded in the ore, mixed with feveral other fubftances. It is fometimes tranfparent and colourlefs, but generally has a tinge of yellow or green. Its hardnefs is 5. Its fpecific gravity varies from 3,4 to 3,726. Its texture is generally fibrous; and fometimes it is found cryftallized in flender prifmatic columns of various lengths *.

* *Hope, Edin. Tranf.* iv. 44.

This mineral was generally confidered as a carbonat of barytes; but Dr Crawford having obferved fome differences between its folution in muriatic acid and that of barytes, mentioned in his treatife on *Muriat of Barytes*, publifhed in 1790, that it probably contains a new earth, and fent a fpecimen to Mr Kirwan that he might examine its properties. Dr Hope had alfo fufpected that its bafis differed from barytes; and accordingly he made a fet of experiments on it in 1791, which were read to the Royal Society of Edinburgh in 1792. Thefe experiments fully proved that it contained a peculiar earth. Mr Kirwan likewife analyfed the ftrontian mineral, and drew precifely the fame conclufions. It has been analyfed alfo by Mr Klaproth of Berlin, and Mr Pelletier of Paris. It confifts of carbonic acid combined with a peculiar earth, to which Dr Hope gave the name of *ftrontites*. This appellation we fhall adopt.

The carbonic acid may be feparated by a heat of 140° Wedgewood, and then the ftrontites remains behind †.

† *Kirwan's Miner.* i. 332.

Strontites has been found in Argylefhire in Scotland, near Briftol in England, and in Pennfylvania ‡. It has been found alfo in France and in Sicily. It is of a white colour. It has a pungent acrid tafte. When pounded in a mortar, the powder that rifes is offenfive to the noftrils and lungs §. It is not poifonous ‖.

‡ *Klaproth,* ii. fect. 39.

213
Its properties.

§ *Hope, ibid.*
‖ *Pelletier.*

One hundred and fixty-two parts of water, at the temperature of 60°, diffolve nearly one part of it. The folution is clear and tranfparent, and converts vegetable blues to a green. Hot water diffolves it in much larger quantities; and as it cools the ftrontites is depofited in colourlefs tranfparent cryftals. Thefe are in the form of thin quadrangular plates, generally parallelograms, the largeft of which feldom exceeds one-fourth of an inch in length. Sometimes their edges are plain, but they oftener confift of two facets, meeting together and forming an angle like the roof of a houfe. Thefe cryftals generally adhere to each other in fuch a manner as to form a thin plate of an inch or more in length and half an inch in breadth. Sometimes they affume a cubic form. They contain about 68 parts in 100 of water. They are foluble in 51,4 parts of water, at the temperature of 60°. Boiling water diffolves nearly half its weight of them. When expofed to the air, they lofe their water, attract carbonic acid, and fall into powder ¶.

¶ *Hope, ibid.*

When ftrontites is thrown into water, it attracts it with a hiffing noife, much heat is produced, and it falls into powder much more rapidly than lime *.

* *Id.*

It combines with fulphur either by fufion in a crucible, or by being boiled with it in water. The fulphuret

(v) Suberic acid decompofes muriat and nitrat of barytes. *Jamefon's Mineral. of Shetland and Arran.*

Silica.

phuret is of a dark yellowiſh brown colour. It is ſoluble in water*.

* *Id.*

214 Its affinities.

The affinities of ſtrontites, as aſcertained by Dr Hope, are as follows:

Sulphuric acid,
Oxalic,
Tartarous,
Fluoric,
Nitric,
Muriatic,
Succinic,
Phoſphoric,
Acetous,
Arſenic,
Boracic,
Carbonic.

Sect. V. *Of Silica.*

215 Method of obtaining ſilica.

If one part of powdered flints or ſand, mixed with three parts of potaſs, be put into a crucible, and kept in a ſtate of fuſion for half an hour, a brittle maſs will be formed almoſt as tranſparent as glaſs, which quickly attracts moiſture from the atmoſphere, and is entirely ſoluble in water. This ſolution is called *liquor ſilicum*, or *liquor of flints*. It was firſt accurately deſcribed by Glauber, a chemiſt who lived about the middle of the 17th century.

If an acid be poured into this liquor, a white ſpongy ſubſtance is precipitated, which may be purified from every accidental mixture by waſhing it in acids, muriatic acid for inſtance. This ſubſtance is called *ſiliceous earth* or *ſilica*. It was firſt diſtinguiſhed as a peculiar earth by Pott in 1746, though it had been known long before; and Cartheuſer, Scheele, and Bergman, proved in ſucceſſion that it could not, as ſome chemiſts had ſuppoſed, be reduced to any other earth.

216 Its properties.

Silica, when dried, is a ſoft white powder, without either taſte or ſmell.

Its ſpecific gravity is 2,66 †.

It is inſoluble in water except when newly precipitated from the liquor ſilicum, and then one part of it is ſoluble in 1000 parts of water ‡. It has no effect on vegetable colours.

It is capable of abſorbing about one-fourth of its weight of water, without letting any drop from it; but on expoſure to the air, the water evaporates very readily §.

Silica may be formed into a paſte with a ſmall quantity of water: this paſte has not the ſmalleſt ductility, and when dried forms a looſe, friable, and incoherent maſs ‖.

Silica is capable of aſſuming a cryſtalline form. Cryſtals of it are found in many parts of the world. They are known by the name of *rock cryſtal*. When pure they are tranſparent and colourleſs like glaſs: they aſſume various forms; the moſt uſual is a hexagonal priſm, ſurmounted with hexagonal pyramids on one or both ends, the angles of the priſm correſponding with thoſe of the pyramids. Their hardneſs is very great, amounting to eleven. Their ſpecific gravity is 2,653 ¶.

† *Kirwan's Miner.* i. 10.
‡ *Ibid.*
§ *Ibid.*
‖ *Scheele.*
¶ *Kirwan's Min.* i. 242.

There are two methods of imitating theſe cryſtals by art. The firſt method was diſcovered by Bergman. He diſſolved ſilica in fluoric acid, the only acid in which it is ſoluble, and allowed the ſolution to remain undiſturbed for two years. A number of cryſtals were then found at the bottom of the veſſel, moſtly of irregular figures, but ſome of them cubes with their angles truncated. They were hard, but not to be compared in this reſpect with rock cryſtal *.

* *Bergman*, ii. 32.

The other method was diſcovered by accident. Profeſſor Seigling of Erfurt had prepared a liquor ſilicum, which was more than uſually diluted with water, and contained a ſuperabundance of alkali. It lay undiſturbed for eight years in a glaſs veſſel, the mouth of which was only covered with paper. Happening to look to it by accident, he obſerved it to contain a number of cryſtals; on which he ſent it to Mr Trommſdorff, profeſſor of chemiſtry at Erfurt, who examined it. The liquor remaining amounted to about two ounces. Its ſurface was covered by a tranſparent cruſt, ſo ſtrong that the veſſel might be inverted without ſpilling any of the liquid. At the bottom of the veſſel were a number of cryſtals, which proved on examination to be ſulphat of potaſs and carbonat of potaſs (w). The cruſt on the top conſiſted partly of carbonat of potaſs, partly of cryſtallized ſilica. Theſe laſt cryſtals had aſſumed the form of tetrahedral pyramids in groups; they were perfectly tranſparent, and ſo hard that they ſtruck fire with ſteel †.

† *Nicholſon's Jour.* i. 217.

Silica endures the moſt violent heat without alteration.

It ſeems incapable of combining with ſulphur or phoſphorus.

217 Effect of heat on mixtures of lime and ſilica;

1. The effect of heat upon lime and ſilica, mixed in various proportions, will appear from the following experiments of Mr Kirwan ‡.

‡ *Mineral.* i. 56.

Proportions.	Heat.	Effect.
50 Lime 50 Silica	150° Wedg.	Melted into a maſs of a white colour, ſemitranſparent at the edges, and ſtriking fire, tho' feebly, with ſteel: it was ſomewhat between porcelain and enamel.
80 Lime 20 Silica	156	A yellowiſh white looſe powder.
20 Lime 80 Silica	156	Not melted, formed a brittle maſs.

218 Magneſia and ſilica:

2. Equal part of magneſia and ſilica melt with great difficulty into a white enamel when expoſed to the moſt violent heat which can be produced §. They are infuſible in inferior heats in whatever proportion they are mixed ‖.

§ *Lavoiſier, Mem. Par.* 1787, p. 598.

219 Barytes and ſilica;

3. The effect of heat on various mixtures of barytes and ſilica will appear from the following experiments of Mr Kirwan ¶.

proportions.

‖ *Achard, Mem. Berl.* 1780, p. 33.
¶ *Mineral.* i. 57.

(w) Potaſs, combined with ſulphuric acid and with carbonic acid.

Silica.

Proportions.	Heat.	Effect.
80 Silica 20 Barytes	155° Wedg.	A white brittle mass.
75 Silica 20 Barytes	150	A brittle hard mass, semi-transparent at the edges.
66 Silica 33 Barytes	150	Melted into a hard somewhat porous porcelain mass.
50 Silica 50 Barytes	148	A hard mass not melted.
20 Silica 80 Barytes	148	The edges were melted into a pale greenish matter between a porcelain and enamel.
25 Silica 75 Barytes	150	Melted into a somewhat porous porcelain mass.
33 Silica 66 Barytes	150	Melted into a yellowish and partly greenish white porous porcelain.

4. The effect of heat on mixtures of strontites and silica is not known.

220 And lime, magnesia, and silica.

5. It follows from the experiments of Achard, that equal parts of lime, magnesia, and silica, may be melted into a greenish-coloured glass, hard enough to strike fire with steel; that when the magnesia exceeds either of the other two, the mixture will not melt; that when the silica exceeds, the mixture seldom melts, only indeed with him in the following proportions; three silica, two lime, one magnesia, which formed a porcelain; and that when the lime exceeds, the mixture is generally fusible *.

* *Mem. Berl. ibid.* and *Jour. de Phys.* xxiv.

221 Affinities of silica.

The affinities of silica are as follows:

Fluoric acid,
Fixed alkali.

Sect. VI. *Of Alumina.*

222 Method of obtaining alumina.

Dissolve alum in hot water, and add to the solution potass as long as any precipitate is formed. Decant off the fluid part, and wash the precipitate in a sufficient quantity of water, and then allow it to dry. The substance thus obtained is called *alumina*. Its properties were first ascertained with accuracy by Margraf.

223 Its properties.

Alumina thus obtained is a very white spongy powder, without any smell or taste.

Its specific gravity is 2,00 †. It is scarcely soluble in water, but may be diffused through it with great facility.

† *Kirwan's Miner.* i. 9

Alumina.

With a small quantity of water it forms a very tough ductile paste, and does not readily mix with more.

In its usual state of dryness it is capable of absorbing $2\frac{1}{2}$ times its weight of water, without suffering any to drop out. It retains this water more obstinately than any of the earths hitherto described. In a freezing cold it contracts more, and parts with more of its water than any other earth; a circumstance which is of some importance in agriculture *.

* *Ibid.*

Alumina has never yet been obtained in a crystallized form. It has no effect whatever on vegetable colours.

The most intense heat does not fuse it, but it has the singular property of diminishing in bulk in proportion to the intensity of the fire to which it is exposed. It becomes at the same time exceedingly hard: Mr Lavoisier rendered it capable of cutting glass; and Mr Boyle had long before done the same thing †.

† *Shaw's Boyle*, iii. 422.

224 Wedgewood's thermometer.

Wedgewood took advantage of this property of alumina, and by means of it constructed an instrument for measuring high degrees of heat. It consists of pieces of clay of a determinate size, and an apparatus for measuring their bulk with accuracy: One of these pieces is put into the fire, and the temperature is estimated by the contraction of the piece. For a more complete description of this important instrument, we refer to the article Thermometer in the *Encycl.*

Alumina is hardly susceptible of combining with sulphur or phosphorus; but from the experiments of La Grange, it appears to have an affinity for carbon ‡.

‡ *Nicholson's Jour.* ii. 101.

225 Effect of heat on mixtures of lime and alumina;

1. The effect of heat on various mixtures of lime and alumina will appear from the following table §:

§ *Kirwan*, i. 56.

Proportions.	Heat.	Effect.
75 Lime 25 Alumina	150° Wedg.	Not melted.
66 Lime 33 Alumina	150	Remained a powder.
33 Lime 66 Alumina	(x)	Melted.
25 Lime 75 Alumina	(x)	Melted.
20 Lime 80 Alumina	(x)	Melted.

226 Magnesia and alumina;

2. Magnesia and alumina have no action whatever on each other, even when exposed to a heat of 150° Wedgewood ‖.

‖ *Ibid.* i. 57.

227 Barytes and alumina;

3. The effect of heat on different mixtures of barytes and alumina will appear from the following experiments of Mr Kirwarn ¶.

¶ *Ibid.*

Kk Proportions.

(x) These three experiments were made by Ehrman: The heat was produced by directing a stream of oxygen gas on burning charcoal, and is the most intense which it has been hitherto possible to produce.

Alumina.

Proportions.	Heat.	Effect.
80 Alumina 20 Barytes	150° Wedg.	Scarcely hardened.
75 Alumina 25 Barytes	156	No fign of fufion, a loofe powder.
66 Alumina 33 Barytes	152	As the former.
50 Alumina 50 Barytes	150	As the former.
20 Alumina 80 Barytes	148	Somewhat harder, but no fign of fufion.
25 Alumina 75 Barytes	150	Harder, but no fign of fufion.

4. Nothing is known concerning the effect of heat on mixtures of ftrontites and alumina.

228 Alumina and filica;

5. Equal parts of alumina and filica harden in the temperature of 160° Wedgewood, but do not fufe *. Achard found them infufible in all proportions in a heat probably little inferior to 150° Wedgewood. Mixtures of thefe two earths in various proportions form *clays*, but thefe are feldom uncontaminated with fome other ingredients.

* Kirwan's Min. i. 58.

229 Lime, magnefia, and alumina;

6. From the experiments of Achard, it appears that no mixture of lime, magnefia, and alumina, in which the lime predominates, is vitrifiable, except they be nearly in the proportions of three lime, two magnefia, one alumina; that no mixture in which magnefia predominates will melt in a heat below 166°; that mixtures in which the alumina exceeds are generally fufible, as will appear from the following table †.

† Ibid. i. 72.

3 Alumina 2 Lime 1 Magnefia	A porcelain.
3 Alumina 1 Lime 2 Magnefia	A porcelain.
3 Alumina 1 Lime 3 Magnefia	Porous porcelain.
3 Alumina 2 Lime 3 Magnefia	Porous porcelain.
3 Alumina 2 Lime 2 Magnefia	Porcelain.

230 Lime, filica, and alumina;

7. From the fame experiments, and thofe of Kirwan, we learn, that in mixtures of lime, filica, and alumina, when the lime exceeds, the mixture is generally fufible either into a glafs or a porcelain, according to the proportions. The only infufible proportions were,

2	3	Lime
1	1	Silica
2	2	Alumina.

That if the filica exceeds, the mixture is frequently fufible into an enamel or porcelain, and perhaps a glafs; and that when the alumina exceeds, a porcelain may often be attained, but not a glafs *.

* Ibid. i. 73.

231 Magnefia, filica, and alumina;

8. As to the mixtures of magnefia, filica, and alumina, when the magnefia exceeds, no fufion takes place at 150°. When the filica exceeds, a porcelain may often be attained; and three parts filica, two magnefia, and one alumina, formed a glafs. When the alumina exceeds, nothing more than a porcelain can be produced †.

† Ibid. i. 71.

232 And lime, magnefia, filica, and alumina.

9. Achard found that equal parts of lime, magnefia, filica, and alumina, melted into a glafs. They fufed alfo in various other proportions, efpecially when the filica predominated.

233 Affinities of alumina.

The affinities of alumina as as follows:

Sulphuric acid,
Nitric,
Muriatic,
Oxalic,
Arfenic,
Fluoric,
Sebacic,
Tartarous,
Succinic,
Saccholactic,
Citric,
Phofphoric,
Formic,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Pruffic.

Sect. VII. *Of Jargonia.*

234 Difcovery of jargonia.

Among the precious ftones which come from the ifland of Ceylon, there is one called *jargon*, which is poffeffed of the following properties.

Its colour is various, grey, greenifh white, yellowifh, reddifh brown, and violet. It is often cryftallized, either in right angular quadrangular prifms furmounted with pyramids, or octahedrals confifting of double quadrangular pyramids. It has generally a good deal of luftre, at leaft internally. It is moftly femitranfparent. Its hardnefs is from 10 to 16: Its fpecific gravity from 4,416 to 4,7 ‡.

‡ Ibid. i. 333.

It lofes fcarcely any of its weight in a melting heat; for Klaproth found that 300 grains, after remaining in it for an hour and a half, were only one-fourth of a grain lighter than at firft §. Neither was it attacked either by muriatic or fulphuric acid, even when affifted by heat. At laft, by calcining it with a large quantity of foda, he diffolved it in muriatic acid, and found that 100 parts of it contained 31,5 of filica, five of a mixture of nickel,

§ Jour. de Phyf. 36. 180.

Glucina.

el and iron, and 68 of an earth possessed of peculiar properties. This earth has been called *jargonia*.

235 Its properties.

Jargonia has a strong resemblance to alumina. It is of a white colour. Its specific gravity probably exceeds 4,000.

It differs from alumina in the compounds which it forms with other bodies, in being insoluble in a boiling solution of pure potass or soda, and in being infusible by heat when mixed with these substances in a state of dryness *.

No more of its properties are yet known.

* *Kirwan's Mineral.* i. p. 14.

Sect. VIII. *Of Glucina.*

236 Discovery of glucina.

In the beryl was discovered, some time ago by Vauquelin, a new earth, to which he gave the name of *glucina*. To obtain it pure, the beryl, reduced to powder, is to be fused with thrice its weight of potass. The mass is to be diluted with water, dissolved in muriatic acid, and the solution evaporated to dryness. The residuum is to be mixed with a large quantity of water, and the whole thrown on a filter. The silica, which constitutes more than half the weight of the stone, remains behind; while the glucina and the other earths, combined with muriatic acid, remain in solution. They are to be precipitated by means of carbonat of potass; the precipitate is to be washed, and then dissolved in sulphuric acid. When the solution, after potass has been added to it, has been evaporated to the proper consistency, alum crystals are gradually formed. When as many of these have been obtained as possible, carbonat of ammonia in excess is to be poured into the liquid, which is first to be filtered and then boiled for some time, when a white powder gradually appears. This powder is *glucina*.

237 Its properties.

It is a soft light powder, without either taste or smell, but has the property of adhering strongly to the tongue. It has no action on vegetable colours, is altogether infusible by heat, and neither hardens nor contracts in its dimensions. It is insoluble in water, but forms with a small quantity of that liquid a paste to a certain degree ductile. It does not combine with oxygen, nor with any of the simple combustibles; but sulphurated hydrogen dissolves it, and forms with it a hydrosulphuret, similar in its properties to other hydrosulphurets. Glucina is soluble in the liquid fixed alkalies; insoluble in ammonia, but soluble in carbonat of ammonia. It combines with all the acids, and forms with them sweet tasted salts; and hence its name, from γλυκος, *sweet*. Its other properties have not been examined.

Sect. IX. *Of Yttria and Agustina.*

238 Discovery and properties of yttria.

Some time before 1788 was discovered, in the quarry of Ytterby in Sweden, a peculiar mineral, called from Professor Gadolin, who first analysed it, *gadolinite*. Its colour is black, and its fracture like that of glass. It is magnetic, and soft enough to be scratched by a knife, and sometimes even by the nail. In this mineral a new earth has been discovered by various chemists, who have agreed to give it the name of *yttria*. When separated from the other substances with which it is combined, viz. the oxides of iron and manganese, a little lime, and a considerable quantity of silica, it has the appearance of a fine white powder, and has neither taste nor smell. It is not melted by the application of heat, has no action on vegetable blues, and is not soluble in water. It is likewise insoluble in pure alkalies; but it dissolves readily in carbonat of ammonia. It combines with acids, and forms with them salts, which have a sweet taste, and at the same time a certain degree of austerity.

Yttria and Agustina.

239 Discovery of agustina.

Trommsdorf has lately discovered in the *Saxon beryl* a new earth, to which he has given the name of *Agustina*, because the salts which it forms have little or no taste. As Trommsdorf's experiments have not hitherto been repeated, the existence of this earth must continue doubtful till the conclusions of the discoverer be confirmed by other philosophers.

240 Remarks on the earths.

These are all the simple earths that have yet been discovered; and the first four of them have a great many common properties. They tinge vegetable blues green, they have a strong affinity for carbonic acid, and combine readily with all acids. They have sometimes been called *alkaline earths*.

None of the earths have been hitherto decompounded, nor has the smallest proof ever been brought that they are compounds. We must therefore, in the present state of chemistry, consider them as simple bodies. Many attempts, indeed, have been made to shew that there was but one earth in nature, and that all others were derived from it. The earth generally made choice of as the simplest was silica (Y). But none of these attempts, notwithstanding the ingenuity of several of the authors, has been attended with the smallest shadow of success.

We have mentioned formerly, that it was almost the universal opinion of chemists that metals were composed of some of the earths united to phlogiston; but of late an attempt has been made to prove that all the earths are metallic oxides, and that they can actually be reduced to the state of metals.

Baron had long ago suspected that alumina had somewhat of a metallic nature; and Bergman had been induced, by its great weight and several other appearances, to conjecture that barytes was a metallic oxide: But the first chemist who ventured to hint that all earths might be metallic oxides was Mr Lavoisier *. About the year 1790, soon after the publication of Mr Lavoisier's book, Mr Tondi and Professor Ruprecht, both of Schemnitz, announced, that they had obtained from barytes, by the application of a strong heat, a metal of the colour of iron, and attracted by the magnet, which they called *borbonium*; from magnesia another, which they called *austrum*; a third from lime, also called *austrum*; and a fourth from alumina, which they denominated *apulum*. Their method of proceeding was to apply a violent heat to the earths, which were surrounded with charcoal in a Hessian crucible, and covered with calcined bones in powder.

* *Chemistry,* p. 217. Eng. Transl.

But their experiments were soon after repeated by Klaproth, Savoresi, and Tihauski; and these accurate chemists

(Y) Mr Sage, however, pitched upon lime.

chemists soon proved, that the pretended metals were all of them *phosphurets of iron*. The iron, by the violence of the heat, had been extracted from the crucible, and the phosphorus from the bones. The earths therefore must still continue a distinct class of bodies: and, as Klaproth has observed, their properties are so exceedingly different from those of metallic oxides, that the supposition of their being composed of the same ingredients is contrary to every fact, and to every analogy with which we are acquainted.

Chap. V. *Of* Caloric.

Nothing is more familiar to us than *heat*; to attempt to define it therefore would be unnecessary. When we say that *a person feels heat*, that *a stone is hot*, the expressions cause no difficulty; every one understands them perfectly: yet in each of these propositions the word *heat* has a distinct meaning. In the one, it signifies the *sensation* of heat; in the other, the *cause* of that sensation. This ambiguity, though of little consequence in common life, leads unavoidably in philosophical discussions to confusion and perplexity. It was to prevent this that the French chemists made choice of the word *caloric* to signify the *cause of heat*. When I put my hand on a hot stone, I experience a certain sensation, which I call the *sensation of heat*; the cause of this sensation is *caloric*.

241 Whether caloric be a substance.

Concerning the nature of caloric, there are two opinions which have divided philosophers ever since they turned their attention to the subject. Some suppose that caloric, like gravity, is merely a property of matter, and that it consists, some how or other, in a peculiar vibration of its particles; others, on the contrary, think that it is a distinct substance. Each of these opinions has been supported by the greatest philosophers; and the obscurity of the subject is such, that both sides have been able to produce exceedingly plausible and forcible arguments. The recent discoveries, however, in this branch of chemistry, have rendered the latter opinion much more probable than the former. Indeed we do not see how it is possible to account for many of the phenomena of nature, unless caloric be considered as a substance, as we trust shall appear from the investigation into which we are about to enter. We mean, then, with the generality of modern chemists, to take it for granted that caloric is a substance, without pretending to be able to demonstrate the truth of our opinion, but merely because we consider it as infinitely more plausible than the other. If the receiver of an air-pump, while it contains a thermometer, be suddenly exhausted of air, the thermometer sinks several degrees, and then gradually rises again to its former height. Now if heat be owing to vibration, how comes it that the small quantity of matter remaining in the receiver is first insufficient, and afterwards sufficient to maintain the temperature? Is it not more probable that part of the caloric was carried off with the air, and that it gradually returned through the glass, which it is capable of pervading, though with difficulty *. When air is let into an exhausted receiver, the thermometer, as Lambert first observed, rises several degrees. Is not this owing to an additional quantity of caloric introduced by the air? The thermometer then sinks slowly. Is not this because the superabundant caloric gradually pervades the glass and flies off? Taking it for granted then that caloric is a substance, we proceed to examine its propertis.

* See *Pictet sur le Feu*, ch. 1.

242 Caloric expands bodies.

1. When bodies become hot, or, which is the same thing, when caloric enters into them, they expand in every direction; and this expansion is proportional to the accumulation of caloric. The first and most obvious property of caloric then is the power of expanding bodies. It does not, however, expand all substances equally, and we are still ignorant of the law which it follows. All that can be done therefore is to collect facts till this law be discovered. A number of these may be seen in the following Table:

Table of the Expansion of various Bodies at different Temperatures.

(A) This mark ‡ implies that, owing to some inaccuracy in making the experiments, the numbers to which it is attached are not to be depended on.

(B) The metal whose expansion is here given was an alloy composed of three parts of copper and one of tin. The figures in some of the preceding columns are to be understood in the same manner. Thus in the last column but two, the metal consisted of two parts of brass alloyed with one of zinc.

Caloric.

243 Exception.

From this table, it appears that the gaſes are more expanded by caloric than fluids, and fluids more than ſolids; and that the expanſion of all bodies hitherto examined, mercury alone excepted, goes on in an increaſing ſeries. To the expanding power of caloric there is one ſingular exception: From 30° to 40° Fahrenheit, *water*, inſtead of being expanded, ſuffers a remarkable contraction, as is evident from the following table of its bulk for every degree between 30° and 40°.

40	100054 *.

* *Blagden.*

From 40° it expands like other ſubſtances on being heated (B).

244 Thermometer.

The expanſion of bodies by caloric has furniſhed us with an inſtrument for meaſuring the various degrees of it in different ſubſtances, we mean the thermometer; and as mercury is the only fluid which expands equably, it is obviouſly the only proper one for thermometers. The thermometer uniformly uſed in this article is that of Fahrenheit, except when ſome other is particularly mentioned.

245 No body without caloric.

2. By means of the thermometer, we learn that there is no body which does not contain coloric, becauſe there is none ſo cold that it cannot be made colder: and cooling a body is nothing elſe but abſtracting a part of the caloric which it contains.

246 Equilibrium of caloric.

3. Caloric cannot be confined in any body while thoſe in its neighbourhood are colder, but continues to ruſh out till every thing is reduced to the ſame temperature. This does not proceed from the attraction of the colder bodies, but from the tendency of caloric to exiſt everywhere in an equal degree of tenſion: For when hot bodies are placed in the exhauſted receiver of an air-pump, as we learn from Mr Pictet †, or in the Torricellian vacuum, as Count Rumford has ſhewn us ‡, the caloric leaves them in the ſame manner, tho' more ſlowly, and they are equally reduced to the temperature of the ſurrounding bodies. This property has been called *the equilibrium of caloric*. The only way therefore to confine or accumulate this ſubſtance in a body, is to ſurround it with bodies which are hotter than itſelf.

† *Sur le Feu*, chap. vi.
‡ *Phil. Tranſ.* 1786, Part I.

247 The particles of caloric repel each other.

4. The equilibrium of caloric ſeems evidently to prove that its particles repel each other. This repulſion will cauſe them when accumulated in any place to fly off in every direction, and to continue to ſeparate till they are oppoſed by caloric in other bodies of the ſame relative denſity with themſelves, which, by repelling them in its turn, compels them to continue where they are. The caloric in bodies therefore is in what has been called by Mr Pictet a ſtate of *tenſion* (C). Its particles are actuated by a force which would make them ſeparate to an indefinite diſtance, were they not confined by the oppoſite force of the caloric which ſurrounds them. The *equilibrium* therefore depends on the balancing of two oppoſite forces; the repulſion between the particles of caloric in the body, which tends to diminiſh the temperature; and the repulſion between the caloric of the body and the ſurrounding caloric, which tends to raiſe the temperature. When the firſt force is greater than the ſecond, as is the caſe when the temperature of a body is higher than that of the ſurrounding bodies, the caloric flies off, and the body becomes colder. When the laſt force is ſtronger than the firſt, as is the caſe when a body is colder than thoſe which are around it, the particles of its caloric are obliged to approach nearer each other, new caloric enters to occupy the ſpace which they had left, and the body becomes hotter. When the two forces are equal, the bodies are ſaid to be of the ſame temperature, and no change takes place *.

* See *Pictet ſur le Feu*, ch. i.

It is the action of theſe oppoſite forces which makes the thermometer a meaſure of temperature. When applied to any body, it continues to riſe or fall till the caloric in it and in the body to which it is applied are of the ſame tenſion, and then it remains ſtationary. The thermometer therefore merely indicates that the temperature of the body to which it is applied is equal to its own. It is obvious that, in order to obtain the real temperature of bodies, the thermometer ſhould be ſo ſmall that the quantity of caloric, which enters or leaves it, may not materially affect the reſult.

This property of caloric ſeems to be the cauſe of the elaſticity of the gaſes, in which, as we ſhall ſhew afterwards, it exiſts in great quantities. Perhaps it is the cauſe of elaſticity in general; for we have no demonſtrative evidence that the particles of elaſtic bodies repel each other (D), and we are certain that all of them contain caloric. Perhaps alſo it is owing to this repulſive property of caloric that the particles of no body actually touch each other; for the leſs caloric we leave in a body, the nearer its particles approach to one another. The expanſion of bodies by caloric ſeems alſo to depend on the ſame property. The particles of caloric uniting with thoſe of the body, endeavour to drag them along when they recede from each other. The expanſion

---

(B) There was a curious fact concerning dilatation obſerved by Mr de Luc. A braſs rod which he uſed as a thermometer became in ſummer *habitually* longer; that is to ſay, that after being for ſome time lengthened by heat, it did not contract by the application of cold to its old length, but continued ſomewhat longer. In winter the contrary phenomenon took place. After being contracted for ſome time by cold, it did not return to its old length on the application of heat, but kept ſomewhat ſhorter. A leaden rod ſhewed theſe effects in a greater degree. Glaſs has not this quality. De Luc ſuſpects that this property is inverſely as the elaſticity of bodies. Glaſs is perfectly elaſtic, and lead is leſs elaſtic than braſs.—*Journ. de Phyſ.* xviii. 369.

(C) The phraſe was firſt uſed by Mr Volta.

(D) We acknowledge that ſeveral philoſophers of the firſt rank, Æpinus for inſtance, and Boſcovich, have ſuppoſed that the particles of all bodies both attract and repel each other: but we cannot help thinking it rather improbable (if it be poſſible) that two ſuch oppoſite properties ſhould exiſt together.

Caloric. sion of bodies therefore ought to be inversely as their cohesion, and directly as the tension of the caloric which they contain. This property of caloric seems likewise to afford an explanation of a very curious fact, which was first, we believe, mentioned by De Luc in his Treatise on the Modifications of the Atmosphere, and afterwards ascertained by Dr George Fordyce, that bodies become absolutely lighter by being heated. He took a glass globe three inches in diameter, with a short neck, and weighing 451 grains; poured into it 1700 grains of water from the New river, London, and then sealed it hermetically. The whole weighed $2150\frac{1}{16}$ grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of snow and salt till some of it was frozen; it was then, after being wiped first with a dry linen cloth, next with clean washed dry leather, immediately weighed, and found to be $\frac{1}{16}$th of a grain heavier than before. This was repeated exactly in the same manner five different times. At each, more of the water was frozen and more weight gained. When the whole water was frozen, it was $\frac{3}{16}$ths of a grain heavier than it had been when fluid. A thermometer applied to the globe stood at 10°. When allowed to remain till the thermometer rose to 32°, it weighed $\frac{3}{16}$ths of a grain more than it did at the same temperature when fluid. We shall shew afterwards that ice contains less caloric than water of the same temperature with it. The balance used was nice enough to mark $\frac{1}{1000}$ part of a grain *. Morveau, too, found, much about the same time, that water put into vessels hermetically sealed, weighed more when frozen than when fluid †: and Mr Chaussier found, that two pounds of sulphuric acid were three grains heavier when frozen than after they had recovered their fluidity ‡. Now, if the particles of caloric repel each other, bodies which contain it in great quantities must be somewhat repelled by each other. The more replete therefore that any body is with caloric, the more it will be repelled by the earth, which always contains a great quantity; and this repulsion must in some degree counteract its gravitation. This explanation was first suggested, we believe, by Dr Black.

248 Bodies become lighter by being heated,

249 And why.

250 Caloric moves more readily upwards than downwards

The same property explains another curious fact discovered by Mr Pictet of Geneva, that caloric moves more readily vertically upwards than downwards. He took a tube of tinplate, two inches in diameter and 44 in length, and enclosed in it a bar of copper four lines in diameter and 33 inches in length, which was placed and fixed exactly in its axis. This tube was exhausted of air, by means of an air-pump, till the manometer § stood at the height of four lines. It was inclosed in another tube of pasteboard, except about two inches, exactly in the middle, to which place the sun's rays were directed for half an hour by means of a concave mirror. The ends of the copper bar were scooped out into concave hemispheres; and into each of these the bulb of a very sensible thermometer was fixed. The tube was placed vertically. The highest thermometer, which we shall call A, rose to 95°, a hundred and one seconds before the lowest B. The thermometer B rose no higher than 95°; but the thermometer A reached 101,75°. To see whether this difference was owing to the thermometers, the tube was inverted, and consequently the highest thermometer in the former experiment was lowest in this. The thermometer B now rose from 49° to 97,25° in 2810″; the thermometer A in 2763″, or 47″ sooner than B. It was evident from this result, that the thermometer A was more sensible than the thermometer B by 47″. If this be subtracted from 101″, the former difference, it will leave 54″, as the difference resulting from position. These experiments were repeated with only this difference, that round the ends of the bar and the bulbs of the thermometers (but without touching the bulbs) some folds of oiled paper were wrapped to confine the caloric. The superior thermometer A rose from 50° to 106,25° in 34 minutes, which was 93″ sooner than the inferior B: it rose to 110,75°, the thermometer B only to 106,25°. The tube being reversed, the thermometer A, which was now lowest, rose from 46° to 115,25° in 40′ 30″, or forty seconds sooner than the thermometer B. This subtracted from 93″, as formerly, leaves 53″ for the difference of situation. The superior thermometer mounted after the burning-glass was removed 0,45°, remained stationary for 80″, and after five minutes had only descended 0,45°: the other did not ascend at all; in one minute it descended 0,225°, and in 6′ 8″ it descended 2,47°. In 22′ 50″ the inferior descended 63,725°, the superior 61,475° *. From these experiments, it is obvious that the particles of caloric move somewhat faster, and in somewhat greater quantity, upwards than downwards; owing, doubtless, to the repulsive power of the caloric in the earth. The small quantity of air that remained in the tube may perhaps be supposed sufficient to account for the difference, without allowing any such tendency upwards in caloric. But it is evident from the experiments of the Florentine academicians on the same subject, with tubes full of air, that even when in great abundance, that fluid hardly affected the rising of the superior thermometer: surely then its effect must be altogether imperceptible when so little of it remained; and in the third and fourth experiments the oiled paper prevented any of the heated air from approaching the thermometer.

§ See Manometer in this Suppl.

* Pictet sur le Feu, chap. 2.

5. If we take a bar of iron and a piece of stone of equal dimensions, and putting one end of each into the fire, apply either thermometers or our hands to the other, we shall find the extremity of the iron sensibly hot long before that of the stone. Caloric therefore does not pass through all bodies with the same celerity and ease. The power that bodies have to allow it a passage through them is called their *conducting power;* those that allow it to pass with facility, are called *good conductors;* those through which it passes with difficulty, are called *bad conductors;* and those which do not allow it to pass at all, *non-conductors.*

251 Conducting power of bodies:

It is probable that all solids conduct heat in some degree, at least this is the case with every one at present known. Wood and charcoal are exceeding bad conductors of caloric (E). Count Rumford informs us, that a piece of

252 Of wood and charcoal;

(E) This fact merits the attention of chemists. It is obvious, that when metallic oxides are surrounded with charcoal powder, their temperature cannot be raised near so high as it otherwise would be. It is not unlikely that some part of the difficulty which has been experienced in attempting to reduce and fuse several metallic substances may have been owing to this cause.

Caloric

of green oak plank was employed to ſtir the melted metal of which cannons were founding at Munich, and it was often allowed to remain a conſiderable time in the furnace; yet the caloric had penetrated to ſo inconſiderable a depth, that at the diſtance of $\frac{1}{20}$th of an inch below the ſurface, the wood did not ſeem to have been the leaſt affected by it; the colour remained unchanged, and it did not appear to have loſt even its moiſture *.

* Rumford's Eſſays, ii. 229.

253 Of glaſs; Glaſs, when not tranſparent (F), is alſo a very bad conductor: and this is the reaſon that it is ſo apt to crack on being heated or cooled ſuddenly; one part of it receiving or parting with its caloric before the reſt, expands or contracts, and deſtroys the coheſion.

254 Of metals; Metals are the beſt conductors of caloric of all the ſolids hitherto examined. The conducting powers of all, however, are not equal. Dr Ingenhouſz procured cylinders of ſeveral metals exactly of the ſame ſize, and having coated them with wax, he plunged their ends into hot water, and judged of the conducting power of each by the length of wax-coating melted. From theſe experiments he concluded, that the conducting powers of the metals which he examined were in the following order †.

† Journ. de Phyſ. 1789, p 68.

Silver,
Gold,
Copper, } nearly equal.
Tin, }
Platinum, }
Iron, } much inferior to the others.
Steel, }
Lead, }

255 Of ſtones and ſolids capable of melting. Next to metals ſtone ſeems to be the beſt conductors; but this property varies conſiderably in different ſtones. Bricks are much worſe conductors than moſt ſtones. All ſolids capable of being melted become non-conductors the moment they are heated to the melting point: the caloric enters them eaſily enough, but it remains in them.

256 Whether fluids be conductors of caloric. A queſtion has lately been agitated among philoſophers, Whether fluids be conductors of caloric? No doubt was entertained of their being not only conductors, but good conductors, till the publication of Count Rumford's Eſſays, in which the author contends, with much plauſibility of reaſoning, that though fluids *carry*, they do not *conduct* heat; or, in other words, let it paſs freely from one particle to another.

257 What led him to this opinion. In a ſet of experiments on the communication of heat, he made uſe of thermometers of an uncommon ſize. Having expoſed one of theſe (the bulb of which was near four inches in diameter) filled with alcohol to as great a heat as it could ſupport, he placed it in a window to cool where the ſun happened to be ſhining. Some particles of duſt had by accident been mixed with the alcohol: theſe being illuminated by the ſun, became perfectly viſible, and diſcovered that the whole liquid in the tube of the thermometer was in a moſt rapid motion, running ſwiftly in oppoſite directions upwards and downwards at the ſame time. The *aſcending* current occupied the axis, the *deſcending* current the ſides of the tube. When the ſides of the tube were cooled by means of ice, the velocity of both currents was accelerated. It diminiſhed as the liquid cooled; and when it had acquired the temperature of the room, the motion ceaſed altogether. This experiment was repeated with lintſeed oil, and the reſult was preciſely the ſame. Theſe currents were evidently produced by the particles of the liquid going individually to the ſides of the tube, and giving out their caloric. The moment they did ſo, their ſpecific gravity being increaſed, they fell to the bottom, and of courſe puſhed up the warmer part of the fluid, which was thus forced to aſcend along the axis of the tube. Having reached the top of the tube, the particles gave out part of their caloric, became ſpecifically heavier, and tumbled in their turn to the bottom.

As theſe internal motions of fluids can only be diſcovered by mixing with them bodies of the ſame ſpecific gravity with themſelves, and as there is hardly any ſubſtance of the ſame ſpecific gravity with water which is not ſoluble in it, Count Rumford had recourſe to the following ingenious method of aſcertaining whether that fluid alſo followed the ſame law. The ſpecific gravity of water is increaſed conſiderably by diſſolving any ſalt in it; he added, therefore, potaſs to water till its ſpecific gravity was exactly equal to that of amber, a ſubſtance but very little heavier than pure water. A number of ſmall pieces of amber were then mixed with this ſolution, and the whole put into a glaſs globe with a long neck, which, on being heated and expoſed to cool, exhibited exactly the ſame phenomena with the other fluids. A change of temperature, amounting only to a very few degrees, was ſufficient to ſet the currents a-flowing; and a motion might at any time be produced by applying a hot or a cold body to any part of the veſſel. When a hot body was applied, that part of the fluid neareſt it aſcended; but it deſcended on the application of a cold body.

If caloric paſs through water only by the internal motion of its particles, as this experiment ſeems to prove, it is evident that every thing which embarraſſes theſe motions muſt retard its tranſmiſſion: and accordingly Count Rumford found this to be the caſe. He took a large lintſeed oil thermometer with a copper bulb and glaſs tube: the bulb was placed exactly in the centre of a braſs cylinder, ſo that there was a void ſpace between them all around 0,25175 of an inch thick. The thermometer was kept in its place by means of four wooden pins projecting from the ſides and bottom of the cylinder, and by the tube of it paſſing through the cork ſtopper of the cylinder. This cylinder was filled with pure water, then held in melting ſnow till the thermometer fell to 32°, and immediately plunged into a veſſel of boiling water. The thermometer roſe from 32° to 200° in 597″. It is obvious that all the caloric which ſerved to raiſe the thermometer muſt have made its way through the water in the cylinder. The experiment was repeated exactly in the ſame manner; but the water in the cylinder, which amounted to 2276 gr. had 192 gr. of ſtarch boiled in it, which rendered it much leſs fluid. The thermometer now took 1109″ to riſe from 32° to 200°. The ſame experiment was again repeated with the ſame quantity of pure water, having 192 258 Proofs of the non-conducting power of water,

(F) When tranſparent, it tranſmits caloric.

Caloric.

192 gr. of eiderdown mixed with it, which would merely tend to embarrafs the motion of the particles. A quantity of ftewed apples were alfo in another experiment put into the cylinder. The following Tables exhibit the refult of all thefe experiments.

Time the Caloric was in paffing into the Thermometer.

Temperature.	Through the Water and Starch.	Thro' the Water and Eiderdown.	Through ftewed Apples.	Through pure Water.
	Seconds.	Seconds.	Seconds.	Seconds.
Therm. rofe from 32° to 200° in	1109	949	1096½	597
Therm. rofe 80°, *viz.* from 80° to 160°, in	341	269	335	172

Time the Caloric was in paffing out of the Thermometer.

Temperature.	Through the Water and Starch.	Thro' the Water and Eiderdown.	Through ftewed Apples.	Through pure Water.
	Seconds.	Seconds.	Seconds.	Seconds.
Therm. fell from 200° to 40° in	1548	1541	1749½	1032
Therm. fell 80°, *viz.* from 160° to 80°, in	468	460	520	277

Now neither the ftarch nor the eiderdown could produce any alteration in the water except impeding its internal motions; confequently whatever impedes thefe motions diminifhes the conducting power of water. But this could not happen unlefs every individual particle actually went from the cylinder to the thermometer. Hence it follows that, if liquids be conductors, their conducting power is but fmall when compared with their carrying power.

259 Shewn to be inconclufive.

All liquids, however, are capable of conducting caloric; for when the fource of heat is applied to their furface, the caloric gradually makes its way downwards, and the temperature of every ftratum gradually diminifhes from the furface to the bottom of the liquid. The increafe of temperature in this cafe is not owing to the carrying power of the liquid. By that power caloric may indeed make its way upwards through liquids, but certainly not downwards. Liquids then are conductors of caloric.

Count Rumford, indeed, has drawn a different conclufion from his experiments. He fixed a cake of ice in the bottom of a glafs jar, covered one-fourth inch thick with cold water. Over this was poured gently a confiderable quantity of boiling water. Now if water were a non-conductor, no caloric could pafs through the cold water, and confequently none of the ice would be melted. The melting of the ice, then, was to determine whether water be a conductor or not. In two hours about half the ice was melted. This one would think, at firft fight, a decifive proof that water is a conductor. But the Count has fallen upon a very ingenious method of accounting for the melting of the ice, without being under the neceffity (as he tells us) of renouncing his theory that fluids are non-conductors.

It is well known that the fpecific gravity of water at 40° is a maximum: if it be either heated above 40°, or cooled down below 40°, its denfity diminifhes. Therefore, whenever a particle of water arrives at the temperature of 40°, it will fink to the bottom of the veffel. Now as the water next the ice was at 32°, it is evident that whenever any part of the hot water was cooled down to 40°, it would fink, difplace the water at 32°, come into contact with the ice, and of courfe melt it. The Count's ingenuity, never without refources, enabled him to prove completely, that the ice employed in his experiment was actually melted in that manner: for when he covered the ice partially with flips of wood, that part which was fhaded by the wood was not melted; and when he covered the whole of the ice with a thin plate of tin, having a circular hole in the middle, only the part exactly under the hole was melted. From thefe facts it certainly may be concluded that the ice was melted by defcending currents of water.

But the point to be afcertained, is not whether there were defcending currents, but whether water be a conductor or not. Now if water be a non-conductor, by what means was the hot water cooled down to 40°? Not at the furface; for the Count himfelf tells us, that there the temperature was never under 108°: not by the fides of the veffel; for the defcending current in one experiment was exactly in the axis: and it follows irrefiftibly, from the experiment with the flips of wood, that thefe defcending currents fell equally upon every part of the furface of the ice; which would have been impoffible if thefe currents had been cooled by the fide of the veffel. The hot water, then, muft have been cooled down to 40° by the cold water below it; confequently it muft have imparted caloric to this cold water. If fo, one particle of water is capable of abforbing caloric from another; that is, *water is a conductor of caloric.* After the hot water has ftood an hour over the ice, its temperature was as follows:

At the furface of the ice	40°
One inch above the ice	80
Two inches - -	118
Three inches - -	128
Four inches - -	130
Seven inches - -	131

How is it poffible to account for this gradual diminution of heat as we approach the ice, if water be a non-conductor? The water, it may be faid, gives out caloric at its furface, falls down, and arranges itfelf according to its fpecific gravity. If fo, how comes it that there is only one degree of difference between the temperature at 4 and at 7 inches above the ice? Thus it appears that the Count's experiment, inftead of demonftrating that water is a non-conductor, rather favours the common opinion that it is a conductor.

260 Mercury and oil proved to be conductors.

The Count tried whether oil and mercury be conductors in the following manner: When water was frozen in a glafs jar by means of a freezing mixture, Count Rumford obferved that the ice firft began to be formed at the fides, and gradually increafed in thicknefs; and that the water on the axis of the veffel, which retained its fluidity longeft, being compreffed by the expanfion of the ice, was forced upwards, and when completely frozen,

Caloric.

frozen, formed a pointed projection or nipple, which was sometimes half an inch higher than the rest of the ice. Upon ice frozen in this manner, he poured olive oil, previously cooled down to 32°, till it stood at the height of three inches above the ice. The vessel was surrounded as high as the ice with a mixture of pounded ice and water. A solid cylinder of wrought iron, $1\frac{1}{4}$th inch in diameter, and 12 inches long, provided with a hollow cylindrical sheath of thick paper, was heated to the temperature of 210° in boiling water; and being suddenly introduced into its sheath, was suspended from the ceiling of the room, and very gradually let down into the oil, until the middle of the flat surface of the hot iron, which was directly above the point of conical projection of the ice, was distant from it only $\frac{2}{10}$ths of an inch. The end of the sheath descended $\frac{1}{10}$th of an inch lower than the end of the hot metallic cylinder. Now it is evident, that if olive oil was a conductor, caloric would pass down through it from the iron and melt the ice. None of the ice, however, was melted; and when mercury was substituted for oil, the result was just the same *; consequently it follows that neither oil nor mercury is a conductor of heat.

* *Rumford*, *Essay* vii. part ii. chap. I.

But this experiment is by no means sufficiently delicate to decide the point. If a thermometer be substituted instead of the nipple of ice, it always rises several degrees; whence it follows that, even in this case, caloric passes downwards; so that the experiment is in fact favourable to the supposition that oil and mercury are conductors.

Count Rumford therefore has not proved that fluids are non-conductors of caloric; and that they are in truth conductors, the author of this article ascertained in the following manner: The liquid of which the conducting power was to be examined was poured into a glass vessel till it filled it about half way; then a hot liquid of less specific gravity was poured over it. Thermometers were placed at the surface, in the centre, and at the bottom of the cold liquid; if these rose, it followed that the liquid was a conductor, because the caloric made its way downwards. For instance, to examine the conducting power of mercury, a glass jar was half filled with that liquid metal, and boiling water then poured over it. The thermometer at the surface began immediately to rise, then the thermometer at the centre, and lastly that at the bottom. The first rose to 118°, the second to 90°, and the third to 86°: the first reached its maximum in 1′, the second in 15′, the third in 25′. The conducting power of water was tried in the same manner with hot oil poured over it; and the result was similar.

Fluids, then, as far as experiments have been made, are conductors of caloric as well as solids; and hence it follows that caloric is capable of making its way thro' all bodies with which we are acquainted. In this respect it differs from all other substances, even from light, which, as far as we know, cannot make its way through all bodies.

261 Transmission of caloric radiant heat.

The motion of caloric through bodies is indeed of two kinds: Through some it seems to move with the same rapidity as through free space; whilst through others, as we have seen, it moves slowly. When it moves through a body with undiminished velocity, it is said to be *transmitted* through it; and when its velocity is prodigiously diminished, it is said to be conducted. Air, and all transparent bodies hitherto examined, have the property of *transmitting* caloric through them; though some of them, as glass, do not transmit it till after they have combined with a certain proportion of it: and probably no body transmits it unless a greater quantity enter than is capable of combining with it in the state in which the body is placed. The phenomena of the transmission of caloric are exactly similar to the transmission of light, and admit of precisely the same explanation. What Scheele and several other chemists have called *radiant heat*, is nothing else than transmitted caloric; as has been completely proved by Dr Herschel. See *THERMOMETRIC Spectrum* in this *Supplement*.

262 Specific caloric of bodies, what.

6. If equal quantities of water and of mercury be placed at the same distance from a fire, the mercury will become hot much sooner than the water. After a sufficient interval, however, both of them acquire the same temperature. Now caloric flows into all bodies while they continue of a lower temperature than those around them, and it flows with equal rapidity into all bodies of the same conducting powers, as is the case with these two fluids: But if equal quantities of caloric were constantly flowing into the mercury and the water, and yet the water took a longer time to become hot than the mercury, it must require a greater quantity of caloric to raise water to a given temperature than it does to raise mercury. Bodies that require a greater quantity of caloric to raise them to a particular temperature than other bodies require, are said to have a greater *capacity* for caloric. That the capacity for caloric is different in different bodies, was first observed by Dr Black. Dr Irvine afterwards investigated the subject, and Dr Crawford published a great number of experiments on it in his *Treatise on Heat*. Professor Wilcke of Stockholm also discovered the same property of bodies. He called the quantity of caloric necessary to raise the temperature of substances a given number of degrees, their *specific caloric*; a term which we shall also employ, because the phrase *capacity for caloric* is liable to a great deal of ambiguity, and has introduced confusion into this subject (F). If two substances of unequal temperatures, as water at 100° and alcohol at 50°, be mixed together, the mixture will be of a temperature different both from that of the water and the alcohol, the water will become colder and the alcohol hotter: the water will give out caloric to the alcohol till both are reduced to the same temperature. Now if it requires just as much caloric to raise alcohol a certain number of degrees as it does to raise water the same number, that is, if these two fluids are of the same specific caloric, it is evident that the temperature of the mixture will be just 75°; for as soon as the water has given out 25° of caloric, the alcohol has acquired 25°, consequently both will be reduced to the same temperature, and will remain stationary; but if the specific caloric of the water be greater than that of the alcohol, the temperature of the mixture will be higher than 75°; for 25° of

(F) The term *specific caloric* has been used in a different sense by Seguin. He used it for the *whole caloric* which a body contains.

Caloric.

of caloric in that case would raise alcohol more than 25°. If the specific-caloric of water be so much greater than that of alcohol, that what raises water 20° will raise alcohol 30°; then the temperature after mixture will be 80°, because when the water has given out 20°, the alcohol will have risen 30°, and of course both will be of the same temperature. On the contrary, if the specific caloric of alcohol were greater than that of water, the temperature of the mixture would be under 75°. If the same quantity of caloric that raised alcohol 20° raised water 30°, then the temperature of the mixture would be 70°. Thus the ratios of the specific caloric of bodies may be discovered by mixing them together at different temperatures.

263 Experiments on specific caloric by Wilcke.

The first set of experiments on this subject, in point of time, were probably those of Mr Wilcke. They were first published in the Stockholm Transactions for 1781, but had been made long before. The manner in which they were conducted is exceedingly ingenious, and they furnish us with the specific caloric of many of the metals. The metal on which the experiment was to be made was first weighed accurately (generally one pound was taken), and then being suspended by a thread, was plunged into a large vessel of tinplate, filled with boiling water, and kept there till it acquired a certain temperature, which was ascertained by a thermometer. Into another small box of tinplate exactly as much water at 32° was put as equalled the weight of the metal. Into this vessel the metal was plunged, and suspended in it so as not to touch its sides or bottom; and the degree of heat, the moment the metal and water were reduced to the same temperature, was marked by a very accurate thermometer. He then calculated what the temperature would have been if a quantity of water equal in *weight* to the metal, and of the same temperature with it, had been added to the ice-cold water instead of the metal.

Let M be a quantity of water at the temperature C, m another quantity at the temperature c, and let their common temperature after mixture be x; according to a rule demonstrated long ago by Richman, $x=\frac{MC+mc}{M+m}$. In the present case the quantities of water are equal, therefore M and m are each $= 1$; C, the temperature of the ice-cold water $= 32$: therefore $\frac{MC+mc}{M+m} = \frac{32+c}{2}$. Now c is the temperature of the metal. Therefore if 32 be added to the temperature of the metal, and the whole be divided by 2, the quotient will express the temperature of the mixture, if an equal weight of water with the metal, and of the same temperature with it, had been added to the ice-cold water instead of the metal.

He then calculated what the temperature of the mixture would have been, if, instead of the metal, a quantity of water of the same temperature with it, and equal to the metal in *bulk*, had been added to the ice-cold water. As the weights of the ice-cold water and the metal are equal, their volumes are inversely as their specific gravities. Therefore the volume of ice-cold water is to a quantity of hot water equal in volume to the metal, as the specific gravity of the metal to that of the water. Let M = volume of cold water, m = volume of hot water, g = specific gravity of the metal, 1 = specific gravity of water; then $m : M :: 1 : g$; hence $m = \frac{M}{g} =$ (M being made $= 1$) $\frac{1}{g}$. Substituting this value of m in the formula, $\frac{MC+mc}{M+m} = x$, in which $M = 1$ and $C = 32$, x will be $= \frac{32g+c}{g+1}$. Therefore if the specific gravity of the metal be multiplied by 32, and the temperature of the metal be added, and the sum be divided by the specific gravity of the metal + 1, the quotient will express the temperature to which the ice-cold water would be raised by adding to it a volume of water equal to that of the metal, and of the same temperature with it.

He then calculated how much water at the temperature of the metal it would take to raise the ice-cold water the same number of degrees which the metal had raised it. Let the temperature to which the metal had raised the ice-cold water be = N, if in the formula $\frac{MC+mc}{M+m} = x$, x be made = N, M = 1, C = 32, m will be $= \frac{N-32}{c-N}$. Therefore if from the temperature to which the ice-cold water was raised by the metal 32 be subtracted, and if from the temperature of the metal be subtracted the temperature to which it raised the water, and the first remainder be divided by the last, the quotient will express the quantity of water of the temperature of the metal which would have raised the ice-cold water the same number of degrees that the metal did.

Now $\frac{N-32}{c-N}$ expresses the specific caloric of the metal, that of water being = 1. For (neglecting the small difference occasioned by the difference of temperature) the weight and volume of the ice-cold water are to the weight and volume of the hot water as 1 to $\frac{N-32}{c-N}$, and the number of particles of water in each are in the same proportion. But the metal is equal in weight to the ice-cold water; it must therefore contain as many particles of matter; therefore the quantity of matter in the metal must be to that in the hot water as 1 to $\frac{N-32}{c-N}$. But they give out the same quantity of caloric; which, being divided equally among their particles, gives to each particle a quantity of caloric inversely as the bulks of the metal and water; that is, the specific caloric of the water is to that of the metal as 1 to $\frac{N-32}{c-N}$ (G).

We shall now give a specimen or two of his experiments, and the calculations founded on them, as above described.

(G) We have altered all these formulas to make them correspond with Fahrenheit's thermometer. They are a good deal simpler when the experiments are made with Celsius's thermometer, as Mr Wilcke did. In it the freezing point is zero; and consequently instead of 32 in the formula, 0 is always substituted.

Gold. *Specific Gravity* 19,040.

It is needlefs to add, that the laft column marks the denominator of the fpecific caloric of the metal, the numerator being always 1, and the fpecific caloric of water being 1. Thus the fpecific caloric of gold is $\frac{1}{19{,}712}$. In exactly the fame manner, and by taking a mean of a number of experiments at different temperatures, did Mr Wilcke afcertain the fpecific caloric of a number of other bodies. He afcertained at the fame time, that the fpecific caloric of a body did not vary with the temperature, but continued always the fame. This will appear evident from the experiments on gold and lead above exhibited.

264 Crawford, Next, in point of time, and not inferior in ingenious contrivances to enfure accuracy, were the experiments of Dr Crawford, made by mixing together bodies of different temperatures. Thefe were publifhed in his *Treatife on Heat*.

265 Lavoifier and La Place, Several experiments on the fpecific caloric of bodies were made alfo by Lavoifier and De la Place, which, from the well-known accuracy of thefe philofophers, cannot but be very valuable.

Their method was exceedingly fimple and ingenious; it was firft fuggefted by De la Place. An inftrument was contrived, to which Lavoifier gave the name of *calorimeter*. It confifts of three circular veffels nearly infcribed into each other, fo as to form three different apartments, one within the other. Thefe three we fhall call the *interior*, *middle*, and *external cavities*. The interior cavity *ffff* (fee fection of the inftrument fig. 4.), into which the fubftances fubmitted to experiment are put, is compofed of a grating or cage of iron wire, fupported by feveral iron bars. Its opening or mouth LM is covered by the lid HG, which is compofed of the fame materials. The middle cavity *bbbb* is filled with ice. This ice is fupported by the grate *mm*, and under the grate is placed a fieve. The external cavity *aaaa* is alfo filled with ice. We have mentioned already, that no caloric can pafs through ice. It can enter ice, indeed, but it remains in it, and is employed in melting it. The quantity of ice melted, then, is a meafure of the caloric which has entered into the ice. The exterior and middle cavities being filled with ice, all the water is allowed to drain away, and the temperature of the interior cavity to come down to 32°. Then the fubftance, the fpecific caloric of which is to be afcertained, is heated a certain number of degrees, fuppofe to 212°, and then put into the interior cavity enclofed in a thin veffel. As it cools, it melts the ice in the middle cavity. In proportion as it melts, the water runs through the grate and fieve, and falls through the conical funnel *ccd* and the tube *xy* into a veffel placed below to receive it. The external cavity is filled with ice, in order to prevent the external air from approaching the ice in the middle cavity and melting part of it. The water produced from it is carried off through the pipe ST. The external air ought never to be below 32°, nor above 41°. In the firft cafe, the ice in the middle cavity might be cooled too low; in the laft, a current of air flows through the machine and carries off fome of the caloric. By putting various fubftances at the fame temperature into this machine, and obferving how much ice each of them melted in cooling down to 32°, it was eafy to afcertain the fpecific caloric of each. Thus, if water, in cooling from 212 to 32, melted one pound of ice, and mercury ,029 of a pound; the fpecific caloric of water was one, and that of mercury ,029. This appears by far the fimpleft method of making experiments on this fubject; and muft alfo be the moft accurate, provided we can be certain that all the melted fnow flows into the receiver. But from an experiment of Mr Wedgewood, one would be apt to conclude that this does not happen. He found that the melted ice, fo far from flowing out, actually *froze* again, and choaked up the paffage.

A table of the fpecific caloric of various bodies was likewife drawn up by Mr Kirwan, and publifhed by Magellan in his Treatife on Heat. 266 And Kirwan.

From all thefe fources we have drawn up the following table, which exhibits at one view the fpecific caloric of thofe bodies on which experiments have hitherto been made. 267 Refult of thefe experiments.

We have added to it a column, expreffing the fpecific caloric of equal bulks of the fame bodies; which feems to be a more accurate way of confidering this fubject, and indeed the only way in which the phrafe *capacity for caloric* is intelligible. This column was formed by multiplying the fpecific caloric of equal weights of the various fubftances into their refpective fpecific gravities.

7. If

(H) The ſpecific caloric of the ſubſtances marked * was aſcertained by Dr Crawford, thoſe marked † by Mr Kirwan, ‡ by Lavoiſier and La Place, ** by Wilcke, ‖ by Count Rumford. § Is the mean of Crawford, Kirwan, and Lavoiſier; ¶ mean of Lavoiſier and Kirwan; (*c*) mean of Crawford and Lavoiſier; (*d*) mean of Wilcke and Crawford; (*e*) mean of Wilcke, Crawford, and Kirwan.

Caloric.

268 Latent caloric, or

7. If a quantity of ice, at a low temperature, suppose at 20°, be suspended in a warm room, it will become gradually less cold, as may be discovered by means of a thermometer, till it reaches the temperature of 32°; but there it stops. The ice, however, dissolves slowly; and at the end of several hours, when it is all just melted, the thermometer still stands at 32°. After this it begins to rise, and soon reaches the temperature of the room. Here the ice continues for several hours colder than the air around it. Caloric must then be continually flowing into it; yet it does not become hotter: it is changed, however, into water. Ice, therefore, is converted into water by a quantity of caloric uniting with it. This caloric has been called *latent caloric*, because its presence is not indicated by the thermometer. It might, perhaps with more propriety, as Professor Pictet observes *, be called *caloric of fluidity*; for there are other cases in which caloric exists in bodies without raising their temperature. This very important discovery was made by Dr Black as early as 1757, and seems to have led the way to all the subsequent discoveries in this part of chemistry, which have almost completely changed the appearance of the science: for the discovery that caloric may exist in bodies while the thermometer cannot indicate its presence, is one of the strongest links in the chain of facts by which the nature of combustion was ascertained.

269 Caloric of fluidity.

* *Sur le Feu*, ch. I.

The caloric which unites with ice, and renders it fluid, appears again during the act of *freezing*. If a quantity of water be carried into a room where the temperature is below the freezing point, suppose at 20°, it cools gradually down to 32°; but it becomes no colder till it is all frozen, which takes up some time. The moment it is all converted into ice, it begins again to cool, and soon reaches the temperature of the room. In this case, the water is surrounded by a cold atmosphere; it must therefore be giving out caloric constantly; yet it does not become colder till it is all frozen, that is to say, till it has lost all its *caloric of fluidity*.

Dr Black proved, by a very accurate experiment, that the quantity of *caloric of fluidity* is sufficient to raise the same quantity of water 140°.

All solids become fluid by absorbing a quantity of caloric. Landriani proved that this is the case with sulphur, alum, nitre, and several of the metals †; and it has been found to be the case with every substance hitherto examined. Fluidity, therefore, is owing to a union between the solid and a certain quantity of caloric.

† *Jour. de Phys.* xxvi.

The late Dr Irvine of Glasgow advanced a theory on this subject different from that of Dr Black. The specific caloric of water being greater than that of ice, it requires a greater quantity of caloric to raise it to a given temperature than it does to raise ice. The caloric does not therefore become *latent*; it only seems to do so from the greater specific caloric of water. This theory was zealously adopted by Dr Crawford. Dr Black observed very justly, that it did not account for the production of fluidity at all. The specific caloric of water is indeed greater than that of ice; but how is the ice convered into water? This is an objection which the advocates for Dr Irvine's, or Dr Crawford's, theory (as it has been improperly called) will not easily answer. Let us now examine whether this theory accounts for the apparent loss of caloric. It follows from Mr Kirwan's experiments, that the specific caloric of water is to that of ice as 10 to 9 (1). Dr Black proved, that as much caloric entered the ice as would have raised it, had it been water, 140°. Let us suppose that it would only have raised the ice 140°; in that case the melted ice ought to have been of the temperature of 158°, for 10 : 9 : : 140 : 126; but it was only 32°: Therefore 126° of caloric have disappeared, and cannot be accounted for by the change of specific caloric. Nor can the accuracy of Dr Black's experiment be suspected: it has been repeated in every part of the world, and varied in every possible way. We cannot doubt, therefore, that caloric unites with substances, and causes them to become fluid, or that *there is in fact a caloric of fluidity different from specific caloric.*

Water also is converted into *steam* by uniting with caloric. Dr Black put an iron vessel, containing four ounces of water at the temperature of 53°, upon a cast-iron table which was red hot. The water rose to the boiling point in three minutes; but it did not afterwards become any hotter. It evaporated, however, in 18 minutes; and the steam was precisely at the temperature of 212°. During the first three minutes, it received 159° of caloric, and as much must have been entering it during every three minutes while the evaporation continued, as the temperature was always much lower than that of the table. This caloric, instead of raising the temperature of the water, was employed in converting it into steam. There is also, therefore, a quantity of latent caloric in steam. It might, as Mr Pictet observes, be called, with propriety, *caloric of evaporation*. This caloric appears again if the steam be condensed. If it be made to pass, for instance, through a pipe surrounded with cold water, it is condensed in the pipe, and drops out from it in the form of water. The caloric of the steam enters into the water around the pipe, and the quantity of it in degrees may be discovered by the number of degrees which it raises that water. By an experiment of this kind, it was proved, that the caloric of evaporation would be sufficient to heat water red hot, were it employed only in raising its temperature, instead of converting it into steam. It is therefore at least equal to 800°. Mr Watt shewed afterwards that it was 920°.

270 Caloric of evaporation.

Even spontaneous evaporation, as Dr Black first observed, is owing to the same cause: and this explains why bodies cool when water is evaporated from their surface;

(1) We do not know how this was ascertained: Not by mixing water and ice surely; because that would be taking for granted the thing to be proved; because it would give a very different result; and what is still worse, the specific caloric in that case would differ according to the temperature and the quantity of water. To give an instance: Mr Gadolin concludes, from 180 experiments made by mixing hot water and ice, that the specific caloric of ice is to that of water only as 1 to 2 *; and had he varied the quantities and the temperatures, he might have obtained several other ratios.

* *Ann de Chim.* xi. 27.

Caloric.

surface; a fact which has been long known, and which has been employed in warm countries to diminish the temperature of liquids, and even to convert them into ice (K). That water is evaporated by uniting with caloric, and not by solution in air, has been proved very completely by De Luc in his Treatise on Meteorology.

The evaporation of alcohol, ether, and every other substance on which experiments have been made, has been found owing to the same cause. Bodies, therefore, are converted into vapour by uniting with caloric.

271 Real zero, what.

8. If caloric, as has been shewn, exists in bodies at the lowest temperature which we are able to procure, and if it exists in them while the thermometer cannot discover its presence—is there any method of ascertaining its absolute quantity in bodies? At what degree would a thermometer stand (supposing the thermometer capable of measuring so low) were the body to which it is applied totally deprived of caloric? or what degree of the thermometer corresponds to the real zero?

The first person (as far as we know), at least since men began to think accurately on the subject, who conceived the possibility of determining this question, was Dr Irvine of Glasgow. He invented a theorem, in order to ascertain the real zero, which has, we know not for what reason, been ascribed by several writers to Mr Kirwan. He took it for granted (and the fact is proved by all the experiments hitherto made) that the specific caloric of bodies continued the same in every degree of temperature, as long as they remained in the same state, that is to say, as long as they continued either solid or fluid or in a state of vapour; but that the specific caloric of the same body while solid was less than while fluid, and less while fluid than while in a state of vapour. He took it for granted, too, that the 140 degrees of caloric which entered ice during its solution without raising its temperature, entered merely in consequence of the increased specific caloric of the water, and that they were exactly proportional to this increased specific caloric. He took it for granted, likewise, that the specific caloric of bodies was proportional to

272 Irvine's theorem to discover it.

(K) Galen informs us, that the ancient Egyptians were accustomed to put water previously boiled into earthen jars, and expose them all night on the upper part of their houses to the air. Before sunrise these vessels were put into the ground, moistened on the outside with water, and then surrounded with fresh plants; by which means the water was preserved cool during the whole day. *Comment. in lib.* vi. *Hippoc. de morbis vulgar.* 4. 10. p. 396.

By a similar process, water, in the East Indies, is converted into ice.

The following singular passage, which has been pointed out to us by the ingenious Dr Barclay, lecturer on anatomy in Edinburgh, furnishes a striking proof that the ancients were led, by a very different method of reasoning, to deduce, from their philosophical theory of the four elements, conclusions concerning the nature of heat not very different from those of the moderns.

"Sic enim res se habet, ut omnia, quæ alantur et quæ crescant, contineant in se vim caloris; sine qua neque ali possent nec crescere. Nam omne, quod est calidum et igneum, cietur et agitur motu suo: quod autem alitur et crescit, motu quodam utitur certo et æquabili; qui quandiu remanet in nobis, tamdiu sensus et vita remanet: refrigerato autem et extincto calore, occidimus ipsi et exstinguimur. Quod quidem Cleanthes his etiam argumentis docet, quanta vis insit caloris in omni corpore: negat enim ullum esse cibum tam gravem, quin is nocte et die concoquatur; cujus etiam in reliquiis inest calor his quas natura respuerit. Jam verò venæ et arteriæ micare non desinunt, quasi quodam igneo motu; animadversumque sæpe est, cùm cor animantis alicujus evolsum ita mobiliter palpitaret, ut imitaretur igneam celeritatem. Omne igitur quod vivit, sive animal sive terra editum, id vivit propter inclusum in eo calorem. Ex quo intellegi debet, eam caloris naturam, vim habere in se vitalem per omnem mundum pertinentem. Atque id faciliùs cernemus, toto genere hoc igneo, quod tranat omnia, subtiliùs explicato. Omnes igitur partes mundi (tangam autem maxumas) calore fultæ sustinentur. Quod primùm in terrena natura perspici potest. Nam et lapidum conflictu atque tritu elici ignem videmus; et recenti fossione

—— *terram fumare calentem;*

atque etiam ex puteis jugibus aquam calidam trahi, et id maxumè fieri temporibus hibernis, quòd magna vis caloris, terræ contineatur cavernis; eaque hieme fit densior; ob eamque caussam, calorem insitum in terris contineat arctiùs.

"Longa est oratio, multæque rationes, quibus doceri possit, omnia, quæ terra concipiat, semina, quæque ipsa ex se generata stirpibus infixa contineat, ea temperatione caloris et oriri et augescere. Atque aquæ etiam admixtum esse calorem, primùm ipse liquor, tum aquæ declarat effusio: quæ neque conglaciaret frigoribus, neque nive pruinaque concresceret, nisi eadem se admixto calore liquefacta et dilapsa diffunderet. Itaque et aquilonibus reliquisque frigoribus durescit humor: et idem vicissim mollitur tepefactus et tabescit calore. Atque etiam maria agitata ventis ita tepescunt, ut intellegi facilè possit, in tantis illis humoribus esse inclusum calorem. Nec enim ille externus et adventicius habendus est tepor, sed ex intimis maris partibus agitatione excitatus: quod nostris quoque corporibus continget, cùm motu atque exercitatione recalescunt. Ipse verò aër, qui natura est maxumè frigidus, minime est expers caloris. Ille verò et multo quidem calore admixtus est: ipse enim oritur ex respiratione aquarum: earum enim quasi vapor quidam aër habendus est. Is autem existit motu ejus caloris, qui aquis continetur. Quam similitudinem cernere possumus in his aquis, quæ effervescunt subditis ignibus. Jam verò reliqua quarta pars mundi, ea et ipsa tota natura fervida est, et ceteris naturis omnibus salutarem impertit et vitalem calorem. Ex quo concluditur, cùm omnes mundi partes sustineantur calore, mundum etiam ipsum simili parique natura in tanta diuturnitate servari: eoque magis, quòd intellegi debet, calidum illud atque igneum ita in omni fusum esse natura, ut in eo insit procreandi vis et caussa gignendi, à quo et animantia omnia, et ea quorum stirpes terra continentur, et nasci sit necesse et augescere. *Cicero de natura Deorum*, lib. ii. c. 9 *et* 10.

to their *abſolute caloric*, or to all the caloric which exiſted in each.

On theſe data he reaſoned in the following manner: Let A be a body in a ſtate of fluidity; B the ſame body in a ſtate of ſolidity. If the ſpecific caloric of A and of B be known, and if it be known how many degrees the caloric, diſengaged during the change of B into A, would raiſe the temperature of A, it may be found by an eaſy proceſs how many degrees all the caloric contained in B would raiſe the temperature of A; and the ſum of theſe two numbers will repreſent in degrees the whole quantity of caloric in A: for the quantity of caloric in A muſt be juſt equal to the caloric in B, together with what entered into it in paſſing from the ſtate of B to that of A. Let the ſpecific caloric of A be 6, that of B 1; and let the quantity of caloric diſengaged during the change of A into B be ſufficient to raiſe the temperature of A 500°. If the ſpecific caloric be proportional to the abſolute caloric, it muſt contain exactly 6 times as much caloric as B. The 500° which entered into A when it changed its ſtate, muſt be juſt 5 times as great as all the caloric of B; becauſe when added to the caloric of B, it formed the caloric in A, which is juſt 6 times as great as the caloric in B. Therefore to diſcover the caloric in B, we have only to divide 500 by 5, or, which is the ſame thing, to ſtate this proportion 6—1 : 500 : : 1 : 100. The caloric in B, therefore, in this caſe is juſt as much as would raiſe the temperature of A 100°. Therefore, if to 100°, the caloric of B, be added 500°, = caloric diſengaged in the paſſage of A to B, this will give 600°, = to all the caloric in A. Therefore, in all caſes, the difference between the numbers expreſſing the ſpecific caloric of the ſolid and fluid, is to the number expreſſing the ſpecific caloric of the ſolid, as the quantity of caloric diſengaged during the paſſage of the fluid into a ſolid is to the quantity of caloric in the fluid.

Dr Crawford embraced this theorem; and concluded, from a number of experiments made on purpoſe to aſcertain the fact, that the real zero was 1268° below 0, or 1300° below the freezing point.

273 Examined,

This ſubject deſerves to be conſidered with attention. If this theorem in fact furniſhes us with the real zero, it is one of the moſt important diſcoveries which has ever been made in chemiſtry; but if it proceeds on erroneous principles, it will only involve us in endleſs mazes of error and abſurdity.

In the firſt place, if the real zero has any meaning at all, it muſt ſignify the degree to which the thermometer (ſuppoſing it could be uſed) would ſink on being applied to a body which contained no heat. It muſt therefore be a fixed point; and were the theorem which we are examining well founded, experiments upon every different ſubſtance, if conducted with accuracy, would lead to the ſame reſult. Let us ſee whether this be the caſe.

From Dr Crawford's experiments, it follows, as we have ſeen, that the real zero is 1268° below 0.

Mr Kirwan, from comparing the ſpecific caloric of water and ice, fixed the real zero at 1048° below 0.

From the experiments of Lavoiſier and La Place on a mixture of water and quicklime, in the proportion of 9 to 16, it follows, that the real zero is 2736° below 0.

From their experiments on a mixture of 4 parts of ſulphuric acid and 3 parts of water, it follows, that the real zero is 5803,4° below 0.

Their experiments on a mixture of 4 parts of ſulphuric acid and 5 of water, place it at 2073,3° below 0.

Their experiments on $9\frac{1}{3}$ parts of nitric acid and 1 of lime, place it at $\frac{1889}{-0{,}01783}$ below 32°*.

These reſults differ from one another ſo enormouſly, and the laſt of them, which makes the real zero a negative quantity, is ſo abſurd, that they are alone ſufficient to convince us that the data on which they are founded are not true. Should it be ſaid that their difference is not owing to any defect in the theorem, but to inaccuracies in making the experiments—we anſwer, that the theorem itſelf is founded on ſimilar experiments; and if experiments of this nature, even in the hands of the moſt accurate chemiſts, cannot be freed from ſuch enormous errors, how can we depend on any conſequences deduced from them? and where, then, is our evidence for the truth of the theorem?

But, farther, there is no proof whatever that the ſpecific caloric of bodies is proportional to their abſolute caloric. The ſpecific caloric of iron is greater than that of water, or even azotic gas; yet ſurely it is very improbable that iron contains more abſolute caloric than either of theſe ſubſtances.

If the ſpecific caloric of bodies has any meaning at all, it can only be, that the ſame quantity of caloric raiſes the temperature of one body a greater number of degrees than it does another. When we ſay that the ſpecific caloric of A is = 6, and that of B = 1, what do we mean, unleſs that the quantity of caloric which raiſes B 6° raiſes A only 1°, or that what raiſes B 60° or 600°, raiſes A only 10° or 100°? When we ſay that the ſpecific caloric of water is 10, and that of ice 9, do we not mean, that the quantity of caloric which raiſes the ice 10° or 100°, raiſes water only 9° or 90°? Yet during the change of ice into water, 140° of caloric enter it without raiſing its temperature; a quantity greater than what can be accounted for by the difference of ſpecific caloric by 126°. The quantity that diſappears, therefore, is *not* proportional to the difference of ſpecific caloric; and therefore any theory which depends on that ſuppoſition cannot be well founded. When water is converted into ſteam, 800° of caloric diſappear, yet the ſpecific caloric of ſteam is to that of water, according to Dr Crawford's own experiments, only as 155 to 100: ſo that no leſs than 283° diſappear, which cannot be accounted for according to this theory.

274 And found inſufficient.

Dr Irvine's theorem, therefore, is inſufficient for aſcertaining the real zero; and hitherto no method has been diſcovered which can ſolve this problem.

275 Caloric exiſts in bodies

9. If there be no body without caloric, if it exiſts in different quantities in different bodies, even when their temperatures are the ſame, and while the thermometer cannot indicate its preſence—in what ſtate does it exiſt in them? We cannot ſurely ſuppoſe that it is contained by them juſt as water is contained by a veſſel of wood or metal, or that they are filled with it in the ſame manner that a hollow globe of tinplate perforated with holes is filled with water when it is plunged into a quantity of that liquid; or that bodies are filled with caloric merely becauſe they are immerſed in an ocean of caloric. Were that the caſe, the ſpecific and abſolute caloric of bodies would always be proportional; and they would of neceſſity be inverſely as the ſpecific gravity of the reſpective bodies; becauſe the leſs the ſpecific gravity, the more room would be left for the particles

* See *Seguin, Ann. de Chim.* vii.

Caloric.

ticles of caloric. But this is by no means the case: the specific gravity of iron, for instance, is greater than that of tin, yet the specific caloric of iron is more than double that of tin: the specific gravity of oxygen gas is greater than that of common air, yet the specific caloric of the first of these substances is more than three times as great as that of the other. There must be something, therefore, in bodies themselves quite different from, and unconnected with, the vacuities between their particles, which disposes some to admit more caloric than others. And what can that be but a disposition in different bodies to unite with a greater or a smaller quantity of caloric, and to retain it with more or less firmness according to their *affinity* for it? Dr Black pointed out, long ago, by discovering latent heat, that caloric unites with bodies; and this seems to be the only real key for unfolding the actions of this extraordinary substance. If caloric be matter, can it be destitute of that property which all other matter possesses, we mean attraction? And if it possesses attraction, must it not combine with those bodies that attract it just as other bodies combine with each other? Must there not be formed a chemical union between caloric and other substances, which can only be broken by chemical means, by presenting a third body which has a greater affinity either for the caloric or the body to which it is united, than they have for each other?

276 **In a state of chemical combination.**

277 **Proved to be the case in liquids, vapours,**

That it unites chemically with some bodies, at least, cannot be doubted, as we have shewn already, that whenever a solid is converted into a liquid, a quantity of caloric enters, and remains in it; and that both the solid and the caloric lose their characteristic properties. This is precisely what takes place in every chemical union. All liquids, therefore, consist of solids combined with caloric. We have seen, too, that liquids are converted into vapours by the very same process. There are therefore, at least, two very large classes of bodies, liquids and vapours, in which we are certain that caloric exists in a state of chemical combination.

278 **And gases;**

There is another class of bodies which resembles vapours in almost all their properties: these are the gases. Like them, they are invisible and elastic, and capable of indefinite expansion. Is it not probable, then, that the gases also, as well as the vapours, owe their properties to caloric? that they also consist of their respective bases combined with that subtile substance? This probability has been reduced to certainty by an experiment of Lavoisier. By adding two tubes to the calorimeter formerly described, he contrived to make known quantities of air to pass through the interior cavity, and to support combustion. He found, that when a pound of oxygen gas was made to combine in this manner with phosphorus, as much caloric was disengaged as melted $87\frac{1}{2}$ pounds of ice*. Now every pound of ice absorbs as much caloric in the act of melting as is sufficient to raise a pound of water 140°. Therefore the whole caloric disengaged was sufficient to raise a pound of water 12250°. All this could not have come from the phosphorus, because it had been converted into a liquid, and must therefore have absorbed instead of parted with caloric, and because the quantity of caloric disengaged in all cases of combustion is proportional, not to the combustible, but to the oxygen absorbed. Oxygen gas, then, is composed of oxygen and caloric: and if this be the case with one gas, why not with all?

* *Lavoisier*, p. i. ch. 9.

We may conclude, therefore, that the gases, as well as liquids and vapours, owe their form to the caloric which they contain. The only difference between them and vapours is, that the latter return to their liquid state by the mere action of cold; whereas most of the gases resist the lowest temperature which it has been possible to apply. It was natural to expect, that if caloric combined chemically with bodies, its affinity would be different for different substances, and that its affinity for some bodies would be so great that it would not leave them to combine with any other. It was natural to expect this, because it is the case with every other substance with which we are acquainted. The difference, then, between the gases and vapours is not surprising. The affinity of the former for caloric is not only much greater than that of the latter, but much greater than that of any other substances.

279 **And to be the cause of their gaseous form.**

It is owing to this strong affinity between oxygen, hydrogen, and azot and caloric, that they cannot be obtained except in a gaseous form: and we shall describe several other substances afterwards exactly in the same circumstances. Had we any substance possessed of a greater affinity for caloric than they have, we should be able, by presenting it, to deprive them of their gaseous form. Doubtless there is a difference in the affinity between these bodies themselves and caloric; but as all of them are already saturated, this difference cannot be discovered. If we could obtain them uncombined with caloric, that is to say, in a concrete state, it would be easy to ascertain this point. Suppose, for instance, that hydrogen had the strongest affinity for caloric, and that we possessed it in a concrete state—it would be easy, by presenting it to the other gases, to deprive their bases of the caloric with which they are united, and thus to obtain them also uncombined with any other substance.

280 **Why caloric appears during combustion,**

But though we are acquainted with no substance that has a greater affinity for caloric than the bases of the gases, there are many substances which have a greater affinity for these bases than caloric has. When any such substance is presented, the base combines with it, and the caloric is left at liberty. Thus, when phosphorus is presented to oxygen gas, the phosphorus and oxygen unite together, and the caloric flies off. We are now, therefore, able to answer one of the questions proposed at the end of the second chapter, Whence comes the caloric which appears during combustion? It is separated from the oxygen, which leaves it in order to enter into a new combination.

281 **And during many chemical combinations.**

The caloric also, which sometimes appears when two bodies combine together, is set at liberty exactly in the same manner. When sulphuric acid and water, for instance, are mixed together, a very considerable heat is produced; a good deal of caloric, therefore, becomes sensible. In this case, the water combines with the acid, and at the same time lets go the caloric with which it was formerly combined, and becomes denser. In the same manner, to give another instance, when water is poured upon quicklime, a very great quantity of caloric becomes manifest. The water in this case combines with the quicklime, and assumes a concrete form, and of course lets go the caloric with which it was previously united.

282 **Why certain mixtures produce cold.**

10. It is no uncommon thing in nature to observe two bodies, after combining together, manifesting a much stronger affinity for a third body than either of them

Caloric.

them had while feparate. Thus, filver has no perceptible affinity for fulphuric acid, neither has oxygen; but unite them together, and they combine with that acid very readily. A great many inftances of the fame kind might be produced. Were there fubftances, then, which, after combining together, have a greater affinity for caloric than any of them had while feparate, this ought not to furprife us, becaufe the fame phenomenon is often obferved in other bodies. Now this is actually the cafe with regard to caloric. Mix together, for inftance, common falt and fnow, the mixture inftantly becomes liquid, and fo cold, that it finks the thermometer down to zero. In this cafe, the fnow and falt united have a much ftronger affinity for caloric than either of them had while feparate; they attract it therefore from other bodies with which they happen to be in contact, till they have obtained a dofe fufficient for their faturation; and this faturation they manifeft by becoming liquid. It is for this reafon that all falts produce cold during their folution in water, when the freezing point of the folution formed is below that of water. All fuch folutions have a ftrong affinity for caloric; they therefore attract it till they are faturated, which appears by their becoming fluid. A number of experiments have been lately made in order to procure artificial cold by means of fuch combinations. The moft complete fet of experiments of that nature with which we are acquainted, is thofe of Mr Walker, publifhed in the Philofophical Tranfactions for 1795. We fhall prefent the refult of his experiments in the following Table:

TABLE of Freezing Mixtures.

Mixtures.		Thermometer finks.
Muriat of ammonia Nitre - - Water - -	5 parts. 5 16	From 50° to 10°.
Muriat of ammonia Nitre - - Sulphat of foda Water - -	5 5 8 16	From 50 to 4.
Nitrat of ammonia Water - -	1 1	From 50 to 4.
Nitrat of ammonia Carbonat of foda Water - -	1 1 1	From 50 to 7.
Sulphat of foda Diluted nitric acid	3 2	From 50 to 3.

In order to produce thefe effects, the falts employed muft be frefh cryftallized, and newly reduced to a very fine powder. The veffels in which the freezing mixture is made fhould be very thin, and juft large enough to hold it, and the materials fhould be mixed together as quickly as poffible. The materials to be employed in order to produce great cold ought to be firft reduced to the temperature marked in the table, by placing them in fome of the other freezing mixtures; and then they are to be mixed together in a fimilar freezing mixture. If, for inftance, we wifh to produce a cold = —46, the fnow and diluted nitric acid ought to be cooled down to 0, by putting the veffel which contains each of them into the 12th freezing mixture in the above table, before they are mixed together. If a ftill greater cold is required, the materials to produce it are to be brought to the proper temperature by being previoufly placed in the fecond freezing mixture. This procefs is to be continued till the required degree of cold has been procured *.

* *Walker, Phil. Tranf.* 1795.

283 Subftances which contain moft caloric.

11. From the facts already known, we may conclude, that the particles of caloric have two properties, that of repelling each other, and of attracting and being attracted by other fubftances. As there is no body in nature which does not contain caloric, we may fafely conclude, that there is no body in nature which has not an affinity for it. When it unites with bodies, though the repulfion of its particles may be overcome by their attraction for the particles of the body, and by the attraction

traction of theſe particles for each other—we cannot ſuppoſe it annihilated: It muſt therefore be the more powerful the greater the quantity of caloric combined in any body is. Probably, then, there is moſt caloric combined with gaſes, leſs with fluids, and leaſt with ſolids. It does not follow, however, from this, that the quantity of caloric combined with any body is proportional to the diſtance between its particles, becauſe that may depend on other cauſes. Thus, though hydrogen gas is much rarer than oxygen gas, it does not follow that hydrogen is combined with more caloric than oxygen, becauſe the rarity may be owing to the ſmaller coheſive force of the particles of hydrogen allowing a ſmaller quantity of caloric to produce a greater effect.

284 Caloric may be added indefinitely to bodies,

If caloric unites *only* chemically with bodies, there ought to be a certain point of ſaturation between it and the ſubſtances with which it combines, becauſe this takes place in all other chemical combinations. Oxygen gas, for inſtance, conſiſts of a certain quantity of oxygen united with caloric. Now if this gas be a *chemical* compound, the two ingredients ought to ſaturate each other in ſuch a manner, that no more of either could be admitted. But it cannot be denied, that more caloric can ſtill be added to oxygen gas, for its temperature may be raiſed at pleaſure as high as we think proper. This, at firſt ſight, ſeems to be an inſuperable objection to the theory, that caloric only combines chemically with bodies. It ought to be remembered, however, that caloric is not ſingular in this reſpect. There are other bodies in nature, and bodies too which certainly combine with other ſubſtances only by affinity, which exhibit the very ſame phenomenon. Water is capable of combining with ſulphuric acid and many other ſalts almoſt in any proportion, at leaſt no limits have hitherto been obſerved. Oxygen, too, combines with almoſt every body in various proportions: We have ſeen, that with almoſt every metal it forms at leaſt two different oxides. Why then may not caloric be capable of uniting in the ſame manner? Allowing, therefore, that it were impoſſible to explain why bodies are capable of combining with caloric after ſaturation, this could be no objection to the theory that it only unites chemically with bodies, becauſe the ſame phenomenon is exhibited by other bodies which it cannot be doubted combine only by means of affinity.

285 And why.

The manner in which theſe other combinations are formed has been already hinted, and ſhall be conſidered more fully afterwards; at preſent we ſhall only attempt to explain the action of caloric. Let us ſuppoſe, then, that caloric is preſented to oxygen; that they combine together in a certain proportion, and ſaturate each other. The product of this combination is oxygen gas; a ſubſtance poſſeſſed of properties very different from thoſe of caloric or oxygen in a concrete ſtate; it is incapable of being decompoſed by any merely mechanical method, and exhibits all the appearances of a ſimple ſubſtance. Let us therefore conſider this compound for a moment as a ſimple ſubſtance. May it not ſtill have an affinity for caloric? and will it not, in that caſe, unite with it? Oxygen gas and caloric have an affinity for each other; accordingly when preſented to one another they combine in a certain proportion, and form a new compound, differing from oxygen gas, properly ſo called, in elaſticity, ſpecific gravity, and ſeveral other particulars. The affinity, however, between oxygen gas and caloric is much feebler than that between oxygen and caloric; for the new compound is eaſily broken, and the caloric abſorbed by many other ſubſtances. We can even conceive this new compound ſtill to have an affinity for caloric, to unite with it, and to form another compound, the affinity between the ingredients of which is ſtill feebler. And in this manner may the indefinite increaſe of temperature be accounted for.

286 Cauſe of the different conducting powers of different bodies.

Subſtances may be conceived to be conductors of caloric inverſely as their affinity for it. Good conductors may have very little affinity for caloric; and for that reaſon it may be eaſily forced through them by the repulſion of its own particles. But thoſe ſubſtances which have a great affinity for caloric, combine with it the moment it is preſented to them; and conſequently it cannot paſs through them. Thus, when it is preſented to ice, the affinity between the two ſubſtances is ſo great, that the caloric unites with the very firſt particles of ice which it meets with. The particles behind theſe cannot receive any caloric, except by attracting it from the particles with which it has already combined. But the affinity of one particle of ice for caloric cannot be greater than that of another particle of ice: and the union of two bodies cannot be broken by a force not greater than that which unites them; therefore the caloric cannot paſs from one particle to another. Conſequently, ſuppoſing all the particles to keep their places, no new caloric could enter. Juſt as when a piece of marble is put into ſulphuric acid, the cruſt of ſulphat of lime which very ſoon covers it prevents the acid from getting to the particles of marble within. But as ſoon as a particle of ice unites with caloric, water, the new compound, leaves its ſtation, and allows the caloric a paſſage to the other particles.

In the ſame manner, when caloric is preſented to water, it combines with the outermoſt ſtratum of particles, and forms with them a compound which cannot be decompoſed by the other particles of the water, becauſe their affinity for caloric is no greater than that of the particles already united with it. No more caloric, then, could gain admiſſion, were it not that (the ſpecific gravity of the new compound being inferior to that of the uncombined water) it immediately changes its place, and allows another ſtratum of particles to occupy its room. Theſe unite with caloric, and are diſplaced in their turn. And in this manner the proceſs goes on, till all the particles have combined with caloric; or, which is the ſame thing, till the whole of the water is heated.

287 How heat paſſes thro' ſolids.

But ſuppoſing the firſt ſtratum of particles to remain in their place after their union with caloric, we can conceive an affinity ſtill to ſubſiſt between the new compound, thus formed, and caloric. In that caſe the new compound, which we ſhall call A, would combine with an additional doſe of caloric, and form a ſecond compound B, differing in ſeveral reſpects from the firſt. We can conceive alſo the affinity between the firſt compound A and caloric to be inferior to that between water and caloric. In that caſe, the ſecond ſtratum of particles of water would ſeparate the additional doſe with which the firſt ſtratum had united. In this manner would two ſtratums of particles combine with caloric. The firſt ſtratum of particles would combine with another doſe of caloric, and form a ſecond compound B as before. But this compound could not now be decompoſed by the ſecond ſtratum of particles,

 becauſe

Caloric.

because they had already united with a dose of caloric; and therefore their affinity for a new dose could be no greater than that of the first stratum of particles. The process of heating could go on no farther. But we can conceive the second compound B, into which the first stratum has entered, still to have an affinity for caloric, to combine with a dose of it, and to form with it a third compound C. We can conceive, at the same time, the affinity between the second compound B and caloric to be less than that between the first compound A and caloric. In that case, the second stratum of particles would take this last dose from the first stratum, and form with it a second compound B. The third stratum of particles, which is still uncombined with caloric, would now attract this new dose from the second stratum, and combine with it. And, supposing the caloric still flowing towards the water, the first stratum would again form the third compound C, by uniting with a fresh dose: this new dose would be again attracted by the second stratum, and the first stratum would again form the third compound C, by uniting with another dose of caloric. Thus three stratums of particles would be combined with caloric; the first stratum would contain three doses, the second stratum two, and the third one. The process of heating would again stop; because now the affinity of the second stratum is no greater than that of the first, nor the affinity of the third stratum greater than that of the second, nor that of the fourth than that of the third. But we can conceive an affinity still to subsist between caloric and the third compound C, into which the first stratum has entered, and this affinity, at the same time weaker than that between the second compound B and caloric. In that case they would combine and form a fourth compound D. This new dose would be attracted by the second stratum of particles, which would combine with it and form the third compound C; the third stratum would attract it from the second, and form with it the second compound B; and the fourth stratum would attract it from the third, and enter into the first compound A. The first stratum would again enter into the fourth compound D; which would be again decomposed by the second stratum; and the compound formed by the second stratum, by the third stratum. The fourth compound D would be again formed by the first stratum, and again decomposed by the second stratum. It would be formed a third time, and could not now be decomposed. Four stratums of particles would now have combined with caloric: the first stratum with four doses; the second, with three doses; the third, with two; and the fourth, with one. We can conceive this process to go on exactly in the same manner, till all the particles of water have combined with a dose of caloric. In that case, the quantity of caloric combined with every stratum of particles would form a regular decreasing series from that part of the water at which the caloric enters to that part which is farthest distant from it. The process of heating would go on very slowly; and the heat of that part of the water which is farthest distant from the source of caloric could never be nearly equal to that of the part which is nearest to that source. This seems in fact to be the manner in which all those solids are heated which are bad conductors of caloric: in all probability it is the way in which all solids are heated.

288 Bodies cool each other reciprocally.

That caloric combines with bodies merely by means of affinity, seems at first sight contrary to fact; for there is no substance whatever which may not be cooled indefinitely merely by surrounding it with other bodies which are colder than itself. Place a piece of hot iron, for instance, in cold water, it is very soon cooled down to the temperature of that liquid. This seems plain enough; the attraction of water for caloric is greater than that of iron: but reverse the experiment; put hot water within cold iron, and the water is cooled in its turn down to the temperature of the iron: so that the iron also has a greater affinity for caloric, as well as the water; which is absurd.

289 And why.

But it ought to be remembered, that caloric not only possesses affinity, but that it has another property also, of which every other species of matter, except perhaps light, seems to be destitute, a repulsion between its own particles. It is necessary for all organised bodies, and probably for all bodies, that they should possess a certain quantity of caloric; and on this account the greatest care has been taken to secure its equal distribution. This seems to be one use at least of its repulsive power; a power which is never destroyed, however closely caloric is united with other bodies. We have shewn already, that this power is increased by diminishing the quantity of surrounding caloric; and when thus increased to a certain degree, it may at last equal, and even exceed, the affinity between the caloric and the bodies to which it is united; and in that case part of the caloric would necessarily fly off. It seems to be in this manner that bodies reciprocally cool each other, and that they have always a tendency to an equilibrium of temperature. Thus steam by cold is converted into water, and water into ice. And the affinity between bodies and that caloric which is employed in regulating the temperature seems to be so weak, that the repulsion between the particles of caloric easily overcomes it, and restores the equilibrium. But the affinity between some substances and caloric is so great, that no diminution of temperature has been found sufficient to overcome it. This is the case, as we have already seen, with oxygen gas.

290 Cause of the difference in the specific caloric of bodies.

The specific caloric of bodies seems to depend on two things; their affinity for caloric, and the distance between their particles. For what is temperature but the disposition of a body to part with caloric? The more caloric a body is disposed to part with, we call its temperature the higher; the less it parts with when a colder body is applied, its temperature is said to be the lower. If oxygen gas parts with no caloric to a thermometer which stands at —10°, we say its temperature is —10; yet we know that even then it contains, in all probability, much more caloric than the mercury in the thermometer does. Now the stronger the affinity between any substance and caloric, the greater quantity of caloric will be required before the repulsion between its particles is sufficient to overcome this attraction; consequently the more caloric is necessary to raise it a given number of degrees. And the farther distant the particles of bodies are, the farther from one another must the particles of caloric be to which they are united; and consequently the weaker must be the repulsion between them.

We cannot deny how new this theory of the action of caloric will appear to those who have been accustomed

Caloric.

ed to look upon Dr Crawford's opinions on this subject as fully proved; nor do we pretend that it can be reconciled with these opinions. But this, we hope, is no proof of its falsehood. We think it can be fairly deduced from Dr Black's doctrine of latent heat: we know, too, that Bergman believed caloric capable of combining chemically with bodies: and Morveau has not only embraced the same opinion, but seems to affirm, that all the combinations into which caloric enters are chemical *. And were this question to be decided by authority, we appeal to all the world, whether other three men could be produced to whose decisions one would more willingly submit (1). We do not, however, mean to rest its evidence on authority; let it be compared with facts, and put to the test of experiment; and by its correspondence with these let it stand or fall.

* *Encyc. Method. Chim.* art. *Affinité.*

291 Caloric hastens solution, and increases the solvent power of water.

12. Caloric both hastens the solution of salts in water, and increases the solvent power of the water; for water dissolves a much greater quantity of almost every salt when hot than when cold. The reason that caloric produces these effects is obvious from those properties of it which have been described. It hastens solution by putting the particles of the fluid in motion, and thus bringing all of them in their turn into contact with the salt: for only those particles can act as solvents which are in contact with the salt. It increases the solvent power of the fluid by combining with it, and forming a compound which has a greater affinity for the salt, and which therefore dissolves more of it than the fluid alone would have done. This new compound is destroyed by cooling; and then the additional dose of the salt which had been dissolved is precipitated.

13. We should come now to the consideration of the two remaining questions proposed at the end of the second chapter, Why do bodies combine with oxygen at one temperature and not at another? And why is caloric necessary to produce this union? But as the difficulty of these questions is not inferior to their importance, we shall delay any attempt to answer them till we come to treat of *affinity*.

292 Methods of obtaining caloric.

14. It now only remains to consider the methods by which caloric may be obtained in a sensible state. These methods may be reduced to four; combustion, percussion, friction, and light: the last of which shall be considered afterwards.

293 Combustion explained.

We have seen already, that the combustion of *simple combustibles and metals* is merely their combination with oxygen, during which the oxygen parts with the caloric with which it was formerly united. Now the very same thing takes place in other combustions. The combustible unites with oxygen, which at the same time gives out its caloric. The change then which the combustible body suffers is not owing to the action of caloric on it, but to its combining with oxygen. The very same change can be brought about without any of the usual phenomena which attend combustion, simply by presenting the oxygen combined with some other body instead of caloric. Nitric acid, for instance, is a body which contains in it a good deal of oxygen: If phosphorus be mixed with this acid, it attracts part of the oxygen, and, without any of the usual phenomena which attend combustion, is converted into phosphoric acid. Strictly speaking, then, combustion is nothing else but the combination of oxygen with the burning body, and the term might therefore be used in every case where such an union takes place; and in this sense indeed it is now employed by several writers. But the term *combustion* is in common language confined to those cases where the oxygen was previously combined with caloric, and where a quantity of heat and light become sensible; and perhaps it would be better, in order to prevent ambiguity, never to employ it in any other sense.

294 Whether it ever takes place when oxygen is not present.

We are not yet absolutely certain that caloric and light may not become sensible in other combinations besides those into which oxygen enters. There are other substances besides oxygen capable of combining with caloric; for instance, hydrogen and azot: and unless their affinity for caloric be greater than for any other substance, they may be capable of combining with other substances, and separating from caloric, at least the impossibility of this has never yet been demonstrated. It is improper, therefore, to appropriate the word *combustion* to the combinations of oxygen, till it can be shewn that the phenomena usually denoted by that name are never owing to any other cause. There is even one case in which these phenomena present themselves, in which we are next to certain that oxygen has no share. There is an affinity between sulphur and iron, and a high temperature promotes their union. When these substances are mixed together, and heated till they just begin to appear red hot, they combine together, and at the same time, as the Dutch chemists first observed, a good deal of caloric and light is evolved. The very same phenomena appear in a vacuum, or in any kind of air whatever. The explanation of them is very simple and obvious. The sulphur or the iron, or perhaps both, had previously been combined with a quantity of caloric; and when they united together, this caloric of course separated from them.

295 Stahl's theory of combustion by the extrication of phlogiston.

The theory of combustion adopted by the earlier chemists was very different from the preceding. Stahl, as has been already explained, considered combustion in every instance as owing to the separation of phlogiston; and this opinion soon became universal. He considered phlogiston as the same thing with the element of fire; which was capable both of becoming fixed in bodies, and of existing in a state of liberty. Two of its properties in this last state were heat and light. The heat and the light, then, which became sensible during combustion, were nothing else, according to Stahl, but two properties of phlogiston or the element of fire.

296 Improved by Macquer,

Macquer, to whose illustrious labours several of the most important branches of chemistry owe their existence, was, we believe, the first person who perceived a striking defect in this theory of Stahl. Sir Isaac Newton had proved that light is a body; it was absurd, therefore, to make it a mere property of phlogiston or the element of fire. Macquer accordingly considered phlogiston as nothing else but light fixed in bodies. This opinion was embraced by a great number of the most distin-

(1) The same opinion has been embraced by Seguin, Pictet, Gadolin, and several other philosophers. We did not mention them, because the theory given above differs in a few particulars from theirs. But we have derived much instruction from their ingenious writings; and many of the facts which we have given were obtained from them.

Caloric. distinguished chemists; and many ingenious arguments were brought forward to prove its truth. But if phlogiston be only light fixed in bodies, whence comes the heat that manifests itself during combustion? Is this heat merely a property of light? Dr Black proved that heat is capable of combining with, or becoming fixed in bodies which are not combustible, as in ice and water; and concluded of course, that it is not a property but a body. From that time heat or caloric was considered by the greatest number of chemists as a distinct substance from phlogiston.

297 Priestley, Soon after this, a phenomenon, which had been observed from the earliest ages, and which probably, for that very reason, had been neglected, began to be attended to; that combustibles would not burn except in contact with air. Dr Priestley observed, that the air in which combustibles had been suffered to burn till they were extinguished, had undergone a very remarkable change; for no combustible would afterwards burn in it, and no annimal could breathe it without suffocation (K). He concluded, as Dr Rutherford had done before him, that this change was owing to phlogiston; that the air had combined with that substance; and that air was necessary to combustion, by attracting the phlogiston, for which it had a strong affinity. If so, phlogiston could not be light any more than caloric; for if it separated from the combustible merely by combining with air, it could not surely display itself in the form of light. The question then recurred with double force, What is phlogiston? Dr

298 And Crawford. Crawford, of whose ingenious experiments on the specific caloric of bodies we have already given an account, without attempting to answer this question, made a considerable improvement in the theory of combustion, by supposing that the phlogiston of the combustible combined with the air, and at the same time separated the caloric and light with which that fluid had been previously united. The heat and the light, then, which appeared during combustion, existed previously in the air. This theory was very different from Stahl's, and certainly a great deal more satisfactory. But still the question, What is phlogiston? remained to be an-

299 Kirwan's theory of phlogiston swered. Mr Kirwan, who had already raised himself to the first rank among chemical philosophers by many important discoveries, and many ingenious investigations of some of the most difficult parts of chemistry, attempted to answer this question, and to prove that phlogiston was the same with hydrogen *. The subject was now brought to a state capable of the most complete decision. Does hydrogen actually exist in all combustible substances? and is it separated from them during every combustion? The French chemists who answered his treatise, shewed that this is by no means the case; and that therefore there was no proof whatever of the identity of phlogiston and hydrogen. And Mr Kirwan in consequence, with that candour which distinguishes superior minds, gave up his opinion as untenable.

* In his *Treatise on Phlogiston.*

300 Refuted.

Mr Lavoisier had already put the question, What proof is there of the existence of phlogiston at all? There is only this single proof, that substances after combustion are different from what they formerly were. That this difference takes place is certainly true; but it is owing, not to the separation of any substance, but to the combination of one. It follows, therefore, that there is no proof whatever of the existence of any such substance as *phlogiston* in nature; and of course we must conclude that no such substance exists (L). 301 Existence of phlogiston disproved.

15. It is well known that heat is produced by the percussion of hard bodies against each other. When a piece of iron is smartly and quickly struck with a hammer, it becomes red hot; and the production of sparks by the collision of flint and steel is too familiar a fact to require being mentioned. No heat, however, has ever been observed to follow the percussion of liquids, nor of soft bodies which easily yield to the stroke. 302 Production of caloric by percussion,

It has long been known, that hammering increases the density of metals. The specific gravity of iron before hammering is 7,788; after being hammered, 7,840: that of platinum before hammering is 19,50; after it, 23,00. Now condensation diminishes the specific caloric of bodies. After one of the clay pieces used in Wedgewood's thermometer has been heated to 120°, it is reduced to one half of its former bulk, though it has lost only two grains of its weight, and its specific caloric is at the same time diminished one third †. But we cannot conceive the specific caloric of a body to be diminished without its giving out at the same time a quantity 303 Owing partly to condensation,

† *T. Wedgewood, Phil. Transf.* 1792.

(K) These very observations had been made almost a century before by Mayow; but chemistry was then in its infancy; little attention was paid to them, and they had been forgotten.

(L) Mr Lavoisier was therefore the author of what is called the *antiphlogistic theory* in chemistry, or the theory which accounts for the phenomena of chemistry without the assistance of phlogiston. It has been so called in opposition to the theory of Stahl, which explained every thing by means of *phlogiston*, and which is therefore called the *phlogistic theory*.

Some chemists have affected to omit Lavoisier's name altogether, when they spoke of the antiphlogistic theory. According to them, that theory was founded upon the experiments and discoveries of other chemists, and Lavoisier had no other merit but that of bringing it into public notice.

That Mr Lavoisier, virtually at least, claimed several of the discoveries of others, we are sorry to be under the necessity of acknowledging; and that many of the experiments, brought forward to disprove the existence of phlogiston, were first made by others, is known to all the world: but it is equally evident, that the first person who actually formed the theory was Lavoisier; and surely the merit lies in that. It is not those who collect the stones, and the timber, and the mortar, but he who lays the plan, and shews how to put the materials together, that is in reality the builder of the house. Who did not know, as well as Newton, that a stone fell to the ground, and that the planets revolved round the sun? and yet, who but Newton could have formed the theory of gravitation? We would not be understood to detract any thing from the merit of the other illustrious philosophers who have adorned the present age, many of whom are at least equal, and some of them superior to Lavoisier: But we are afraid that envy, or some worse motive, guided the pen of *one* at least of the most active and virulent antagonists of that illustrious and unfortunate philosopher. It must not, however, be concealed, that his theory of combustion is incomplete. See COMBUSTION in this *Supplement*.

Caloric. quantity of caloric; and we know for certain that caloric is evolved during condensation. A thermometer placed within a condenser rises several degrees every time air is thrown in *. We can even see a reason for this. When the particles of a body are forced nearer each other, the repulsive power of the caloric combined with them is increased, and consequently a part of it will be apt to fly off. Now, after a bar of iron has been heated by the hammer, it is much harder and brittler than before. It must then have become denser, and consequently must have parted with caloric. It is an additional confirmation of this, that the same bar cannot be heated a second time by percussion until it has been exposed for some time to a red heat. It is too brittle, and flies to pieces under the hammer. Now brittleness seems in most cases owing to the absence of the usual quantity of caloric. Glass *unannealed*, or, which is the same thing, that has been cooled very quickly, is always extremely brittle. When glass is in a state of fusion, there is a vast quantity of caloric accumulated in it, the repulsion between the particles of which must of course be very great; so great indeed, that they would be disposed to fly off in every direction with inconceivable velocity, were they not confined by an unusually great quantity of caloric in the surrounding bodies: consequently if this surrounding caloric be removed, the caloric of the glass flies off at once, and more caloric will leave the glass than otherwise would leave it, because the velocity of the particles must be greatly increased. Probably then the brittleness of glass is owing to the deficiency of caloric; and we can scarcely doubt that the brittleness of iron is owing to the same cause, if we recollect that it is removed by the application of new caloric. Part therefore of the caloric which appears in consequence of percussion seems to proceed from the body struck; and this is doubtless the reason why those bodies, the density of which is not increased by percussion, as liquids and soft substances, are not heated at all.

* Darwin, *Phil. Transf.* 1788.

304 And partly to combustion.

We say *part* of the caloric, because, often at least, part of it is probably owing to another cause. By condensation, as much caloric is evolved as is sufficient to raise the temperature of some of the particles of the body high enough to enable it to combine with the oxygen of the atmosphere. The combination actually takes place, and a great quantity of additional caloric is separated by the decomposition of the gas. That this happens during the collision of flint and steel cannot be doubted; for the sparks produced are merely small pieces of iron heated red hot by uniting with oxygen during their passage through the air, as any one may convince himself by actually examining them. Mr Lane has shewn that iron produces no sparks in the vacuum of an air-pump; but Mr Kirwan has observed that they are produced under common spring water; and we know that iron at a certain temperature is capable of decomposing water.

305 Sparks emitted by quartz stones on elision.

When quartz, rock-crystal (M), or other very hard stones, are struck against one another they emit sparks. If they be often made to emit sparks above a sheet of white paper, there are found upon it a number of small black bodies, not very unlike the eggs of flies. These bodies are hard but friable, and when rubbed on the paper leave a black stain. When viewed with a microscope, they seem to have been melted. Muriatic acid changes their colour to a green, as it does that of lavas *. These substances evidently produced the sparks by being heated red hot. Lamanon (N) supposes that they are particles of quartz combined with oxygen. Were that the case, the phenomenon would be precisely similar to that which is produced by the collision of flint and steel. That they are particles of quartz cannot be doubted; but to suppose them combined with oxygen is contrary to all experience: for these stones never shew any disposition to combine with oxygen even when exposed to the most violent heat. La Metherie made experiments on purpose to see whether Lamanon's opinion was well founded; but they all turned out unfavourable to it. And Mongé ascertained, that the particles described by Lamanon were pure crystal unaltered, with a quantity of black powder adhering to them. 306 He concludes accordingly, that these fragments had been raised to so high a temperature during their passage through the air, that they set fire to all the minute bodies that came in their way †. We must therefore either suppose that all the caloric was produced by mere condensation, which is not probable, or acknowledge that we cannot explain the phenomenon.

* Lamanon, *Journ. de Phys.* 1785.

306 Cause of this unknown.

† *Ann. de Chim.* xvi. 206.

307 Emission of caloric on friction.

16. Caloric is not only produced by percussion, but also by friction. Fires are often kindled by rubbing pieces of dry wood smartly against one another. It is well known that heavy loaded carts sometimes take fire by the friction between the axle-tree and the wheel. Now in what manner is the caloric evolved or accumulated by friction? Not by increasing the density of the bodies rubbed against each other, as happens in cases of percussion; for heat is produced by rubbing soft bodies against each other, the density of which therefore cannot be increased by that means, as any one may convince himself by rubbing his hand smartly against his coat. It is true, indeed, that heat is not produced by the friction of liquids, but then they are too yielding to

308 Not owing to condensation,

(M) These stones are composed of almost pure silica.

(N) This ingenious and unfortunate young man, to whom we are indebted for these facts, fell a victim to his ardour for knowledge. He accompanied La Perouse in his last voyage, and was murdered with the most savage cruelty, together with La Langle and several others, by the natives of the island of Maouna. When a man of genius, anxious to acquire honest fame, and a man too so nobly disinterested as Lamanon, thus falls prematurely before he has attained the object of his wishes,

" Cut off from nature's and from glory's course!
" Which never mortal was so fond to run,"

who can withhold the tribute of regret and admiration, when they

—— " Conjecture what he might have proved,
" And think life only wanting to his fame."

Caloric.

309 Nor to decrease of specific caloric,

to be subjected to strong friction. It is not owing to the specific caloric of the rubbed bodies decreasing; for Count Rumford found that there was no sensible decrease *, nor, if there were a decrease, would it be sufficient to account for the vast quantity of heat which is sometimes produced by friction.

* Nicholson's Journ. ii. 106.

Count Rumford took a cannon cast solid and rough as it came from the foundery; he caused its extremity to be cut off, and formed, in that part, a solid cylinder attached to the cannon $7\frac{3}{4}$ inches in diameter and $9\frac{8}{10}$ inches long. It remained joined to the rest of the metal by a small cylindrical neck. In this cylinder a hole was bored 3,7 inches in diameter and 7,2 inches in length. Into this hole was put a blunt steel borer, which by means of horses was made to rub against its bottom; at the same time a small hole was made in the cylinder perpendicular to the bore, and ending in the solid part a little beyond the end of the bore. This was for introducing a thermometer to measure the heat of the cylinder. The cylinder was wrapt round with flannel to keep in the heat. The borer pressed against the bottom of the hole with a force equal to about 10,000 lb. avoirdupois, and the cylinder was turned round at the rate of 32 times in a minute. At the beginning of the experiment the temperature of the cylinder was 60°; at the end of 30 minutes, when it had made 960 revolutions, its temperature was 130°. The quantity of metallic dust or scales produced by this friction amounted to 837 grains. Now, if we were to suppose that all the caloric was evolved from these scales, as they amounted to just $\frac{1}{948}$ part of the cylinder, they must have given out 948° to raise the cylinder 1°, and consequently 66360° to raise it 70° or to 130°, which is certainly incredible †.

† Ibid.

310 Nor to combustion;

Neither is the caloric evolved during friction owing to the combination of oxygen with the bodies themselves or any part of them. By means of a piece of clock-work, Mr Pictet made small cups (fixed on the axis of one of the wheels) to move round with considerable rapidity, and he made various substances rub against the outsides of these cups, while the bulb of a very delicate thermometer placed within them marked the heat produced. The whole machine was of a size sufficiently small to be introduced into the receiver of an air-pump. By means of this machine a piece of adamantine spar was made to rub against a steel cup in air: sparks were produced in great abundance during the whole time, but the thermometer did not rise. The same experiment was repeated in the exhausted receiver of an air-pump (the manometer standing at four lines); no sparks were produced, but a kind of phosphoric light was visible in the dark. The thermometer did not rise. A piece of brass being made to rub in the same manner against a much smaller brass cup in air, the thermometer (which almost filled the cup) rose 0,3°, but did not begin to rise till the friction was over. This shews us that the motion produced in the air carried off the caloric as it was evolved. In the exhausted receiver it began to rise the moment the friction began, and rose in all 1,2°. When a bit of wood was made to rub against the brass cup in the air, the thermometer rose 0,7°, and on substituting also a wooden cup it rose 2,1°, and in the exhausted receiver 2,4°, and in air condensed to $1\frac{1}{4}$ atmospheres it rose 0,5° *.

* *Pictet sur le Feu*, ch. 9.

If these experiments be not thought conclusive, we have others to relate, which will not leave a doubt that the heat produced by friction is not connected with the decomposition of oxygen gas. Count Rumford contrived, with his usual ingenuity, to enclose the cylinder above described in a wooden box filled with water, which effectually excluded all air, as the cylinder itself and the borer were surrounded with water, and at the same time did not impede the motion of the instrument. The quantity of water amounted to 18,77 lbs. avoirdupois, and at the beginning of the experiment was at the temperature of 60°. After the cylinder had revolved for an hour at the rate of 32 times in a minute, the temperature of the water was 107°; in 30 minutes more it was 178°; and in 2 hours and 30 minutes after the experiment began, the water *actually boiled*. According to the computation of Count Rumford, the caloric produced would have been sufficient to heat 26,58 lbs. avoirdupois of ice-cold water boiling hot; and it would have required 9 wax candles of a moderate size, burning with a clear flame all the time the experiment lasted, to have produced as much heat. In this experiment all access of water into the hole in the cylinder where the friction took place was prevented. But in another experiment, the result of which was precisely the same, the water was allowed free access *.

* *Nicholson, ibid.*

311 And consequently at present inexplicable.

The caloric, then, which appears in consequence of friction, is neither produced by an increase of the density, nor by an alteration in the specific caloric of the substances exposed to friction, nor is it owing to the decomposition of the oxygen of the atmosphere.—Whence then is it derived? This question we are altogether unable to answer. We cannot, however, think that the conclusion which Count Rumford is disposed to draw from his experiments is warranted by the premises. He supposes, that because we cannot explain the manner that caloric is accumulated by friction, there is no such substance as caloric at all, but that it is merely a *peculiar kind of motion*. We would beg leave to ask, how the facts mentioned in the former part of this chapter, many of which were furnished by this ingenious philosopher himself, and all of which combine to render the existence of caloric as a substance probable, can be destroyed and set aside, merely because there are other phenomena in nature connected with caloric which cannot be accounted for? Were it possible to prove that the accumulation of caloric by friction is *incompatible* with its being a substance, in that case Count Rumford's conclusion would be a fair one; but this surely has not been done. We are certainly not yet sufficiently acquainted with the laws of the motion of caloric (allowing it to be a substance) to be able to affirm with certainty that friction could not cause it to accumulate in the bodies rubbed. This we know at least to be the case with electricity. Nobody has been hitherto able to demonstrate, in what manner it is accumulated by friction; and yet this has not been thought a sufficient reason to deny its existence.

312 This no proof that caloric is not a body.

313 Analogy between caloric and electricity.

Indeed there seems to be a very close analogy between caloric and electric matter. Both of them tend to diffuse themselves equally, both of them dilate bodies, both of them fuse metals, and both of them kindle combustible substances. Mr Achard has proved, that electricity can be substituted for caloric even in those cases where its agency seems peculiarly necessary; for he found that, by constantly supplying a certain quantity of the electric fluid, eggs could be hatched just as when they are kept

Caloric.

kept at the temperature of 103°. An accident indeed prevented the chickens from actually coming out; but they were formed and living, and within two days of bursting their shell. Electricity has also a great deal of influence on the heating and cooling of bodies. Mr Pictet exhausted a glass globe, the capacity of which was 1200,199 cubic inches, till the manometer within it stood at 1,75 lines. In the middle of this globe was suspended a thermometer which hung from the top of a glass rod fixed at the bottom of the globe, and going almost to its top. Opposite to the bulb of this thermometer two lighted candles were placed, the rays of which, by means of two concave mirrors, were concentrated on the bulb The candles and the globe were placed on the same board, which was supported by a non-conductor of electricity. Two feet and a half from the globe there was an electrifying machine, which communicated with a brass ring at the mouth of the globe by means of a metallic conductor. This machine was kept working during the whole time of the experiment; and consequently a quantity of electric matter was constantly passing into the globe, which formed an atmosphere not only within it, but at some distance round, as was evident from the imperfect manner in which the candles burned. When the experiment began the thermometer stood at 49,8°. It rose to 70,2° in 732″. The same experiment was repeated, but no electric matter thrown in; the thermometer rose from 49,8° to 70,2° in 1050″; so that the electricity hastened the heating almost a third. In the first experiment the thermometer rose only to 71,3°, but in the second it rose to 77°. This difference was doubtless owing to the candles burning better in the second than the first experiment; for in other two experiments made exactly in the same manner, the maximum was equal both when there was and was not electric matter present. These experiments were repeated with this difference, that the candles were now insulated, by placing their candlesticks in dishes of varnished glass. The thermometer rose in the electrical vacuum from 52,2° to 74,7° in 1050″; in the simple vacuum in 965″. In the electrical vacuum the thermometer rose to 77°; in the simple vacuum to 86°. It follows from these experiments, that when the globe and the candles communicated with each other, electricity hastened the heating of the thermometer; but that when they were insulated separately, it retarded it *. One would be apt to suspect the agency of electricity in the following experiment of Mr Pictet: Into one of the brass cups formerly described, a small quantity of cotton was put to prevent the bulb of the thermometer from being broken. As the cup turned round, two or three fibres of the cotton rubbed against the bulb, and without any other friction the thermometer rose five or six degrees. A greater quantity of cotton being made to rub against the bulb, the thermometer rose 15 degrees †.

* *Pictet sur le Feu.* ch. 6.

† *Ibid.* ch. 9.

314 Electricity may be an agent in the heating of bodies by friction.

We do not mean to draw any other conclusion from these facts, than that electricity is very often concerned in the heating of bodies, and that probably some such agent is employed in accumulating the heat produced by friction. Supposing that electricity is actually a substance, and taking it for granted that it is different from caloric, does it not in all probability contain caloric as well as all other bodies? Has it not a tendency to accumulate in all bodies on friction, whether conductors or non-conductors? May it not then be accumulated in those bodies which are rubbed against one another? or, if they are good conductors, may it not pass through them during the friction in great quantities? May it not part with some of its caloric to these bodies, either on account of their greater affinity or some other cause? and may not this be the source of the caloric which appears during friction?

Light.

CHAP. VI. *Of* LIGHT.

315 Newtonian theory of light.

By means of *light* bodies are rendered visible. Light has been considered as a substance composed of small particles moving in straight lines from luminous bodies with inconceivable rapidity. The discoveries of Newton established this opinion on the firm basis of mathematical demonstration; and since his time it has been generally embraced. Huyghens, indeed, and Euler, advanced another (o). They considered light as a subtile fluid, filling all space, which rendered bodies visible by its undulations. But they supported their hypothesis rather by starting objections to the theory of Newton, than by bringing forward direct proofs. Their objections, even if valid, instead of establishing their own opinions, would prove only that the phenomena of light are not completely understood; a truth which no man will refuse to acknowledge, whatever side of the question he adopts. Newton and his disciples, on the contrary, have shewn that the known phenomena of light are *inconsistent* with the undulations of a fluid, and have brought forward a great number of direct arguments, which it has been impossible to answer, in support of their theory. It can hardly be doubted, therefore, that the Newtonian theory of light is the true one.

316 Velocity of light.

Dr Bradley, who, by a number of very accurate experiments, and a process of reasoning peculiarly ingenious, discovered the aberration of light of the fixed stars, has shewn from it that the velocity of light is to that of the earth in its orbit as 10313 to 1. Light therefore moves at the rate of 195218 miles in a second.

317 Divisible into seven rays.

Light, by means of a prism, may be separated into seven rays, differing from each other in colour; red, orange, yellow, green, blue, indigo, violet. None of these are capable of farther decomposition. Marat, indeed, pretended that he had reduced them to three; but his experiments are now known to have been merely philosophical frauds.

318 Differing in refrangibility.

When light passes obliquely into a denser medium, it is *refracted towards* the perpendicular; when into a rarer, *from* the perpendicular. Sir Isaac Newton discovered that the rays differed in their refrangibility in the order in which they have been named, the red being the least, the violet the most refrangible. Mr Blair has observed, that the ratios of the refrangibility of the different rays, though not their order, vary somewhat in different mediums *.

* *Edinburgh Phil. Trans.* iii.

When light passes within a certain distance of a body, parallel

(o) Dr Franklin did the same, without taking any notice of these philosophers, of whose opinions perhaps he was ignorant. See *Trans. Philad.* III. 5.

Light.

parallel to which it is moving, it is bent *towards* it; when it passes at a greater distance, it is bent *from* it.

319 Inflection, deflection,

The first of these properties is called *inflection*, the second *deflection*. Now the rays differ in these properties in the order in which they were named; the red being *most*, the violet *least*, inflexible and deflexible. This was suspected by David Rittenhouse *, but was first demonstrated by the ingenious experiments of Mr Brougham †.

* *Transf. Philad.* ii.

† *Phil. Transf.* 1796.

320 And reflexity.

When light falls upon a visible body, some of it is reflected back; and the more polished or the whiter any surface is, the more light it reflects. The rays of light differ also in reflexity, the red being the most, the violet the least reflexible. This discovery we owe to the same ingenious gentleman ‡.

‡ *Phil. Transf.* 1796.

These properties of light constitute the subject of Optics; to which we refer those who wish to see them investigated. We mention them here because they prove that light is acted on by other bodies, that it is subjected to the laws of attraction, and consequently that it possesses *gravity*.

2. The particles of light seem also, like those of caloric, to possess the property of repelling one another; at least their rapid motion, in all directions, from luminous bodies, seems to be owing to some such property.

321 Light capable of entering bodies,

3. Light is capable of entering into bodies, and remaining in them, and of being afterwards extricated without any alteration. Father Beccaria, and several other philosophers, have shewn us by their experiments, that there are a great many substances which become luminous after being exposed to the light. This property was discovered by carrying them instantly from the light into a dark place, or by darkening the chamber in which they were exposed. Most of these substances, indeed, lose this property in a very short time, but they recover it again on being exposed to the light; and this may be repeated as often as we please. We are indebted to Mr Canton for some very interesting experiments on this subject, and for discovering a composition which possesses this property in a remarkable degree. He calcined some common oyster shells in a good coal fire for half an hour, and then pounded and sifted the purest part of them. Three parts of this powder were mixed with one part of the flowers of sulphur, and rammed into a crucible which was kept red hot for an hour. The brightest parts of the mixture were then scraped off, and kept for use in a dry phial well stopped. When this composition is exposed for a few seconds to the light, it becomes sufficiently luminous to enable a person to distinguish the hour on a watch by it. After some time it ceases to shine, but recovers this property on being again exposed to the light. Light then is not only acted upon by other bodies, but it is capable of uniting with them, and afterwards leaving them without any change.

It is well known that light is emitted during combustion; and it has been objected to this conclusion, that these bodies are luminous only from a slow and imperceptible combustion. But surely combustion cannot be suspected in many of Father Beccaria's experiments, when we reflect that one of the bodies on which they were made was his own hand, and that many of the others were altogether incombustible; and the phenomena observed by Mr Canton are also incompatible with the notion of combustion. His pyrophorus shone only in consequence of being exposed to light, and lost that property by being kept in the dark. It is not exposure to light which causes substances capable of combustion at the temperature of the atmosphere to become luminous, but exposure to air. If the same temperature continues, they do not cease to shine till they are consumed; and if they cease, it is not the application of light, but of caloric, which renders them again luminous: but Canton's pyrophorus, on the contrary, when it had lost its property of shining, did not recover it by the application of heat, except it was accompanied by light. The only effect which heat had was to increase the separation of light from the pyrophorus, and of course to shorten the duration of its luminousness. Two glass globes, hermetically sealed, containing each some of this pyrophorus, were exposed to the light and carried into a dark room. One of them, on being immersed in a bason of boiling water, became much brighter than the other, but in ten minutes it ceased to give out light; the other remained visible for more than two hours. After having been kept in the dark for two days, they were both plunged into a bason of hot water; the pyrophorus which had been in the water formerly did not shine, but the other became luminous, and continued to give out light for a considerable time. Neither of them afterwards shone by the application of hot water; but when brought near to an iron heated so as scarcely to be visible in the dark, they suddenly gave out their remaining light, and never shone more by the same treatment: but when exposed a second time to the light, they exhibited over again precisely the same phenomena; even a lighted candle and electricity communicated some light to them. Surely these facts are altogether incompatible with combustion, and fully sufficient to convince us that light alone was the agent, and that it had actually entered into the luminous bodies.

It has been questioned, indeed, whether the light emitted by pyrophori be the same with that to which they are exposed. Mr Wilson has proved, that in many cases at least it is different, and in particular that on many pyrophori the blue rays have a greater effect than any other, and that they cause an extrication of red light. Mr de Grosser has shewn the same thing with regard to the diamond, which is a natural pyrophorus *. Still, however, it cannot be questioned that the luminousness of these bodies is owing to exposure to light, and that the phenomenon is not connected with combustion.

* *Jour. de Phys.* xx. 270.

322 And of being combined with them.

But light appears capable, not only of entering into bodies, but of combining with them chemically. The phenomena of the phosphori seem to be instances of this, and a great many facts concur to prove that light enters into the composition of oxygen gas. When vegetables grow in the light, they give out oxygen gas; but no oxygen is extricated in the dark, even though heat be applied †. From this it is evident, that the separation of this gas from plants, or perhaps the decomposition of the water which they contain, depends upon the action of light; and that as this decomposition is chemical, the light to produce it must either combine with the oxygen or the hydrogen, or at least contribute to the combination of some other substance with one or other of them. When the oxides of gold or silver are exposed to light, they are reduced to the metallic state ‡, and at the same time a quantity of oxygen gas is extricated.

† *Priestley and Ingenhousz.*

‡ *Scheele.*

Light.

cated *. In this case, it is evident that the light must either combine with the oxygen or the metals. If a quantity of nitric acid be exposed for some time to the light, it becomes yellow, as is well known, and a quantity of oxygen gas is found floating on its top. If it be now carried to a dark place, the oxygen is gradually absorbed, and the acid becomes colourless. In this case, nitric acid is decomposed by means of light, and resolved into *nitrous acid* and oxygen gas. The light must therefore have combined either with the nitrous acid or the oxygen. But no change whatever appears to have been produced in the nitrous acid; for if it be obtained in the dark by any other process, it has precisely the same properties. The oxygen, on the contrary, is converted into a *gas*. It is more probable, then, that the light has combined with the oxygen than with the acid. Hence there is reason to suspect that light makes one of the ingredients of oxygen gas. Caloric has already been shewn to make another ingredient.

* Berthollet.

323 Light which appears during combustion supposed combined with oxygen gas.

During combustion, a quantity of light as well as caloric is almost always evolved. We must conclude, therefore, that light makes a part of the composition either of the combustibles themselves, or of the oxygen gas with which they unite. We have already shewn that oxygen gas probably contains light; and this probability is confirmed by another fact. Substances may be combined with oxygen without the emission of any light, provided the oxygen be not in the state of a gas. If phosphorus, for instance, be put into nitric acid, it attracts oxygen, and is converted into phosphoric acid without the emission of any light. Now if the light which appears during combustion had been combined with the combustible, it ought to appear in all cases when that combustible is united with oxygen, whether the oxygen has previously been in the state of a gas or not. But as this is not the case, we may certainly infer, that the light which appears during combustion is extricated, not from the combustible, but from the oxygen gas. And this seems at present to be the opinion of the greater number of philosophers.

But we must acknowledge, that this conclusion is not without its difficulties, and difficulties, too, which, in the present state of chemistry, it does not seem possible to surmount.

324 Difficulties attending this opinion.

In the first place, it is evident, that light *may* be produced during combustion, though the oxygen be not in the state of a gas: For if nitric acid be poured upon oil of turpentine, the oil takes fire, and burns with the greatest rapidity, and a great deal of light is emitted. This combustion is occasioned by the oxygen of the acid combining with the ingredients of the oil. It follows, therefore, if the light emitted was previously combined with the oxygen, that oxygen must contain light when not in the state of a gas. Mr Proust has shewn that a great variety of similar combustions may be produced. But what is very remarkable, by proper caution the very same combinations may be made to take place without the visible emission of any light. In that case they take place very slowly, as happens also when phosphorus decomposes nitric acid; so that the emission or non-emission of light seems to depend not upon the state of the oxygen, so much as upon the rapidity or slowness of the combination. It is true, indeed, as the late Dr Hutton of Edinburgh observed, that light may be emitted in these slow combinations though it be not visible; and this is very probably the case: but then the proof is destroyed that light exists in oxygen gas, from its not appearing during combinations in which the oxygen did not exist previously in a gaseous state.

In the second place, the colour of the light emitted during combustion differs almost always according to the combustible. During the combustion of phosphorus, tin, and zinc, the light emitted is white; during that of sulphur and bismuth, blue. Now if this light were united with the oxygen, why does it not appear always of the same colour, whatever be the combustible?

In the last place, the phenomena of phosphori shew that light is capable of entering into other bodies as well as oxygen gas; and the emission of light on the collision of two flint stones, when no oxygen gas can be decomposed, is a proof of the same kind, which cannot be got over.

In the present state of chemistry, therefore, it cannot be concluded, that the light emitted during combustion does not exist in the combustibles as well as in the oxygen.

325 Light heats bodies.

4. Light has the property of heating bodies. All bodies, however, are not heated by it. Those which are perfectly transparent, or which allow all the light to pass throw them, suffer no alteration in their temperature. Thus light may be concentrated upon water or glass without producing any effect. Neither does it produce much change upon those bodies (mirrors for instance) that reflect all or nearly all the light which falls upon them. And the smallness of the alteration of temperature is always proportional to the fineness of the polish, or, which is the same thing, to the quantity of light which is reflected. So that we have reason to conclude, that if a substance could be procured which reflected all the light that fell upon it, the temperature of such a substance would not be at all affected by light falling upon it. Dr Franklin exposed upon snow pieces of cloth of different colours (white, red, blue, black) to the light of the sun, and found that they sunk deeper, and consequently acquired heat, in proportion to the darkness of their colour. Now it is well known that dark-coloured bodies, even when equally exposed to the light, reflect less of it than those which are light-coloured. But since the same quantity falls upon each, it is evident that dark-coloured bodies must absorb and retain more of it than those which are light-coloured. That such an absorption actually takes place is evident from the following experiment. Mr Thomas Wedgewood placed two lumps of luminous or phosphorescent marble on a piece of iron heated just under redness. One of the lumps of marble which was blackened over gave out no light; the other gave out a great deal. On being exposed a second time in the same manner, a faint light was seen to proceed from the clean marble, but none at all could be perceived to come from the other. The black was now wiped off, and both the lumps of marble were again placed on the hot iron: The one that had been blackened gave out just as little light as the other *. In this case, the light which ought to have proceeded from the luminous marble disappeared: it must therefore have been stopped in its passage out, and retained by the black paint. Now black substances are those which absorb the most light, and they are the bodies which are most heated by exposure to light. Cavallo observed, that a thermometer

* Phil. Trans. 1792.

thermometer with its bulb blackened ſtands higher than one which has its bulb clean, when expoſed to the light of the ſun, the light of day, or the light of a lamp *. Mr Pictet made the ſame obſervation; and took care to aſcertain, that when the two thermometers were allowed to remain for ſome time in a dark place, they acquired preciſely the ſame height. He obſerved, too, that when both thermometers had been raiſed a certain number of degrees, the clean one fell a good deal faſter than the other †. But it is not a ſmall degree of heat alone which can be produced by means of light. When its rays are concentrated by a burning-glaſs, they are capable of ſetting fire to combuſtibles with eaſe, and even of producing a temperature at leaſt as great, if not greater, than what can be procured by the moſt violent and beſt conducted fires. In order to produce this effect, however, they muſt be directed upon ſome body capable of abſorbing and retaining them; for when they are concentrated upon tranſparent bodies, or upon fluids, mere air for inſtance, they produce little or no effect whatever. We may conclude, therefore, in general, that in all caſes when light produces heat it is abſorbed.

* Phil. Tranſ. 1780.

† Sur le Feu, ch. 4.

326

Heat renders bodies luminous,

5. All bodies become luminous when their temperature is raiſed a certain number of degrees. No fact is more familiar than this; ſo well known indeed is it, that little attention has been paid to it. When a body becomes luminous by being heated in a fire, it is ſaid in common language to be *red hot*. It follows from all the experiments hitherto made, that the temperature at which they become red hed hot is nearly the ſame in all bodies.—It ſeems to be, pretty near 800°. A red hot body continues to ſhine for ſome time after it has been taken from the fire and put into a dark place. The conſtant acceſſion, then, either of light or heat is not neceſſary for the ſhining of bodies: but if a red hot body be blown upon by a ſtrong current of air, it ceaſes to ſhine immediately ‡. Conſequently the moment the temperature of a body is diminiſhed by a certain number of degrees, it ceaſes to be luminous.

‡ T. Wedgewood, Phil. Tranſ. 1792.

Whenever a body reaches the proper temperature, it becomes luminous, independent of any contact of air; for a piece of iron wire becomes red hot while immerſed in melted lead §.

§ Id. ibid.

327

Except the gaſes.

To this general law there is one remarkable exception. It does not appear that the gaſes become luminous even at a much higher temperature. The following ingenious experiment of Mr T. Wedgewood ſeems to ſet the truth of this exception in a very clear point of view. He took an earthen ware tube B (fig. 5.), bent ſo in the middle that it could be ſunk, and make ſeveral turns in the large crucible C, which was filled with ſand. To one end of this tube was fixed the pair of bellows A; at the other end was the globular veſſel D, in which was the paſſage F, furniſhed with a valve to allow air to paſs out, but none to enter. There was another opening in this globular veſſel filled with glaſs, that one might ſee what was going on within. The crucible was put into a fire; and after the ſand had become red hot, the air was blown through the earthen tube by means of the bellows. This air, after paſſing through the red hot ſand, came into the globular veſſel. It did not ſhine; but when a piece of gold wire E was hung at that part of the veſſel where the earthen ware tube entered, it became faintly luminous. A proof, that though the air was not luminous, it had been hot enough to raiſe other bodies to the ſhining temperature.

328

Inquiry into the cauſe of theſe phenomena.

6. Thus it appears that light and heat reciprocally produce each other; that the fixation of light in bodies always produces heat, and that the application of a ſufficiently ſtrong heat always occaſions the extrication of light. Are heat and light, then, owing to the ſame cauſe? Does light become caloric merely by being fixed in bodies? and does caloric aſſume the appearance of light whenever it is extricated from them? In ſhort, are caloric and light merely names for the ſame ſubſtance, called *caloric* when it is fixed in bodies, and *light* when in a ſtate of liberty?

To theſe queſtions it may be anſwered, That if caloric and light were one and the ſame ſubſtance, they ought to produce preciſely the ſame effects. Now this is not the caſe: a black body is not heated ſooner by mere caloric than any other, though the contrary takes place when both are expoſed to the light *. Heat cannot make growing vegetables exhale oxygen gas, though light does it almoſt inſtantaneouſly. When oxy-muriatic acid (a compound of oxygen and muriatic acid) is expoſed to the light, a quantity of oxygen gas flies off, and nothing remains but common muriatic acid. Light then decompoſes this acid; for if you wrap up a bottle in black cloth, ſo as to exclude light, and then expoſe it equally to the ſun, no ſuch decompoſition takes place. Now this decompoſition cannot be produced by mere caloric. If the acid be heated, it ſimply evaporates without being altered. Chaptal has proved (P), that the rays of light directed on certain parts of glaſſes, containing ſolutions of ſalts, cauſe them to cryſtallize in that part in preference to any other †. Theſe obſervations have been confirmed and extended by Mr Dorthes ‡. Now caloric produces no ſuch effects, nor has the temperature any influence on the phenomenon.

* T. Wedgewood, Phil. Tranſ. 1792.

† Mem. Toulouſe, iii.

‡ Ann. de Chim. ii. 32.

Theſe facts are ſufficient to ſhew that light and caloric, even when they have entered into bodies, produce different effects, and that therefore they have different properties (Q). But if the only difference between them were, that the one is in a ſtate of liberty, the other in that of combination, the moment light entered a body it ought to be no longer light but caloric, and conſequently ought to produce preciſely the ſame effects with caloric: And ſince this is not the caſe, we are warranted ſurely to conclude that light and caloric are not the ſame, but

(P) Petit made the ſame obſervations in 1722. See *Memoirs of the Academy of Sciences* for that year, p. 95. and 331.

(Q) We muſt acknowledge, however, that the following ingenious experiments of Profeſſor Pictet might be adduced, to prove that light and caloric poſſeſs at leaſt *one* property in common, that of moving in ſtraight lines.

He placed two concave mirrors of tin, of nine inches focus, at the diſtance of twelve feet two inches from one another. In the focus of one of them he placed a ball of iron two inches in diameter, heated ſo as not to be viſible

Light.

but different substances (R). How then does caloric occasion the appearance of light, and light that of caloric?

329 Supposed owing to the mutual repulsion of light and caloric.

We have seen already, that there is no body in nature which does not contain caloric; and light has such an influence upon every thing, it produces such important changes upon the animal and vegetable kingdoms, it can be extricated from such a vast number of bodies, that in all probability we may conclude with regard to it also, that it exists in all, or in almost all, the bodies in nature. We have no means of ascertaining either the quantity of light or of caloric that exists in bodies; but if we were to judge from the quantity which appears during combustion, we must reckon it very considerable. Now, may there not exist a repulsion between the particles of caloric and light? It is not easy, at least, to see why light flies off during combustion with such rapidity, if this be not the case. If such a repulsion actually exists, it will follow that caloric and light cannot be accumulated in the same body beyond a certain proportion. If the caloric exceed, it will tend to drive off the light; if the light, on the contrary, happens to prevail, it will displace the caloric.

If caloric and light actually exist in all bodies, there must be an affinity between them and all other bodies; and this affinity must be so great, as to render ineffectual the repulsion which exists between light and caloric. Let us suppose now, that these two substances exist in all bodies in certain proportions, it will follow, that the more either of caloric or light is added to any body, the stronger must the repulsion between their particles become; and if the accumulation be still going on, this repulsion will soon become great enough to balance their affinity for the body in which they exist, and consequently will dispose them to fly off. If caloric, for instance, be added to a body, whenever the body arrives at a certain temperature it becomes luminous, because part of the light which was formerly combined with it is driven off. This temperature must depend partly upon the affinity between the body and caloric, and partly upon its affinity for light. Pyrophori, for instance, the affinity between which and light does not seem to be very great, become luminous at a very moderate temperature. This is the case with the pyrophorus of Canton. A great many hard bodies become luminous when they are exposed to a moderate heat; fluor, for instance, carbonat of barytes, spar, sea-shells, and a great many others, which are enumerated by Mr Thomas Wedgwood *.

The same ingenious gentleman has observed, that gold, silver, copper, and iron, become luminous when heated in times inversely proportional to their specific calorics †. Now the specific calorics of these metals are in the following order:

Iron,
Copper,
Silver,
Gold.

They

* *Phil. Trans.* 1792, p. 1.

† *Ibid.*

visible in the dark; in the other was placed the bulb of a thermometer. In six minutes the thermometer rose from 4° to 14° (*Reaumur*). A lighted candle, which was substituted for the ball of iron, made the thermometer rise in one experiment from 4,6° to 14°; in another, from 4,2° to 14,3°. In this case both light and heat appeared to act. In order to separate them, he interposed between the two mirrors a plate of clear glass. Before the interposition of the glass, the thermometer had risen from 2° to 12°, where it was stationary. After the interposition of the glass it sunk in nine minutes to 5,7°; and when the glass was again removed it rose in seven minutes to 11,1°; yet the light which fell on the thermometer did not seem at all diminished by the glass. Mr Pictet therefore concluded, that the caloric had been reflected by the mirror, and that it had been the cause of the rise of the thermometer. In another experiment, a glass matrass was substituted for the iron ball, nearly of the same diameter with it, and containing 2044 grains of boiling water. Two minutes after a thick screen of silk, which had been interposed between the two mirrors, was removed, a Fahrenheit's thermometer, which was in the other focus, rose from 47° to $50\frac{1}{8}$; and the moment the matrass was removed from the focus the thermometer again descended. On repeating the experiment, with this variation, that the bulb of the thermometer was blackened, it rose from $51\frac{1}{8}$ to $55\frac{1}{4}$.

The mirrors of tin were now placed at the distance of 90 inches from each other; the matrass with the boiling water in one of the foci, and a very sensible air thermometer in the other, every degree of which was equal to $\frac{1}{18}$th of a degree of Reaumur. Exactly in the middle space between the two mirrors, there was placed a very thin common glass mirror, suspended in such a manner that either side could be turned towards the matrass. When the polished side of this mirror was turned to the matrass, the thermometer rose only 0,5°; but when the side covered with tinfoil, and which had been blackened with ink and smoke, was turned toward the matrass, the thermometer rose 3,5°. In another experiment, when the polished side of the mirror was turned to the matrass the thermometer rose 3°, when the other side 9,2°. On rubbing off the tinfoil, and repeating the experiment, the thermometer rose 18°. On substituting for the glass mirror a piece of thin white pasteboard of the same dimensions with it, the thermometer rose 10°. On putting a matrass full of snow into one of the foci (the mirrors in this experiment were $10\frac{1}{2}$ feet distant from each other), the air thermometer *sunk* several degrees, and rose again when the matrass was removed. When nitric acid was poured on the snow, the thermometer sunk 5° or 6° lower.

Taking it for granted that these experiments proved the motion of caloric in straight lines like light, Mr Pictet endeavoured to discover the velocity of its motion. For this purpose he placed two concave mirrors at the distance of 69 feet from each other; the one of tin as before, the other of plaster gilt, and 18 inches in diameter. Into the focus of this last mirror he put the air thermometer, and the bullet of iron heated as before into that of the other. A few inches from the face of the tin mirror there was placed a thick screen, which was removed as soon as the bullet reached the focus. The thermometer rose the instant the screen was removed, without any perceptible interval: hence he concluded, that the time caloric takes in moving 69 feet is too short to be measured. See *Pictet sur le Feu*, chap. iii.

(R) See more on this subject under *Thermometric Spectrum* in this *Supplement*.

Light. They become luminous, therefore, when expofed to the fame degree of heat, in the following order:

Gold,
Silver,
Copper,
Iron.

Now the fmaller the fpecific caloric of any body is, the lefs muft be the quantity of caloric neceffary to raife it a given number of degrees; the fooner therefore muft it arrive at the temperature at which it gives out light. It was natural to expect, then, if the emiffion of light from a body by the application of heat be owing to the repulfion between caloric and light, that thofe bodies fhould become luminous fooneft in which that repulfion increafes with the greateft rapidity; and this we fee is precifely the cafe. The only queftion to be determined before drawing this conclufion is, Whether the fame quantity of caloric entered all of them? That depends upon their conducting power, which, according to Ingenhoufz, is in the following order:

Silver,
Gold,
Copper,
Iron.

We fee, then, that this conducting power is nearly in the order in which thefe metals become luminous; fo that the greateft quantity of caloric would enter thofe which become fooneft luminous. Now this is juft what ought to happen, provided the expulfion of light from a luminous body, by the application of heat, be owing to the repulfion between the particles of caloric and light.

The repulfion between the different rays of light and caloric does not feem to be equal; the repulfion between the blue rays and caloric feems to be greater than that between the red rays and caloric; and the repulfion between all the rays and caloric feems to be directly as their refrangibility: accordingly, when heat is applied to a body, the blue rays efcape fooner, and at a lower temperature, than the red rays and others which are moft refrangible. When fulphur, for inftance, is burnt at a low temperature, the colour of the flame is blue; and when examined by the prifm, it is found to confift of the violet, indigo, blue, and fometimes of a fmall quantity of the green rays*; but when this fubftance is burnt at a high temperature, the colour of the flame is white, all the rays feparating together. When bodies have continued to burn for fome time, they may be fuppofed to have loft the greater part of the moft refrangible rays; hence the red appearance of bodies, charcoal for inftance, that have burnt for fome time, the only rays which remain to feparate being the orange, yellow, and red†.

* *Morgan, Phil. Tranf.* 1785.

† *Ibid.*

The blue rays feem not only to repel caloric with greater force, but likewife to have a greater affinity for other bodies than the red rays have; for they decompofe the oxide of filver (or rather the muriat of filver) much fooner, and to a greater extent, than the red rays‡: hence we fee the reafon why the application of the blue rays to Mr Wilfon's pyrophori and to the diamond caufes an extrication of red rays.

‡ *Sennebier.*

We have feen already, that the gafes are not heated red hot by the application of heat. It would follow from this, that the gafes do not contain light: but the contrary is certain; for light is actually extricated during the combuftion of hydrogen, and muft therefore have exifted either in the oxygen or hydrogen gas, or in both. Probably therefore the reafon that heat does not extricate light from the gafes is, that the affinity between their bafes and light is exceedingly ftrong: it would therefore require a more than ufual temperature to produce its extrication; and on account of the great dilatability of thefe gafes, which always tends to diminifh the repulfion between the caloric and light, this temperature cannot be applied. It is eafy to fee, upon the fuppofition that there exifts a repulfion between caloric and light, why the accumulation of light fhould produce heat, and why light only occafions heat in thofe bodies that abforb it.

Such is the theory of the caufe of the reciprocal extrication of light and caloric by the application of thefe fubftances refpectively to bodies, which has been propofed by feveral ingenious chemifts (s); and we acknowledge frankly, that it appears to us by far the moft plaufible of all the explanations of this phenomenon with which we are acquainted.

330 Objections to which this theory is liable.

It is not, however, beyond the reach of objections, and objections too, we are afraid, altogether incompatible with its truth. Were the repulfion between caloric and light the only caufe of the luminoufnefs of hot bodies, the continual application of heat would furely in time feparate the whole of the light which was combined with the body, and then it would ceafe to be luminous altogether; but we have no reafon to fuppofe that bodies ever ceafe to become luminous by the continued application of heat. Claveus kept melted, and confequently red hot, gold for months in a furnace; but he does not fay that its luminoufnefs was diminifhed, far lefs deftroyed; and had fuch a remarkable phenomenon taken place, certainly he would not have failed to inform us; but fo far from that, he exprefsly fays that it fuffered no alteration (T) §.

§ *Shaw's Boyle*, iii. 268.

Whether light would continue to extricate a great deal of caloric during fo long a time, has never been tried: but we have no reafon for fuppofing that its power to produce that effect is ever exhaufted; for bodies, after being expofed to the fun for years, and even for ages, are juft as much heated by it as ever. But thefe effects, far from being inexhauftible, ought, according to the theory, to come very fpeedily to an end. It is certainly probable, then, as other philofophers have fuppofed, that though light and caloric are not precifely one and the fame fubftance, they are fome how or other intimately connected, and are either compofed of different proportions of the fame ingredients, or the one enters into the compofition of the other.

One

(s) Particularly by Dr Parr, who is faid to be the author of a paper on this fubject, publifhed in the *Exeter Memoirs*.

(T) A gentleman, to whom we mentioned this objection, obferved, that in the cafe of bodies long expofed to heat, the light which appears to proceed from them, might, in fact, be extricated from the atmofphere by the caloric communicated to it from the heated body. This thought is new and ingenious, and might eafily be put to the teft of experiment. Some of the facts mentioned in the text are rather hoftile to it; but fhould it prove well founded, it would go far to remove moft of the difficulties in which the theory of light is at prefent involved.

Light.

331 Scheele's theory of light and caloric.

* In his *Treatise on Fire.*

One of the first theories of this kind (for the opinion of Stahl has been already discussed) was formed by Mr Scheele*, one of the most extraordinary men and greatest philosophers that ever existed. Without the assistance of education or of wealth, his genius burst forth with astonishing lustre; and at an age when most philosophers are only rising into notice, he had finished a career of discoveries which have no parallel in the annals of chemistry. Whoever wishes to behold ingenuity combined with simplicity, whoever wishes to see the inexhaustible resources of chemical analysis, whoever wishes for a model in chemical researches—has only to peruse and to study the works of Scheele (T). After a vast number of experiments, conducted with astonishing ingenuity, he concluded, that caloric was composed of a certain quantity of oxygen combined with phlogiston; that radiant heat, a substance which he supposed capable of being propagated in straight lines like light, and not capable of combining with air, was composed of oxygen united with a greater quantity of phlogiston, and light of oxygen united with a still greater quantity. He supposed, too, that the difference between the rays depended upon the quantity of phlogiston: the red, according to him, contained the least; the violet, the most phlogiston. By *phlogiston* Mr Scheele seems to have meant *hydrogen*. It is needless therefore to examine his theory, as it is now known that the combination of hydrogen and oxygen forms not caloric but water (U). The whole fabric therefore has tumbled to the ground; but the importance of the materials will always be admired, and the ruins of the structure shall remain eternal monuments of the genius of the builder.

332 De Luc's theory.

† In his *Idées sur la Meteorologie.*

Mr de Luc, so well known for his important meteorolgical labours, has advanced another theory†. According to him, light is a body which moves constantly in straight lines, with such rapidity that its gravitation towards other substances bears no sensible proportion to its motion. Light has the property of combining with another unknown substance, and the compound formed is caloric, which possesses very different properties from light. Caloric is constantly describing helicoidal curves round an axis, which accounts for the slowness of its apparent motion. Light produces or increases heat, partly by increasing the expansive power of caloric, and partly by combining with the *unknown substance*, and forming new caloric; caloric, on the other hand, is always decomposed when bodies become luminous. This theory is certainly ingenious, and would remove many of the difficulties which we at present labour under in attempting to explain the phenomena of caloric and light. It is, however, liable to other difficulties which could not be easily surmounted. But it is needless to examine these, as the theory itself is supported by no evidence whatever, and cannot therefore be admitted.

Another theory has been advanced by the late Dr Hutton of Edinburgh (V); a man of undoubted genius, but of rather too speculative a turn of mind, and who sometimes involved himself in difficulties from his very ingenuity. All his writings display evident marks of the profound philosopher: they contain much instruction; and even his mistakes are not without their use: but unfortunately his manner is so peculiar, that it is scarcely more difficult to procure the secrets of science from Nature herself, than to dig them from the writings of this philosopher. He supposes that there are two kinds of matter, gravitating matter and light; the last of which wants gravity, and consequently neither possesses magnitude (W) nor momentum. Light has the power of being fixed in bodies; and then it becomes either caloric or phlogiston, which differs in some particulars from caloric, but in what, the Doctor does not precisely tell us. 333 Hutton's theory.

Part of this theory we have examined already when we attempted to prove that light and caloric were different substances. The other part of the theory seems to involve a contradiction; for how could light become fixed in a body, unless it were attracted by it? and if light possesses attraction, it surely cannot be destitute of gravity; for what is gravity but *attraction* (X)?

Thus, notwithstanding the ingenuity of the philosophers who have attempted to investigate this part of chemistry, the connection between light and caloric is still unknown. We must content ourselves, therefore, with considering them at present as distinct substances, and leave the solution of the many difficulties which at present perplex us to the more happy labours of future inquirers.

Part

(T) This Newton of chemistry died in 1786, at the age of 44. His moral character, according to Mr Erhart and others, who were the companions of his youth, and Messrs Gadolin, Espling, and those who knew him in his latter days, was irreproachable and praise worthy. His outward appearance was not expressive of the great mind which lay concealed as it were under a veil. He seldom joined in the usual conversations and amusements of society, having as little leisure as inclination to do so; for what little time he had to spare from the hurry of his profession (an apothecary), was constantly filled up in the prosecution of experiments. It was only when he received visits from his friends, with whom he could converse upon his favourite science, that he indulged himself in a little relaxation. For such friends he had a sincere affection, as he had also for those that lived at a distance, and even for such as were not personally known to him. He kept up a regular correspondence with Messrs Erhart, Meyer, Kirwan, Crell, and several other chemists. See *Crell's Life of Scheele.*

(U) This candid philosopher afterwards acknowledged, that the proofs for the composition of water were complete: but we do not know exactly how he attempted to reconcile his theory of heat with the belief that water was composed of oxygen and hydrogen; two opinions which are certainly incompatible.

(V) See his dissertations on different subjects of natural philosophy.

(W) Indeed Dr Hutton refused this property to gravitating matter also; following, in this particular, the theory of the celebrated Boscovich.

(X) We hope not to be accused of disputing merely about the meaning of a word, till what is said on this subject in the chapter of the present article, which treats of *Affinity*, has been examined.

Part II. Of COMPOUND BODIES.

Water.

To those bodies which are composed of *two simple substances* combined together, for want of a better name we have given the appellation of *compound bodies*. They may be reduced under five classes:

1. Water,
2. Alcohol,
3. Oils,
4. Alkalies,
5. Acids.

These shall be the subject of the five following chapters; and we shall finish this part of the article with some observations on *Affinity*.

Chap. I. *Of* Water.

Water is a well-known liquid, found in abundance in every part of the world, and absolutely necessary for the existence of animals and vegetables.

When pure, in which state it can be obtained only by distillation, it is transparent, and destitute of colour, taste, and smell.

334 Weight of water. A cubic foot of water, at the temperature of 55°, weighs, according to the experiments of Professor Robison of Edinburgh (see *Specific Gravity*, Encycl.), 998,74 avoirdupois ounces, of 437,5 grains troy each, or only 1,26 ounces less than 1000 avoirdupois ounces; so that rain water, at the same temperature, will weigh pretty nearly 1000 ounces. The specific gravity of water is always supposed = 1,000, and it is made the measure of the specific gravity of every other body.

335 Ice. When water is cooled down to 32°, it assumes the form of ice. If this process goes on very slowly, the ice assumes the form of crystalline needles, crossing each other at angles either of 60° or 120°, as Mr de Mairan has remarked; and it has been often observed in large crystals of determinate figures. Ice, while kept at a temperature considerably below 32°, is very hard, and may be pounded into the finest dust. It is elastic. Its specific gravity is less than that of water.

336 Steam. When water is heated to the temperature of 212°, it boils, and is gradually converted into steam. Steam is an invisible fluid like air, but of a less specific gravity. It occupies about 1200 times the space that water does. Its elasticity is so great, that it produces the most violent explosions when confined. It is upon this principle that the steam-engine has been constructed. See Steam and *Steam-Engine*, Encycl.

337 Boiling point of water. The phenomena of boiling are owing entirely to the rapid formation of steam at the bottom of the vessel. The boiling point of water varies according to the pressure of the atmosphere. In a vacuum water boils at 90°; and when water is confined in Papin's digester, it may be almost heated red hot without boiling. The

338 Impregnated with various salts. mixture of various salts with water affect its boiling point considerably. Mr Achard made a number of experiments on that subject; the result of which may be seen in the following Tables *:

* *Trans. Berlin*, 1785.

Class I. *Salts which do not affect the Boiling Point.*
Sulphat of copper.

Class II. *Salts which raise the Boiling Point.*

A saturated solution of	Muriat of soda	Raises the boiling point	10,35°
	Sulphat of soda		5,6
	Sulphat of potass		0,9
	Nitrat of potass		3,5°
	Boracic acid		2,2
	Carbonat of soda		2.35

Water. This augmentation varies with the quantity of salt dissolved. In general, it is the greater the nearer the solution approaches to saturation.

Class III. *Salts which lower the Boiling Point.*

Borax,	In a small quantity, lowers the boiling point - - - - -	1,350°
	Saturated solution of, - -	0,22
Sulphat of magnesia,	In a small quantity,	2,47
	Saturated solution of	1,1
Alum,	A very small quantity of, - -	0,0
	A greater quantity, - -	0,7
	A saturated solution of, - -	0,0
Sulphat of lime,	in any proportion,	2,02
Sulphat of zinc,		0,45
Sulphat of iron,		0,22
Acetite of lead,		1,24

Class IV.

Muriat of ammonia,	Small quantity of, lowers the boiling point - - -	0,45
	Saturated solution of, raises do.	9,79
Carbonat of potass,	Small quantity of, lowers do.	0,45
	Saturated solution of, raises do.	11,2

Water was once supposed to be incompressible, but 339 Water compressible. the contrary has been demonstrated by Mr Canton. The Abbé Mongez made a number of experiments, long after that philosopher, on the same subject, and obtained similar results.

Water was believed by the ancients to be one of the 340 Opinion about its nature. four elements of which every other body is composed; and, according to Hippocrates, it was the substance which nourishes and supports plants and animals. That water was an unchangeable element continued to be believed till the time of Van Helmont, who made plants grow for a long time in pure water: From which experiment it was concluded, that water was convertible into all the substances found in vegetables.—Mr Boyle having digested pure water in a glass vessel hermetically sealed for above a year, obtained a quantity of earthy scales; and concluded, in consequence, that he had converted it partly into an earth *. He obtained the same earth by distilling water in a tall glass vessel over a slow fire †. Margraf repeated the experiment with the same result, and accordingly drew the same conclusion. But the opinion of these philosophers was never very generally received. The last person who embraced it was probably Mr Waselton, who published his experiments on the subject in the *Journal de Physique* for 1780. Mr Lavoisier had proved, as early as 1773, that the glass vessels in which the distillation was performed lost a weight exactly equal to the earth obtained. Hence it follows irresistibly, that the appearance of the earth, which was silica, proceeded from the decomposition of the vessels; for glass contains a large proportion of silica. It has been since shewn by Dr Priestley, that water always decomposes glass when applied to its surface for a long time in a high temperature.

* *Shaw's Boyle*, iii. 417.

† *Ibid.* i. 267.

We have formerly mentioned, that water is composed of oxygen and hydrogen. This great discovery has con-

Water. contributed more perhaps than any other to the advancement of the science of chemistry, by furnishing a key for the explanation of a prodigious number of phenomena. The evidence, therefore, on which it rests, and the objections which have been made to it, deserve to be examined with peculiar attention.

341 History of the discovery of its composition.

The first person probably who attempted to discover what was produced by burning hydrogen gas was Scheele. He concluded, that during the combustion oxygen and hydrogen combined, and that the product was caloric.

In 1776 Macquer, assisted by Sigaud de la Fond, set fire to a bottle full of hydrogen gas, and placed a saucer above the flame, in order to see whether any fuliginous smoke would be produced. The saucer remained perfectly clean; but it was moistened with drops of a clear liquid, which they found to be pure water *.

Next year Bucquet and Lavoisier exploded oxygen and hydrogen gas, and made an attempt to discover what was the product; about the nature of which they had formed different conjectures. Bucquet had supposed that it would be carbonic acid gas; Lavoisier, on the contrary, suspected that it would be sulphuric or sulphurous acid. What the product was they did not discover; but they proved that no carbonic acid gas was formed, and consequently that Mr Bucquet's hypothesis was ill founded †.

In the beginning of the year 1781, Mr Warltire, at the request of Dr Priestley, fired a mixture of these two gases contained in a copper vessel; and observed, that after the experiment the weight of the whole was diminished. Dr Priestley had previously, in the presence of Mr Warltire, performed the same experiment in a glass vessel. This vessel became moist in the inside, and was covered with a sooty substance ‡, which Dr Priestley afterwards supposed to be a part of the mercury used in filling the vessel §.

In the summer of 1781, Mr Henry Cavendish, who had been informed of the experiments of Priestley and Warltire, set fire to 500,000 grain measures of hydrogen gas, mixed with about $2\frac{1}{2}$ times that quantity of common air. By this process he obtained 135 grains of pure water. He also exploded 19,500 grain measures of oxygen gas with 37,000 of hydrogen gas, and obtained 30 grains of water, containing in it a little nitric acid. From these experiments he concluded that water was a compound.—Mr Cavendish must therefore be considered as the real discoverer of the composition of water. He was the first who ascertained that water was produced by firing oxygen and hydrogen gas, and the first that drew the proper conclusion from that fact. Mr Watt, indeed, had also drawn the proper conclusion from the experiments of Dr Priestley and Mr Warltire, and had even performed a number of experiments himself to ascertain the fact, before Mr Cavendish had communicated his; but he had been deterred from publishing his theory by some experiments of Dr Priestley, which appeared contrary to it ‖. He has therefore a claim to the merit of the discovery; a claim, however, which does not affect Mr Cavendish, who knew nothing of the theory and experiments of that ingenious philosopher.

* Macquer's *Dictionary*, art. *Gas, inflammable*.

† *Mem. Par.* 1781, 470.

‡ *Priestley*, v. 395.

§ *Phil. Trans.* lxxiv. 332.

‖ *Ibid.* lxxv. 330.

Meanwhile, in the winter 1781-2, Mr Lavoisier, who had suspected that when oxygen and hydrogen gas were exploded, sulphuric or sulphurous acid was produced, made an experiment in order to ascertain the fact, at which Mr Gingembre assisted. They filled a bottle, capable of holding six pints (French), with hydrogen gas, to which they set fire, and then corked the bottle, after pouring into it 2 oz. (French) of lime-water. Through the cork there passed a copper tube, by means of which a stream of oxygen gas was introduced to support the flame. Though this experiment was repeated three times, and instead of lime-water a weak solution of alkali and pure water were substituted, they could not observe any product whatever *. This result astonished Mr Lavoisier exceedingly: he resolved, therefore, to repeat the experiment on a larger scale, and if possible with more accuracy. By means of pipes furnished with stop-cocks, he put it in his power to supply both gases as they should be wanted, that he might be enabled to continue the burning as long as he thought proper.

The experiment was made by Lavoisier and La Place on the 24th of June 1783, in the presence of Messrs Le Roi, Vandermonde, several other academicians, and Sir Charles Blagden, who informed them that Mr Cavendish had already performed it, and that he had obtained water †. They continued the inflammation till all their stock of gases was wasted, and obtained about 295 grains of water, which, after the most rigid examination, appeared to be perfectly pure. From this experiment Lavoisier concluded, that water was composed of oxygen and hydrogen. Mr Mongé soon after performed the same experiment, and obtained a similar result: and it was soon after repeated again by Lavoisier and Meusnier on a scale sufficiently large to put the fact beyond doubt ‡.

† *Ibid.* p. 472.

‡ *Ibid.* p. 474.

342 Proofs of the composition of water.

The proofs that water is a compound are of two kinds; it has been actually composed, and it has been decomposed.

343 Experiment of Lavoisier and Meusnier.

With regard to the composition of water, we shall relate the celebrated experiment made by Lavoisier and Meusnier in the month of February 1785, in the presence of a numerous deputation from the academy of sciences, and so many other spectators, that it may be considered as having been performed in public. Every precaution was taken to ensure success. The gases had been prepared with care, and held for some time over a solution of potass, in order to deprive them of any acidity which they might accidentally contain; and before entering into the glass globe where they were to be burnt, they were made to pass over newly calcined potass, to deprive them of the water which they might happen to retain in solution. The hydrogen gas had been obtained by passing steam through iron at a white heat; the oxygen gas was procured from the red oxide of mercury. The combustion took place in a large glass globe, into which the gases were admitted by means of tubes furnished with stop-cocks; and the most ingenious contrivances were employed to ascertain exactly the quantities of each which were consumed (y). The whole machine is described at large by Mr Meusnier in the Memoirs of the Academy of Sciences for 1782.

(y) A variety of instruments have been invented by the French chemists for that purpose. These instruments they have denominated *Gazometers*.

Water.

The quantities of gas employed, after deducting the 432 grains of residuum which were not consumed, were 2794,76 grains of oxygen gas, and 471,125 of hydrogen gas. After taking from these 32,25 grains, = the humidity of which the oxygen gas was deprived by the calcined potass, and 44,25 grains, = the weight which the hydrogen lost by the same process, there remains altogether 3188,4 grains of gas.

The quantity of water obtained amounted to 3219 grains; the specific gravity of which was to distilled water as 1,0051 to 1. This quantity was 30 grains more than the gas employed. The difference, no doubt, was owing to a small error in estimating the weight of the gases; which indeed it is extremely difficult to avoid, as the weight is altered by the smallest difference of temperature. This water had a slight smell, and a taste sensibly acid; it reddened slightly blue paper, and effervesced with the carbonat of potass. 1152 grains of that water being saturated with potass, and evaporated to dryness, left 20 grains of a salt which melted on the fire like nitre. It follows from this experiment, that the quantity of acid contained in the whole water would not have been quite sufficient to have formed 56 grains of nitre.

The residuum weighed, as has been already observed, 432 grains; its volume was equal to 444 grains of oxygen gas; it was diminished by nitrous gas (z) precisely as gas would be which contained 0,24 parts of oxygen; it rendered lime-water somewhat turbid, which indicated the presence of carbonic acid gas.

From the comparison of the weights, and volumes of the gases consumed, it was concluded that water consists of 0,85 parts, by weight, of oxygen, and 0,15 of hydrogen.

344 Experiment of Le Fevre de Gineau.

This experiment was soon after repeated by Mr Le Fevre de Gineau upon a still larger scale, and in the presence of a great number of spectators. It continued for no less than 12 days, and was performed with the most rigorous exactness of which experiments of that nature will admit *.

* Journ. de Phys. 1788, p. 457.

The oxygen gas employed, which had been procured from the black oxide of manganese, occupied the space of 35085,1 cubic inches, and weighed 18298,5 grains.

The hydrogen gas was obtained by dissolving iron in diluted sulphuric acid. Its volume was 7496,7 cubic inches, and its weight 4756,3 grains.

	Grains.
The two gases therefore amounted to -	23054,8
From which taking the residuum after combustion, which amounted to - -	2831,0
There remains for the quantity consumed	20223,8
The water found in the glass globe after the combustion amounted to - - - -	20139,0
And there were carried off by the residuum	54,0
In all - -	20193,0

Which is just 30 grains less than the weight of the gases which disappeared, or $\frac{1}{674}$ part of their weight. This difference arose from the same difficulties which attended the experiment of Lavoisier. As the errors are on different sides, we are warranted to conclude that this was the case, and that it was not owing to any real difference between the gases and the product.

The water was examined in the presence of Messrs Lavoisier, Le Roi, Mongé, Berthollet, Bayen, and Pelletier. Its specific gravity was to that of distilled water as 1,001025 to 1. It contained no sulphuric nor muriatic acids; yet it had an acid taste, and converted vegetable blues to a red. 6606 grains of it required for saturation 36 grains of carbonat of potass, and furnished by evaporation 26,5 grains of crystals of nitre. The whole water, therefore, would have required 109,7 grains of carbonat of potass for saturation.

This water affected lime-water a little; and it was found that the residuum of the gas contained some carbonic acid gas. This residuum formed a 19th part of the volume of the two gases employed, and an eight of their weight. It contained 462 grains of carbonic acid gas, or about $\frac{1}{6}$th part; the rest was azotic gas, with about $\frac{1}{11}$th of oxygen.

This experiment gave the proportions of oxygen and hydrogen in water as follows:

Oxygen - - -	,848
Hydrogen - -	,152
	1,000

This is so near the determination of Mr Lavoisier, that it must be considered as a very strong confirmation of it.

345 Experiment of Seguin, Fourcroy, and Vauquelin.

In the year 1790, another similar experiment was performed by Seguin, Fourcroy, and Vauquelin, in the presence of a number of commissioners appointed by the Academy of Sciences. Every precaution was taken to ascertain the quantity of gas employed with the utmost exactness, and to exclude all atmospherical air as completely as possible.

The hydrogen gas was procured by dissolving zinc in sulphuric acid diluted with 7 parts of water. The oxygen gas was obtained by distilling oxy-muriat of potass (A).

The quantity of hydrogen gas employed amounted to 862,178 grains troy. The quantity of oxygen gas amounted to 13475,198 cubic inches (French). Its purity was such, that it contained three cubic inches of azotic gas in the 100. The whole gas, therefore, contained 404,256 cubic inches. There were likewise in the glass vessel in which the combustion took place 15 cubic inches (French) of atmospheric air, which consisted of 11 cubic inches of azotic and four of oxygen gas. So that the whole oxygen gas employed amounted to 13074,942 cubic inches; and it contained besides 415,256 cubic inches of azotic gas. They ascertained by experiment, that a cubic inch of this oxygen gas, thus diluted with $\frac{3}{100}$ of azot, weighed ,4040 of a grain troy. Now, according to the experiments of Lavoisier, a cubic inch (French) of azotic gas weighs only ,3646 of a grain troy. Consequently the weight of pure oxygen gas is greater than ,4040; and by calculation they shewed it to amount to ,4051 of a grain troy. The weight of the whole oxygen gas employed, therefore, was 5296,659 grains troy; and that of the azotic gas mixed with it 151,402 grains troy.

The

(z) This gas shall be afterwards described. It has the property of absorbing almost instantaneously the oxygen gas with which it comes into contact. It is therefore often used, in order to discover how much oxygen gas exists in any mixture.

(A) A salt composed of oxy-muriatic acid and potass.

Water.

The combustion continued 185 hours; and during all that time our philosophers never quitted the laboratory. The flame was exceedingly small, and the heat produced by no means great. This was owing to the very small stream of hydrogen, which was constantly flowing into the vessel.

The water obtained amounted to 5943,798 grains troy, or 12 oz. 7 dwts. and 15,798 grains. It exhibited no mark of acidity, and appeared in every respect to be pure water. Its specific gravity was to that of distilled water as 18671 to 18670; or nearly as 1,000053 to 1.

The residuum of gas in the vessel after combustion amounted to 987 cubic inches (French); and on being examined, was found to consist of the following quantities of gases:

Azotic gas, - - - - - -	467 cubic inches.
Carbonic acid gas, - - -	39
Oxygen gas, - - - - - -	465
Hydrogen gas, - - - -	16
Total - -	987

The weight of which is as follows:

Azotic gas, - - - - - - -	170,258 gr. troy.
Carbonic acid gas, - - - -	23,306
Oxygen gas, - - - - - - -	188,371
Hydrogen gas, - - - - - -	0,530
Total, - -	382,465

Now the weight of the whole gases employed was, - - - -	6310,239 gr. troy.
That of the water obtained, and of the residuum, - - - -	6326,263
Or - - - - - - - - -	16,024 grains

more than had been employed. This small quantity must have been owing to common air remaining in the tubes, and other parts of the apparatus, in spite of all the precautions that were taken to prevent it; if it did not rather proceed from unavoidable errors in their valuations.

	Gr Troy
The quantity of azotic gas introduced was	151,178
The quantity found in the residuum was	170,258
There was therefore a surplus of - - -	19,080 gr.

As sufficient precautions had been taken to prevent the introduction of carbonic acid gas, the quantity found in the residuum must have been formed during the process. There must therefore have been a small quantity of carbon introduced. Now zinc often contains carbon, and hydrogen has the property of dissolving carbon: probably, then, the carbon was introduced in this manner. The carbonic acid found in the residuum amounted to 23,306 grains, which, according to Lavoisier's calculation, is composed of 8,958 grains of carbon, and 14,348 grains of oxygen.

Subtracting these 8,958 grains of carbon, and the ,530 of a grain of hydrogen, which remained in the vessel, from the total of hydrogen introduced, there will remain 852,690 grains for the hydrogen that disappeared.

Subtracting the 14,348 grains of oxygen which entered into the composition of the carbonic acid, and the residuum of oxygen, which amounted to 188,371 grains, the quantity of oxygen that disappeared will amount to 5093,940 grains.

Water.

Hydrogen that disappeared, -	852,690 gr. troy.
Oxygen, - - - - - - - -	5093,940
Total, - -	5946,630
Quantity of water obtained,	5943,798
Which is less than the gases consumed by - - - - -	2,832 grains *.

Such are the principal experiments upon which the opinion is founded that water is a compound. Let us examine them, and see whether they are sufficient to establish that opinion. The circumstances which chiefly claim our attention, and which have been chiefly insisted on, are these:

* Ann. de Chim. viii. 225.

346 Objections to the composition of water examined.

1. The whole of the gases was not consumed.
2. In the residuum were found several substances which were not introduced, and which must therefore have been formed during the combustion.
3. The water obtained was seldom perfectly pure. It generally contained some nitric acid.
4. As only part of the gases were consumed, and as all gases contain water in them, might not the gas which disappeared have been employed in forming the other substances found in the residuum? and might not the water obtained have been merely what was formerly dissolved in the gases, and which had been precipitated during the experiment?

That the whole of the gases was not consumed will not surprise us, if we recollect that it is impossible for that to take place, allowing them to be perfectly pure, except they be mixed in precisely the proper proportions; and not even then, except every particle of them could be raised to the proper temperature. Now how can this be done in experiments of that nature?

But how is it possible to procure a large quantity of gas completely pure? And supposing it were possible, how can every particle of atmospheric air be excluded? In the last experiment, notwithstanding every precaution, 15 cubic inches (French) were admitted; and there is reason to believe from the results, that the quantity was even considerably greater than this. But if any atmospheric air be admitted, there must be a residuum of azotic gas.

In the first experiment, it had been previously ascertained that the oxygen gas employed contained $\frac{1}{12}$th of azotic, or about 233,05 grains; and the residuum contained at most 329,1 grains, or 96,05 grains more than what had for certain pre-existed in the gases.

In the second experiment, the azot in the residuum amounted at most to $\frac{1}{6}$th of the oxygen gas employed. But the oxygen was procured from the black oxide of manganese, which always yields a quantity of azot as well as of carbonic acid. It has been ascertained, that the azot, mixed with oxygen gas procured in that manner, often exceeds $\frac{1}{8}$th.

In the third experiment, the azotic gas found in the residuum amounted to 170,258 grains; and the quantity contained in the gases before combustion amounted to 151,178 grains: the surplus, therefore, amounted to 19,08 grains.

Now, is it not much more probable that these inconsiderable quantities of azot, which in the last experiment amounted to no more than $\frac{1}{331}$ part by weight of the whole gas employed, pre-existed in the gases before the combustion began, though their extreme minuteness prevented them from being discovered, than that they were formed during the experiment: a supposition

Water.

position which is directly contradicted by a great number of well ascertained facts.

As to the carbonic acid gas, which in the second experiment amounted to $\frac{1}{25}$th of the gases employed, it was evidently derived from the manganese, which almost constantly contains it. And when carbonic acid is once mixed with oxygen, it is difficult to separate it by means of lime-water, except a large quantity be used, as Mr Cavendish has well observed. The reason is, that oxygen gas has the property of dissolving carbonic acid, as Mr Welter has remarked *. Mr le Fevre de Gineau ascertained by experiment, that 1870 cubic inches of oxygen gas, which did not affect lime-water, lost between $\frac{1}{18}$th and $\frac{1}{40}$th of its weight when washed in *milk of lime* (B).

* *Ann. de Chim.* iii. 91.

In a second experiment, he previously washed the two gases in milk of lime, and the residuum after combustion contained *no* carbonic acid gas. In a third experiment he washed only the oxygen, and obtained products equally free from carbonic acid. It is certain, then, that the *carbonic acid* is but an accidental mixture. As to the carbonic acid of the third experiment above related, which amounted only to $\frac{1}{131}$ part of the gases employed, the source of it has been already pointed out.

As to the nitric acid, the quantity of nitre obtained in Mr Lavoisier's experiment was 56 grains; which, according to Mr Kirwan's calculation, contain 30,156 grains of nitric acid; a quantity considerably less than $\frac{1}{100}$th part of the gases which disappeared. In the second experiment, the nitre obtained amounted to 80,7 grains; which, according to Kirwan, contain 43,456 grains of nitric acid, or less than $\frac{1}{217}$th part of the gases consumed. Now, as nitric acid is composed of oxygen and azot, both of which were present in the vessel, it is easy to see how it was produced. And that its production is merely accidental, and not necessary, is evident from the last experiment, in which no nitric acid was formed. It has been ascertained, indeed, that the formation of this acid during these experiments is quite arbitrary. It never is formed when the combustion goes on so slowly as to produce but little heat, as Seguin has ascertained †; because oxygen and azot do not combine except at a high temperature. Nor is it formed even at a high temperature, as Mr Cavendish has proved ‡, except there be a deficiency of hydrogen; because hydrogen has a stronger affinity for oxygen than azot has.

† *Ann. de Chim.* ix. 48.

‡ *Phil. Transf.* 1784.

The quantity of water obtained in the first experiment was just 30 grains more than the weight of the gases which had disappeared: the water obtained in the second was precisely 30 grains less than the gases consumed: and in the third experiment, the difference was only 16 grains. The quantities of gas operated upon were large; in all of the experiments several thousand grains, and in one of them above 20 thousand. Now, how is it possible that the water produced should correspond so exactly with the gases consumed (for the differences are so small as not to merit any attention), unless the water had been formed by the combination of these gases?

Dr Priestley, however, who made a great many experiments on this subject, drew from them a very different conclusion; and thought he had proved, that during the combustion the two gases combined, and that the combination was nitric acid. This theory was adopted, or rather it was suggested, by Mr Keir, who has supported it with a great deal of ingenuity *.

* *Keir's Dictionary*, art. *Nitrous Acid.*

Let us examine these experiments of Dr Priestley †, and see whether they warrant the conclusions he has drawn from them. The gases were exploded in vessels of copper. He found that the quantity of water obtained was always *less* than that of the gases which he had used. He obtained also a considerable quantity of nitric acid. In the experiment made on the largest quantity of the gases, and from which he draws his conclusions, the quantity of liquid obtained amounted to 442 grains. This liquid was examined by Mr Keir. It was of a green colour, 72 grains of brown oxide of copper were deposited in it, and it contained a solution of nitrat of copper (copper combined with nitric acid). Mr Keir analysed this liquor: It consisted of pure water and nitrat of copper; and Mr Keir concluded that the nitric acid formed amounted to $\frac{1}{20}$th of the oxygen gas employed. Mr Berthollet, however, has shewn that it could not have amounted to more than $\frac{1}{44}$th part ‡. Let us suppose, however, that it amounted to $\frac{1}{20}$th. A quantity of oxygen and hydrogen gas has disappeared: What has become of them? They have combined, says Dr Priestley, and formed nitric acid. This nitric acid is only $\frac{1}{20}$th of their weight: Dr Priestley supposes, however, that it contains the whole oxygen and hydrogen that existed in these gases, and that all the rest of the weight of these gases was owing to a quantity of water which they had held in solution. Oxygen gas, then (for we shall neglect the hydrogen, which Dr Priestley was not able to bring into view at all), is composed of one part of oxygen and 19 of water. Where is the proof of this? Dr Priestley informs us, that he ascertained by experiment that half the weight of carbonic acid gas was pure water. Supposing the experiment accurate (c), what can be concluded from it? Surely to bring it forward in proof, that oxygen gas consists of $\frac{19}{20}$th parts, or almost wholly of water, is downright trifling. It is impossible, therefore, from Dr Priestley's experiments, allowing his suppositions and conjectures their utmost force, to account for the disappearing

† *Phil. Transf.* 1788.

‡ *Ann de Chim.* iii. 86.

(B) Lime mixed with water till it is of the thickness of *milk*, or rather of *cream*.

(C) He informs us that the carbonat of barytes does not yield its carbonic acid by means of heat (this Dr Hope has shewn to be a mistake); but that, when the vapours of water are passed over it, the gas is disengaged: and he determines, by the water missing, how much has combined with the gas. According to him, 60 grains of water enter into the composition of 147 grains of gas. But, besides assigning too small a weight to the gas, he forgot that its temperature was high, and that therefore it was capable of combining with much more water than in its usual state: nor did he ascertain whether more of this water was deposited on the vessels; and yet, by neglecting this precaution, Morveau has shewn that Mr Kirwan, in a similar experiment, obtained a result nine times greater than it ought to have been. *Encycl. Method. Chim.* art. *Air.*

Water.

pearing of the two gases, or the appearance of the water, without admitting that this liquid was actually composed of oxygen and hydrogen. If we add to this, that no oxygen gas has hitherto (as far as we know at least) been procured absolutely free from some admixture of azot, and that his oxygen was always procured either from red oxide of lead, or from black oxide of manganese, or red oxide of mercury, all of which substances yield a considerable proportion of azot; that in one experiment, in which he observes that his oxygen was *very pure*, as it had been obtained from red oxide of mercury, Mr Berthollet (D) ascertained, by actually making the experiment, that part of the *very same* oxide which Dr Priestley had employed yielded a gas, $\frac{1}{7}$d of which was azot *; if we add, that it has been proved beyond the possibility of doubt, and to Dr Priestley's own satisfaction, that nitric acid is composed of oxygen and azot—we shall find it no difficult matter to explain the origin of that acid in Dr Priestley's experiments: and if we recollect that in Seguin's experiment, upon a much larger scale indeed than Dr Priestley's, no nitric acid at all was formed, it will be impossible for us to believe for a moment that the compound formed by oxygen and hydrogen is nitric acid. Thus Dr Priestley's experiments rather confirm than destroy the theory of the composition of water. We obtain from them, however, one curious piece of information, that the presence of copper increases the quantity of nitric acid formed. This curious fact, with a variety of others of a similar nature, will perhaps afterwards claim our attention; but at present we must consider another theory which this phenomenon suggested, and which was first proposed, we believe, by Mr de la Metherie (E).

* Ann. de Chim. iii. 94.

Had the French chemists, it has been said, employed copper vessels in their experiments, they would have obtained three times the quantity of nitric acid. This acid, therefore, must in their experiments have been decomposed, after having been formed, for want of a base to combine with; and the azot which appeared in the residuum was owing to this decomposition. Hydrogen and oxygen, therefore, do not form water, but azot (F). Let us examine the experiment of Mr Le Fevre by this theory, as the quantity of azot was accurately ascertained. The nitric acid obtained amounted to 43,456 grains; three times that quantity is 130,368 grains, into which 23054 grains of gas were converted; which is impossible. Or even supposing that the decomposition had been going on during the whole experiment, which is directly contrary to Dr Priestley's experiments, and which there is no reason whatever to suppose, but every reason against—still the whole azot amounted only to $\frac{1}{8}$th of the quantity of gas employed, allowing this gas to have contained no azot, which was evidently not the case. It appears, then, that this hypothesis, even if it could be admitted, would be totally inadequate to account for the phenomena. But if we were to examine it by Mr Seguin's experiment, its absurdity would be still more glaring. In that experiment the azotic gas amounted to only 19 grains, and the quantity of gas which disappeared was 5946 grains: so that were the hypothesis true, oxygen and hydrogen gas would consist of one part of oxygen and hydrogen and 312 parts of water; a supposition so enormously absurd, that it is impossible for any person even to advance it.

It is impossible, therefore, for the phenomena which attend the combustion of oxygen and hydrogen gas to be accounted for in any way consistent with common sense, except we suppose that water is formed.

347 Decomposition of water.

But the experiments above related, conclusive as they appear, are not the only ones by which this important fact has been ascertained. Messrs Van Trooftwyk and Dieman, assisted by Mr Cuthbertson, filled a small glass tube, $\frac{1}{8}$th of an inch in diameter and 12 inches long, with distilled water. One end of this tube was sealed hermetically; but, at the same time, a small gold wire had been passed through it. Another wire passed thro' the open end of the tube, and could be fixed at greater or smaller distances from the first wire. By means of these wires, they made a great number of electrical explosions pass through the water. Bubbles of air appeared at every explosion, and collected at the top of the tube. When electric sparks were passed through this air, it exploded and disappeared almost completely. It must therefore have consisted of a mixture of oxygen and hydrogen gas, and this gas must have been formed by the decomposition of the water: for they had taken care to deprive the water before hand of all its air, and they used every precaution to prevent the access of atmospherical air; and, besides, the quantity of gas produced did not diminish, but rather increased, by continuing to operate a number of times upon the same water, which could not have been the case had it been merely air dissolved in water: nor would atmospherical air have exploded and left only a very small residuum, not more than $\frac{1}{80}$th part. They had taken care also to prove that the electric spark did not contribute to form hydrogen gas; for on passing it through sulphuric and nitric acids, the product was not hydrogen, but oxygen gas *.

* Jour. de Phys. xxxv. 369.

These experiments have been since repeated by Dr Pearson, assisted by Mr Cuthbertson. He produced, by means of electricity, quantities of gas from water, amounting to 56,5488 cubes of $\frac{1}{10}$th of an inch each; on nitrous gas being added to which, it suffered a diminution

(D) Mr Berthollet had supplied Dr Priestley with the oxide. He had received two ounces of it from Mr Le Blanc, one of which he sent to Dr Priestley, and the other he reserved.

(E) Another favourite theory of La Metherie was, that gases themselves are destitute of gravity, and that they owe their whole weight to the water with which they are combined: that during combustion the water of the two gases is deposited; and that the gases themselves escape through the vessel and are lost. He complains bitterly that this theory had never been noticed by his antagonists; as if it were necessary to refute a hypothesis which is not supported by any proof whatever, and as if it had not been proved that oxygen increases the weight of metals, and consequently possesses gravity.

(F) This, as has been formerly explained, was the original opinion of Dr Priestley; to which, though he does not explain himself fully, he evidently still adheres. There is then no difference between his theory and this, except what relates to the decomposition of the nitric acid.

nution of bulk, and nitrous acid appeared to have been formed: It muſt therefore have contained oxygen gas. When oxygen gas was added to the remainder, and an electric ſpark paſſed through it, a diminution took place preciſely as when oxygen and hydrogen gas are mixed: It muſt therefore have contained hydrogen. When an electric ſpark was paſſed through the gas thus produced from water, the gas diſappeared, being no doubt converted into water *.

* Nicholſon's Journal, i. 242.

Such are the proofs by which the compound nature of water is aſcertained; and we do not believe that any phyſical fact whatever can be produced which is ſupported by more complete evidence.

But what becomes of the caloric which was previouſly combined with theſe gaſes? It paſſes through the veſſel and is loſt, and its weight is too inconſiderable to make any ſenſible variation in the quantity of the product. If we were to judge from analogy, we would conclude, that the oxygen and hydrogen, while in the ſtate of gas, are probably ſomewhat lighter than after they are condenſed into water; but the difference, if it exiſts, can ſcarcely be ſenſible.

348 Combination and affinity of water.

Water is capable of combining with a vaſt number of ſubſtances: all bodies, indeed, which are ſoluble in water form a chemical union with it.

Its affinity for other bodies is doubtleſs various, tho' we have no method of aſcertaining this difference, except in thoſe bodies which have no affinity, or but a very ſmall affinity, for each other; and it is only in a few even of theſe that this difference can be aſcertained. If muriat of barytes be poured into lime-water, the lime is precipitated, owing, no doubt, to the ſuperior affinity of the muriat for water. Several very curious inſtances of the affinity of different ſalts for water have been mentioned by Mr Quatremere Dijonval. When the ſolutions of nitrat of lime and nitrat of magneſia in water are mixed together, the nitrat of magneſia is precipitated. Muriat of magneſia is alſo precipitated by muriat of lime, and ſulphat of magneſia by ſulphat of lime: ſo that it would ſeem that the ſalts which have magneſia for their baſis, have a leſs affinity for water than thoſe whoſe baſis is lime †.

† *Journ. de Phyſ.* xvii.

Water has the property of diſſolving oxygen gas. If a quantity of common air be confined for ſome time above water, the whole of the oxygen is abſorbed, and nothing but the azotic gas remains. This fact was firſt obſerved by Mr Scheele.

Chap. II. *Of* Alcohol.

349 Diſcovery of alcohol.

Wine has been known from the earlieſt ages. The Scriptures inform us, that Noah planted a vineyard and drank wine; and the heathen writers are unanimous in aſcribing the invention of this liquor to their earlieſt kings and heroes. Beer, too, ſeems to have been diſcovered at a very remote period. It was in common uſe in Egypt in the time of Herodotus ‡. Tacitus informs us, that it was the drink of the Germans §. Whether the ancients had any method of procuring ardent ſpirits from theſe or any other liquors, does not appear. The Greeks and Romans ſeem to have been ignorant of ardent ſpirits altogether, at leaſt we can diſcover no traces of any ſuch liquor in their writings. But among the northern nations of Europe, intoxicating liquors were in uſe from the earlieſt ages. Whether theſe liquors reſembled the beer of the Germans, we do not know. It is certain, at leaſt, that the method of procuring ardent ſpirits by diſtillation was known in the dark ages; and it is more than probable that it was practiſed in the north of Europe much earlier. They are mentioned expreſsly by Thaddæus, Villanovanus, and Lully *.

‡ Lib. ii. n. 77.

§ *De Morib. Germ.* ch. xxiii.

* *Berg.* 4th. art. ii. 4.

350 Method of procuring it.

Ardent ſpirits, ſuch as brandy, for inſtance, rum, and whiſky, conſiſt almoſt entirely of three ingredients, water, *alcohol* or *ſpirit of wine*, to which they owe their ſtrength, and a ſmall quantity of a peculiar oil, to which they owe their flavour.

The alcohol may be ſeparated from the water by the following proceſs. Into the whiſky or other ardent ſpirit a quantity of potaſs is to be put, which has juſt immediately before been expoſed for about half an hour in a crucible to a red heat, in order to deprive it of moiſture. Potaſs in this ſtate has a ſtrong attraction for water; it accordingly combines with the water of the ſpirit, and the ſolution of potaſs thus formed ſinks to the bottom of the veſſel, and the alcohol, which is lighter, ſwims over it, and may eaſily be decanted off; or, what is perhaps better, the ſolution of potaſs may be drawn off from below it by means of a ſtop-cock placed at the bottom of the veſſel. It is impoſſible to fix the quantity of potaſs which ought to be uſed, becauſe that muſt depend entirely on the ſtrength of the ſpirit; but it is of no conſequence though the potaſs employed be a little more than enough. The alcohol thus obtained contains a little potaſs diſſolved, which may be ſeparated by diſtilling it in a water bath with a very ſmall heat. The alcohol paſſes over, and leaves the potaſs behind. It is proper not to diſtil to dryneſs. This proceſs is firſt mentioned by Lully. Alcohol may be obtained in the ſame manner from wine and from beer; which liquids owe their ſtrength entirely to the quantity of that ſubſtance which they contain.

351 Its properties.

Alcohol is a tranſparent liquor, colourleſs like water, of a pleaſant ſmell, and a ſtrong penetrating agreeable taſte.

It is exceedingly fluid, and has never been frozen, though it has been expoſed to a cold ſo great that the thermomer ſtood at —69° †.

† At *Hudſon's Bay.*

Its ſpecific gravity when pure is about 0,800.

It is exceedingly volatile, boiling at the temperature of 176°; in which heat it aſſumes the form of an elaſtic fluid, capable of reſiſting the preſſure of the atmoſphere, but which condenſes again into alcohol when that temperature is reduced. In a vacuum it boils at 56°, and exhibits the ſame phenomena: ſo that were it not for the preſſure of the atmoſphere, alcohol would always exiſt in the form of an elaſtic fluid, as tranſparent and inviſible as common air. This ſubject was firſt examined with attention by Mr Lavoiſier ‡. The fact, however, had been known long before.

‡ *Journ. de Phyſ.* 1785.

Alcohol has a ſtrong affinity for water, and is miſcible with it in all proportions. The ſpecific gravity of all the different mixtures, in every proportion, and in all the different degrees of temperature, from 32° to 100°, has been lately aſcertained with great accuracy by Sir Charles Blagden and Mr Gilpin. But as a very full account of theſe intereſting experiments has been given in the Encyclopædia in the article Spirituous *Liquors*, we do not think ourſelves at liberty to repeat it here.

If alcohol be ſet on fire, it burns all away with a blue flame without leaving any reſiduum. Boerhaave obſerved, Alcohol.

observed, that when the vapour which escapes during this combustion is collected in proper vessels, it is found to consist of nothing but water. Junker had made the same remark: and Dr Black suspected, from his own observations, that the quantity of water obtained, if properly collected, exceeded the weight of the alcohol consumed. This observation was confirmed by Lavoisier; who found that the water produced during the combustion of alcohol exceeded the alcohol consumed by about $\frac{1}{7}$th part*.

352 Opinions concerning its composition.

Different opinions were entertained by chemists about the nature of alcohol. Stahl thought that it was composed of a very light oil, united by means of an acid to a quantity of water. According to Junker, it was composed of phlogiston, combined with water by means of an acid. Cartheuser, on the other hand, affirmed, that it contained no acid, and that it was nothing else than pure phlogiston and water. But these hypotheses were mere assertions supported by no proof whatever. Lavoisier was the first who attempted to analyse it.

* Mem. Par. 1781. p. 493.

353 Lavoisier's analysis.

He set fire to a quantity of alcohol in close vessels, by means of the following apparatus: BCDE (fig. 6.) is a vessel of marble filled with mercury. A is a strong glass vessel placed over it, filled with common air, and capable of containing about 15 pints (French). Into this vessel is put the lamp R filled with alcohol, the weight of which has been exactly determined. On the wick of the lamp is put a small particle of phosphorus. The mercury is drawn up by suction to the height IH. This glass communicates by means of the pipe LK with another glass vessel S filled with oxygen gas, and placed over a vessel of water T. This communication may be shut up at pleasure by means of the stop-cock M.

Things being thus disposed, a crooked red-hot iron wire is thrust up through the mercury, and made to touch the phosphorus. This instantly kindles the wick, and the alcohol burns. As soon as the flame begins to grow dim, the stop-cock is turned, and a communication opened between the vessels S and A; a quantity of oxygen gas rushes in, and restores the brightness of the flame. By repeating this occasionally, the alcohol may be kept burning for some time. It goes out, however, at last, notwithstanding the admission of oxygen gas.

The result of this experiment, which Mr Lavoisier repeated a great number of times, was as follows:

The quantity of alcohol consumed amounted to 76,7083 grains troy.

The oxygen gas consumed amounted to 266,82 cubic inches, and weighed 90,506 grains troy.

The whole weight of the substances consumed, therefore, amounted to 167,2143 grains.

After the combustion, there were found in the glass vessel 115,41 cubic inches of carbonic acid gas, the weight of which was 78,1192 grains troy. There was likewise found a considerable quantity of water in the vessel, but it was not possible to collect and weigh it. Mr Lavoisier, however, estimated its weight at 89,0951 grains; as he concluded, with reason, that the whole of the substances employed were still in the vessel. Now the whole contents of the vessel consisted of carbonic acid gas and water; therefore the carbonic acid gas and water together must be equal to the oxygen gas and alcohol which had been consumed.

But 78,1192 grains of carbonic acid gas contain, according to Mr Lavoisier's calculation†, 55,279 grains of oxygen: 90,506 grains, however, of oxygen gas had disappeared; therefore 35,227 grains must have been employed in forming water.

† Mem. Par. 1781.

35,227 grains of oxygen gas require, in order to form water, 6,038 grains of hydrogen gas; and the quantity of water formed by this combination is 41,265 grains. But there were found 89,095 grains of water in the glass vessel; therefore 47,83 grains of water must have existed ready formed in the alcohol.

It follows from all these data, that the 76,7083 grains of alcohol, consumed during the combustion, were composed of

22,840	Carbon,
6,038	Hydrogen,
47,830	Water.
76,7*	

* Mem. Par. 1784.

Such were the consequences which Mr Lavoisier drew from his analysis. He acknowledged, however, that there were two sources of uncertainty, which rendered his conclusions not altogether to be depended upon. The first was, that he had no method of determining the quantity of alcohol consumed, except by the difference of weight in the lamp before and after combustion; and that therefore a quantity might have evaporated without combustion, which, however, would be taken into the sum of the alcohol consumed. But this error could not have been great; for if a considerable quantity of alcohol had existed in the state of vapour in the vessel, an explosion would certainly have taken place. The other source of error was, that the quantity of water was not known by actual weight, but by calculation.

354 Ingredients of alcohol.

To this we may add, that Mr Lavoisier was not warranted to conclude from his experiment, that the water found in the vessel, which had not been formed by the oxygen gas used, had existed in the alcohol in the state of water: he was intitled to conclude from his data, that the ingredients of that water existed in the alcohol before combustion; but not that they were actually combined in the state of water, because that combination might have taken place, and in all probability did partly take place, during the combustion. It follows, therefore, from Mr Lavoisier's experiments, that alcohol, supposing he used it perfectly pure, which is not probable, is composed of

0,2988	parts carbon,
0,1840	parts hydrogen,
0,5172	parts oxygen.
1,0000	

But it gives us no information whatever of the manner in which these ingredients are combined. That alcohol contains oxygen, has been proved by a very ingenious set of experiments performed by Messrs Fourcroy and Vauquelin. When equal parts of alcohol and sulphuric acid are mixed together, a quantity of caloric is disengaged, sufficient to elevate the temperature of the mixture to 190°. Bubbles of air are emitted, the liquor becomes turbid, assumes an opal colour, and at the end of a few days a deep red. When examined, the sulphuric acid is found to have suffered no change; but the alcohol is decomposed, partly converted into water and partly into ether, a substance which we shall describe immediately. Now, it is evident that the alcohol could not have been converted into water unless it had contained oxygen*.

* Nicholson's Journal, i. 391.

When equal parts of sulphuric acid and alcohol are mixed together and heat applied, the mixture boils at 208°, Alcohol. 208°, and a liquid equal to half the weight of the alcohol comes over into the receiver. This liquid is *ether*.

355 Ether. Ether is obscurely hinted at in some of the older chemical authors, but little attention was paid to it till a paper appeared in the Philosophical Transactions for 1730, written by a German, who called himself *Frobenius* (G), containing a number of experiments on it. In this paper it first received the name of *ether*.

356 Its properties. Ether is limpid and colourless, of a very fragrant smell, and a hot pungent taste. Its specific gravity is 0,7394. It is exceedingly volatile, boiling in the open air at 98°, and in a vacuum at —20°. Were it not therefore for the pressure of the atmosphere, it would always exist in a gaseous state. Ether unites with water in the proportion of ten parts of the latter to one of the former*. It is exceedingly inflammable, and, when kindled in the state of vapour, burns with rapidity, or rather explodes, if it be mixed with oxygen gas.

* *Count de Lauraguais.*

357 Theory of its formation. Chemists entertained various opinions respecting the nature of ether. Macquer supposed that it was merely alcohol deprived by the acid of all its water. But it was generally believed that the acid entered partly into its composition. Since the nature of acids has become better known, a great number of philosophers have supposed that ether is merely alcohol combined with a quantity of oxygen furnished by the acid. The real composition of this singular substance has been lately ascertained by the experiments of Fourcroy and Vauquelin.

" A combination (say they) of two parts of sulphuric acid and one part of alcohol elevates the temperature to 201°, becomes immediately of a deep red colour, which changes to black a few days afterwards, and emits a smell perceptibly ethereal.

" When we carefully observe what happens in the combination of equal parts of alcohol and concentrated sulphuric acid exposed to the action of caloric in a proper apparatus, the following phenomena are seen :

" 1. When the temperature is elevated to 208°, the fluid boils, and emits a vapour which becomes condensed by cold into a colourless, light, and odorant liquor, which from its properties has received the name of *ether*. If the operation be properly conducted, no permanent gas is disengaged until about half the alcohol has passed over in the form of ether. Until this period there passes absolutely nothing but ether and a small portion of water, without mixture of sulphurous or of carbonic acid.

" 2. If the receiver be changed as soon as the sulphurous acid manifests itself, it is observed that no more ether is formed, but the sweet oil of wine, water, and acetous acid, without the disengagement hitherto of a single bubble of carbonic acid gas. When the sulphuric acid constitutes about four-fifths of the mass which remains in the retort, an inflammable gas is disengaged, which has the smell of ether, and burns with a white oily flame. This is what the Dutch chemists have called *carbonated hydrogen gas*, or *olefiant gas*, because when mixed with the oxy-muriatic acid it forms oil. At this period the temperature of the fluid contained in the retort is elevated to 230° or 234°.

" 3. When the sweet oil of wine ceases to flow, if the receiver be again changed, it is found that nothing more passes but sulphurous acid, water, carbonic acid gas; and that the residuum in the retort is a black mass, consisting for the most part of sulphuric acid thickened by carbon.

" The series of phenomena here exposed will justify the following general inductions :

" 1. A small quantity of ether is formed spontaneously, and without the assistance of heat, by the combination of two parts of concentrated sulphuric acid and one part of alcohol.

" 2. As soon as ether is formed, there is a production of water at the same time ; and while the first of these compositions takes place, the sulphuric acid undergoes no change in its intimate nature.

" 3. As soon as the sulphurous acid appears, no more ether is formed, or at least very little ; but then there passes the sweet oil of wine, together with water and acetous acid.

" 4. The sweet oil of wine having ceased to come over, nothing further is obtained but the sulphurous and carbonic acids, and at last sulphur, if the distillation be carried to dryness.

" The operation of ether is therefore naturally divided into three periods : the first, in which a small quantity of ether and water are formed without the assistance of heat ; the second, in which the whole of the ether which can be obtained is disengaged without the accompaniment of sulphurous acid; and the third, in which the sweet oil of wine, the acetous acid, the sulphurous acid, and the carbonic acid, are afforded. The three stages have no circumstance common to all, but the continual formation of water, which takes place during the whole of the operation.

" The ether which is formed without the assistance of caloric, and the carbon which is separated without decomposition of the sulphuric acid, prove that this acid acts on alcohol in a manner totally different from what has hitherto been supposed. It cannot, in fact, be affirmed, that the acid is altered by the carbon, because daily experience shews that no sensible attraction takes place between these two bodies in the cold; neither can it be affected by the hydrogen ; for in that case sulphurous acid would have been formed, of which it is known that no trace is exhibited during this first period. We must therefore have recourse to another species of action, namely, the powerful attraction exercised by the sulphuric acid upon water. It is this which determines the union of the principles which exist in the alcohol, and with which the concentrated acid is in contact : but this action is very limited if the acid be small in quantity ; for an equation of affinity is soon established, the effect of which is to maintain the mixture in a state of repose.

" Since it is proved that ether is formed in the cold by the mixture of any quantities of alcohol and sulphuric acid, it is evident that a mass of alcohol might be completely changed into ether and vegetable acid by using a sufficient abundance of sulphuric acid. It is equally evident that the sulphuric acid would not by this means undergo any other change than that of being diluted with a certain quantity of water. This observation proves that alcohol contains oxygen, because water cannot exist without this principle, which must be afforded by the alcohol only, since the sulphuric acid suffers no decomposition.

" We must not, however, imagine, from these facts, that ether is alcohol minus oxygen and hydrogen. Its properties alone would contradict this ; for a quantity of carbon proportionally greater than that of the hydrogen

(G) The name was supposed to have been feigned.

drogen is at the same time separated. It may, in fact, be conceived that the oxygen, which in this case combines with the hydrogen to form water, not only saturated that hydrogen in the alcohol, but likewise the carbon. So that, instead of considering ether as alcohol minus hydrogen and oxygen, we must, by keeping an account of the precipitated carbon and the small quantity of hydrogen contained in the water which is formed, regard it as alcohol plus hydrogen and oxygen.

"The foregoing are the effects produced by a combination of alcohol and sulphuric acid, spontaneously produced without foreign heat. Let us, in the next place, observe how this combination is effected when caloric is added. The phenomena are then very different, tho' some of the results are the same.

"In the first place, we must observe, that a combination of sulphuric acid and alcohol in equal parts does not boil at less than 207 degrees of temperature, while that of alcohol alone boils at 176. Now since ebullition does not take place till the higher temperature, it is clear that the alcohol is retained by the affinity of the sulphuric acid, which fixes it more considerably. Let us also consider that organic bodies, or their immediate products, exposed to a lively brisk heat, without the possibility of escaping speedily enough from its action, suffer a partial or total decomposition, according to the degree of temperature. Alcohol undergoes this last alteration when passed through an ignited tube of porcelain. By this sudden decomposition it is converted into water, carbonic acid, and carbon. The reason, therefore, why alcohol is not decomposed when it is submitted alone to heat in the ordinary apparatus for distillation, is, that the temperature at which it rises in vapours is not capable of effecting the separation of its principles; but when it is fixed by the sulphuric acid or any other body, the elevated temperature it undergoes, without the possibility of disengagement from its combination, is sufficient to effect a commencement of decomposition, in which ether and water are formed, and carbon is deposited. Nothing more therefore happens to the alcohol in these circumstances than what takes place in the distillation of every other vegetable matter in which water, oil, acid, and coal, are afforded.

"Hence it may be conceived that the nature of the products of the decomposition of alcohol must vary according to the different degrees of heat; and this explains why at a certain period no more ether is formed but the sweet oil of wine and acetous acid. In fact, when the greatest quantity of the alcohol has been changed into ether, the mixture becomes more dense, and the heat which it acquires previous to ebullition is more considerable. The affinity of the acid for alcohol being increased, the principles of this acid become separated; so that, on the one hand, its oxygen seizes the hydrogen, and forms much water, which is gradually volatilized; while, on the other, the ether retaining a greater quantity of carbon, with which at that temperature it can rise, affords the sweet oil of wine. This last ought therefore to be considered as an ether containing an extraordinary portion of carbon, which gives it more density, less volatility, and a lemon yellow colour.

"During the formation of the sweet oil of wine, the quantity of carbon which is precipitated is no longer in the same proportion as during the formation of ether.

"What we have here stated concerning the manner in which ether is formed by the simultaneous action of the sulphuric acid and heat, appears so conformable to truth, that nearly the same effects may be produced by a caustic fixed alkali. In this case also a kind of ether and a sweet oil of wine are volatilized, and coal is precipitated. It is therefore only by fixing the alcohol that the sulphuric acid permits the caloric to operate a sort of decomposition. It may also be urged as a proof of this assertion, that the sulphuric acid, which has served to make ether as far as the period at which the sweet oil of wine begins to appear, is capable of saturating the same quantity of alkali as before its mixture with the alcohol *".

Ether may also be obtained by means of several other acids. The different liquids thus formed are distinguished by prefixing the name of the acid used in the process. Thus the ether above described is called *sulphuric ether*; that obtained by means of nitric acid, *nitric ether*, and so on. There are several minute shades of difference between these various ethers, which have not yet been properly inquired into.

* *Nicholson's Journ.* i. 391.

358 Substances soluble in alcohol.

Alcohol is capable of dissolving a great many bodies. A considerable number of these, with the quantities soluble, is exhibited in the following tables.

I. *Substances dissolved in large Quantities.*

Names of the Substances.	Temperature.	240 parts of alcohol dissolve
Nitrat of cobalt	54,5°	240 parts
copper	54,5	240
alumina	54,5	240
magnesia	180,5	694
Muriat of zinc	54,5	240
alumina	54,5	240
magnesia	180,5	1313
iron	180,5	240
copper	180,5	240
Acetite of lead	113	
copper †		
Benzoic acid	135,5	
Sulphat of magnesia		
Nitrat of zinc decomposed		
iron decomposed		
bismuth decomposed		

† *Withering, Phil. Trans.* lxxii. 336.

II. *Subſtances diſſolved in ſmall Quantities.*

Names of the Subſtances.	240 parts of alcohol at the boiling temperature diſſolve
Muriat of lime	240 parts
Nitrat of ammonia	214
Oxy-muriat of mercury	212
Succinic acid	177
Acetite of ſoda	112
Nitrat of ſilver	100
Refined ſugar	59
Boracic acid	48
Nitrat of ſoda	23
Acetite of copper	18
Muriat of ammonia	17
Arſeniat of potaſs	9
Acidulated oxalat of potaſs	7
Nitrat of potaſs	5
Muriat of potaſs	5
Arſeniat of ſoda	4
Barytes	
Strontites

‡ *Withering, Ibid.*
§ *Macquer, ibid.*

Theſe have been chiefly borrowed from tables which Mr de Morveau publiſhed in the *Journal de Phyſique* July 1785, and which were drawn up for the moſt part from the experiments deſcribed in Wenzel's Treatiſe on Affinities.

359 Its affinities. The affinities of alcohol are very imperfectly known. Thoſe ſtated by Bergman are as follows:

Water,
Ether,
Volatile oil,
Sulphurets of alkalies.

Chap. III. *Of* Oils.

360 Diſcovery of oil. Oil, which is of ſuch extenſive utility in the arts, was known at a very remote period. It is mentioned in Geneſis, and during the time of Abraham was even uſed in lamps *. The olive was very early cultivated, and oil extracted from it in Egypt. Cecrops brought it from Sais, a town in Lower Egypt, where it had been cultivated from time immemorial, and taught the Athenians to extract oil from it. In this manner the uſe of oil became known in Europe †. But the Greeks ſeem to have been ignorant of the method of procuring light by means of lamps till after the ſiege of Troy; at leaſt Homer never mentions them, and conſtantly deſcribes his heroes as lighted by torches of wood.

* *Gen.* xv. 17.
† *Herodot.* lib. ii. 59. and 62.

Oils are divided into two claſſes, *Fixed* and *Volatile*; each of which is diſtinguiſhed by peculiar properties.

361 Fixed oils. I. The fixed oils, called alſo *fat* or *expreſſed* oils, are numerous, and are obtained, partly from animals and partly from vegetables, by ſimple expreſſion. As inſtances, we ſhall mention whale oil or train oil, obtained from the blubber of the whale; olive oil, obtained from the fruit of the olive; lintſeed oil and almond oil, obtained from lintſeed and almond kernels. Fixed oils may alſo be obtained from poppy ſeeds, hemp ſeeds, beech maſt, and many other vegetable ſubſtances.

All theſe oils differ from each other in ſeveral particulars, but they alſo poſſeſs many particulars in common. Whether the oily principle in all the fixed oils is the ſame, and whether they owe their differences to accidental ingredients, is not yet completely aſcertained, as no proper analyſis has hitherto been made; but it is exceedingly probable, as all the oils hitherto tried have been found to yield the ſame products. In the preſent ſtate of our knowledge, it would be uſeleſs to give a particular deſcription of all the fixed oils, as the differences between them have not even been accurately aſcertained. We ſhall content ourſelves, therefore, with giving the characters which diſtinguiſh fixed oils in general, and an analyſis of one oil, by way of ſpecimen.

362 Their properties. Fixed oils are inſoluble in alcohol, which diſtinguiſhes them from volatile oils. They are alſo inſoluble in water.

They have an unctuous feel, are tranſparent while fluid, are deſtitute of ſmell, and have a mild inſipid kind of taſte.

They are all ſuſceptible of becoming ſolid by expoſure to a ſufficient degree of cold. Olive oil and almond oil freeze at $10\frac{1}{4}$ degrees ‡.

‡ *Chaptal's Chemiſtry*, Engliſh Tranſl. iii. 43.

They are capable of being converted into vapour by heat; but require for that purpoſe a temperature conſiderably ſuperior to that of boiling water. Olive oil boils at 600°, and moſt of the fixed oils hitherto tried require nearly the ſame degree of heat.

When in the ſtate of vapour they take fire on the approach of an ignited body, and burn with a yellowiſh white flame. It is upon this principle that candles and lamps burn. The tallow or oil is firſt converted into the ſtate of vapour in the wick; it then takes fire, and ſupplies a ſufficient quantity of heat to convert more oil into vapour; and this proceſs goes on while any oil remains. The wick is neceſſary to preſent a ſufficiently ſmall quantity of oil at once for the heat to act upon. If the heat were ſufficiently great to keep the whole oil at the temperature of 600°, no wick would be neceſſary, as is obvious from oil catching fire ſpontaneouſly when it has been raiſed to that temperature.

363 Analyſis of olive oil. Mr Lavoiſier analyſed olive oil by burning it in preciſely the ſame apparatus as that which he employed for analyſing alcohol.

The

The quantity of oil consumed amounted to 15,79 grains troy.

The quantity of oxygen gas amounted to 50,86 gr. troy. The whole amount therefore of the substances consumed during the combustion is 66,65 grains troy.

The carbonic acid obtained amounted to 44,50 gr. There was also a considerable quantity of water, the weight of which could not be accurately ascertained: but as the whole of the substances consumed were converted into carbonic acid gas and water, it is evident that if the weight of the carbonic acid be subtracted from the weight of these substances, there must remain precisely the weight of the water. Mr Lavoisier accordingly concluded, by calculation, that the weight of the water was 22,15 grains. Now the quantity of oxygen in 44,50 grains of carbonic acid gas is 32,04 grains, and the oxygen in 22,15 grains of water is 18,82 grains; both of which taken together amount to 50,86 grains, precisely the weight of the oxygen gas employed. There does not appear therefore to be any oxygen in olive oil.

The quantity of carbon in 44,50 grains of carbonic acid gas is 12,47 grains; and the quantity of hydrogen in 22,15 grains of water is 3,32 grains; both of which, when taken together, amount to 15,79 grains, which is the weight of the oil consumed.

It follows, therefore, from this analysis, that 15,79 grains of olive oil are composed of

12,47 Carbon,
3,32 Hydrogen.

Olive oil therefore is composed of about

79 Carbon,
21 Hydrogen.

100*

* Mem. Par. 1784. and Jour. de Phys. for 1787, July.

In what manner these substances are combined, cannot be learned from this analysis. Whether they combine directly, and saturate each other in that proportion, as is most probable – or whether the hydrogen is combined previously with a part of the carbon, and that compound combining with a certain quantity of carbon, forms oil, is altogether uncertain. Yet these questions are of the utmost importance; and till the method of solving them be discovered, we never can acquire any precise ideas about the constituent parts of a great number of substances, which, though formed ultimately of the same ingredients, differ very much in their properties from one another; as wax and oil; alcohol, sugar, and ether.

364 Rancidity.

When fixed oils are exposed to the atmosphere, they become thick, acquire a brown colour, and a peculiarly unpleasant smell: they are then said to be *rancid*. When oil is poured upon water, so as to form a thin layer on its surface, and is in that manner exposed to the atmosphere, these changes are produced much sooner, the oil becomes thicker, and assumes an appearance very much resembling wax. Berthollet, who first examined these phenomena with attention, ascribed them to the action of light: but Sennebier observed, that no such change was produced on the oil though ever so long exposed to the light, provided atmospherical air was excluded; but that it took place on the admission of oxygen gas, whether the oil was exposed to the light or not *. It cannot be doubted, then, that it is owing to the combination of oxygen. All substances that are capable of supplying that principle, the metallic oxides for instance, and several of the acids, produce the same effect upon oils; and it is a known fact, that oil is capable of reducing many of the metallic oxides to the metallic state, and consequently that it has a stronger affinity for oxygen.

* Ann. de Chim. xi. 89.

Mr Chaptal has supposed that oils become rancid merely because they contain a quantity of mucilage, with which the oxygen combines; and that when oxygen combines with fixed oils, it produces a different effect, converting them into what is called *drying oils*.

It is certain that oils contain a quantity of mucilage; but some change is evidently produced on the oils themselves by rancidity; for no agitation in water is capable of restoring them to their former state, although water deprives them of their mucilage. 365 Drying oils. *Drying oils*, so called because they are capable of *drying* completely when spread out, a property which renders them useful in painting, seem, as Sennebier observes, to be completely deprived of mucilage; for, in order to render an oil drying, it must be boiled, which evaporates or decomposes all the mucilage: they seem also to lose part of their hydrogen †.

† Berthollet.

366 Fixed oils dissolve sulphur,

Fixed oils are capable of dissolving sulphur at their boiling temperature. The solution is very fetid, owing to a partial decomposition of the oil. Hydrogen gas flies off, having a quantity of sulphur dissolved in it. When the solution cools, the sulphur crystallizes.

367 And phosphorus.

Fixed oils dissolve phosphorus. The solution is luminous, from the slow combustion of the phosphorus.

Fixed oils are capable of combining with many of the metallic oxides. The compounds are called *metallic soaps*. Several of the oxides are decomposed by being boiled in oils.

Fixed oils combine also with the alkaline earths and with alumina. The compounds are called *earthy soaps*.

368 Their affinities.

The affinities of the oils are as follows:

Lime,	Nitric acid,
Barytes,	Muriatic,
Fixed alkalies,	Sulphurous,
Magnesia,	Sulphuric,
Ammonia,	Acetous,
Oxide of mercury,	Sulphur,
Other metallic oxides (H),	Phosphorus (I).
Alumina.	

369 Volatile oils.

II. Volatile oils, called also *essential oils*, are all obtained from vegetables. They have a strong aromatic smell, and a pungent acrid taste. They are so volatile that they may be distilled by the heat of boiling water. They are soluble in alcohol, but not in water. They evaporate on the application of heat, without leaving any stain behind them, which is not the case with the fixed oils. By this test, accordingly, it is easy to discover whether they have been adulterated with any of the fixed oils. Let a drop of the volatile oil fall upon a sheet of writing paper, and then apply a gentle heat

(H) Their order not well ascertained.

(I) The first column was ascertained by Berthollet. The last is to be considered as unconnected with the first. On account of the affinity of these two classes of bodies for each other, it has not been possible to discover which of them has the greatest affinity for oil.

heat to it. If it evaporates without leaving any ſtain upon the paper, the oil is pure; but if it leaves a ſtain, it has been contaminated with ſome fixed oil or other.

Volatile oils are very numerous, and differ from one another, in fluidity and weight, in their freezing point, and in ſeveral other particulars. Little attention has been paid to the greateſt part of them, becauſe few of them have been found of any uſe. The principal quality for which they are valued is their odour. Some of them are obtained by expreſſion, as oil of bergamot, lemons, oranges; others by diſtillation, as oil of peppermint, thyme, lavender, &c. It would be uſeleſs, even if it were poſſible, to give a particular deſcription of all the volatile oils.

370 Their properties.

They are more inflammable than the fixed oils; a quality which they owe to their volatility. As far as experiments have hitherto been made, they ſeem to conſiſt of carbon and hydrogen; but nothing is known concerning the proportions of theſe ingredients. They thicken when expoſed to the air, probably by combining with oxygen, and form *reſins* (K).

When expoſed to cold, or when kept for a long time, ſome of them depoſite cryſtals reſembling the acid of benzoin (L).

They diſſolve ſulphur, and form what have been called *balſams of ſulphur*.

They are capable of combining with moſt of the ſubſtances that unite with fixed oils. Their affinities, which certainly differ from thoſe of fixed oils, have not yet been properly aſcertained.

Chap. IV. *Of* Alkalies.

371 Properties of alkalies.

Substances poſſeſſed of the following properties are called *alkalies*:

1. Incombuſtible.
2. Capable of converting vegetable blues to a green.
3. A hot cauſtic taſte.
4. Very ſoluble in water, even when combined with carbonic acid.

There are three alkalies, *potaſs*, *ſoda*, and *ammonia*. The two firſt are called *fixed* alkalies, becauſe a very violent heat is neceſſary to volatilize them; the laſt is called *volatile* alkali, becauſe it very eaſily aſſumes a gaſeous form, and is conſequently diſſipated by a very moderate degree of heat.

Sect. I. *Of Potaſs.*

372 Method of procuring potaſs.

If a ſufficient quantity of wood be burnt to aſhes, and theſe aſhes be afterwards waſhed repeatedly with water till it comes off free from any taſte, and if this liquid be filtrated and evaporated to dryneſs, the ſubſtance which remains behind is *potaſs*; not, however, in a ſtate of purity, for it is contaminated with ſeveral other ſubſtances; but ſufficiently pure to exhibit many of its properties. In this ſtate, it occurs in commerce under the name of *potaſh*. It may be purified conſiderably, by putting it in a crucible, keeping it red hot for ſome time; then diſſolving it in water, filtrating it, and evaporating it again to dryneſs. By the following method it may be obtained nearly pure: Mix together equal quantities of nitre and carbon, and put them by little and little into a red hot crucible. They burn with a vivid flame, and leave behind them a quantity of potaſs. This is to be diſſolved in water, filtrated, and evaporated to dryneſs. Or potaſs may be obtained by burning tartar wrapt up in brown paper and placed in a crucible (M).

The potaſs procured by theſe laſt proceſſes is exceedingly white; it is not, however, quite pure; for it is combined with a ſubſtance which blunts all its properties conſiderably. This ſubſtance is carbonic acid gas; from which it may be ſeparated by diſſolving it, and mixing with it an equal quantity of lime made into a paſte with water. The lime has a greater affinity for carbonic acid gas, and therefore combines with it; and the pure potaſs remains diſſolved in the water, and may be ſeparated from the lime by filtrating the mixture. This proceſs, however, muſt be performed in cloſe veſſels; for there is a little carbonic acid gas in the atmoſphere, which would again combine with the potaſs if it were allowed to ſtand expoſed to the air.

It is then to be evaporated till a thick pellicle appears on its ſurface, and afterwards allowed to cool; and all the cryſtals which have formed are to be ſeparated, for they conſiſt of foreign ſalts. The evaporation is then to be continued in an iron pot; and, during the proceſs, the pellicle which forms on the ſurface is to be carefully taken off with an iron ſkimmer. When no more pellicle appears, and when the matter ceaſes to boil, it is to be taken off the fire, and muſt be conſtantly agitated while cooling with an iron ſpatula. It is then to be diſſolved in double its own weight of cold water. This ſolution is to be filtered and evaporated in a glaſs retort till it begin to depoſite regular cryſtals. If the maſs conſolidates ever ſo little by cooling, a ſmall quantity of water is to be added, and it muſt be heated again. When a ſufficient number of cryſtals have been formed, the liquor which ſwims over them, and which has aſſumed a very brown colour, muſt be decanted off, and kept in a well-cloſed bottle till the brown matter has ſubſided, and then it may be evaporated as before, and more cryſtals obtained. The cryſtals may then be diſſolved in pure water. By this proceſs, which was invented by Mr Lowitz of Peterſburgh *, potaſs may be obtained in a ſtate of the greateſt purity. The ſhape of its cryſtals is very different, according to the way in which they have been produced. When allowed to form in the cold, they are octahedrons in groups, and contain 0,43 of water: When formed by evaporation

* *Nicholſon*, i. 164.

(K) Reſins are concrete vegetable juices; the diſtinguiſhing property of which is inſolubility in water and ſolubility in alcohol. *Common reſin*, or *roſin*, from which they derive their name, is one of them; and ſealing wax conſiſts almoſt entirely of another.

(L) See a paper by Margueron on this ſubject, *Ann. de Chim.* xxi. 174.

(M) That potaſs was known to the ancient Gauls and Germans, cannot be doubted, as they were the inventors of ſoap, which, Pliny informs us, they compoſed of aſhes and tallow. Theſe aſhes (for he mentions the aſhes of the beech tree particularly) were nothing elſe but potaſs; not, however, in a ſtate of purity. *Plinii*, lib. xviii. c. 51. The κονια, ιος, mentioned by Ariſtophanes and Plato, appears to have been a ley made of the ſame kind of aſhes.

Alkalies.

tion on the fire, they assume the figure of very thin transparent blades of extraordinary magnitude, which, by an assemblage of lines crossing each other in prodigious numbers, present an aggregate of cells or cavities, commonly so very close, that the vessel may be inverted without losing one drop of the liquid which it contains†.

* Nicholson, i. 164.

Pure potash is so exceedingly corrosive, that when applied to any part of the body, it destroys it almost instantaneously. On account of this property, it has been called *caustic*, and is often used by surgeons under the name of the *potential cautery*, to open abscesses, and destroy useless or hurtful excrescences.

373 Black's discovery of the cause of its causticity.

As potash is never obtained at first in a state of purity, but always combined with carbonic acid, it was long before chemists understood to what the changes produced upon it by lime were owing. According to some, it was deprived of a quantity of mucilage, in which it had formerly been enveloped; while, according to others, it was rendered more active by being more comminuted. At last, in 1756, Dr Black published the celebrated experiments which we have so often mentioned; in which he proved, by the most ingenious and satisfactory analysis, that the *potash* which the world had considered as a simple substance, was really a compound, consisting of potash and carbonic acid; that lime deprived it of this acid; and that it became more active by becoming more simple.

374 Meyer's theory.

While Dr Black was thus occupied in Scotland, Mr Meyer was employed in Germany in the same researches; from which, however, he drew very different conclusions. His Essays on Lime appeared in 1764. Pouring into lime-water a solution of potash (*carbonat of potash*), he obtained a precipitate, which he found not to differ from limestone. The alkali had therefore deprived the lime of its causticity and its active properties; and these very properties it had itself acquired. From which he concluded, that the causticity of lime was owing to a particular acid with which it had combined during its calcination. The alkali deprived the lime of this acid, and therefore had a stronger affinity for it. To this acid he gave the name of *acidum pingue* or *causticum*. It was, according to him, a subtile elastic mixt, analogous to sulphur, approaching very nearly to the nature of fire, and actually composed of an acid principle and fire. It was expansible, compressible, volatile, astringent, capable of penetrating all vessels, and was the cause of causticity in lime, alkalies, and metals. This theory was exceedingly ingenious, and it was supported by a vast number of new and important facts. But notwithstanding the reputation and acknowledged genius and merit of its author, it never gained many followers; because the true theory of causticity, which had been already published by Dr Black, soon became known on the continent; and, notwithstanding some opposition at first, soon carried conviction into every unprejudiced mind. Even Mr Meyer himself readily acknowledged its truth and importance, though he did not at first, on that account, give up his own theory.

When potash is exposed to the action of fire, it first becomes soft, and melts into a transparent liquid at the commencement of ignition.

When exposed to the air, it attracts moisture very fast, and is soon converted into a liquid. It attracts, at the same time, carbonic acid gas, for which it has a very strong affinity. It is impossible, then, to keep potash in a state of purity, except in very close vessels.

375 Sulphuret of potash.

It unites readily with sulphur, and forms *sulphuret of potash*. This compound may be formed two ways; either by melting the ingredients together, or by boiling them in water, and then filtrating the solution. Sulphuret of potash when dry, in which state it is obtained by the first process, is of a brown colour. It is soluble in water, and very soon attracts moisture.

While dry it produces no change upon the air of the atmosphere, as Messrs Dieman, Van Trooftwyck, Nieuwland, and Bondt, ascertained by experiment *. But when moistened with water, it very soon absorbs all the oxygen gas which happens to be in the vessel in which it is enclosed, and leaves nothing but azotic gas. This fact was first observed by Scheele, and induced him to use sulphuret of potash for an *eudiometer*, or instrument to measure the quantity of oxygen contained in any given portion of atmospheric air.

* Ann. de Chim. xiv. 294.

If sulphuret of potash be allowed to remain moist, and in contact with the atmosphere, it is gradually converted into sulphat of potash by the sulphur combining with oxygen, and forming sulphuric acid. At the same time the sulphuret emits a fetid smell, which is known to be the odour of sulphurated hydrogen gas. The sulphuret then decomposes the water with which it is mixed. Very little sulphurated hydrogen gas, however, is emitted, except an acid (the sulphuric, for instance) be poured upon the mixture, and then it is given out very copiously. The reason of this is, that there is an affinity between the potash and this gas. Accordingly it is retained by the potash after it is formed. But as the acids have a much stronger affinity for potash, as soon as any of them is poured in the gas is obliged to separate †.

† Ibid.

If liquid sulphuret of potash be kept in close vessels, it is not decomposed except in part; because as soon as the alkali is saturated with the sulphurated hydrogen gas, the action of the sulphur on the water is at an end ‡.

‡ Ibid.

The explanation of the action of this sulphuret on the atmosphere, which the Dutch chemists above-mentioned give from these data, is as follows:

Sulphuret of potash decomposes water; sulphurated hydrogen gas is formed, and absorbed by the alkali. This gas has a strong affinity for oxygen, which it absorbs from the atmosphere: the hydrogen combines with this oxygen, and forms water; and the sulphur is again precipitated, or rather left combined with the potash. Water is again decomposed by the attraction of the sulphur for oxygen; new sulphurated hydrogen gas is again formed; again absorbed; again attracts oxygen gas; and is again decomposed. And this process goes on till the whole of the sulphur has combined with oxygen, and consequently till the sulphuret is converted into a sulphat §.—The only part of this theory which requires confirmation, is the action of sulphurated hydrogen gas on oxygen gas, and the consequent formation of water. And this they have rendered not improbable, by shewing that sulphurated hydrogen gas combined with alkali has the property of absorbing oxygen gas from the atmosphere ‖.

§ Ibid.

‖ Ibid. p. 305.

376 Phosphuret of potash.

Potash unites with phosphorus by fusion, and forms a phosphuret of potash. Little is known concerning its properties, except that it produces phosphurated hydrogen gas.

Potash seems also capable of combining with carbon.

Potash does not combine with the metals; but it unites with many of their oxides.

When

Alkalies.

When a ſolution of potaſs is boiled upon ſilica recently procured, it diſſolves part of it. As the ſolution cools, it aſſumes the appearance of a jelly, even though previouſly diluted with 17 times its own weight of water *.

* Bergman, ii. 32.

377 Glaſs.

When equal parts of ſilica and potaſs are melted together, they combine and form *glaſs*. A ſubſtance which, whether we conſider its hardneſs, beauty, and tranſparency, its amazing ductility, while hot, or the difficulty of decompoſing it, muſt be allowed to be one of the moſt uſeful compounds ever invented by man.

When the quantity of potaſs is double or triple that of the ſilica, the glaſs is ſoluble in water, and forms what is called *liquor ſilicum*.

Potaſs ſeems alſo capable of combining in the ſame manner with barytes, lime, magneſia, and alumina; but theſe combinations have never been examined with attention. Lime, however, is often added to the materials for making glaſs, and is ſuppoſed to increaſe its hardneſs and ſolidity.

The metallic oxides have the property of rendering glaſs more fuſible, and of communicating various colours to it; they accordingly very often make a part of its compoſition. The colours communicated by theſe oxides will appear from the following Table:

Metallic Oxides.	Colour communicated to Glaſs.
Oxide of gold and tin,	Purple.
Silver,	Yellow or golden.
Iron,	Pale green.
Lead,	Colourleſs.
Zinc,	White.
Antimony,	Green (N).
Arſenic,	White.
Cobalt,	Blue.
Nickel,	Blue (O).
Mangaueſe,	Red.
Tungſten,	Colourleſs.
Molybdenum,	Colourleſs.
Uranium,	Grey (opaque).
Titanium,	White (opaque).
Tellurium,	White.
Chromum,	Green.

378 Soap.

Potaſs combines readily with fixed oils, and forms the compound known by the name of *ſoap*.

379 Potaſs, whether a compound.

Potaſs has never yet been decompoſed. Several chemiſts, indeed, have conjectured, that it was a compound of lime and azot; and ſome perſons have even endeavoured to prove this by experiment; but none of their proofs are at all ſatisfactory. We ought, therefore, in ſtrict propriety, to have aſſigned it a place in the firſt part of this article: but this would have ſeparated the alkalies from each other, and would have introduced a confuſion into the article, which would have more than counterbalanced the logical exactneſs of the arrangement. Beſides, we are certain, from a variety of facts, that all the alkalies are compounds: One of them has actually been decompounded; and the other two have been detected in the act of formation, though the ingredients which compoſe them have not hitherto been diſcovered.

Whether potaſs contains lime is a different queſtion. Were we to judge from analogy, we ſhould ſuppoſe, that the four alkaline earths, and the three alkalies, poſſeſs one common principle. They have a great number of common properties, and perhaps ought to be claſſed altogether under the name of *alkalies*.

That azot enters into the compoſition of all theſe bodies, as Fourcroy has conjectured, is far from improbable. One alkali, as we ſhall ſoon ſee, actually contains azot. But no concluſion can be drawn till future diſcoveries have lifted off the veil which at preſent obſtructs our view.

The affinities of potaſs are as follows: 380 Its affinities

Sulphuric acid,
Nitric,
Muriatic,
Sebacic,
Fluoric,
Phoſphoric,
Oxalic,
Tartarous,
Arſenic,
Succinic,
Citric,
Formic,
Lactic,
Benzoic,
Sulphurous,
Acetous,
Saccholactic,
Boracic,
Nitrous,
Carbonic,
Pruſſic,
Oil,
Sulphur,
Phoſphorus,
Water.

The place of the metallic oxides has not yet been aſcertained.

Sect. II. *Of Soda.*

Soda, called *mineral alkali*, becauſe it is found in the earth, was known to the ancients under the names of νιτρον and *nitrum* (P). It was long confounded with potaſs; and perhaps was never properly diſtinguiſhed from it till Du Hamel publiſhed a paper on the ſubject in 1736.

Its properties, while pure, are preciſely the ſame with thoſe of potaſs, excepting only that its affinity for other bodies is not ſo ſtrong; it does not, therefore, require any particular deſcription. We ought to mention, however, that it differs from potaſs in one particular; potaſs attracts moiſture in the air, but ſoda parts with it, and when expoſed to the atmoſphere, ſoon crumbles down into a dry powder. 381 Properties of ſoda.

It is capable of combining with all the ſubſtances with which potaſs unites; but it forms compounds poſſeſſed, in general, of very different properties from thoſe of the compounds into which potaſs enters.

It

(N) If the glaſs be made with ſoda.

(O) But reddiſh if the glaſs be formed of ſoda. *Klaproth.*

(P) The λιτρον of the Athenians was evidently the ſame ſubſtance; and ſo was the נתר of the Hebrews.

Alkalies.

It is reckoned more proper than potaſs for forming glaſs and ſoap.

Some chemiſts have ſuppoſed that it is compoſed of magneſia and azot; but their proofs are inſufficient.

The order of its affinities is the ſame with that of potaſs.

Sect. III. *Of Ammonia.*

382 Diſcovery of ammonia.

Ammonia (q), volatile alkali, or *hartſhorn*, as it is called in commerce, is mentioned as early as the 15th century. Both Baſil Valentine and Raymond Lully deſcribed the methods of procuring it. Dr Black was the firſt who diſtinguiſhed pure ammonia from the carbonat of ammonia, or ammonia combined with carbonic acid; and Dr Prieſtley firſt diſcovered the method of obtaining it in a ſtate of complete purity.

To obtain pure ammonia, mix common ſal ammoniac with three parts of ſlacked lime; apply heat; and receive the product in a veſſel filled with mercury ſtanding in a baſon of mercury. A gas comes over, which is pure ammonia*. This gas is tranſparent like common air, and is not condenſed by cold.

* *Prieſtley on Air*, iii. 371.

383 Its properties.

Its ſpecific gravity is 0,000732. It is to common air as 600 to 1000†.

† *Kirwan on Phlog.* p. 28.

It has a very ſtrong, but not unpleaſant ſmell. Animals cannot breathe it without death. When a lighted candle is let down into this gas, it goes out three or four times ſucceſſively; but at each time the flame is conſiderably enlarged by the addition of another flame of a pale yellow colour, and at laſt this flame deſcends from the top of the veſſel to the bottom‡.

‡ *Prieſtley*, ii. 381.

Water abſorbs this gas with avidity. It diſappears almoſt inſtantly on the introduction of a little water. From an experiment of Dr Prieſtley, it appears that water ſaturated with this gas is of the ſpecific gravity 1,1435§.

§ *Ibid.* p. 372.

This water acquires the ſmell of ammonia. It has a very ſtrong diſagreeable taſte, and converts vegetable colours to a green.

Ammonia in the ſtate of gas has no effect upon ſulphur or phoſphorus. Carbon abſorbs it; probably becauſe it contains water. Neither hydrogen nor azot produce any alteration on it ‖.

‖ *Ibid.* p. 377.

Alcohol and ether abſorb it in conſiderable quantity ¶.

¶ *Ibid.*

384 Its component parts.

Dr Prieſtley diſcovered, that when electric exploſions were made to paſs through this gas, its bulk was gradually augmented to thrice the ſpace which it formerly occupied. It was then moſtly converted into hydrogen gas. He diſcovered, too, that heat produced the very ſame effect*. Theſe experiments prove that hydrogen enters as an ingredient into the compoſition of ammonia.

* *Ibid.* 389.

Mr Scheele obſerved, that when ammonia was treated with the oxides of mangançſe, gold, or mercury, the oxides were reduced; the ammonia diſappeared; and nothing remained but a quantity of azotic gas. Theſe facts induced Bergman to conjecture, that ammonia was compoſed of hydrogen and azot: a conjecture which has been fully confirmed by the experiments of Berthollet.
