the air thus exploded is ſtrongly attracted by the fronting part of the other body, and muſt fly thither in preference to any other point. If, moreover, the fronting part of A be prominent or pointed, this effect will be produced in a ſuperior degree; and the current of electrified air, which will begin very early, will increaſe this diſpoſition to transference in this way by rarefying the air; a change which the whole courſe of electric phenomena ſhews to be highly favourable to this transference, although we cannot perhaps form any very adequate notion how it contributes to this effect. This ſeems to be the reaſon why a great exploſion and ſnap, with a copious transference of electricity, is generally preceded by a hiſſing noiſe like the ruſhing of wind, which ſwells to a maximum in the loud ſnap itſelf.

208. If two prominences, preciſely ſimilar, and electrified in the contrary way to the ſame degree, are preſented to each other, we cannot ſay from which the current ſhould take its commencement, or whether it ſhould not equally begin from both, and a general diſperſion of air laterally be the effect; but ſuch a ſituation is barely poſſible, and muſt be infinitely rare. The current will begin from the ſide which has ſome ſuperiority of propelling force. We are diſpoſed to think that this current of material electrified ſubſtance muſt ſuffer great change during its paſſage, by mixing with the current in an oppoſite electrical ſtate coming from the other body. Any little maſs of the one current muſt ſtrongly attract a contiguous maſs of the other, and certain changes ſhould ſurely ariſe from this mixture. Theſe may, in their turn, make a great change in the *mechanical* motions of the air; and, inſtead of producing a *quaqua verſum* diſperſion of air from between the bodies, as ſhould reſult from the meeting of oppoſite ſtreams, it may even produce a collapſing of the air by the mutual ſtrong attractions of the little maſſes. Many valuable experiments offer themſelves to the curious inquirer. Two little balls may be thus preſented to each other, and a ſmoke may be made with roſin to occupy the interval between them. Motions may be obſerved which have certain analogies that would afford uſeful information to the mechanical inquirer. There muſt be ſomething of this mixture of currents in all ſuch transferences, and the moſt minute differences in the condition of a little parcel of the air may greatly affect the future motions. The moſt promiſing form of ſuch experiment would be to uſe two points of the ſame ſubſtance, ſhape, and ſize, and electrified to the ſame degree in oppoſite ſenſes.

209 After all care has been taken to inſure ſimilarity, there remains one eſſential difference, that *the one current is redundant in electric fluid, and the other deficient*. This circumſtance *muſt* produce characteriſtic differences of appearance. And are there not ſuch differences? Is not the pencil and the ſtar of light a characteriſtic difference? And does not this well-ſupported fact greatly corroborate the opinion of Dr Franklin, that the electric phenomena reſult from the redundancy and deficiency of *one* ſubſtance, and not from two diſtinct ſubſtances operating in a ſimilar manner? For the diſtinction in appearance is a mechanical diſtinction. Motion, direction, velocity, are perceivable in it. Locomotive forces are concerned in it; but they are ſo implicated with forces which probably reſemble chemical affinities, hardly operating beyond contact, that to extricate their effects from the complicated phenomenon ſeems a deſperate problem.

Characteriſtic differences of poſitive and negative electricity.

There is ſome hitherto inexplicable chemical compoſition and decompoſition taking place in the transference of electricity. Of this a numerous train of obſervations made ſince the dawn of the pneumatic chemiſtry leaves us no room to doubt. The emerſion or production of light and heat is a remarkable ſign and proof. Now *this takes place along the whole path of transference;* therefore the proceſs is by no means completed at the point from which the active cauſe proceeds; and although there be certain appearances that are pretty regular, they are ſtill mixed with others of the moſt capricious anomaly. The zigzag form of the moſt condenſed ſpark, totally unlike, by its ſharp angles, to any motions producible by accelerating forces, which motions are, without exception, curvilineal, makes us doubt exceedingly whether the luminous lines which we obſerve are ſucceſſive appearances of the ſame matter in different places, or whether they be not rather ſimultaneous, or nearly ſimultaneous, coruſcations of different parcels of matter in different places, indicating chemical compoſitions taking place almoſt at once; and this becomes more probable, when we reflect on what has been ſaid already of the jumbling of oppoſite currents; ſuch mixtures ſhould be expected. We have ſeen a darted flaſh of lightning which reached (in a direction nearly parallel to the horizon) above three miles from right to left; and it ſeemed to us *to be co-exiſtent;* we could not ſay at which end it began. The thunder began with a loud crack, and continued with a moſt irregular rumbling noiſe about 15 ſeconds, and ſeemed equal on both hands. We imagine that it was really a ſimultaneous ſnap, in the whole extent of the ſpark, but of different ſtrength in different places; different portions of the ſonorous agitation were propagated to the ear in ſucceſſion by the ſonorous undulations of air, cauſing it to ſeem a lengthened ſound. Such would be the appearance to a perſon ſtanding at one end of a long line of ſoldiers who diſcharge their firelocks at one inſtant. It will ſeem a running fire, of different ſtrength in different parts of the line, if the muſkets have been unequally loaded. It is inconceivable that this long zigzag ſpark can mark the track of an individual maſs of electrified air. The velocity and momentum would be enormous, and would ſweep off every thing in its way, and its path could not be angular. The ſame muſt be aſſerted of the ſtreams of light in our experiments. The velocity is ſo unmeaſurable that we cannot tell its direction. There may be very little local motion, juſt as in the propagation of ſound, or of a wave on the ſurface of water. That particular change of mutual ſituation among the adjoining atoms which occaſions chemical ſolution or precipitation may be produced in an inſtant, over a great extent, as we know that a parcel of iron filings, lying at random on the ſurface of quickſilver, will, in one inſtant, be arranged in a certain manner by the mere neighbourhood of a magnet. Is not this like the ſimultaneous precipitation of water along the whole path of a diſcharge?

But ſtill there muſt be ſome cauſe which gives theſe ſimultaneous coruſcations a ſituation with reſpect to each other, that has a certain regularity. Now the luminous *trains* (for they are not uniform *lines* of light) of almoſt continuous ſparks which are arranged between a positive and a negative point, seem to us to indicate emanation from the positive, and reception by the negative point. The general line has a considerable resemblance to the path of a body projected from the positive point, repelled by it, and attracted by the negative point. This will appear to the mechanician on a very little reflection. If the curve were completely visible, it would somewhat resemble those drawn between P and N in fig. 35. PABN overpasses the point N, and comes to it from behind; P*ab*N lies within the other, and arrives in a direction nearly perpendicular to the axis; PαBN describes a straight line, and arrives in the direction PN. As the chemical composition advances, the light is disengaged or produced, and therefore the appearances are more rare as we advance farther in the direction in which they are produced; and there would perhaps be no appearance at all at the point where the motion ends, were it not that the few remaining parcels, where the compositions or decompositions have not been completed, are crowded together at the negative point, *incomparably* more than in any other part of the track. We think that these considerations offer some explanation of the appearance of the pencil and star, which are so uniformly characteristic of the positive and negative electricities; but we see many grounds of uncertainty and doubt, and offer it with due diffidence.

210 Lichtenberg's electric writing affords distinctive marks of + and —

The curious figures observed by Mr Lichtenberg, formed by the dust which settles on a line drawn on the face of a mirror by the positive and by the negative knobs of a charged jar, are also uniformly characteristic of the two electricities. These are mechanical distinctions, indicating certain differences of accelerating forces. We must refer the curious reader to Lichtenberg's Dissertations in the *Gottingen Commentaries*; to the *Publication of the Haarlem Society*; to the *Gotha Magazine*; to *Dissertations by Spath* at Altdorff, and other German writers.

211 Dissipation of electricity into the air is proportional to the density.

It only remains for us to take notice of the general laws of the dissipation of electricity into the air, and along imperfect insulators. On this subject we have some valuable experiments of Mr Coulomb, published in the Memoirs of the Academy of Sciences of Paris for 1785.

These experiments were made with the assistance of an electrometer of a particular construction, which shall be described under the article ELECTROMETER.

The general result of Mr Coulomb's experiments was, that the momentary dissipation of moderate degrees of electricity is proportional to the degree of electricity at the moment. He found that the dissipation is not sensibly affected by the state of the barometer or thermometer; nor is there any sensible difference in bodies of different sizes or different substances, or even different figures, provided that the electricity is very weak.

212. But he found the dissipation greatly affected by the different states of humidity of the air. Saussure's hygrometer has its scale distinctly related to the quantity of water dissolved in a cubic foot of the air. The following little Table shews an evident relation to this in the dissipation of electricity:

Hygrometer.	Grains water in cubic foot.	Dissipation per minute.
69	6,197	$\frac{1}{60}$
75	7,295	$\frac{1}{41}$
80	8,045	$\frac{1}{29}$
87	9,221	$\frac{1}{14}$

Hence it follows, that the dissipation is very nearly in the triplicate ratio of the moisture of the air. Thus if

$$\frac{60}{41} \text{ be considered as } = \left(\frac{7,197}{6,180}\right)^m \text{ we have } m = 2,764$$

$$\frac{60}{29} \; . \; . \; . \; . \; . \; = \left(\frac{8,045}{6,180}\right)^m \text{ gives } m = 2,76$$

$$\frac{60}{14} \; . \; . \; . \; . \; . \; = \left(\frac{9,220}{6,180}\right)^m \text{ gives } m = 3,61$$

Hence, at a medium, $m = 3,40$.

We should have observed, that the ingenious author took care to separate this dissipation by immediate contact with the air, from what was occasioned by the imperfect insulation afforded by the supports.

213 Diminution of repulsion is double of the dissipation.

It must also be remarked here, that the immediate object of observation in the experiments is the diminution of repulsion. This is found to be, in any given state of the air, a certain proportion of the whole repulsion at the moment of diminution: but this is double of the proportion of the density of the electric fluid: for it must be recollected, that the repulsions by which we judge of the dissipation are mutual, exerted by every particle of fluid in the ball *t* of Coulomb's electrometer, on every particle in the ball *a*. It is therefore proportional to the electric density of each; and therefore, during the whole dissipation, the densities retain their primitive proportion; therefore, the diminution of the repulsion being as the diminution of the products of the densities, it is as the diminution of the squares of either. If therefore the density be represented by d, the mutual repulsion is representable by d^2, and its momentary diminution by the fluxion of d^2; that is, by $2d\dot{d}$, or $2\dot{d} \times d$. Now $2\dot{d} \times d$ is to d^2 as $2\dot{d}$ is to d; and therefore the diminution of repulsion observed in our experiment bears to the whole repulsion twice as great a proportion as the diminution of density, or the quantity of fluid dissipated bears to the whole quantity at the moment. For example, if we observe the repulsion diminished $\frac{1}{40}$, we conclude that $\frac{1}{80}$ of the fluid has escaped.

214. Mr Coulomb has not examined the proportion between the dissipations from bodies of different sizes. A great and a small sphere, communicating by a very long canal, have superficial densities, and tendencies to escape, inversely proportional to the diameters. A body of twice the diameter has four times the surface; and tho' the tendency to escape be twice as small, the surface is four times as great. Perhaps the greater surface may compensate for the smaller density, and the quantity of fluid actually gone off may be greater in a large sphere. This may be made the subject of trial.

215 Dissipation depends on the state of the air.

It must be kept in mind, that the law of dissipation ascertained by these experiments, relates to one given state of the air, and that it does not follow that in another state, containing perhaps the same quantity of water, the dissipation shall be the same. The air is such a hetea heterogeneous and variable compound, that it may have very different affinities with the electric fluid. Mr Coulomb thought that he ſhould infer from his numerous experiments, that the diſſipation did not increaſe in the ratio of the cube of the water diſſolved in the air, unleſs it was nearly as much as it could diſſolve in that temperature. This indeed is conformable to general obſervation: for air is thought dry when it dries quickly any thing expoſed to it; that is, when not nearly ſaturated with moiſture. Now it is well known, that what is thought dry air is favourable to electricity.

216 Diſſipation by imperfect inſulators.

The diſſipation along imperfect inſulators is brought about in a way ſomewhat different from the manner of its eſcaping by electrifying the contiguous air and going off with it. It ſeems to be chiefly, if not ſolely, along the ſurface of the inſulating ſupport that the electricity is diffuſed, and that the diffuſion is produced there chiefly by the moiſture which adheres to it. It is not very eaſy to form a clear notion of the manner, but Mr Coulomb's explanation ſeems as ſatisfactory as any we have ſeen.

Procedure thereof.

Water adheres to all bodies, ſticking to their ſurfaces. This adheſion prevents it from going off when electrified; and it is therefore ſuſceptible of a higher degree of electrification. If we ſuppoſe that the particles of moiſture are uniformly diſpoſed along the ſurface, leaving ſpaces between them, the electricity communicated to one particle muſt attain a certain denſity before it can fly acroſs the inſulating interval to the next. Therefore, when ſuch an imperfect conductor is electrified at one end, the electricity, in paſſing to the other, will be weakened at every ſtep. If we take three adjacent particles *a*, *b*, *c*, of this conducting matter, we learn, from nº 105, that the motion of *b* is ſenſibly affected only by the difference of *a* and *c*; and therefore that the paſſage of electricity from *b* to *c* requires that this difference be ſuperior or equal to the force neceſſary for clearing this coercive interval. Let a particle paſs over. The electric denſity of the particle *b* of conducting matter is diminiſhed, while the denſity of the particle on the other ſide of *a* remains as before. Therefore ſome will paſs from *a* to *b*, and from the particle preceding *a* to *a*; and ſo on, till we come to the electrified end of this imperfect inſulator. It is plain from this conſideration, that we muſt arrive at laſt at a particle beyond *c*, where the whole repulſion of the preceding particle is juſt ſufficient to clear this interval. Some will come over, whoſe repulſion, now acting in the oppoſite direction, will hinder any fluid from ſupplying its place in the particle which it has quitted. Here the transference will ſtop, and beyond this the inſulation is complete. There is therefore a mathematical relation between the inſulating power and the length of the canal, which may be aſcertained by our theory; and thus another opportunity obtained for comparing it with obſervation. That this inveſtigation may be as ſimple as poſſible, we may take a very probable caſe, namely, where the inſulating, or, to name it more graphically, the coercive, interval is equal in every part of the canal.

217 Theory thereof.

Let R be the coercive power of the inſulator; that is, let R be the force neceſſary for clearing the coercive interval. Let a ball C (fig. 36.) be ſuſpended by a ſilk thread AB, and let C repreſent the quantity of its redundant fluid; and let the denſity in the different points of the canal be as the ordinates AD, P*d*, &c. of ſome curve line D*d*B, which cuts the axis in B where the thread begins to inſulate completely. Let P*p* be an element of the axis. Draw the ordinate *pf*, the tangent *df*F, and the normal *d*E, and *fe* perpendicular to P*d*. Let AC be $= r$, AP $= x$, P*d* $= y$. Then P*p* $= \dot{x}$, and $de = -\dot{y}$. We have ſeen that the only ſenſible action on the particle of fluid in P is $-\frac{\dot{y}y}{\dot{x}}$ (ſee nº 105), when the action of the redundant fluid in the globe on the particle P, having the denſity y, is repreſented by $\frac{Cy}{(r+x)^2}$. Therefore we have $\frac{\dot{y}y}{\dot{x}} =$ R, the coercive power of the thread. This is ſuppoſed to be conſtant. Therefore $\frac{Pd \times de}{Pp}$ is equal to ſome conſtant line R. But P*p*, or $fe : de = Pd : PE$. Therefore the ſubnormal PE is a conſtant line. But this is the property of the parabola alone; and the curve of denſity D*d*B is a parabola, of which the parameter is 2 PE, or 2 R.

Cor. 1. The denſities in different points of an imperfect inſulator are as the ſquare roots of their diſtance from the point of complete inſulation: For $Pd^2 : AD^2 = BP : BA$. 218 Variation of denſity in the inſulator.

2. The length of canal required for inſulating different denſities of electricity are as the ſquares of the denſities. For AB $= \frac{AD^2}{2\,PE}$; and PE has been ſhewn to be a conſtant quantity. Indeed we ſee in the demonſtration, that BP would inſulate a ball, whoſe electric denſity is P*d*, and BA : BP $= AD^2 : Pd^2$. 219 Length neceſſary for inſulation $\div$ denſity ².

3. The length neceſſary for inſulation is inverſely as the coercive force of the canal, and may be repreſented generally by $\frac{D^2}{R}$. For AB is $= \frac{DA^2}{2\,PE} = \frac{D^2}{2\,R}$. 220 Alſo $\div \frac{1}{\text{coercion}}$.

Mr Coulomb has verified theſe concluſions by a very ſatisfactory ſeries of experiments, by the aſſiſtance of his delicate electrometer, which is admirably ſuited for this trial. The ſubject is ſo intereſting to every zealous ſtudent of electricity, that Mr Canton, Dr B. Wilſon, Mr Waitz, Wilcke, and others, have made experiments for eſtabliſhing ſome meaſure of the conducting powers of different ſubſtances. It was one of the firſt things that made the writer of this article ſuppoſe that electric action was in the inverſe duplicate ratio of the diſtances: for, as early as 1763, he had found that the lengths of capillary tubes neceſſary for inſulation were as the ſquares of the repulſions of the ball which they inſulated. The mode of reaſoning offers of itſelf, and the fluxionary expreſſion of the inſulating power, *viz.* $\frac{\dot{d}d}{\dot{x}}$ led immediately to a force proportional to $\frac{1}{x^2}$. Numerous experiments were made, which we do not give here, becauſe the public are already poſſeſſed of thoſe of Mr Coulomb.

This diſcuſſion explains, in a ſatisfactory manner, the operation of the condenſer, as deſcribed by Mr Volta. The weak degrees of electricity, which are rendered ſufficiently ſenſible by the inſulation of the plate of dry marble, are completely inſulated by the perhaps thin ſtratum that has been ſufficiently dried, while the reſt conducts with an efficacy ſufficient for permitting the accumulation. Explanation of the efficacy of Volta's *condenſer*.

When

221. When we reflect on the theory now delivered, we ſee that the formulæ determine the diſtribution of the fluid along an imperfect conductor in a certain manner, on the ſuppoſition that a *certain determinate* doſe has been imparted to the ball: Becauſe this doſe, by diffuſing itſelf from particle to particle of the conducting matter, will diffuſe itſelf all the way to B, in ſuch a manner that the repulſion ſhall everywhere be in equilibrio with the *maximum* of the coercive force of the inſulating interval. But it muſt be farther noticed, that this reſiſtance is not *active*, but coercitive, and we may compare it to friction or viſcidity. Any repulſion of electric fluid, which falls ſhort of this, will not diſturb the ſtability of the fluid ſpread along the canal, according to any law whatever. So that if AD repreſent the electric denſity of the globe, and remain conſtant, any curve of denſity will anſwer, if $\frac{d\dot{d}}{\dot{x}}$ be everywhere leſs than R. It is therefore an indeterminate problem to aſſign, in general, the diſpoſition of fluid in the canal. The denſity is as the ordinates of a parabola only on the ſuppoſition that the maximum of R is everywhere the ſame. And, in this caſe, the diſtances AB is a minimum: for, in other caſes of denſity, we muſt have $\frac{d\dot{d}}{\dot{x}}$ leſs than R. If, therefore, we vary a ſingle element of the curve D d B, in order that the ſtability of the fluid may not be diſturbed, having $\dot{d}$ conſtant, we muſt neceſſarily have $\dot{x}$ larger, that $\frac{d\dot{d}}{\dot{x}}$ may ſtill be leſs than R; that is, we muſt lengthen the axis.

We ſee alſo, that to aſcertain the diſtribution in a conducting canal is a determinate problem; whereas, in imperfect conductors, it is indeterminate, but limited by the ſtate of the fluid, when it is ſo diſpoſed that in every point the action of the fluid is in equilibrio with the maximum of reſiſtance. This conſideration will be applied to a valuable purpoſe in the article Magnetism.

222 Explanation of a curious and important fact; and method of increaſing a charge.

This doctrine gives, in our opinion, a very ſatisfactory explanation of the curious obſervations of Mr Brookes and Mr Cuthbertſon, mentioned in nº 167. namely, that damping the inſide of a coated jar diminiſhes the riſk of exploſion, and enables it to hold a higher charge. We learn here, that there is no denſity ſo great but that the leaſt imperfect conductor will inſulate it, if long enough; and that the coercive quality of an imperfect conductor may be conceived ſo conſtituted from A towards B, that the denſities ſhall diminiſh in any ratio that we pleaſe, ſo that the variation of denſity (the cauſe of motion) may everywhere, even to the inſulating point B, be very ſmall. However great the conſtipation at the edge of the metallic coating may be, an imperfect conductor may be continued outward from that edge, and may be ſo conſtituted, that the conſtipation ſhall diminiſh by ſuch gentle gradations, that an exploſion ſhall be impoſſible. An uniform dampneſs will not do this, but it will diminiſh the abruptneſs of the variation of denſity. The ſtate of denſity beyond the edge of the coating of a charged jar, very clean and dry, may be repreſented by the parabolic arch D i a. This may be changed by damping, or properly dirtying (to uſe Mr Brookes's phraſe), to D f B; which is evidently preferable. We think it by no means difficult to contrive ſuch a continuation of imperfectly conducting coating. Thus, if gold leaf can be ground to an impalpable powder, it may be mixed with an oil varniſh in various proportions. Zones of this gold varniſh may be drawn parallel to the edge of the coating, decreaſing in metal as they recede from the edge. By ſuch contrivances it may be poſſible to increaſe the retentive power to a great degree.

223 Cautions in deducing meaſures from experiments.

This doctrine farther teaches us, that many precautions muſt be taken when we are making experiments from which meaſures are to be deduced; and it points them out to the mathematician. In particular, when bodies, ſupported by inſulators, are electrified to a high degree, the ſupports may receive a quantity of fluid, which may greatly diſturb the reſults; and this quantity, by exerting but a weak action on the parts of the canal, may continue for a very long time, and not be removed but with great difficulty. In ſuch caſes, it will be neceſſary to uſe new ſupports in every experiment. Not knowing, or not attending to this circumſtance, many erroneous opinions have been formed in ſome delicate departments of electrical reſearch.

Mr Coulomb's experiments on this ſubject are chiefly valuable for having ſtated the relation between the intenſity of the electricity, or, as he expreſſes it, the electric denſity, and the lengths of ſupport neceſſary for the complete inſulation. But, as the abſolute intenſities have all been meaſured by his electrometer, and he has not given its particular ſcale, we cannot make much uſe of them till this be done by ſome electrician.

224 Inſulating powers of various ſubſtances.

Mr Coulomb found that a thread of gum lac was the moſt perfect of all inſulators, and is not leſs than ten times better than a ſilk thread as dry as it can be made, if we meaſure its excellence by its ſhortneſs. In a conſiderable number of experiments, he found that a thread of gum lac, of 1,5 inches long, inſulated as well as a fine ſilk thread of 15 inches. When the thread of ſilk was dipped in fine ſealing-wax, it was equal to the pure lac, if ſix inches long, or four times its length. If we meaſure their excellence by the intenſities with which they inſulate, lac is three times better than the dry thread, and twice as good as the thread dipped in ſealing-wax: ſo that a fibre of ſilk, even when included in the lac, diminiſhes its inſulating power. We alſo learn that the diſſipation along theſe ſubſtances is not entirely owing to moiſture condenſed or adherent on their ſurfaces, but to a ſmall degree of conducting power. We have repeated many of theſe experiments, and find that the conducting power of ſilk thread depends greatly on its colour. When of a brilliant white, or if black, its conducting power ſeems to be the greateſt, and a high golden yellow, or a nut brown, ſeemed to be the beſt inſulators; doubtleſs the dyeing drug is as much concerned as the fibre.

Glaſs, even in its dryeſt ſtate, and in ſituations where moiſture could have no acceſs to it, *viz.* in veſſels containing cauſtic alkali dried by red heat, or holding freſh made quicklime, appeared in our experiments to be conſiderably better than ſilk; and where drawn into a ſlender thread, and covered with gum lac (melted), inſulated when three times the length of a thread of lac; but we found at the ſame time, that extreme fineneſs was neceſſary, and that it diſſipated in proportion to the ſquare of its diameter. It was remarkably hurt by having a bore, however fine, unleſs the bore could alſo be be coated with lac. Human hair, when completely freed from every thing that water could waſh out of it, and then dried by lime, and coated with lac, was equal to ſilk. Fir, and cedar, and larch, and the roſe-tree, when ſplit into filaments, and firſt dried by lime, and afterwards baked in an oven which juſt made paper become faintly brown, ſeemed hardly inferior to gum lac.

The *white woods*, as they are called, and mahogany, were much inferior. Fir baked, and coated with melted lac, ſeems therefore the beſt ſupport when ſtrength is required. The lac may be rendered leſs brittle by a minute portion of pure turpentine, which has been cleared of water by a little boiling, without ſenſibly increaſing its conducting power. Lac, or ſealing wax, diſſolved in ſpirits, is far inferior to its liquid ſtate by heat.

Theſe obſervations may be of uſe for the conſtruction of electrical machines of other electrics than glaſs.

General reflections.

We have now given a compariſon of the hypotheſis of Mr Æpinus with the chief facts obſerved in electricity, diverſified by every circumſtance that ſeemed likely to influence the reſult, or which is of importance to be known. We truſt that the reader will agree with us in ſaying that the agreement is as complete as can be expected in a theory of this kind; and that the application not only ſeems to explain the phenomena, but is practically uſeful for directing us to the procedures which are likely to produce the effect we wiſh. Thus, ſhould our phyſiological opinions ſuggeſt that copious transference of fluid is proper, our hypotheſis points out the moſt effectual and the moſt convenient methods for producing it. We learn how to conſtipate the fluid in a quieſcent ſtate, or how to abſtract as much of it as poſſible from any part of a patient; we can do this even in the internal parts of the body. We had once an opportunity of ſeeing what we thought the cure of a paralyſis of the gullet. Electricity was tried, firſt in the way of ſparks, and then ſmall ſhocks taken acroſs the trachea. Theſe could not be tolerated by the patient. The ſurgeon wiſhed to give a ſhock to the œſophagus without affecting the trachea. We recommended a leaden piſtol bullet at the end of a ſtrong wire, the whole dipped in melted ſealing wax. This was introduced a little way, we think not more than three inches, into the gullet, which the palſy permitted. A very ſlight charge was given to it in a few ſeconds; and the firſt ſhock produced a convulſion in the muſcle, and the ſecond removed the diſorder completely. Here the ball formed the inner, and the gullet the outer, coating of the Leyden phial.

The theory of Æpinus is only a hypotheſis.

Notwithſtanding the flattering teſtimony given by the great conformity of this doctrine with the phenomena, we ſtill chooſe to preſent it under the title of a hypotheſis. We have never ſeen the electric fluid in a ſeparate ſtate; nor have we been able to ſay in what caſes it abounds, or when it is deficient. After what we have ſeen in the late experiments of that philanthropic philoſopher Count Rumford on the production of heat by friction, we think that we cannot be too cautious on what grounds we admit inviſible agents to perform the operations of Nature. We think that all muſt acknowledge that thoſe experiments tend very much to ſtagger our belief in the exiſtence of a fluid *ſui generis*, a fire, heat, caloric, or what we pleaſe to call it; and all will acknowledge, that no better proofs can be urged for the exiſtence of an electric fluid.

225 The reality of an electric fluid is denied.

Accordingly, many acute and ingenious perſons have rejected the notion of the exiſtence of an electric fluid, and have attempted to ſhew that the phenomena proceed, not from the preſence of a peculiar *ſubſtance*, but from peculiar *modes*; as we know that ſound, and ſome concomitant motions and other mechanical appearances, are the reſults of the elaſtic undulations of air; and as Lord Bacon and others have explained the effects of fire by elaſtic undulations of the integrant particles of tangible matter.

Requiſites for a juſt theory.

We have ſeen nothing, however, of this kind that appears to give any explanation of the motions, preſſures, and other mechanical appearances of electricity. We peremptorily require, that every doctrine which claims the name of an explanation, ſhall be perfectly conſiſtent with the acknowledged laws of mechaniſm; and that the explanation ſhall conſiſt in pointing out thoſe mechanical laws of which the facts in electricity are particular inſtances. It is no difficult matter to preſent an intricate or complex phenomenon to our view, in ſuch a form that it ſhall have ſome reſemblance to ſome other complex phyſical fact, more familiar, perhaps, but not better underſtood. The ſpecious appearance of ſimilarity, and the more familiar acquaintance with the other phenomenon, diſpoſe us to conſider the compariſon as a ſort of explanation, or, at leaſt, an illuſtration, and to have a ſort of indolent acquieſcence in it as a theory.

But this will not do in the preſent queſtion: For we have here ſelected a particular circumſtance, the obſerved motions occaſioned by electricity, and called *attractions* and *repulſions*—a circumſtance which admits of the moſt accurate examination and compariſon with any explanation that is attempted. In ſuch a caſe, a vague picture would ſpeedily vaniſh into air, and prove to be nothing but figurative expreſſions.

226 No advantage is gained by the hypotheſis of two fluids.

Many philoſophers, and among them ſome reſpectable mathematicians, have ſupported the doctrine of Du Fay, Symmer, Cigna, &c. who employ two fluids as agents in all electrical operations. It muſt be granted that there are ſome appearances, where the explanation by means of two fluids ſeems, at firſt ſight, more palpable and eaſier conceived. But whenever we attempt to obtain *meaſures*, and to ſay what will be the preciſe kind and degree of the action, we find ourſelves obliged to aſſign to the particles of thoſe fluids actuating mechanical forces preciſely equivalent to thoſe aſſigned by Æpinus to his ſingle fluid. Then we have to add ſome myſterious unexplained connections, both with each other and with the other particles of tangible matter. If we except Mr Prevoſt, in his *Eſſai ſur les Forces Magnetiques et Electriques*, we do not recollect an author who has ventured to ſubject his ſyſtem to ſtrict examination, by pointing out to us the laws of action according to which he conceives the particles influence each other. We ſhall have a proper opportunity, in the article Magnetism, to give this author's theory the attention it really merits. We venture to ſay, that all the chemical theories of electricity labour under theſe inconveniences, and have acquired their influence merely from the inattention of their partiſans

tisans to the laws of mechanical motion, and require, in order to reconcile them with those laws, the adoption of powers similar to Æpinus's attractions and repulsions. Slight resemblances to phenomena, which stand equally in need of explanation, have contented the partisans of such theories, and figurative language and metaphorical conceptions have taken place of precise discussion. It would be endless to examine them all.

227 Hypothesis of Professor Russel.

The most specious of any that we know was publicly read in the university of Edinburgh by the late Mr James Russel, Professor of natural philosophy; a person of the most acute discernment, and an excellent reasoner. It was delivered to his pupils, not as a *theory*, but as a *conjecture*, founded on Lord Kames's theory of spontaneous evaporation, which had obtained a very general reception; a conjecture, said the Professor, founded on such resemblances as made a similarity of operation very probable, and was an incitement and direction to the philosopher to a proper train of experimental discussion. We say this on the authority of his pupils in the years 1767, 1768, and 1769, and of some notes in his own hand-writing now in our possession.

Mr Russel considered the electrical phenomena as the results of the action of a substance which may be called the *electrical fluid*, which is connected with bodies by attractive and repulsive forces acting at a distance, and diminishing as the distance increases.

Mr Russel speaks of the electric fluid as a compound of several others; and, particularly, as containing elementary fire, and deriving from it a great elasticity, or mutual repulsion of its particles. This, however, is different from the elasticity or mutual repulsion of the particles of air, because it acts at a distance; whereas the particles of air act only on the adjoining particles. By this constitution, bodies containing more electric fluid than the spaces around them repel each other.

The particles of this electric fluid attract the particles of other bodies with a force which diminishes by distance.

The characteristic ingredient of this fluid is *ELECTRICITY properly so called.* This is united with the elastic fluid by chemical affinity, which Mr Russel calls *elective attraction*, a term introduced into chemistry by Dr Cullen and Dr Black. This extends to all distances, but not precisely by the same law as the mutual repulsion of the particles of the other fluid, and in general, it represses the repulsions of that fluid while in this state of composition. This *electricity*, moreover, attracts the particles of other bodies, but with certain elections. Non-electric or conducting bodies are attracted by it at all distances, but electrics act on it only at very small and insensible distances. At such distances its particles also attract each other.

By this constitution, the compound electric fluid repels its own particles at all considerable distances, but attracts at very small distances. It attracts conducting bodies at all distances, but non-conductors only at very small distances. The phenomena of light and heat are considered as marks of partial decomposition, and as proofs of the presence of elementary fire in the compound: the smell peculiar to electricity, and the effect on the organ of taste, are proofs of decomposition and of the complex nature of the fluid.

Bodies (conductors) containing electric fluid, repel each other at considerable distances, but, if forced very near, attract each other. Electrics can contain it only in consequence of the *electricity* in the compound. Part of this electricity must be attached to the surface in a non-elastic state; because when it is brought so near as to be attracted, its particles are within the spheres of each other's action, and this redoubled attraction overcomes the repulsion occasioned by its union with the other ingredient; and the electric fluid is partly decomposed, and the *electricity*, properly so called, adheres to the surface of the electric, *as the water of damp air adheres to a cold pane of glass in our windows.* Also, by this constitution, electric fluid may appear in two states; elastic, like air, when entire; and unelastic, like water, when partly decomposed by the attraction of electrics.

Electricity may be forced into this unelastic union by various means; by friction, which forces the electric fluid contained in the air into close contact, and thus occasions this decomposition of the fluid and the union of its *electricity* with the surface. This operation is compared by Mr Russel to the forcible wetting of some powders, such as lycoperdon, which cannot be wetted without some difficulty and mechanical compression; after which it adheres to water strongly. It may be thus united in some natural operations, as is observed in the melting and freezing of some substances in contact with electrics; and it may be thus forced into union by means of metallic coatings, into which the electric fluid is forced by an artful employment of its mutual repulsions. This operation is compared to the condensation of the moisture of damp air by a cold pane of the window; and the evacuation of the other side of the coated pane is compared to the evaporation of the moisture from the other side of the window, pane in consequence of the heat which must emerge from the condensed vapour. We find in the Professor's notes above-mentioned many such partial analogies, employed to shew the students that such things are seen in the operations of Nature, and that his conjecture merits attention.

The intelligent reader will see that the general results of this constitution of the electric fluid will tally pretty well with the ordinary electrical phenomena; and, accordingly, this *conjecture* was received with great satisfaction. We remember the being much pleased with it, as we heard it applied by Mr Russel's pupils, many of whom will recollect what is here put on record. But the attentive reader will also see, that all this intricate combination of different kinds of attraction and repulsion is nothing but mere accommodations, of hypothetical forces to the phenomena. How incomparably more beautiful is the simple hypothesis of Æpinus, which, without any such accommodations tallies so precisely with all the phenomena that have yet been observed? Here no distinction of action is necessary, and all the varieties are consequences of a circumstance perfectly agreeable to general laws; namely, that the internal structure of some substances may be such as obstructs the motion of the electric fluid through the pores—Nothing is more likely.

228 Hypothesis of Mr de Luc.

Several years after the death of the Scotch Professor in 1773, a theory very much resembling this acquired great authority, being proposed to the philosophers by the celebrated naturalist Mr de Luc. This gentleman having long cultivated the study of meteorology with unwearied assiduity and great success,

and

and having been so familiarly conversant with expansive fluids, and the affinities of their compounds, was disposed to see their operations in almost all the changes on the surface of this globe. Electricity was too busy an actor in our atmosphere to escape his particular notice. While the mechanical philosophers endeavoured to explain its effects by accelerating forces attracting and repelling, Mr de Luc endeavoured to explain them by means of the expansive properties of aeriform fluids and gases, and by their chemical affinities, compositions, and decompositions. He had formed to himself a peculiar opinion concerning the constitution of our atmosphere, and had explained the condensation of moisture, whether of steam or of damp aeriform fluids, in a way much more refined than the simple theory of Dr Hooke, *viz.* solution in air. He considers the compound of air and fire as the *carrier* of the water held in solution in damp air, and the fire as the general carrier of both the air and the moisture. Even *fire* is considered by him as a *vapour*, of which *light* is the *carrier*. When this damp air or steam is applied to a cold surface, such as that of a glass pane, it is decomposed. The water is attracted by the pane by chemical affinity, and attaches itself to the surface. The fire, thus set at liberty, acts on the pane in another way, producing the equilibrium of temperature, and the expansion of the pane. Acting in the same manner on the moisture which chances to adhere to the other side, in a proportion suited to its temperature, it destroys their union, enters into chemical combination with the moisture, and fits it for uniting with the air on the other side, or carries it off. Having read Mr Volta's theory of *electric influences*, by which that philosopher was enabled to give a scientific narration and arrangement of the phenomena of the *electrophorus* newly invented by himself, and which is called an explanation of those phenomena, Mr de Luc imagined that he saw a close analogy between those *influences* on the plates of the electrophorus and the *hygroscopic* phenomena of the condensation and evaporation of moisture. In short, he was struck with the resemblance between the condensation of moisture on one side of a glass pane, and its evaporation from the other; and the accumulation of electric fluid on one side of a coated pane, and the abstraction of it from the other. Subsequent examination pointed out to him the same analogy between all other *hygroscopic* and *electric* phenomena.

He therefore immediately formed a similar opinion concerning the electric operations. It may be expressed briefly as follows:

229. The electrical phenomena are the operations of an expansive substance, called the *electric fluid.* This consists of two parts: 1. *Electric matter*, which is the gravitating part of the compound; and *electric deferent fluid*, or *carrying fluid*, by which alone the electric matter seems to be carried from one body to another. The resemblance between the hygroscopic and electrical phenomena are affirmed to be *.

* See *Idées sur la Meteorologie*, § 266. &c.

1. As watery vapour or steam is composed of fire, the deferent fluid, and water, the gravitating part, so *electric fluid* is composed of the *electric deferent fluid*, and *electric matter.*

2. As *vapours* are partly decomposed when too dense for their temperature, and then their *deferent fluid* becomes free, and shews itself as *fire*; so *electric fluid* that is too dense is decomposed, and its *deferent fluid* manifests itself in the *phosphoric* and *fiery* phenomena of *electricity*.

3. As *fire* quits the *water* of *vapour*, to unite itself with a body less warm; so the *electric deferent* quits the *electric matter*, in part, to go to other bodies which have proportionally less of it.

In this analogy, however, there is a distinction. *Fire*, in quitting the *water* in *vapour*, remains actuated by nothing but its expansive force; remains free, and extends itself till the equilibrium of temperature is restored; but the *electric deferent*, when disengaged from *electric matter*, in order to restore its peculiar equilibrium, is actuated by *tendencies* to distinct bodies, and acts by this *tendency* in thus restoring the *electric equilibrium;* and it is only in consequence of this *tendency* that it quitted the *electric matter*. This *tendency* is then directed to some body in the vicinity.

4. As the *fire* of *vapour* pervades all bodies, to restore the *equilibrium of temperature*, depositing the *water;* so the *electric deferent* quits the *electric matter*, to restore the *electric equilibrium* in an instant, and for this purpose pervades all bodies, depositing on them the *electric matter* which it carried, but differently, according to their natures.

5. As *fire* and *water*, while composing *vapour*, retain their *tendencies* and *affinities* by which they produce the *hygroscopic* phenomena; so the ingredients of the *electric fluid*, even in their state of union, retain their *tendencies* and *affinities*, which produce the greatest part of the *electric phenomena*.

6. In particular, the *electric matter* retains its *tendencies* and *affinities;* and farther, the *electric affinities* are, like the *hygroscopic*, without any choice.

Here, however, there is a farther distinction. The affinities of *water* respect only *hygroscopic* substances; but those of *electric matter* respect all substances, and therefore respect the common atmospheric fluids.

7. When *fire* quits the *water* of *vapour*, to form the *equilibrium of temperature*, it remains in the place where *vapour* most abounds, but is partly *latent*, not exerting its powers; so in the restoration of the equilibrium of the *electric deferent* among neighbouring bodies, those which have proportionally most *electric matter* also retain most *deferent fluid*, but in a *latent* state.

8. As two masses of *vapour* may be in *expansive equilibrium* (which others call balancing each others elasticity), although the *vapours* contain very different proportions of *fire* and *water;* so two masses of *electric fluid* may be in *expansive equilibrium*, although one contains much more *electric matter* in the same bulk, provided that the *electric deferent* be also more copious.

The chief distinction that mingles with these analogies is, that the *affinity* of *water* to *hygroscopic* substances operates only in contact, whereas *electric matter* tends to distant bodies; and these distances are very different in regard to different bodies.

Such is the resemblance which has appeared so strong to Mr de Luc. It is evidently the same which furnished the conjecture to Mr Russel, and which he considered mechanically, in order to explain the phenomena of electric motions to students of mechanical philosophy. The only resemblance seems to us to appear in the condensation of moisture contained in damp air.

Mr de Luc, led by the habits of his former studies, attempts

attempts to explain every thing by the relations which were moſt familiar to him, *affinities* and *expanſive forces.* Let us attend a little to the manner in which he explains one or two of the moſt general facts.

1. *The conditions of conductors and non-conductors.*

230. This diſtinction depends on the differences in the *tendency* to diſtant bodies: there are great differences in theſe diſtances according to the nature of the bodies; and from this ariſe great differences of phenomena, independent of inſulation or non-inſulation, which are only the ſenſible diſtinctions of theſe claſſes of bodies. *Electric matter* tends to *conductors* at great diſtances; but having reached them it does not adhere, and remains free to move round them, being dragged by the *deferent fluid;* but its tendency to *non-conductors* is only at ſmall and inſenſible diſtances; and having come into contact, it adheres, and can no longer be dragged by the *deferent fluid.*

Hence the operation of *conductors* and *non-conductors;* and there is no other foundation for the notion of *idio-electrics* and *non-electrics*, or electrics by communication. A part of a *non-conductor* takes as much *electric matter* as it can from the ſubſtance furniſhing it; but cannot communicate it to another part, except very ſlowly; therefore, to communicate it to the whole ſurface, we muſt cover it with a conductor (Surely this is a diſtinction in the body, independent of the diſtance of mutual tendency!).

Hence, too, the property of *non-conductors* by which the electric fluid is *benumbed* (*engourdi*) or cramped; therefore we can accumulate a great deal in them; and it will remain long, being *benumbed;* and if it be determined to quit them at once, the current will be much more denſe than when quitting an equal conducting ſurface.

Since *conductors* do not fix the *electric fluid*, it *muſt circulate round them.* It is urged to this motion by its *expanſive power*, by which it would diſperſe from a body with inconceivable velocity, and perhaps the rapidity of its motion would decompoſe it, and cauſe ſome *light* to emerge; but it is at the ſame time impelled by its *tendency* to bodies. Thus, by theſe two forces, it runs to a *conducting body*, and muſt circulate round it as the planets do round the ſun. In this circulation, if it come to any great projection, it cannot follow the outline, becauſe ſo abrupt; it therefore flies off at all points and protuberances. It will be the more difficult to keep to an abrupt outline as the ſtratum in circulation is more copious or deeper, becauſe a greater maſs is with greater difficulty turned round a ſharp angle. It is more inclined to eſcape if another body be near, and it immediately becomes a ſatellite to that body.

Thus all bodies get a ſhare of electric fluid, circulating round conductors, and *benumbed* or *cramped* in *non-conductors.* Bodies of this laſt claſs receive their portion by the air as *hygroſcopic ſubſtances* receive their water by the *fire.*

All the differences in the tendencies to bodies proceed from the *electric matter.* The *deferent fluid* follows other laws; namely, 1. Its tendency to all ſubſtances is greater than that of the *electric matter* to any one. 2. The tendency (and alſo that of the *electric matter*) is always from the body which contains moſt of it to that which contains leaſt. 3. The body which contains moſt of the one alſo contains moſt of the other. 4. The *deferent fluid* has a particular affinity (chemical) with the *electric matter.* 5. All theſe tendencies are leſſened by an increaſe of diſtance. 6. The *electric matter*, when compoſing *electric fluid*, has more or leſs *expanſive force* as it is united to more or leſs *deferent fluid.*

Explanation of Charged Plates.

Mr de Luc ſays (§ 286.), that his SYSTEM was ſuggeſted by Volta's *Theory of Electric Influences.* Theſe (ſays he) had been pretty well generaliſed before, but with little improvement to the ſcience, till Mr Volta diſcovered a circumſtance which, in his opinion, connected by a general theory many phenomena which had formerly no obſerved relation to any thing. This was, that *when a body electrified poſitively brings a neighbouring body communicating with the ground into the negative ſtate, its own poſitive electricity is weakened while it remains in that neighbourhood, but is recovered when the other body is removed.* "Such is the diſtinguiſhing law of Mr Volta's theory, which brings all the phenomena of electric influences under his theory, beginning with thoſe of coated glaſs, which were formerly ſo obſcure, becauſe they were not referred to their true cauſe, &c. 231.

"My SYSTEM (Mr de Luc ſays) concerning the nature of the *electric fluid* explains the laws of Mr Volta's theory; and of conſequence explains, like it, all the phenomena which it comprehends: but it reaches much farther, ſeeing that more general laws comprehend a greater number of phenomena.

"In the phenomena of coated glaſs, I plainly ſaw one of the procedures of *watery vapour.* Suppoſe a glaſs pane, moiſtened on both ſides, and having the temperature of the ſurrounding bodies. Suppoſe that warmer *vapour* comes to one ſide. It is condenſed on the ſurface; that is, it is decompoſed, the *water* adheres to the ſurface, and the *fire* penetrates the glaſs, heats it, and increaſes the evaporation from the other ſide, by entering into combination with the *water*, and carrying it off with it. More *vapour* is condenſed on the ſide A; more *fire* reaches the ſide B, and carries off more *water.* But as this happens only becauſe the *fire* alſo raiſes the *temperature* of the pane, it is evident that the condenſation on the ſide A, and the evaporation from B, muſt gradually ſlacken, and the *maximum of accumulation* in A, and of evaporation from B, will take place when the temperature of the pane is the ſame with that of the hot *vapour.*

"The electrical phenomena of coated glaſs are perfectly ſimilar. The *electric fluid* reaches the ſide A, is decompoſed, and the *electric matter* is there *benumbed* and fixed. The *deferent fluid* penetrates the pane, and carries off the *electric matter* from the ſide B. This goes on, but ſlackens; and the maximum of accumulation and evacuation obtains when the ſide A has acquired the ſame intenſity of electricity with the charging machine. More is accumulated in A than is abſtracted from B; becauſe B is farther from the ſource (he might have added, that part of the fire is expended in raiſing the temperature of the pane): but the accumulation is inactive, becauſe the *electric matter* is *benumbed* and fixed. Though the *electric matter* is much diminiſhed in B, yet the *electric fluid* in its coating has as much expanſive force as that of the ground; becauſe

because it has a surplus of deferent fluid. The absolute quantity of *electric matter* in both sides is somewhat augmented."

232. This explanation of the Leyden phial comprehends the whole of Mr de Luc's theory; and the constitution of the electric fluid, and its various affinities, expansive powers and tendencies, are all assigned to it in subserviency to this explanation, or deduced from those phenomena. As the author, in all his writings, claims some superiority over other naturalists for more general and comprehensive views, and for more scrupulous attention to precision and measurement, and particularly for more solicitude that no natural agent be omitted that has any share in the procedure—he surely will not be offended, although we should state such difficulties and objections as occur to us in the consideration of this SYSTEM (as he chooses to call it) of electricity.

We wish that it had been expressed in the plain and precise language of mechanical and chemical science; for he reasons entirely from the nature of expansive forces, tendencies, and affinities. His language will appear to some readers, as it does to us, rather to express the conduct of intelligent beings, acting with choice, and for a purpose, than the laws of lifeless matter. His account would have been less agreeable, it is true, but more instructive, and less apt to be mistaken. Metaphorical language is seldom used without the risk of metaphorical conceptions; and the reader is very apt to think that he has acquired a notion of the subject, while he is really thinking of a thing of a different nature. We apprehend that a great deal of this happens in this instance, and that when the narration is stripped of its figurative language, it will be found without that connection and analogy which it seems to possess.

We also wish that the explanation had been derived from some well-established principle. The whole of it is *professedly* founded on a resemblance between the *phenomena* of electricity, and some things said of watery vapour; but these are not the *phenomena* of watery vapour, but Mr de Luc's *hypothesis* (he will pardon us the term, which we prefer to *system*) concerning *watery vapours*. We do not think it philosophical to explain one hypothesis by another. Our illustrious countrymen, Bacon and Newton, disapproved of this practice; and their rules of philosophising have still currency among philosophers. Explanation, in our opinion, is the pointing out some acknowledged general fact in nature, and shewing that the particular phenomenon is an example of it. We do not see this in Mr de Luc's explanation; because we do not see the *facts* in the case of watery vapours to which the *phenomena* of electricity are said to have a resemblance. The phenomena we mean are chiefly the *motions*, and the *transferences* of the powers producing such motions; we do not speak of the *light*, and some other phenomena, because Mr de Luc does not speak of them in this explanation. We shall even admit the *transference* as a *phenomenon*, although we do not see any substance transferred: but we see a power of producing certain motions where that power did not formerly appear; and the appearance of this power is all the authority adduced, even by Mr de Luc, for the transference. We must now add, that the electric phenomena, which Mr de Luc calls like the phenomena of watery vapour, are all *suppositions;* and that therefore the explanation is a system of suppositions, *framed* so as to be like the system of watery vapour. For Mr de Luc will grant, that, on the one hand, we see nothing like the water in the electric phenomena; and, on the other hand, there is nothing in watery vapour like the motions of the electrometers, which are the only PHENOMENA from which Mr de Luc professes to reason.

We also fear that the very curious experiments of Count Rumford on the melting of ice, and the propagation of heat through liquids, will oblige Mr de Luc to change the tasks of the ingredients, both of *vapour* and of *electric* fluid. *Water*, and not *fire*, seems to be the *carrier* or *deferent fluid;* and we think that Franklin and Æpinus have made it highly probable that electricity, and not air, is the carrier.

We have also great difficulty in conceiving (indeed we cannot conceive) how the *deferent fluid*, from which the *electric matter* has been detached by its superior *affinity* with the side A, can overcome the *same superior affinity* of the *electric matter* with the side B (A), and carry it off; how the *deferent fluid* penetrates the non-conducting pane, in order to carry off the *electric matter* in the form of *fluid;* and how it cannot do this, except by means of a *conducting canal*, into which *it is expressly said that it does not penetrate.* It must not be said that it runs along the surface of this canal: for the smallest wire will be a sufficient conductor, covered a foot thick with sealing wax. This indeed, according to Mr de Luc, allows the deferent *fluid* to pass; but it must also, according to him, strain it pretty clear of all *electric matter*. For we cannot help thinking, that the process (although purely ideal) has a closer resemblance to what we should observe in a stream of muddy water poured on a strainer, both sides of which are previously foul. If we were disposed to amuse ourselves with a figurative hypothesis, we could give one on the principle of filtration that is very pretty, and pat to the purpose, of glass coated, and charged and discharged by conducting canals.

With respect to the suggestion of this theory by Volta's theory of electric influences, and the ignorance of naturalists before that time of the true state of things, we must observe, that Mr Russel proposed the same analogy to the consideration of his hearers many years before; and it was very generally known. The electric influences had been fully detailed by Æpinus and Wilcke in 1759, and applied with peculiar address and force of evidence by Mr Cavendish before 1771; and they were described nearly in the same way by Lane, Lichtenberg, and others.

And with respect to Mr Volta's general principle, which Mr de Luc prizes so highly, and by which he explains every thing, we must observe, that *it is not true as a phenomenon in electricity;* but, on the contrary, *the positive state of a body is rendered stronger, or more remarkable, by inducing the negative state on a neighbouring body.* See n° 52 and 66.—Mr Volta was misled by the appearances of the electrophorus, which had engaged all his attention, and modelled all his notions on these subjects. His

(A) We may here ask, How comes there to be such a quantity of electric matter already lodged in B?—Is it benumbed? or in what state is it?

His obſervations had been confined to diſks; and though theſe are excellent inſtruments for producing very ſenſible effects, they are quite unfit for examining the general nature of electric influences. Even without much knowledge of dynamics, a perſon muſt perceive that the action of their different parts on the electrometer may be very different, by reaſon of their different poſitions and diſtances from it. Beſides, the electrometers of the apparatus deſcribed by Mr de Luc in ſect. 440. &c. *did not* indicate the real condition of the diſks to which they were attached, but the condition of the remote ends of overcharged conductors of conſiderable length. Therefore, although all the electrometers fell lower when the other group of diſks was brought near, the poſitive ſtate of the neareſt diſk was greatly augmented. The moſt unexceptionable apparatus for this purpoſe would be a row of poliſhed balls on inſulating ſtands, placed in contact, the whole charged poſitive; and when another ſuch group, or a long body, is brought near, let the balls be ſeparated at once, and examined apart by a very ſmall electrometer, made in the form of our figure 8. We preſume to ſay that, if the other group is properly managed, and made to communicate thoroughly with the ground, the poſitive electricity of the balls neareſt to it will be found greatly augmented, and that every one of them will be found in that preciſe ſtate of electrification that is pointed out by the Æpinian theory. Mr de Luc has made and narrated the experiments with the diſks, and the curious figures obſerved by Lichtenbergh, with great judgment and fidelity; and they are claſſical and valuable experiments for the examination of the theory. We may here mention a very neat way of executing the apparatus of balls, which was practiſed by a young friend, who was ſo kind as to make the experiments for us, when our thoughts were turned to Mr de Luc's theory. Each ball was mounted on a ſlender glaſs rod varniſhed. The lower end of the ſtalk was fixed in a little block of wood which had a ſquare hole through it, by which it ſlided ſteadily along a horizontal bar of mahogany, ſupported at the ends about an inch from the table. The balls were made to ſeparate at once, and equally, from each other, by a chequer-jointed frame, ſuch as is ſeen in the toyſhops, carrying a company of foot ſoldiers, who open and cloſe their ranks and files by pulling or puſhing the ends of the frame. Taking out the pins of the middle joints of this chequered frame-work, and widening the holes for receiving the glaſs ſtalks, it is plain that all the balls will ſeparate at once, in the very ſtate of electricity in which they were when in the neighbourhood of the non-inſulated group. This apparatus conſiſted of ſix balls. We found the ball next the other group much more ſtrongly poſitive than before bringing that group near; and it was generally the third ball which ſeemed equally electric in both ſituations. We added nine balls more, connecting the whole by a ſimilar contrivance; and found it a moſt inſtructive apparatus for the theory of the diſtribution of the electric fluid. We wiſh that it had occurred to us when the nº 62, &c. were under conſideration.

With reſpect to the condition in which the electric matter is ſaid to be lodged in the ſide A of the coated pane, where Mr de Luc ſays that it is fixed, *engourdi*, in the *non-conducting ſurface* (which condition Mr de Luc conſiders as characteriſtic of ſuch ſubſtances), we muſt ſay that the deſcription of its ſtate is by no means agreeable to what we have obſerved. The powers of this *electric matter* are no more *benumbed* or enervated (it is a very unphiloſophical phraſe), than if it were in a *conducting* body at the ſame diſtance from the oppoſite coating. If coatings be applied to a block of glaſs of two or three inches in thickneſs, and if the electrification be ſo moderate that it would not fly from the one coating to the other when the glaſs is removed—no ſenſible difference will be found between the electricity of the two coatings with or without the glaſs. The electric matter in the ſide A has not its powers *engourdi;* they are *balanced* by the powers of the ſide B.

But how will Mr de Luc explain the charging a pane negatively? How will he bring off a quantity of *electric matter*, greater (according to his own account) than what will be *benumbed* on the other ſide? Nay, we muſt aſk, where does he find it? Is there a quantity already *benumbed* there? What is to revive it?

Let us now conſider a little the conſtitution of the ingredients of this electric fluid, by which all theſe things are brought about. And in doing this, let us baniſh, when poſſible, all figurative language; and, in the preciſe and dry phraſeology of dynamics, let us ſpeak of the motion of ſingle particles of the *electric fluid, deferent fluid*, and *electric matter*. By *expanſive power*, muſt certainly be meant ſuch a power as that by which air, gaſes, inflamed gunpowder, ſteam, and the like, enlarge their bulk, and which is clearly manifeſted as a mechanical preſſure, by burſting veſſels, impelling bullets or piſtons, &c. as well as by the actual enlargement of the bulk of the fluid. We have no other indications of its being a *force;* and therefore our notions of its mode of acting muſt be derived ſolely from what we *underſtand* of this power in air or the other fluids. Newton's *Principia* are our authority for ſaying that all that we know of it is, that it acts as a number of corpuſcles would act, which repel each other with a force inverſely proportional to their diſtances; this action not extending beyond the adjoining corpuſcle, not even to the ſecond. We know a good deal of the propagation of preſſure and progreſſive motion through ſuch a fluid, when it is confined in a veſſel, or ſyſtem of veſſels, of any form, and ſome few ſimple circumſtances which take place in the elaſtic undulations which may be excited and propagated through it. We have but a *very indiſtinct notion* of the motions which one maſs of ſuch a fluid will produce in another maſs, when both are at liberty to expand. This is very indiſtinct; but we are certain that it will be like the motion of two maſſes of air blown or driven againſt each other. Now theſe electric fluids, by their expanſive powers, muſt act like thoſe others with which we are more familiarly acquainted. And here we venture to ſay, that the appearances in electricity are ſo far from being like theſe, that we cannot imagine any thing more remarkably different. We ſhall mention but one thing. Every mark that we have for the preſence of *electric fluid* obliges us to grant, that in an overcharged body it is crowded into the external ſurface, ſo that the quantity has little or no relation to the quantity of matter in any body, but merely to its ſurface. This is quite unlike air, or any other expanſive fluid, which is uniformly diſtributed through the whole ſpace comprehended by the ſurface which bounds it. We never ſaw any thing like

like ſtreams of this *electric fluid*, impelling or any way acting on each other, except in the transference by ſparks; and there it was indeed like the motions of air, for it was not *electric fluid*, nor *electric matter*, but *electrified air*.

Let us next conſider the *tendencies* by which the relations of theſe expanſive fluids to other bodies are produced, and the electric motions are ſaid to be explained. We obſerve that Mr de Luc avoids the uſe of the words *attraction* and *repulſion*, ſo much employed by the British philoſophers. He conſiders theſe tendencies as determinate impulſions, and adopts the doctrine of *Le Sage of Geneva*, who has not only laid Newton under great obligations, by a mechanical explanation of gravity, but has alſo explained expanſion, elaſticity, chemical affinity, and all ſpecific tendencies, to the ſatisfaction of the moſt eminent mathematicians. To ſuch only Mr de Luc profeſſes to addreſs himſelf. who are not contented with a doctrine which ſuppoſes bodies to act where they are not. But, unfortunately, Mr le Sage has never obliged the world with this explanation. We are not moſt eminent mathematicians; but we are able to prove, that Mr le Sage's favourite theorem, mentioned by Mr de Luc in § 157, 158, as demonſtrated by Mr Prevoſt, the editor of *Lucrece Neutonien*, is a complete dereliction of the firſt principles of Mr le Sage, and is alſo incompatible with mechanical laws. Mr de Luc ſhould have given a demonſtration of the theorem on which all his ſyſtem reſted; otherwiſe it is only reviving "*dixit philoſophus, ergo verum.*"

But let us ſee what theſe tendencies perform. Mr de Luc ſays, that the fluid, ſetting out from a body by its expanſive power, would move in a ſtraight line with inconceivable velocity, and would immediately deſert even this globe, were it not deflected by its tendency to other bodies. We do not ſee whence this immenſe velocity is derived. But let it go off; it is deflected from its rectilineal courſe by its tendency to ſome conducting body, which it reaches, but cannot, nor does not enter; and therefore *muſt continually circulate round it, as the planets circulate round the ſun*, following its outline, if not too abrupt, but flying off from all points in the direction of the axis of the point, &c. Here we are at home; for this is a plain dynamical problem of central forces. All that we ſhall ſay on this head is, that Mr de Luc has certainly not conſidered the planetary motions with attention, when he hazarded this very comprehenſive propoſition. If he will take the trouble to do this, he will ſee that every part of it is inconſiſtent with the acknowledged laws of mechaniſm, and that the motions are abſolutely impoſſible. Beſides, we know that it will not fly off from a hundred points placed together, which is a ſtill more abrupt line, if they do not project beyond the brim of a pit in which they ſtand; yet this pit only makes the outline more abrupt. We farther believe, that no perſon can form to himſelf any diſtinct notion of ſuch circulations round every conducting body; they will be more numerous, and infinitely more confuſed and jarring, than all the vortices of Des Cartes. How can ſuch motions take place round a bunch of braſs wire buried in ſealing wax? Yet he muſt grant that they really happen there; or what prevents the *electric fluid* from being *ſtrained* clear of all electric matter in paſſing through the air?

We would alſo aſk, why the tendency is always *from the body containing moſt of the fluid to that containing leaſt?* It is not enough to ſay that it is ſo: this would only be contriving a thing to ſuit a purpoſe; a reaſon ſhould be given if we pretend to explain. Now the tendency to a diſtant body *is to the matter* in that body, without any relation to the fluid in it, or in the body from which it came.

On the whole, we cannot think this theory is any thing but telling a ſtory of ideal beings, in very figurative language, which gives it ſome animation and intereſt. The different affinities, tendencies, and powers, are only ways of expreſſing certain *ſuppoſed* events, and ſuited to thoſe events: but it gives no explanation of the *obſerved mechanical phenomena* of electricity, ſhewing from acknowledged principles that they muſt be ſo.

What a difference between this laboured and intricate mechaniſm, and the ſimple, perſpicuous, and diſtinct theory of Æpinus! Even Mr Ruſſel's explanation is more intelligible, and more applicable to the *motions* which are really obſerved. That gentleman ſaw the neceſſity of conſidering them as the ſubjects of *mechanical diſcuſſion*, and that all that was wanted was to find out what law of diſtant action would tally with the phenomena. The Scotch philoſopher was careful to warn his hearers that he only propoſed a *conjecture*. The Swede calls his performance *Tentamen Theoriæ*, &c. and begins and concludes it with expreſsly ſaying, that it is only a *hypotheſis*. The Engliſh nobleman calls his diſſertation an *Attempt* to explain ſome of the phenomena, &c. None of theſe philoſophers call their works a SYSTEM, which comprehends all theories, whether that of Volta or of any other ſucceſsful inquirer.

We hope to be excuſed for treating ſo largely of this ſubject. It ſtruck us as a very proper example of the bad conſequences of indulging in figurative language. It muſt be very ſeducing, when ſo ſcrupulous and ſo eminent a philoſopher as Mr de Luc is led aſtray by it.

We conclude this long article by obſerving, that 233.
whatever may be the fate of Mr Æpinus's *hypothetical theory*, his claſſification of the facts, and his preciſe determination of the *mechanical phenomena* to be expected from any propoſed ſituation and condition of the ſubſtances, will ever remain, and be an unerring direction in future experiments; and the whole is an illuſtrious ſpecimen of ingenuity, addreſs, and good reaſoning. We hope to make this ſtill more evident, when we apply it to the quiet and manageable phenomena of MAGNETISM

Pondere et menſurâ.

APPENDIX;

CONTAINING AN ABSTRACT OF MR COULOMB'S EXPERIMENTS.

MR COULOMB in the *Mem. de l'Acad. de Paris* for 1786, relates ſeveral experiments made for aſcertaining the diſpoſition or diſtribution of the electric fluid in an overcharged body. Their general reſults were,

1. That the fluid is diſtributed among bodies according to their figure, without any elective affinity to any kind of ſubſtance.

For when a ball, or body of conducting matter, and of any ſhape, is electrified to any particular degree, as indicated

indicated by his electrometer, if it be touched by another equal and similar body, similarly situated in respect of the touching points, the electricity is always reduced to $\frac{1}{2}$.

2. In an overcharged conducting body, the fluid diffuses itself entirely along the surface, without penetrating into the interior parts.

The conducting body AB (fig. 37.) had pits *a*, *b*, &c. made in various parts of its surface. They were half an inch in diameter, and some of them $\frac{1}{10}$th, others $\frac{2}{10}$ths, others $\frac{3}{10}$ths, &c. in depth. *c* represents the edge of a small circle of gilt paper, $\frac{1}{4}$th of an inch in diameter, fixed perpendicularly on the end of a fine thread of gum lac. The body was electrified and touched with this little electroscope, by setting it flat down on the surface. The circle *c* was then presented to an electrometer which moved 90 degrees by a force not exceeding $\frac{1}{6000}$th of a French grain. When this contact was made with the even surface of the conductor, it was strongly electrified, and particularly when it touched any eminence, or the ends of long cylinders, &c. The paper being exceedingly thin, and placed in full contact, it may be supposed to bring off with it the quantity of fluid corresponding to that part of the surface, or rather a greater quantity. But when it was made to touch the bottom, even of the shallowest of these pits, it did not affect the electrometer in the least.

He demonstrates the following elementary theorem:

The attraction or repulsion being supposed to be proportional to the inverse of any power *m* of the distance; that is, being as $\frac{1}{x^m}$: if *m* be greater than 3, the action of all the masses of fluid which are at a finite distance is nothing in comparison with the action in contact; and therefore the fluid must be uniformly diffused, in the same way as if each particle acted only on the adjoining particles.

But if *m* be less than 3, for example, if *m* be 2, as seems to be the case in electricity, the action of all the masses at a finite distance is not infinitely small in comparison with the action in contact, and the redundant fluid must go toward the surface, and no redundant fluid will be retained in the interior parts. The demonstration is to this effect.

Let A*a*BF (fig. 38.) be a perfectly conducting body of any shape, and let *dae* be a thin slice separated from the rest by the plane *de;* let *dce* be precisely equal and similar to *dae*, and let *abc* be perpendicular to the separating plane; then the action of all the particles in the thin slice *dae* (when estimated in the direction *ab*) on the particle *b*, must balance the action of all the rest of the fluid in the body; for *b* is supposed to be at rest. Now, as the law of continuity will be observed in *any* distribution of the fluid, *through the whole body*, it is plain that, by taking *ab* sufficiently small, the difference of density at *a* and at *c* may be infinitely small; therefore the action of the fluid in *dae* will be infinitely near to an equilibrium with the action of *dce;* and the action of the fluid in the rest of the body on the particle *b* will be infinitely small. This cannot be, when the action of a mass of fluid at a finite distance is not infinitely small in comparison with the action in contact, unless we suppose that the quantity of fluid at a finite distance is also infinitely small, or nothing; that is, unless the whole redundant fluid is constipated on the surface, and the interior parts are merely saturated.

The preceding propositions are quite analogous to propositions in Mr Cavendish's dissertation in the Philosophical Transactions for 1771.

In the Memoirs of the same Academy for 1787, Mr Coulomb endeavours to ascertain the density of the fluid in different bodies which touch each other. When the bodies do not differ extremely in magnitude, he determines this by the immediate application of them to the electrometer; but when one is extremely small in comparison with the other, he first determines the force of the large body, and then touches it 20 or 40 times with the small one, till the force of the large body is reduced to $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, &c. The general result was, that when the surfaces of the spheres had the proportion expressed in the first column of the following Table, then the density in the small one had the proportion expressed by the numbers of the second column, and never attained the magnitude 2.

1	1
4	1,08
16	1,3
64	1,65
Infinite	2

This is extremely different from the proportions which obtain when the two spheres communicate by very long slender canals, which he found exactly conformable to the determinations of the theory: but in Mr Coulomb's experiments the spheres touched each other, and had no other communication.

He then endeavours to ascertain the density of the fluid in the different parts of the surface of these touching spheres, in order to obtain some experimental knowledge of the distribution. He touched them (while in mutual contact) with the little paper circle, and examined its electricity by his electrometer, and made his estimation on the supposition that it brought off one-half of the electricity of the touched part.

When the globes were equal, he found the density to be 0 in the point of contact, and scarcely sensible till he took the paper 30 degrees from the point of contact. From this it increased rapidly to 60°; slowly from thence to 90°; and from thence to 180° it was almost uniform. The densities were nearly

0	at	0°
1	—	30
4	—	60
5	—	90
6	—	180

He also found, that the more the globes differed in bulk, the more is the density changed in the small globe, and it is the more uniform in the great one, increasing rapidly from 0, at the point of contact, to about 7°, and beyond this being sensibly uniform.

Hence we may conclude, that the electricity is diffused with almost perfect uniformity in a globe communicating with another at a great distance by a slender canal (as Mr Cavendish has demonstrated); while, from the reasoning employed before, it is probable that it is also uniformly diffused all along the canal; and therefore, that the quantities in two such globes are very nearly as the diameters, and the densities inversely as the diameters, as Mr Cavendish demonstrated, on the supposition that the fluid in the canal is incompressible.

He found that a small globe, placed between two equally large ones, shewed electricities of the same kind with that of the other two, when the radius of the

great one was not more than five times that of the middle one, but ſhewed no electricity when the diſproportion was greater.

When three equal globes were in contact, the denſity of fluid in the middle globe was $\frac{1}{1,34}$ of that of the other two. A ſmall globe being removed to a very ſmall diſtance from an overcharged great one, *after having been in contact*, ſhewed oppoſite electricity in the fronting point; when a little farther off, it was neutral; and beyond this, it was overcharged.

The diameters being 11 and 8, the fronting point of the ſmall one was negative till the diſtance was 1; here it was neutral, and when it was removed farther, it was poſitive. When the diameters were 11 and 4, the ſmall globe was negative till their diſtance was 2, where it was neutral. When the diameters were 11 and 2, the diſtance which rendered the ſmall globe neutral in the fronting point was $2\frac{1}{2}$.

All theſe facts are perfectly conformable to a mathematical deduction, from the ſuppoſition that the redundant fluid is ſpread over the ſurface, and that the interior points are neutral. If any ſort of doubt ſhould remain in the minds of thoſe who are not converſant in ſuch diſcuſſions, it muſt be greatly removed by the fact, that it is quite indifferent whether one or both globes be ſolid, or be an extremely thin ſhell.

When an electrified body is touched with a long wire, and by another of equal diameter and length, coated to any thickneſs with lac or ſealing wax, the two wires take off preciſely the ſame quantity of electricity. This was demonſtrated by touching a globe repeatedly till the electricity was reduced to $\frac{1}{2}$.

Hence we muſt conclude, that the electric fluid does not form active atmoſpheres around bodies, by the action of whoſe particles in contact (mathematical or phyſical) the phenomena of attraction and repulſion are produced, but by the action of the fluid in the body, agreeable to the theory of Æpinus.

Such are the obſervations of Mr Coulomb. They are extremely valuable, becauſe they confirm in the completeſt manner the legitimate conſequences of the theory.

We think that the materiality of that which is transferred from place to place in the exhibition of electric phenomena, is greatly confirmed by ſome obſervations of Mr Wilſon's in the Pantheon. When a ſpark was taken from the whole of the long wire extended in that vaſt theatre, the ſenſation was ſo different from a ſpark which conveyed even a much greater quantity of fluid from a pretty large, but compact, ſurface, that they could hardly be compared. The laſt was like the abrupt twitch with the point of a hooked pin, as if pulling off a point of the ſkin; the ſpark from the long wire was more like the forcible piercing with a needle, not very ſharp, breaking the ſkin, and puſhing it inward. We had this account from the Doctor in converſation. He aſcribed it, with ſeeming juſtice, to the momentum acquired by the fluid accelerated along that great extent of wire.

Electricity, Electrometer.

Animal Electricity. See Galvanism, in this Supplement.

ELECTROMETER, is an inſtrument which meaſures the quantity of electricity in any electrified body. The moſt common electrometers are deſcribed in the article Electricity (*Encycl.*), n° 27, and 182—233. A very valuable one is likewiſe deſcribed in n° 85. of the article Electricity in this volume; but there are ſtill two electrometers, of which we have hitherto given no account, though they are of ſuch value, that to paſs them unnoticed would be unpardonable. The firſt, which is incomparably the moſt accurate and delicate inſtrument of the kind that we have ſeen, was invented by Mr Coulomb, and is adapted to aſcertain the ſmalleſt quantity of redundant electricity. The ſecond is a late invention of Mr Cuthbertſon, the ingenious improver of the air-pump, and is employed only to meaſure the charge of large jars and batteries.

Electrometer, by *Mr Coulomb* of the Royal Academy of Sciences at Paris, deſcribed in the Memoirs for 1785.

Mr Coulomb had made ſome experiments in examination of Dr Hook's theory of ſprings "*ut tenſio ſic vis*;" and found, that it was ſurpriſingly exact, in regard to the force neceſſary for twiſting elaſtic wires. Having ſuſpended a nicely turned metal cylinder by a fine wire in the direction of its axis, and having given it ſeveral turns, and left it to regain its natural poſition, he obſerved, that it performed all its revolutions of untwiſting and twiſting in times preciſely equal, whether theſe oſcillations were of a few degrees, or conſiſted of ſeveral revolutions. He thence concluded, that the force with which the wire endeavoured to regain its natural poſition was exactly proportional to its diſtance from it. Engaged, ſoon after, by order from the Miniſter of Marine, in an examination of the phenomena of the mariner's compaſs, he took this method of ſuſpending his needles, in order to obtain exact meaſures of the forces which cauſed them to deviate from the magnetic meridian. He made ſome obſervations with needles ſo ſuſpended; which are highly valuable to the philoſopher engaged in that ſtudy. When his ſucceſs in this reſearch had fully gratified his wiſhes, he turned his thoughts to the examination of the law of electric action by the help of an electrometer ſuſpended in the ſame manner. It is conſtructed as follows:

Electrometer.

ABDC (fig. 1.) repreſents a glaſs cylinder, 12 inches in diameter and in height. This is covered by a glaſs plate fitted to it by a projecting fillet on the under ſurface. This cover is pierced with two round holes of $1\frac{1}{2}$th inches in diameter. One of them *f* is in the centre, and it receives the lower end of the glaſs tube *f h*, of 24 inches height, which is fixed in the hole with a cement made of ſealing wax, or other electric ſubſtance. The top of this tube receives the braſs collar H (fig. 2. n° 3.), bored truly cylindrical, and having a ſmall ſhoulder, which reſts on the top of the tube. This collar is faſtened with cement, and receives the hollow cylinder *e* (fig. 2. n° 2.), to which is joined the circular plate *a b*, divided on the edge into 360 degrees. It is alſo pierced with a round hole G in the centre, which receives the cylindrical pin *i* (fig. 2. n° 1.), having

Plate XXVII.

a milled head *b*, and an index *i o*, whose point is bent down, so as to mark the divisions on the circle *a b*. This pin turns stiffly in the hole G, and the cylinder Φ turns steadily in the collar H. To the lower end of the centre pin is fastened a little pincer *q*, formed like the end of a port-crayon, and tightened by the ring *q*, so as to hold fast the suspension wire, the lower end of which is grasped by a similar pincer P *o* (fig. 3.), tightened by the ring *φ*. The lower end *φ o* is cylindrical, and it is of such weight as to strain the wire perfectly straight, but without any risk of breaking it. It may be made half of the weight that will just break it.

This pincer is enlarged at C, and pierced with a hole, which receives tightly the arm *g* C *q* of the electrometer. This is eight inches long, and consists of a dry silk thread, or slender straw of some grass completely dried, and dipped in melted gum lac or fine sealing wax, and held upright before a clear fire, till it form a slender cylinder of about $\frac{1}{10}$th of an inch in diameter. This occupies six of the eight inches, from *g* to *q*: the remaining two inches is a fine thread of the lac or sealing-wax, as it drains off in forming the arm. At *a* is a ball of pith of elder or fine cork, one-fourth or one-half of an inch in diameter, made very smooth, and gilded. It is balanced by a vertical circle *g* of paper, of large dimensions, stiffened with varnish. The resistance of the air to this plane soon checks the oscillations of the arm.

The whole is seen in its place in fig. 1. where the arm hangs horizontally about the middle of the height of the great cylinder. In its oscillations the ball *a* moves round in a circle, whose centre is in the axis of the whole instrument. Its situation is indicated by a graduated circle Z O Q, drawn on a slip of paper, and adhering to the glass with varnish. The electrified body, whose action is to be observed, is another small ball of cork *t*, also gilt, or a brass ball well polished. This is carried by a stalk of gum lac *m φ*, inclosing a dry silk thread. This stalk is grasped by a clamp of cleft deal, or any similar contrivance which lies firm on the glass cover. When this ball is let down through the hole *m*, it stands so as to touch the ball *a* on the arm when that ball is opposite *o* on the graduated circle.

To electrify the ball *t*, we employ the insulating handle, fig. 4. which is a slender stick of sealing wax or lac, holding a metal wire that carries a small polished metal ball. We touch with it some electrified body, such as the prime conductor of a machine, the knob of a jar, &c. Introduce this electrified ball cautiously into the hole *m*, and touch the ball *t* with it. The ball *a* is immediately repelled, and goes to a distance, twisting the suspension-wire, till the force of twist exerted by the wire balances the mutual repulsion of the balls *t* and *a*.

Such is the process for examining the law of electric action. But when we would examine the action of different bodies in different states, another apparatus is wanted. This is represented by the piece *c* A *d* (fig. 5.), consisting of a plug of sealing wax A, which fits tight into the hole *m*, and is pierced by the wire *c d*, hooked at *c*, to receive a wire connecting it occasionally with an electrified body, and having below a polished metal ball *d*.

The instrument is fitted for observation in the following manner: Turn the milled button *b* at top, till the twist-index *i o* is on the mark *o* of the twist circle. Then turn the whole in the collar H, till the ball *a* stands opposite to the mark *o* of the paper circle *z* OQ, and at the same time touches the ball *t* or *d*.

The observation is made thus: The ball *t* is electrified as already said, and *a* is repelled, and retires from *t*, twisting the wire, and, after a few oscillations, settles at a distance corresponding to the repulsion. Now turn the twist-index, so as to force the ball *a* nearer to *t*. We estimate the force of this new repulsion by adding the motion of the twist-index to the angle at which the ball first rested. By turning the twist-index still more, we bring the balls still nearer, and have a measure of another repulsion.—And thus may we obtain as many measures as we please.

In this way Coulomb ascertained the relation between the repulsion and the distance to be the inverse duplicate ratio of the distances. He discovered the law of dissipation by air in contact, and the relation which this bears to the primitive repulsion, by observing the gradual approach of *a* to *t* as the electricity dissipates from both, and by slackening the twist-index till the ball *a* retires to its primitive distance. He ascertained the dissipation along imperfect conductors and the length necessary for insulation, by completely insulating the ball *t*, and observing the loss by air in contact with it, and then sliding a metal rod down the insulating stalk, till the dissipation began to exceed what took place by the air alone. He examined the proportion of redundant fluid in communicating bodies, by connecting them alternately with the piece, fig. 5.; as also by electrifying one ball, and observing its repulsive force, and then sharing its electricity with another, and observing the diminution. He examined the graduation of his electrometer, by sharing the electricity of one ball with an equal ball, which gave him the position that indicated one-half; and, by repeating this, for one-fourth, &c. in the same manner as we practised and related in Electricity (*Suppl.*), n° 141, &c.

An example of one or two of those trials will give a clear conception of the conclusions deduced from these observations.

The ball *t* was introduced and electrified; *a* was repelled, and settled at 40°; the index was twisted 140°, which brought *a* to 20; and the time was noted. The electricity gradually dissipated, and *a* came nearer to *t*. The index was untwisted 30°, and *a* retired a little beyond 20°; but on waiting a few seconds, it stood exactly at 20°. The time was again noted. The interval was exactly three minutes. The conclusion from the experiment was as follows:

When the ball was brought to 20°, the repulsion was evidently 140 + 20, or 160. Three minutes afterwards it was 210 + 20, or 130; and 30° were lost in three minutes, or 10° per minute. The mean force was 145. Therefore the mean loss per minute was $\frac{10}{145}$. Observe also, that the primitive force corresponding to the distance was 40; and the force corresponding to 20 was 160, or inversely as 20^2 to 40^2.

But observe, that the distances were not measured by the angles, but by the chord of the angles. The obliquity of action must also be accounted for; and the real lever is less than the arm, in the proportion of radius to the cosine of $\frac{1}{2}$ the angle.

The wire used by Coulomb in his first experiments on the law of action was of such strength, that $\frac{1}{340}$th of a French grain, applied at the point *a*, held it fast till

till the twist-index was turned 360°; so that one degree corresponded to $\frac{1}{121400}$ of a grain. A foot of this wire weighed $\frac{1}{16}$th of a grain. Experience having shewn that this was a sensibility far exceeding what was necessary for the measures that he had in view, and made the instrument too delicate for common uses, he substituted much stronger and shorter wires, and recommends much smaller dimensions for the whole instrument. We have made two of only five inches in diameter and 14 inches high; the arm *a g* being 2$\frac{1}{2}$ inches, and the suspension a single fibre of silk, carrying 30 grains. It is far more sensible than Bennet's gold leaf electrometer. The same instrument, with a silver wire suspension, and a thread of lac projecting from the end *g*, as an index to coincide more closely with the scale, is sufficiently nice for all experiments of measurement. It is always proper to have the diameter of the cylinder double the length of the arm, that the action of the glass may not disturb the position of the arm. It is greatly improved by having a round hole in the bottom of the instrument, in which the cylinder C *o* of the lower pincer may hang freely: this prevents much tedious oscillation. For ordinary experiments, for measuring charges of batteries, and the like, a much less delicate instrument, with a suspension-wire strained at both ends, is abundantly delicate, and vastly more manageable. The wire should extend as far below the arm as above it, and should be grasped below, by a pincer turning by a milled head in a hole at the end of a slender spring. This enables us to adjust the instrument speedily. Having placed the twist-index at o, turn this lower button gently till the ball *a* points exactly to o on the paper circle. Even in this coarsest state we have found it more delicate, and much more exact, than the electrometer described in ELECTRICITY (*Suppl.*), n° 85. which was much more costly, and liable to accidents. Coulomb's electrometer has the great advantage of wasting very little electricity; whereas Henly's, or Brookes's, or de Luc's, waste it very fast when it is intense.

We improved it greatly by taking away the apparatus with the ball *t*, and substituting the piece, fig. 5. for it, after changing its construction a little. Instead of the wire *c d*, we used the smallest glass tube that we could varnish on the inside, by drawing through it a silk thread dipped in varnish. Having varnished it with lac both within and without, a brass ball *d* was fixed on its lower end, and a fine wire, with a ball at top, was put down into the tube, so as to touch the ball below. When the plug was fitted into the hole *m* once for all, the situation of the ball *d* suffered no alteration. When delicate experiments are to be made, the upper ball *c* is touched by the charger, fig. 4. which electrifies *d*. C is immediately drawn out with a glass forceps; and thus *d* is left completely insulated. When external electricity, such as the faint electricity of the atmosphere is to be examined, the wire is allowed to remain in the tube.—*N. B.* A scrupulous experimenter, who may object to the straining spring recommended above, may substitute a small weight, which will be constant in its action.

The reader will observe, that this electrometer, as hitherto managed, measures only repulsions. It is not so easy to measure attractions with it; and Mr Coulomb was obliged to take a very circuitous method, during which a great deal of electricity was dissipated. In this respect, the electrometer described in the article ELECTRICITY (*Suppl.*) has the advantage; but in every other respect, Mr Coulomb's is the finest electrometer that has yet been published, giving *absolute* measures, and this with great accuracy. The Hon. Mr Cavendish has employed the construction in his most valuable experiments on the force of gravity (*Phil. Trans.* 1798, Part II.); an experiment which Newton would have been delighted with observing.

Cuthbertson's ELECTROMETER is thus described by himself in the last number of the second volume of *Nicholson's Philosophical Journal.* GH (fig. 6.) is an oblong piece of wood, about 18 inches in length and six in breadth, in which are fixed three glass supporters, D, E, F, mounted with brass balls, *a*, *c*, *b*. Of these supporters E and F are exactly of the same length; but D is four inches shorter. Under the brass ball *a* is a long brass hook; the ball *c* is made of two hemispheres, the under one being fixed to the brass mounting, and the upper turned with a groove to shut upon it, so that it can be taken off at pleasure. The ball *b* has a brass tube fixed to it, about three inches long, cemented on the top of F, and the same ball has a hole at the top, of about one-half inch diamater, corresponding with the inside of the tube. AB is a straight brass wire, with a knife-edged centre in the middle, placed a little below the centre of gravity, and equally balanced with a hollow brass ball at each end, the centre, or axis, resting upon a proper shaped piece of brass fixed in the inside of the ball *c*; that side of the hemisphere towards *c* is cut open, to permit the end *c* A of the balance to descend till it touches the ball *a*, and the upper hemisphere C is also cut open to permit the end *c* B to ascend; *i* is a weight, weighing a certain number of grains, and made in the form of a pin with a broad head; the ball B has two holes, one at the top, and the other at the bottom; the upper hole is so wide, as to let the head of the pin pass through it, but to stop at the under one, with its shank hanging freely in *b*; *k* is a common Henley's quadrant electrometer; and when in use it is screwed upon the top of *c*.

It is evident, from the construction, that if the foot stand horizontal, and the ball B be made to touch *b*, it will remain in that position without the help of the weight *i*; and if it should by any means receive a very low charge of electric fluid, the two balls *b*, B, will repel each other; B will begin to ascend, and, on account of the centre of gravity being above the centre of motion, the ascension will continue till A rest upon *a*. If the balance be set again horizontal, and the pin *i* be put into its place in B, it will cause B to rest upon *b*, with a pressure equal to that weight, so that more electric fluid must be communicated than formerly before the balls will separate; and as the weight in B is increased or diminished, a greater or less quantity of electric fluid will be required to effect a separation.

When this instrument is to be applied to a jar, or battery, one end of a wire L must be inserted into a hole in *b*, and the other end into a hole of any ball proceeding from the inside of a battery, as M. A chain, or wire, or any body through which the charge is to pass, must be hung to the hook at *m*, and carried from thence to the outside of the battery, as is represented by the line N. *k* must be screwed upon *c*, with its index towards A. The reason of this instrument being added, is to shew, by the index continuing to rise, that the charge of the battery is increasing, because the other

other part of the inſtrument does not act till the battery has received its required charge.

It is almoſt needleſs to obſerve that this inſtrument conſiſts of three electrometers, viz. Henley's electrometer, Lane's diſcharging electrometer conſiderably improved, and Brookes's ſteelyard electrometer improved likewiſe. By this combination and theſe improvements, we poſſeſs all that can be required in an electrometer for batteries and large jars; for, by k, we ſee the progreſs of the charge; by the ſeparation of B b, we have the repulſive power in weight; and by the ball A, the diſcharge is cauſed when the charge has acquired the ſtrength propoſed.

In the journal from which this abſtract is taken, the reader will find ſome curious experiments made with batteries by means of this electrometer; but one will be ſufficient to explain its uſe. Prepare the electrometer in the manner ſhewn in the figure, with the jar M annexed, which contains about 168 ſquare inches of coating. Take out the pin in B, and obſerve whether the ball B will remain at reſt upon b; if not, turn the adjuſting ſcrew at C till it juſt remains upon A. Put into B the pin, marked i, weighing 15 grains; take two inches of watch-pendulum wire, fix to each end a pair of ſpring tongs, as is repreſented at G m, hook one end to m, and the other to the wire N, communicating with the outſide of the jar; let the uncoated part of the jar be made very clean and dry; and let the prime conductor of an electrical machine, or a wire proceeding from it, touch the wire L; then, if the machine be put in motion, the jar and electrometer will charge, as will be ſeen by the riſing of the index of k; and when charged high enough, B will be repelled by b, and A will deſcend and diſcharge the jar through the wire which was confined in the tongs, and the wire will be fuſed and run into balls. The ingenious author, by breathing through a glaſs pipe into the jar, damped it a little in the inſide. Then loading B with a pin of 30 grains, he obtained ſuch a charge as fuſed eight inches of watch pendulum wire, diſpoſed exactly as the two inches were diſpoſed in the former experiment. By repeating and varying his experiments, he found that double quantities of electrical fluid, in the form of a diſcharge, will melt four times the length of wire of a certain diameter.

ELECTROPHORUS. See Electricity in this *Supplement*.

ELEPHAS, the Elephant. See *Encyclopædia*; where the natural hiſtory of this huge and ſagacious animal is detailed at conſiderable length. Since that article was publiſhed, we have ſeen the third volume of the Aſiatic Reſearches, in which ſome important queſtions, which we were then obliged to leave in uncertainty, ſeem to be decided by John Corſe, Eſq. They relate, 1*ſt*, To the mode in which elephants copulate; which Buffon aſſerts (and in proof of his aſſertion adduces the ſtructure and poſition of the generative organ in the female) to be performed while that female remains recumbent on the back; but which Mr Corſe inſiſts from ocular evidence, takes place after the manner in which the horſe copulates with the mare. 2*d*, To the method of receiving nouriſhment from the mother; which is not, as Buffon avers, by the trunk, but by the mouth, which ſucks the dug, while the trunk of the young animal graſps it round to preſs out the milk. 3*d*, To the period of their going with young; which Mr Corſe conceives cannot be leſs than two years; whereas Buffon and Pennant aſſign only nine months for the geſtation of their young. His reaſons for this ſuppoſition are unanſwerable, and ſhall be given in his own words.

"As far as I know, the exact time an elephant goes with young has not yet been aſcertained; but it cannot be leſs than two years, as one of the elephants brought forth a young one, twenty one months and three days after ſhe was taken. She was obſerved to be with young in April or May 1788, and ſhe was only taken in January preceding; ſo that it is very likely ſhe muſt have had connection with the male ſome months before ſhe was ſecured, otherwiſe they could not have diſcovered that ſhe was with young, as a fœtus of leſs than ſix months cannot well be ſuppoſed to make any alteration in the ſize or ſhape of ſo large an animal. The young one, a male, was produced October 16, 1789, and appeared in every reſpect to have arrived at its full time. The gentleman to whom it belongs examined its mouth a few days after it was brought forth, and found that one of its grinders on each ſide had partly cut the gum."

When Mr Corſe wrote his memoir, the young elephant was active and well, and beginning to eat a little graſs. In Africa the Hottentots feed on the elephant; and M. Vailant declares, that an elephant's foot, when baked in their manner, is a moſt delicious morſel.

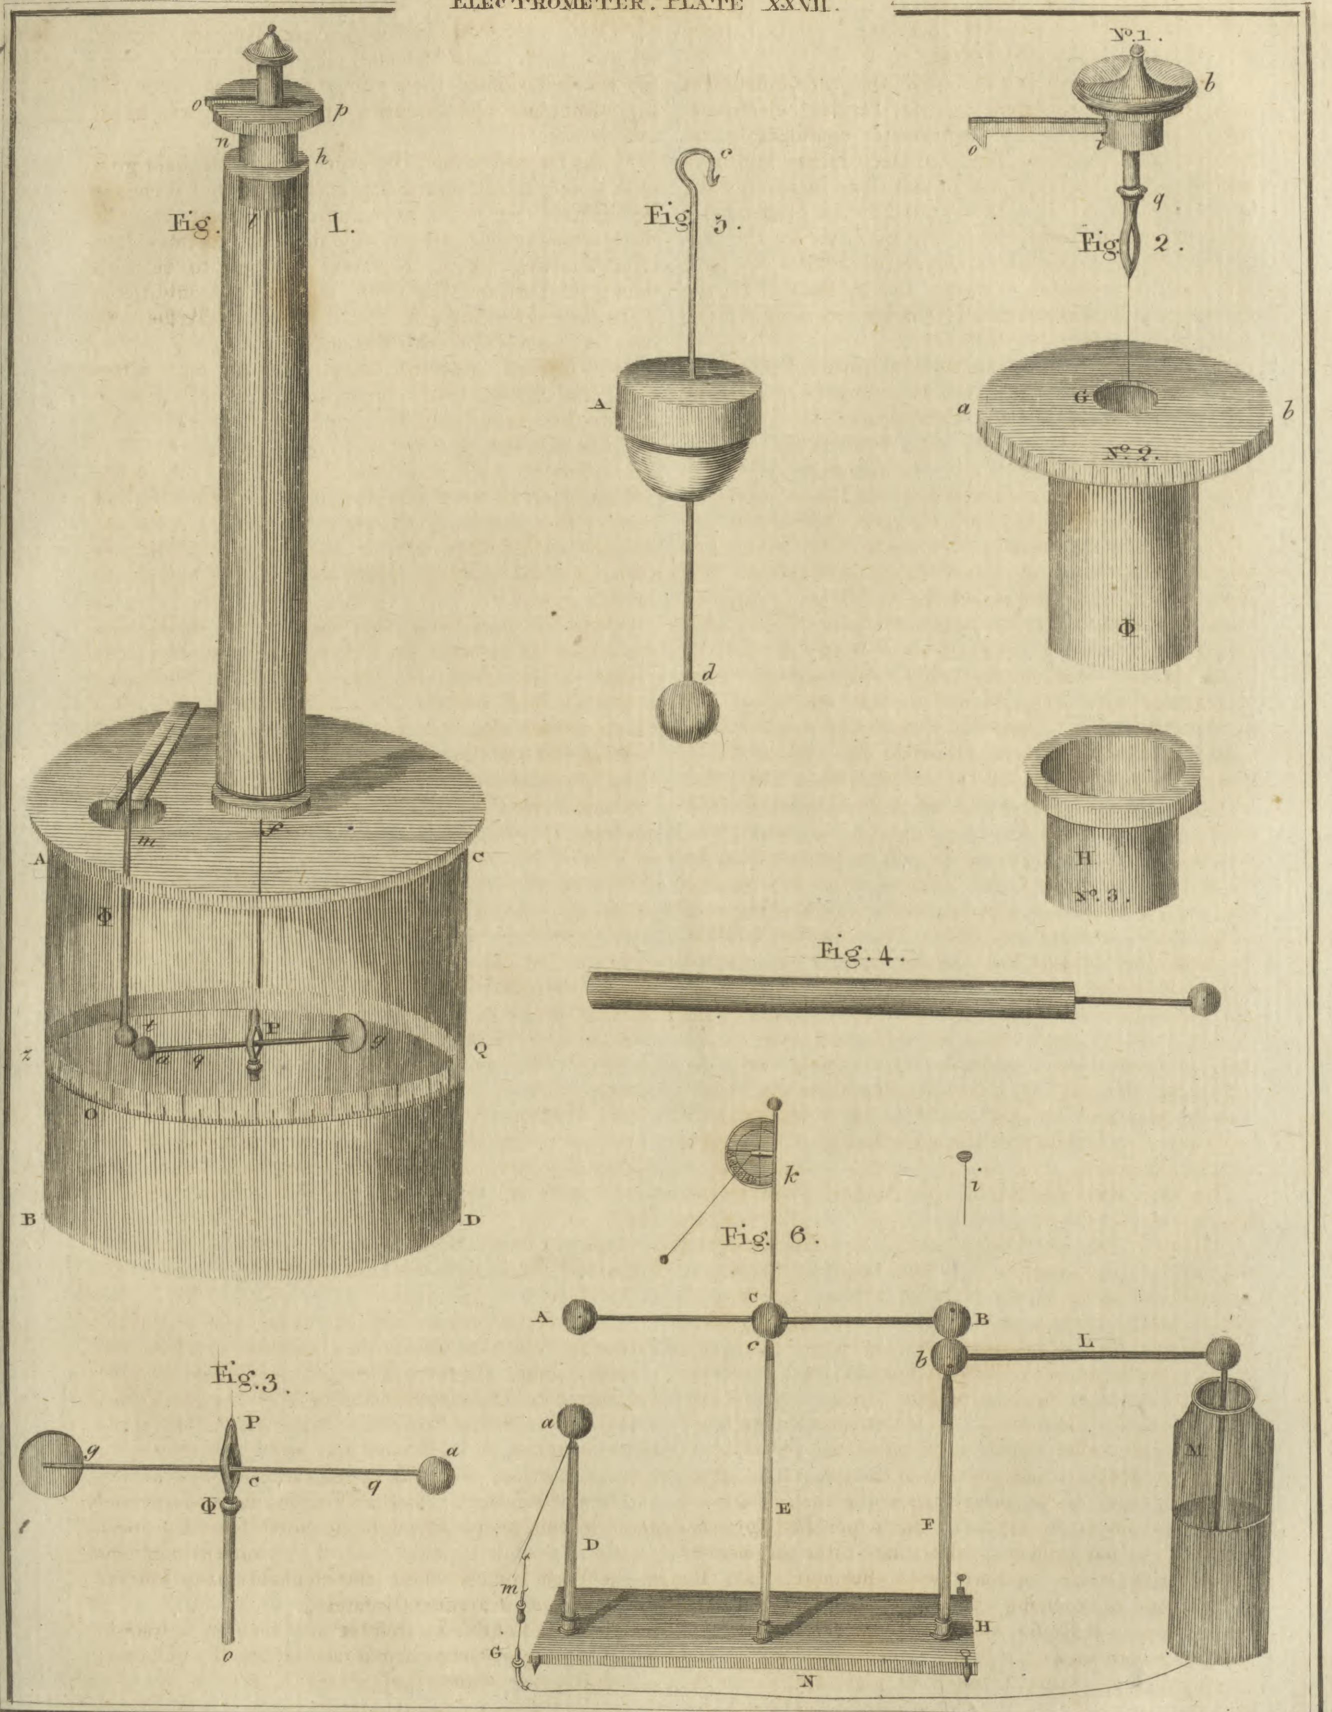
ELEPHANTIASIS (ſee Medicine, n° 352. *Encycl.*) is one of the moſt dreadful maladies with which the human race is anywhere afflicted. It is not indeed common, if it be found at all, in the temperate climates of Europe; but it is frequent in the Eaſt and Weſt Indies, where it too often baffles the ſkill of the ableſt phyſicians. In the ſecond volume of the Aſiatic Reſearches we have the following preſcription for its cure:

"Take of fine freſh white arſenic one tólá, or 105 grains; of picked black pepper ſix times as much: let both be well beaten at intervals for four days ſucceſſively in an iron mortar, and then reduced to an impalpable powder in one of ſtone with a ſtone peſtle, and thus completely levigated, a little water being mixed with them. Make pills of them as large as tares or ſmall pulſe, and keep them dry in a ſhady place. One of thoſe pills muſt be ſwallowed morning and evening with ſome betel leaf, or in countries where betel is not at hand, with cold water: if the body be cleanſed from foulneſs and obſtructions by gentle cathartics and bleeding before the medicine is adminiſtered, the remedy will be ſpeedier."

This preſcription, we are told, is an old ſecret of the Hindoo phyſicians, which they conſider as a powerful remedy againſt all corruptions of the blood, whether occaſioned by the elephantiaſis or the venereal diſeaſe, which they call the *Perſian* fire, and which they apply likewiſe to the cure of cold and moiſt diſtempers, or palſy, diſtortions of the face, relaxation of the nerves, and ſimilar diſeaſes. As the Hindoos are an ingenious and ſcientific people, it might be worth ſome European phyſician's while to make trial of this ancient medicine in the Weſt Indies, where the elephantiaſis or kindred diſeaſes prove ſo frequently fatal.

ELEVATION, in architecture, denotes a draught or deſcription of the principal face or ſide of a building; called alſo its *upright* or *orthography*.

ELLIPSE, or Ellipsis, is one of the conic ſections,



D. Lizars Sculp.t

tions, popularly called an *oval;* being called an *ellipse* or *ellipsis* by Apollonius, the first and principal author on the conic sections, because in this figure the squares of the ordinates are *less* than, or *defective* of, the rectangles under the parameters and abscisses. See *Conic Sections*, Encycl.

ELLIPSOID, is an elliptical spheroid, being the solid generated by the revolution of an ellipse about either axis.

ELLIPTOIDE, an infinite or indefinite ellipsis, defined by the indefinite equation $ay^{m+n} = bx^m.\overline{a-x}^n$ when m or n are greater than 1: for when they are each = 1, it denotes the common ellipse.

There are several kinds or degrees of elliptoides, denominated from the exponent $m + n$ of the ordinate y. As the cubical elliptoide, expressed by $ay^3 = bx^2.\overline{a-x}$; the biquadratic, or sursolid $ay^4 = bx^2.\overline{a-x}^2$; &c.

EMINENTIAL EQUATION, a term used by some algebraists, in the investigation of the areas of curvilineal figures, for a kind of assumed equation that contains another equation eminently, the latter being a particular case of the former.

ENAMELLING OF VESSELS FOR THE KITCHEN. In the year 1779 the Society of Emulation in Paris proposed as a prize question, "To discover a composition fit for making kitchen utensils which should be free from the disadvantages attending copper, lead, tinned vessels, glazed earthen-ware, &c. which should be as strong as possible, less costly than the vessels used at present, and which should be able to bear the highest degree of kitchen fire, and the most sudden changes from heat to cold."

In consequence of this proposal, Mr Sven Rinman of the Royal Academy of Stockholm, without any intention of being a candidate for the premium offered by the Society of Emulation, instituted a set of experiments on small vessels of copper and hammered iron, with the view of giving to them a coating of what may properly be called *enamel*, which should not have the defects of tinning, and which, when applied to iron, should take from it the inconveniency of rusting, and of blackening many sorts of victuals when they are dressed in it. These experiments he submitted to the academy, of which he was a member; and as we think them important, we shall lay the substance of them before our readers.

The most common, and the cheapest, kind of white enamel that is to be met with in the shops (which is an opaque white glass, composed of powdered quartz, of glass of lead, and of calx of tin), was tried for coating kitchen-utensils; and he found that it was excellent for the purpose, as it produced a coating, which was not only clean and agreeable in its appearence, but possessed likewise all the power of resisting the action of fire and of acids that could be desired. But, as it is very difficult to apply, is very dear for common use, and is besides considered as not being capable of resisting violent blows or falls, he made various experiments with substances of less price; of which the following are certainly worthy of being related.

1. The white semi-transparent fluor spar was reduced into a fine powder, with an equal quantity of unburnt gypsum, and afterwards calcined in a strong fire with a white heat; the whole being, from time to time, carefully stirred. The vessel which he intended to coat, having first been wetted by dipping it in water, had as much of the aforesaid powder applied to its inside, by means of a very fine silk sieve, as would adhere to it of itself, or could be made to do so by pressing it with the finger. After this vessel had been dried and gradually heated, it was exposed to a sudden and violent heat, partly in a coal-fire, kept up by a pair of bellows (the vessel being at the same time covered, so that no coals or ashes could fall into it), and partly in an assaying furnace.

In the coal-fire, and with a heat as violent as is commonly used to make copper-solder run, the mixture was melted, in about the space of a minute, into an opaque white enamel, which evenly covered the surface of the copper, and fixed itself pretty firmly to the metal; it also bore hard blows without breaking, and resisted the trials made by boiling things in it, and by applying acids to it. The forementioned mixture was also reduced into a fine powder in a glass mortar, and made into a sort of thin paste with water; it was then applied to the vessel with a small brush, an operation as easy as that of applying any other wet colouring matter. He likewise tried this paste, by covering vessels with it in the same way the potters apply their common glazing for stone-ware. By both the above-mentioned processes he obtained a very smooth coating, particularly by the latter, which is more quickly performed. When the paste is applied, the vessel should be made a little warm, so also should the paste itself.

If the constituent parts of these two substances be considered (that is to say, that gypsum is composed of calcareous earth saturated with vitriolic (sulphuric) acid, and fluor spar of a particular acid united to siliceous earth; also, that the whole, when put into the fire without the addition of any other substance, is, of all earthy or stony mixtures, that which the most easily melts into an opaque white glass, not very brittle), and if, on the other hand, the action of acids be attended to—we shall easily conceive these substances must attach themselves strongly to copper, and that the varnish formed by them cannot afterwards be dissolved or acted upon by acids.

The greatest difficulty attending on this simple mixture is, the strong and sudden heat necessary to apply it with effect, that heat being greater than is commonly to be obtained in an assaying furnace. On that account, M. Rinman endeavoured to render it more fusible by the addition of some other substance.

Of his experiments made with this view, some failed, and others succeeded. We shall record only such as were successful, and at same time attended with such moderate expence as not to preclude them from common use.

2. With the substances employed in his first experiment, which, with the author, we shall henceforth call n° 1. he mixed an equal quantity of what is called *fusible glass (vitrum fusibile)*, composed of six parts of lime, four of fluor spar, two of quartz reduced into a fine powder, and one tenth of a part of manganese; the whole having been calcined, and ground with water in the manner colours are ground, he spread it on the vessel with a brush. This mixture ran pretty well upon the copper in the coal fire; it also attached itself very strongly to it, and produced an enamel which was firm and hard, and seemed likely to bear wear; but it was of a dark grey colour, and without any brillian-

cy.

cy. The mixture did not melt more readily in the assaying furnace.

Two parts of n° 1. with one part of the fusible glass, and a quarter of a part of manganese, had nearly the same effect. This last mixture, indeed, was rather more easily melted, but it had a darker colour.

3. Eight parts of n° 1. with one half of a part of borax, one quarter of a part of nitre, and half a part of manganese, were melted, in the space of ten minutes, into a brown liver-coloured glass; which, in the assaying furnace, produced upon the copper vessel a black enamel, which had a dull surface. In other respects it was firm, even, and hard; but it did not sufficiently cover the vessel by a single application, nor was it capable of resisting the action of acids.

4. One part of the brown glass mentioned in the last experiment, with three parts of n° 1. became in the assaying furnace with a red heat, almost as fluid as the last, and held an even and smooth surface; but it was of a dark colour, and had not any brilliancy. It was not sensibly acted upon by vitriolic (sulphuric) acid.

5. Four parts of n° 1. mixed with one half of a part of litharge, were melted in a crucible, with the help of the bellows, in five minutes, so as to become as fluid as water. This mixture, during the fusion, emitted a smell of sulphureous acid, and formed an opaque glass of a straw colour; which, after being ground, as usual, and spread upon a copper vessel, produced an enamel which covered the vessel very evenly, and was without bubbles. It was likewise, perhaps, the hardest of all, but could not be melted in the assaying furnace, requiring a stronger fire kept up by the bellows. It preserved its straw colour, but without any lustre, and resisted the action of acids better than the common glazing of the potters.

6. Mr Rinman mixed together equal quantities of gypsum, fluor spar, and what the potters call *white lead* (A), and which serves for the basis of their glazing. This mixture, after being calcined, melted in five minutes, with the assistance of a pair of bellows, into a very white, hard, and opaque enamel, which was very easily poured out of the crucible. This enamel, treated like the others, ran very freely, equally, and without bubbles, by the heat of the assaying furnace. It was also pretty hard and strong, but without any lustre, and had green and yellow spots, occasioned by the acids of the gypsum and flour spar, which had acted upon the copper during the fusion of the enamel. It, however, bore melting two or three times, and then appeared of a white colour; it was but very little affected by other acids.

7. Equal parts of fluor spar, of gypsum, of litharge, and of pure flint glass, powdered and mixed together, melted in five minutes, by the help of a pair of bellows, and produced a white and hard glass, very like that of the last experiment, but rather harder. After being applied on the vessel in the usual manner, it formed, with the greatest heat of an assaying furnace, an enamel of a yellowish white colour, firm and hard, but without lustre. In order to avoid the formation of bubbles, care was taken (as ought always to be done in enamelling) to remove the vessel from the fire as soon as it had acquired a brilliant appearance therein, or as soon as the enamel was completely melted.

8. Twelve parts of glass of lead, or of litharge, with eight parts of flint glass, and two of flowers of zinc, were melted, in the space of seven minutes, into a clear yellow glass, which, when used for enamelling, was disposed to form bubbles; but, by continuing the heat for a longer time, the bubbles were dispersed; and he obtained a pretty good enamel, of a yellow brown colour with a greenish cast, very hard and firm. It resisted the action of the vegetable acids, like the enamels already spoken of, but it was a little attacked by the mineral acids.

9. He powdered and mixed together five parts of flour spar, five parts of gypsum, two parts of minium, one half of a part of borax, two parts of flint glass, one half of a part of calx of tin, and only one twenty-fifth of a part of calx of cobalt. This mixture was melted in a crucible in six minutes, by help of the bellows, and produced an opaque glass of a pearl colour, a little inclining to blue, on account of the calx of cobalt. It was pretty hard, and, after being ground with water in the usual way, it became of a very good consistence, so as to be very fit for spreading over vessels, to which it adhered very strongly. If any bubbles formed on the vessel during its drying, they might be rubbed down with the finger, and the whole surface rendered smooth and even. After being warmed, and gradually heated, it was put into an assaying furnace made very hot with birch charcoal, which had been just kindled under the muffle. After a minute it melted, and began to appear brilliant; so that he found it necessary to take out the vessel very quickly, which was already very evenly coated with a thick, and sufficiently hard, enamel, the surface of which, however, had no brilliancy.

The colour remained always inclining to green, because the copper had been a little attacked by the acids of the gypsum and flour spar during the fusion; but in other respects this enamel was very firm, was very little hurt by slight blows, and bore very well sudden changes of heat and cold. Weak acids had no action upon it; but he had some reason to think that it would, in length of time, have been acted upon, to a certain degree, by vitriolic (sulphuric) acid. Its colour, except the forementioned shade of green, was white, with a dull, and rather changeable surface.

The calx of cobalt which has been just mentioned, and which Mr Rinman made use of merely with the intention of obtaining a fine colour, was prepared by saturating a solution of cobalt in aquafortis (nitric acid) with common salt, and evaporating to dryness; by which means he obtained a fine rose-coloured calx. A very small quantity of this calx, when mixed with any fusible glass, gives it a beautiful blue colour.

Of the various species of enamel, which had been described in the course of these experiments, and which may be all applied, with more or less advantage, to kitchen utensils, the least expensive are n^os 1, 2, and 5; but they are also those which require the greatest heat. On the other hand, n° 9. may be recommended as

(A) This substance is itself a mixture, being composed of four parts of lead and one of tin.

as the most easy of fusion, and, at the same time, very durable when used for coating vessels in which victuals are to be dressed, which is here the principal object, and is of far greater importance than the brilliant appearance resulting from the enamel generally used by artists, which however may be employed when the saving of expence is not regarded.

The enamels hitherto described are not applicable to vessels made of iron, though they may be employed to cover copper with great advantage. Iron will not indeed bear the common practice of enamellers, namely, to be put into the fire and taken out again several times; for the sparks which fly from iron, when in a hot fire, detach and carry off the enamel from the parts contiguous to those where the sparks are formed. The acids, too, of the gypsum and fluor spar, made use of in the enamels already mentioned, acted upon the iron during the fusion of the enamel, from which resulted bubbles and bare spots, which entirely spoiled the appearance of the work. Our author therefore continued his experiments with a view to discover a proper enamel for vessels made of this metal.

10. He reduced into a very fine powder, and ground together, nine parts of minium (red oxide of lead), six parts of flint glass, two parts of pure potash, two parts of purified nitre, and one part of borax. This mixture was put into a large crucible, which it only half filled; he covered the crucible so that no coals could fall into it, and gradually increased the fire under it. When the effervescence had entirely ceased, he caused the mixture to melt, by using the bellows for four or five minutes; by these means he obtained a clear and compact glass, which he poured out of the crucible upon a piece of marble. Having quenched it in water, and reduced it to a very fine powder in a glass mortar, he ground it with water to the consistence of a very thin paste. He then covered an iron vessel with it on both sides, which, after having dried and heated it by degrees, he put under a muffle well heated in an assaying furnace. The enamel melted very readily in the space of half a minute, and with a very brilliant appearance. He immediately withdrew the vessel, and let it cool: it was found to be entirely coated with a beautiful enamel of a black colour; which colour appeared to be caused by a thin layer of calcined iron, which might be seen through the transparency of the enamel.

A copper vessel having been covered with the same enamel, the fine colour of the copper was visible through the thin coat of glass; and it was as well defended from rust by this coating as it would have been by an enamel of a stronger kind.

11. To hinder the colour of the metal from being seen through the coating, he added to the mixture, used in the preceding experiment, only one hundredth part of the calx of cobalt described in n° 9. The whole was melted into a beautiful blue glass; it was prepared for enamelling, and applied in the manner before described, upon another iron vessel. The enamel proved to be smooth, thick, and brilliant, like the preceding, but it covered the vessel more perfectly; it was of a fine blue colour, with some black spots in those parts where it had been most thinly applied.

12. The glass of n° 10. reduced into powder, and ground with potters white lead, of which mention has already been made, melted with the same facility; it produced a very smooth enamel, of a grey colour, but more firm and hard than the former, and, on account of the addition made to it, of a still less price. By mixing with the same glass a small quantity of crocus martis, he obtained a very fine enamel, of a dark red colour, not to mention other colours in it still more beautiful. The crocus martis he used in this experiment was prepared from a solution of iron in aqua regia (nitro-muriatic acid), which was evaporated to dryness, and the matter thus edulcorated and calcined.

13. In order to render the forementioned enamel more solid, and to give it what is called *body*, he melted together a mixture of twelve parts of flint glass, eighteen parts of minium, four parts of potash, four parts of nitre, two parts of borax, three parts of calx of tin, and one eighth part of calx of cobalt, observing always the usual precautions. He obtained a glass of a light blue colour, which, after having been ground with water, and spread upon small iron basins, or tea cups, produced, by means of a brisk fire in an assaying furnace, an enamel which was smooth and even, and of a pearl colour. The coating was of a proper thickness, to obtain which requires a certain degree of dexterity and practice. He also tried to paint upon this enamel with what is called *mineral purple (purpura mineralis)*, which he used with a little powdered quartz, nitre, and borax; it produced a very beautiful red colour.

Though this last mentioned composition is more beautiful when applied upon iron, and more even than the preceding, it has the disadvantage, on account of the salts which it contains, of not resisting the action of the stronger vegetable acids, and still less that of the mineral ones. But as a vessel when coated with this enamel bears, without any injury, sudden changes of heat and cold, and also to have any greasy mixtures baked or boiled in it (even those which are of a caustic alkaline nature, or those which contain the usual weak acids which are used in the preparation of our food), it may be applied to vessels of various kinds, among others, to tea cups; particularly as it is neither brittle nor subject to crack, provided it is not exposed to violent blows. It is hardly necessary to say, that this enamel can only be applied upon vessels made of hammered iron, and not upon those of cast iron, these last being always too thick to be heated with sufficient quickness; for the greater is the space of time necessary to make the vessels red hot, the greater is the quantity of scales formed upon them, and, of course, the enamel becomes more injured.

Our author makes some other judicious observations on the enamel for iron, of which he has described the composition, and says, that, independent of its use for coating kitchen utensils, it might be made to serve many other purposes, such as preserving things made of that metal, not only from rust, but also, as he proved by experiment, to a certain degree, from calcination.

ENCAUSTIC PAINTING. See PAINTING in this *Supplement*.

ENFIELD (William, L. L. D.), well known in the learned world by several useful and elegant publications, was born at Sudbury, on March 29. O. S. 1741, of parents in a humble walk of life, but of very respectable characters. His amiable disposition and promising talents early recommended him to the Rev.

Enfield.

Mr Hextall, the diffenting minifter of that place, who took great care of his education, and infufed into his young mind that tafte for elegance in compofition which ever afterwards diftinguifhed him.

In his 17th year he was fent to the academy at Daventry, then under the direction of the Rev. Dr Afhworth, where he paffed through the ufual courfe of inftruction preparatory to the office of the miniftry; and with fuch fuccefs did he cultivate the talents of a preacher, and of an amiable man in fociety, that, on leaving the academy, he was at once chofen, in 1763, minifter of the very refpectable congregation of Benn's Garden in Liverpool.

In that agreeable town he paffed feven of the happieft years of his life, very generally beloved and efteemed. He married, in 1767, the daughter of Mr Holland draper in Liverpool, with whom he paffed all the reft of his days in moft cordial union. His literary reputation was extended, during his refidence in this place, by the publication of two volumes of fermons, which were very well received, and have ferved to grace many pulpits befides that in which they were originally preached. A collection of hymns and of family prayers, which he alfo publifhed at Liverpool, did credit to his tafte and judgment.

About 1770, he was invited to take a fhare in the conduct of the academy at Warrington, and alfo to occupy the place of minifter to the diffenting congregation there, both vacant by the death of the Rev. Mr Seddon. His acceptance of this honourable invitation was a fource of variety of mixed fenfations and events to him, of which anxiety and vexation compofed too large a fhare for his happinefs. No affiduity on his part was wanting in the performance of his various duties; but the difeafes of the inftitution were radical and incurable; and perhaps his gentlenefs of temper was ill adapted to contend with the difficulties, in matter of difcipline, which feem entailed on all diffenting academies, and which, in that fituation, fell upon him, as the domeftic refident, with peculiar weight. He always, however, poffeffed the refpect and affection of the beft difpofed of the ftudents; and there was no reafon to fuppofe that any other perfon, in his place, could have prevented that diffolution which the academy underwent in 1783.

During the period of his engagement there, his indefatigable induftry was exerted in the compofition of a number of works, moftly, indeed, of the clafs of ufeful compilations, but containing valuable difplays of his powers of thinking and writing. The moft confiderable was his "Inftitutes of Natural Philofophy" (quarto, Johnfon, 1783); a clear and well-arranged compendium of the leading principles, theoretical and experimental, of the fciences comprifed under that head. And it may be mentioned, as an extraordinary proof of his diligence and power of comprehenfion, that, on a vacancy in the mathematical department of the academy, which the ftate of the inftitution rendered it impoffible to fupply by a new tutor, he prepared himfelf, at a fhort warning, to fill it up; and did fill it with credit and utility, though this abftrufe branch of fcience had never before been a particular object of his ftudy. He continued at Warrington two years after the academy had broken up, taking a few private pupils.

In 1785, receiving an invitation from the principal diffenting congregation at Norwich, he accepted it, and firft fixed his refidence at Thorpe, a pleafant village near the city, where he purfued his plan of taking a limited number of pupils to board in his houfe. He afterwards removed to Norwich itfelf; and, at length, fatigued with the long cares of education, entirely ceafed to receive boarders, and only gave private inftructions to two or three felect pupils a few hours in the morning. This too he at laft difcontinued, and devoted himfelf folely to the duties of his congregation, and the retired and independent occupations of literature. Yet, in a private way and fmall circle, few men had been more fuccefsful in education, of which many ftriking examples might be mentioned, and none more fo than the members of his own family. Never, indeed, was a father more defervedly happy in his children; but the eldeft, whom he had trained with uncommon care, and who had already, when juft of age, advanced in his profeffional career fo far as to be chofen town-clerk of Nottingham, was moft unfortunately fnatched away by a fever a few years fince.

This fatal event produced effects on the doctor's health which alarmed his friends. The fymptoms were thofe of *angina pectoris*, and they continued till the ufual ferenity of his mind was reftored by time and employment. Some of the laft years of his life were the moft comfortable: employed only in occupations which were agreeable to him, and which left him mafter of his own time; witneffing the happy fettlement of two of his daughters; contracted in his living within the domeftic privacy which he loved; and connected with fome of the moft agreeable literary companions, and with a fet of the moft cordial and kind-hearted friends that perhaps this ifland affords, he feemed fully to enjoy life as it flowed, and indulged himfelf in pleafing profpects for futurity. Alas! an unfufpected and incurable difeafe was preparing a fad and fudden change: a fchirrous contraction of the rectum, the fymptoms of which were miftaken by himfelf for a common laxity of the bowels, brought on a total ftoppage, which, after a week's ftruggle, ended in death. Its gradual approach gave him an opportunity to difplay all the tendernefs, and more than the ufual firmnefs of his nature. He died November 3. 1797, amidft the kind offices of mourning friends, and his laft hours were peace!

Befides the literary performances already mentioned, Dr Enfield completed, in 1791, the laborious tafk of an abridgment of "Brucker's Hiftory of Philofophy," which he comprifed in two volumes quarto. It may be truly faid, that the tenets of philofophy and the lives of its profeffors were never before difplayed in fo pleafing a form, and with fuch clearnefs and elegance of language. Indeed it was his peculiar excellence to arrange and exprefs other mens ideas to the utmoft advantage. Perhaps, at the time of his deceafe, there was not in England a more perfect mafter of what is called the middle ftyle in writing, combining the qualities of eafe, elegance, perfpicuity, and correctnefs, entirely free from affectation and fingularity, and fitted for any fubject. If his caft of thought was not original, yet it was free, enlarged, and manly. What he was in the capacity of a teacher of religion, his feveral congregations will teftify with grateful and affectionate remembrance. Few minifters have paid fuch unremitting attention to the perfection of their pulpit compofitions;

Enfield || Engrafting.

fitions; nor was it only by detached difcourfes that he inculcated the truths of morality and religion, but by methodical plans of inftruction, drawn up with great care and comprehenfion. The valuable ftores of this kind which he left behind him will not be configned to oblivion; but, it is hoped, will inform and improve numbers to whom the voice of the preacher could never have extended. In delivery, his manner was grave and impreffive, depending rather on the weight of juft enunciation than on the arts of oratory. Little need be added to this fketch of the moral qualities of the excellent man above commemorated. If moderation, compliancy, and gentlenefs were ever prevalent in him to a degree of excefs, who that knew him will blame an excefs which opened his foul to every emotion and office of affection and friendfhip?

This account of Dr Enfield, which is taken from the *Monthly Magazine*, is acknowledged by its author to be the effufion of friendfhip; but we believe that the panegyric, though high, is in general juft. It is our duty, however, to warn our readers againft placing implicit confidence in the Doctor's reprefentation of ancient philofophy; for though we have frequently found him correct, and have therefore quoted him with approbation ourfelves, we have likewife found him fometimes miftaking the fenfe of his authors. In a work like his, miftakes were indeed unavoidable; for when he refolved to comprefs the fubftance of Brucker's five volumes within the compafs of two, he could not avoid fometimes giving what he thought the *fenfe* of the ancients, when accuracy required their very *words* to be given. This we believe to be the fource of thofe errors in his elegant hiftory, which we have heard others unjuftly attribute to defign; for had it been his *defign* to deceive, he would not furely have ftored his margin with references to enable every reader to detect the deceit.

ENGINEER, is the appellation of him whofe profeffion it is to contrive or make any kind of ufeful engine or machine. He is denominated either a civil or military engineer, according as the objects of his profeffion refpect civil or military purpofes. See FORTIFICATION, *Encycl.* and MACHINE in this *Supplement*.

ENGONASIS, in aftronomy, the fame as Hercules, one of the northern conftellations.

ENGRAFTING. See GRAFTING, *Encycl.* where it is faid that there is little hope of producing mixed fruits by engrafting one tree upon another of the fame clafs. We confefs ourfelves to be unwilling to relinquifh this opinion; but it would be very unfair to withhold from the public any fact which feems to militate againft it, and has come to our knowledge. We fhall therefore tranfcribe from the *Philofophical Magazine* the following communication from Dr Thornton, lecturer on medical botany at Guy's Hofpital, refpecting a fuppofed *lufus naturæ*, which he confiders as the confequence of engrafting.

In the firft volume of the *Philofophical Tranfactions*, N° 29. publifhed November 1667, you have the following communication, intitled,

"Some Hortulan Experiments about the engrafting of Oranges and Lemons or Citrons, whereby is produced an individual Fruit, half Orange and half Lemon, growing together as one Body upon the fame Tree."

Enneadecateris || Scotch Epifcopalians.

We have here orange trees (faith the intelligence from Florence) that bear a fruit which is citron on one fide and orange on the other. They have been brought hither out of other countries, and they are now much propagated by engrafting. This was confirmed to us (fays the editor of the Tranfactions of the Royal Society) by a very ingenious Englifh gentleman, who afferted, that himfelf not only had feen, but bought of them, anno 1660, in Paris, whither they had been fent by Genoa merchants; and that on fome trees he had found an orange on one branch and a lemon on another branch (which is not fo remarkable as what follows); as alfo, one of the fame fruit, half orange and half lemon; and fometimes three quarters of one and a quarter of the other.

In the third part of the Reports of the Board of Agriculture, among the foreign communications, we fee, with equal pleafure and aftonifhment, an account of the American apple, which, by a peculiar mode of budding (A), is half fweet and half four, half white and half red, without the leaft confufion of the refpective halves.

At Mr Mafon's, florift, Fleet-ftreet, oppofite the Bolt and Tun, there is a production now, September 1798, to be feen half peach and half nectarine. It has all the foftnefs and yellow down of the peach, and the fleek red fmoothnefs of the nectarine; fuppofed to be a *lufus naturæ*, but probably is rather the fportings of art than of nature, and which perhaps will be the caufe why we fhall in future fee many other fuch vegetable wonders, which, as we fee, were known to our anceftors.

ENNEADECATERIS, in chronology, a cycle or period of 19 folar years, being the fame as the golden number and lunar cycle, or cycle of the moon.

EPISCOPACY, the government of the church by diocefan bifhops. See *Encycl.*

SCOTCH EPISCOPALIANS, are a fociety of Chriftians, certainly as refpectable, if not fo numerous, as any other in the kingdom which diffents from the worfhip and difcipline of the eftablifhed church. For many years, however, the public worfhip of that fociety was profcribed by the legiflature; and there is reafon to fufpect that its real principles are not yet univerfally underftood. If this be fo, it furely becomes the editors of a work in which fome account is given of almoft every denomination of Chriftians down to the novel fect which ftyles its members BEREANS, to do juftice to the venerable remains of what was once the eftablifhed church of their native country.

I Eftablifhment of Epifcopacy in Scotland.

That the reformation from popery was, in Scotland, tumultuous and irregular, is known to all Europe; and very few of our readers can be ignorant that there was neither

(A) the manner in which the extraordinary nectarine-peach firft produced in this country was effected, was by inferting the bud of one fruit upon the ftock bearing a different fort.

neither order in the reformed church, nor decency in her worship, till James VI. with much address, accomplished the establishment of a very moderate episcopacy. To this form of church-government the better part of the nation was sufficiently attached; and it continued to be the ecclesiastical polity, supported by the state, till the grand rebellion, when it was overthrown by the partizans of the *national covenant*. It was restored, however, in 1662; and again abolished in 1689 by that convention which placed the Prince and Princess of Orange on the ancient throne of the Scottish monarchs.

2
No liturgy used in the Scotch church,

These events are so universally known, that it is sufficient in this place barely to mention them; but there are probably many of our readers who do not know that, during the whole period of her legal establishment, the Scotch episcopal church had no public liturgy. It appears indeed, that the first reformers made use of the English book of common prayer; and there is on record sufficient evidence that John Knox himself, though he disapproved of some things in that book, had no objection either to stated forms of prayer in general, or to a subordination among the ministers of the gospel; but his successor Andrew Melvil, who possessed neither his learning nor his worth, had influence enough to introduce into the church a perfect parity of ministers, and to excite among the people a very general abhorrence of liturgical worship. So rooted indeed was that abhorrence, that, as every one knows, an attempt to introduce into the church of Scotland a book of common prayer, copied with some alterations from that of England, produced the *solemn league and covenant*, which involved in one common ruin the unfortunate Charles and his darling Episcopacy. At the restoration of the monarchy, the Episcopal constitution of the church was restored, but no new attempt was made to establish the use of a public liturgy; and except at the ordinations of the clergy, when the English forms were used, no service book was seen in a Scottish church.

3
Except at ordinations.

For some years after Episcopacy had ceased to be the religion of the state, the deprived clergy made no alteration in their modes of social worship. Having refused to transfer to King William that allegiance which they had sworn to King James, they were treated, during his reign, with such severity, that on the Lord's day they durst not venture further than to officiate "in their own hired houses, where they received such friends as chose to come in unto them;" and in those small congregations, if congregations they may be called, they continued to pray, if not extempore, at least without book, till the accession of Anne to the throne of her ancestors. The attachment of that Princess, not only to the constitution, but also to the worship of the church of England, was well known to them; and they very reasonably thought, that they could not more effectually recommend themselves to her protection than by adopting the use of the English liturgy, which the most enlightened among them had long professed to admire. It was accordingly introduced by degrees into Scotland; and an act of parliament being passed on the 3d of March 1712, "to prevent the disturbing of those of the Episcopal communion in that part of Great Britain called Scotland, in the exercise of their religious worship, and in the use of the liturgy of the church of England," that liturgy was universally adopted by the Scotch Episcopalians; and public chapels, which had hitherto been prohibited, were everywhere built, and well frequented.

4
Introduction of the English liturgy.

That those who had refused allegiance to King William and Queen Anne should scruple to pay it to a new family, clogged as it was by so many oaths, can excite no wonder; nor is it at all wonderful that, for their attachment to the abdicated family, the public worship of the Scotch Episcopalians was, after the insurrection of 1715 and 1716, laid under some restraints. These, however, were neither rigorously severe, nor of long duration; and by the year 1720, their congregations were as numerous as formerly, consisting, especially in the northern counties, of men of all ranks, even such as held offices of trust under the established government, who frequented the Episcopal chapels in preference to the parish churches.

Hitherto the Episcopalians had been safely conducted through all dangers and difficulties by the prudence of Dr Rose, the deprived bishop of Edinburgh; but soon after his death, which happened on the 20th of March 1720, divisions broke out among them, which threatened to prove more fatal to their church than any persecution to which they had yet been subjected. For reasons which will be seen afterwards, it is proper to trace those divisions from their source.

5
Sources of division among the Scotch Episcopalians.

No native of Britain, who knows any thing of the history of his country, can be ignorant that Dr. Sancroft, the archbishop of Canterbury, and five other bishops, were at the Revolution deprived of their sees by an act of parliament; because, like the Scotch bishops, they could not bring themselves to transfer to King William and Queen Mary that allegiance which they had so lately sworn to King James. As those prelates were extremely popular for the vigorous opposition which they had given to some of the Popish projects of the late king, and as a number of inferior clergymen, of great eminence for piety and learning, were involved in the same fate with them—it need not excite great surprise, that a sweeping deprivation, which, in all its circumstances, was perhaps without a precedent in ecclesiastical history, produced a schism in the church of England. The deprived clergy, considering the bishops who were placed in the sees thus vacated as intruders, and all who adhered to them as schismatics, opened separate chapels under the authority of the primate and his nonjuring suffragans; and contended, that they and their adherents constituted the only orthodox and catholic branch of the church in England.

Both churches, however, made use of the same liturgy; and during the lives of the deprived prelates, there was no other apparent difference in their worship than what necessarily resulted from their paying allegiance to different sovereigns. But this uniformity was not of long duration. The bishops, who had been possessed of sees before the Revolution, were scarcely dead, when their successors, being under no civil restraint, found, in the principles which they had brought with them from the establishment, the means, not only of dividing their own little church, but likewise of sowing the seeds of dissension among their brethren in Scotland.

It has been observed elsewhere *, that in the church of England there are three opinions respecting the nature and end of the Lord's Supper, which, in opposition to each other, have been all patronised by men of great eminence for theological learning. It appears, indeed,

* Supper of the Lord, Encycl.

Scotch Episcopalians.

indeed, from the first liturgy set forth by authority in the reign of King Edward VI. that the reformers of that church from the errors of popery unanimously held the Lord's Supper to be a eucharistical sacrifice; and this opinion, which has been adopted by great numbers in every age since, seems to have been the most prevalent of the three among those clergy who were deprived of their livings at the Revolution. It is indeed countenanced by several passages in the present order for the administration of the Lord's Supper; and therefore, though there are other things in that order which cannot be easily reconciled to it, archbishop Sancroft and his suffragans, whatever their own opinions might be, chose not to widen the breach between themselves and the establishment, by deviating in the smallest degree from the form in which they had been accustomed to celebrate that sacrament. Their successors, however, in office, were men of different dispositions. Considering themselves as totally unconnected with the state, and no longer bound by the act of uniformity, one party, at the head of which was bishop Collier, the celebrated ecclesiastical historian (A), judged it proper to make such alterations in the communion office as might render it more suitable to their own notions of the Lord's Supper, and bring it nearer, both in matter and form, to the most ancient liturgies of the Christian church.

Of the proposed alterations, some were perhaps proper in their circumstances; whilst others, to say the best of them, were certainly needless, if not inexpedient. They were accordingly *all* opposed by another powerful party of nonjurors; and the questions in dispute were referred, first to Dr Rose, the deprived bishop of Edinburgh, and afterwards to Dr Atterbury and Dr Potter, the bishops of Rochester and Oxford. What judgment the two English prelates gave in this controversy we know not; but that of bishop Rose did him much honour. Declining the office of umpire between the parties, he recommended mutual forbearance and occasional communion with each other, according to either form; and employed a gentleman, well versed in ecclesiastical literature, to prove that such a compliance of bishop's with each others innocent prejudices was not uncommon in the purest times.

These disputes among the English nonjurors, and the appeal which was made to Dr Rose, drew, more closely than hitherto it had been drawn, the attention of the Scotch Episcopal clergy, not only to their own liturgy, which had been authorised by King Charles I. but likewise to the most ancient liturgies extant, as well as to what the fathers of the first three centuries have taught concerning the nature of the Lord's Supper. The consequence was, that such of them as were scholars soon discovered, that the Scotch communion office approached much nearer to the most ancient offices than the English; and a powerful party was formed for reviving the use of it in Scotland.

Had those men aimed at nothing farther, it is probable they would have met with very little opposition. Their opponents, who, in general, were less learned than they, were so strongly attached to the house of Stuart, that they would have adopted almost any thing sanctioned by the royal martyr's authority; but the advocates for the Scotch office knew not where to stop. 6

Revival of ancient usages.

They wished to introduce some other usages of the primitive church; such as the commemoration of the faithful departed, and the mixture of the eucharistic cup (See *Supper of the Lord*, n° 2. and 3. *Encycl.*); and their brethern, perceiving no authority from Charles I. for these things, and being accustomed to consider them as Popish practices, a violent controversy was ready to burst forth about what every enlightened mind must consider as matters of very little importance.

That the eucharistic cup was in the primitive church mixed with a little water, is a fact incontrovertible; that the practice was harmless and decent, it is wonderful that any man should deny: but that such a mixture is *essential* to the sacrament, we cannot believe, for the reasons assigned in the article referred to; and therefore it ought surely to have been no object of contention.

That the faithful departed were commemorated in the primitive church long before the invention of purgatory, is known to every scholar; that in those days such a commemoration tended to invigorate the faith and the charity of Christians, it would, in our opinion, be very easy to prove; and that at present every Christian prays in private for his deceased friends, we have proved elsewhere by arguments, of the confutation of which we are under no apprehension (See *Greek-church* in this *Supplement*): but we see not the *necessity* of introducing such prayers into public worship at any period; and we perceive impropriety in doing it at a period when, from various circumstances, they may cause weak brethren to err. But those who pleaded for the revival of this practice in the beginning of the current century, were blinded by their very erudition (B); and those who opposed it seem not to have been acquainted with

(A) This very learned, though violent man, of whom the reader will find some account in the *Encyclopædia*, was, with Dr Hickes and others, consecrated by the deprived prelates, for the purpose of preserving the Episcopal succession in what they considered as the true church of England.

(B) Paradoxical as this assertion may at first sight appear, nothing is more certain than that erudition, and even science, if *partially* cultivated, is as likely to blind as to enlighten the understanding. When a man devotes all his time, and all his attention, to *one* pursuit, he contracts such a fondness for it, as gradually to consider it as the *only* valuable pursuit, which will infallibly lead to truth, and to nothing but truth; and in this disposition of mind, he is ready to embrace the most extravagant absurdity to which it may conduct him. Of this the reader will find one very striking instance in page 547 of this volume, where the celebrated Euler appears so devoted to his darling analysis, as to place implicit confidence in it, even when he himself seems sensible that it had led him to a conclusion contrary to common sense, and the nature of things. That Dr Bentley was a very eminent philologist, is universally known; that his emendatory criticisms on the Classics are often happy, no man will deny; and yet, misled by his favourite pursuits, he never pronounces more dogmatically than when the dogma which he utters is untenable. We appeal to his criticisms on Milton. Perhaps there is not a man alive

Scotch Episcopalians.

with the workings of a benevolent and devout mind, or indeed to have known in what the essence of a prayer consists.

The ancient usages, however, were not the only subjects which, on the death of bishop Rose, furnished matter for controversy among the Scotch Episcopalians. That excellent prelate, together with the deprived archbishop of Glasgow, and the deprived bishop of Dunblain, had, from time to time, as they saw occasion, raised to the Episcopal dignity some of the most deserving Presbyters of the church; but it was resolved, for what reason we do not very well know, that none of the new bishops should be appointed to vacant dioceses during the life of any one prelate who had possessed a legal establishment; so that bishop Rose, who survived all his brethren, was for several years the ecclesiastical governor of the whole Episcopal church in Scotland. On his death, therefore, though there were four bishops in Scotland, and two Scotch bishops residing in London, there was not one of those prelates who could claim to himself the authority of a diocesan over any portion of the Catholic church. This they at first unanimously acknowledged; and one of them, in the name of himself and his brethren, recommended to the clergy of the diocese of Edinburgh to elect, after the primitive plan, a successor to their late venerable diocesan. The advice was followed; the election was made, and approved by the bishops: and Dr Fullarton, the bishop chosen, became bishop of Edinburgh, by the same means and the same authority as, in the primitive church, St Cyprian became bishop of Carthage, or Cornelius bishop of Rome.

The clergy in other districts, following the example of those in Edinburgh, diocesan Episcopacy was about to be revived throughout all Scotland upon principles purely ecclesiastical, when some of the bishops, whom Dr Rose had left behind him merely for preserving the Episcopal succession, conceived a new and very extraordinary constitution for the Scotch Episcopal church.

7 College of bishops.

Whether they were envious of their colleagues, and offended that none of the elections had fallen upon them; whether they were so ignorant as not to know that diocesan Episcopacy had subsisted long before the conversion of the Roman empire, in absolute independence on the state; or that they were actuated, as there is reason to suspect, by some political principle which they could not with safety avow;—so it was, that they opposed diocesan Episcopacy of every kind, and proposed to govern the whole Scotch church by a college of bishops. Against this unprecedented scheme the more learned bishops opposed all their influence; and being exceedingly disagreeable to the inferior clergy, it was very soon abandoned by its authors themselves, who, after some acrimonious controversy, were glad to come to an agreement with their diocesan brethren.

8 Those divisions healed.

Of this agreement, or *concordate* as it was called, the following were the principal articles: 1. "That the Scotch or English liturgy, and no other, might be indifferently used in the public service; and that the peace of the church should not be disturbed by the introduction of any of the ancient usages which had lately excited such dissensions. 2. That no man should thenceforward be consecrated a bishop of the Scotch church without the consent and approbation of the majority of the bishops. 3. That the bishops, by a majority of voices, should choose one of their number to preside in the meetings of his brethren, and to convocate such meetings when he judged them necessary: that this president should be styled *Primus Episcopus*, or more shortly *Primus*; but that he should not possess metropolitical power, or claim any kind of jurisdiction without the bounds of his own diocese or district. 4. That upon the vacancy of any diocese or district, the presbyters should neither elect, nor submit to, another bishop, without receiving a mandate by the Primus, issued with the consent of the majority of his colleagues."

This concordate was in 1731-2 subscribed by all the bishops then in Scotland, who immediately became diocesans, and thought no more of the college system. It was afterwards, with a few additions, for ascertaining more precisely the prerogatives of the Primus; for regulating the conduct of synods; for exempting bishops from the jurisdiction of other bishops, in whose districts they might chance to reside; and for preventing inferior clergymen from deserting their congregations, or removing from one district to another, without the consent of the bishops of both—thrown into the form of canons; and these canons have continued to be the code of the Scotch Episcopal church down to the present day.

9 Political opinions.

The members, and more especially the clergymen of this church, had always been considered as unduly attached to the family of Stuart; and though there was undoubtedly at first some ground for that suspicion, the writer of this article knows, from the most incontrovertible evidence, that it was continued too long, and carried by much too far. Jacobitism was imputed

---

alive who will refuse to Dr Warburton the praise of learning and ingenuity. The address with which he detects the double doctrines of the ancient philosophers, is sometimes almost astonishing; yet, misled by his own ardour in this pursuit, he discovers hidden meanings everywhere, and has found a rational system of religion in some of the ancient mysteries, where there is every reason to believe that nothing in reality was to be found but atheism and vice. Just so it is with the ardent reader of the Christian fathers. If he devote all his time to the study of their writings, he not only becomes enamoured of his employment, but acquires gradually such a veneration for the character of his masters (and venerable they undoubtedly are) as renders him afraid to question any thing which they advance, and unable to distinguish between their testimony, which is deserving of all credit, and their reasonings, which are often inconclusive. We trust it is needless to disclaim any wish to discourage, by this note, the study either of the Christian fathers, the Greek philosophers, philological criticism, or the modern analysis; we only wish to dissuade men of letters from devoting their whole time to any *one* pursuit whatever; for they may depend upon it, that such *partial* studies contract the mind. One of the most eminent mathematicians at present in England is reported to have declared his contempt of the *Paradise Lost*, because he found in it nothing *demonstrated!*

Scotch Episcopalians.

ted to the society as its dinstinguishing tenet; but the members of that society have at all times contended, that their distinguishing tenets were the apostolical institution of Episcopacy, and in the exercise of those powers which are purely spiritual, the independency of the church upon the state. In politics, indeed, they have unanimously maintained, that the only ruler of princes or *legislatures* is God, and not the people. They are, of course, no friends to the fashionable doctrine of resistance, which they believe to be not only condemned in express terms by Christ and two of his apostles, but to be also the source of that anarchical tyranny which lately deluged Europe with blood. They consider a limited monarchy, like that of Britain, as the most perfect form of civil government which the world has ever seen; and hereditary monarchy is infinitely preferable to one that is elective: and with respect to the title of the monarch, when they take a retrospective view of the origin of all civil governments, they cannot but look upon a permanent and unquestioned establishment as an indication of the plan and determination of Providence furnishing the best right to a crown which any modern sovereign can claim.

10 Persecution

Surely these are harmless opinions; and yet the worship of those who held them was, in 1746 and 1748, laid under such restraints as were calculated to produce disaffection where it did not previously exist. Two laws were then enacted against the Scotch Episcopalians; which, under the pretence of eradicating their attachment to the house of Stuart, were so contrived as to preclude such of their clergy as were willing to pay allegiance to the reigning sovereign, and to pray for the royal family by name, from reaping the smallest benefit from their loyalty. The experiment was tried by some of them; of whom one venerable person, who was never suspected of undue attachment to the house of Stuart, is still alive; but he, and his complying brethren, had their chapels burnt, and were themselves imprisoned, as if they had been the most incorrigible Jacobites. This was a kind of persecution which, since the Reformation, has had no precedent in the annals of Britain. A priest of the church of Rome, by renouncing the errors of Popery, has at all times been qualified to hold a living in England; a dissenting minister, of whatever denomination, might at any time be admitted into orders, and rise to the highest dignities of the English church;—but while the laws of 1746 and 1748 remained in force, there was nothing in the power of a Scotch Episcopal clergyman to do from which he could reap the smallest benefit. By taking the oaths to government, he was not qualified to hold a living in England, or even to enjoy a toleration in Scotland; and his clerical character being acknowledged by the English Bishops, he could not by those prelates be canonically reordained.

Upon the clergy, however, those laws of uncommon rigour were not long rigorously executed. After a few years, the burning of chapels, and the imprisoning of ministers, were occurrences far from frequent; but the

11 Toleration.

laws to which we allude affected likewise the political privileges of such laymen as frequented the Episcopal chapels: and in that part of their operation, those laws were never relaxed till 1792, when they were wholly repealed, and the Episcopalians in Scotland tolerated like other well affected dissenters from the national establishment.

While Episcopacy was the established form of church government in Scotland, the clergy of that church subscribed a confession of faith summed up in twenty five articles, which the reader will find in the history attributed to John Knox. It is sufficient to observe in this place, that in essentials it differs little from the articles of most other reformed churches; and in every thing which does not immediately relate to *papistry*, it is moderate and unexceptionable; perhaps more so than the present confession of either of the British churches. During the period which intervened between the Revolution and the year 1792, no subscription was indeed required from Scotch Episcopalian clergymen to any summary of Christian doctrine; but at their ordinations, those clergy solemnly professed their belief of all the canonical books of the Old and New Testaments; declared their persuasion that those books contain sufficiently all doctrines necessary to salvation, through faith in Jesus Christ; and were obliged to read daily in their chapels the English book of Common Prayer, which contains the Apostles, Nicane, and Athanasian creeds. But now those clergymen are enjoined by act of parliament to subscribe the 39 articles of the church of England; so that the principles of their faith are well known. No doubt there are differences of opinion among them about the sense of some of those articles; and it is well known that there are similar differences among the English clergy themselves: but there is every reason to believe, that the faith of the Scotch Episcopalians has, in every important point, been at all times orthodox.

12 Faith of the Scotch Episcopal church.

We are aware, that they have been represented as unfriendly to the English service; but such a representation appears to be either a wilful falsehood, or the offspring of ignorance. The only reformed liturgy that ever had the sanction of a civil establishment in Scotland, is *the Book of Common Prayer, and Administration of the Sacraments, and other parts of Divine Service* authorised by King Charles I. In that book, the order of administration of the Lord's Supper differs in some particulars from the English order, and is unquestionably better adapted to the opinions of those who consider that holy ordinance either as an euchthe holy ordinance either as an eucharistical sacrifice, or as a feast upon a sacrifice. In the one or other of these lights, the Lord's Supper is viewed by a great majority of the Scotch Episcopalians; and of course the Scotch communion office is used in a great majority of their chapels: but it is not used in them all. Their bishops, who, when in England, communicate with the established church, leave the inferior clergy at liberty to use either the English or the Scotch form, as is most agreeable to themselves and to the people among whom they minister; and to silence the clamour of symbolizing with the church of Rome, which was some years ago either ignorantly or maliciously raised against them, they altered the *arrangement* of the Scotch prayer of consecration, so as not only to bring it nearer to the most primitive forms, but also to make it absolutely inconsistent with the real presence, as taught either by the church of Rome or by the Lutheran churches. On this subject, see *Greek-Church*, n° 17. in this *Supplement*.

13 Their worship.

Thus have we given a short view of the distinguishing principles of what must surely be considered as a very respectable society of Christians, and the only reformed

14 English clergymen in Scotland.

formed *Episcopal* society in that part of Great Britain called Scotland. There are, indeed, chapels in Scotland distinct from the church of which we have been treating, where the English liturgy is read by clergymen who have received Episcopal ordination either in England or in Ireland; but those chapels being all independent of each other, and under the inspection of no bishop, the persons who frequent them seem to be rather Congregationalists than Episcopalians, and certainly do not constitute what can, with any propriety, be called an *Episcopal church*.

EQUANT, in astronomy, a fanciful circle, introduced into science to remove some of the defects of the Ptolemaic system of the universe. In this artificial system of epicycles and eccentric circles, the idea of circular and equable motion was by no means abandoned; but while each of the heavenly bodies revolved in its own orb, the centre of that orb was supposed to be carried at the same time round the circumference of another circle. The more obvious inequalities were thus explained with a geometrical precision. With all its nice combination, however, of circles, the system was soon found to have defects; to remove which, the fine contrivance of the equant was introduced. Though the angular motion of a planet viewed from the earth was confessed to be unequal, a point could be conceived from which it would be seen to move with perfect uniformity. That point was made the centre of the equant, and lay at the same distance from the centre of the eccentricity on the one side, as the earth was removed on the other. "Nothing (says Dr Smith, from whom this account of the equant is taken) can more evidently shew how much the repose and tranquillity of the imagination is the ultimate end of philosophy, than the invention of this equalizing circle."

EQUATION OF A CURVE. See ALGEBRA (*Encycl.*) Part III. chap. ii.

Secular EQUATION, in astronomy. See ASTRONOMY in this *Supplement*, n° 25—38.

EQUICURVE CIRCLE, the same with *CIRCLE of Curvature*, which see in this Supplement.

ERGETT EL KRANE, ERGETT Y'DIMMO } Two Abyssinian shrubs of the genus MIMOSA, which see *Encycl.*

ERKOOM, an Abyssinian bird, part of a large tribe, "in which (says Mr Bruce) the greatest variety lies in his beak and horn. The horn he wears sometimes upon the beak and sometimes upon the forehead above the root of the beak." This bird is by naturalists called the *Indian crow* or *raven*; and our author, though he seems to think this classification improper, admits that he has one charecteristic of the raven; he walks, and does not hop or jump in the manner that many others of that kind do; but then he at times runs with very great velocity, and, in running, very much resembles the turkey or bustard when his head is turned from you.

The colour of the eye of this bird is of a dark brown, or rather reddish, cast, but darker still as it approaches the pupil; he has very large eyelashes, both upper and lower, but especially his upper. From the point of the beak to the extremity of the tail is three feet ten inches; the breadth, from one point of the wing to the other extended, is six feet, and the length twenty-two inches; the length of the neck ten inches, and its thickness three inches and a half; the length of the beak, measuring the opening near the head straight to the point, ten inches; and from the point of the beak to the root of the horn, seven inches and three eighths. The whole length of the horn is three inches and a half. The length of the horn, from the foot to the extremity where it joins the beak, is four inches. The thickness of the beak in front of the opening is one inch and seven eighths. The thickness of the horn in front is one inch and five-eighths. The horn in height, taken from the upper part of the point to the beak, two inches. The length of the thighs seven inches, and that of the legs six inches and five eighths. The thickness in profile seven lines, and in front four lines and a half. It has three toes before and one behind, but they are not very strong, nor seemingly made to tear up carcases. The length of the foot to the hinder toe is one inch six lines, the innermost is one inch seven lines, the middle two inches two lines, and the last outer one two inches one line. This bird is all of a black, or rather black mixed with soot-colour; the large feathers of the wing are ten in number, milk-white both without and within. The tip of his wings reaches very nearly to his tail; his beak and head measured together are eleven inches and a half, and his head three inches and a quarter. At his neck he has those protuberances like the Turkey-cock, which are light blue, but turn red upon his being chafed, or in the time the hen is laying.

The erkoom, though not easily raised, flies (says our author) both strong and far. It has a rank smell, and is said in Abyssinia to feed upon dead carcases. This, however, he thinks a mistake, as he never saw it following the army, nor approaching a dead carcase; and as often as he had occasion to open this bird, he found in its stomach nothing but the green scarabeus or beetle. It builds in large thick trees, always, if it can, near churches; has a covered nest like that of a magpie, but four times as large as the eagle's. It places its nest firm upon the trunk, without endeavouring to make it high from the ground: the entry is always on the east side.

ETON is a place which, on account of its college, should not be omitted in a repository of arts, sciences, and literature; and as no notice is taken of it in the *Encyclopædia*, we shall deviate for once from the plan which we had laid down for this Supplement, and which is, not to admit into it descriptions of places in our own island that may be visited by the greater part of our readers with little trouble.

Though in a different county, namely, Buckinghamshire, Eton may be said to be one and the same town with Windsor, for which see *Encycl.* It is pleasantly situated on the banks of the Thames, in a delightful valley, which is of a remarkably healthy soil. Its college was founded by Henry VI. for the support of a provost and seven fellows, one of whom is vice-provost, and for the education of seventy King's scholars, as these are called who are on the foundation. These, when properly qualified, are elected, on the first Tuesday in August, to king's college Cambridge, but they are not removed till there are vacancies in the college, and then they are called according to seniority; and after they have been three years at Cambridge, they claim a fellowship. Besides those on the foundation there

Eton.

there are seldom less than three hundred scholars, and often many more, who board at the masters houses, or within the bounds of the college. The school is divided into upper and lower, and each of these into three classes. To each school there is a master and four assistants or ushers. The revenue of the college is about L. 5000 a-year. Here is a noble library, and in the great court is a fine statue of the founder, erected at the expence of a late provost Dr Godolphin dean of St Paul's. The chapel is in a good style of Gothic architecture. The schools and other parts, which are in the other style of building, are equally well, and seem like the design of Inigo Jones.

At Eton there is a singular, and we think a laudable, festival called the *Montem*, celebrated triennially (formerly duennially) by the scholars of the school upon Whit-Tuesday. The following account of this festival, taken from the Monthly Magazine, will probably be acceptable to many of our readers.

It commences by a number of the senior boys taking post upon the bridges or other leading places of all the avenues around Windsor and Eton soon after the dawn of day. These youths so posted are chiefly the best figures, and the most active of the students; they are all attired in fancy dresses of silks, satins, &c. and some richly embroidered, principally in the habits or fashion of running footmen, with poles in their hands; they are called *salt-bearers*, and demand salt, i. e. a contribution from every passenger, and will take no denial.

When the contribution is given, which is *ad libitum*, a printed paper is delivered with their motto and the date of the year, which passes the bearer free through all other salt-bearers for that day, and is as follows, viz.

"Pro more et monte,
1799, (A)
Vivant Rex et Regina."

These youths continue thus collecting their salt at all the entrances for near seven miles round Windsor and Eton, from the dawn of day until about the close of the procession, which is generally three o'clock in the afternoon.

The procession commences about twelve o'clock at noon, and consists of the Queen's and other bands of music; several standards borne by different students; all the Etonian boys, two and two, dressed in officers uniforms; those of the king's foundation wearing blue, the others scarlet uniforms, swords, &c.

The Grand Standard bearer.

The Captain, or Head Boy of Eton School.

The Lieutenant, or Second Boy.

His Majesty, attended by the Prince of Wales, and other male branches of the royal family on horseback, with their suite.

The Queen and Princesses in coaches, attended by their suite.

Band of music, followed by a great concourse of the Nobility and Gentry in their carriages and on horseback.

The procession commences in the great square at Eton, and proceeds through Eton to Slough, and round to Salt Hill, where the boys all pass the king and queen in review, and ascend the Montem: here an oration is delivered, and the grand standard is displayed with much grace and activity by the standard bearer, who is generally selected from among the senior boys.

Eton, Eudiometer.

There are two extraordinary salt-bearers appointed to attend the king and queen, who are always attired in fanciful habits, in manner of the other salt-bearers already described, but superbly embroidered. These salt-bearers carry each an embroidered bag, which not only receives the royal salt, but also whatever is collected by the out-stationed salt-bearers. The donation of the king and queen, or, as it is called upon this occasion, the *royal salt*, is always fifty guineas each; the Prince of Wales thirty guineas; all the other princes and princesses twenty guineas each. As soon as this ceremony is performed, the royal family return to Windsor. The boys are all sumptuously entertained at the tavern at Salt Hill; and the beautiful gardens at that place are laid out for such ladies and gentlemen as choose to take any refreshments, the different bands of music performing all the time in the gardens.

About six o'clock in the evening all the boys return in the same order of procession as in the morning (with the exception only of the royal family), and, marching round the great square in Eton school, are dismissed. The captain then pays his respects to the royal family at the queen's lodge, Windsor, previous to his departure for King's College, Cambridge; to defray which expence, the produce of the montem is presented to him; and upon Whit-Tuesday, in the year 1796, it amounted to more than 1000 guineas. The day concludes by a brilliant display of beauty, rank, and fashion, a promenade on Windsor Terras, bands of music performing, &c. and the scene highly enlivened and enriched by the affable condescension of the royal family, who indiscriminately mix with the company, and parade the Terrace till nearly dark.

Spontaneous EVAPORATION. See Weather, no 17, &c. *Encycl.*

EUDIOMETER, an instrument for ascertaining the purity of the atmospherical air. Many have been the contrivances of chemists for this purpose (see Eudiometer, *Encycl.*); but perhaps the best eudiometer is that of *Morveau* (or *Guyton*, as he now chooses to call himself), of which mention has been made in Chemistry, n° 420. in this Supplement. The following short description will make the nature and use of this instrument plain to every reader.

AB, (Plate XXVIII.) represents a small glass retort with a long neck; its whole capacity being from seven to nine solid inches. It must be chosen of such a curvature that, when the neck is set upright, the bulb may form at its lower part a cavity to retain the matters introduced. The extremity of the neck of this retort is ground with emery to enter the glass tube CD, which is open at both ends, and about 12 or 15 inches in length. The retort then closes the tube in the manner of a ground stopper, and intercepts all external communication. A cylindrical glass vessel F is provided, of the form of a common jar, in which the glass tube CD may be entirely plunged beneath the level of the water. Lastly, the sulphuret of potash is prepared and broken into pieces sufficiently small to be introduced into

(A) Or whatever the year may be.

into the retort. These are to be inclosed, dry and even hot, in a bottle for use. These constitute the whole apparatus and preparation of materials.

When it is required to examine an aeriform fluid, by separating its oxygen, two or three pieces of the sulphuret, of the size of a pea, are put into the retort. It is then filled with water, taking care to incline it so that all the air may pass out from the bulb. The orifice of the retort is then to be closed, and inverted into the pneumatic tube, in order that the gas proposed for examination may be transferred into it in the usual manner. By an easy manœuvre of alternately inclining the retort in different directions, all the water is made to flow out of the bulb in which the sulphuret remains. When this is done, the retort is placed in the vertical situation, and its extremity introduced into the tube of glass CD, which must always be under water. A small lighted taper is then to be placed under the bulb. To support the retort in its position, the jar is provided with a wooden cover, in which there is a notch to receive it.

The first impression of the heat dilates the gaseous fluid so much that it descends almost to the bottom of the tube, which is disposed expressly for its reception; otherwise the partial escape would prevent an accurate determination of its change of bulk. But as soon as the sulphuret begins to boil, the water quickly rises, not only in the inferior tube, but likewise in the neck of the retort, notwithstanding the application, and even the increase of the heat.

If the fluid be absolutely pure vital air, the absorption is total. In this case, to prevent the rupture of the vessel by too sudden refrigeration, the ascent of the water must be rendered slower, either by removing the taper, or by increasing the perpendicular height; which will not prevent the absorption from continuing while any gas remains which is proper to support combustion.

If the fluid be common air, or oxygen mixed with any other gas, the quantity of water which has entered the retort must be accurately measured after the cooling. It represents the volume of air absorbed. Care must be taken to inclose the remaining gas under the same pressure, by plunging the retort to the level of the line at which the inclosed water rests, before the orifice is stopped.

This operation of measuring, which is very easy when measuring vessels are at hand, may be habitually performed by a slip of paper pasted on the neck of the retort, upon which divisions are drawn from observation, and which must be covered with varnish to defend it from the action of the water.

EUDOXUS of Gnidus was a celebrated philosopher of the school of Pythagoras. His first preceptor was Archytas, by whom he was instructed in the principles of geometry and philosophy. About the age of twenty-three he came to Athens; and though his patrimony was small, by the generous assistance of Theomedon a physician, he was enabled to attend the schools of the philosophers, particularly that of Plato. The liberality of his friend's afterwards supported him during a visit to Egypt, where he was introduced by Agesilaus to king Nectanebis II. and by him to the Egyptian priests. It has been said that he accompanied Plato into Egypt; but this is inconsistent with chronology; for Nectanebis II. reigned in Egypt from the second year of the hundred and fourth Olympiad, to the second year of the hundred and seventh; and it was before Plato opened his school, that is, before the ninety-eighth Olympiad, about the fortieth year of his age, that he visited Egypt. Eudoxus is highly celebrated by the ancients for his skill in astronomy; but none of his writings on this or any other subject are extant. Aratus, who has described the celestial phenomena in verse, is said to have followed Eudoxus. He flourished about the ninety-seventh Olympiad, and died in the fifty-third year of his age. *Enfield's Hist. of Philosophy.*

EVECTION is used by some astronomers for the libration of the moon, being an inequality in her motion, by which, at or near the quadratures, she is not in a line drawn through the centre of the earth to the sun, as she is at the syzygies, or conjunction and opposition, but makes an angle with that line of about 2° 51′. The motion of the moon about her axis only is equable; which rotation is performed exactly in the same time as she revolves about the earth; for which reason it is that she turns always the same face towards the earth nearly, and would do so exactly, were it not that her monthly motion about the earth, in an eliptic orbit, is not equable; on which account the moon, seen from the earth, appears to librate a little upon her axis, sometimes from east to west, and sometimes from west to east; or some parts in the eastern limb of the moon go backwards and forwards a small space, and some that were conspicuous are hid, and then appear again.

The term *evection* is used by some astronomers to denote that equation of the moon's motion which is proportional to the sine of double the distance of the moon from the sun, diminished by the moon's anomaly. This equation is not yet accurately determined; some state it at 1° 30′, others at 1° 16′, &c. It is the greatest of all the moon's equations, except the equation of the centre. *Hutton's Dictionary.*

EVENLY EVEN NUMBER. See NUMBER, *Encycl.*

Evenly Odd Number. See NUMBER, *Encycl.*

EVOLVENT, in the higher geometry, a term used by some writers for the involute or curve resulting from the evolution of a curve, in contradistinction to that evolute or curve supposed to be opened or evolved. See EVOLUTE and INVOLUTE, *Suppl.*

EVOLUTE, in the higher geometry, a curve first proposed by Huyghens, and since much studied by mathematicians. It is any curve supposed to be evolved or opened, by having a thread wrapped close upon it, fastened at one end, and beginning to evolve or unwind the thread from the other end, keeping the part evolved or wound off tight stretched; then this end of the thread will describe another curve, called the *involute*. Or the same involute is described the contrary way, by wrapping the thread upon the evolute, keeping it always stretched. For the INVOLUTION and EVOLUTION *of Curves*, see INVOLUTION in this Supplement.

Imperfect EVOLUTE, a name given by M. Reaumur to a new kind of evolute. The mathematicians had hitherto only considered the perpendiculars let fall from the involute on the convex side of the evolute: but if other lines not perpendicular be drawn upon the same points, provided they be all drawn under the same angle, the effect will still be the same; that is, the oblique lines will all intersect in the curve, and by their intersections form the infinitely small sides of a new curve, to to which they would be so many tangents. Such a curve is a kind of evolute, and has its radii; but it is an imperfect one, since the radii are not perpendicular to the first curve or involute.

EUPHON, a musical instrument invented lately by Dr Chladni of Wittenberg, well known by his various publications on philosophical subjects, especially the theory of musical sounds. The euphon consists of forty-two immoveable parallel cylinders of glass of equal length and thickness; but its construction, tone, and the method of playing it, are totally different from those of the harmonica, with which indeed it has nothing in common but the glass. See HARMONICA, *Encycl.*

Dr Chladni gives the following account of his invention. In his 19th year he began to learn to play the harpsichord; and he afterwards read a great many of the principal works on the theory of music, by which he found that the physico-mathematical part of that science was far more defective than other branches of natural philosophy. Being therefore possessed with an idea that his time could not be better employed than in endeavouring to make discoveries in this department, he accordingly tried various experiments on the vibrations of strings and the different kinds of vibration in cylindric pieces of wood, first discovered, through calculation, by the elder Euler; and found, that though a great deal had been said on the nature of these elastic bodies, yet the manner of vibration and the proportion of tones in other elastic bodies, which do not proceed, as in the former, in straight lines, but depend on the vibration of whole surfaces, were totally unknown, and that the little which had been written on that subject, by some authors, did not correspond with nature. He had already long remarked, that every plate of glass or metal emitted various tones according as it was held and struck in different places; and he was desirous to discover the cause of this difference, which no one had ever examined. He fixed in a vice the axle of a brass plate which belonged to a polishing machine, and found, that by drawing the bow of a violin over it, he produced very different tones, which were stronger and of longer duration than those obtained merely by striking it.

The observation, that not only strings but also other elastic bodies may be made to produce sounds by drawing a violin bow over them, Dr Chladni does not give as a discovery of his own; as the so called iron violin has been long known, and as he had read of an instrument constructed in Italy*, where glass or metal bells were made to sound by means of two or more violin bows drawn over them. But the idea of employing this instrument to examine vibrating tones was first entertained by himself. Having accurately remarked the tones produced by the abovementioned metal plate, he found that they gave a progression which corresponded with the squares of 2, 3, 4, &c.

* In all probability the *Harmonica* of the Abbé Mazzuchi.

Not long before he had read, in the Transactions of the Royal Society of Gottengen, the observations of Mr Lichtenberg on the phenomena produced by strewing pounded resin over a glass plate or cake of resin, and he repeated many of his experiments. This led him to the idea that, perhaps, the various vibratory movements of such a plate would be discovered by a diversity of phenomena, if he strewed over it sand or any thing of the like kind. By this experiment there was produced a star-formed figure; and the author, having continued his researches, published the result of them in a work entitled, Discoveries respecting the Theory of Sound, printed at Leipsic in 1787.

Whilst he was employed in these investigations, he resolved to invent a new musical instrument; and he began to consider whether it might not be possible by rubbing glass tubes in a straight line, with the wet fingers, to produce sounds in the same manner as is done in the harmonica by rubbing them circularly. That glass tubes, like those in his euphon, would not merely by such rubbing emit any tones, he had long known by theory and experience; and he therefore applied himself to the solution of the difficult question, in what manner the instrument ought to be constructed to answer the intended purpose? After various fruitless attempts for a year and a half, during which his imagination was so full of the idea, that sometimes in his dreams he thought he saw the instrument and heard its tones, that is, like those of the harmonica, but with more distinctness and less confusion, he at length, in a state between sleeping and waking, obtained a solution of the problem which had given so much employment to his thoughts. On the second of June 1789, being tired with walking, he sat down on a chair, about nine in the evening, to enjoy a short slumber; but scarcely had he closed his eyes when the image of an instrument, such as he wished for, seemed to present itself before him, and terrified him so much that he awoke as if he had been struck by an electric shock. He immediately started up in a kind of enthusiasm; and made a series of experiments, which convinced him that what he had seen was perfectly right, and that he had it now in his power to carry his design into execution. He made his experiments and constructed his first instrument in so private a manner that no person knew any thing of them. On the 8th of March 1790 his first instrument of this kind was completed; and in a few days he was able to play on it some easy pieces of music. It was now necessary to give to this instrument, as it was entirely new, a new name; and that of *euphon*, which signifies an instrument that has a pleasant sound, appeared to him the most proper.

It was not, however, brought to perfection at once, for he made a second instrument which was an improvement of the first, and a third which was an improvement of the second. In sound, indeed, and particularly in the higher tones, the first was equal to either of the other two; but the construction was deficient in strength, so that every week some hours were necessary to keep it in proper repair; and it was impossible to convey it the distance of a mile without almost totally destroying it. Dr Chladni also, for want of better tubes, employed those used for thermometers, and marked the whole and half tones by a coating of sealing-wax on the under side; but as the wax, owing to the moisture and vibration, often cracked and flew off, it was attended with danger to the eyes. It was therefore extremely difficult to give to the construction of the instrument sufficient strength; but this the inventor at length accomplished, so that his new euphon cannot be injured or put out of tune either by playing or by carriage. The third instrument was somewhat different from the first and second; as the fore part, which in the two former rose upwards with an oblique angle, stood at at right angles, so that it could be transported with ease in a particular carriage made for that purpose. Instead of the thermometer tubes used in the first, the Doctor now employs tubes of different colours. In the second instrument those for the whole tones were of dark green glass; but he used for the half tones, in both, a milk white kind of glass. In a word, the euphon has some resemblance to a small writing-desk. When opened, the abovementioned glass tubes, of the thickness of the barrel of a quill and about 16 inches long, are seen in a horizontal position. They are wetted with water, by means of a spunge, and stroked with the wet fingers in the direction of their length, so that the increase of the tone depends merely on the stronger or weaker pressure, and the slower or quicker movement of the fingers. The number of tubes at present is forty-two. In the back part there is a perpendicular sounding-board divided in the middle, through which the tubes pass. It appears therefore that the euphon ought not to be considered as an altered or improved harmonica, but as a totally new and different instrument. In regard to sweetness of sound, it approaches very near to the harmonica; but it has several advantages which no unprejudiced person, who examines both instruments, will deny.

1. It is simpler, both in regard to its construction and the movement necessary to produce the sound, as neither turning nor stamping is required, but merely the movement of the finger. 2. It produces its sound speedier; so that as soon as it is touched you may have the tone as full as the instrument is capable of giving it; whereas, in the harmonica, the tones, particularly the lower ones, must be made to increase gradually. 3. It has more distinctness in quick passages, because the tones do not resound so long as in the harmonica, where the sound of one low tone is often heard when you wish only to hear the following tone. 4. The unison is purer than is generally the case in the harmoniea, where it is difficult to have perfect glasses, which in every part give like tones with mathematical exactness. It is however as difficult to be tuned as the harmonica. 5. It does not affect the nerves of the performer; for a person scarcely feels a weak agitation in the fingers; whereas in the harmonica, particularly in concords of the lower notes, the agitation extends to the arms, and even through the whole body of the performer. 6. The expence of this instrument will be much less in future than that of the harmonica. 7. When one of the tubes breaks, or any other part is deranged, it can be soon repaired, and at very little expence; whereas, when one of the glasses of the harmonica breaks, it requires much time, and is very difficult to procure another capable of giving the same tone as the former, and which will correspond sufficiently with the series of the rest.

EUPHORBIA (See *Encycl.*). Of this plant three new species were discovered by Le Vaillant during his last travels into the interior parts of Africa. The first, which he calls the CUCUMBER-EUPHORBIA, adheres to the earth no otherwise than by a few slender roots. It rises to the height of nine or ten inches only; and exactly resembles a cucumber, of which it has the bent shape. It contains abundance of milky juice, which appeared to him as caustic as that of the great euphorbia. Its colour, which is a yellowish-green, tinted with a beautiful shade of violet towards the root, gives it a very attractive appearance: but woe betide the man who should be tempted to eat of it! as it is a virulent poison. The second, to which he gave the name of the MELON-RIBBED EUPHORBIA, does not rise more than three or four inches from the ground, to which it adheres by a collection of fibrous roots, issuing from several tubercles disposed in the manner of a crown. The stem forms a flatted globe excavated at the summit, and has ribs like the apple which in France is called *calville blanche*. These ribs are elevated, thick, and convex, have a greenish colour, and are marked with brown transversal bands. From the summit of the ribs issue several little tufts of pedunculate flowers. The third he called the CATERPILLAR-EUPHORBIA, because when he first found it, he thought he perceived on it several beautiful caterpillars. The description of it in a few words is as follows: From a very large tuberous root, which here and there throws out a few thready fibres, issue several stalks almost of the length of the finger: they creep along the ground, are twisted, woody, destitute of leaves, and furnished with several rows of round tubercles, each guarded by two prickles.

Plate XXVIII. fig. 1. — Fig. 2. — Fig. 3.

All these kinds of euphorbia are to be dreaded, the last two in particular; because being low and mixed with the herbage like mushrooms, animals, as they feed, run the risk of eating them with their pasture. Our author confirms the account which has been given in the *Encyclopædia* of the savages poisoning the reservoirs of water with this plant, in order to procure the game which shall drink of it. To effect the death of the animal, it is necessary that the poison reach the blood and mingle with it. Yet, unconceivable as it may be, the animal, though poisoned, is not the less wholesome food, as our author says he has experienced. However great may be the proportion of euphorbia thrown into a pond of water, he is persuaded that it never diffuses itself through the whole mass. It is his opinion, that the poison is a resinous juice, which, being from its nature incapable of combining with water, swims on the surface, and there forms a shining greenish oil, which with a little attention may be discerned by the naked eye when the surface is smooth. I tried (says he) the qualities of this oil on myself, taking with a straw, from the surface of the basin, a single drop, which I put upon my tongue; and it gave me that kind of burning pain which a caustic occasions. I then took up some water from the reservoir in the hollow of my hand, and blowing off the oily fluid which swam on the surface, I dipped the end of my tongue into the remainder, but could not perceive in it the slightest taste different from that of water itself. He seems to think that milk is an antidote to the poison of euphorbia; because he squeezed some of the juice into a bason of milk and gave it to an ape, which swallowed part of it without the least injury. He confesses, however, that the dose was trifling.

EUSTYLE, is the best manner of placing columns, with regard to their distance; which, according to Vitruvius, should be four modules, or two diameters and a quarter.

EXCENTRIC, or EXCENTRIC CIRCLE, in the ancient Ptolomaic astronomy, was the very orbit of the planet itself, which it was supposed to describe about the earth, and which was conceived excentric with it; called also the deferent.

Instead of these excentric circles round the earth, the moderns make the planets describe elliptic orbits about the sun; which accounts for all the irregularities of their motions, and their various distances from the earth, &c. more justly and naturally.

EXCENTRIC, or *Excentric Circle*, in the new astronomy, is the circle described from the centre of the orbit of a planet, with half the greatest axis as a radius; or it is the circle that circumscribes the elliptic orbit of the planet.

EXCHANGE. See *Encycl.* under that word, and likewise under *BILLS of Exchange*, where the antiquity of such bills, especially among the Chinese, is mentioned. In Professor Beckmann's History of Inventions the reader will find an ordinance of the year 1394 concerning the acceptance of bills of exchange, and also copies of two bills of the year 1404, which sufficiently prove that the method of transacting business by bills of exchange was fully established in Europe so early as the fourteenth century; and that the present form and terms were even then used. The ordinance, which was issued by the city of Barcelona, decreed that bills of exchange should be accepted within twenty-four hours after they were presented, and that the acceptance should be written on the back of the bill.

But there are questions relating to bills of exchange of much greater importance than their antiquity; and these questions are not yet decided. For instance, Ought a bill of exchange to be considered by the law merely as a *deposit* belonging to the drawer, and successively confided to the remittees? or should it be considered as transferable *property*, at all times absolutely vested in the holder, whose neglect therefore, when it vitiates the value, falls wholly on himself?

In a work published 1798 by Professor Busch of Hamburgh, entitled, *Additions to the Theoretical and Practical Delineation of Commerce* (A), the reader will find some arguments, which, to say the least of them, are certainly plausible, to prove that bills of exchange ought to be at all times considered as the absolute property of the holder. This theory is then applied to the difficult and still unsettled case of the holder of a bill having many indorsements, where the drawer, drawee, and early indorsers, have all failed. It is evident that, if the holder proves under each bankruptcy the whole amount of the bill, he will receive much more than his due. May he make his election where to prove the whole demand, and where to prove the residue? or ought he not (which seems most equitable) to be compelled to prove his debt against his immediate predecessor only?—the assignees of that predecessor proving in their turn, in like manner (each party once only), back to the drawer. This is a case of great importance to discounters, and the reader will find some judicious observations on it in the Professor's work.

EXEGESIS, or EXEGETICA, in algebra, is the finding, either in numbers or lines, the roots of the equation of a problem, according as the problem is either numeral or geometrical.

EXPECTATION OF LIFE, in the doctrine of life annuities, is the share, or number of years of life, which a person of a given age may, upon an equality of chance, expect to enjoy.

By the expectation or share of life, says Mr Simpson (*Select Exercises*, p. 273), is not here to be understood that particular period which a person hath an equal chance of surviving; this last being a different and more simple consideration. The expectation of a life, to put it in the most familiar light, may be taken as the number of years at which the purchase of an annuity, granted upon it, without discount of money, ought to be valued. Which number of years will differ more or less from the period abovementioned, according to the different degrees of mortality to which the several stages of life are incident. Thus it is much more than an equal chance, according to the table of the probability of the duration of life which the same author has given us, that an infant, just come into the world, arrives not to the age of ten years; yet the expectation or share of life due to it, upon an average, is near twenty years. The reason of which wide difference is the great excess of the probability of mortality in the first tender years of life, above that respecting the more mature and stronger ages. Indeed if the numbers that die at every age were to be the same, the two quantities above specified would also be equal; but when the said numbers become continually less and less, the expectation must of consequence be the greater of the two.

EXPONENTIAL CALCULUS, the method of differencing, or finding the fluxions of exponential quantities, and of summing up those differences, or finding their fluents.

EXPONENTIAL *Curve*, is that whose nature is defined or expressed by an exponential equation; as the curve denoted by $a^x = y$, or by $x^x = y$.

EXPONENTIAL *Equation*, is one in which is contained an exponential quantity: as the equation $a^x = b$, or $x^x = ab$, &c.

EXPONENTIAL *Quantity*, is that whose power is a variable quantity; as the expression a^x, or x^x. Exponential quantities are of several degrees and orders according to the number of exponents or powers, one over another.

EXTRA-CONSTELLARY STARS, such as are not properly included in any constellation.

EXTRA-Mundane Space, is the infinite, empty, void space, which is by some supposed to be extended beyond the bounds of the universe, and consequently in which there is really nothing at all. The phrase *extramundane space* has been so long in use among our best writers, that it is now impossible to banish it from the language; and yet it has been the source of some extravagant mistakes. Many philosophers consider space as something *real*, distinct both from body and mind; and no less a man than Dr Clarke considered it as an attribute of the Deity. Yet we think nothing more evident, than that if body had never existed, space would never have been thought of; and if this be so, extramundane space, instead of denoting any *real* thing, or attribute infinitely extended, can mean nothing more than the *possibility* of enlarging the corporeal universe, however widely extended it may be. See METAPHYSICS, *Encycl.* Part II. ch. iv.

(A) Professor Busch published in 1792 a work entitled *A Theoretical and Practical Delineation of Commerce.*

Extrados, Extremes.

EXTRADOS, the outside of an arch of a bridge, vault, &c. See ARCH in this *Supplement*.

EXTREMES CONJUNCT, and *Extremes Disjunct*, in spherical trigonometry, are, the former the two circular parts that lie next the assumed middle part; and the latter are the two that lie remote from the middle part. These were terms applied by Lord Napier in his universal theorem for resolving all right-angled and quadrantal spherical triangles, and published in his *Logarithmorum Canonis Descriptio*, ann. 1614. In this theorem, Napier condenses into one rule, in two parts, the rules for all the cases of right angled spherical triangles, which had been separately demonstrated by Pitiscus, Lansbergius, Copernicus, Regiomontanus, and others. In this theorem, neglecting the right angle, Napier calls the other five parts circular parts, which are, the two legs about the right angle, and the complements of the other three, viz. of the hypothenuse, and the two oblique angles. Then taking any three of these five parts, one of them will be in the middle between the other two, and these two are the extremes conjunct when they are immediately adjacent to that middle part, or they are the extremes disjunct when they are each separated from the middle one by another part.

F.

Face, Falconry.

FACE or FAÇADE, in architecture, is sometimes used for the front or outward part of a building, which immediately presents itself to the eye; or the side where the chief entrance is, or next the street, &c.

FALCONRY, is a species of sport, about the antiquity of which there has been some dispute. Under the word HAWKING, *Encycl.* we have deduced what we thought sufficient evidence of its being practised among the Thracians, and likewise among the Britons before the invasion of this island by the Romans. Flavius Blondus, however, and Laurentius Valla, both writers of the 15th century, and the latter, one of the most learned men of his time, affirm that no nation or people were accustomed to catch either land or water fowls with any rapacious bird trained for the purpose.

We were pleased to see our own opinion, so different from this, completely established by the learned labours of Professor Beckmann. So early (says he) as the time of Ctesias (and he refers to the page and edition of his author) hares and foxes were hunted in India by means of rapacious birds. The account of Aristotle *, however, is still more to the purpose, and more worthy of notice. "In Thrace (says he) the men go out to catch birds with hawks. The men beat the reeds and bushes which grow in marshy places, in order to raise the small birds, which the hawks pursue and drive to the ground, where the fowlers kill them with poles." The same account is to be found in another book ascribed also to Aristotle; and which appears, at any rate, to be the work of an author not much younger. Respecting Thrace, which is situated above Amphipolis, a wonderful thing is told, which might appear incredible to those who had never heard it before. It is said that boys go out into the fields, and pursue birds by the assistance of hawks. When they have found a place convenient for their purpose, they call the hawks by their names, which immediately appear as soon as they hear their voices, and chase the birds into the bushes, where the boys knock them down with sticks and seize them. What is still more wonderful, when these hawks lay hold of any birds themselves, they throw them to the fowlers; but the boys, in return, give them some share of the prey. *De mirabilibus auscultat.* cap. 128.

* *Hist Animal*, lib. ix. cap. 6.

In this passage, there are two additions which render the circumstance still more remarkable. The first is, that the falcons appeared when called by their names; and the second, that of their own accord they brought to the fowlers whatever they caught themselves. Nothing is here wanting but the spaniel employed to find out game, the hood which is put upon the head of the hawk while it stands on the hand, and the thong used for holding it, to form a short description of falconry as still practised. Our falconers, when they have taken the bird from the hawk, give him, in return, a small share of it; and in the like manner the Thracian hawks receive some part of their booty.

Other writers after Aristotle, such as Antigonus, Ælian, Pliny, and Phile, have also given an account of this method of fowling. Ælian, who seldom relates any thing without some alteration or addition, says, that in Thrace nets were used, into which the birds were driven by the hawks; and in this he is followed by the poet Phile. Ælian, also, in another place describes a manner of hunting with hawks in India, which, as we are told by several travellers, is still practised in Persia, where it is well understood, and by other eastern nations.

The Indians (says he) hunt hares and foxes in the following manner: They do not employ dogs, but eagles, crows, and, above all, kites, which they catch when young, and train for that purpose. They let loose a tame hare or fox, with a piece of flesh fastened to it, and suffer these birds to fly after it, in order to seize the flesh, which they are fond of, and which, on their return, they receive as the reward of their labour. When thus instructed to pursue their prey, they are sent after wild foxes and hares in the mountains; these they follow in hopes of obtaining their usual food, and soon catch them and bring them back to their masters, as we are informed by Ctesias. Instead of the flesh, however, which was fastened to the tame animals, they receive as food the entrails of the wild ones which they have caught.

It seems, therefore, that the Greeks received from India

Falk

dia and Thrace the firſt information reſpecting the method of fowling with birds of prey; but it does not appear that this practice was introduced among them at a very early period. In Italy, however, it muſt have been very common, for Martial and Apuleius ſpeak of it as a thing every where known: the former calls a hawk the fowler's ſervant.

The Profeſſor traces the hiſtory of this art with great learning down to the preſent time. It was carried to the higheſt perfection at the principal courts of Europe (he ſays) in the 12th century, when the ladies kept hawks, which were as much fondled by thoſe who wiſhed to gain their ſavour as lap dogs are at preſent. Among the oldeſt writers on falconry, as an art, he reckons Demetrius, who about the year 1270 was phyſician to the Emperor Michael Paleologus. His book, written in Greek, was firſt printed at Paris in 1612 with a Latin tranſlation; but its precepts (ſays our author) would be thought of very little value at preſent. For an account of the modern art of FALCONRY, ſee *Encyclopædia*.

FALK (John Peter), known to the world as one of the ſcientific travellers employed by the late Empreſs of Ruſſia to explore her vaſt dominions, was born in Weſtrogothia, a province in Sweden, about the year 1727. He ſtudied medicine in the univerſity of Upſal, and went through a courſe of botany under the celebrated Linnæus, to whoſe ſon he was tutor. He publicly defended the diſſertation (A) which that famous botaniſt had compoſed on a new ſpecies of plants, which he called *aſtromeria*.

In the year 1760, he was ſo deeply affected with depreſſion of ſpirits, that M. de Linné, in the view of obliging him to take exerciſe and diſſipation, ſent him to travel over the iſland of Gothland, to make a collection of the plants it produces, and the various kinds of corals and corallines which the ſea leaves on its ſhores. This voyage was attended with no diminution of his diſtemper, which found a continual ſupply of aliment in a ſanguine melancholy temperament, in a too ſedentary way of life, and in the bad ſtate of his finances.

Profeſſor Forſkael having left Upſal for Copenhagen in 1760, Falk followed him thither, in the deſign of applying, by the advice of M. de Linné, to be appointed aſſiſtant to M. Forſkael in his famous journey thro' Arabia; but notwithſtanding all the pains that M. Œder, and ſeveral other men of literary reputation at Copenhagen, took in his behalf, his application failed, as the ſociety that were to go on that important expedition was already formed. Obliged, with much diſcontent, to return, he herboriſed as he travelled, and enriched the Flora Suecica with ſeveral new diſcoveries.

A man in office at St Peterſburgh having written to M. Linné to ſend him a director for his cabinet of natural hiſtory, M. Falk accepted the poſt, which led him to the chair of profeſſor of botany at the apothecaries garden at St Peterſburgh, a place that had been long vacant. His hypochondriac complaint ſtill continued to torment him. When the Imperial Academy of Sciences was preparing in 1768 the plan of its learned expeditions, it took M. Falk into its ſervice, though his health was uncertain. He was recalled in 1771; but having got only to Kaſan in 1773, he there obtained permiſſion to go and uſe the baths of Kiſliar, from which he returned again to Kaſan at the end of the year, with his health apparently better.

Falk.

But his diſeaſe ſoon returned with redoubled violence. From the month of December 1773 he had never quitted his bed, nor taken any other nouriſhment than bread dried in the Swediſh manner (knækebrœd), of which he ſcarcely took once a day ſome mouthfuls dipped in tea. At firſt he received the viſits of a few friends; but afterwards denied himſelf to them, and was reduced to the ſtricteſt ſolitude. When M. Georgi, member of the ſociety of natural hiſtory at Berlin, who had been deſtined to aſſiſt and relieve the profeſſor in the duties of his expedition, went to ſee him on this occaſion, nothing ſeemed left of him but a ſkeleton of a wild and terrifying aſpect. The few words he drew from him conſiſted in complaints, occaſioned by a hoſt of diſeaſes which kept his body in torture, and threw him into the moſt cruel ſleepleſſneſs. The laſt evening M. Georgi kept him company till midnight. He ſpoke little, and ſaid nothing that could give reaſon to ſuſpect the deſign he was meditating. His hunter, and at the ſame time his truſty ſervant, offered to ſit up with him the night; but he could not be perſuaded to conſent.

M. Georgi being requeſted the next day, March 31, to come to the lodging of the unfortunate gentleman, he found him lying before his bed, covered with blood; beſide him lay a razor, with which he had given himſelf a ſlight wound in the throat, the fatal piſtol, and a powder-horn; all together preſenting a tremendous ſpectacle. He had put the muzzle of the piſtol againſt his throat, and, reſting the pommel upon his bed, he diſcharged the contents in ſuch a manner, that the ball, having gone through his head, had ſtuck in the cieling. His ſoldier had ſeen him ſtill ſitting up in his bed at four o'clock, at which time he uſually fell into a ſhort ſlumber. In his chamber was found a note written the evening before, betraying throughout the diſtracted ſtate of his mind, but nothing declaratory of his deſign, or that was of any importance.

M. Falk, like all hypochondriac perſons, was not very communicative, and on certain occaſions was diſtruſtful. But, at the ſame time, he was of a ſedate temper, complaiſant, and upright, which made it a very eaſy matter to bear with him, and ſecure to him the indulgence of all his acquaintance. His extreme ſobriety had enabled him to make ſome ſavings from his pay, though he was very beneficent; it was not, therefore, indigence that drove him to this act of violence. He was of a cold conſtitution, preferring ſolitude and quiet to ſociety, to the company of his friends, and to ordinary amuſements, which yet he did not ſhun, except in the latter period of his life. As to religion, he ſhewed on all occaſions more reſpect for it than any ſtrong effuſions of zeal. It was ſolely to be aſcribed to the violence of his diſtemper, and the weakneſs of mind which it brought on, that led him to put a period to his days. The fate of this unfortunate ſcholar was generally and juſtly lamented.

His papers were found in the greateſt diſorder. They contain,

(A) In the collection known under the title of *Linnæi Amænitates Academicæ*.

Farmer.

contain, however, very uſeful and important relations. He particularly made it his buſineſs to inquire about the Kirguiſes, and other Tartarian nations; and as he frequently remained for the ſpace of nine months together in the ſame place, he was enabled to procure ſatisfactory notions concerning the objects of his inveſtigations. The Imperial Academy, in 1774, appointed Profeſſor Laxmann to arrange his manuſcripts in order for publication; which was done accordingly.

FARMER (Richard, D. D.), ſo well known as one of the commentators on Shakeſpeare, was a man of ſuch pleaſing, though ſingular manners, that we regret the very imperfect account which we muſt give of his life. One of us, who had the pleaſure of being a little known to him, has been ſo much delighted with the natural eaſe and pleaſantry of his converſation, that we made all the inquiries which we judged requiſite to enable us to draw up ſuch a biographical ſketch of this agreeable man as might be acceptable to our readers, and not unworthy of his character; but theſe inquiries were made in vain. Thoſe to whom we applied knew little more of the incidents of his life than what we had previouſly found in a miſcellany, of which the writers ſeem to conſider it as a principle of duty to vilify the character of every perſon who, like Dr Farmer, is the friend of order, and the enemy of ſudden or rapid innovations. To that miſcellany, therefore, we muſt be beholden for many facts; but we ſhall certainly copy none of its malevolence.

Dr Farmer was born at Leiceſter 1735; but what was the ſtation of his father we have not learned. Of his ſchool education he received part, perhaps the whole, in his native town; and from ſchool he was removed to the univerſity of Cambridge, where he devoted himſelf chiefly to claſſical learning and the belles lettres. In 1757 he was admitted to the degree of bachelor of arts; in 1760 to that of maſter of arts; a bachelor of divinity in 1767, and a doctor of divinity in 1775; in which year he was alſo elected maſter of Emanuel on the deceaſe of Dr Richardſon, and principal librarian on the deceaſe of Dr Barnardiſton.

The diſturbances in America having by this time become ſerious, the univerſity of Cambridge, with numberleſs other loyal bodies, voted an addreſs to the king, approving of the meaſures adopted by government to reduce the factious coloniſts to their duty. The addreſs, however, was not carried unanimouſly. It was, of courſe, oppoſed by Jebb, ſo well known for his free opinions in politics and religion, and by ſome others, of whom one man, a member of the caput, carried his oppoſition ſo far, as actually to refuſe the key of the place which contained the ſeal neceſſary on ſuch occaſions. In this emergency, Dr Farmer, who was then vice-chancellor, is ſaid to have forced open the door with a ſledge-hammer; an exploit which his democratical biographers affect to ridicule, by calling it *his courtly zeal*, and the occaſion of all his ſubſequent preferments.

If it be indeed true that he broke the door in pieces with his own hands, his conduct muſt be acknowledged to have been not very decorous; but if the office which he filled be taken into conſideration, we apprehend it would be as difficult to prove that conduct eſſentially wrong, as to vindicate the obſtinate arrogance of him who occaſioned it. The ſeal was the property of the univerſity, of which this outrageous ſupporter of the bill of rights was but an individual member. The univerſity had reſolved that it ſhould be employed for a certain purpoſe, which it was the duty of the vice chancellor to carry into effect; and ſince the ſeal was refuſed to him, he had no alternative but to get poſſeſſion of it by force. We hope, however, that he employed a ſervant to break the door; and, indeed, as vice-chancellor, he muſt have had ſo many ſervants at his command, that it is not conceivable he would wield the ſledge hammer himſelf.

Some time after this he was made a prebendary of Canterbury, we believe through the recommendation of Lord North, then premier; and it was at Canterbury that the writer of this ſketch had the happineſs of being introduced to him, and witneſſing his hoſpitality. After enjoying his prebend for ſeveral years, he reſigned it on being preferred, by the preſent premier, to a reſidentiaryſhip of St Paul's; and we have reaſon to believe that he declined a biſhopric, which was offered to him as a reward for the conſtitutional principles which he was at pains to propagate, not only in his college, but, as far as his influence went, through the whole univerſity.

It has been ſaid that the delights of the pipe and the bottle in Emanuel parlour outweighed, in his eſtimation, the dazzling ſplendor of the mitre; but he had other and better reaſons for preferring a private to a public ſtation. In early life, at leaſt before he was advanced in years, he had felt the power of love, and had ſuffered ſuch a diſappointment as ſunk deep in his mind, and for a time threatened his underſtanding. From that period, though he retained his faculties entire, he acquired ſome peculiarities of manner, of which he was ſo far conſcious as to be ſenſible that they would hardly become the character of a biſhop: being likewiſe ſtrongly attached to dramatic entertainments, which, if we miſtake not, the Engliſh biſhops never witneſs, and delighting in clubs, where he could have rational converſation without ſtate or ceremony of any kind—he very wiſely preferred his reſidentiaryſhip to the higheſt dignity in the church. At the time of his death, which happened in the autum of 1797, he was a fellow of the Royal and Antiquarian Societies, maſter of Emanuel college, principal librarian of the public library in the univerſity, one of the canons reſidentiary of St Paul's, chancellor of the dioceſe of Lichfield and Coventry, and prebendary of Worceſter.

Though a good claſſical ſcholar, Dr Farmer has been celebrated only for that kind of literature which is connected with the Engliſh drama; and having a ſtrong predilection for old Engliſh writers, he ranked high among the commentators upon Shakeſpeare. His 'Eſſay upon the Learning of Shakeſpeare,' dedicated to Mr Cradock, the intelligent reſident of Gumley-Hall in Leiceſterſhire, has paſſed through ſeveral editions. This eſſay was, in fact, the firſt foundation of his fame, which an unconquerable indolence prevented him from carrying to that height to which the exerciſe of his literary talents could not have failed to raiſe it. So great indeed was his love of eaſe, that after having announced for ſubſcriptions a hiſtory of Leiceſterſhire, and actually begun to print it, rather than ſubmit to the fatigue of carrying it through the preſs, he returned the ſubſcriptions, and preſented the MSS. and plates to Mr Nichols, Farmer.

Nichols, the respectable printer of the Gentleman's Magazine, who has since carried on the history with a degree of spirit, ability, and industry, perhaps unprecedented in this department of literature.

Indolence and the love of ease were indeed the Doctor's chief characteristics; and to them, with the disappointment already mentioned, may be attributed a want of propriety in his external appearance, and in the usual forms of behaviour belonging to his station. The prevailing features of his character distinguished themselves by several oddities: There were three things, it was said, which the master of Emanuel loved, *viz.* old port, old clothes, and old books; and three things which no one could persuade him to perform, *viz.* to rise in the morning, to go to bed at night, and to settle an account. When in Cambridge, if an old house were pulled down, the master of Emanuel was always there in an old blue great coat, and a rusty hat. When in London, he was sure to be found in the same garb at an old book-stall, or standing at the corner of a dirty lane, poring through his glass at an old play-bill.

This character is not drawn by a friendly pencil; but it is nevertheless not unjust. His inattention to the common decencies of dress and behaviour was notorious, insomuch that, in the company of strangers, the eccentricity of his appearance and of his manners made him sometimes be taken for a person half crazed. The writer of this sketch saw him one morning at Canterbury dressed in stockings of unbleached thread, brown breeches, and a wig not worth a shilling; and when a brother prebendary of his, remarkable for elegance of manners, and propriety of dress, put him in mind that they were to attend on the archbishop, Dr Farmer replied, that it had totally escaped him; but he went home, and dressed himself like a clergyman. That he sat late reading, and occasionally drinking brandy and water, cannot be denied; and it is literally true, that he could not easily be prevailed upon to settle his accounts. His accounts with some of his pupils, when tutor of his college, were never settled to the day of his death; and the young gentlemen not unfrequently took advantage of this unconquerable indolence to borrow of him considerable sums, well knowing that there was little chance of a demand being ever made upon their parents. One gentleman, in particular, told a friend of ours, who was himself a pensioner of Emanuel, that when he left that college, he was near fifty pounds in debt to Dr Farmer; "a debt (said he) which I would have scrupulously paid, but, after repeated solicitations, I could get no bill from him."

Having been a warm partizan of government during the American war, it will readily be believed that Dr Farmer was the determined enemy of levellers and anarchists. He was such a whig as those who placed King William on the throne; and of course deemed a violent tory by our present republicans, of whom, to say the truth, he could hardly speak with temper. By his enemies he is admitted to have been a man of generosity. As he obtained money easily, so he parted with it easily. Whilst he was always ready to relieve distress, his bounty was frequently bestowed on the patronage of learned men and learned publications. He was, accordingly, a favourite with all good men who knew him. In his own college he was adored; in the university he had, for many years, more influence than any other individual; and, with all his eccentricities, his death was a loss to that learned body, which, in the opinion of some of its members, will not soon be made up.

A short time before his death, his character was thus justly and ably drawn by the celebrated Dr Parr:

"Of any undue partiality towards the master of Emanuel College, I shall not be suspected by those persons who know how little his sentiments accord with mine, upon some ecclesiastical, and many political matters. From rooted principle and ancient habit he is a tory; I am a whig; and we have both of us too much confidence in each other, and too much respect for ourselves, to dissemble what we think, upon any grounds, or to any extent. Let me then do him the justice which, I am sure, that he will ever be ready to do to me. His knowledge is various, extensive, and recondite. With much seeming negligence, and perhaps, in later years, some real relaxation, he understands more, and remembers more, about common and uncommon subjects of literature, than many of those who would be thought to read all the day and meditate half the night. In quickness of apprehension, and acuteness of discrimination, I have not often seen his equal. Through many a convivial hour have I been charmed by his vivacity: and upon his genius I have reflected, in many a serious moment, with pleasure, with admiration, but not without regret that he has never concentrated and exerted all the great powers of his mind in some great work, upon some great subject. Of his liberality in patronising learned men I could point out numerous instances. Without the smallest propensities to avarice, he possesses a large income; and, without the mean submission of dependence, he is risen to a high station. His ambition, if he has any, is without insolence; his munificence is without ostentation; his wit is without acrimony; and his learning without pedantry."

Fascination.

FASCINATION, the art of bewitching, enchantment, an unseen inexplicable influence. Under the title SERPENS (*Encycl.* n° 22.) we have mentioned several instances of the fascinating power of the rattle-snake, which were related by men of character, and certainly gained some degree of credit among men of science. In Vaillant's New Travels into the Interior Parts of Africa, an account is given of similar instances of fascination by African servants, some of them witnessed by himself, and others reported to him by men of veracity.

On the confines of the European colony, at a place called *Swart-land*, our traveller saw a shrike on the branch of a tree, tremble as if in convulsions, whilst it uttered the most piercing cries of distress. Closer attention led him to discover upon the next branch of the same tree a large serpent, that, with stretched-out neck, and fiery eyes, though perfectly still, was gazing on the poor animal. He shot the serpent; but, in the mean time, the bird had died. Having measured the distance between the place where the shrike was seen in convulsions and that occupied by the serpent when it was shot, he found it to be three feet and a half; which convinced him and his attendants that the bird had not died either from the bite or the poison of its enemy. Indeed he stripped it before the whole company, and made them observe that it was untouched, and had not received the slightest wound.—In another district of Africa, during the course of the same travels, he saw

Fascination

saw a small mouse die in convulsions, occasioned by the fascinating power of a serpent, at the distance of two yards from it; and when he consulted his Hottentots upon this incident, they expressed, he says, no sort of astonishment, but assured him that the serpent had the faculty of attracting and fascinating such animals as it wished to devour.

We have already had occasion to remark how regardless this author is of inconsistencies in his narrative; and we perceive something like an inconsistency in the narratives before us. Though his Hottentots expressed no surprise at the fascination of the mouse, and declared that nothing was more common, he says expressly, that to those who witnessed the fascination of the shrike, the fact appeared so extraordinary, that they could hardly believe it, even after they had seen it.

The most wonderful instance of fascination which we have anywhere met with, was that of a Captain in the Dutch service at the Cape, who, after assuring our traveller that it is an event which happens very frequently, proceeded thus: "My testimony ought to have the more weight, as I had once nearly become myself a victim to this fascination. While in garrison at Ceylon, and amusing myself, like you, in hunting in a marsh, I was, in the course of my sport, suddenly seized with a convulsive and involuntary trembling, different from any thing I had ever experienced, and at the same time was strongly attracted, and in spite of myself, to a particular spot of the marsh. Directing my eyes to this spot, I beheld, with feelings of horror, a serpent of an enormous size, whose look instantly pierced me. Having, however, not yet lost all power of motion, I embraced the opportunity before it was too late, and saluted the reptile with the contents of my fusee. The report was a talisman that broke the charm. All at once, as if by a miracle, my convulsion ceased; I felt myself able to fly; and the only inconvenience of this extraordinary adventure was a cold sweat, which was doubtless the effect of my fear, and of the violent agitation my senses had undergone."

This instance of fascination differs in one very material circumstance from the two somewhat similar instances mentioned in the *Encyclopædia*. In both these, the eyes of the persons fascinated were fixed on the eyes of the snake; but here the Dutch Captain was strongly attracted towards the serpent before he saw, or even suspected, that so formidable an enemy was in his neighbourhood. If the story therefore be true, the effect which he describes could not possibly have been the effect of fear, but of some unseen influence on his whole nervous system.

The subject has of late attracted the attention of men of science, whose local situation gives them an opportunity of making experiments upon different serpents, with a view to ascertain whether they really possess or not this most unaccountable of all powers. In the year 1796 was printed at Philadelphia, *a Memoir concerning the Fascinating Faculty which has been ascribed to the Rattle-snake, and other American Serpents*, by Benjamin Smith Barton, M. D. Professor of natural history and botany in the university of Pennsylvania. In this memoir, the manner in which the fascinating power is supposed to be exerted is thus stated by the ingenious professor:

"The snake, whatever its species may be, lying at the bottom of the tree or bush upon which the bird or squirrel sits, fixes its eyes upon the animal it designs to fascinate or enchant. No sooner is this done, than the unhappy animal is unable to make its escape. It now begins to utter a most piteous cry, which is well known by those who hear it, and understand the whole machinery of the business, to be the cry of a creature enchanted. If it is a squirrel, it runs up the tree for a short distance, comes down again, then runs up, and, lastly, comes lower down. 'On that occasion (says an honest, but rather credulous writer*), it has been observed, that the squirrel always goes down more than it goes up.' The snake still continues at the root of the tree, with its eyes fixed on the squirrel, with which its attention is so entirely taken up, that a person accidentally approaching, may make a considerable noise without the snake's so much as turning about. The squirrel, as before mentioned, comes always lower, and at last leaps down to the snake, whose mouth is already wide open for its reception. The poor little animal then, with a piteous cry, runs into the snake's jaws, and is swallowed at once, if it be not too big; but if its size will not allow it to be swallowed at once, the snake licks it several times with its tongue, and smoothens it, and by that means makes it fit for swallowing."

* *Professor Peter Kalm.*

From Dr Barton's memoir, it appears that the North American Indians are by no means of one opinion respecting the fascinating power of the rattle-snake. Some intelligent friends of his, well acquainted with the manners, religious opinions, and superstitious prejudices of those people, informed him, that though they had often heard the Indians speak of the ingenuity of these reptiles in catching birds, squirrels, &c. they did not recollect having ever heard them say that snakes *charm* birds. On the other hand, however, a Mohegan Indian told the Doctor himself, that the Indians are of opinion, that the rattle-snake can charm, or betwitch, squirrels and birds, and that it does this with its rattle, which it shakes, thereby inviting the animals to descend from the trees, after which they are easily caught. According to this Indian, his countrymen do not think that the snake, in any manner, accomplishes the business with its eyes. A Choktah Indian assured the Doctor, that the rattle snake does charm birds, &c.; but he was honest enough to confess, that he did not know in what manner it does it. The interpreter, through whom the conversation was carried on with this Indian, said that the snake charms by means of its rattle.

This opinion of the interpreter was the opinion of Dr Mead. That eminent naturalist, controverting, about fifty years ago, the common opinion, that Providence has furnished the rattle-snake with its rattle to give warning to travellers, was the first who asserted that this singular appendage is given to the animal to terrify squirrels and small birds, which are then so stupified by the sight of so formidable an enemy, that at length they drop down, and become its prey; and that this is what the Indians call *fascination*. The same opinion has been adopted by professor Blumenbach of Gottingen, who, in his Manual of Natural History, thus expresses himself on this curious subject:

"That squirrels, small birds, &c. fall down spontaneously from trees into the mouth of the rattle-snake, lying

lying below them, is an undisputed fact; and is the less surprising, as the like phenomena have been remarked in regard to other snakes, and also toads, hawks, and cats; all of which, in certain circumstances, as appears, have the power of drawing towards them small animals, merely by fixing their eyes stedfastly on them. In regard to the rattle-snake, this effect is produced by the rattle in its tail, the hissing noise of which makes squirrels, &c. whether through curiosity, mistake, or terror, seem to approach the animal as it were spontaneously. At any rate, I know, from the information of intelligent eye-witnesses, that it is a common stratagem of the young savages in America to conceal themselves in the bushes, where they imitate the hissing noise of the rattle-snake, and by these means attract squirrels, which they are then enabled to catch."

To this opinion Dr Barton opposes an insuperable objection. It is, that this fascinating power is by no means peculiar to the rattle-snake. With regard to the stratagem of the savages, he thinks that Dr Blumenbach has been imposed upon; as neither he, nor any other person of whom he made the inquiry, ever heard of such a stratagem. The young Indians, he says, place a reed cross-wise in their mouth, and by a tremulous motion of the lips, imitate the cry of young birds; by which means they entice the old ones, so that they can easily shoot them: And this practice may have given rise to the story of their imitating the hissing noise of the rattle-snake.

Some have supposed that serpents, under certain circumstances, emit from their bodies a stupifying vapour; and that it is this vapour which produces the effect called *fascination:* But against this opinion Dr Barton alleges the following arguments: "I know, indeed (says he), that in some of the larger species of serpents, inhabiting South America and other countries, there is evolved in the stomach, during the long and tedious process of digestion in these animals, a vapour or a gas, whose odour is intensely fetid. I have not, however, found that this is the case with the rattle-snake, and other North American serpents, that I have examined. But my own observations on this head have not been very minute. I have made inquiry of some persons (whose prejudices against the serpent tribe are not so powerful as my own), who are not afraid to put the heads and necks of the black snake, and other serpents that are destitute of venemous fangs, into their mouths, and have been informed, that they never perceived any disagreeable smell to proceed from the breath of these animals. I have been present at the opening of a box which contained a number of living serpents; and although the box had been so close as to admit but a very small quantity of fresh air, although the observation was made in a small warm room, I did not perceive any peculiarly disagreeable effluvium to arise from the bodies of these animals. I am, moreover, informed by a member of this society *, who has, for a considerable time, had a rattle-snake under his immediate care, that he has not observed that any disagreeable vapour proceeds from this reptile. On the other hand, however, it is asserted by some creditable persons of my acquaintance, that a most offensive odour, similar to that of flesh in the last stage of putrefaction, is continually emanating from every part of the rattle-snake, and some other species of serpents. This odour extends, under certain circumstances, to a considerable distance from the body of the animal. Mr William Bartram assures me, that he has observed 'horses to be sensible of, and greatly agitated by it, at the distance of forty or fifty yards from the snake. They shewed (he says) their abhorrence by snorting, winnowing, and starting from the road, endeavouring to throw their riders, in order to make their escape." This fact, related by a man of rigid veracity, is extremely curious; and, in an especial manner, deserves the attention of those writers who imagine that this fetid emanation from serpents is capable of affecting birds, at small distances, with a kind of asphyxy. It even gives *some* colour of probability to the story related by Metrodorus, and preserved in the Natural History of Pliny *."

* *American Philosophical Society.*

* *Lib.* 28. *Cap.* 14.

Some experiments, however, which were made in Philadelphia a little before the Doctor composed his memoir, seem to have been decisive not only as to the fetor, but as to every thing which resembles fascination in the rattle-snake. Birds which were put into a cage which contained a rattle-snake, flew or ran *from* the reptile, as though they were sensible of the danger to which they were exposed. The snake made many attempts to catch the birds, but could seldom succeed. When a dead bird was thrown into the cage, the snake devoured it immediately. He soon caught and devoured a living mole, an animal much more sluggish than the bird. Dr Barton himself saw a snow-bird (see EMBERIZE, *Encycl.*) in a cage with a large rattle-snake. The little animal had been thus imprisoned for several hours when he first saw it, but it exhibited no signs of fear. It hopped about from the floor of the cage to its roost, and frequently perched on the snake's back. Its chirp was nowise tremulous, but perfectly natural. It ate the seeds which were put into the cage; and by its whole actions most evidently demonstrated that its situation was not uneasy.

Having thus disposed of the doctrines of some of his predecessors, Dr Barton proceeds to say: "The result of not a little attention to the subject has taught me, that there is but one wonder in the business;—the wonder that the story should ever have been believed by a man of understanding and of observation." Fascination, we are informed, is almost entirely limited to birds that build low, and "in almost every instance, I found that the supposed fascinating faculty of the serpent was exerted upon the birds at the particular season of their laying their eggs, of their hatching, or of their rearing their young, still tender and defenceless. I now began to suspect that the cries and fears of birds supposed to be fascinated originated in an endeavour to protect their nest or young. My inquiries have convinced me that this is the case."

The rattle-snake, which is the laziest of all the serpent tribe, never moves in a spiral manner or climbs up trees; but the black-snake, and some other species of the genus coluber, do. When impelled by hunger, and incapable of satisfying it by the capture of animals on the ground, they begin to glide up trees or bushes upon which a bird has its nest. The bird is not ignorant of the serpent's object. She leaves her nest, whether it contains eggs or young ones, and endeavours to oppose the reptile's progress. In doing this, she is actuated by the strength of her instinctive attachment to her eggs, or of affection to her young. Her cry is melancholy,

 her

her motions are tremulous. She expofes herfelf to the moft imminent danger. Sometimes fhe approaches fo near the reptile that he feizes her as his prey. But this is far from being univerfally the cafe. Often fhe compels the ferpent to leave the tree, and then returns to her neft.

It is a well known fact, that among fome fpecies of birds, the female, at a certain period, is accuftomed to compel the young ones to leave the neft; that is, when the young have acquired fo much ftrength that they are no longer entitled to all her care. But they ftill claim fome of her care. Their flights are aukward, and foon broken by fatigue. They fall to the ground, where they are frequently expofed to the attacks of the ferpent, which attempts to devour them. In this fituation of affairs, the mother will place herfelf upon a branch of a tree or bufh, in the vicinity of the ferpent. She will dart upon the ferpent, in order to prevent the deftruction of her young: but fear, the inftinct of felf-prefervation, will compel her to retire. She leaves the ferpent, however, but for a fhort time, and then returns again. Oftentimes fhe prevents the deftruction of her young, attacking the fnake with her wings, her beak, or her claws. Should the reptile fucceed in capturing the young, the mother is expofed to lefs danger; for, whilft engaged in fwallowing them, he has neither inclination nor power to feize upon the old one. But the appetite of the ferpent tribe is great: the capacity of their ftomachs is not lefs fo. The danger of the mother is at hand when the young are devoured. The fnake feizes upon her: and this is the cataftrophe, which crowns the tale of fafcination!

FAUSSE Braye, in fortification, an elevation of earth, about three feet above the level ground, round the foot of the rampart on the outfide, defended by a parapet about four or five fathoms diftant from the upper parapet, which parts it from the berme and the edge of the ditch. The fauffe-braye is the fame with what is otherwife called *Chemin des rondes*, and *Baffe enceinte*; and its ufe is for the defence of the ditch.

FEATHER-edged, is a term ufed by workmen for fuch boards as are thicker on one edge, or fide, than on the other.

FELTING, the method of working up wool or hair into a kind of cloth or ftuff, without either fpinning or weaving it. In this country felting it little practifed except in hat-making; and as nine-tenths of thofe who are employed in the manufacturing of hats know nothing of the principles on which they proceed, the following obfervations on the mechanifm of felting muft to them be both agreeable and ufeful. They are by M. Monge, and taken from the *Annales de Chemie*.

If we examine, in a microfcope, human hair, wool, the hair of a rabbit, hare, beaver, &c. however great the magnifying power of the inftrument may be, the furface of each hair appears perfectly fmooth and even; or at leaft, if any inequalities are to be perceived, they feem rather to arife from fome difference in the colour and tranfparency of particular parts of thefe fubftances than from the irregularity of their furfaces; for their image, when viewed by a folar microfcope, is terminated by even lines, without any roughnefs. The furface of thefe objects, however, is by no means fmooth; on the contrary, it appears to be formed either of *lamellæ* which cover each other from the root to the point, pretty much in the fame manner as the fcales of a fifh cover the animal from the head to the tail; or, more probably, of zones placed one over the other, like what is obferved in the ftructure of horns: to this conformation it is that the fubftances here treated of owe their difpofition to what is called felting.

If, with one hand, we take hold of a hair by the root, and draw it between two fingers of the other, from the root towards the point, we are hardly fenfible of any friction or refiftance, nor can we diftinguifh any found; but if, on the contrary, we hold the hair at the point, and draw it between the fingers, from the point toward the root, we are fenfible of a refiftance which did not exift in the former cafe; a fort of tremulous motion is likewife produced, which is not only perceptible to the touch, but may alfo be diftinguifhed by the ear.

It is evident, therefore, that the texture of the furface of a hair is not the fame from the root towards the point as from the point towards the root; and that a hair, when grafped, muft offer more refiftance in fliding or moving progreffively towards the point than towards the root; *i. e.* in moving with its point foremoft.

If a hair, after being taken hold of by the fore-finger and thumb, be rubbed by them, in the longitudinal direction of the hair, a progreffive motion takes place, and this motion is always towards the root. This effect does not at all depend on the nature of the fkin of the fingers or its texture; for if the hair be turned, fo that the point is placed where the root was, the movement then becomes contrary to what it was before; that is to fay, it is always directed towards the root.

What is obferved, in the above inftance, is entirely analogous to what happens when country children, by way of fport, introduce an ear of rye or barley between the wrift and the fhirt, the points of the beards of which are directed outwards. By the various motions of the arm, this ear, fometimes catching againft the fhirt, fometimes againft the fkin, takes a progreffive motion backwards, and foon gets up to the arm-pit. It is very clear that this effect is produced by the beards of the ear, and indeed chiefly by the afperities upon thofe beards; which, being all directed towards the point, do not permit the ear to move in any other direction than towards that part to which it was united to the ftalk. There is no doubt that it is the fame with refpect to hair; and that its furface is befet with afperities, which, being laid one upon the other, and turned towards the points, permit no motion but towards the root.

A tight knot, made in the middle of a hair, is very difficult to untie by the ufual means, on account of the extreme thinnefs of the hair; but if we place the hair in the bend of the hand, fo that the knot is in a line with the little finger, and, after grafping the hair by clofing the hand, we ftrike the fift feveral times againft the knee, the afperities of one end of the hair being now in a contrary direction to thofe of the other, each of the ends recedes a little, one of them one way, the other the contrary way; the knot is thereby opened, and, by introducing a pin into the eye which is formed, it is very eafy to finifh untying it.

Thefe obfervations, which it would be ufelefs to multiply, relate to long hair, that having been taken as an example; but they apply with equal propriety to wool, furs,

furs, and in general to every kind of animal hair. The ſurface of all theſe is therefore to be conſidered as compoſed of hard *lamellæ* placed one upon another, like tiles, from the root to the point; which *lamellæ* allow the progreſſive motion of the hair towards the root, but prevent a ſimilar motion towards the point.

From what has been ſaid, it is eaſy to explain why the contact of woollen ſtuffs is rough to the ſkin, while that of linen or cotton cloths is ſmooth; the reaſon is, the aſperities upon the ſurface of the fibres of the wool (notwithſtanding the flexibility of each particular fibre), by fixing themſelves in the ſkin, produce a diſagreeable ſenſation, at leaſt till we are accuſtomed to it; whereas the ſurface of the fibres of hemp or flax, of which linen is made, being perfectly ſmooth, do not cauſe any ſuch ſenſation. It is alſo evident, that the injury ariſing to wounds or ſores, from the application of wool, does not proceed from any chemical property, but is occaſioned ſolely by the conformation of the ſurface of the fibres: the aſperities of which attach themſelves to the raw and expoſed fleſh, which they ſtimulate and irritate to ſuch a degree as to produce inflammation.

This conformation is the principal cauſe of that diſpoſition to what is called felting, which the hair of all animals in general poſſeſſes.

The hatter, by ſtriking the wool with the ſtring of his bow (ſee Hat, *Encycl.*), ſeparates the hairs from each other, and cauſes them to ſpring up in the air; the hairs fall again on the table, in all poſſible directions, ſo as to form a layer of a certain thickneſs, and the workman covers them with a cloth, which he preſſes with his hands, moving them backwards and forwards in various directions. This preſſure brings the hairs againſt each other, and multiplies their points of contact; the agitation of them gives to each hair a progreſſive motion toward the root; by means of this motion the hairs are twiſted together, and the *lamellæ* of each hair, by fixing themſelves to thoſe of other hairs which happen to be directed the contrary way, keep the whole in that compact ſtate which the preſſure makes it acquire. In proportion as the maſs becomes compact, the preſſure of the hands ſhould be increaſed; not only to make it more cloſe, but alſo to keep up the progreſſive motion and twiſting of the hairs, which then takes place with greater difficulty: but throughout the whole of this operation, the hairs fix themſelves only to each other, and not to the cloth with which they are covered, the fibres of which, as we have already ſaid, are ſmooth, and have not that diſpoſition to felting which we have deſcribed above.

It may not be amiſs here to explain why that hair which is intended for making hats is always cut off with a ſharp inſtrument (although that cannot be done without loſing a part of its length), and not plucked out by the roots, as might be done after ſoftening the ſkin: the reaſon is, the bulb of the hair, which in the latter caſe would come out with it, would render that end which was fixed in the ſkin thick and obtuſe; and it would conſequently be leſs diſpoſed to introduce itſelf among the contiguous hairs, and to contribute by its progreſs motion to the contexture of the maſs.

The above deſcribed conformation of the ſurface of hairs and wool is not the only cauſe which produces their diſpoſition to felting. It is not ſufficient that every hair poſſeſſes the forementioned tendency to move progreſſively towards the root, and that the inclined *lamellæ*, by hooking themſelves to each other, preſerve the maſs in that ſtate to which compreſſion has brought it; but it is alſo neceſſary that the hairs ſhould not be ſtraight, like needles; if they were ſo, preſſing and rubbing them together would merely cauſe them to continue their progreſſive motion, without changing their direction; and the effect of thoſe operations would only be to make them move from the centre of the maſs, without producing any compactneſs in it. Every hair muſt therefore be twiſted or curled in ſuch a manner that the extremity which is towards the root may be diſpoſed to change its direction perpetually, to twiſt itſelf about other hairs, and to incline towards itſelf again, in caſe it ſhould be determined thereto by any change in the poſition of the reſt of its length. It is becauſe wool has naturally this crooked form that it is ſo proper for felting, and that it may be made uſe of for that purpoſe without undergoing any previous preparation.

But the hairs of the beaver, the rabbit, the hare, &c. being naturally ſtraight, cannot be employed alone in felting till they have undergone a preliminary operation; which conſiſts in rubbing or combing them, before they are taken off the ſkin, with a bruſh dipped in a ſolution of mercury in aquafortis (nitric acid). This liquor, acting only on one ſide of the ſubſtance of the hairs, changes their direction from a right line, and gives them that diſpoſition to felting which wool naturally poſſeſſes.

When the hairs are not intended to enter into the body of the maſs, but are only to be employed in making a ſort of external coating, ſuch as is ſometimes given to the outer ſurface of hats, the operation juſt mentioned need not be performed; but the felt on which they are to be fixed being finiſhed; the hair is uniformly ſpread upon the ſurface to which the coating is to be applied; and, being covered with a cloth, it is preſſed with the hands, and agitated for a certain time. By theſe means, the hairs introduce themſelves, by the root, a certain depth into the felt, and are there fixed by their *lamellæ* in ſuch a manner as not to be eaſily extracted. A particular direction is afterwards given to them by means of a bruſh, and they are made to keep this direction by having a hot iron paſſed over them. If the agitation were continued for a longer time, theſe hairs, not having their ſtraightneſs deſtroyed by the operation before deſcribed, would paſs entirely through the felt, going out at the oppoſite ſurface, as each hair follows exactly the direction it acquired at the beginning.

It is owing to the very ſame circumſtances which make wool and hair capable of felting, that woollen cloth is thickened by fulling. See Fulling in this Supplement.

FERGUSSON (Robert), who at an early period of life obtained a conſiderable degree of celebrity as a Scottiſh poet, was born at Edinburgh on the 5th of September 1750, according to a manuſcript account of him with which we have been favoured by a relation. In the biographical ſketch prefixed to the Perth edition of his poems he is ſaid to have been born in 1751.

His father William Ferguſſon poſſeſſed, as well as himſelf, ſome talents for poetry; but, marrying early, and being wiſer than his ſon, he abandoned the muſes

for

Ferguſſon. for trade, and was employed in different mercantile houſes, firſt in Aberdeen and afterwards in Edinburgh. At the time of his death he was an accountant in the Britiſh Linen Hall; but never acquired any thing like opulence.

During the years of infancy and childhood the conſtitution of our poet was ſo weak, that little hopes were entertained of his arriving at manhood. By the care, however, and attention of his parents, he gradually acquired ſtrength, and at the age of ſix was put to an Engliſh ſchool, where his proficiency in reading and reciting was uncommonly great. At the age of ſeven he was ſent to the high ſchool of Edinburgh, where he continued four years, and with very little labour made a rapid progreſs in the knowledge of the Latin tongue; but for ſome reaſon or other he was removed from the high ſchool to the grammar ſchool of Dundee, whence, after two years, he was ſent to the univerſity of St Andrew's. A gentleman of the name of Ferguſſon had left burſaries in that univerſity for the education of two boys of the ſame name; and Mr William Ferguſſon having with difficulty obtained one of them for his ſon, was induced to educate him at St Andrew's in preference to Edinburgh.

Though at no period of his life a ſevere ſtudent, our poet's attainments in ſcience were ſuch as to keep alive in the univerſity the hopes which had been formed of him at ſchool; and he was confeſſedly the firſt mathematician of his ſtanding. On this account we are told that he became the favourite of Dr Wilkie, who was then profeſſor of natural philoſophy in the univerſity of St Andrew's; but it is not improbable that the Doctor valued him as much for his poetical genius as for his ſkill in geometry; for Wilkie was a poet himſelf, and Mr Ferguſſon had already written ſeveral ſmall poems which attracted conſiderable notice, as well from the profeſſors as from his fellow-ſtudents. But whatever was the bond of union, Dr Wilkie patroniſed the youthful poet; and the poet ſhewed afterwards that he was not ungrateful. Upon the Doctor's death, he publiſhed, in the Scottiſh dialect, a beautiful eclogue to his memory, in which the peculiar merits of that eccentric genius are appreciated with great judgment. See Wilkie, in this Supplement.

During the laſt winter that he reſided in St Andrew's, our poet had collected materials for a tragedy on the death of Sir William Wallace, and had even completed two acts of the play; but having ſeen a ſimilar work on the ſame ſubject, he abandoned his deſign; "becauſe (ſaid he to a friend) whatever I publiſh ſhall be original, and this tragedy might be conſidered as a copy."

Having finiſhed his ſtudies at the univerſity, he returned to Edinburgh without reſolving on any permanent employment. His father had deſigned him for the church; but he was now dead, and our author turned a deaf ear to the intreaties of his mother, and of every other friend who endeavoured to perſuade him to fulfil his father's intention. He was then adviſed to ſtudy phyſic; but he declined it, becauſe, he ſaid, that, when reading the deſcription of diſeaſes, he fancied that he felt the ſymptoms of them all in himſelf. To the law, however, he could not ſtart the ſame objection; and he began to ſtudy it, but made no progreſs. At this his relation and the editor of his poems expreſs no ſurpriſe; for, according to them, it was a ſtudy the moſt improper for him, as it could not be expected that a genius ſo lively would ſubmit to the drudgery of that dry and ſedentary profeſſion.

That the law was a very improper profeſſion for a man of his narrow fortune is indeed true; but we truſt that his two biographers will not conſider us as intending any offence to them, if we embrace the preſent opportunity of expoſing the folly of a very common remark, that a lively genius cannot ſubmit to what is abſurdly called a dry ſtudy. We might inſtance different lawyers at our own bar, who, with great poetical talents in their youth, have riſen to the ſummit of their profeſſion; but to avoid perſonal diſtinctions at home, we ſhall take our examples from England. The genius of the late Earl of Mansfield was at leaſt as lively as that of Mr Ferguſſon, and if he had pleaſed he could have been equally a poet; yet he ſubmitted to the drudgery of ſtudying a law ſtill drier than that of Scotland. To the fine taſte of Atterbury biſhop of Rocheſter, and to his claſſical compoſitions both in proſe and verſe, no man is a ſtranger who is at all converſant in Engliſh literature: yet that elegant ſcholar and poet, after he had riſen to the dignity of Dean of Carliſle, ſubmitted to the drudgery of ſtudying, through the medium of barbarous Latin, the eccleſiaſtical law of England from the earlieſt ages; and declared, that by dint of perſeverance he came in time to reliſh it as much as the ſtudy of Homer and Virgil. Whatever be thought of Milton's political principles, no man can read his controverſial writings, and entertain a doubt but that he could have ſubmitted to the drudgery of ſtudying the law.

The truth is, and it is a truth of great importance, that a man of real vigour of mind may bring himſelf to delight in any kind of ſtudy which is uſeful and honourable. Such men were Lord Mansfield, the Biſhop of Rocheſter, and Milton; but, whether through ſome radical defect in his nervous ſyſtem, or in conſequence of early diſſipation, Mr Ferguſſon, with many eſtimable qualities, was ſo utterly deſtitute of this mental vigour, that rather than ſubmit to what his friends call drudgery, he ſeems to have looked with a wiſhful eye to ſome ſinecure place.

With this view he paid a viſit to an uncle who lived near Aberdeen, a man of great learning and in opulent circumſtances, in hopes that, by his intereſt, he might be ſettled in a poſt ſuitable to his merit: But how deluſive were his hopes! His uncle indeed received him with every mark of affection; but his fondneſs gradually cooled, and at the end of ſix months he ordered him abruptly to leave his houſe, without having endeavoured to procure for him any ſettlement.

To a mind like Ferguſſon's, feelingly alive, ſuch treatment from ſo near a relation, to whom he had always behaved with becoming reſpect, muſt have been dreadfully galling. Stung with indignation, he returned to his mother's at Edinburgh; and as ſoon as he recovered from a ſevere illneſs, brought upon him by diſappointment and the fatigue of his journey, he compoſed two elegies; one on "The Decay of Friendſhip," and the other "Againſt Repining at Fortune," both occaſioned by his adventure in the North. How much he felt the daſhing of his hopes, is apparent from the following pathetic lines in the Decay of Friendſhip:

But,

But, ah! theſe youthful ſportive hours are fled,
These ſcenes of jocund mirth are now no more;
No healing ſlumbers 'tend my humble bed,
No friends condole the ſorrows of the poor.

And what avail the thoughts of former joy?
What comfort bring they in the adverſe hour?
Can they the canker-worm of Care deſtroy,
Or brighten Fortune's diſcontented lour?

So deſtitute was he at this period, that he ſubmitted to copy papers in the commiſſary clerk's office, we believe at ſo much the ſheet; but not liking the employment, and quarrelling with the commiſſary clerk-depute, he ſoon left the office in diſguſt.

Hitherto he had lived rather in obſcurity; and happy had it been for him if in that obſcurity he had been ſuffered to remain; happy had it been for him, had his converſation been leſs faſcinating, and his company leſs courted by the frolic and the gay. Poſſeſſing an inexhauſtible fund of wit, the beſt good nature, much modeſty, and great goodneſs of heart, he was viewed with affection by all to whom he was known; but his powers of ſong, and almoſt unrivalled talents for mimickry, led him oftener into the company of thoſe who wiſhed for him merely to enliven a ſocial hour, than of ſuch as by their virtue were inclined, and by their influence were able, to procure him a competent ſettlement for life. The conſequence of this was great laxity of manners. His moral principles indeed were never corrupted, nor, as we have reaſon to believe, his faith in revelation ſhaken; but there is no doubt but that, courted as he was by the ſyren voice of pleaſure, he yielded to many temptations, and in the hours of ebriety committed actions which, in his cooler moments, he reflected on with abhorrence.

His conſcience was indeed frequently rouſed. Being on a viſit to a friend at Haddington, and ſauntering one day near the churchyard, he was accoſted by a clergyman, who ſeemed to be no ſtranger to the kind of life which he led. This judicious divine contrived to draw his attention to the ſhortneſs of time, the length of eternity, death and judgment, and the awful ſtate that awaits the wicked in an unſeen world; and the converſation made a deep impreſſion on his mind. It ſeemed, however, to be effaced from his memory by the diſſipation of Edinburgh, till it was recalled with double effect by the following accident:

In the room adjoining to that in which he ſlept was a ſtarling, which being ſeized one night by a cat that had found its way down the chimney, awaked Mr Ferguſſon by the moſt alarming ſcreams. Having learned the cauſe of the alarm, he began ſeriouſly to reflect how often he, an immortal and accountable being, had in the hour of intemperance ſet death at defiance, though it was thus terrible in reality even to an unaccountable and ſinleſs creature. This brought to his recollection the converſation of the clergyman, which, aided by the ſolemnity of midnight, wrought his mind up to a pitch of remorſe that almoſt bordered on frantic deſpair. Sleep now forſook his eyelids; and he roſe in the morning, not as he had formerly done, to mix again with the ſocial and the gay, but to be a recluſe from ſociety, and to allow the remembrance of his paſt follies to prey upon his vitals. All his vivacity now forſook him; thoſe lips which were formed to give delight, were cloſed as by the hand of death; and "on his countenance ſat horror plum'd."

From this ſtate of gloomy deſpondency, however, he began gradually to recover; and, except that a ſettled melancholy was viſible in his countenance, his health was completely reſtored, when one evening he fell and cut his head ſo dreadfully, that from the loſs of blood he became delirious. In this deplorable ſtate he continued for ſeveral months, till, being quite exhauſted by want of ſleep and conſtant ſpeaking, he expired on the 16th of October 1774. He was interred in the Canongate churchyard, where his friends erected a monument to his memory, which has been ſince removed to make way for a larger and more elegant monument by his enthuſiaſtic admirer the late poet Burns.

Thus died Robert Ferguſſon, a young man of the brighteſt genius and of the beſt heart, who, had he joined prudence to his uncommon talents, muſt have riſen to great eminence in the republic of letters; but, as a late juvenile poet has obſerved of him——

Complete alike in head and heart,
But wanting in the prudent part,
He prov'd a poet's lot.

Of his poems no general character can be given. The ſubjects of them are ſometimes uncommon and generally local or temporary. They are of courſe very unequal. But ſuch of them as are in the Scottiſh dialect have been univerſally admired by his countrymen; and when it is conſidered that they were compoſed amidſt a round of diſſipation, they will be allowed to furniſh complete evidence of his genius and his taſte.

FERMAT (Peter), who was counſellor of the parliament of Touloufe in France, flouriſhed in the 17th century, and died in 1663. He was a man of great talents, and a very general ſcholar; but being contemporary and intimately connected with Des Cartes, Merſenne, Torricelli, and Huygens, he was naturally led to devote much of his time to the mathematical ſciences. He was (ſays Dr Hutton) a firſt rate mathematician, and poſſeſſed the fineſt taſte for pure and genuine geometry, which he contributed greatly to improve, as well as algebra.

Fermat was author of, 1. A Method for the Quadrature of all ſorts of Parabolas.—2. Another on Maximums and Minimums: which ſerves not only for the determination of plane and ſolid problems, but alſo for drawing tangents to curve lines, finding the centres of gravity in ſolids, and the reſolution of queſtions concerning numbers: in ſhort, a method very ſimilar to the fluxions of Newton.—3. An Introduction to Geometric Loci, plane and ſolid.—4. A Treatiſe on Spherical Tangencies: where he demonſtrates in the ſolids the ſame things as Vieta demonſtrated in planes.—5. A Reſtoration of Apollonius's two Books on Plane Loci.—6. A General Method for the dimenſion of Curve Lines. Beſides a number of other ſmaller pieces, and many letters to learned men; ſeveral of which are to be found in his *Opera Varia Mathematica*, printed at Touloufe, in folio, 1679.

FERMENTATION is a chemical proceſs which has been already conſidered in the *Encyclopædia*, and will be again reſumed in this *Supplement* under the title *Animal and Vegetable* SUBSTANCES. In this place we mean nothing more than to give ſuch directions, principally

Fermentation.

cipally from Mr Richardson of Hull, for the proper fermentation of malt liquors as have not been fully detailed in the article BREWING (*Encycl.*).

This author controverts, we do not think very successfully, the conclusions drawn by Mr Henry from the experiments, of which the reader will find an account in the article FERMENTATION (*Encycl*); but it is not his theory with which we are at present concerned, but his practice as that of an experienced and enlightened brewer. Having treated of *Worts*, and the proper method of boiling them, for which see WORT in this *Supplement*, and having given an historical view of the process of fermentation, of which a pretty accurate abridgement is inserted in the articles BREWING and FERMENTATION (*Encycl.*), he proceeds thus:

"The agency of air, in the business of fermentation, is very powerful; but as all fermentable subjects have an abundant supply, we are rather to provide for the egress of their own, than to suffer the admission of the external air, by which a great number of the fine, volatile, oleaginous parts of the subject would be carried off, and a proportionate injury in flavour and spirituosity sustained. Hence such a covering should be provided for the gyle-tun as would barely allow the escape of the common air produced by the operation; whilst the *gas*, or fixed air, from its greater density, resting upon the surface of the beer the whole depth of the curb, prevents the action of the external air, and consequently the escape of those fine and valuable parts just mentioned.

"But towards the conlusion of vinous fermentation, this aerial covering begins to lose its efficacy; which points out the necessity of then getting the beer into casks as soon as possible, that the consequences may be prevented, of exposing so large a surface, liable to so copious an evaporation. Amongst these, a loss of spirituosity is not the least; for this evaporation is more and more spirituous, as the action approaches the completion of vinous fermentation; and that once obtained, the loss becomes still more considerable, if still exposed to the air; whence it might be termed the distillation of Nature, in which she is so much superior to art, that the ethereal spirit rises pure and unmixed, whilst the highest rectification of the still produces at best but a compound of aqueous and spirituous parts.

"Nor is this entirely conjecture. Experience teaches us, that we cannot produce so strong a beer in summer, *ceteris paribus*, as in winter; the reason is, not because the action of fermentation does not realize so much spirit in warm weather, but because the fermenting liquor, after the perfection of vinosity, continues so long in a state of rarefaction, that the spirituous parts are dissipated in a much greater degree at that time than at any other, in a similar state of progression. And this doctrine of natural distillation seems to account for that increase of strength obtainable from long preservation, in well closed casks, and, more particularly so, in glass bottles; for Nature, in her efforts to bring about her grand purpose of resolving every compound into its first principles, keeps up a perpetual internal struggle, as well as an external evaporation; and if the latter be effectually prevented, the former must be productive of additional spirituosity, so long as the action keeps within the pale of vinous fermentation.

"In order to maintain a due regulation of the fermenting power, and to answer the several purposes of the operation, a scrupulous attention to the degree of heat at which the action commences, and a particular regard to the quality and quantity of the ferment employed, are indispensably necessary." The degree of heat must be ascertained by the thermometer, and regulated by experience: the quantity of yeast can be ascertained only by the intention of the artist.

Fezzan.

FEZZAN is a kingdom in the anterior of Africa, placed in the vast wilderness as an island in the ocean. The following account of it was given to Mr Lucas the African traveller by an old shereef, a native of Fezzan; and that account was confirmed by the governor of Mesurata, who had himself visited Fezzan, and who, having treated the traveller with great kindness, ought not to be suspected of having wantonly deceived him.

According to this account, Fezzan is situated to the south of Mesurata (see MESURATA in this *Suppl.*), and the traveller from the latter place to the former arrives in eight days at Wadan, where refreshments are procured for the caravan. From thence in five hours they reach the desart of Soudah, where no vegetable is seen to grow but the talk, a tree from which the lemon-coloured wood is taken which forms handles for tools. The passage of the desart takes up some days, when the traveller finds a miserable village, producing nothing but dates, brackish water, and Indian corn; from this village a day's journey conducts to the town of Sebbah, where are the remains of an ancient castle, and other venerable ruins, and in four days more he reaches Mourzouk, the capital of Fezzan.

This city is situated on the banks of a small river, surrounded by a high wall for defence, and is distant from Mesurata 390 computed miles. Eastward of Mourzook is the town of Queela, in which are the remains of ancient buildings; the size of the cisterns, and the construction of the vaulted caves, exhibit instances of ancient splendour. South of which place is Jermah, distinguished by numerous and majestic ruins, on which are many inscriptions. Tessouwa lies eastward, near which was a river which the shereef remembers, but is now overwhelmed in the moving sands. N. E. from Mourzouk, distant about 120 miles, is the large town of Temmiswa, where the caravans of pilgrims from Bornou and Nigritia, by way of Cairo to Mecca, provide their stores for the desart.

In the town or province of Mendrah is a large quantity of *trona*, a species of fossil alkali, that floats on the surface or settles on the banks of its spreading lakes, great quantity of which is sent to Tripoli, and shipped for Turkey, Tunis, and Morocco; at the latter place it is used as an ingredient in the red dye of the leather. Mendrah is about 60 miles south of Fezzan. The territory of Fezzan extends but little westward, being confined by barren mountains. The smaller towns of this kingdom are said to be about one hundred; these towns are chiefly inhabited by husbandmen and shepherds; in every town a market is regularly held; mutton and goat's flesh are sold by the quarter, usually from thirty-two to forty grains of gold, or from four to five shillings English. The flesh of camels is dearer, and divided into smaller parts.

The houses are of clay, with flat roofs composed of branches

Fezzan.

branches of trees, on which earth is laid; this is sufficient in a climate where it never rains. The heats in summer, from April to November, are intense, and the hot winds blow from the south-east, south, and south-west, with such violence as to threaten suffocation; when it changes to the west or north-west a reviving freshness ensues.

The dress of the inhabitants is like that of the Moors of Barbary, consisting of a large pair of trowsers, a shirt which hangs over the trowsers, a kind of waistcoat without sleeves, and a jacket with tight sleeves; over the jacket is a loose robe which reaches below the knee, a girdle of crimson, and a long cloth called a *barrakon* or *albaicque*, like a highland plaid, is worn; stockings of leather, laced like half-boots, and slippers; on the head a red cap and turban; sometimes over the whole they throw a long cloak with a hood, called a *burnoose*. In summer they throw off all but the shirt and the cap.

The people bear very high degrees of heat, but any cold affects them sensibly. Their diseases are chiefly of the inflammatory and putrid kind; the small pox is common. Their old women are their principal physicians. For pains in the head they cup and bleed; for those in the limbs, they bathe in the hot lakes. They have a multitude of noxious and loathsome animals; the air is crowded with mosquitos, and their persons are over-run with the vermin which affect the beggars of Europe.

In their persons they incline to the negro, of a deep swarthy complexion, with curly black hair; they are tall, but indolent, inactive, and weak. In their common intercourse, distinction of rank seems to be forgotten; rich and poor, master and man, converse, eat, and drink together; they are, however, generous and hospitable.

An extensive plain composes the kingdom of Fezzan: the soil is generally a light sand, the springs are abundant, and few regions in Africa exhibit a richer vegetation. The land produces the talk, the white-thorn, date trees, the olive and lime, apricot, pomegranate, and fig: Indian corn and barley are the favourite objects of cultivation; of wheat there is little raised. The tame animals are, the sheep, cow, goat, and camel; and the wild are, the ostrich, antelopes of various kinds, one of which is called the huadee, which when chased plunges with address from a precipice, and lights on its hams.

The food of the lower class consists of flour of Indian corn, seasoned with oil and fruit; those of superior rank eat wheat bread and flesh. Fezzan produces much salt; the water has in general a mineral taste, but the favourite beverage is a liquor from the date tree, which acquires, when fermented, an intoxicating strength. In religion they are rigid Mahomedans, but tolerant. Their government monarchical; their present king is descended from one of the shereefs of Taffilet, who about 400 years since obtained the crown. Till the present century the kingdom was independent, when the Bashaw of Tripoli conquered and made it tributary; the reigning sovereign has nearly thrown off this yoke. In Fezzan, the descendants of the prophet are highly privileged, their property and persons are inviolable; they are exempt from certain punishments. This class are in general either princes or merchants.

The revenue is composed of a tax on towns and villages, a tax on every camel load of goods (except provisions) which enters the capital, fines for offences, lands of persons dying without heirs, and a tax on gardens and date trees. Gold dust by weight is the chief medium of payment; but for convenience they are furnished with small papers of gold dust of different values, from two *xarbes* or one and a half upwards; for smaller articles corn or flour are used as a medium. One grain of gold is equal to $1\frac{1}{2}$d. sterling. The Fezzan grain is the same as in England.

The justice of the sovereign is highly extolled; small offences are punished by the bastinado, and the punishments increase to fine, imprisonment, and death. Trusting to their natural defence, their towns are without guard, and they have no standing forces. The only war the shereef remembered was undertaken against a people inhabiting the mountains of Tibesti, which is separated from the people of Fezzan by a wide and sandy desart. These people are wild and savage, and had plundered a caravan belonging to the king, who sent an army of between 3 and 4000 men against and subdued them. The country of these people produces much senna. The vales of Tibesti are said to be fertile in corn and pasture for cattle, particularly camels. The people live in huts, and profess various religions, some the Mahomedan, others are attached to their ancient idolatry.

The people of Fezzan carry on a considerable trade with Tripoli, Bornou, Nigritia, &c. At the end of October, when the heats are abated, the caravans depart from Mourzouk in small parties of ten or twelve, unless in time of war. They lay in provisions of dates, meal, and mutton salted, dried in the sun, and boiled in oil or fat. The merchants have agents in the chief towns, to whom they send the slaves they purchase.

The caravans to Tripoli carry the *trona*, senna, gold and slaves brought from the southern countries; and in return bring back cutlery, woollen, silks, dollars, copper, and brass.

That to Bornou carries brass and copper, for the currency of the country, imperial dollars, and various manufactures; but of their own produce only a preparation of dates, and meal of Indian corn; and they take in return slaves, gold dust, and civet.

To Cashna, an empire in Nigritia, they carry cowries, brass to make rings and bracelets, horses, several kinds of manufactures, and the Gooroo nuts; and in return take gold dust, slaves, cotton cloth, dyed goats skins, hides, senna, and civet, for the countries south of the Niger, where also they convey sabre blades and Dutch knives, coral, brass beads, looking glasses, dollars, &c. and receive back gold dust, slaves, cotton cloths, goat skins, Gooroo nuts, cowries, and ivory.

A caravan of pilgrims sets out likewise in the autumn of every second or third year from Mourzouk, the capital of Fezzan, to Mecca. They proceed to Temessa, over the mountain of Ziltan, and thence to Sibbul, a place subject to Tripoli; and thence nearly in a line with the Mediterranean sea to Cairo, and thence to Mecca by the customary route.

As not one celestial observation has been taken to determine any latitude between Benin and Tripoli, all the positions are fixed by estimation, reckoning fifteen or sixteen miles for a day's journey. Mr Rennell places Mourzook, Mourzouk, the capital of Fezzan, in lat. 27°. 20′, or 260 miles from Masurata.

FIGURATE NUMBERS are such as do or may represent some geometrical figure, such as a triangle, pentagon, or pyramid, &c. These numbers are treated of at great length by Maclaurin in his Fluxions; Simson in his Algebra; and Malcolm in his Arithmetic; but the following account of them by Dr Hutton is as perspicuous as any that we have seen:

Figurate numbers are distinguished into orders, according to their place in the scale of their generation, being all produced one from another, viz. by adding continually the terms of any one, the successive sums are the terms of the next order, beginning from the first order, which is that of equal units 1, 1, 1, 1, &c.; then the second order consists of the successive sums of those of the first order, forming the arithmetical progression 1, 2, 3, 4, &c.; those of the third order are the successive sums of those of the second, and are the triangular numbers 1, 3, 6, 10, 15, &c; those of the fourth order are the successive sums of those of the third, and are the pyramidal numbers 1, 4, 10, 20, 35, &c.; and so on, as below:

Order.	*Name.*	*Numbers.*					
1.	Equals,	1,	1,	1,	1,	1,	&c.
2.	Arithmeticals,	1,	2,	3,	4,	5,	&c.
3.	Triangulars,	1,	3,	6,	10,	15,	&c.
4.	Pyramidals,	1,	4,	10,	20,	35,	&c.
5.	2d Pyramidals,	1,	5,	15,	35,	70,	&c.
6.	3d Pyramidals,	1,	6,	21,	56,	126,	&c.
7.	4th Pyramidals,	1,	7,	28,	84,	210,	&c.

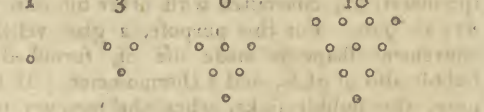
The above are all considered as different sorts of triangular numbers, being formed from an arithmetical progression whose common difference is 1. But if that common difference be 2, the successive sums will be the series of square numbers: if it be 3, the series will be pentagonal numbers, or pentagons; if it be 4, the series will be hexagonal numbers, or hexagons; and so on. Thus:

Arithmeticals.	*1st Sums*, or *Polygons.*	2d *Sums*, or 2d *Polygons.*
1, 2, 3, 4	Tri. 1, 3, 6, 10	1, 4, 10, 20
1, 3, 5, 7	Sqrs. 1, 4, 9, 16	1, 5, 14, 30
1, 4, 7, 10	Pent. 1, 5, 12, 22	1, 6, 18, 40
1, 5, 9, 13	Hex. 1, 6, 15, 28	1, 7, 22, 50
&c.		

And the reason of the names triangles, squares, pentagons, hexagons, &c. is, that those numbers may be placed in the form of these regular figures or polygons, as here below:

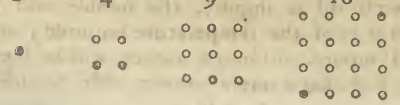
Triangles.

1 3 6 10



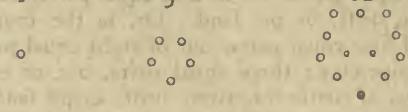
Squares.

1 4 9 16



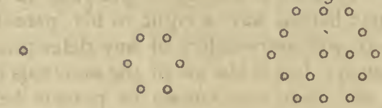
Pentagons.

1 5 12



Hexagons.

1 6 15



But the figurate numbers of any order may also be found without computing those of the preceding orders; which is done by taking the successive products of as many of the terms of the arithmeticals 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the number which denominates the order of figurates required, and dividing those products always by the first product. Thus the triangular numbers are found by dividing the products 1×2, 2×3, 3×4, 4×5, &c. each by the first product 1×2; the first pyramids by dividing the products $1 \times 2 \times 3$, $2 \times 3 \times 4$, $3 \times 4 \times 5$, &c. by the first $1 \times 2 \times 3$. And, in general, the figurate numbers of any order n, are found by substituting successively 1, 2, 3, 4, 5, &c. instead of x in this general expression $\frac{x \cdot \overline{x+1} \cdot \overline{x+2} \cdot \overline{x+3} \cdot \&c.}{1 \cdot 2 \cdot 3 \cdot 4 \cdot \&c.}$; where the factors in the numerator and denominator are supposed to be multiplied together, and to be continued till the number in each be less by 1 than that which expresses the order of the figurates required.

FILTER (See *Encycl.*) It is well known that vessels made of a particular kind of porous stone are employed as filtering basins for freeing water, intended to be drunk, from various kinds of impurity. In sea voyages such filtering basins must be highly useful; and they are frequently found useful at land where no water can be had but from stagnant pools, or springs flowing through clay. The stone, however, of which they are made is not every where to be found; and therefore different persons have endeavoured to employ the art of the potter to supply their place.

In the year 1790 a patent was granted to a female potter, for her invention of the following composition for this purpose; viz. four equal parts, out of nine equal parts, of tobacco-pipe clay; and five equal parts, out of nine equal parts, of coarse sea, river, drift, or pit sand; these two materials, in the above proportions, are sufficient for the purpose of making small basins, and other vessels, to contain a quantity not exceeding one gallon of water, or other liquid. But the composition, when confined to these two materials, and in these proportions, often flies or cracks in the fire, if larger basins, or other vessels, are attempted to be made with it. She, therefore, in the second instance, composes her filtering basins of equal parts of tobacco-pipe clay and coarse sea, river, drift, or pit sand; in the third instance, of three equal parts, out of nine equal parts, of tobacco-pipe clay; one equal part, out of nine equal parts, of Stourbridge clay, or clay from the surface of coal mines, or any other clay of the same quality; one equal part, out of nine equal parts, of Windsor, Filter.

or other loam, of the fame quality with Windfor loam; and four equal parts, out of nine equal parts, of coarfe river, fea, drift, or pit fand. Or, in the fourth inftance, of four equal parts, out of eight equal parts, of tobacco-pipe clay; three equal parts, out of eight equal parts, of coarfe fea, river, drift, or pit fand; and one equal part, out of eight equal parts, of that burnt ground clay of which crucibles are made.

If the lady who invented, or pretends to have invented, thefe bafins, have a right to her patent, far be it from us to wifh our readers of any defcription to incroach upon it; but as the ufe of the materials of which her bafins are made was known to potters before fhe was born, they may certainly compound thefe materials in proportions different from hers, without doing her any legal injury. As fhe varies her own proportions fo much, we think it probable that fome proportion differing a little from them all, may anfwer the purpofe of filtering veffels equally well; and it is almoft needlefs to add, that with this precaution any potter may make fuch veffels, for which he would undoubtedly have a great demand.

A patent has likewife been granted to Mr Jofhua Collier of Southwark for a very ingenious contrivance for filtering and fweetening water, oil, and all other liquids. Of this contrivance, which combines the application of machinery with the antifeptic properties of charcoal (See CHEMISTRY n° 34. *Supplement*), we fhall give a detailed account.

Fifh-oil is one of the liquids which he had it particularly in view to free from all its impurities in fmell, tafte, and colour; and the chemical procefs employed by him for this purpofe, confifts in pouring a quantity of any fpecies of fifh-oil, or a mixture of different forts of fifh-oil, into any convenient veffel, which is to be heated to the temperature of 110 or 120 degrees of Fahrenheit's fcale, and then adding of cauftic mineral alkali, of the fpecific gravity commonly defcribed as 1.25, or of fuch ftrength that a phial containing 1000 grains of diftilled water will contain 1250 grains of thefe lees, a quantity equal to four parts of the 100 by weight of the quantity of oil; the mixture is then to be agitated, and left to ftand a fufficient time for the falts and fediments to fubfide; it is then drawn off into another veffel, containing a fufficient quantity of frefh burnt charcoal, finely powdered, or any other fubftance poffeffing antifeptic properties, in a powdered or divided ftate, with an addition of a fmall proportion of diluted fulphuric acid, fufficient only to decompofe the fmall quantity of faponaceous matter ftill fufpended in the oil, which appears by the oil becoming clear at the furface: the contents of this veffel are alfo agitated, and the coaly faline and aqueous particles left to fubfide; after which the oil is paffed through proper ftrainers, herein after defcribed, and is thereby rendered perfectly tranfparent and fit for ufe.

The principle of the improved ftrainers, or filtering machines, confifts in the means applied to combine hydroftatic preffure, which increafes according to the perpendicular height of the fluid, with the mode of filtering *per afcenfum*, thereby procuring the new and peculiar advantage that the fluid and its fediment take oppofite directions. A great advantage attending this invention is, that the dimenfions of the chamber in which the fediment is received, may be varied, while the filtering furface remains the fame. To adapt the machines not only to the purpofe of families, work-houfes, hofpitals, public charities, the navy, or the merchant fervice, but alfo to all the purpofes of oil-men, of diftillers, of the laboratory, the brewery, &c. chambers of various capacities muft be provided for the fediment and precipitated matter. With refpect to the oil-trade, the fpace required is very great, efpecially for fpermaceti, or Brafil bottoms. In the various purpofes of the laboratory, no limits can be fixed, but all dimenfions will be occafionally required: in diftilleries and breweries they may be fmaller in proportion; and in that defigned for water and for domeftic ufe, a very fmall chamber will be fufficient. When water is to be fweetened, or freed from any putrid or noxious particles, it paffes, in its way to the filtering chamber, through an iron-box, or cylinder, containing charcoal finely powdered, or any other antifeptic fubftance infoluble in water, the water being forced into it by hydroftatic preffure, through a tube of any fufficient height. This box has two apertures to receive and deliver the fluid, and thefe are opened and clofed by cocks, or fcrews, or any other method ufed for fuch purpofes; and being affixed to the machine by other fcrews, may be eafily detached from the fame. Thus, whenever the charcoal begins to lofe its antifeptic properties, the box is removed and heated till it is red hot; by which means the foreign matter efcapes through the fmall apertures; after which the box is cooled, and the charcoal becomes fweet, pure, and equally fit for ufe as at firft, though the procefs be ever fo often repeated.

Another part of the invention confifts in filtering machines in the form of ftills, in which charcoal may be repeatedly burned after any fluid fubftances have paffed through it, for the purpofe of freeing them either from putrid or noxious particles, or of difcharging their colouring matter; which filtering ftills are fo contrived, that the fluid may pafs through in any quantity, without difplacing the charcoal: the part of the fluid remaining interfperfed among the charcoal, may be driven over by heat, and be employed for many inferior purpofes of the arts or manufactures. Laftly, the heat may be raifed fo as to purify the charcoal, as has been before defcribed in the machines for water. The flue of thofe ftills is fo conftructed that water may be employed to cool them without the lofs of time requifite for their gradually parting with their heat to the furrounding atmofphere, fo as to be fit for a fubfequent operation.

But it was not merely to the purifying of oils and various liquids that Mr Collier turned his attention. To his filtering apparatus are attached inftruments for afcertaining the comparative qualities of oils, which depend in part on the principle of their fpecific gravities; fpermaceti oil, contrafted with other fifh oils, being as 875 to 920. For this purpofe, a glafs veffel of any convenient fhape is made ufe of, furnifhed with a bubble alfo of glafs, and a thermometer. If the oil is pure, this bubble finks, when the mercury rifes to a certain ftandard, by the application of the hand, or any other heat to the veffel containing the oil. If the fpermaceti oil is impure, the bubble will ftill float, though it is of the temperature required; and the degree of impure, or foreign matter, will be fhewn by the ftate of the thermometer at which the bubble finks.

Filter.

To determine what tendency oils ufed for burning have to congeal in cold weather, a freezing mixture is put in a phial of thin glafs, or any other convenient veffel; into this a thermometer is immerfed, and a fingle drop of the oil, under experiment, fuffered to fall on the outfide of the veffel, where it immediately congeals: as the cold produced by the mixture gradually ceafes, it is eafy to obferve by the thermometer at what point of temperature the oil becomes fluid, and runs down the fide of the glafs.

Plate XXIII.

A fhort defcription of this apparatus will make its principles plain to every reader. A (fig. 1.) is the ciftern into which the water or other liquor to be filtered is put. B B is a tube opening into the bottom of the ciftern A, and bent along the bottom of the machine conveying the fluid into CCC the filtering chamber, which is covered with leather bound down round its circular rim, and through which leather the water is percolated. DD, The bafon rifing above the level of the chamber and receiving the filtered liquor. E, The fpout by which it runs off into a pitcher or other veffel. F, Another fpout furnifhed with a cock to draw off the foul water from the chamber when neceffary. GGG, The air tube, which begins above the level of the chamber, is covered with a button, which faves the leather from being cut, and has a fmall lateral aperture for the air to be carried off. This pipe paffes along the bottom and up the fide, and rifing above the level of the water in the ciftern, is there clofed, except a fmall lateral aperture through which the air efcapes. H, A guard or rim with crofs bars put over the leather to keep it from being forced up by the water. It is faftened down by means of two notches on oppofite fides of the guard, by which it locks into two ftaples rivetted into the bottom of the bafon. I, The lid fliding down to cover the water from duft, and fufpended at pleafure by means of KK, two fprings on each tube for that purpofe. LMNO, A cylindrical box containing charcoal, which is connected with the above by means of the tube P, and a continuation of the tube B. LM, The water tube B continued below the charcoal apparatus, fo that the fluid may pafs through the fame into the cylinder, from whence it enters the chambers at P, fo as to be filtered through the leather as before defcribed. RR, Collars which may be unfcrewed at pleafure, fo as to detach the charcoal apparatus whenever the charcoal requires to be purified by heat. SS, Two cocks to direct the fluid through the charcoal cylinder, or immediately into the filtering chamber.

Fig. 2. A, A tub or ciftern containing the oil to be filtered, and fupplying a tube of fufficient height for the hydroftatic preffure to operate. BB, A main tube of wood, tin, leather, or cloth, to which any number of bags, of the fize and fhape of corn facks, or any CC, convenient fize or fhape may be connected. Thefe are bound to DDD, ftraight double iron bars, furnifhed with a hinge at one end and a fcrew at the other, by opening which the bags may be emptied. F, A trough underneath, made to receive the filtered oil from the receivers EEE.

Fig. 3. A, A funnel cafk or ciftern, into which the fluid is put which paffes down. B, A tube fitted into the fame, through which it enters. C, An iron ftill, or ftill of any other fubftance capable of fuftaining heat, full of finely powdered and fifted charcoal, through the head of which the fluid paffes into any receiver. D, A fire-place of any conftruction to drive over the fluid remaining interfperfed among the charcoal, and alfo to purify the charcoal by an increafe of temperature when required. E, A cock to let water into the flues to cool the apparatus for a fubfequent operation.

Fig. 4. The trial glafs with its thermometer.

Fire.

FIRE. See that article *Encycl.* and Caloric and Combustion, *Chemistry-Index* in this *Suppl.*

Extinction of Fire is fometimes a matter of fo much confequence, that every thing which promifes to be effectual for that purpofe is worthy of attention. In the nineteenth number of Mr Nicholfon's Journal of Philofophy, Chemiftry, and the Arts, we have the following compofition for extinguifhing fire, invented by M. Von Aken.

Burnt alum - - - - -	pounds	30
Green vitriol powdered - - -		40
Cinabrefe or red ochre in powder -		20
Potter's clay, or other clay, alfo powdered		200
Water - - - - - - -		630

With 40 meafures of this mixture an artificial fire was extinguifhed under the direction of the inventor by three perfons, which would have required the labour of 20 men and 1500 meafures of common water. Sig. Fabbroni was commiffioned to examine the value of this invention, and found in his comparative trials with engines of equal power, worked by the fame number of men, that the mixture extinguifhed the materials in combuftion in one fixth part lefs time, and three eighths lefs of fluid than when common water was ufed. He obferved, as might indeed have been imagined from the nature of the material, that the flame difappeared wherever the mixture fell, and that the faline, metallic, and earthy matters, formed an impenetrable lute round the hot combuftible matter, which prevented the accefs of the air, and confequently the renewal of the deftructive procefs.

This recipe, Mr Nicholfon informs us, is taken from N° 85. of *Giornale Letterario di Napoli*, in which it was inferted in the form of a letter from Sig. Fabbroni to Sig. D. Luigi Targioni of Naples; and the author of the letter eftimates the price of the compofition at about one halfpenny per pound.

The reafon affigned by Mr Nicholfon for giving this abridged account a place in his valuable work, will be admitted by him and the public as a fufficient reafon for our adopting it into our's. It is, that fuch inventions are worthy of the attention of philofophers and economifts, even though in the firft applications they may prove lefs advantageous than their inventors may be difpofed to think. It is fcarcely probable that this practice in the large way, with an engine throwing upwards of 200 gallons (value about L. 3, 10s.) each minute, would be thought of or adopted, or that a fufficient ftore of the materials would be kept in readinefs; fince at this rate the expenditure for an hour would demand a provifion to the amount of L. 210 fterling. But in country places the procefs, or fome variation of it, might be applied with fufficient profit in the refult; more efpecially if it be confidered that common falt or alum, or fuch faline matter as can be had and mixed with the water, together with clay, chalk, or lime, ochreous earth or common mud, or even thefe laft without any falt, may anfwer the purpofe of the

the lute with more or less effect, and extinguish an accidental fire with much greater speed and certainty than clear water would do.

Fire-Balls are meteors, of which some account has been given in the *Encyclopædia*, as well as of various hypotheses which have been framed respecting their nature and their origin. Since that article was published, a new and very singular hypothesis has been framed by Professor Chladni of Wittenberg, who maintains it by arguments, which, however fanciful, are yet worthy of the reader's notice *.

* Phil. Mag. Nos 5 and 7.

He supposes that fire-balls, instead of being collections of the electrical fluid floating in the highest regions of our atmosphere, are masses of very dense matter formed in far distant parts of space, and subjected to similar laws with the planets and comets. He endeavours to prove that their component parts must be dense and heavy; because their course shews, in so apparent a manner, the effects of gravity; and because their mass, though it distends to a monstrous size, retains sufficient consistency and weight to continue an exceedingly rapid movement through a very large space, without being decomposed or dissolved, notwithstanding the resistance of the atmosphere. It seems to him probable, that this substance is by the effect of fire reduced to a tough fluid condition; because its form appears sometimes round and sometimes elongated, and as its extending till it bursts, as well as the bursting itself, allows us to suppose a previous capability of extension by elastic fluidity. At any rate, it appears to be certain, that such dense matter at so great a height is not collected from particles to be found in our atmosphere, or can be thrown together into large masses by any power with which we are acquainted; that no power with which we are acquainted is able to give to such bodies so rapid a projectile force in a direction almost parallel to the horizon; that the matter does not rise upwards from the earth, but exists previously in the celestial regions, and must have been conveyed thence to our earth. In the opinion of Dr Chladni, the following is the only theory of this phenomenon that agrees with all the accounts hitherto given, which is not contrary to nature in any other respect, and which besides seems to be confirmed by various masses found on the spot where fire-balls fell.

As earthy, metallic, and other particles form the principal component parts of our planets, among which iron is the prevailing part, other planetary bodies may therefore consist of similar, or perhaps the same component parts, though combined and modified in a very different manner. There may also be dense matters accumulated in smaller masses, without being in immediate connection with the larger planetary bodies dispersed throughout infinite space; and which, being impelled either by some projecting power or attraction, continue to move until they approach the earth or some other body, when, being overcome by its attractive force, they immediately fall down. By their exceedingly great velocity, still increased by the attraction of the earth and the violent friction in the atmosphere, a strong electricity and heat must necessarily be excited; by which means they are reduced to a flaming and melted condition, and great quantities of vapour and different kinds of gases are thus disengaged, which distend the liquid mass to a monstrous size, till, by a still farther expansion of these elastic fluids, it must at length burst. Dr Chladni thinks also, that the greater part of the *shooting stars*, as they are called, are nothing else than fire-balls; which differ only from the latter in this, that their peculiarly great velocity carries them past the earth at a greater distance, so that they are not so strongly attracted by it as to fall down; and therefore, in their passage through the high regions of the atmosphere, occasion only a transient electric flash, or actually take fire for a moment, and are again speedily extinguished, when they get to such a distance from the earth that the air becomes too much rarefied for the existence of fire.

The grounds on which Dr Chladni supports this opinion are various relations, well authenticated, of the motions of those meteors, and the phenomena which accompany their bursting. Besides those mentioned in the *Encyclopædia*, he lays a particular stress on the account which he received from *M. Baudin*, Professor of philosophy at Pau, of a remarkable fiery meteor seen in Gascony on the 24th of July 1790. On the evening of that day M. Baudin was in the court of the castle of Marmes with a friend, the atmosphere being perfectly clear, when they suddenly found themselves surrounded by a whitish light, which obscured that of the full moon, then shining with great lustre. On looking upwards, they observed, almost in their zenith, a fire-ball of a larger diameter than the moon, and with a tail equal in length to five or six times the diameter of the body. The ball and the tail were of a pale white colour, except the point of the latter, which was almost as red as blood. The direction of this meteor was from south to north.

"Scarcely (says M. Baudin) had we looked at it for two seconds when it divided itself into several portions of considerable size, which we saw fall in different directions, and almost with the same appearance as the bursting of a bomb. All these different fragments became extinguished in the air; and some of them, in falling, assumed that blood-red colour which I had observed in the point of the tail. It is not improbable that all the rest may have assumed the same colour; but I remarked only those which proceeded in a direction towards Mormes, and which were particularly exposed to my view.

"About two minutes and a half, or three minutes after, we heard a dreadful clap of thunder, or rather explosion, as if several large pieces of ordnance had been fired off together. The concussion of the atmosphere by this shock was so great, that we all thought an earthquake had taken place. The windows shook in their frames, and some of them, which probably were laid to and not closely shut, were thrown open. We were informed next day, that in some of the houses at Houga, a small town about half a mile distant from Mormes, the kitchen utensils were thrown from the shelves; so that the people concluded there had been an earthquake. But as no movement was observed in the ground below our feet, I am inclined to think that all these effects were produced merely by the violent concussion of the atmosphere.

"We proceeded into the garden while the noise still continued, and appeared to be in a perpendicular direction above us. Some time after, when it had ceased, we heard a hollow noise, which seemed to roll along the

the chain of the Pyrenees in echoes, for the diftance of 15 miles. It continued about four minutes, becoming gradually more remote, and always weaker; and at the fame time we perceived a ftrong fmell of fulphur.

"While we were endeavouring to point out to fome perfons prefent the place where the meteor had divided itfelf, we obferved a fmall whitifh cloud, which arofe perhaps from the vapour of it, and which concealed from us the three ftars of the Great Bear, lying in the middle of thofe forming the femicircle. With fome difficulty, however, we could at laft diftinguifh thefe ftars again behind the thin cloud. There arofe, at the fame time, a frefh gentle breeze.

"From the time that elapfed between the burfting of the ball and the explofion which followed, I was inclined to think that the meteor was at the height of at leaft feven or eight miles, and that it fell four miles to the north of Mormes. The latter part of my conjecture was foon confirmed by an account which we received, that a great many ftones had fallen from the atmofphere at Juliac, and in the neighbourhood of Barbotan. One of thefe places lies at the diftance of about four miles to the north of Mormes, and the other at about the diftance of five to the north-northweft."

M. de Carrits Barbotan, the friend who was with the Profeffor in the court and garden of Mormes when the meteor firft attracted their attention, was at Juliac two days afterwards, and confirmed to him the truth of this circumftance. It appeared, likewife, from the account of feveral intelligent perfons, highly worthy of credit, that the meteor burft at a little diftance from Juliac, and that the ftones which fell were found lying in a fpace almoft circular, about two miles in diameter. They were of various fizes. Some were *feen to fall*, which, when found, weighed 18 or 20 pounds, and which had funk into the earth from two to three feet. M. de C. Barbaton tranfmitted one weighing 18 pounds to the Academy of Sciences at Paris; and M. Bandin was told, that fome were found which weighed even 50 pounds. He examined a fmall one, and found it very heavy in proportion to its fize: it was black on the outfide; of a greyifh colour in the infide, and interfperfed with a number of fmall fhining metallic particles. On ftriking it with a piece of fteel, it produced a few fmall dark red fparks, not very lively. A mineralogift, to whom a like piece of ftone from the fame meteor was fhewn at Paris, defcribed it as a kind of grey flag mixed with calcareous fpar, the furface of which exhibited vitrified blackifh calx of iron. The Profeffor was told alfo, that fome ftones were found totally vitrified.

Such (fays Dr Chladni) is the account given by Baudin of this meteor; the phenomena of which he endeavours to explain from accumulations in the upper parts of the atmofphere.

According to all the obfervations hitherto made with any accuracy on fire-balls, the height at which they were firft perceived was always very confiderable, and by comparing the angles under which they were feen from different points, often 19 German miles, and even more; their velocity, for the moft part, feveral miles in a fecond; and their fize always very great, often a quarter of a mile, and even more, in diameter. They were all feen to fall moftly in an oblique direction; not one of them ever proceeded upwards. All of them have appeared under the form of a globular mafs, fometimes a little extended in length, and highly luminous; having behind it a tail, which, according to every appearance, was compofed of flames and fmoke. All of them burft after they were feen to move through a large fpace, fometimes over feveral diftricts, with an explofion which fhook every thing around. In every inftance where there has been an opportunity of obferving the fragments that fell after they burft, and which fometimes have funk to the depth of feveral feet into the earth, they were found to confift of fcorious maffes, which contained iron in a metallic or calcined ftate, pure, or elfe mixed with different kinds of earth and fulphur. All the ancient and modern accounts, written partly by naturalifts and partly by others, are fo effentially fimilar, that the one feems to be only a repetition of the other. This conformity in accounts, the authors of which knew nothing of thofe given by others, and who could have no intereft in fabricating fimilar tales, can fcarcely have arifen from accident or fiction, and gives to the related facts, however inexplicable many of them may feem, every degree of credibility.

In the third volume of Pallas's Travels, we have an account of a mafs of iron difcovered by him in Siberia, which Dr Chladni confiders as having been undoubtedly a fire-ball, or the fragment of a fire-ball. This problematical mafs was found between Krafnojarfk and Abekanfk in the high flate mountains, quite open and uncovered. It weighed 1600 pounds; had a very irregular and fomewhat compreffed figure like a rough granite; was covered externally with a ferruginous kind of cruft; and the infide confifted of malleable iron, brittle when heated, porous like a large fea fponge, and having its interftices filled with a brittle hard vitrified fubftance of an amber yellow colour. This texture and the vitrified fubftance appeared uniformly throughout the whole mafs, and without any traces of flag or artificial fire.

Dr Chladni fhews, with a great deal of ingenuity, that this mafs neither originated by the wet method, nor could have been produced by art, the burning of a foreft, by lightning, or by a volcanic eruption. It appears to him, therefore, in the higheft degree probable, that it is of the fame nature with fire-balls, or, as they have fometimes been called, *flying dragons*. The Tartars, as we are informed by Pallas, confidered this mafs as a facred relic which had dropped down from heaven; and this circumftance Dr Chladni confiders as no flight confirmation of his opinion, which he farther fupports by the following reafonings:

"1. As fire-balls confift of denfe and heavy fubftances, which, by their exceedingly quick movement, and the friction thence excited by the atmofphere, become electric, are reduced to a ftate of ignition, and melted by the heat, fo that they extend to a great fize, and burft; it thence follows, that in places where fragments, produced by the burfting of a fire-ball, have been found, fubftances endowed with all thefe properties muft alfo have been found. Iron, however, the principal component part of all the maffes hitherto found (and he fpeaks of many befides that of Pallas), poffeffes all thefe properties in a very eminent degree. The weight and toughnefs of the principal component parts of fire-balls, which

which muſt be very conſiderable, ſince, with the greateſt poſſible diſtention, they retain conſiſtence enough to proceed with the utmoſt velocity through ſuch an immenſe ſpace without decompoſition of their maſs, and without their progreſs being obſtructed by the reſiſtance of the air, agree perfectly well with melted iron; their dazzling white light has by many obſervers been compared to that of melted iron; iron alſo exhibits the ſame appearances of flaming, ſmoking, and throwing out ſparks, and all theſe phenomena are moſt beautiful when they take place in vital air. Of the extenſion by elaſtic fluids expanded by the heat, and of the contraction which follows from cold, traces may be diſcovered in the internal ſpongy nature of the iron maſſes which have been found, and in the globular depreſſions of the exterior hard cruſt; the latter of which gives us reaſon to ſuppoſe, that in theſe places there have been air-bubbles, which, on cooling, ſunk down. The mixture of ſulphur found in various maſſes, agrees alſo exceedingly well with the phenomena of fire-balls, and eſpecially with the great inflammability of ſulphur in very thin impure air; for it is well known that ſulphur in an air-pump will take fire in air in which few other bodies could do the ſame. In regard to thoſe maſſes in which no ſulphur was found, this may have ariſen from the ſulphur eſcaping in vapour, ſince ſome time after the appearance of fire-balls a ſtrong ſmell of ſulphur has been perceived. The brittleneſs of the Siberian iron maſs when heated, may ariſe from ſome ſmall remains of ſulphur, which may perhaps be the cauſe of the facility with which fragments of this maſs, as well as of another found at Aix-la-Chapelle, could be roaſted.

"2. The whole texture of the maſſes betrayed evident ſigns of fuſion. This, however, cannot have been occaſioned by any common, natural, or artificial fire; and particularly for this reaſon, becauſe iron ſo malleable is not fuſible in ſuch fire, and when it is fuſed with the addition of inflammable matters, loſes its malleability, and becomes like common raw iron. The vitrified ſubſtance in the Siberian maſs is equally incapable of being fuſed in a common fire. The fire, then, muſt have been much ſtronger than that produced by the common, natural, and artificial means; or the fuſion muſt have been effected by the force of exceedingly ſtrong electricity; or perhaps both cauſes may have been combined together.

"3. It is totally incomprehenſible how, on the high ſlate mountains, where the Siberian maſs was found, at a conſiderable diſtance from the iron mines; in the chalky ſoil of the extenſive plains of America, where for a hundred miles around there are no iron mines, and not even ſo much as a ſtone to be found; and at Aix-la-Chapelle, where, as far as the author knows, there are no iron works—ſo many ferruginous particles could be collected in a ſmall ſpace as would be neceſſary to form maſſes of 1600, 15,000, and 17,000, up to 33,600 pounds. This circumſtance ſhews that theſe maſſes could as little have been fuſed by lightning as by the burning of a foreſt or of foſſile coal. Theſe maſſes were found quite expoſed and uncovered, and not at any depth in the earth, where we can much more readily admit ſuch an accumulation of ferruginous particles to have been melted by the effects of lightning.

"Should it be aſked how ſuch maſſes originated, or by what means they were brought into ſuch an inſulated poſition? this queſtion would be the ſame as if it were aſked how the planets originated. Whatever hypotheſes we may form, we muſt either admit that the planets, if we except the many revolutions which they may have undergone, either on or near their ſurface, have always been ſince their firſt formation, and ever will be the ſame; or that Nature, acting on created matter, poſſeſſes the power to produce worlds and whole ſyſtems, to deſtroy them, and from their materials to form new ones. For the latter opinion there are, indeed, more grounds than for the former, as alternations of deſtruction and creation are exhibited by all organiſed and unorganiſed bodies on our earth; which gives us reaſon to ſuſpect that Nature, to which greatneſs and ſmallneſs, conſidered in general, are merely relative terms, can produce more effects of the ſame kind on a larger ſcale. But many variations have been obſerved on diſtant bodies, which, in ſome meaſure, render the laſt opinion probable. For example, the appearing and total diſappearing of certain ſtars, when they do not depend upon periodical changes. If we now admit that planetary bodies have ſtarted into exiſtence, we cannot ſuppoſe that ſuch an event can have otherwiſe taken place, than by conjecturing that either particles of matter, which were before diſperſed through infinite ſpace in a more ſoft and chaotic condition, have united together in large maſſes by the power of attraction; or that new planetary bodies have been formed from the fragments of much larger ones that have been broken to pieces, either perhaps by ſome external ſhock, or by an internal exploſion. Let whichever of theſe hypotheſes be the trueſt, it is not improbable, or at leaſt not contrary to nature, if we ſuppoſe that a large quantity of ſuch material particles, either on account of their too great diſtance, or becauſe prevented by a ſtronger movement in another direction, may not have united themſelves to the larger accumulating maſs of a new world; but have remained inſulated, and, impelled by ſome ſhock, have continued their courſe through infinite ſpace, until they approached ſo near to ſome planet as to be within the ſphere of its attraction, and then by falling down to occaſion the phenomena before mentioned."

Whether Chladni be a philoſopher of the French ſchool we know not; but ſome parts of his theory tend ſtrongly towards materialiſm; and the arguments by which he attempts to prop thoſe parts are peculiarly weak. When he talks of *Nature* producing worlds, he either ſubſtitutes Nature for Nature's God, or utters jargon which has no meaning. In what ſenſe the word Nature is uſed by every philoſopher of a ſound mind, we have elſewhere been at ſome pains to ſhew (ſee River, n° 116. *Encycl.*); but how abſurd would it be to ſay, that the ſyſtem of general laws, by which the Author and Governor of the univerſe connects together its various parts, and regulates all their operations, poſſeſſes, independently of Him, "the power to produce worlds and whole ſyſtems, to deſtroy them, and from their materials to form new ones!"

As Chladni admits, or talks as if he admitted, the creation of matter, it would be wrong to impute to him this abſurdity; but if by *Nature* he means God, and he can conſiſtently mean nothing elſe, we beg leave to affirm, that it is *directly contrary* to every notion which

which we can form of Nature in *this fenfe*, "to fuppofe that a large quantity of material particles, either on account of the *diftance*, or becaufe prevented by a *ftronger movement* in another direction, have not united themfelves to the larger accumulating mafs of a new world, but remained infulated, and impelled by fome fhock, have continued their courfe through infinite fpace, &c." Is there any diftance to which God cannot reach, or any movement fo ftrong as to refift his power? Our author's language is indeed confufed, and probably his ideas were not very clear. When he fpeaks of the particles of matter being at firft difperfed through infinite fpace, and afterwards united by the power of attraction, he revives the queftion which was long ago difcuffed between Newton and Bentley, and difcuffed in fuch a manner as fhould have filenced for ever the bablings of thofe who form worlds by attraction.

"The hypothefis (fays Newton) of matter's being at firft evenly fpread through the heavens, is, in my opinion, inconfiftent with the hypothefis of innate gravity without a fupernatural power to reconcile them; and therefore infers a Deity. For if there be innate gravity, it is impoffible now for the matter of the earth, and all the planets and ftars, to fly up from them, and become evenly fpread through all the heavens, without a fupernatural power; and certainly that which can never be hereafter without a fupernatural power, could never be heretofore without the fame power." Dr Chladni, indeed, does not fay that his particles of matter were *evenly* difperfed through infinite fpace; but fuch muft be his meaning, if he has any meaning: for matter *unevenly* difperfed muft, by an innate attraction, be united as foon as it exifts, and fo united as not to leave fmall fragments of it to wander, we know not why, through the tracklefs void. Turn matter on all fides, make it eternal or of late production, finite or infinite, there can be no regular fyftem produced but by a voluntary and meaning agent; and therefore, if it be true that fire-balls are maffes of denfe matter, coeval with the planetary fyftem, exifting in the celeftial regions, and thence conveyed to our earth, they muft have been formed, and their motions impreffed upon them, by the Author of Nature for fome wife purpofe, though by us that purpofe may never be difcovered. One thing feems pretty clear, that wherever they may be formed, the phenomena attending their burfting, account fufficiently for the notions of thunderbolts which have been generally entertained in all ages, and in every country.

*Greek-*FIRE (fee *Wild-*FIRE, *Encycl.*). In the fecond volume of Mr Nicholfon's Philofophical Journal, we have the following receipt for making this compofition, taken from fome manufcripts of Leonard de Vinci, who flourifhed in the end of the fifteenth and beginning of the fixteenth centuries, and who appears to have advanced far before his contemporaries in phyfical fcience. Take the charcoal of willow, nitre, brandy, refin, fulphur, pitch, and camphor. Mix the whole together over the fire. Plunge a woollen cord in the mixture, and form it into balls, which may afterwards be provided with fpikes. Thefe balls, being fet on fire, are thrown into the enemy's veffels. It is called the Greek fire, and is a fingular compofition, for it burns even upon the water. Callinicus the architect taught this compofition to the Romans (of Conftantinople), who derived great advantage from it, particularly under the emperor Leo, when the Orientals attacked Conftantinople. A great number of their veffels were burned by means of this compofition.

The compofition of the Greek fire thus given by Vincini is found in nearly the fame words in fome of the writings of Baptifta Porta; whence it appears that both authors derived their information from the fame fource. A compofition which burnt without accefs to the atmofphere could not fail to fill the minds of our forefathers with wonder; but the modern difcoveries in chemiftry have difclofed the fecret, by fhewing, that the combuftion is carried on by means of the oxygen contained in the nitre.

Rafant or *Razant* FIRE, is a fire from the artillery and fmall arms, directed parallel to the horizon, or to thofe parts of the works of a place that are defended.

Running FIRE is when ranks of men fire one after another; or when the lines of an army are drawn out to fire on account of a victory; in which cafe each fquadron or battalion takes the fire from that on its right, from the right of the firft line to the left, and from the left to the right of the fecond line, &c.

FISHING, the art of catching fifh. See ANGLING, FISHERY, and FISHING, &c. *Encycl.*

Chinefe FISHING. We venture to give this appellation to fome very ingenious contrivances of the people of China for catching in their lakes, not only fifh, but water-fowl. For the purpofe of catching fifh they have trained a fpecies of pelican, refembling the common corvorant, which they call the *Leu-tze*, or fifhing-bird. It is brown, with a white throat, the body whitifh beneath, and fpotted with brown; the tail is rounded, the irides blue, and the bill yellow. Sir George Staunton, who, when the embaffy was proceeding on the fouthern branch of the great canal, faw thofe birds employed, tells us, that on a large lake, clofe to the eaft fide of the canal, are thoufands of fmall boats and rafts, built entirely for this fpecies of fifhery. On each boat or raft are ten or a dozen birds, which, at a fignal from the owner, plunge into the water; and it is aftonifhing to fee the enormous fize of fifh with which they return, grafped within their bills. They appeared to be fo well trained, that it did not require either ring or cord about their throats to prevent them from fwallowing any portion of their prey, except what their mafter was pleafed to return to them for encouragement and food. The boat ufed by thefe fifhermen is of a remarkable light make, and is often carried to the lake, together with the fifhing birds, by the men who are there to be fupported by it.

The fame author faw the fifhermen bufy on the great lake Wee-chaung-hee; and he gives the following account of a very fingular method practifed by them for catching the fifh of the lake without the aid of birds, of net, or of hooks.

To one fide of a boat a flat board, painted white, is fixed, at an angle of about 45 degrees, the edge inclining towards the water. On moonlight nights the boat is fo placed that the painted board is turned to the moon, from whence the rays of light ftriking on the whitened furface, give to it the appearance of moving water; on which the fifh being tempted to leap as on their element, the boatmen, rifing with a ftring the board, turn the fifh into the boat.

Water-fowl are much fought after by the Chinefe and

Fistula. and are taken upon the same lake by the following ingenious device. Empty jars or gourds are suffered to float about upon the water, that such objects may become familiar to the birds. The fisherman then wades into the lake with one of those empty vessels upon his head, and walks gently towards a bird; and lifting up his arm, draws it down below the surface of the water without any disturbance or giving alarm to the rest, several of whom he treats in the same manner, until he fills the bag he had brought to hold his prey. The contrivance itself is not so singular, as it is that the same exactly should have occurred in the new continent, as Ulloa asserts, to the natives of Carthagena, upon the lake Ciènega de Tesias.

FISTULA Lachrymalis is a disease which, in all its stages, has been treated of in the article Surgery, chap. xiv. *Encycl.* A work, however, has been lately published by James Ware surgeon, in which there is the description of an operation for its cure considerably different from that most commonly used, and which, while it is simple, the author's experience has ascertained to be successful.

In the cure of this disease, which is very troublesome, and not very uncommon, it is a well known practice to insert a metallic tube in the nasal duct of the lachrymal canal: but the advantage derived from this operation is not at all times lasting. Among other causes of failure, Mr Ware notices the lodgment of inspissated mucus in the cavity of the tube. To remedy this defect, he recommends the following operation.

"If the disease has not occasioned an aperture in the lachrymal sac, or if this aperture be not situated in a right line with the longitudinal direction of the nasal duct, a puncture should be made into the sac, at a small distance from the internal juncture of the palpebræ, and nearly in a line drawn horizontally from this juncture towards the nose with a spear-pointed lancet. The blunt end of a silver probe, of a size rather smaller than the probes that are commonly used by surgeons, should then be introduced through the wound, and gently, but steadily, pushed on in the direction of the nasal duct, with a force sufficient to overcome the obstruction in this canal, and until there is reason to believe that it has freely entered into the cavity of the nose. The position of the probe, when thus introduced, will be nearly perpendicular; its side will touch the upper edge of the orbit; and the space between its bulbous end in the nose and the wound in the skin will usually be found, in a full-grown person, to be about an inch and a quarter, or an inch and three-eighths. The probe is then to be withdrawn, and a silver style, of a size nearly similar to that of the probe, but rather smaller, about an inch and three-eighths in length, with a flat head, like that of a nail, but placed obliquely, that it may fit close on the skin, is to be introduced through the duct, in place of the probe, and to be left constantly in it. For the first day or two after the style has been introduced, it is sometimes advisable to wash the eye with a weak saturnine lotion, in order to obviate any tendency to inflammation which may have been excited by the operation; but this in general is so slight, that our author has rarely had occasion to use any application to remove it. The style should be withdrawn once every day for about a week, and afterwards every second or third day. Some warm water should each time be injected through the duct into the nose, and the instrument be afterwards replaced in the same manner as before. Mr Ware formerly used to cover the head of the style with a piece of diachylon plaster spread on black silk, but has of late obviated the necessity for applying any plaster by blackening the head of the style with sealing wax.

Fistula, Flank.

"The effect (says he) produced by the style, when introduced in the way above mentioned, at first gave me much surprise. It was employed with a view similar to that with which Mr Pott recommends the introduction of a bougie; viz. to open and dilate the nasal duct, and thus to establish a passage, through which the tears might afterwards be conveyed from the eye to the nose. I expected, however, that whilst the style continued in the duct the obstruction would remain, and of course that the watering of the eye, and the weakness of the sight, would prove as troublesome as they had been before the instrument was introduced. I did not imagine that any essential benefit could result from the operation until the style was removed, and the passage thereby opened. It was an agreeable disappointment to me to find that the amendment was much more expeditious. The watering of the eye almost wholly ceased as soon as the style was introduced; and in proportion as the patient amended in this respect, his sight also became more strong and useful. The style, therefore, seems to act in a twofold capacity: first, it dilates the obstructed passage; and then, by an attraction somewhat similar to that of a capillary tube, it guides the tears through the duct into the nose.

"The wound that I usually make into the sac, if the supperative process has not formed a suitable aperture in this part, is no larger than is just sufficient to admit the end of the probe or style; and this, in general, in a little time, becomes a fistulous orifice, through which the style is passed without occasioning the smallest degree of pain. The accumulation of matter in the lachrymal sac, which, previous to the operation, is often copious, usually abates soon after the operation has been performed; and, in about a week or ten days, the treatment of the case becomes so easy, that the patient himself, or some friend or servant who is constantly with him, is fully competent to do the whole that is necessary. It consists solely in withdrawing the style two or three times in the week, occasionally injecting some warm water, and then replacing the instrument in the same way in which it was done before.

"It is not easy to ascertain the exact length of time that the style should be continued in the duct. Some have worn it many years, and, not finding any inconvenience from the instrument, are still afraid and unwilling to part from it. Others, on the contrary, have disused it at the end of about a month or six weeks, and have not had the smallest return of the obstruction afterwards."

The author relates so many successful cases of this operation, that we thought it our duty to record his method in this Supplementary volume of our general repository of arts and sciences; for a successful practice, as well in surgery as in physic, must rest on the basis of experience.

Oblique or Second FLANK, or *Flank of the Curtain*, is that part of the curtain from whence the face of the opposite bastion can be seen, being contained between the lines rasant and fichant, or the greater and

and less lines of defence; or the part of the curtain between the flank and the point where the fichant line of defence terminates.

Covered, Low, or *Retired FLANK*, is the platform of the casemate, which lies hid in the bastion, and is otherwise called the *orillon*.

Fichant FLANK, is that from whence a cannon playing, fires directly on the face of the opposite bastion.

Rasant or *Razant FLANK*, is the point from whence the line of defence begins, from the conjunction of which with the curtain the shot only raseth the face of the next bastion, which happens when the face cannot be discovered but from the flank alone.

FLIE or FLY, that part of the mariner's compass on which the thirty-two points of the wind are drawn, and over which the needle is placed, and fastened underneath.

FLOATING BODIES are such as swim on the surface of a fluid, of which the most important are ships, and all kinds of vessels employed in war and in commerce. Every seaman knows of how much consequence it is to determine the stability of such vessels, and the positions which they assume when they float freely and at rest on the water. To accomplish this, it is necessary to state the principles on which that stability and these positions depend; and this has been done with so much ingenuity and science by GEORGE ATWOOD, Esq; F. R. S. in the Philosophical Transactions for the year 1796, that we are persuaded a large class of our readers will thank us for inserting an abstract of his memoir in this place.

A floating body is pressed downwards by its own weight in a vertical line that passes through its centre of gravity; and it is sustained by the upward pressure of a fluid, acting in a vertical line that passes through the centre of gravity of the immersed part; and unless these two lines be coincident, so that the two centres of gravity may be in the same vertical line, the solid will revolve on an axis, till it gains a position in which the equilibrium of floating will be permanent. Hence it appears, that it is necessary, in the first place, to ascertain the proportion of the part immersed to the whole; for which purpose the specific gravity of the floating body must be known; and then it must be determined, by geometrical or analytical methods, in what positions the solid can be placed on the surface of the fluid, so that the two centres of gravity already mentioned may be in the same vertical line when a given part of the solid is immersed under the surface of the fluid. When these preliminaries are settled, something still remains to be done. Positions may be assumed in which the circumstances just recited concur, and yet the solid will assume some other position in which it will permanently float. If a cylinder, *e. g.* having its specific gravity to that of the fluid on which it floats as 3 to 4, and its axis to the diameter of the base as 2 to 1, be placed on the fluid with its axis vertical, it will sink to a depth equal to a diameter and a half of the base; and while its axis is preserved in a vertical position by external force, the centres of gravity of the whole solid and of the immersed part will remain in the same vertical line: but when the external force that sustained it is removed, it will decline from its upright position, and will permanently float with its axis horizontal. If the axis be supposed to be half of the diameter of the base, and be placed vertically, the solid will sink to the depth of three eighths of its diameter; and in that position it will float permanently. If the axis be made to incline to the vertical line, the solid will change its position until it settles permanently with the axis perpendicular to the horizon.

Whether, therefore, a solid floats permanently, or oversets when placed on the surface of a fluid, so that the centre of gravity of the solid and that of the part immersed shall be in the same vertical line, it is said to be in a position of equilibrium; and of this equilibrium there are three species, viz. the equilibrium of stability, in which the solid floats permanently in a given position; the equilibrium of instability, in which the solid, though the two centres of gravity already mentioned are in the same vertical line, spontaneously oversets, unless supported by external force; and the equilibrium of indifference, or the insensible equilibrium, in which the solid rests on the fluid indifferent to motion, without tendency to right itself when inclined, or to incline itself farther.

If a solid body floats permanently on the surface of a fluid, and external force be applied to incline it from its position, the resistance opposed to this inclination is termed the stability of floating. Among various floating bodies, some lose their quiescent position, and some gain it, after it has been interrupted, with greater facility and force than others.

Some ships at sea (*e. g.*) yield to a given impulse of the wind, and suffer a greater inclination from the perpendicular than others. As this resistance to heeling or pitching, duly regulated, has been deemed of importance in the construction of vessels, several eminent mathematicians have investigated rules for determining the stability of ships from their known dimensions and weight, without recurring to actual trial. To this class we may refer Bouguer, Euler, Fred. Chapman, and others; who have laid down theorems for this purpose, founded on a supposition that the inclinations of ships from their quiescent positions are evanescent, or, in a practical sense, very small.

"But ships at sea (says our ingenious author) are known to heel through angles of 10°, 20°, or even 30°; and therefore a doubt may arise how far the rules, demonstrated on the express condition that the angles of inclination are of evanescent magnitude, should be admitted as practically applicable in cases where the inclinations are so great."—"If we admit that the theory of statics can be applied with any effect to the practice of naval architecture, it seems to be necessary that the rules, investigated for determining the stability of vessels, should be extended to those cases in which the angles of inclination are of any magnitude likely to occur in the practice of navigation."

A solid body placed on the surface of a lighter fluid, at the depth corresponding to the relative gravities, cannot change its position by the combined actions of its weight and the pressure of the fluid, except by revolving on some horizontal axis which passes through the centre of gravity: but as many axes may be drawn through this point of the floating body in a direction parallel to the horizon, and the motion of the solid respects one axis only, this axis must be determined by the figure of the body and the particular nature of the case. When this axis of motion, as it is called, is determined, Floating.

termined, and the ſpecific gravity of the ſolid is known, " the poſitions of permanent floating will be obtained, firſt by finding the ſeveral poſitions of equilibrium through which the ſolid may be conceived to paſs, while it revolves round the axis of motion; and ſecondly, by determining in which of thoſe poſitions the equilibrium is permanent, and in which of them it is momentary and unſtable."

Such as we have now briefly ſtated are the general principles on which are founded Mr Atwood's inveſtigations for determining the poſitions aſſumed by homogeneous bodies, floating on a fluid ſurface; and alſo for determining the ſtability of ſhips and of other floating bodies. We cannot farther accompany him in his elucidation of them, in the problems to the ſolution of which they lead, and in the important practical purpoſes of naval architecture to which they are referred. The whole paper, comprehending no leſs than 85 pages, is curious and valuable; it abounds with analytical and geometrical diſquiſitions of the moſt elaborate kind; and it ſerves to enlarge our acquaintance with a ſubject that is not only highly intereſting to the ſpeculative mathematician, but extremely uſeful in its practical application.

With this latter view, the author ſeems to have directed his attention to the various objects of inquiry which this article comprehends. They are ſuch as intimately relate to the theory of naval architecture, ſo far as it depends on the pure laws of mechanics, and they contribute to extend and improve this theory. The union of thoſe principles that are deduced from the laws of motion, with the knowledge which is derived from obſervation and experience, cannot fail to eſtabliſh the art of conſtructing veſſels on its true baſis, and gradually to lead to farther improvements of the greateſt importance and utility. To this purpoſe, the author obſerves, that

" If the proportions and dimenſions adopted in the conſtruction of individual veſſels are obtained by exact geometrical menſurations, and calculations founded on them, and obſervations are made on the performance of theſe veſſels at ſea; experiments of this kind, ſufficiently diverſified and extended, ſeem to be the proper grounds on which theory may be effectually applied in developing and reducing to ſyſtem thoſe intricate, ſubtil, and hitherto unperceived cauſes, which contribute to impart the greateſt degree of excellence to veſſels of every ſpecies and deſcription. Since naval architecture is reckoned amongſt the practical branches of ſcience, every voyage may be conſidered as an experiment, or rather as a ſeries of experiments, from which uſeful truths are to be inferred towards perfecting the art of conſtructing veſſels: but inferences of this kind, conſiſtently with the preceding remark, cannot well be obtained, except by acquiring a perfect knowledge of all the proportions and dimenſions of each part of the ſhip; and ſecondly, by making and recording ſufficiently numerous obſervations on the qualities of the veſſel, in all the varieties of ſituation to which a ſhip is uſually liable in the practice of navigation."

In the valuable miſcellany entitled the *Philoſophical Magazine*, there is a paper on this ſubject by Mr John George Engliſh, teacher of mathematics and mechanical philoſophy; which, as it is not long, and is eaſily underſtood, we ſhall take the liberty to tranſcribe.

" However operoſe and difficult the calculations neceſſary to determine the ſtability of nautical veſſels may, in ſome caſes, be, yet they all depend, ſays this author, upon the four following ſimple and obvious theorems, accompanied with other well-known ſtereometrical and ſtatical principles.

" *Theorem* 1. Every floating body diſplaces a quantity of the fluid in which it floats, equal to its own weight: and conſequently, the ſpecific gravity of the fluid will be to that of the floating body, as the magnitude of the whole is to that of the part immerſed.

" *Theorem* 2. Every floating body is impelled downward by its own eſſential power, acting in the direction of a vertical line paſſing through the centre of gravity of the whole; and is impelled upward by the re-action of the fluid which ſupports it, acting in the direction of a vertical line paſſing through the centre of gravity of the part immerſed: therefore, unleſs theſe two lines are coincident, the floating body thus impelled muſt revolve round an axis, either in motion or at reſt, until the equilibrium is reſtored.

" *Theorem* 3. If by any power whatever a veſſel be deflected from an upright poſition, the perpendicular diſtance between two vertical lines paſſing through the centres of gravity of the whole, and of the part immerſed reſpectively, will be as the ſtability of the veſſel, and which will be poſitive, nothing, or negative, according as the metacentre is above, coincident with, or below, the centre of gravity of the veſſel.

" *Theorem* 4. The common centre of gravity of any ſyſtem of bodies being given in poſition, if any one of theſe bodies be moved from one part of the ſyſtem to another, the correſponding motion of the common centre of gravity, eſtimated in any given direction, will be to that of the aforeſaid body, eſtimated in the ſame direction, as the weight of the body moved is to that of the whole ſyſtem.

" From whence it is evident, that in order to aſcertain the ſtability of any veſſel, the poſition of the centres of gravity of the whole, and of the part immerſed, muſt be determined; with which, and the dimenſions of the veſſel, the line of floatation, and angle of deflection, the ſtability or power either to right itſelf or overturn, may be found.

" In ſhips of war and merchandiſe, the calculations neceſſary for this purpoſe become unavoidably very operoſe and troubleſome; but they may be much facilitated by the experimental method pointed out in the New Tranſactions of the Swediſh Academy of Sciences, firſt quarter of the year 1787, page 48.

" In river and canal boats, the regularity and ſimplicity of the form of the veſſel itſelf, together with the compact diſpoſition and homogeneal quality of the burden, render that method for them unneceſſary, and make the requiſite calculations become very eaſy. Veſſels of this kind are generally of the ſame tranſverſe ſection throughout their whole length, except a ſmall part in prow and ſtern, formed by ſegments of circles or other ſimple curves; therefore a length may eaſily be aſſigned ſuch, that any of the tranſverſe ſections being multiplied thereby, the product will be equal to the whole ſolidity of the veſſel. The form of the ſection ABCD is for the moſt part either rectangular, as in fig. 1. trapezoidal as in fig. 2. or mixtilineal

Plate XXVIII.

Floating.

tilineal as in fig. 3. in all which MM reprefents the line of floatation when upright, and EF that when inclined at any angle MXE; alfo G reprefents the centre of gravity of the whole veffel, and R that of the part immerfed.

"If the veffel be loaded quite up to the line AB, and the fpecific gravity of the boat and burden be the fame, then the point G is fimply the centre of gravity of the fection ABCD; but if not, the centres of gravity of the boat and burden muft be found feparately, and reduced to one by the common method, namely, by dividing the fum of the momenta by the fum of weights, or areas, which in this cafe are as the weights. The point R is always the centre of gravity of the fection MMCD, which, if confifting of different figures, muft alfo be found by dividing the fum of the momenta by the fum of the weights as common. Thefe two points being found, the next thing neceffary is to determine the area of the two equal triangles MXE, MXF, their centres of gravity *o*, *o*, and the perpendicular projected diftance *n n* of thefe points on the water line EF. This being done, through R, and parallel to EF, draw RT = a fourth proportional to the whole area MMCD, either triangle MXE or MXF, and the diftance *n n*; through T, and at right angles to RT or EF, draw TS meeting the vertical axis of the veffel in S the metacentre; alfo through the points G, B, and parallel to ST, draw NGW and BV; moreover through S, and parallel to EF, draw WSV, meeting the two former in V and W; then SW is as the ftability of the veffel, which will be pofitive, nothing, or negative, according as the point S is above, coincident with, or below, the point G. If now we fuppofe W to reprefent the weight of the whole veffel and burden (which will be equal to the fection MMCD multiplied by the length of the veffel), and P to reprefent the required weight applied at the gunwale B to fuftain the veffel at the given angle of inclination; we fhall always have this proportion: as VS : SW : : W : P; which proportion is general, whether SW be pofitive or negative; it muft only, in the latter cafe, be fuppofed to act upward to prevent an overturn.

"In the rectangular veffel, of given weight and dimenfions, the whole procefs is fo evident, that any farther explanation would be unneceffary. In the trapezoidal veffel, after having found the points G and R, let AD, BC be produced until they meet in K. Then, fince the two fections MMCD, EFDC are equal, the two triangles MMK, EFK are alfo equal; and therefore the rectangle EK × KF = KM × KM = $\overline{KM}^2$; and fince the angle of inclination is fuppofed to be known, the angles at E and F are given. Confequently, if a mean proportional be found between the fines of the angles at E and F, we fhall have the following proportions:

"As the mean proportional thus found : fine ∠E : : KM : KF, and as the faid mean proportional : fine ∠F : : KM : KE; therefore ME, MF become known: from whence the area of either triangle MXE or MXF, the diftance *nn*, and all the other requifites, may be found.

"In the mixtilineal fection, let AB = 9 feet = 108 inches, the whole depth = 6 feet = 72 inches, and the altitude of MM the line of floatation 4 feet or 48 inches; alfo let the two curvelinear parts be circular quadrants of two feet, or 24 inches radius each. Then the area of the two quadrants = 904·7808 fquare inches, and the diftance of their centres of gravity from the bottom = 13·8177 inches very nearly; alfo the area of the included rectangle *abie* = 1440 fquare inches, and the altitude of its centre of gravity 12 inches; in like manner, the area of the rectangle AB*cd* will be found = 5184 fquare inches, and the altitude of its centre of gravity 48 inches: therefore we fhall have

Momentum of the two quad.	= 904·7808	×	13·8177	=	12501·98966016
Moment. of the rectan. *abie*	= 1440·	×	12	=	17280·
Moment. of the rectan. AB*cd*	= 5184·	×	48	=	248832·
	7528·7808				278613·98966016

"Now the fum of the momenta, divided by the fum of the areas, will give $\frac{278613\cdot98966016}{7528\cdot7808} = 37\cdot006$ inches, the altitude of G, the centre of gravity of the fection ABCD above the bottom. In like manner, the altitude of R, the centre of gravity of the fection MMCD, will be found to be equal $\frac{123093\cdot98966016}{4936\cdot7808}$ = 24·934 inches; and confequently their difference, or the value of GR = 12·072 inches, will be found.

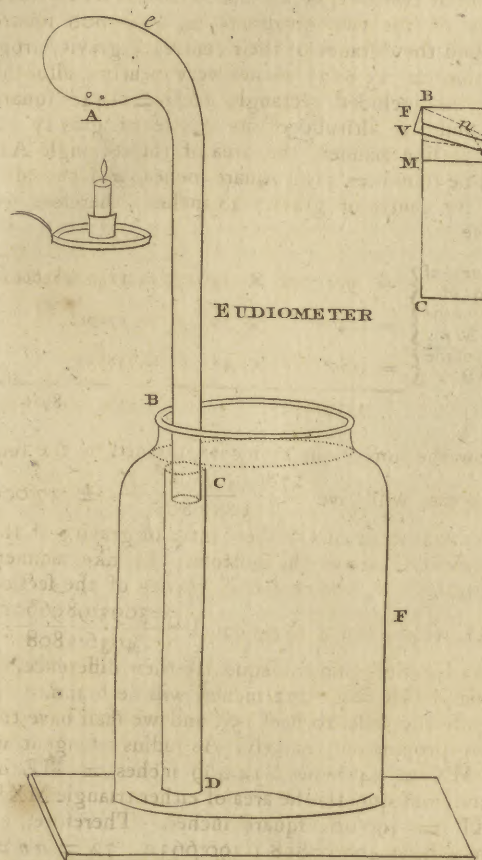
Suppofe the veffel to heel 15°, and we fhall have the following proportion; namely, As radius : tangent of 15° : : MX = 54 inches : 14.469 inches = ME or MF; and confequently the area of either triangle MXE or MXF = 390·663 fquare inches. Therefore, by theorem 4th, as 4936·7808 : 390·663 : : 72 = *nn* = $\frac{2}{3}$ AB : 5·6975 inches = RT; and, again, as radius : fine of 15° : : 12.072 = GR : 3·1245 inches = RN; confequently RT—RN = 5.6975—3·1245 = 2·573 inches = SW, the ftability required.

"Moreover, as the fine of 15° : radius : : 5·6975 = RT : 22·013 = RS, to which, if we add 24·934, the altitude of the point R, we fhall have 46·947 for the height of the metacentre, which taken from 72, the whole altitude, there remains 25·053; from which, and the half width = 54 inches, the diftance BS is found = 59·529 inches very nearly, and the angle SBV = 80°—06′—42″; from whence SV = 58·645 inches.

Again: Let us fuppofe the mean length of the veffel to be 40 feet, or 480 inches, and we fhall have the weight of the whole veffel equal to the area of the fection MMCD = 4936.7808 multiplied by 480 = 2369654·784 cubic inches of water, which weighs exactly 85708 pounds avoirdupois, allowing the cubic foot to weigh 62.5 pounds.

"And, finally, as SV : SW (*i. e.*) as 58·645 : 2·573 : : 85708 : 3760 +, the weight on the gunwale which will fuftain the veffel at the given inclination. Therefore a veffel of the above dimenfions, and weighing 38 tons, 5 cwts. 28 lbs. will require a weight of 1 ton, 13 cwts. 64 lbs. to make her incline 15°.

"In this example, the deflecting power has been fuppofed to act perpendicularly on the gunwale at B; but if the veffel is navigated by fails, the centre velique muft be found; with which, and the angle of deflection, the projected diftance thereof on the line SV may be obtained; and then the power, calculated as above neceffary



EUDIOMETER

necessary to be applied at the projected point, will be that part of the wind's force which causes the vessel to heel. And conversely, if the weight and dimensions of the vessel, the area and altitude of the sails, the direction and velocity of the wind be given, the angle of deflection may be found."

FLUENT, or FLOWING QUANTITY, in the doctrine of fluxions, is the variable quantity which is considered as increasing and decreasing; or the fluent of a given fluxion, is that quantity whose fluxion being taken, according to the rules of that doctrine, shall be the same with the given fluxion. See FLUXIONS, *Encycl.*

FLUIDS (MOTION IN). See HYDROSTATICS and RESISTANCE OF FLUIDS, *Encycl.* and MOTION in this *Supplement*.

FOGEDAR, the military governor of a subordinate district in India, who has sometimes the additional office of collecting the revenues.

FOLIATE, a name given by some to a curve of the 2d order, expressed by the equation $x^3+y^3=axy$, being one species of defective hyperbolas, with one asymptote, and consisting of two infinite legs crossing each other, forming a sort of leaf. It is the 42d species of Newton's Lines of the 3d Order.

FORCER, in mechanics, is properly a piston without a valve. For, by drawing up such a piston, the air is drawn up, and the water follows; then pushing the piston down again, the water, being prevented from descending by the lower valve, is forced up to any height above, by means of a side branch between the two.

FORDYCE (James, D. D.), so well known to serious readers by his sermons to young women, and other specimens of pulpit eloquence, was born at Aberdeen in the year 1720. His father was a man much esteemed, and held, more than once, the office of chief magistrate in his native city; and his mother was a woman of good sense, amiable temper, and exemplary piety. This respectable pair had the singular felicity of transmitting superior talents to almost every individual of a numerous family; of one of which, viz. David Fordyce, the reader will find some account in the *Encyclopædia.*

The subject of this memoir, who was their fourth son, acquired, as well as his brother, the rudiments of classical learning at the grammer school of Aberdeen, whence he was removed to the Marischal college and university in the same city. Having completed a regular course of study both in philosophy and theology, he was licensed, when very young, according to the forms of the church of Scotland, to be a preacher of the gospel; and was soon afterwards preferred to the place of second minister in the collegiate church of Brechin in the county of Angus. After remaining there for some years, he received a presentation to the church of Alloa near Stirling; and though the inhabitants of that parish were prepossessed in favour of another minister whom they knew, and prejudiced against Mr Fordyce whom they did not know; so narrow minded and totally destitute of taste was his colleague in Brechin, that he judged it expedient to hazard the consequences of a removal. He was aware that he entered on his new charge under a considerable degree of popular odium; but he thought it more probable that he should be able to overcome that odium, than conciliate the affections of a sour fanatic. In this expectation he was not deceived. The prejudices of the good people in Alloa were very quickly removed, not more by the able and impressive manner in which he conducted the public services of the Lord's day, than by the amiable and condescending spirit with which he performed the more private duties of visiting and catechising in the different districts of his parish; duties which, as they were wont to be performed by the Scotch clergy, contributed much more than preaching to the religious instruction of the lower classes of the people.

It was during his residence at Alloa that Mr Fordyce first distinguished himself as an author by the successive publication of the three following sermons. The first, upon the eloquence of the pulpit, was annexed to "the Art of Preaching" by his brother David; the second, upon the methods of promoting edification by public institutions, was preached at the ordination of the Rev. Mr Gibson minister of St Ninian's, a neighbouring parish, in the year 1754, and published, with the charge and notes, in 1755; and the third, upon the delusive and persecuting spirit of popery, was preached the same year before the synod of Stirling and Perth; and being published, came very quickly to a second edition. But the sermon which most strongly arrested the attention, both of the audience before which it was delivered, and of the public to which, in 1760, it was given from the press, was that on the *folly, infamy, and misery of unlawful pleasure*, preached before the General Assembly of the Church of Scotland. The choice of such a subject, on such an occasion, excited the surprise of all his hearers, and tempted the younger part of them to smile at the very reading of the text; but this unseasonable mirth was soon converted into seriousness. The picture exhibited in this sermon is the work of a master; and we have been assured by a friend who heard it preached, that the spirit and elegance of the composition was so seconded by the solemnity and animation with which it was delivered, that it made a very striking impression, not only upon the more respectable part of the audience, but upon minds of noted levity: It raised indeed its writer's fame as a pulpit orator to an unrivalled eminence among his brethren in Scotland.

About this time, and we believe in consequence of this sermon, Mr Fordyce received from the university of Glasgow a diploma, creating him Doctor in Divinity; and if there is yet any thing honourable in academical degrees, prostituted as they have long been by an undistinguishing distribution, the honour could not have been conferred with greater propriety on any man in the church to which he then belonged.

In that church he did not long remain. Soon after the publication of this singular sermon, and his consequent acquisition of academical honours, he accepted of an invitation from a society of Protestant dissenters, who had their place of meeting in Monkwell-street, London, to become colleague and successor to their pastor, who was then old and infirm, and who died, indeed, in the space of a few months. This gave occasion to the Doctor to display his oratory once more both from the pulpit and the press in a sermon on the death of Dr Lawrence. He was now sole pastor to

Fordyce.

the congregation of Monkwell-ſtreet; and preached for many years with great powers of eloquence and fervour of piety, to an audience always crowded and often overflowing.

When a preacher obtains, with or without merit, an uncommon ſhare of popularity, a conſiderable proportion of his hearers will ever conſiſt of thoſe, who are guided in their choice rather by curioſity and faſhion, than by ſound judgment. The attachments of ſuch people are as capricious and variable as their minds; and they change their preacher as they change their dreſs, not from their own taſte, for in general they have none; but from the deſire of being where others are, of doing what others do, and of admiring what others admire. Dr Fordyce appreciated juſtly the value of ſuch mens approbation, and knew it eventually by experience; but he was more than compenſated for the loſs of hearers of this deſcription by the ſteady adherence of others, whoſe eſteem was moſt deſirable, becauſe it was grounded upon the dictates of a ſound underſtanding.

At laſt, about Chriſtmas 1782, when his health, which had long been declining, rendered it neceſſary, in his own opinion, and in the opinion of his phyſicians, to diſcontinue his public ſervices, he reſigned his charge in Monkwell-ſtreet, and retired to a villa in Hampſhire, in the neighbourhood of the Earl of Bute, who honoured him with his friendſhip, and to whoſe valuable library he had free acceſs. Afterwards he removed to Bath, where having, with Chriſtian patience, ſuffered much from an aſthmatic complaint, to which he had been ſubject for ſome years, on the 1ſt of October 1796 he expired without a groan.

Were we to hazard an opinion of Dr Fordyce's intellectual powers from ſuch a peruſal of his works as we muſt acknowledge to have been haſty, we would ſay that he was a man of genius rather than of judgment; that his imagination was the predominant faculty of his mind; and that he was better fitted, by an addreſs to the paſſions, to enforce the practice of virtue, than, by the exertions of his own underſtanding, to vindicate ſpeculative truth, or to detect the ſophiſtry of error. From this remark, we cannot be ſuſpected of a wiſh to leſſen his character in the public eſteem; for his talents, as they appear to us, are ſurely of more value to a preacher than thoſe which are perhaps better adapted to literary or ſcientific purſuits. In none of his works indeed do we perceive any evidence either of profound ſcience, or of various erudition; though we doubt not but thoſe works are every thing which their author intended them to be. Of his ſermons to young women, which have attracted moſt general notice, it would be preſumptuous in us to give a character; for though we ſat down many years ago to read them, we could not get through; and we have never made a ſecond attempt. As far as we can depend upon what we recollect of theſe far-famed diſcourſes, the cenſure paſſed on them by Mrs Wolſtoncraft ſeems to be juſt. Their author, however, was certainly qualified to excel, and actually did excel as a preacher. We have already mentioned with approbation three or four of his occaſional ſermons; but perhaps the fineſt ſpecimen of pulpit oratory which ever fell from his pen, is the charge which he delivered at the ordination of his ſucceſſor in the meeting of Monkwell-ſtreet. It is indeed one of the moſt valuable diſcourſes of the kind that we have ſeen, and ſhould be read with attention by every clergyman of every denomination, who wiſhes to diſcharge his duty with credit to himſelf and with advantage to his people.

Fordyce, Formula.

The effect of Dr Fordyce's addreſſes from the pulpit was much heightened, not only by an action and an elocution, which he ſtudied with care and practiſed with ſucceſs; but by the figure of his perſon, which was peculiarly dignified, and by the expreſſion of his countenance, which was animated at all times, but animated moſt of all when lighted up by the ardour of his ſoul in the ſervice of God. By ſome of his hearers, it was obſerved that, on many occaſions, he ſeemed not merely to ſpeak, but to look conviction to the heart. His eye, indeed, was particularly bright and penetrating, and he had carefully attended to the effect which an orator may often produce upon an audience by the judicious uſe of that little, but invaluable organ.

With reſpect to his theological ſentiments, we are aſſured (A), they were in no extreme, but liberal, rational, and manly. He ſeems to have been untainted by that rage of innovation, which of late has ſo completely disfigured the creed, as well religious as political, of the great body of Engliſh diſſenters. The conſequence was, that he lived on terms of friendſhip with men of very oppoſite ſentiments; with Price a republican and Arian, and with Johnſon, who, though he hated a whig and a Preſbyterian, reſpected talents and worth wherever he found them.

We ſhall conclude this ſhort ſketch of Dr Fordyce's life and character with the following liſt of his works, of which ſome have been tranſlated into ſeveral languages. 1. A Sermon and Charge, at the ordination of the Rev. Mr Gibſon Miniſter of St Ninian's, 1754. 2. Another Ordination Sermon on the Eloquence of the Pulpit, annexed to his brother's "Art of Preaching," 1754. 3. A Sermon on the Spirit of Popery, 1754. 4. A Sermon on the Folly, Infamy, and Miſery of Unlawful Pleaſure, 1760. 5. A Sermon on the Death of Dr Lawrence, 1760. 6. Sermons to Young Women, 2 vols. 1765. 7. A Sermon on the Character and Conduct of the Female Sex, 1776. 8. Addreſſes to Young Men, 2 vols. 1777. 9. A Charge at the Ordination of the Rev. James Lindſay, in Monkwell-ſtreet, 1783. 10. FORMULA, a theorem or general rule or expreſſion, for reſolving certain particular caſes of ſome problem, &c. So $\frac{1}{2}s + \frac{1}{2}d$ is a general formula for the greater of two quantities whoſe ſum is s and difference d; and $\frac{1}{2}s - \frac{1}{2}d$ is the formula, or general value, for the

(A) By his ſucceſſor in Monkwell-ſtreet, to whoſe ſermon, preached on occaſion of the Doctor's death, our readers are indebted for every thing valuable in this ſhort memoir.

the less quantity. Also $\sqrt{dx - x^2}$ is the formula, or general value of the ordinate to a circle, whose diameter is d, and abscis x.

FORSTER (John Reinhold, LL. D.) professor of natural history in the university of Halle, member of the academy of sciences at Berlin, and of other learned societies, was born at Dirschau, in West Prussia, in the month of October 1729, and was formerly a Protestant clergyman at Dantzick. He had a numerous family, and the emoluments of his office were slender. He therefore quitted Dantzick, and went, first to Russia, and thence to England, in quest of a better settlement than his own country afforded. In the dissenting academy at Warrington he was appointed tutor in the modern languages, with the occasional office of lecturing in various branches of natural history. For the first department he was by no means well qualified; his extraordinary knowledge of languages, ancient and modern, being unaccompanied by a particle of taste; and his use of them being all barbarous, though fluent. As a natural historian, a critic, geographer, and antiquary, he ranked much higher; but unfortunately these were acquisitions of little value in his academical department.

At length he obtained the appointment of naturalist and *philosopher* (if the word may be so used) to the second voyage of discovery undertaken by Capt. Cook; and from 1772 to 1775 he accompanied that immortal navigator round the world. On his return he resided in London till the improper conduct of himself and his son made it expedient for them both to leave the kingdom. Fortunately he received an invitation to Halle, where, for 18 years, he was a member of the philosophical and medical faculties. Among his works are: An Introduction to Mineralogy, or, An accurate Classification of Fossils and Minerals, &c. London, 1768, 8vo. A Catalogue of the Animals of North America, with short Directions for collecting, preserving, and transporting all kinds of Natural Curiosities, London, 1771, 8vo. Observations made during a Voyage round the World, on Physical Geography, &c. London, 1778. He was the author of a great many productions in English, Latin, or German, and of several papers in the Philosophical Transactions. He translated into English, Bougainville's Voyage round the World, and Kalm's, Bossu's, and Reidsel's Travels. He was employed likewise, when in England, in the Critical Review; and he wrote various detached papers on different subjects, which have been inserted in foreign journals and the transactions of learned academies.

He died at Halle on the 16th of December 1798, in the 70th year of his age.

FORSTER (George), the son of the preceding, was born at Dantzick, and accompanied his father to England when he was about twelve years of age. He was entered a student in the academy at Warrington, and soon acquired a very perfect use of the English tongue. He also distinguished himself greatly by his attainments in science and literature in general; adding to an excellent memory, quick parts and a fertile imagination. His temper was mild and amiable; in which he much differed from his father, one of the most quarrelsome and irritable of men; by which disposition, joined to a total want of prudence in common concerns, he lost almost all the friends his talents had acquired him, and involved himself and family in perpetual difficulties.

The case was very different with the subject of this memoir; for when Dr Forster was appointed naturalist to Captain Cook, his son, through the interest of the friends whom his good nature had made, was associated with him in his office. The voyage continued during the space of three years; and on their return the two Forsters published jointly a botanical work in Latin, containing the characters of a number of new *genera* of plants, discovered by them in their circumnavigation. Thus far they acted properly in the service of government for the advancement of science; but in publishing another work their conduct was not proper.

The father had come under an engagement not to publish separately, from the authorised narrative, any account of the voyage; and this engagement he and his son were determined to violate. An account of the voyage, therefore, was published in English and German by *George;* and the language, which is correct and elegant, was undoubtedly his; but those who knew both him and his father, are satisfied that the matter proceeded from the joint stock of their observations and reflections. Several parts of the work, and particularly the elaborate investigations relative to the languages spoken by the natives of the South Sea Islands, and the speculations concerning their successive migrations, are thought to be strongly impressed with the genius of the elder Forster.

That a work thus surreptitiously ushered into the world was not patronised by those with whom the authors had so ungratefully broken faith, could excite no wonder, even though the publication itself had been otherwise unexceptionable; but this was far from being the case. It abounds with reflections injurious to the government whose servants they had been, and not just to the navigators employed on voyages of discovery. The younger Forster, too, had some time before published a book replete with factious sentiments; and the coldness with which he and his father were both treated in consequence of such conduct, determined them to leave London.

We have already related all that we know of the father, who was recommended to our notice only by his connection with the illustrious Cook; and of the son, there is a short account in the Monthly Magazine, by Charles Pougens, fraught with those impious and seditious reflections which so frequently disgrace a miscellany, which would otherwise be highly valuable. According to this author, George Forster was desirous to settle in France. Avaricious of glory, and an idolator of liberty, Paris was the city most suitable to his taste and character of any in Europe. Notwithstanding this, he was soon constrained to leave it: the interest of his family demanded this sacrifice; for a learned man, who sails round the world, may enrich his memory, but he will not better his fortune. He was accordingly obliged to accept the place of professor of natural history in the university of Cassel. But his factious spirit accompanied him whithersoever he went. It is well known, that the petty princes of Germany have long been in the practice of hiring out their troops to more opulent sovereigns engaged in war. This practice, which we are not disposed to defend, not only scandalized our Cosmopolite, but so irritated

ritated his temper and offended his pride, becaufe, forfooth, the Prince of Heffe-Caffel would not by *him* be perfuaded to relinquifh it, that he did every thing in his power, we are told, to withdraw himfelf from a fituation fo unfuitable to a thinking being. Every thing in his power! Did the Prince retain him in the univerfity contrary to his inclination? The univerfity of Caffel muft be contemptible indeed, if the prelections of fuch a man as George Forfter were of fuch confequence to it.

He got away, however; and the fenate of Poland having offered him a chair in the univerfity of Wilna, Forfter accepted of the invitation. But although this office was very lucrative, and the enlightened patriots of that country did not neglect to procure him all the literary fuccours of which he ftood in need, he could not be long happy in a femi-barbarous nation, in which liberty was fuffered to expire under the intrigues of Ruffia and Pruffia.

On this, with wonderful confiftency, the man who could not endure the defpotifm of Heffe, or even the ariftocracy of England, accepted of the propofitions of that friend to liberty Catharine II.; who, jealous of every fpecies of glory, wifhed to fignalize her reign, by procuring to the Ruffian nation the honour of undertaking, after the example of England and France, a new voyage of difcovery round the world. Unfortunately for the progrefs of knowledge, the war with the Ottoman Porte occafioned the mifcarriage of this ufeful project.

But Forfter could not long remain in obfcurity. The different publications with which he occafionally enriched natural hiftory and literature, encreafed his reputation. The Elector of Mentz accordingly appointed him prefident of the univerfity of the fame name; and he was difcharging the functions of his new office when the French troops took poffeffion of the capital. This philofophical traveller, who had ftudied fociety under all the various afpects arifing from different degrees of civilization; who had viewed man fimple and happy at Otaheite;—an eater of human flefh in New Zealand, corrupted by commerce in England, depraved in France by luxury and atheifm, in Brabant by fuperftition, and in Poland by anarchy;—beheld with wild enthufiafm the dawnings of the French revolution, and was the firft, fays M. Pougens, to promulgate republicanifm in Germany.

The *Mayencois*, who had formed themfelves into a national convention, fent him to Paris, in order to folicit their *reunion* with the French republic. But, in the courfe of his miffion, the city of Mentz was befieged and retaken by the Pruffian troops. This event occafioned the lofs of all his property; and what was ftill more difaftrous, that of his numerous manufcripts, which fell into the hands of the Prince of Pruffia.

Our biographer, after conducting his hero through thefe fcenes of public life, proceeds to give us a view of his domeftic habits and private principles. He tells us, that he formed a connection (whether a marriage or not, the ftudied ambiguity of his language leaves rather uncertain) with a young woman named *Therefa Hayne*, who, by the illumination of French philofophy, had divefted herfelf of all the prejudices which, we truft, the ladies of this country ftill confider as their honour, as they are certainly the guardians of domeftic peace. Mifs Hayne was indignant at the very *name of duty*. With Eloifa fhe had taken it into her head that

> Love, free as air, at fight of human ties,
> Spreads his light wings, and in a moment dies.

She was frank enough, however, fays our author, to acknowledge the errors of her imagination; and from this expreffion, and his calling her afterwards Forfter's wife, we are led to fuppofe that fhe was actually married to him. But their union, of whatever kind, was of fhort duration. Though the lady is faid to have been paffionately attached to celebrated names, the *name* of George Forfter was not fufficient to fatisfy her. He foon ceafed, we are informed, to *pleafe* her; fhe therefore transferred her affections to another; and, as was very natural for a woman who was indignant at the name of duty, fhe proved falfe to her hufband's bed. Forfter, however, pretended to be fuch a friend to the *modern* rights of men and women, that he defended the character of his Therefa againft crowds who condemned her conduct. Nay, we are told, that he confidered himfelf, and every other hufband who ceafes to pleafe, as the *adulterer of nature*. He therefore laboured ftrenuoufly to obtain a divorce, to enable Therefa Hayne to efpoufe the man whom fhe preferred to himfelf. Strange, however, to tell, the prejudices even of this Cofmopolite were too ftrong for his principles. While he was endeavouring to procure the divorce, he made preparations at the fame time, by the ftudy of the oriental languages, to undertake a journey to Thibet and Indoftan, in order to remove from that part of the world, in which both his heart and his perfon had experienced fo fevere a fhock. But the chagrin occafioned by his misfortunes, joined to a fcorbutic affection, to which he had been long fubject, and which he had contracted at fea during the voyage of circumnavigation, abridged his life, and prevented him frem realifing this double project. He died at Paris, at the age of 39, on the 13th of February 1792.

This is a ftrange tale; but we truft it will not prove ufelefs. The latter part of it at leaft fhows, that when men diveft themfelves of the principles of religion, they foon degenerate from the dignity of philofophers to the level of mere fenfualifts; and that the woman who can, in defiance of decorum and honour, transfer her affections and her perfon from man to man, ranks no higher in the fcale of being than a female brute of more than common fagacity. It fhews likewife, that the contempt of our modern fages for thofe partial attachments which unite individuals in one family, is a mere pretence; that the dictates of nature will be heard; and the laws of nature's God obeyed. George Forfter, though he was fuch a zealous advocate for liberty and equality, as to vindicate the adultery of his wife; yet felt fo fenfibly the wound which her infidelity inflicted on his honour, that he could not furvive it, but perifhed, in confequence, in the flower of his age.

Royal FORT, is one whofe line of defence is at leaft 26 fathoms long.

Star Fort, is a fconce or redoubt, conftituted by reentering and faliant angles, having commonly from five to eight points, and the fides flanking each other.

FOSSIL-Meal, otherwife called *lac lune*, mineral argaric, Fossil, Foulahs.

argaric, and guhr, is, according to M. Fabbroni, a mixed earth, which exhales an argillaceous odour, and throws out a light whitish smoke when sprinkled with water. It is abundant in Tuscany, where it is employed for cleaning plate. It does not effervesce with acids; is infusible in the fire, in which it loses an eighth part of its weight, though it becomes scarcely diminished in bulk; and, according to the analysis made by M. Fabbroni, consists of the following component parts: Siliceous earth 55, magnesia 15, water 14, argil 12, lime 3, iron 1. With this earth, which is found near Casteldelpiano in the territories of Sienna, M. Fabbroni composed bricks, which, either baked or unbaked, floated in water. Hence he infers, that the floating bricks, which Pliny mentions as peculiar to Massilua and Calento, two cities in Spain, must have been made of fossil meal. Bricks made of that substance resist water exceedingly well, and unite perfectly with lime; they are subject to no alteration either by heat or cold; and about a twentieth part of argil may be added with advantage to their composition, without depriving them of the property of floating. M. Fabbroni tried their resistance, and found it very little inferior to that of common bricks; but it is much greater in proportion to their lightness. One of these bricks, seven inches in length, four and a half in breadth, and one inch eight lines in thickness, weighed only 14¼th ounces; whereas a common brick weighed 5 pounds 6¾ths ounces.

Bricks of fossil-meal may be of important benefit in the construction of reverberating furnaces; as they are such bad conductors of heat, that a person may bring one half of them to a red heat, while the other is held in the hand. They may be employed also for buildings that require to be light; for constructing cooking places on board ships; and also floating batteries, the parapets of which, if made of these bricks, would be proof against red hot bullets; and, lastly, for constructing powder magazines.

FOULAHS, or Foolahs, a people in Africa, inhabiting a country on the confines of the great desert (see Sahara in this *Suppl.*), along the parallel of nine degrees north. They partake much of the negro form and complexion; but have neither the *jetty* colour, *thick* lips, nor *crisped* hair of the negroes. They have also a language distinct from the Mandinga, which is the prevailing one in this quarter. The Foulahs occupy, at least as sovereigns, several provinces or kingdoms, interspersed throughout the tract comprehended between the mountainous border of the country of Sierra Leona on the west, and that of Tombuctoo on the east; as also a large tract on the lower part of the Senegal river; and these provinces are insulated from each other in a very remarkable manner. Their religion is Mahomedanism; but with a great mixture of Paganism, and with less intolerance than is practised by the Moors.

The principal of the Foulah states is that within Sierra Leona; and of which Teemboo is the capital. The next in order appears to be that bordering on the south of the Senegal river, and on the Jaloffs; this is properly named Siratik. Others of less note are Bondon, with Foota-Torra adjacent to it, lying between the rivers Gambia and Falemé; Foola-doo and Brooko along the upper part of the Senegal river; Wassela beyond the upper part of the Niger; and Massina lower down on the same river, and joining to Tombuctoo on the west.

Foulahs, Francais.

The kingdom of the Foulahs, situated between the upper part of the Gambia river and the coast of Sierra Leona, and along the Rio Grande, is governed by a Mahometan sovereign; but the bulk of the people appear to be Pagans. From the circumstances of their long hair, their lips, and comparatively light colour, Major Rennel is decidedly of opinion, that the Foulah's are the Leucæthiops of Ptolemy and Pliny. The former, as he observes, places the Leucæthiops in the situation occupied by the Foulahs; and by the name which he gave them, he evidently meant to describe a people *less* black than the generality of the Ethiopians. Hence it may be gathered that this nation had been traded with, and that some notices respecting it had been communicated to Ptolemy. It may also be remarked, that the navigation of Hanno terminated on this coast; and as this was also the term of Ptolemy's knowledge, it may justly be suspected that this part of the coast was described from Carthaginian materials.

Those who have perused the Journal of Messrs Watt and Winterbottom through the Foulah country in 1794, and recollect how flattering a picture they give of the urbanity and hospitality of the Foulah's, will be gratified on finding that this nation was known and distinguished from the rest of the Ethiopians at a remote period of antiquity.

The contrast between the Moorish and Negro characters is as great as that between the nature of their respective countries, or between their form and complexion. The Moors appear to possess the vices of the Arabs without their virtues; and to avail themselves of an intolerant religion, to oppress strangers: whilst the Negroes, and especially the Mandingas, unable to comprehend a doctrine that substitutes opinion or belief for the social duties, are content to remain in their humble state of ignorance. The hospitality shewn by these good people to Mr Park, a destitute and forlorn stranger, raises them very high in the scale of humanity: and I know of no fitter title, says Mr Rennel, to confer on them than that of the *Hindoos of Africa*; at the same time, by no means intending to degrade the Mahomedans of India by a comparison with the African Moors.—See *Major Rennels Geographical Illustrations of Mr Park's Journey, and of North Africa at large*, printed for the African Association.

FRANCAIS (Port des), the name given by Perouse to a bay, or rather harbour, which he undoubtedly discovered on the north-west coast of America. It is situated, according to him, in 58° 37′ N. Lat. and in 139° 50′ W. Long. from Paris. When the two frigates which he commanded approached it, as they were stretching along the coast from south to north, he perceived from his ship a great reef of rocks, behind which the sea was very calm. This reef appeared to be about three or four hundred toises in length from east to west, and to be terminated, at about two cables length, by the point of the continent, leaving a pretty large opening; so that Nature seemed to have made, at the extremity of America, a harbour like that of Toulon, only more vast in her designs and in her means: this new harbour was three or four leagues deep.

Some officers, who had been dispatched in boats to reconnoitre this harbour, gave a report of it extremely favourable;

Francais. favourable; and on the 3d of July 1786, the two frigates entered it, and anchored near its mouth in three fathoms and a half, rocky bottom. The bay, however, was quickly founded, and much better anchoring ground discovered at an island in the middle of it, where the ships might ride in 20 fathoms water with muddy bottom. This ground was taken possession of, an observatory erected on the island, which was only a musket shot from the ships, and a settlement formed for their stay in the harbour. From a report made by one of the officers who had penetrated towards the bottom of the bay, Perouse had conceived the idea of finding perhaps a channel by which he might proceed into the interior of America; but he was disappointed. The bottom of the bay, indeed, according to him, is one of the most extraordinary places in the world. It is a bason of water, of a depth in the middle that could not be fathomed, bordered by peaked mountains of an excessive height, covered with snow, without a blade of grass upon this immense collection of rocks, condemned by Nature to perpetual sterility. "I never (says he) saw a breath of air ruffle the surface of this water; it is never troubled but by the fall of enormous pieces of ice, which continually detach themselves from five different glaciers, and which in falling make a noise that resounds far in the mountains. The air is in this place so very calm, and the silence so profound, that the mere voice of a man may be heard half a league off, as well as the noise of some sea birds which lay their eggs in the cavities of these rocks."

It was at the extremity of this bay that he was in hopes of finding a passage into the interior of America. He imagined that it might terminate in a great river, of which the course might lie between two mountains; and that this river might take its source in the great lakes to the northward of Canada. Two channels were indeed found, stretching, the one to the east, and the other to the west; but both were very soon terminated by immense glaciers.

In Port des Français the variation of the compass is 28° east, and the dip of the needle 74°. The sea rises there seven feet and a half at full and change of the moon, when it is high water at one o'clock. The sea breezes, or perhaps other causes, act so powerfully upon the current of the channel, that M. Perouse saw the flood come in there like the most rapid river; while, in other circumstances, at the same period of the moon, it may be stemmed by a boat. In this channel he lost two shallops and twenty men. In his different excursions, he found the high water mark to be about 15 feet above the surface of the sea. These tides are probably incident to the bad season. When the winds blow with violence from the southward, the channel must be impracticable, and at all times the currents render the entrance difficult; the going out of it also requires a combination of circumstances, which may retard the departure of a vessel many weeks; there is no getting under way but at the top of high water; the breeze from the west to the north-west does not often rise till toward eleven o'clock, which does not permit the taking advantage of the morning tide; finally, the easterly winds, which are contrary, appeared to him to be more frequent than those from the west, and the vast height of the surrounding mountains never permits the land breezes, or those from the north, to penetrate into the road. Francais.

As this port possesses great advantages, M. Perouse thought it a duty incumbent on him to make its inconveniences also known. It seemed to him that this anchorage is not convenient for those ships which are sent out at a venture for trafficking in skins; such ships ought to anchor in a great many bays, and always make the shortest stay possible in any of them; because the Indians have always disposed of their whole stock in the first week, and all lost time is prejudicial to the interests of the owners: but a nation which should form the project of establishing factories similar to those of the English in Hudson's Bay, could not make choice of a place more proper for such a settlement. A simple battery of four heavy cannon, placed upon the point of the continent, would be fully adequate to the defence of so narrow an entrance, which is also made so difficult by the currents. This battery could not be turned or taken by land, because the sea always breaks with such violence upon the coast, that to disembark is impossible. The fort, the magazines, and all the settlements for commerce, should be raised upon Cenotaph Island (A), the circumference of which is nearly a league: it is capable of being cultivated, and there is plenty of wood and water. The ships not having their cargo to seek, but being certain of having it collected to a single point, would not be exposed to any delay: some buoys, placed for the internal navigation of the bay, would make it extremely safe and easy. The settlement would form pilots, who, better versed than we are in the set and strength of the current at particular times of tide, would ensure the entrance and departure of the ships. Finally, continues the author, our traffic for otters skins has been so very considerable, that I may fairly presume there could not, in any part of America, be a greater quantity of them collected.

The climate of this coast seemed to Perouse much milder than that of Hudson's Bay in the same latitude. Pines were measured of six feet diameter, and 140 high; while those of the same species at Prince of Wales's Fort and Fort York, are of a dimension scarce sufficient for studding sail-booms. Vegetation is also very vigorous during three or four months of the year; and our author thinks, that Russian corn, as well as many common plants, might thrive exceedingly at Port des Français, where was found great abundance of celery, lupine, the wild pea, yarrow, and andive. Among these pot herbs were seen almost all those of the meadows and mountains of France; such as the angelica, the butter cup, the violet, and many species of grass proper for fodder. The woods abound in gooseberries, raspberries, and strawberries; clusters of elder trees, the dwarf willow, different species of briar which grow in the shade, the gum poplar tree, the poplar, the sallow, the horn-beam; and, finally, superb pines, fit for the masts

(A) This name was given to the island in the bay from the monument erected on it to the memory of their unfortunate companions.

Francais. masts of our largest ships. Not any of the vegetable productions of this country are unknown in Europe. M. de Martinière, in his different excursions, met with only three plants which he thought new; and it is well known, that a botanist might do the same in the vicinity of Paris.

The rivers were filled with trout and salmon; and as the Indians sold these fish to the French in greater quantities than they could consume, they had very little fishing in the bay, and that only with the line. They caught some ling, a single thornback, some plaice, *fletans* or *faitans*, of which some were more than 100 pounds in weight (B), and a fish resembling the whiting, but a little larger, which abounds on the coast of Provence, where it is known by the name of *poor priest*. Perouse calls these fish *capelans*. In the woods they met with bears, martens, and squirrels; but they saw no great variety of birds, though the individuals were very numerous.

"If the animal and vegetable productions of this country resemble those of a great many others, its appearance (says our author) can be compared to nothing. The views which it presents are more frightful than those of the Alps and the Pyrenees; but at the same time so picturesque, that they would deserve the visits of the curious, were they not at the extremity of the world. The primitive mountains of granite or schistus, perpetually covered with snow, upon which are neither trees nor plants, have their foundation in the sea, and form upon the shore a kind of quay; their slope is so rapid, that after the first two or three hundred toises, the wild goats cannot climb them; and all the gullies which separate them are immense glaciers, of which the tops cannot be discerned, while the base is washed by the sea. At a cable's length from the land there is no bottom at less than 160 fathoms. The sides of the harbour are formed by secondary mountains, the elevation of which does not exceed from 800 to 900 toises; they are covered with pines, and overspread with verdure, and the snow is only seen on their summits: they appeared to be entirely formed of schistus, which is in the commencement of a state of decomposition; they are extremely difficult to climb, but not altogether inaccessible.

"Nature assigns inhabitants to so frightful a country, who as widely differ from the people of civilized countries as the scene which has just been described differs from our cultivated plains; as rude and barbarous as their soil is rocky and barren, they inhabit this land only to destroy its population: at war with all the animals, they despise the vegetable substances that grow around them. I have seen (says our author) women and children eat some raspberries and strawberries; but these are undoubtedly viands far too insipid for men, who live upon the earth like vultures in the air, or wolves and tigers in the forests.

"Their arts are somewhat advanced, and in this respect civilization has made considerable progress; but that which softens their ferocity, and polishes their manners, is yet in its infancy. The mode of life they pursue excluding all kind of subordination, they are continually agitated by fear or revenge; prone to anger, and easily irritated, they are continually attacking each other dagger in hand. Exposed in the winter to perish for want, because the chase cannot be successful, they live during the summer in the greatest abundance, as they can catch in less than an hour a sufficient quantity of fish for the support of their family; they remain idle during the rest of the day, which they pass at play, to which they are as much addicted as some of the inhabitants in our great cities. This gaming is the great source of their quarrels. If to all these destructive vices they should unfortunately add a knowledge of the use of any inebriating liquor, M. Perouse does not hesitate to pronounce, that this colony would be entirely annihilated." Francais.

Like all other savages, they are incorrigible thieves; and when they assumed a mild and placid appearance, the Frenchmen were sure that they had stolen something. Iron, of which they appeared to know the use, and of course the value, most excited their cupidity; and when our navigators were engaged in caressing a child, the father was sure to seize the opportunity of taking up, and concealing under his skin-garment, every thing of that metal which lay within his reach, and was not too heavy to be carried off.

M. Rollin, surgeon major of one of the frigates, thus describes these people. "They have very little similarity to the Californians; they are taller, stouter, of a more agreeable figure, and greater vivacity of expression: they are also much their superiors in courage and sense. They have rather a low forehead, but more open than that of the Southern Americans; their eyes are black and very animated; their eyebrows much fuller; their nose of the usual size, and well formed, except being a little widened at the extremity; their lips thinner; their mouth moderately large; their teeth fine and very even; their chin and ears very regular.

"The women also have an equal advantage over those of the preceding tribes; they have much more mildness in their features and grace in their limbs.—Their countenance would be even very agreeable, if, in order to set it off, they did not make use of a strange custom of wearing in the lower lip an elliptical piece of wood, lightly grooved on its circumference and both its sides, and which is commonly half an inch thick, two in diameter, and three in length.

"This singular ornament, besides being a great deformity, is the cause of a very troublesome as well as disgusting involuntary flow of saliva. This appendage is peculiar to the women; and female children are made to undergo the preparatory operations from the time of their birth. For this purpose, the lower lip is pierced with a kind of pin of copper or gold, which is either left in the opening, or its place supplied with a ring of the same material, till the period of puberty. The aperture is then gradually enlarged, by substituting first a small piece of wood of the form mentioned above, then a larger one; and so on, increasing its size by degrees till it reaches the dimensions just stated.

"This extraordinary custom shews the great power of dilatation in the lip, and may encourage medical practitioners

(B) This is a flat fish, longer and not so square as the turbet. Its back is covered with small scales; and those which are taken in Europe are much less than the fletans of Port des Français titioners in their attempts to remedy deformities of this part by the use of the knife.

"The general colour of these people is olive, a fainter tinge of which is apparent in their nails, which they suffer to grow very long; the hue of the skin, however, varies in different individuals, and in various parts of the same individual, according to their exposure to the action of the air and sun.

"Their hair is, in general, neither so coarse nor black as that of the South Americans. Chesnut coloured hair is by no means unfrequent among them. Their beard is also fuller, and their armpits and parts of sex better provided with hair.

"The perfect evenness of their teeth led me at first to suspect that it was the effect of art; but after an attentive and minute examination, I could perceive no wearing away of the enamel, and I saw that this regularity is natural. They tattoo and paint their face and body, and bore their ears and the cartilage of their nose.

"Some writers have imagined, that the custom of painting the face and body, so generally adopted by the Africans, Americans, and West Indians, is only intended as a preservative against noxious insects. I think, however, that I am warranted in asserting its sole end to be ornament. I found it to prevail among the inhabitants of Easter Island and the natives of *Port des Français*, without observing among them either venomous insects or reptiles. Besides, I remarked that they wore paint only when they paid us a visit; for they made no use of it when in their own houses."

M. Perouse himself speaks not so favourably of the women as M. Rollin. "They are (he says) the most disgusting of any on the earth, covered with stinking skins, which are frequently untanned; and yet they failed not to excite desires in some persons, in fact of no small consequence: they at first started many difficulties, giving assurances by their gestures that they ran the risk of their lives; but being overcome by presents, they had no objection to the sun being a witness, and absolutely refused to retire into the wood." There can be no doubt that this planet is the god of these people, since they frequently addressed themselves to it in their prayers; but our voyagers saw neither temple nor priest, nor the least trace of public worship at stated times. They burn their dead.

FRE'GATES FRANÇAISE *Basse de*, the name given by La Perouse to a dangerous reef of sunken rocks which he discovered in the Pacific ocean. On the north-west extremity of this reef they perceived an islet or split rock from 20 to 25 fathoms in height and about 50 toises in diameter. From this islet the reef extends more than four leagues to the south-east; and upon the extremity of the point in that direction, the frigates had almost struck before the breakers were observed. This was during a fine clear night and smooth sea. With great propriety, the Commodore returned in the morning to ascertain the geographical situation of this unknown rock; and he estimated the islet to be in 23° 45′ N. Lat. and 168° 10′ W. Long. from Paris.

FRICTION, in mechanics, is a subject of great importance both to the practical engineer and to the speculative philosopher. It is therefore our duty to correct, in this Supplement, the mistakes into which we fell when treating of that subject in the *Encyclopædia*. What we have there taught of friction (see MECHANICS, Sect. II. § 8.) is taken from Ferguson; but it has been shewn by Mr Vince, that the experiments from which his conclusions were drawn were not properly instituted. That eminent mathematician and philosopher therefore entered upon the investigation of the subject anew, and endeavoured, by a set of experiments, to determine the following questions:

1. Whether friction be a uniformly retarding force?

2. The quantity of friction?

3. Whether the friction varies in proportion to the pressure or weight?

4. Whether the friction be the same on whichever of its surfaces a body moves?

1. With respect to the first of these questions, the author truly observes, that if friction be a uniform force, the difference between it and the given force of the moving power employed to overcome it must also be uniform; and that therefore the moving power, if it be a body descending by its own weight, must descend with a uniformly accelerated velocity, just as when there was no friction. The spaces described from the beginning of the motion will indeed be diminished in any given time on account of the friction; but still they must be to each other as the squares of the times employed. See DYNAMICS in this *Supplement*.

2. A plane was therefore adjusted parallel to the horizon, at the extremity of which was placed a pulley, which could be elevated or depressed, in order to render the string which connected the body and the moving force parallel to the plane. A scale accurately divided was placed by the side of the pulley perpendicular to the horizon, by the side of which the moving force descended; upon the scale was placed a moveable stage, which could be adjusted to the space through which the moving force descended in any given time; which time was measured by a well-regulated pendulum clock vibrating seconds. Every thing being thus prepared, the following experiments were made to ascertain the law of friction.

3. *Exp.* 1. A body was placed upon the horizontal plane, and a moving force applied, which, from repeated trials, was found to descend $52\frac{1}{4}$ inches in 4″; for by the beat of the clock, and the sound of the moving force when it arrived at the stage, the space could be very accurately adjusted to the time: The stage was then removed to that point to which the moving force would descend in 3″, upon supposition that the spaces described by the moving power were as the squares of the times; and the space was found to agree very accurately with the time: the stage was then removed to that point to which the moving force ought to descend in 2″, upon the same supposition, and the descent was found to agree exactly with the time: lastly, the stage was adjusted to that point to which the moving force ought to descend in 1″, upon the same supposition, and the space was observed to agree with the time. Now, in order to find whether a difference in the time of descent could be observed by removing the stage a little above and below the positions which corresponded to the above times, the experiment was tried, and the descent was always found too soon in the former, and too late in the latter case; by which the author was assured, that the spaces first mentioned corresponded exactly to the times. And, for the greater certainty, each descent was repeated eight or ten times; and

and every caution used in this experiment was also made use of in all the following.

Exp. 2. A second body was laid upon the horizontal plane, and a moving force applied which descended $41\frac{3}{4}$ inches in 3″; the stage was then adjusted to the space corresponding to 2″, upon supposition that the spaces descended through were as the squares of the times, and it was found to agree accurately with the time; the stage was then adjusted to the space corresponding to 1″, upon the same supposition, and it was found to agree with the time.

Exp. 3. A third body was laid upon the horizontal plane, and a moving force applied, which descended $59\frac{5}{8}$ inches in 4″; the stage was then adjusted to the space corresponding to 3″, upon supposition that the spaces descended through were as the squares of the times, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 2″, upon the same supposition, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 1″, and was found to agree with the time.

Exp. 4. A fourth body was then taken and laid upon the horizontal plane, and a moving force applied, which descended 55 inches in 4″; the stage was then adjusted to the space through which it ought to descend in 3″, upon supposition that the spaces descended through were as the squares of the times, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 2″, upon the same supposition, and was found to agree with the time; lastly, the stage was adjusted to the space corresponding to 1″, and it was found to agree exactly with the time.

Besides these experiments, a great number of others were made with hard bodies, or those whose parts so firmly cohered as not to be moved *inter se* by the friction; and, in each experiment, bodies of very different degrees of friction were chosen, and the results all agreed with those related above; we may therefore conclude, that the *friction of hard bodies in motion is a uniformly retarding force.*

But to determine whether the same was true for bodies when covered with cloth, woollen, &c. experiments were made in order to ascertain it; when it was found, in all cases, that the retarding force increased with the velocity; but, upon covering bodies with paper, the consequences were found to agree with those related above.

4. Having proved that the retarding force of all hard bodies arising from friction is uniform, the quantity of friction, considered as equivalent to a weight without inertia drawing the body on the horizontal plane backwards, or acting contrary to the moving force, may be immediately deduced from the foregoing experiments. For let M = the moving force expressed by its weight; F = the friction; W = the weight of the body upon the horizontal plane; S = the space through which the moving force descended in the time t expressed in seconds; $r = 16\frac{1}{12}$ feet; then the whole accelerative force (the force of gravity being unity) will be $\frac{M - F}{M + W}$; hence, by the laws of uniformly accelerated motions, $\frac{M - F}{M + W} \times r\,t^2 = S$, consequently $F = M - \frac{\overline{M \times W} \times S}{r\,t^2}$. To exemplify this, let us take the case of the last experiment, where $M = 7$, $W = 25\frac{3}{4}$, $S = 4\frac{7}{12}$ feet, $t = 4''$; hence $F = 7 - \frac{32\frac{3}{4} \times 4\frac{7}{12}}{16\frac{1}{12} \times 16} = 6.417$; consequently the friction was to the weight of the rubbing body as 6.4167 to 25.75. And the great accuracy of determining the friction by this method is manifest from hence, that if an error of one inch had been made in the descent (and experiments carefully made may always determine the space to a much greater exactness), it would not have affected the conclusion $\frac{1}{600}$dth part of the whole.

5. We come, in the next place, to determine whether friction, *cæteris paribus*, varies in proportion to the weight or pressure. Now if the whole quantity of the friction of a body, measured by a weight without inertia equivalent to the friction drawing the body backwards, increases in proportion to its weight, it is manifest that the retardation of the velocity of the body arising from the friction will not be altered; for the retardation varies as $\frac{\text{Quantity of friction}}{\text{Quantity of matter}}$; hence, if a body be put in motion upon the horizontal plane by any moving force, if both the weight of the body and the moving force be increased in the same ratio, the acceleration arising from that moving force will remain the same, because the accelerative force varies as the moving force divided by the whole quantity of matter, and both are increased in the same ratio; and if the quantity of friction increases also as the weight, then the retardation arising from the friction will, from what has been said, remain the same, and therefore the whole acceleration of the body will not be altered; consequently the body ought, upon this supposition, still to describe the same space in the same time. Hence, by observing the spaces described in the same time, when both the body and the moving force are increased in the same ratio, we may determine whether the friction increases in proportion to the weight. The following experiments were therefore made in order to ascertain this matter:

Exp. 1. A body weighing 10 oz. by a moving force of 4 oz. described in 2″ a space of 51 inches; by loading the body with 10 oz. and the moving force with 4 oz. it described 56 inches in 2″; and by loading the body again with 10 oz. and the moving force with 4 oz. it described 63 inches in 2″.

Exp. 2. A body, whose weight was 16 oz. by a moving force of 5 oz. described a space of 49 inches in 3″; and by loading the body with 64 oz. and the moving force with 20 oz. the space described in the same time was 64 inches.

Exp. 3. A body weighing 6 oz. by a moving force of $2\frac{1}{2}$ oz. described 28 inches in 2″; and by loading the body with 24 oz. and the moving force with 10 oz. the space described in the same time was 54 inches.

Exp. 4. A body weighing 8 oz. by a moving force of 4 oz. described $33\frac{1}{2}$ inches in 2″; and by loading the body with 8 oz. and the moving force with 4 oz. the space described in the same time was 47 inches.

Exp. 5. A body whose weight was 9 oz. by a moving force of $4\frac{1}{2}$ oz. described 48 inches in 2″; and by loading the body with 9 oz. and the moving force with $4\frac{1}{2}$ oz. the space described in the same time was 60 inches.

Exp. 6. A body weighing 10 oz. by a moving force of

3 oz. deſcribed 20 inches in 2″; by loading the body with 10 oz. and the moving force with 3 oz. the ſpace deſcribed in the ſame time was 31 inches; and by loading the body again with 30 oz. and the moving force with 9 oz. the ſpace deſcribed was 34 inches in 2″.

From theſe experiments, and many others which it is not neceſſary here to relate, it appears, that the ſpace deſcribed is always increaſed by increaſing the weight of the body and the accelerative force in the ſame ratio; and as the acceleration ariſing from the moving force continued the ſame, it is manifeſt, that the retardation ariſing from the friction muſt have been diminiſhed, for the whole accelerative force muſt have been increaſed on account of the increaſe of the ſpace deſcribed in the ſame time; and hence (as the retardation from friction varies as $\frac{\text{Quantity of friction}}{\text{Quantity of matter}}$) *the quantity of friction increaſes in a leſs ratio than the quantity of matter or weight of the body.*

6. We come now to the laſt thing which it was propoſed to determine, that is, whether the friction varies by varying the ſurface on which the body moves. Let us call two of the ſurfaces A and *a*, the former being the greater, and the latter the leſs. Now the weight on every given part of *a* is as much greater than the weight on an equal part of A, as A is greater than *a*; if therefore the friction was in proportion to the weight, *cæteris paribus*, it is manifeſt, that the friction on *a* would be equal to the friction on A, the whole friction being, upon ſuch a ſuppoſition, as the weight on any given part of each ſurface multiplied into the number of ſuch parts or into the whole area, which products, from the proportion above, are equal. But from the laſt experiments it has been proved, that the friction on any given ſurface increaſes in a leſs ratio than the weight; conſequently the friction on any given part of *a* has a leſs ratio to the friction on an equal part of A than A has to *a*, and hence the friction on *a* is leſs than the friction on A, that is, the ſmalleſt ſurface has always the leaſt friction.

As this concluſion is contrary to the generally received opinion, Mr Vince thought it proper to confirm it by a ſet of experiments made with different bodies of exactly the ſame degree of roughneſs on their two ſurfaces.

Exp. 1. A body was taken whoſe flat ſurface was to its edge as 22 : 9, and with the ſame moving force the body deſcribed on its flat ſide $33\frac{1}{2}$ inches in 2″, and on its edge 47 inches in the ſame time.

Exp. 2. A ſecond body was taken whoſe flat ſurface was to its edge as 32 : 3, and with the ſame moving force it deſcribed on its flat ſide 32 inches in 2″, and on its edge it deſcribed $37\frac{1}{2}$ inches in the ſame time.

Exp. 3. He took another body and covered one of its ſurfaces, whoſe length was 9 inches, with a fine rough paper, and by applying a moving force, it deſcribed 25 inches in 2″; he then took off ſome paper from the middle, leaving only $\frac{5}{8}$ths of an inch at the two ends, and with the ſame moving force it deſcribed 40 inches in the ſame time.

Exp. 4. Another body was taken which had one of its ſurfaces, whoſe length was 9 inches, covered with a fine rough paper, and by applying a moving force it deſcribed 42 inches in 2″; ſome of the paper was then taken off from the middle, leaving only $1\frac{3}{8}$ inches at the two ends, and with the ſame moving force it deſcribed 54 inches in 2″; he then took off more paper, leaving only $\frac{1}{4}$ of an inch at the two ends, and the body then deſcribed, by the ſame moving force, 60 inches in the ſame time.

In the two laſt experiments the paper which was taken off the ſurface was laid on the body, that its weight might not be altered.

Exp. 5. A body was taken whoſe flat ſurface was to its edge as 30 : 17; the *flat* ſide was laid upon the horizontal plane, a moving force was applied, and the ſtage was fixed in order to ſtop the moving force, in conſequence of which the body would then go on with the velocity acquired until the friction had deſtroyed all its motion; when it appeared from a mean of 12 trials that the body moved, after its acceleration ceaſed, $5\frac{2}{7}$ inches before it ſtopped. The *edge* was then applied, and the moving force deſcended through the ſame ſpace; and it was found, from a mean of the ſame number of trials, that the ſpace deſcribed was $7\frac{1}{3}$ inches before the body loſt all its motion, after it ceaſed to be accelerated.

Exp. 6. Another body was then taken whoſe flat ſurface was to its edge as 60 : 19, and by proceeding as before, on the flat ſurface it deſcribed, at a mean of 12 trials, $5\frac{1}{8}$ inches, and on the edge $6\frac{1}{12}$ inches, before it ſtopped, after the acceleration ceaſed.

Exp. 7. Another body was taken whoſe flat ſurface was to its edge as 26 : 3, and the ſpaces deſcribed on theſe two ſurfaces, after the acceleration ended, were, at a mean of ten trials, $4\frac{1}{7}$ and $7\frac{7}{10}$ inches reſpectively.

From all theſe different experiments it appears, that the ſmalleſt ſurface had always the leaſt friction, which agrees with the conſequence deduced from the conſideration that the friction does not increaſe in ſo great a ratio as the weight; we may therefore conclude, that *the friction of a body does not continue the ſame when it has different ſurfaces applied to the plane on which it moves, but that the ſmalleſt ſurface will have the leaſt friction.*

To the experiments inſtituted by Mr Ferguſon and others, from which concluſions have been drawn ſo different from theſe, our author makes the following objections: It was their object to find what moving force would *juſt* put a body at reſt in motion; and having, as they thought, found it, they thence concluded, that the accelerative force was then equal to the friction. But it is manifeſt, as Mr Vince obſerves, that any force which will put a body in motion muſt be *greater* than the force which oppoſes its motion, otherwiſe it could not overcome it; and hence, if there were no other objection than this, it is evident, that the friction could not be very accurately obtained: but there is another objection which totally deſtroys the experiment ſo far as it tends to ſhew the quantity of friction, which is the ſtrong coheſion of the body to the plane when it lies at reſt; and this is confirmed by the following experiments. *1ſt*, A body of $12\frac{3}{4}$ oz. was laid upon an horizontal plane, and then loaded with a weight of 8 lb. and ſuch a moving force was applied as would, when the body was juſt *put* in motion, continue that motion without any acceleration; in which caſe the friction muſt be juſt equal to the accelerative force. The body was then ſtopped, when it appeared that the ſame moving force which had *kept* the body in motion before, Friction, Frigorific.

fore, would not *put* it in motion, and it was found necessary to take off $4\frac{1}{2}$ oz. from the body before the same moving force *would* put it in motion; it appears therefore, that this body, when laid upon the plane, at rest, acquired a very strong cohesion to it. 2*dly*, A body whose weight was 16 oz. was laid at rest upon the horizontal plane, and it was found that a moving force of 6 oz. would just *put* it in motion; but that a moving force of 4 oz. *would*, when it was just put in motion, *continue* that motion without any acceleration, and therefore the accelerative force must *then* have been equal to the friction, and not when the moving force of 6 oz. was applied.

From these experiments, therefore, it appears how very considerable the cohesion was in proportion to the friction when the body was in motion; it being, in the latter case, almost $\frac{1}{3}$d, and in the former it was found to be very nearly equal to the whole friction. All the conclusions therefore deduced from the experiments, which have been instituted to determine the friction from the force necessary to *put* a body in motion, have manifestly been totally false; as such experiments only shew the resistance which arises from the cohesion and friction conjointly.

Our author concludes this part of his subject with the following remark upon n° 5: "It appears from all the experiments (says he) which I have made, that the proportion of the increase of the friction to the increase of the weight was different in all the different bodies which were made use of; no general rule therefore can be established to determine this for *all* bodies, and the experiments which I have hitherto made have not been sufficient to determine it for the *same* body."

He then proceeds to establish a theory upon the principles which he has deduced from his experiments. That theory is comprehended in five propositions, of which the object of the first is "to find the time of descent, and the number of revolutions made by a cylinder rolling down an inclined plane in consequence of its friction.

II. "To determine the space through which a body, projected on an horizontal plane with a given velocity, will move before it stops, or before its motion becomes uniform.

III. "To find the centre of friction.

IV. "To determine, from the given velocity with which a body begins to revolve about the centre of its base, the number of revolutions which that body will make before all its motion be destroyed.

V. "To find the nature of the curve described by any point of a body affected by friction when it descends down any inclined plane."

To give the solutions of these problems, with the corollaries deduced from them, would swell this article to very little purpose; for they would be unintelligible to the mere mechanic, and the mathematician will either solve them for himself, or have recourse to the original memoir, where he will find solutions at once elegant and perspicuous.

FRIGORIFIC MIXTURES, are those which experience has taught philosophers to employ for the purpose of producing artificial cold. Some of these mixtures are enumerated under the title COLD (*Encycl.*), and a much more accurate list of them is given, together with the principle upon which they produce their effect, in the article CHEMISTRY, n° 282. (*Suppl.*). There is one mixture, however, not mentioned in that list, which was employed by Seguin, and seems, on many accounts, to be the most eligible that has yet been proposed. Considering the muriats (see CHEMISTRY-*Index*, *Suppl.*) as a class of salts best suited for the purpose, he gave the decided preference to muriat of lime in crystals; and his method was to mix the crystals, previously pulverised, with an equal weight of uncompressed snow.

By means of this mixture Mr W. H. Pepys junior, of the London Philosophical Society, with the assistance of some friends, froze, on the 8th of February 1799, 56 lbs. averdupoise of mercury into a solid mass. The mercury was put into a strong bladder and well secured at the mouth, the temperature of the laboratory at the time being + 33°. A mixture consisting of muriat of lime 2 lb. at + 33°, and the same weight of snow at + 32° gave — 42° (A). The mercury was put as gently as possible into this mixture (to prevent a rupture of the bladder), by means of a cloth held at the four corners. When the cold mixture had robbed the mercury of so much of its heat as to have its own temperature thereby raised from — 42° to + 5, another mixture, the same in every respect as the last, was made, which gave, on trial with the thermometer, — 43°. The mercury was now received into the cloth, and put gently into this new mixture, where it was left to be cooled still lower than before.

In the mean time five pounds of muriat of lime, in a large pail made of tinned iron, and japanned inside and outside, was placed in a cooling mixture in an earthenware pan. The mixture in the pan, which consisted of 4 lb. of muriat of lime and a like quantity of snow, of the same temperature as the former, in one hour reduced the 5 lb. of muriat in the pail to — 15°. The mixture was then emptied out of the earthen pan, and four large corks, at proper distances, placed on its bottom, to serve as rests for the japanned pail which was now put into the pan. The corks answered the purpose of insulating the inner vessel, while the exterior one kept off the surrounding atmosphere, and preserved the air between the two at a low temperature.

To the 5 lb. of muriat of lime which had been cooled, as already noticed, to — 15°, and which still remained in the metallic vessel, was now added snow, uncompressed and free from moisture, at the usual temperature of + 32°. In less than three minutes the mixture gave a temperature of — 62°: a degree of cold which perhaps was never before produced in this country, being 94° below the freezing point of water.

The mercury, which, by immersion in the second cooling mixture to which it was exposed, was by this time reduced to — 30°, was now, by the means employed before, cautiously put into the last made mixture of the temperature of — 62°. A hoop with net-work fastened to its upper edge, and of such a breadth in the rim

(A) The thermometer made use of in this experiment was filled with tinged alcohol, and accurately divided according to Fahrenheit's scale.

Frigorific. him that the net-work, when loaded with the bladder of mercury, could not reach its lower edge, was at the bottom of the mixture, to prevent the bladder from coming in contact with the veſſel; by which means the mercury was ſuſpended in the middle of the mixture. As ſoon as the bladder was ſafely depoſited on the net-work, the veſſels were carefully covered over with a cloth, to impede the paſſage of heat from the ſurrounding atmoſphere into the freezing materials. The condenſation of moiſture from the atmoſphere by the agency of ſo low a temperature was greater than could have been expected: it floated like ſteam over the veſſels, and, but for the interpoſed covering, would have given the mixture more temperature than was deſirable.

After one hour and forty minutes they found, by means of a ſearcher introduced for the purpoſe, that the mercury was ſolid and fixed. The temperature of the mixture at this time was — 46, that is, 16° higher than when the mercury was put into it.

Our young philoſophers having neglected to ſling the hoop and net-work in ſuch a manner as might have enabled them to lift it out of the mixture at once, with the bladder and its contents, were obliged to turn out the whole contents of the pail into a large evaporating capſule made of iron. This was not effected without the mercury ſtriking againſt its bottom and being fractured, though it received a conſiderable increaſe of temperature from the capſule. The fracture was ſimilar to that of zinc, but with parts more cubical. The larger pieces were kept for ſome minutes before fuſion took place, while others were twiſted and bent into various forms, to the no ſmall gratification and ſurpriſe of thoſe who never witneſſed or expected to ſee ſuch an effect produced on ſo fuſible a metal.

In experiments of the kind here deſcribed, all the exterior veſſels ſhould be of earthen-ware or wood, which being bad conductors of heat, prevent the ingredients from receiving heat from the atmoſphere and ſurrounding objects with the ſame facility that they would through metals; and, for a ſimilar reaſon, the interior veſſels are beſt of metal, that they may allow the heat to paſs more readily from the ſubſtance to be cooled into the frigorific mixture employed for that purpoſe.

Muriat of lime is certainly the moſt powerful, and at the ſame time the moſt economical ſubſtance that can be employed for producing artificial cold; for its firſt coſt is a mere trifle, being a reſiduum from many chemical proceſſes, as the diſtillation of pure ammonia, &c. and often thrown away: beſides, it may be repeatedly uſed for ſimilar experiments, nothing being neceſſary for this purpoſe but filtration and evaporation to bring it to its firſt ſtate. The evaporation ſhould be carried on till the ſolution becomes as thick as a ſtrong ſyrup, and upon cooling the whole will be cryſtalliſed: it muſt then be powdered, put up in dry bottles, well corked, and covered with bladder or cement to prevent liquefaction; which otherwiſe would ſoon take place, owing to the great affinity the muriat has for moiſture.

The powerful effects produced by the frigorific mixture of muriat of lime and ſnow, preſent a wide field for experiments to determine the poſſibility of fixing ſome of the gaſes by intenſe cold. And we are happy to be informed by Mr Pepys, that, as ſoon as an opportunity offers, he and his friends mean to make ſome experiments with that view, and to communicate the reſult of them to the editor of the valuable miſcellany * from which we have taken this account of his experiment on mercury.

* The Philoſophical Magazine.

Frio ‖ Fuel

FRIO, a ſmall iſland on the coaſt of the Brazils, ſituated in 32° 2′ ſouth lat. and 41° 31′ 45″ weſt lon. The land of Frio is high, with a hollow in the middle, which gives it, at a diſtance, the reſemblance of two ſeparate iſlands. The paſſage between the iſland and the continent is about a mile broad, and ſeemed to Sir Eraſmus Gower to be clear from ſhoals.

FROST, as is well known in Scotland, is particularly deſtructive to the bloſſom of fruit trees; and the following method of ſecuring ſuch trees from being damaged by early froſts may be acceptable to many of our readers. A rope is to be interwoven among the branches of the tree, and one end of it brought down ſo as to be immerſed in a bucket of water. The rope, it is ſaid, will act as a conductor, and convey the effects of the froſt from the tree to the water. This idea is not new; for the following paſſage may be found in Colerus: " If you dig a trench around the root of a tree, and fill it with water, or keep the roots moiſt till it has bloomed, it will not be injured by the froſt. Or, in ſpring, ſuſpend a veſſel filled with water from the tree. If you wiſh to preſerve the bloom from being hurt by the froſt, place a veſſel of water below it, and the froſt will fall into it." *Philoſophical Magazine*, n° 11.

FUEL, whatever is proper to burn, or make a fire, either for warming a room or dreſſing victuals. The fuel moſt generally uſed in Great Britain is pit-coal, which is a very expenſive article; and that expence is greatly increaſed by the waſte of coal occaſioned by the injudicious manner in which fires in open chimneys are commonly managed. The enormous waſte of fuel in London, for inſtance, may be eſtimated by the vaſt dark cloud which continually hangs over that great metropolis, and frequently overſhadows the whole country far and wide; for this denſe cloud is certainly compoſed almoſt entirely of unconſumed coal, which has eſcaped by the chimneys, and continues to ſail about in the air, till, having loſt the heat which gave it volatility, it falls in a dry ſhower of extremely fine black duſt to the ground, obſcuring the atmoſphere in its deſcent, and frequently changing the brighteſt day into more than Egyptian darkneſs.

" I never (ſays Count Rumford) view from a diſtance, as I come into town, this black cloud which hangs over London, without wiſhing to be able to compute the immenſe number of chaldrons of coals of which it is compoſed; for could this be aſcertained, I am perſuaded ſo ſtriking a fact would awaken the curioſity, and excite the aſtoniſhment of all ranks of the inhabitants; and perhaps turn their minds to an object of economy to which they have hitherto paid little attention."

The object to which the benevolent author more particularly wiſhes to direct the public attention, is the lighting of a coal fire, in which more wood ſhould be employed than is commonly uſed, and fewer coals; and as ſoon as the fire burns bright, and the coals are well lighted, and not before, more coals ſhould be added to increaſe the fire to its proper ſize.

Kindling balls, compoſed of equal parts of coal,—charcoal,—and clay, the two former reduced to a fine powder,

powder, well mixed and kneaded together, with the clay moiſtened with water, and then formed into balls of the ſize of hens eggs, and thoroughly dried, might be uſed with great advantage inſtead of wood for kindling fires. Theſe kindling balls may be made ſo inflammable as to take fire in an inſtant and with the ſmalleſt ſpark, by dipping them in a ſtrong ſolution of nitre, and then drying them again; and they would neither be expenſive nor liable to be ſpoiled by long keeping. Perhaps a quantity of pure charcoal, reduced to a very fine powder, and mixed with the ſolution of nitre in which they are dipped, would render them ſtill more inflammable.

The Count thinks that the fires which are made in the open chimneys of elegant apartments might be greatly improved by preparing the fuel; for nothing (ſays he) was ever more dirty, inelegant, and diſguſting, than a common coal fire.

Fire balls, of the ſize of gooſe eggs, compoſed of coal and charcoal in powder, mixed up with a due proportion of wet clay, and well dried, would make a much more cleanly, and in all reſpects a pleaſanter fire, than can be made with crude coals; and, he believes, would not be more expenſive fuel. In Flanders, and in ſeveral parts of Germany, and particularly in the duchies of Juliers and Bergen, where coals are uſed as fuel, the coals are always prepared before they are uſed, by pounding them to a powder, and mixing them up with an equal weight of clay, and a ſufficient quantity of water to form the whole into a maſs, which is kneaded together and formed into cakes; which cakes are afterwards well dried and kept in a dry place for uſe. And it has been found, by long experience, that the expence attending this preparation is amply repaid by the improvement of the fuel. The coals, thus mixed with clay, not only burn longer, but give much more heat than when they are burnt in their crude ſtate.

It will doubtleſs appear extraordinary to thoſe who have not conſidered the ſubject with ſome attention, that the quantity of heat produced in the combuſtion of any given quantity of coals ſhould be increaſed by mixing the coals with clay, which is certainly an incombuſtible body; but the phenomenon may be explained in a ſatisfactory manner.

The heat generated in the combuſtion of any ſmall particle of coal exiſting under two diſtinct forms, namely, in that which is combined with the flame and ſmoke which riſe from the fire, and which, if means are not found to ſtop it, goes off immediately by the chimney and is loſt—and the radiant heat which is ſent off from the fire in all directions in right lines:—It is therefore reaſonable to conclude, that the particles of clay, which are ſurrounded on all ſides by the flame, arreſt a part at leaſt of the combined heat, and prevent its eſcape; and this combined heat, ſo arreſted, heating the clay red hot, is retained in it, and being changed by this operation to radiant heat, is afterwards emitted, and may be directed and employed to uſeful purpoſes. In the compoſition of fire-balls, the Count thinks it probable that a certain proportion of chaff, of ſtraw cut very fine, or even of ſaw-duſt, might be employed with great advantage.

FULLING of woollen cloths (ſee the method of performing the operation under the article Fulling, *Encycl.*) depends, like Felting, ſo entirely upon the ſtructure of wool and hair, that the following obſervations, which are not unimportant, will be intelligible to every reader who has peruſed that article in this *Supplement*.

The aſperities with which the ſurface of wool is every where ſurrounded, and the diſpoſition which it has to aſſume a progreſſive motion towards the root, render the ſpinning of wool, and making it into cloth, difficult operations. In order to ſpin wool, and afterwards to weave it, we are obliged to cover its fibres with a coating of oil, which, filling the cavities, renders the aſperities leſs ſenſible; in the ſame way as oil, when rubbed over the ſurface of a very fine file, renders it ſtill leſs rough. When the piece of cloth is finiſhed, it muſt be cleanſed from this oil; which, beſides giving it a diſagreeable ſmell, would cauſe it to ſoil whatever it came in contact with, and would prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil, it is carried to the fulling-mill, where it is beat with hammers in a trough full of water, in which ſome clay has been mixed; the clay combines with the oil, which it ſeparates from the cloth, and both together are waſhed away by the freſh water which is brought to it by the machine; thus, after a certain time, the oil is entirely waſhed out of the cloth.

But the ſcouring of the cloth is not the only object in fulling it; the alternate preſſure given by the mallets to the piece of cloth, occaſions, eſpecially when the ſcouring is pretty far advanced, an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compoſe one of the threads, whether of the warp or the woof, aſſume a progreſſive movement, introduce themſelves among thoſe of the threads neareſt to them, then into thoſe which follow; and thus, by degrees, all the threads, both of the warp and the woof, become felted together. The cloth, after having, by the above means, become ſhortened in all its dimenſions, partakes both of the nature of cloth and of that of felt; it may be cut without being ſubject to ravel, and, on that account, we are not obliged to hem the edges of the pieces of which clothes are made. Laſtly, As the threads of the warp and thoſe of the woof are no longer ſo diſtinct and ſeparated from each other, the cloth, which has acquired a greater degree of thickneſs, forms a warmer clothing. Knit worſted alſo is, by fulling, rendered leſs apt to run, in caſe a ſtitch ſhould drop in it.

FULMINATING Gold. } See Chemistry, *Suppl.* nos 849 and 850.
Fulminating Silver.

Mr Berthollet, the inventor of fulminating ſilver, having contented himſelf with a general and conciſe deſcription of this ſubject, many practical chemiſts have failed in their attempts to prepare it; and others, forming their opinions from the ſpecimens which they had made, have been expoſed to great danger; as will appear from the following relation:

An ounce of fine ſilver was diſſolved in the courſe of eight hours in an ounce of pure nitrous acid, of the London Pharmacopœia, diluted previouſly with three ounces of diſtilled water in a glaſs matraſs. The ſolution being poured off, the reſiduary black powder and the matraſs were waſhed with ſeven or eight ounces of warm diſtilled water, and this was added to the ſolution. The black powder, being gold, was rejected; ſome gold being thus ſeparable from any ſilver of commerce.

To the foregoing diluted ſolution, pure lime-water prepared

Fulminating.

prepared with distilled water was added gradually; for the solution ought not to be poured into the lime water. When about thirty pints of lime-water had been expended, and the precipitate had subsided, more lime-water was added, by successive pints, as long as it caused any precipitation. For it was deemed fitter that the precipitation should not be perfected, than that an excess of lime-water should be used; the earthy pellicle of the excessive lime-water being apt to mix with the precipitate. The clear liquor being poured away, the precipitate was poured off, and washed into a filter.

When the saline liquor had drained from it, two ounces of distilled water were poured on the magma; and when this water had passed, fresh portions were successively added and passed, until the whole quantity of water thus expended in washing away the nitrous calcareous salt amounted to a quart.

The filter being then unfolded, to let the magma of oxide of silver spread on the flattened paper, it was placed on a chalk-stone to accelerate the exsiccation, and was gradually dried in the open air; a cap of paper being placed loosely over it to exclude the dust.

When the weather served, the cap was removed, to expose the oxide to the rays of the sun; although this was not deemed necessary; and exsiccation was promoted by cutting the oxide into thin slices. When perfectly dry it weighed 1 oz. 4 dwts. and about one-fifth of it was considered as oxygen.

When aqua ammoniæ puræ of any pharmacopœia is used with this oxide, either in the small quantity which blackens it completely, or in a greater quantity, the black matter which subsides, and which has been represented by systematic writers as the fulminating compound, has no such property, any farther than may be owing to the matter deposited from the alkaline solution during the exsiccation.

The alkaline liquor containing the fulminating silver ought to be poured off from the insoluble powder, and exposed in a shallow vessel to the air. In consequence of the exhalation, black shining crystals form on the surface only, and soon join to form a pellicle. As this pellicle adheres a little to the sides of the vessel, or maintains its figure, the liquor may be poured off by a gentle inclination of the vessel.

This liquor will yield another pellicle in the same way; but the third or fourth pellicle will be paler than the former, and weaker in the explosion. The first pellicles, when slowly dried, explode by the touch of a feather, or by their being heated to about 96°.

The quantity of water in the ordinary aqua ammoniæ puræ renders it less active in the solution of the oxide, and is an impediment to the speedy formation and separation of the fulminating silver; and an experimenter who has often used twenty grains of the oxide to produce successive pellicles of fulminating silver, which may be separately exploded with safety, and who has perceived that the pellicles never explode whilst wet, if they be not heated, would, in all probability, resolve on the following improvement, and expose himself to the unforeseen danger of it.

Distilled water was impregnated with as much pure ammoniac as it could easily retain under the ordinary temperature of the air. A quantity of this strong ammoniacal liquor, equal in bulk to a quarter of an ounce of water, was placed in a small bottle, and 24 grains of the oxide of silver, ground to fine powder, were added. The bottle, being almost filled, was corked, to prevent the formation of that film which usually appeared in consequence of the exhalation of the ammoniac in other experiments.

Function ‖ Fust.

During the solution of the oxide, bubbles of the gaseous kind arose from it, and the solution acquired a blue colour. As no film appeared, the bottle was agitated three or four times in the course of as many hours, in order to promote the solution of a small quantity of blackened oxide which remained at the bottom. The experimenter considering this as an ample provision for twenty different charges, to be exploded in different circumstances, in the presence of the society, intended to pour off the solution into as many small vessels, and to weigh the residuary black powder, after allowing two hours more for the solution.

On the sixth hour he took his usual precaution of wearing spectacles; and observing that a small quantity of black powder still remained undissolved, and that no film was yet formed at the surface, he took the bottle by the neck to shake it; knowing that it might explode by the heat of his hand, if he were to grasp it, and that the explosion in this circumstance might wound him dangerously.

In the instant of shaking, it exploded with a report that stunned him. The bottle was blown into fragments so small as to appear like glass coarsely powdered. The hand which held it was impressed as by the blow of a great hammer, and lost the sense of feeling for some seconds; and about 52 small grains of glass were lodged, many of them deeply, in the skin of the palm and fingers. The liquor stained his whole dress, and every part of the skin that it touched. Thus it appeared that fulminating silver may be made which will explode even when cold and wet, by the mere disturbance of the arrangement of its parts, in the aqueous fluid.

In subsequent experiments, privately and carefully conducted, it seemed that the property of exploding in the cold liquor, by mere commotion, depended on the unusual quantity or poximity of the explosive molecules in a given bulk of the liquor. And the flat bottoms, as well as the sides, of the thick vessels of glass or potters-ware, whether they stood on boards or iron plates, were always beaten to small fragments.

This afforded a curious instance of the possible equilibrium between the powers tending to retain the caloric and those which effect the expulsion of it; and experiments and considerations of this kind seemed to promise a true solution of the phenomena of Rupert's drops.

FUNCTION, a term used in analytics for an algebraical expression, anyhow compounded of a certain letter or quantity with other quantities or numbers; and the expression is said to be a function of that letter or quantity. Thus $a - 4x$, or $ax + 3x^2$, or $2x - a\sqrt{a^2 - x^2}$, or x^c, or c^x, is each of them a function of the quantity x.

FURD-Y-HUCKEECUT, in Bengal, signifies a paper of description.

Furd-y-Sowal, paper of request.

FUST, in architecture, the shaft of a column, or the part comprehended between the base and the capital, called also the naked.

G,

G.

Gaguedi.

GAGUEDI, a tree peculiar to Lamalmon, in Abyſſinia, is thus deſcribed by Mr Bruce. The leaves are long, and broader as they approach the end. The point is obtuſe; they are of a dead green, not unlike the willow, and placed alternately one above the other on the ſtalk. The calyx is compoſed of many broad ſcales lying one above the other, which operates by the preſſure upon one another, and keeps the calyx ſhut before the flower arrives at perfection. The flower is monopetalous, or made of one leaf; it is divided at the top into four ſegments; where theſe end, it is covered with a tuft of down, reſembling hair, and this is the caſe at the top alſo. When the flower is young and unripe, they are laid regularly ſo as to incloſe one another in a circle. As they grow old and expand, they ſeem to loſe their regular form, and become more confuſed, till at laſt, when arrived at its full perfection, they range themſelves parallel to the lips of the calyx, and perpendicular to the ſtamina, in the ſame order as a roſe. The common receptacle of the flower is oblong, and very capacious, of a yellow colour, and covered with ſmall leaves like hair. The ſtile is plain, ſimple, and upright, and covered at the bottom with a tuft of down, and is below the common receptacle of the flower.

Our author ſays that he has obſerved, in the middle of a very hot day, that the flowers unbend themſelves more, the calyx ſeems to expand, and the whole flower to turn itſelf towards the ſun in the ſame manner as does the ſunflower. When the branch is cut, the flower dries as it were inſtantaneouſly, ſo that it ſeems to contain very little humidity.

GALVANISM.

1 Galvaniſm improperly called *animal electricity*.

GALVANISM is the name now commonly given to the influence diſcovered nearly eight years ago by the celebrated Galvani, profeſſor of anatomy at Bologna, and which, by him and ſome other authors, has been called *animal electricity*. We prefer the former name, becauſe we think it by no means proved that the phenomena diſcovered by Galvani depend either upon the electric fluid, or upon any law of animal life. While that is the caſe, it is ſurely better to diſtinguiſh a new branch of ſcience by the name of the inventor, than to give it an appellation which probably may, and in our opinion certainly does, lead to an erroneous theory.

M. Galvani was engaged in a ſet of experiments, the object of which was to demonſtrate, if poſſible, the dependence of muſcular motion upon electricity. In the courſe of this inveſtigation, he had met with ſeveral new and ſtriking appearances which were certainly electrical; ſoon after which, a fortunate accident led to the diſcovery of the phenomena which conſtitute the chief ſubject of this article. The ſtrong reſemblance which theſe bore to the electrical facts which he had before obſerved, led almoſt irreſiſtibly to the concluſion that they all depended upon the ſame cauſe. This opinion he immediately adopted; and his ſubſequent experiments and reaſonings were naturally directed to ſupport it. The ſplendor of his diſcovery dazzled the imaginations of thoſe who proſecuted the enquiry; and for ſome time his theory, in ſo far at leaſt as it attributed the whole to the agency of the electric fluid, was ſanctioned by univerſal approbation. Of late, however, this opinion has rather loſt ground; and there are now many philoſophers who conſider the phenomena as totally unconnected with electricity.

2 Diſcovery of galvaniſm.

3 Object of this article.

We propoſe, in the *firſt* place, to enumerate the chief facts which have been aſcertained on the ſubject; we ſhall then enquire, whether or not the cauſe of the appearances be the electric fluid; and, *thirdly*, we ſhall examine how far it has been proved that this cauſe is neceſſarily connected with animal life.

Whilſt Galvani was one day employed in diſſecting a frog, in a room where ſome of his friends were amuſing themſelves with electrical experiments, one of them having happened to draw a ſpark from the conductor at the ſame time that the profeſſor touched one of the nerves of the animal, its whole body was inſtantly ſhaken by a violent convulſion. Aſtoniſhed at the phenomenon, and at firſt imagining that it might be owing to his having wounded the nerve, he pricked it with the point of his knife, to aſſure himſelf whether or not this was the caſe, but no motion of the frog's body was produced. He now touched the nerve with the inſtrument as at firſt, and directed a ſpark to be taken at the ſame time from the machine, on which the contractions were renewed. Upon a third trial, the animal remained motionleſs; but obſerving that he held his knife by the handle, which was made of ivory, he changed it for a metallic one, and immediately the movements took place, which never was the caſe when he uſed an electric ſubſtance.

After having made a great many ſimilar experiments with the electrical machine, he reſolved to proſecute the ſubject with atmoſpheric electricity. With this view he raiſed a conductor on the roof of his houſe, from which he brought an iron wire into his room. To this he attached metal conductors, connected with the nerves of the animals deſtined to be the ſubjects of his experiments; and to their legs he faſtened wires which reached the floor. Theſe experiments were not confined to frogs alone. Different animals, both of cold and warm blood, were ſubjected to them; and in all of them conſiderable movements were excited whenever it lightned. Theſe preceded thunder, and correſponded with its intenſity and repetition; and even when no lightning appeared, the movements took place when any ſtormy cloud paſſed over the apparatus. That all theſe appearances were produced by the electric fluid was obvious.

Having ſoon after this ſuſpended ſome frogs from the iron paliſades which ſurrounded his garden, by means of metallic hooks fixed in the ſpines of their backs, he obſerved that their muſcles contracted frequently and involuntarily as if from a ſhock of electricity. Not doubting that the contractions depended on the electric fluid, he at firſt ſuſpected that they were connected with changes in the ſtate of the atmoſphere. He ſoon

found,

found, however, that this was not the caſe; and having varied, in many different ways, the circumſtances in which the frogs were placed, he at length diſcovered that he could produce the movements at pleaſure by touching the animals with two different metals, which, at the ſame time, touched one another either immediately or by the intervention of ſome other ſubſtance capable of conducting electricity.

All the experiments that have yet been made may be reduced to the following, which will give the otherwiſe uninformed reader a preciſe notion of the ſubject.

Lay bare about an inch of a great nerve, leading to any limb or muſcle. Let that end of the bared part which is fartheſt from the limb be in cloſe contact with a bit of zinc. Touch the zinc with a bit of ſilver, while another part of the ſilver touches, either the naked nerve, if not dry, or, whether it be dry or not, the limb or muſcle to which it leads. Violent contractions are produced in the limb or muſcle, but not in any muſcle on the other ſide of the zinc.

Or, touch the bared nerve with a piece of zinc, and touch, with a piece of ſilver, either the bared nerve, or the limb; no convulſion is obſerved, till the zinc and ſilver are alſo made to touch each other.

4 Has engaged much ſcientific attention.

A fact ſo new, illuſtrated by many experiments and much ingenious reaſoning, which Profeſſor Galvani ſoon publiſhed, could not fail to attract the attention of phyſiologiſts all over Europe; and the reſult of a vaſt number of experiments, equally cruel and ſurpriſing, has been from time to time laid before the public by Valli, Fowler, Monro, Volta, Humboldt, and others.

Frogs, unhappily for themſelves, have been found the moſt convenient ſubjects for theſe experiments, as they retain their muſcular irritability and ſuſceptibility of the galvanic influence very long. Many hours after they have been decapitated, or have had their brain and ſpinal marrow deſtroyed, ſtrong convulſions can be produced in them by the application of the metals. A leg ſeparated from the body will often continue capable of excitement for ſeveral days. Nay, very diſtinct movements have been produced in frogs pretty far advanced in the proceſs of putrefaction. Different kinds of fiſhes, and many other animals both of cold and warm blood, have been ſubjected to ſimilar experiments, and have exhibited the ſame phenomena; but the warm blooded animals loſe their ſuſceptibility of galvaniſm, as of every other ſtimulus, very ſoon after death.

5 The metals.

Almoſt any two metals will produce the movements; but, it is believed, the moſt powerful are the following, in the order in which they are here placed: 1. Zinc; 2. Tin; 3. Lead; in conjunction with, 1. Gold; 2. Silver; 3. Molybdena; 4. Steel; 5. Copper. Upon this point, however, authors are not perfectly agreed.

The proceſs by which theſe ſingular phenomena are produced, conſiſts in effecting, by the uſe of the exciting apparatus, a mutual communication between any two points of contact, more or leſs diſtant from one another, in a ſyſtem of nervous and muſcular organs. The ſphere of this mutual communication may be regarded as a complete circle, divided into two parts. 6 Animal and excitatory arcs.
That part of it which conſiſts of the organs of the animal under the experiment, has been called *the animal arc;* that which is formed by the galvanic inſtruments has been called *the excitatory arc*. The latter uſually conſiſts of more pieces than one; of which ſome are named *ſtays*, *braces*, &c. others *communicators*, from their reſpective uſes.

7 Experiments of the French inſtitute.

A very numerous train of experiments on galvaniſm has been made by a committee of the Phyſical and Mathematical Claſs of the National Inſtitute of France; and as their report comprehends a vaſt number of the moſt important facts which are yet known on the ſubject, we ſhall preſent our readers with the ſubſtance of it (A).

The immenſe maſs of matter which reſulted from the experiments of the committee, is, in their report, preſented, not in the order in which the experiments were made, but in a ſort of claſſification, by means of which a more diſtinct knowledge of the ſubject is obtained at one view. The facts are arranged under theſe ſix heads. *1ſt*, Reſults of the different combinations and diſpoſitions of the parts of the *animal arc*. *2d*, Account of what has been obſerved of the nature and the different diſpoſitions of the *excitatory arc*. *3d*, Circumſtances not entering into the compoſition of the galvanic circle, which, nevertheleſs, by their influence, modify, alter, or entirely prevent the ſucceſs of the experiments. *4th*, Means propoſed for varying, diminiſhing, or reſtoring the ſenſibility to galvaniſm. *5th*, Attempts to compare the phenomena of galvaniſm with thoſe of electricity. *6th*, Additional experiments, performed by M. Humboldt, in the preſence of the members of the committee; which have a reference to ſeveral of the proofs ſtated in the foregoing articles.

8 On the animal arc.

I. To the number of twenty experiments were made on the *animal arc*. The firſt ſeven of theſe were directed to aſcertain the relations between the nerves and thoſe muſcles over which they are diſtributed. In the laſt thirteen, the nerves were cut aſunder, or ſubjected to ligatures; the ſection or ligature being always between the extremities of the arc. Nerves taken from different animals, or from different parts of the ſame animal, and joined in one and the ſame arc, were among the particular ſubjects of theſe experiments; as were alſo the ſolitary nerve, and the ſolitary muſcle, included between the extremities of the *excitatory arc*. There were interpoſed, too, in the courſe of theſe experiments, portions of nerves, and of muſcles, diſtinct from thoſe parts. And, in ſome of the experiments, the animal was without the ſkin and the epidermis.

The following are inferences which have been deduced from theſe experiments:

9 Inferences.

1. The animal arc may conſiſt either of nerves and muſcles together, or of nerves alone, without muſcles (B).

2. Nerves are, therefore, the eſſential part of the animal

(A) The members of the committee were, M. M. Coulomb, Sabbatier, Pelletan, Charles, Fourcroy, Vauquelin, Guyton, *alias* Morveau, and Hallé. M. M. Venturi, De Modene, and M. Humboldt, aſſiſted in the experiment.

(B) We are ſtrongly inclined to doubt the truth of this propoſition. Dr Fowler was at firſt led to think that contractions could be excited in a limb without the metals having any communication with it, except through the medium of the nerve. Recollecting, however, that a very ſmall quantity of moiſture ſerves as a conductor of galvaniſm, he ſuſpected, and our opinion perfectly coincides with his, that in every caſe where contractions are nimal arc; for the mufcles are always more or lefs interfected by the nerves; and are, confequently, in part, a nervous organ.

3. All the parts of the animal arc muft be either mutually continuous, or at leaft contiguous to one another. But even contiguity is fufficient to enable the galvanic phænomena to take place.

4. The fection or ligature of a nerve interrupts not the galvanic phenomena, if the parts which are cut afunder or bound up ftill remain in clofe contiguity to one another.

5. No diverfity of the parts forming the animal arc, though thefe be taken from different parts of the fame animal, or even from different animals, will have power to impair its galvanic fufceptibility, provided only that thefe parts be ftill mutually contiguous.

6. If the *integrity* or galvanic fufceptibility of the animal arc be fufpended by the feparation of any of its parts to fome diftance from one another, it may be reftored by the interpofition of fome fubftances, not of an animal nature, between the divided parts. Metallic fubftances are in particular fit for this ufe. But the mutual contiguity of all the fubftances entering into the compofition of the arc muft ever be carefully preferved. Mr Humboldt difcovered that a bit of frefh morelle (*Helvella mitra Linn.*) will fupply the place of a part of the nerve.

7. The mufcular organs which indicate, by contraction, the prefence of the galvanic influence, are always thofe in which the nerves of a complete animal arc have their ultimate termination.

From this it follows, that the mufcles affected by galvanifm are always thofe correfponding to that extremity of the arc which is the moft remote from the origin of the nerves of which it is compofed.

8. When all the nerves of the animal arc originate towards one of its extremities, then only thofe mufcles which correfpond with the oppofite extremity are fufceptible of galvanic convulfions.

9. When an animal arc confifts of more than one fyftem of different nerves, which have all their origin about the middle of the arc, then will the mufcles of thefe feveral fyftems of nerves be moved alike at both the extremities of the arc.

10. It feems likewife to appear, from a variety of thefe experiments, that the opinion of thofe is inadmiffible, who afcribe the phænomena of galvanifm to the concurrence of two different and reciprocally correfponding influences, one belonging to the nerve, the other to the mufcle, and who compare the relations between the nerve and the mufcle, in thefe phænomena, to thofe between the interior and the exterior coating of the Leyden phial.

11. It appears, laftly, that the covering of the epidermis, in the entire animal body, acts as an obftacle to the decifive difplay of the effects of galvanifm; and that,

---

are produced in a limb without any apparent communication between the metals and the mufcles, except through the medium of a nerve, the communication is in fact completed by the moifture upon the furface of the nerve. In this cafe, the animal arc may be confidered as confifting of three pieces, difpofed in the following order; the nerve, the mufcle, and the water adhering to the furface of the nerve. The latter, indeed, ought rather to be confidered as a part of the excitatory arc. "When a nerve (fays Dr Fowler), which for fome time has been detached from furrounding parts, is either carefully wiped quite dry with a piece of fine muflin, or (left this fhould be thought to injure its ftructure) fuffered to remain fufpended till its moifture has evaporated, no contractions can be excited in the mufcles, to which it is diftributed, by touching it alone with any two metals in contact with each other; but if it be again moiftened with a few drops of water, contractions inftantly take place. And, in this way, by alternately drying and moiftening the nerve, contractions may at pleafure be alternately fufpended and renewed for a confiderable time. It may, indeed, be contended, that the moifture foftened, and thus reftored elafticity and free expanfion to the dried cellular membrane furrounding the fibres, of which the trunk of a nerve is compofed; and thus, by removing conftraint, gave free play to their organization.

"But from obferving, that in every other inftance where contractions are produced by the mutual contact of the metals, a conducting fubftance is interpofed between them and the mufcles as well as between them and the nerve; I think it would be unphilofophical not to allow, that, in the inftance in queftion, the moifture, adhering to the furface of the nerve, formed that requifite communication between the metals and the mufcles." We know of no accurate experiment by which it has ever been fhewn, that contractions can be produced in a limb without a communication being eftablifhed between the metals and nerve, and again between the mufcles and the metals, either directly, or through fome medium capable of conducting galvanifm.

To remove the only objection which can be made to Dr Fowler's experiment, and of which we have feen that he was himfelf aware, namely, that the nerve while dry is incapable of performing its functions, we repeated it in the following manner: A fmall, but vigorous and lively, male frog was decapitated, and the fciatic nerve being laid bare from the knee upwards, was cut through where it paffes out of the pelvis. Fifteen minutes after the head was cut off, the nerve having been cautioufly feparated from the furrounding parts, and coated with tinfoil in the ufual manner, a filver probe was applied to it and its coating, without any other communication with the mufcles, and ftrong contractions took place in the leg. The nerve was now very carefully dried with a piece of fine linen, and the probe was applied as before to the tinfoil and the nerve; no movement whatever took place. Things remaining precifely in this fituation, one end of the probe being ftill in contact with the nerve and its coating, the other end was applied to the mufcles of the thigh, and the leg immediately contracted as ftrongly as ever. Upon moiftening the nerve, the contractions were again produced by applying the probe to the nerve and tinfoil alone. We find from this experiment, which we have feveral times repeated with the utmoft care, and with the fame refult, that the dry nerve retained its functions completely. This appears to us perfectly decifive of the queftion.

that, though from its extreme tenuity, it may not altogether prevent these effects, yet it cannot but very materially diminish them.

10 Experiments on the excitatory arc. II. The *Excitatory Arc* is usually formed of three different pieces, made of different metals. Of these, one must be in contact with the nerve; the other must touch the muscle; and the third must form the mean of communication between these two. This arrangement, though not indispensably necessary, is at least the most convenient.

In respect to the excitatory arc, the committee examined, 1st, The application of metallic substances to form it: in respect to which they endeavoured to ascertain the number and the diversity of the pieces of metal of which this arc may be composed; the metallic mixtures or alloys which are capable of being employed for this use; the particular degree of the friction of one metal upon another, which is favourable to the exhibition of the phenomena; the different states, in respect to galvanism, of metals differently mineralized. 2dly, The effects of the use of carbonic substances in forming the excitatory arc. 3dly, The effects in the same formation, of bodies, which are either non-conductors, or else very imperfect conductors of electricity, such as jet, asphaltus, sulphur, amber, sealing-wax, diamond, &c. 4thly, The consequences of the interposition of water, and of substances moistened with water, between the different parts of the excitatory arc. In forming their excitatory arcs, too, they made themselves the chord of the arc; they introduced into it animal substances which had lost their vitality; they rubbed the supporters with the dry fingers, so as to mark them with nothing but the traces of the perspiration from the skin. They made, likewise, some experiments for the purpose of ascertaining the relations between, on the one hand, the extent and magnitude of the surfaces of the parts composing the arc, and, on the other, the effects produced by its energy. From their experiments they have also drawn some inferences concerning the relative efficiencies of the several constituent parts of the exciting arc. It is impossible for us here to relate in detail all this train of experiments. The following corollaries express the substance of those general truths, which their authors were led to infer from them.

1. The excitatory arc possesses the greatest power of galvanism, when it is composed of at least three distinct pieces; each of a peculiar nature: the metals, water, and humid substances, carbonaceous matters, and animal substances, stripped of the epidermis, being the only materials out of which these pieces may be formed. 11 Inferences.

2. Nevertheless the excitatory arc appears to be not destitute of exciting energy, even when it consists but of one piece or of several pieces, all of one proper substance (c). In general it must be owned, identity of nature in the constituent pieces, and particularly in the supports forming the extremities of the arc, diminishes, in a very sensible manner, its galvanic energy.

3. The slightest difference of nature induced upon the parts, whether by any feeble alloy, or by friction with extraneous substances, is at any time sufficient to communicate to the excitatory arc that full power in which the identity of its composition may have made it defective.

4. As the animal arc is susceptible of being in part made up of metallic substances, or such others as are adapted to enter into the composition of the excitatory arc; so, on the other hand, the excitatory arc admits of being in part formed of those substances which are the proper components of the animal arc.

5. The energies of both the excitatory and the animal arcs are alike suspended by the separation of their component parts, or at least by the separation of these parts to a certain distance.

6. Even the smallest degree of moisture is sufficient to

(c) We do not think it has ever been proved, that one piece of metal, or several pieces of the same metal, are capable of forming the excitatory arc. It is admitted on all hands, that the slightest alloy communicates galvanic energy to a piece of metal; that is, renders it capable of forming the excitatory arc. It is also known, that the metallic oxides are much less perfect conductors of galvanism than their corresponding reguli, to make use of an antiquated expression. It appears to us, that in all cases where one metal appears to act, more especially where friction with the fingers, or breathing on a piece of metal formerly inert, give it galvanic powers; in all these cases, we think it probable that a slight degree of oxidation, produced in some part of the surface of the metal, gives it activity by destroying the homogeneity of its nature. We do not find that this circumstance has been in general sufficiently attended to. Dr Wells having discovered that charcoal acts powerfully as an exciter when applied along with a metal, found that by friction it also can be rendered capable of acting singly. What change is thus produced in it we can only conjecture; but that it is something which destroys the identity of its structure, rendering it in some measure a heterogeneous substance, must be admitted.

Candour forces us to acknowledge, that in one of Mr Humboldt's experiments, it seems very difficult to point out any want of homogeneity in the exciting arc. He put into a china cup some mercury exactly purified; he placed the whole near a warm stove, in order that the entire mass might assume an equal temperature: the surface was clear without the appearance of oxidation, humidity, or dust. A thigh of a frog, prepared in such a manner that a crural nerve and a bundle of muscular fibres of the same length hung down separately, was suspended by two silken threads above the mercury. When the nerve alone touched the surface of the metal, no irritation was manifested; but as soon as the muscular bundle and the nerve touched the mercury together, they fell into convulsions so brisk, that the skin was extended as in an attack of tetanus. This is by far the most decisive experiment which has been tried on the same side of the question; but as it must be admitted, that in most cases two metals are absolutely necessary, and that a single metal often derives activity from circumstances so slight, that we could not *a priori* have expected that they were capable of producing any change; we feel ourselves compelled to conclude, that in M. Humboldt's experiment some similar very slight circumstance had escaped unobserved; perhaps some gilding, or ornaments with metallic colours, in a state of oxidation.

to join the parts of the excitatory arc, and to determine their effects upon the animal arc.

7. The influence upon the state of the atmosphere, and of surrounding circumstances, upon the success of the experiments of galvanism, is, consequently, very great. In order, therefore, to perform these experiments with due accuracy, the state of the hygrometer, and of other meteorological instruments, must be vigilantly inspected during their progress; and the influence of the persons making the experiment upon the sphere within which it is made, must likewise be carefully attended to.

8. The experiments which were made to ascertain the nature of the animal arc, together with those made upon the excitatory arc, with a view to the comparison of the effects of the flesh of animals, with or without the epidermis, and of the different effects of this epidermis, when it is wet and when it is dry, appear to suggest to us, that the epidermis is one of those substances which diminish or interrupt the efficacy of the excitatory arc. The epidermis is, as well as the hairs and bristles of animal bodies, among the number of those substances which deserve the appellation of *idio-electrics*.

9. Examine the substances which are fit for the formation of the excitatory arc, and you will find that the greater part of those which have been successfully put to this use are substances capable of acting as conductors of the electrical fluid; but that the substances which interrupt the operation of galvanism are generally such as are well known also to resist the transmission of electricity.

10. Lastly, it appears, that the galvanic energy depends, not only upon the nature and arrangement of the component parts of the excitatory arc, but on their extent too, and on the magnitudes of their transmitting surfaces.

12 Experiments relating to circumstances different from the arcs.

III. The committee appear to have used no less care and discernment in experiments upon those circumstances which, though different from the structure of the galvanic circle and its two constituent arcs, have, however, *a decisive influence upon the exhibition of the phænomena of galvanism.* Some curious observations were made on the differences in the state of the parts exposed to the galvanic action. It was ascertained, that frogs fresh from the ditches did by no means exhibit the same phænomena as those which had been during some days preserved in the house; nor did the limbs of animals, when recently stripped of the skin, present the same appearances as after they had been subjected to a variety of galvanic experiments; nor were the same effects to be produced upon the parts of animal bodies which, after a certain number of trials, had been left for a while at rest, and then taken up again, as upon those which had been subjected to one continued train of experiments. The committee next examined the variations in the success of the experiments upon a strong lively frog, which may be produced by varying the mode in which the *communicator* is carried from the one *supporter* to the other: when the communicator is brought into contact with the supporter, or is withdrawn from actual contact with it; when the *communicator* is brought slowly, or when it is brought rapidly, into contact with the *supporter;* the effects are nearly the same: and a smart convulsion is, in all these cases, produced at the moment of the commencement of the mutual contact, or of its cessation. But when the frog is fatigued, the effects are different. These successive experiments likewise affect the results of one another, by means even of their succession solely. And they are also naturally subject to be influenced by the nature of the media amidst which they are performed; such as common air, water, an electrical atmosphere. The following are the inferences which have been deduced from this class of these experiments.

1. In many cases the galvanic energy is excited by exercise, is exhausted by continued motion, is renovated by rest. 13 Inferences.

2. The multiplicity of the causes by which the experiments of galvanism are liable to be influenced to success or failure, is so great, that we cannot, as yet, be too cautious in either rejecting or believing these accounts which we hear of the success of any such experiments; unless when we are able accurately to appreciate all the influencing circumstances.

3. This is remarkably confirmed by a fact, which the committee have related in their paper, and which respects the continuation of the galvanic spasm.

The communicator being supported by the hand, and resting, seemingly, without change of position, still upon the same point of contact, there is known to take place a real change in the galvanic contact, although the communicator have remained thus apparently motionless.

From this, it may be farther inferred, that the smallest possible change in the relative situations of the parts of the galvanic circle and the excitatory arc, is capable of producing an effect upon the susceptible animal, and of occasioning mistakes in regard to the success of the experiment, if the utmost care be not taken to notice and estimate every variation that can happen.

4. The truth of the foregoing proposition is farther confirmed by the experiments upon the manner in which the galvanic movements are affected by the advancing or the withdrawing of the communicator. For these experiments fully evince the necessity for the most vigilant observation of every movement in the process of an experiment, not only collectively, but in their succession, and at the different periods of the operation.

5. It should seem that there are, in the formation of the excitatory arc, independently of its modes of acting in the galvanic operations, certain enervating, and certain exciting dispositions; of which some not only augment or diminish the energy in the present instance, but, besides, dispose the animal to a greater or a smaller susceptibility, under subsequent experiments.

6. In order to accuracy of experiment, and to the correct ascertaining of the effects of an experiment, it is of great importance to know the precise state of the animal, the manner in which it has been preserved and sustained to the present moment, the state of the atmosphere, particularly as it is indicated by the hygrometer, by the barometer, the thermometer, and the electrometer.

7. It were to be wished, that in making a statement of experiments of different sorts, these should be arranged in the order of their efficacy, and that there might thus be formed a *galvanic scale*, which should help us to determine the precise degree of the galvanic

susceptibility

fusceptibility of any animal in this or that particular ftate or pofition, fhould direct us in fubjecting every fuch animal only to experiments fuitable to its particular fusceptibility ; fhould enable us to eftimate, from the *efficacy* or *inefficacy* of our experiments, the galvanic value of the circumftances in which we every day find ourfelves, and fhould enable us to judge when the fuccefs or mifcarriage of an experiment can afford room for certain conclufions abfolutely negative or affirmative.

14 Experiments on the galvanic fufceptibility of animal bodies, &c.

IV. In their experiments upon *the means of varying, diminifhing, and renewing the fufceptibility of animal bodies* to the influence of galvanifm, the committee examined, 1ft, the influence of electricity upon that fufceptibility ; 2d, the effects of the mufcular organs, and of certain liquors, fuch as alcohol, the oxygenated muriatic acid, the folutions of potafh and opium, upon the galvanic properties ; 3d, and at the medical fchool of Paris they made a number of experiments, in order to afcertain what new modifications the galvanic energy undergoes in various cafes of fuffocation or afphyxia. Thefe laft-mentioned experiments were made upon hot-blooded animals, of which fome were reduced into the ftate of afphyxia by fubmerfion, fome by ftrangulation, fome by the action of gafes, while others were killed *in vacuo* by the difcharge of the electric fpark. In that fuffocation which was produced by fulphurated hydrogenous gas, by carbonic vapours, and by fubmerfion, in which the animal was fufpended by the hinder feet, the galvanic fufceptibility was entirely deftroyed. The galvanic fufceptibility was only fufpended by fuffocation produced by the pure carbonic acid confined under mercury. It was diminifhed, but not deftroyed, in thofe cafes of fuffocation, which were occafioned by fulphurated hydrogenous gas that had loft a portion of its fulphur, by gas ammoniac, gas azote, or fuch gafes as had been exhaufted of their pure air by refpiration ; and the fame thing was found to take place in animals which had perifhed by total fubmerfion. But the galvanic fufceptibility furvived unaltered in fuffocations brought on by fubmerfion in mercury, by pure hydrogenous gas, by carbonated hydrogenous gas, by oxygenated muriatic acid, by fulphureous acid ; as alfo when the fuffocation was occafioned by ftrangulation, by the abftraction of the air in the air-pump, or by difcharges from an electrical battery. The refults of the experiments at the medical fchool fuggefted the following reflections :

15 Reflections.

1. Though it be true that all cafes of fuffocation refemble one another in the privation of refpirable air, and in the fufpenfion of the functions of refpiration, and of the circulation of the blood ; yet, in their other circumftances, they are fubject to great differences, arifing from diverfity of nature in the fubftances by which they are occafioned.

2. Of thefe caufes, fome appear to act with a more thorough efficacy, penetrating at once all parts of the nervous and mufcular fyftems. Others again feem to act but fuperficially, producing only pulmonary afphyxia, with its immediate effects.

3. One of the moft remarkable changes not confined to the organs of refpiration, confifts in the alterations produced on the galvanic fufceptibility. In that refpect the various cafes of afphyxia differ greatly one from another.

4. The ftate of the irritability of the mufcles, when examined by means of bodies, the mechanical action of which caufes the mufcles to contract by irritating them, is far from always correfponding to the ftate of their galvanic fufceptibility.

5. Laftly, the caufes of fuffocation or afphyxia, do not act upon all parts of the mufcular fyftem in the fame manner ; but the heart is very often found in a ftate extremely different from that of the other mufcles.

16 Comparifon of the phenomena of galvanifm with thofe of electricity.

V. *The comparifon between the phenomena of galvanifm and thofe of electricity* is perhaps one of the moft interefting objects of attention in the whole body of animal phyfiology. It is well known that Galvani was accidentally led to his difcovery by obferving the motions of fome frogs, at a certain diftance from an electrical machine difcharging fparks. The committee from the inftitute made, therefore, fome attempts to afcertain the relations between electricity and galvanifm. Having firft paid due attention to the fufceptibility of animals toward the influence of electricity, they then fought to difcover to what precife degree animals divefted of the natural covering of the epidermis were liable to be affected by the variations of the electrical fluid in the atmofphere around them. Next, comparing the fufceptibility of electricity with the fufceptibility of galvanifm, they perceived that quantities of the electrical fluid, fuch as are ftill capable of being very accurately meafured by the electrometer, are, however, often too weak to act upon a frog that retains the moft perfect fenfibility to all the energy of galvanifm. The members of the committee purpofe to profecute farther their experiments upon this part of the fubject.

17 Refults of fome experiments by Humboldt.

VI. The following are the general refults of the experiments made by M. Humboldt in the prefence of the committee :

1. There is no truth in the affertion of certain phyfiologifts, that the experiments of galvanifm fail when tried upon the heart and thofe other mufcles of which the contractions depend not upon volition ; for thefe organs have been found to be actually fubject to the influence of galvanifm (D).

2. The effects of galvanifm are liable to be interrupted by the conftriction of a nerve, whenever both the nerve and the conftricting ligature are enveloped in the flefh of the animal body (E).

3. The powers of the exciting arc may be renovated or deftroyed, even though its fupporters remain the fame, and although the extremities of the arc be unchanged. Only the relations of the intermediate matters require to be altered.

4. There are atmofpheres of galvanifm.

5. There are fubftances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvanifm.

M. Humboldt had performed alfo other experiments which,

(D) This was demonftrated fix years ago by Dr Fowler.

(E) Dr Valli made this obfervation foon after the difcovery of galvanifm.

which, when he attempted to repeat them before the committee, could not be brought to succeed, on account, as was supposed, of the season of the year.

Such are the principal results of this valuable train of experiments upon galvanism. From them our readers will perceive that this interesting subject is still very imperfectly understood, and will form some idea of the importance of the discoveries which a diligent prosecution of it promises to the philosopher and the physician.

18 Effects of galvanism upon some of the organs of sense.

The effects of galvanism upon some of the organs of sense are no less striking than those which we have seen it capable of producing upon the muscles.

If the upper and under surfaces of the tongue be coated with two different metals, and these be brought into contact with each other, a peculiar sensation, resembling taste, is produced in the tongue the moment that the metals touch each other. With the greater number of metals this sensation is scarcely perceptible; but with zinc and gold, zinc and silver, or zinc and molybdena, it is very strong and disagreeable. Dr Fowler thinks it is strongest with zinc and gold; to us it appears a good deal stronger with zinc and silver. It is sensibly stronger when the zinc is applied to the upper, and the silver to the under surface of the tongue, than when this order is inverted. The sensation is most distinct when the tongue is of the ordinary temperature, and the metals of the same temperature with the tongue. Any considerable increase or diminution of heat in either greatly lessens the effect. Mr Subsir of Berlin, in his *Theorie des Plaisers*, p. 155, (published in 1767) takes notice of the disagreeable taste produced by silver and lead in contact upon the tongue. This is the first instance of galvanism that had been made public.

To ensure complete success to the experiment, the metals ought to be allowed to remain some time in contact with the tongue before they are made to touch each other, that the taste of the metals themselves may not be confounded with the sensation produced by their mere contact. Whatever has a tendency to blunt the sensibility of the tongue, as opium, alcohol, acids, and the like, diminishes the effect of the metals.

It is difficult to describe the sensation thus produced accurately. It has been called *subacid;* but we think it more nearly resembles the effect produced by allowing a grain or two of nitre to lie upon the tongue for some time, than any other taste with which we are acquainted. Joined to this, there is evidently a metallic taste, which varies with the metal employed; but we are inclined to consider this as the ordinary effect of the metals upon the tongue, which cannot be perfectly distinguished from that occasioned by their mutual contact.

This taste can also be produced by applying one of the metals to the tongue, and the other to any part of the Schneiderian membrane. Professor Robison has made many experiments of this kind, the result of which is contained in a letter to Dr Fowler. "I find (says he), that if a piece of zinc be applied to the tongue, and be in contact with a piece of silver which touches any part of the lining of the mouth, nostrils, ear, urethra, or anus, the sensation resembling taste is felt on the tongue. If the experiment be inverted, by applying the silver to the tongue, the irritation produced by the zinc is not sensible, except in the mouth and the urethra, and is very slight. I find the irritation by the zinc strongest when the contact is very slight, and confined to a narrow space, and when the contact of the silver is very extensive, as when the tongue is applied to the cavity of a silver spoon. When the zinc touches in an extensive surface, the irritation produced by a narrow contact of the silver is very distinct, especially on the upper side of the tongue, and along its margin. This irritation seems to be mere pungency, without any resemblance to taste, and it leaves a lasting impression like that made by caustic alkali.

"When a rod of zinc, and one of silver, are applied to the roof of the mouth, as far back as possible, the irritations produced by bringing their outer ends into contact are very strong, and that by the zinc resembles taste in the same manner as when applied to the tongue."

M. Volta found, that when a tin cup, filled with an alkaline liquor, is held in one or both hands previously moistened with water, if the point of the tongue is dipped in the liquor, an acid taste is perceived. This is at first distinct and pretty strong, but gradually yields to the alkaline taste of the liquor. The acid taste is still more remarkable, when, instead of an alkaline liquor, an insipid mucilage is made use of. The same philosopher found, that when a cup made of tin, or, what is better, of zinc, was filled with water, and placed upon a silver support, if the point of the tongue was applied to the water, it was found quite insipid, till he laid hold of the silver support, with the hand well moistened, when a very distinct and very strong acid taste was immediately perceived.

If one of the metals be applied to the tongue, and the other to the ball of the eye, a pale luminous flash is perceived when they are brought into contact with each other, and the sensation resembling taste is at the same time produced in the tongue. A flash is, in like manner, produced when one of the metals is applied to the eye, and the other to any part of the palate, fauces, or inside of the cheek. This experiment requires a good deal of attention in the performance; care must be taken not to press the piece of metal against the ball of the eye, lest a flash should be produced by the mere mechanical pressure. It should be cautiously introduced between the eye-lids, till it just touch any part of the ball; and it should be allowed to remain in that situation for some time before it is brought into contact with the other piece of metal, that the parts may be so far accustomed to it as to admit of the sensations produced being properly attended to. The experiment succeeds very well with tin and silver; but the flash is more bright when zinc and gold are used. The piece of metal which is applied to the ball of the eye must be finely polished, otherwise the mechanical irritation is sometimes so great as to prevent the flash from being perceived. Dr Robison has observed, that the brightness of the flash corresponds with the extent of contact of the metal with the tongue, palate, fauces, or cheek.

If a piece of one of the metals be placed as high up as possible between the gums and the upper lip, and the other in a similar situation with respect to the under lip, a very vivid flash of light is observed at the moment that they are brought into contact, and another at the instant of their separation. While they remain in contact, no flash is observed.

When a rod of silver is thrust as far as possible up one

one of the noſtrils, and then brought into contact with a piece of zinc placed upon the tongue, a very ſtrong flaſh of light is produced in the correſponding eye at the inſtant of contact. We have ſometimes imagined that the flaſh in this experiment was produced before the metals actually touched; but in this we may have been deceived.

The following curious experiment was firſt made by Profeſſor Robiſon: "Put a plate of zinc into one cheek, and a plate of ſilver (a crown piece) into the other, at a little diſtance from each other. Apply the cheeks to them as extenſively as poſſible. Thruſt in a rod of zinc between the zinc and the cheek, and a rod of ſilver between the ſilver and the other cheek. Bring their outer ends ſlowly into contact, and a ſmart convulſive twitch will be felt in the parts of the gums ſituated between them, accompanied by bright flaſhes in the eyes. And theſe will be diſtinctly perceived before contact, and a ſecond time on ſeparating the ends of the rods, or when they have again attained what may be called *the ſtriking diſtance.* If the rods be alternated, no effect whatever is produced."—The flaſhes produced in this laſt experiment are rather more vivid than any which we have been able to excite by the other methods. The convulſive twitches are very diſtinct, and ſomewhat painful, but quite different from the ſenſation produced by an electric ſhock. If the edges of the tongue be allowed to touch the plates of metal in the cheeks, the ſenſation reſembling taſte is felt very ſtrongly; but this does not in the leaſt impair the other effects of the experiment.

No method has yet, we believe, been diſcovered of applying the galvanic influence ſo as to affect the ſenſes of ſmelling or hearing. We have tried many experiments with this view, chiefly on the organs of ſmelling, but hitherto without any ſucceſs (F). Neither has the ſenſe of touch been affected by it, unleſs, indeed, the following experiment be conſidered in that view: Let a ſmall portion of the cuticle be removed from any part of the body by a ſharp knife, and carry the inciſion to ſuch a depth that the blood ſhall juſt begin to ooze from the cutis vera. Let a piece of zinc be applied here, and a piece of ſilver to the tongue; when they are brought into contact, a very ſmart irritation will be felt at the wound.

Some very ſingular facts of this kind have been diſcovered by M. Humboldt, who had the reſolution to make himſelf the ſubject of many well-deviſed experiments. One of the moſt remarkable of theſe is the following: He cauſed two bliſtering plaſters to be applied on the deltoid muſcle of both his own ſhoulders. When the left bliſter was opened, a liquor flowed out, which left no other appearance on the ſkin than a ſlight varniſh, which diſappeared by waſhing. The wound was afterwards left to dry up: this precaution was neceſſary, in order that the acrid humour which the galvanic irritation would produce, might not be attributed to the idioſyncriſis of the veſſels. This painful operation was ſcarcely commenced on the wound, by the application of zinc and ſilver, before the ſérous humour was diſcharged in abundance; its colour became viſibly dark in a few ſeconds, and left on the parts of the ſkin where it paſſed traces of a brown inflamed red. This humour having deſcended towards the pit of the ſtomach, and ſtopped there, cauſed a redneſs of more than an inch in ſurface. The humour, when traced along the epidermis, left ſtains, which, after having been waſhed, appeared of a bluiſh red. The inflamed places having been imprudently waſhed with cold water, increaſed ſo much in colour and extent, that M. Humboldt, as well as his phyſician Dr Schalleru, who aſſiſted at theſe experiments, entertained ſome apprehenſion for the conſequences.

Having now taken notice of the principal facts that are hitherto known in galvaniſm, we proceed to conſider ſome of the leading opinions on the ſubject. 19

Phenomena of galvaniſm ſuppoſed to reſult from electricity;

The firſt writers upon the diſcovery of Galvani ſeem almoſt univerſally to have taken it for granted, that the phenomena depend on the electric fluid; and leaving this very important queſtion behind them, proceeded to explain how this fluid produces ſuch effects. The celebrated diſcoverer of this influence himſelf conſiders a muſcle as the perfect prototype of a Leyden phial. When a muſcle contracts upon a connection being formed, by means of one or more metals between its external ſurface and the nerve which penetrates it, M. Galvani contends, that, previouſly to this effect, the inner and outer parts of the muſcle contain different quantities of the electric fluid; that the nerve is conſequently in the ſame ſtate, with reſpect to that fluid, as the internal ſubſtance of the muſcle; and that, upon the application of one or more metals between its outer ſurface and the nerve, an electrical diſcharge takes place, which is the cauſe of the contraction of the muſcle. Thus the nerve is ſuppoſed to perform the office of the wire connected with the internal ſurface of the phial; and the excitatory arc is conſidered merely as a conductor.

This theory appears to us juſt as incapable of explaining the phenomena of galvaniſm as it is inconſiſtent with the known laws which regulate the motions of the electric fluid. We ſhall not conſider it minutely; for we hope it will ſoon appear highly probable, if not certain, that the electric fluid has no ſhare in the production of the phenomena in queſtion. If this be the caſe, all the different modifications of that theory muſt of courſe fall to the ground. At preſent we ſhall content ourſelves with aſking the following queſtions:

20 This ſuppoſition ill founded.

1. How is it poſſible for the electric fluid to be condenſed in a muſcle, which is wholly ſurrounded by ſubſtances capable of conducting that fluid?

2. If we ſuppoſe there is ſome non-deſcript non-conducting ſubſtance placed between the external and internal

(F) Profeſſor Robiſon has long ago obſerved, that the flavour of a pinch of ſnuff taken from a box made of tin-plate, which has been long in uſe, ſo that the tin coating is removed in many places, is extremely different from that of ſnuff when taken from a new box, or a box lined with tin-foil. The ſame difference is obſerved when we rub a piece of pure tin, or of pure iron and a half worn tinned plate, with the finger. Alſo, if we rub a caſt ſteel razor, and a common table knife conſiſting of iron and ſteel welded together. This is ſurely owing to a cauſe of the ſame kind.

ternal parts of a muſcle, which may admit of the one being poſitively, and the other negatively electrified at the ſame time—how comes it to paſs that a diſcharge does not take place, and a conſequent contraction enſue, when any ſubſtance whatever, capable of conducting the electric fluid, is interpoſed between the nerve and the external ſurface of the muſcle? For example, when the nerve and muſcle are laid bare, and the animal thrown into water; or when the nerve is cut through, and the end applied to the external ſurface of the muſcles.

3. How does it happen, when one diſcharge actually takes place, in conſequence of the application of the excitatory arc, that the balance is not inſtantly reſtored? That this does not happen, appears by the ſame muſcle and nerve being capable of producing many hundreds of ſimilar, and equally ſtrong diſcharges, without any apparent means of the equilibrium being again diſturbed.

We have never ſeen any anſwers to theſe queſtions which appeared to us at all ſatisfactory; and till we have ſeen them anſwered, we muſt be excuſed for diſbelieving M. Galvani's theory.

One of the earlieſt writers, and one of the moſt aſſiduous inveſtigators of the phenomena of galvaniſm, is Dr Valli. He differs in opinion from Galvani upon ſeveral points; but agrees with him in thinking electricity and galvaniſm the ſame. Let us conſider the proofs by which he ſupports this doctrine.

"I have aſſerted (ſays he), that the nervous fluid is the ſame with electricity, and with good reaſon; for

21 Proofs by which Valli endeavours to ſupport it,

"Subſtances which conduct electricity are conductors likewiſe of the nervous fluid.

"Subſtances which are not conductors of electricity do not conduct the nervous fluid.

"Non-conducting bodies, which acquire by heat the property of conducting electricity, preſerve it likewiſe for the nervous fluid.

"Cold, at a certain degree, renders water a non-conductor of electricity as well as of the nervous fluid.

"The velocity of the nervous fluid is, as far as we can calculate, the ſame with that of electricity.

"The obſtacles which the nerves, under certain circumſtances, oppoſe to electricity, they preſent likewiſe to the nervous fluid.

"Attraction is a property of the electric fluid, and this attraction has been diſcovered in the nervous fluid.

"We here ſee the greateſt analogy between theſe fluids; nay, I may even add, the characters of their identity."

That there is a conſiderable analogy between ſome of the effects of the electric fluid and ſome of the phenomena of galvaniſm, we readily admit; but that "the characters of their identity" are anywhere to be found, we abſolutely deny. In the above paſſage, Dr Valli conſiders it as certain that the nervous fluid is the cauſe of the phenomena diſcovered by Galvani. But it has never been demonſtrated irrefragably, that any ſuch thing as a nervous fluid exiſts, and ſtill leſs that this is the ſame with the influence diſcovered by Galvani.

22 Inconcluſive and

That bodies are, in general, conductors or non-conductors of galvaniſm, according as they are conductors or non-conductors of electricity, we believe to be true; but this rule is by no means without exception, as it certainly would be, if galvaniſm and electricity were the ſame. There is an experiment of Dr Fowler's, which ſeems to ſhew that water is a more powerful conductor of galvaniſm than mercury; though the reverſe is generally allowed as to electricity.

If the abdomen of a frog be filled with water, and a ſilver probe paſſed through it ſo as to touch the ſciatic nerves, no contractions are produced; neither do they appear when the probe is touched above the ſurface of the water with a piece of zinc. But if the zinc be applied to the probe at the ſurface of the water, contractions are produced as vigorous as if both the metals touched the nerve. Here the water ſerves as a conducting medium between the nerves and the point where the metals touch each other: but if the abdomen be filled with mercury inſtead of water, no contractions are produced by applying the ſilver probe to the nerves, and touching the probe with the zinc at the ſurface of the mercury. We do not ſee how this experiment can be accounted for, except by allowing that water is a more powerful conductor of galvaniſm than mercury.

If this experiment ſhould be thought inconcluſive, we have the authority of M. Humboldt, and of the committee of the National Inſtitute of France, for ſaying that there are ſubſtances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvaniſm. This is certainly ſufficient to take away all weight from Dr Valli's two firſt reaſons for conſidering theſe two fluids as the ſame, viz. that all conductors of electricity are likewiſe conductors of galvaniſm; and that all bodies which do not conduct the former are alſo non-conductors of the latter. Theſe two are by far the moſt important of his reaſons; and if they were true in their full extent, they would certainly ſhew a very ſtriking analogy, though they would by no means deſerve the appellation of "characters of identity."

As to the Doctor's two next propoſitions, which regard the effects of heat and cold in rendering bodies conductors or non-conductors, they are, in fact, only branches of the two firſt; and as we have ſeen that theſe are not univerſally true, we might admit that they are correct in this particular, without weakening our argument. For this reaſon we ſhall not conſider them minutely; but we may obſerve that Dr Fowler's experiments ſhew that boiling water, and water cooled down to the freezing point, both conduct this influence as well as water at the ordinary temperature of the atmoſphere. If any change in the conducting power takes place beyond theſe points, it may with greater probability be aſcribed to the changes of form which the water undergoes, than to the increaſe or diminution of its temperature.

We confeſs ourſelves perfectly ignorant of any data upon which Dr Valli could found a calculation, the reſult of which could ſhew that the velocity of the nervous fluid is the ſame with that of electricity. Suppoſe we ſhould take it into our heads to aſſert that the velocity of galvaniſm is the ſame with that of light, we apprehend our author could not eaſily demonſtrate the contrary. Neither, in all probability, would he conſider this aſſertion of ours as a ſufficient proof that galvaniſm and light are the ſame.

With regard to the next propoſition, that "the obſtacles which the nerves, under certain circumſtances, oppoſe to electricity, they preſent likewiſe to the nervous fluid;" we may remark, that any obſtacle which

 deſtroys

destroys the functions of a nerve completely, will prevent the muscles which are supplied by that nerve from contracting upon the application of any stimulus whatever (G). It does not, however, by any means follow, that the passage of either the galvanic or the electric fluid is prevented. The nerves may still be very good conductors of both, though the muscle is deprived of all power of contracting. That there are obstacles, however, which the nerves, under certain circumstances, present to the passage of electricity, but which they do not under the same circumstances present to galvanism, we think abundantly demonstrated by Dr Valli's own experiments.

23 Inconsistent with his own experiments,

"I have frequently observed (says he) that the legs, of which the nerves had been tied at a certain distance from the muscles, did not feel the action of a certain quantity of artificial electricity, although they were violently convulsed by exciting that which was inherent and peculiar to them." What then was the cause of the difference observed in these cases between the effects of galvanism and electricity? Was it, that the quantity or degree of the former exceeded that of the latter? Be it so.

Dr Valli informs us, that in his experiments, an electric charge which could flash through a thickness of air equal to .035 of an inch, produced no movement in the leg of a frog of which the crural nerve was tied, while the other leg, of which the nerve was left free, underwent considerable movements.

That the influence discovered by Galvani can pass through an exceeding thin plate of air, is certain, as it is transmitted from link to link of a chain, where no considerable force is used to bring the links into contact. Dr Robison's experiment, too, in which the flashes of light are distinctly observed before the rods of silver and zinc touch each other, is another proof of the same fact; and, if we be not deceived, the same thing takes place when a rod of silver thrust up the nostril is applied to a piece of zinc in contact with the tongue. But that it will only pass through an exceeding thin plate of air, any man may convince himself by an experiment first tried by Dr Fowler, which is easily repeated. If a stick of sealing-wax be coated with tinfoil, it will be found a very good conductor; but if, with a sharp pen-knife, an almost imperceptible division be made across the tinfoil, even this interruption of continuity in the conductor will be found sufficient effectually to bar the passage of galvanism.

We find, then, that a quantity of the electric fluid which can pass through a plate of air of the thickness of .035 of an inch, is obstructed by a ligature upon a nerve, while the galvanic influence passes readily along a nerve included in a ligature, but is obstructed completely by making an almost imperceptible division in a good conductor. The plate of air in this case surely is not near .035 of an inch in thickness. It results incontestibly, from a comparison of these two experiments, that there is, between these two agents, some other difference besides the mere degree of intensity.

We come now to the last reason which our author assigns for his belief that galvanism, or, as he chooses to call it, the *nervous fluid*, is the same with electricity. It will be found a very important one. That property by which bodies charged with the electric fluid attract or repel other bodies, according as they are in the same or the opposite state of electricity from themselves, is so striking, and at the same time so universal, that it has been very properly adopted as the measure of this fluid. If it were true, then, that the galvanic influence possessed the same properties of attraction and repulsion as the electric fluid, this circumstance would certainly increase the analogy between them very much. As we have already seen, however, that they differ in other essential points, even if it were true that they agreed in this, it could constitute no proof of their identity. But if, on the other hand, we should find that this assertion of our author is founded on error, and that the galvanic influence possesses in no degree whatever those properties of attraction and repulsion which have always been justly considered as essential characteristics of the electric fluid, we shall then be fully justified in asserting, that these two agents, however much they may resemble each other in some less important particulars, are in their nature totally distinct and unconnected. 24

And with the knowledge of electricity.

Let us examine the proofs by which Dr Valli's assertion is supported. He tells us, that he observed the hairs of a mouse, attached to the nerves of frogs, by the tinfoil with which he surrounded them, alternately attracted and repelled by each other, whenever another metal was so applied as to excite contractions in the frogs. We are very far from meaning to insinuate that Dr Valli did not see, or think he saw, what he thus describes; but that the motion of the hairs must have arisen from some cause, different from that to which he ascribed it, cannot admit of a doubt; for hairs, in such a state of electricity as he supposes, never attract, but always repel each other.

Dr Fowler, who has paid particular attention to this part of his subject, has many times repeated this experiment, both in the manner described by Dr Valli and with every variation in the disposition of the hairs which he could devise: but whether they were placed on the metals, the nerves, or the muscles, or upon all at the same time, he has never in any instance been able to observe them agitated in the slightest degree. He has made similar experiments upon a dog, and upon a large and lively skate, by disposing, in the same way that Valli did the hairs of a mouse, flakes of the finest flax, swan-down, and gold leaf: but although the contractions produced in the skate, by the contact of the metals, were so strong as to make the animal bound from the table, not the least appearance of electricity was indicated. He next suspended from a stick of glass, fixed in the ceiling of a close room, some threads, five feet in length, of the flax used in the former experiment; and brought some frogs recently killed, and insulated upon glass, as near to them as possible without touching: but the threads were in nowise affected by the contractions produced in the frogs.

In a very ingenious paper upon galvanism by Dr Wells,

(G) We do not here mean that contraction which muscles are susceptible of long after death, upon having their fibres mechanically irritated, which is produced by what physiologists have called the *vis insita*, and which is perfectly known to our cooks, as it was to their predecessors in the Roman kitchens, as the foundation of the art of crimping. We at present confine ourselves to contraction produced through the medium of the nerves.

25 Reafoning of Dr Wells on the fame fubject,

Wells, which is publifhed in the London Philofophical Tranfactions for 1795, that gentleman maintains the opinion, that the influence difcovered by Galvani is electrical. He admits, that it is not attended with thofe appearances of attraction and repulfion which are held to be the tefts of the prefence of electricity; but he contends, that "neither ought figns of attraction and repulfion to be in this cafe prefented on the fuppofition that the influence is electrical; fince it is neceffary, for the exhibition of fuch appearances, that bodies, after becoming electrical, fhould remain fo during fome fenfible portion of time; it being well known, for example, that the paffage of the charge of a Leyden phial, from one of its furfaces to the other, does not affect the moft delicate electrometer, fufpended from a wire, or other fubftance, which forms the communication between them."

26 Inconclufive likewife.

That the charge of a Leyden phial does not, in paffing along a wire, affect an electrometer, is certain; and it is equally true, that we have no means of applying an electrometer to a quantity of galvanifm in a ftate of reft in a body. If this influence ever exifts in fuch a ftate, we have no teft by which we can difcover its prefence; and it is only from the effects which it produces *in tranfitu* that we know of its exiftence. But the electric fluid, in paffing from link to link of a chain, fenfibly affects an electrometer; and in Dr Fowler's experiment with the fkate, for example, as more than one piece of metal is employed as an exciter, the fluid, in paffing from one piece to another, fhould have affected the light fubftances which were placed upon them. This appears to us a fufficient anfwer to the objection ftarted by Dr Wells: but the fame objection having been lately made to us by a gentleman from whom we fhall always receive every fuggeftion with uncommon deference, we thought it worth while to try the following experiment:

Three hours after a frog had been decapitated, it fhewed ftrong figns of galvanic fufceptibility. One of the fciatic nerves being coated with tinfoil in the ufual manner, the leg was laid upon a plate of zinc. A gentleman was defired to lay hold of the nerve and its coating with the fingers of one hand, which had been previoufly dipped in water, while with the other hand, alfo wet, he held the end of a fmall brafs chain about two inches in length. Another gentleman now took hold of the other end of the chain, and, with a filver probe, held in his other hand, touched the plate of zinc. The influence being thus made to pafs through the chain, the leg contracted vigoroufly; but a very fenfible electrometer, held fo near to the chain as almoft to touch it, was neither attracted nor repelled. In performing this experiment, it was neceffary to have the hands wet, as the dry cuticle tends much to obftruct the paffage of galvanifm; but the utmoft care was taken that the chain fhould be perfectly dry, otherwife the influence might have been tranfmitted by the moifture upon its furface without paffing through the chain itfelf.

To avoid the poffibility of this happening, the experiment was varied in the following manner: The frog's leg was laid upon a plate of zinc, and the nerve upon a plate of filver. A gentleman now took a filver probe, and one end of the brafs chain in contact with it, in one hand; and in the other hand he held the other end of the chain in contact with a rod of zinc. He now touched the filver plate with the rod of filver, and the zinc plate with the rod of zinc. As the influence was not now to be made to pafs through his body, there was no neceffity for his hands being wet; the whole excitatory arc was therefore made completely dry. In this way very ftrong contractions were excited in the leg, and ftill the electrometer was not affected in the fmalleft degree when brought near the chain.

It is proper to obferve, that Dr Valli, in his affertion that attraction is a property of galvanifm, does not reft entirely upon his own obfervation: a committee of the Academy of Sciences at Paris performed the following experiment along with him: "They placed a prepared frog in a veffel which contained the electrometer of M. Coulomb, charged negatively and pofitively by turns. In both cafes, in exciting the animal in the common way, the ball of the electrometer was attracted." It appears to us that Dr Valli and the committee have been deceived by the friction produced by the motion of the animals under their experiments having excited fo much electricity as to affect the electrometer. The firft time we tried the experiment abovementioned with the brafs chain, we were almoft mifled by a fimilar circumftance. Inftead of an artificial electrometer, which we happened not to have at hand, we made ufe of a very long and flender human hair; and we found that it was ftrongly attracted by the chain. Upon an attentive examination, however, we found that this did not arife from the action of the influence paffing thro' the chain, but from the ftate of the hair itfelf, which was fo highly electrical as to be ftrongly attracted by every conducting fubftance which it approached. Upon fubftituting another hair, which fhewed no mark of being either pofitively or negatively electrified, it was neither attracted nor repelled by the chain. From the above, or fome fimilar circumftance, it is probable that Dr Valli's miftake has originated; but we are confident, that whoever will repeat the experiment with fufficient attention, will find the refult precifely as we have defcribed it.

Perhaps it may ftill be faid, that although we have never been able to difcover attraction and repulfion as properties of galvanifm, this may arife from our not being able to accumulate this influence in fufficient quantity. To this reafoning, if reafoning it can be called, we oppofe the following confiderations, which ftate a diffimilarity in the phenomena of electricity and galvanifm, that feems abfolutely irreconcileable with the identity of the caufe. 27

27 Demonftration, that the phenomena of galvanifm and of electricity refult not from the fame caufe.

Nothing is more completely eftablifhed in the fcience of electricity than this, that all thofe appearances which we call *attractions, repulfions, abftractions, and accumulation of electric fluid*, are precifely fimilar to what would be the appearances, if electricity were a fluid, whofe particles repel each other, and attract the particles of other matter, according to a certain law (See Electricity, *Suppl.*). Of all thofe phenomena, the moft remarkable is the accumulation of electric energy (to give it no more definite name), by means of thin idioelectrics, coated with non-electrics; fuch, namely, as are exhibited by the Leyden phial, the condenfer, the doubler, &c.

If the phenomena of galvanifm are produced by the paffage of electric fluid from one extremity of the excitatory arc to the other, this paffage will be regulated by the known laws of electricity. It may therefore be accumulated

accumulated *(in transitu)* by means of an apparatus similar to the coated pane, or to the condenser. Professor Robison, with this view, made the following experiments :

1. He made a part of the conductor to his condenser, or collector of atmospheric electricity, consist of a long glass rod, on one side of which was fastened (with varnish) a very narrow slip of tinfoil; there was a fine point at one end of this rod, and a gold leaf electrometer at the other. This apparatus was insulated at one end of a room 19 feet long, having a window in the middle of each side. A small electric machine was placed at the other end. On a dry day, with a gentle breeze in a direction across the room, both windows were opened a little way, so that there was a continual stream of air across the room. The machine was worked ; and after a short time had elapsed, the electrometer began to diverge, gradually opened, and at last struck the conducting slips on each side, and then collapsed, and again began to diverge. The windows were shut ; and immediately, without working the machine, the electrometer diverged rapidly, and touched the sides of the phial every minute and half. This continued so long, that there seemed to be no end to it. The Professor now made a cut across the tinfoil with a very sharp knife ; the electrometer now diverged very feebly, and $7\frac{1}{2}$ minutes elapsed before it touched the sides. He passed the knife a second time through the cut. This widened it (though scarcely sensible to the eye), because the knife had been blunted by the glass in the first operation. All divergency of the electrometer was now at an end ; and although the machine was worked till the electric smell was sensible at the door to a person who happened to come in at this time, no tendency to divergence was observed. (*N. B.* the top of the electrometer had no conducting substance about it, except the slip of tinfoil).

The cut, being examined with a microscope furnished with a micrometer, was $\frac{31}{1000}$th of an inch. It was now filled up, by binding over it another slip of tinfoil. A plate of talc, whose thickness did not exceed the 900th of an inch, was coated on one side in a circle of $1\frac{1}{2}$ inch diameter. The electrometer was removed, and the coated side of the talc was put into close contact with the slip of tinfoil on the glass rod. A stand of tin, whose top was a plate of $1\frac{1}{2}$ inch diameter, smeared over with mercury, was placed in contact with the other side of the talc, and they were pressed into very close and continuous contact.

The machine being now worked, the coated talc received a charge in about 5 minutes sufficient to give a very smart shock : and this was repeated with great regularity every five or six minutes. The windows were now thrown open, and the room cleared of its former contents of air, till none of those present could perceive any electric smell. The machine was now worked again. But after half an hour, only a very faint twitch was felt ; but enough to shew that an accumulation was taking place. The windows were now half shut. After working the machine about five minutes, a faint twitch was obtained ; after a quarter of an hour more, there was a moderate shock.

In this state of things, the apparatus was examined as a condenser, by first taking out the sharp point by an insulating handle, and then removing the tin stand. Examined in this way, it appeared plainly that, even when all the windows were open, the accumulation began almost as soon as the machine was worked. Nay, it was found, on another day equally favourable, that a plate of talc $\frac{47}{1000}$ or $\frac{50}{1000}$ of an inch thick, took a charge, although a cut of $\frac{31}{1000}$ wide did not allow the electricity to fly across it. This is perfectly similar to all our experiments on coated glass. The thickness which admits an accumulation is almost incomparably greater than the distance to which a spark will fly, or a concussion is producible, in the same intensity of electricity.

2. The above described apparatus was insulated, and a wire connected with each end. To one wire was joined a thin plate of lac, coated on the side next the wire; and to the other a piece of moist leather covered with tin-foil. These plates were rubbed together by means of insulating handles. The plate of coated talc quickly took a charge.

The same plate of talc, and afterwards another plate not more than half as thick, was now made part of the excitatory arc, and sometimes part of the animal arc. Sometimes plates of varnish, incomparably thinner than either of these, were employed. But all Professor Robison's attempts to produce an accumulation of galvanic energy in this way were fruitless. The second form of the electrical experiment was adopted, as having a somewhat greater resemblance to the supposed procedure of galvanism; but the well-informed electrician will easily perceive, that the first form is far more delicate and decisive.

The internal procedure in the electric and galvanic convulsions is therefore so different, nay, opposite, that we cannot bring ourselves to think that the appearances are operations of the same agent (H).

We have now gone over all the points of resemblance which, in Dr Valli's opinion, constitute the characters of the identity of galvanism and electricity. We think that, without going farther, we might safely rest our assertion, that these two agents are perfectly distinct and unconnected with each other. But there are several other circumstances which merit attention. 28

Farther considerations on electricity and galvanism.

No electrical phenomenon can take place between two bodies, unless these bodies be in opposite states of electricity with regard to each other. Now, how are we to account for the accumulation of electricity in any body, or part of a body, surrounded on all hands by conducting substances? The experiments of Galvani succeed equally well, whether the subjects of them be insulated or surrounded by conductors; whether performed in the driest air or under water (I) ; whether, by

(H) What if it were called *metallorgasm*, which translates exactly metallic irritation, or metallegersism, from μεταλλον, and εγερσις *excitatio*.

(I) Dr Fowler mentions an exception to this. " When the separated leg of a frog was held under water, and formed part of the circuit through which this influence had to pass in order to excite another leg, it never contracted ; although it did, and strongly, when held above the surface." In this case it is plain, that the frog's leg by means of an electrical machine, we charge the animal and the metals till every part of them strongly affect the electrometer, or whether we reverse the experiment and electrify them negatively, still no change is produced in the force or frequency of the actions excited by the application of the metals. Is there any electrical experiment which could continue to give the same result in such opposite circumstances? or is there any possibility of accounting for it consistently with the known laws of the electric fluid?

The writers on this subject who adopt the electric theory, instead of attempting to explain how the electric fluid can be condensed in a body surrounded by conducting substances, have recourse to the analogy of the gymnotus, torpedo, and other fishes of the same kind. Here, say they, we have in fact the electric fluid accumulated in such a situation, and there is no reasoning against facts. We answer, that these animals are all furnished with organs of a very peculiar structure, which may possibly be fitted for the purpose of such a condensation. Besides, we apprehend it has never been incontestibly proved that these singular animals derive their powers from the electric fluid. Without wishing to enter into this question, which is foreign to our present subject, we may remark that Mr Walsh discovered, that the shock of the torpedo would not pass through a small brass chain; a circumstance in which it differs remarkably both from electricity and from the influence discovered by Galvani.

It were worth while to try Professor Robison's methods of accumulation in the examination of the convulsions occasioned by the torpedo. The Professor suspects that the popular horror at the lamprey, and the accounts of cramps and pains produced by it, have their source in some similar powers of that animal.

Dr Valli's reasoning on this part of the subject is very curious. He takes it for granted that the gymnotus owes its influence to the electric fluid. Then, though the gymnotus gives shocks and emits sparks, while the torpedo only gives shocks without emitting sparks, he says it would be absurd to assert that the torpedo derives its influence from a cause different from the gymnotus. Again, though the influence discovered by Galvani neither gives shocks nor emits sparks, it would still be absurd to maintain that it is not the same as the electric fluid, and as the influence of the gymnotus and torpedo. To dissent from any part of this very logical deduction, he declares would be contrary to the laws of philosophising! *Risum teneatis?*

Afraid, probably, that his readers might be tempted to offend against these new laws, he proceeds to strengthen them by the analogy of animals and vegetables retaining an uniform temperature *in media*, warmer or colder than their own bodies; from which he argues that they may also have a power of accumulating electricity, and retaining it in a particular part, though their whole bodies are conductors. But the cases are in no respect similar. Neither animals nor vegetables accumulate caloric in any particular part of their bodies in preference to any other part. They have no power of *retaining* caloric in their bodies more strongly than any other bodies do; for if they are placed in a medium colder than themselves, they are continually imparting caloric to that medium. Neither is there the smallest proof, from any experiments yet published, that when placed in a medium warmer than themselves, they do not continually absorb caloric from it. The existence of a frigorific power in animals appears to us exceedingly problematical; but if it were proved to exist, it would by no means demonstrate that animals or vegetables have a faculty of declining to absorb caloric from bodies warmer than themselves. It is readily admitted, that animals and vegetables have a power, within certain limits, of preserving their temperature higher than that of the surrounding medium; nor is there any thing surprising in this, as the caloric, which they are continually receiving by the decomposition of oxygenous gas, is dissipated slowly. But if we should allow that animals have a similar faculty of generating the electric fluid; from the nature of that fluid it must be continually communicated, not only to every part of the bodies of the animals themselves, the whole of which are conductors, but to every conducting substance contiguous to them: and this must take place, not slowly, like the dissipation of caloric, but instantaneously, so as to render any sensible accumulation impossible.

29 Difference in their mode of excitement,

Galvanism differs from electricity in nothing more remarkably than in the mode of its excitement and discharge. To produce the phenomena discovered by Galvani, no operation at all similar to the friction of an electric upon a conducting substance is necessary (K). The nerves and muscles have only to be laid bare, and a communication formed between them by means of the excitatory arc, when the contractions immediately ensue. In the case of electricity, a single discharge having restored the equilibrium, no farther effects can be produced till this has been again destroyed by some means capable of producing a condensation in one quarter and a comparative rarefaction in another. The fact is very different with regard to galvanism; for with it the number of shocks which may be given appears to be infinite. Nay, they frequently become stronger in proportion as they have been longer continued: this influence differing extremely in this particular, too, from the electric fluid, which, besides being itself exhausted, never fails in a remarkable manner to exhaust the contractile power of the muscles.

30 And in the duration of their effects.

The permanence of the effects of galvanism is still more striking in the experiments upon the organ of taste. When the metals are applied to the tongue, the sensation

---

leg had in fact formed no part of the circuit through which the influence passed; the influence had been transmitted by the water in which the leg was held.

(K) It is true, as we have noticed above, that galvanic energy is sometimes communicated to a conducting substance by rubbing it upon some other substance; but this has no resemblance to the excitement of electricity by friction. The galvanic energy is communicated in this case to a *conducting* substance, and it succeeds as readily when both the bodies are of this class as when one of them is an idio-electric. But no electric phenomenon has ever been produced by the friction of two conducting bodies upon each other; one of them must be an idio-electric, and it is in this one that the excitement takes place.

ſenſation produced is not ſudden and tranſient; but ſo long as the metals are in contact with the tongue and with each other, ſo long does the taſte continue; and, after ſome time, it becomes inſufferably diſagreeable. M. Volta, who adopts the electric theory with various modifications, ſenſible of the permanence of the effect, in his curious experiments abovementioned ſuppoſes, that a ſtream of electricity paſſes from the tin cup to the liquor, from this to the tongue of the perſon making the experiment, then through his body, and returns through the water upon his hands to the cup; and thus he ſuppoſes the fluid to move perpetually in a circle. It is ſurely unneceſſary for us to obſerve, that the ſuppoſition of a ſtream of electricity continually moving in a circle in this manner, is wholly inconſiſtent with the laws which appear in every caſe to regulate the motions of that fluid. The ſame obſervation applies to the manner in which he explains moſt of the other phenomena of galvaniſm.

The electric fluid cannot be put in motion but by deſtroying the equilibrium to which it perpetually tends; but whenever this is deſtroyed, all that is required to produce a diſcharge is, that a ſingle conducting ſubſtance be placed between the two points in which it is unequally diſtributed. Here again there is a very wide diſtinction between this fluid and the influence diſcovered by Galvani. M. Volta divides all conductors of galvaniſm into two claſſes; 1ſt, Dry conductors, comprehending metals, pyrites, ſome other minerals, and charcoal; and, 2d, Moiſt conductors. He aſſerts, that it is abſolutely neceſſary, in order to the production of the phenomena, that two conductors of the firſt claſs touch each other immediately on one hand, while at their other extremities they touch conductors of the ſecond claſs. Whether this be admitted or not, we have already ſtated our opinion that the action of two different ſubſtances is abſolutely neceſſary in order to excite contractions: and although it is contended by ſome writers that a ſingle piece of metal has ſometimes been found ſufficient, yet even they muſt allow that, in by far the greater number of caſes, it has been found neceſſary to make uſe of two metals, and that the effect is even heighened in general by employing three. In the whole ſcience of electricity, we do not know a ſingle fact which bears the ſlighteſt analogy to this. Never in a ſingle inſtance has it been found, that the effects of a Leyden phial have been increaſed by uſing a conductor formed of two or more metals in procuring the diſcharge.

Before leaving the ſubject of conductors, we may take notice of a very curious and important fact mentioned by Dr Valli. "Amongſt men," ſays he, "there are ſome individuals who are good conductors, others who are leſs ſo; and ſome again who appear to be almoſt non-conductors. I was one day carrying on, with three of my friends, ſome experiments upon frogs. A frog was put in water, and we each by turn eſſayed its power. Two of us excited ſtrong convulſions, the third only feeble ones, and the fourth none at all. This experiment was repeated frequently with the ſame reſult. This is not the only example I could adduce of the reality of this fact, but I do not think it neceſſary to dwell any longer upon it." We have met with one individual who is not ſenſible of any peculiar ſenſation when the metals are applied to his tongue. This ſeems in ſome meaſure to corroborate Dr Valli's obſervation. It is apprehended, however, that all men are equally good conductors of electricity. 31 Some men non-conductors of galvaniſm.

There is ſtill another very marked diſtinction between the effects of galvaniſm and electricity. No ſhock at all reſembling that produced by the electric fluid has ever been felt by any perſon whoſe body was made a part of the chain conducting the galvanic influence, while a very ſmall quantity of the electric fluid is immediately felt (L). In Dr Robiſon's experiment with the plates of zinc and ſilver in the cheeks, there is no doubt a convulſive twitch diſtinctly felt in the gums; but, as we have already obſerved, the ſenſation thus produced is quite different from that which is felt from an electric ſhock (M).

There is an experiment related by Dr Valli, which ſeems to ſhew that nothing like an electric ſhock is felt, even when this influence is tranſmitted through a nerve, ſo as to excite convulſions. Having laid bare the nerves of a fowl's wing, without cutting them, and without killing the fowl, upon applying the metals very ſmart movements were produced, but the animal remained perfectly tranquil. Nor was this owing to the fowl

(L) There is an exception to this rule which ought to be taken notice of. M. Cotugno informs us, that when he was one day employed in diſſecting a live mouſe, he received a ſenſible ſhock from the animal. But as neither he nor any other perſon has ever been ſimilarly affected in any other inſtance, it ſeems pretty certain that he was deceived into the belief of a ſhock from the ſenſation produced by the ſtruggles of the animal he diſſected.

(M) "No one (ſays M. Humboldt) can ſpeak more decidedly on this ſubject than myſelf, having made ſeveral experiments on my own perſon, the ſeat of which, in ſome inſtances, was the ſocket of a tooth which I had cauſed to be extracted; in others, certain wounds which I made in my hand; and in others, the excoriations produced by four bliſtering plaſters." The following is the reſult of theſe painful experiments. The galvanic irritation is always painful, and the more ſo in proportion as the irritated part is more injured and the time of irritation more prolonged. The firſt ſtrokes are felt but ſlightly; the five or ſix following are much more ſenſible, and even ſcarcely to be endured, until the irritated nerve becomes inſenſible from continued ſtimulus. The ſenſation does not at all reſemble that which is cauſed by the electric commotion and the electric bath; it is a peculiar kind of pain, which is neither ſharp, pungent, penetrating, nor by intermiſſions, like that which is cauſed by the electric fluid. We may diſtinguiſh a violent ſtroke, a regular preſſure, accompanied by an unintermitting glow, which is incomparably more active when the wound is covered with a plate of ſilver and irritated by a rod of zinc, than when the plate of zinc is placed on the wound, and the ſilver pincers are uſed to eſtabliſh the communication.

fowl being in a ſtate of inſenſibility; for when the nerves were pricked or irritated it ſcreamed violently. But all animals ſhew ſigns of great uneaſineſs from an electric ſhock.

In general, it muſt be confeſſed, that animals under experiments of this kind ſeem reſtleſs and uneaſy. The great diſtinction of which we ſpeak at preſent, conſiſts in this, that the electric fluid produces a ſhock and uneaſy ſenſation when any part of the body is introduced into the conducting chain; while the influence diſcovered by Galvani, on the contary, when merely tranſmitted through the body in this manner, gives no ſhock, nor any ſenſation whatever, inſomuch that we are not ſenſible of its paſſage. If this influence be made to act directly on a nerve, there is, no doubt, ſome kind of irritation produced, as appears from the effect of the metals upon the tongue, the eye, and other nervous parts; but ſtill this action bears no analogy to that of the electric fluid. As the application of the metals to the organs of ſenſe, produces in each organ the peculiar ſenſation for which it is conſtructed, as taſte in the tongue, light in the eye, &c. ſo when nerves intended merely for muſcular motion are ſubjected to the action of galvaniſm, the effect produced is motion in the muſcles on which they are diſtributed.

If this view of the matter be juſt, it will explain why no ſhock is felt when the human body is made a part of the conducting chain. In that caſe the influence does not, in all probability, act directly upon any nerve; and we ſee that this influence poſſeſſes no power, like the electric fluid, of producing a convulſive ſhock, when merely paſſed through any part of the body; but it has this peculiar property, when paſſed directly through a nerve, it excites that nerve to perform the function for which it was intended by nature. To this it will no doubt be objected, that contractions may be excited in different parts of a frog without any diviſion being made in its ſkin; and here it may be ſuppoſed that the influence is not made to paſs directly through a nerve. But it ought to be recollected that the ſkin of theſe animals is abundantly ſupplied with nerves, whoſe trunks communicate at different places with thoſe which ſupply the muſcles; and that the contractions are always ſtrong and eaſily excited, in proportion as they are applied near to the courſe of any of the nerves which go to the muſcles. But though we had no doubt that the influence might be tranſmitted through the bodies of theſe animals, as well as through the human body, without any contractions being produced, we have thought it worth while to aſcertain the fact by the following experiment.

A frog was prepared in the uſual manner by coating its ſciatic nerve with tinfoil, and laying the leg upon a plate of zinc. Another frog, in a very vigorous ſtate, had its fore legs and cheſt attached to a rod of ſilver, and its poſterior extremities to a rod of zinc. The ſilver rod was applied to the tinfoil and nerve of the prepared frog, and the zinc rod to the plate of zinc upon which the leg was laid. Immediately very ſtrong contractions took place in the leg; but no motion, nor the ſlighteſt mark of uneaſineſs, appeared in the other frog through the body of which the influence muſt have paſſed. It is neceſſary in this experiment to dry the body of the frog which is to ſerve as a conductor very carefully, otherwiſe the influence might be tranſmitted by the water upon its ſurface without paſſing through its body.

There is an experiment mentioned by Dr Fowler, which ſhews a ſtriking difference between electricity aud galvaniſm. It was inſtituted with a view to aſcertain the effects of the latter upon the blood-veſſels. The Doctor relates it as follows: "Having laid bare and ſeparated from ſurrounding parts and from each other, the crural artery and nerve in the thigh of a full grown frog, I cut out the whole of the nerve between the pelvis and the knee: I then inſinuated beneath the artery a thin plate of ſealing wax, ſpread upon paper, and broad enough to keep a large portion of the artery completely apart from the reſt of the thigh. The blood ſtill continued to flow through the whole courſe of the artery in an undiminiſhed ſtream. The artery, thus partially inſulated, was touched with ſilver and zinc, which were then brought into contact with each other; but no contraction whatever was produced in any muſcle of the limb. This experiment was frequently repeated upon ſeveral different frogs, both in whom the nerve was, and in whom it was not divided. The reſult was uniformly the ſame. But vivid contractions were produced in the whole limb when an electric ſpark, or even a full ſtream of the aura was paſſed into the artery."

Before taking leave of this branch of our ſubject, it may be proper to take notice of one fact, which may be thought to militate againſt the doctrine we have endeavoured to eſtabliſh. It is ſaid that a frog, exhauſted and brought near to a charged electrophorus, has been found to reſume its ſuſceptibility. We think this fact may be accounted for without admitting any connection between galvaniſm and electricity, merely by ſuppoſing that the irritability of the muſcles, which had been exhauſted, was reſtored by the application of a moderate ſtimulus, (the electric fluid), of a kind different from thoſe by which it had been exhauſted. Such of our readers as are acquainted with the writings of modern phyſiologiſts on the ſubject of muſcular irritability, will know that facts of this kind are very common. Thus it has been found by M. Humboldt, that the oxygenated muriatic acid has often reſtored irritability. To this explanation it will no doubt be objected, that the application of other ſtimuli, as alcohol and a ſolution of potaſh, inſtead of reſtoring, totally deſtroy the ſuſceptibility of galvaniſm. Suſpecting, that although theſe ſubſtances in a concentrated ſtate deſtroy the ſuſceptibility, yet that when ſufficiently diluted, they might be found to have the oppoſite effect, we tried the following experiment, which confirmed our conjecture.

A frog, 57 hours after it had been decapitated, had ceaſed for above an hour to be capable of excitement by the application of the metals in any way that could be deviſed. A few drops of alcohol being diluted with about a tea-ſpoonful of water, the nerve and the muſcles which had been laid bare, as well as the whole ſkin of the animal, were wet with it. Upon the application of an excitatory arc, compoſed of four pieces, gold, zinc, ſilver, and tinfoil, a few very ſlight contractions of the toes were diſtinctly obſerved. After this, no means that we could think of produced the ſmalleſt excitement. Alcohol was now applied in a more concentrated ſtate, but without any effect. The ſame four

four pieces of metal which produced the contractions of the toes, had been uſed before the diluted alcohol was applied, but without effect. We have not tried the application of potaſh much diluted.

From what has been ſaid, we think we are fully warranted in ſaying, that although ſome of the phenomena diſcovered by Galvani bear a ſtriking reſemblance to ſome of thoſe produced by the electric fluid; yet there are others, and theſe not the leaſt important, which differ ſo widely from any effects which have ever been ſeen to ariſe from that fluid, that they muſt derive their origin from ſome other cauſe. Our readers may probably think that we have dedicated too much time to this queſtion; but as we conceive it to be the moſt important point which can be diſcuſſed on this ſubject, we thought it worth while to conſider it at ſome length; and we were the more convinced of the neceſſity of doing ſo, from this conſideration, that there are ſtill ſome writers of high authority who maintain the hypotheſis, that galvaniſm and electricity are the ſame.

32 The galvanic influence probably foreign from animals.

The next queſtion that occurs to us with regard to the nature of galvaniſm is, whether or not it depends upon any law of animal life? To us it appears rather more probable, that the influence which incites the muſcles of animals to contract in the experiments of Galvani, is ſomething quite foreign to the animals themſelves; as much ſo as the electric fluid of the Leyden phial is to the animal which receives a ſhock from it, in both caſes the body of the animal acting as a mere conductor. Upon this queſtion, however, we confeſs that we have neither facts nor arguments to adduce ſufficient to warrant our drawing any certain concluſion. It will doubtleſs be aſked, if this influence be ſomething foreign to the bodies of animals, why do we never find it acting anywhere but in their bodies? why is it not, like the electric fluid, capable of being made evident to the ſenſes by its effects upon inanimate matter? The only anſwer which we are in a condition to give to this queſtion is, that it may very poſſibly be capable of producing important effects upon inanimate matter, nay, theſe effects may be the ſubject of our daily obſervation; but for want of our being ſufficiently acquainted with galvaniſm to point out the relation between theſe effects and their cauſe, the effects themſelves are either not explained at all, or aſcribed perhaps to ſome other power, with which they have no connection. In like manner, the electric fluid has doubtleſs been producing moſt important effects from the beginning of time; but, prior to the diſcovery of that fluid, theſe were either not explained at all, or conſidered as originating from ſome cauſe which, in fact, had no ſhare in their production.

The great difficulty is to obtain ſome teſt by which we may detect the galvanic influence when actually preſent in inanimate matter. Hitherto we have no ſuch teſt; nor ſhould we know that ſuch an influence exiſts, but for the effects which it produces upon the bodies of animals through the medium of their nerves. If we had any means of aſcertaining its exiſtence, either in a ſeparate ſtate, or conjoined with inanimate matter, the ſcience would make a rapid progreſs, as it would be eaſy to diverſify experiments ſo as to diſcover its nature and effects. To detect it in a ſeparate ſtate is, in all probability, impoſſible; but that the zeal and ingenuity of philoſophers will one day be able to diſcover ſome teſt of its preſence in inanimate matter, there ſeems no reaſon to doubt.

We have made many experiments with a view to diſcover ſuch a teſt, but hitherto without the ſmalleſt ſucceſs. In the trials we have already made, our views have been chiefly confined to the diſcovery of ſome chemical effects of this influence upon inanimate matter. M. Volta and other writers, having conſidered the ſenſation produced by it upon the tongue as ſimilar to that occaſioned by acids, we were not without hopes that it would be found to reſemble that claſs of ſubſtances in ſome of its other properties. We have therefore tranſmitted it through liquids tinged with the moſt delicate vegetable colours; but no change in theſe colours has been effected by the tranſmiſſion of many galvanic ſhocks. We have alſo tried, in the ſame way, alkaline liquors, without any effect. We next diſſolved in water different neutral ſalts, and other compound bodies, of which the parts are held together by the weakeſt affinities; but no change has been obſerved to be produced in them by the tranſmiſſion of this influence. Our want of ſucceſs, however, ſhall not deter us from continuing our efforts; we ſhall vary the nature of our experiments in every way that ſhall occur to us as likely to be attended with advantage; and if we ſhould ultimately fail, we truſt that others will be more fortunate. Every new fact which is diſcovered upon the ſubject tends to facilitate this inveſtigation, by furniſhing us with new guides to direct the courſe of our experiments.

33 Dr Fowler heſitates on this point,

Dr Fowler is of opinion, that this influence, whatever it may be, is not derived from the metals alone, but that the animals at leaſt contribute to its production, as well as indicate its preſence; and he ſeems to have been led to adopt this theory chiefly from two conſiderations, neither of which appears to us to have much weight. They are the following: The neceſſity of a communication between the metals and the muſcles, as well as between the metals and the nerves; and the obſervation, that animals have a more complete controul over its effects than one would expect them to have over an influence wholly external to them. But the communication between the metals and the muſcles may be neceſſary to the contraction of the latter, tho' not to the production of galvaniſm; which, however, for want of any obvious effect, is not obſerved. That animals have ſome controul over the effects of galvaniſm upon themſelves, may be very true; but this circumſtance does not appear to us capable of proving any thing, as they have a controul over the effects of other ſtimuli in the ſame way. Thus, an animal of any reſolution can bear, without betraying any uneaſy ſenſation, a blow which, inflicted unexpectedly, would have produced a convulſive ſtart. The will does not in any degree controul the effects produced by galvaniſm upon our ſenſes of taſte, ſeeing &c.; that is, the ſenſations are produced, though we may have reſolution not to betray them. But, ſays Dr Fowler, the will is not able to controul the effects of electricity, when the electricity is otherwiſe ſufficiently ſtrong to excite muſcles to contraction. This argument may tend to ſhew, that galvaniſm differs from electricity; but as it muſt be admitted, that we can reſiſt the contractions naturally produced by the application of other foreign ſtimuli, it by no means proves that animals have any power of preventing

preventing the excitement or tranfmiffion of galvanifm. Befides, though we cannot prevent an involuntary contraction of our mufcles from taking place when an electric fhock of confiderable ftrength is paffed through them, yet any man may with his hand draw fparks from the prime conductor of an electric machine without fhrinking, though even thefe fparks would, if he were off his guard, produce a convulfive ftart.

34 We think without reafon.

If the galvanic influence exifted ready formed in the mufcles or nerves of animals, the only thing requifite to the production of the contractions would be to make a communication between the nerves and mufcles, by means of any fingle fubftance capable of conducting this influence; as water, for example: but the reverfe is known to be true. It may be faid, however, that, although there is no proof that any influence naturally refides in the nerves or mufcles capable of producing the effects mentioned by M. Galvani, thefe fubftances may ftill, by fome power, independent of the properties they poffefs in common with dead matter, *contribute* to the excitement of the influence, which is fo well known to exift in them after a certain application of metals. Upon this part of the fubject, the obfervations of Dr Wells will be found to merit confiderable attention.

"It is known (fays that gentleman), that if a mufcle and its nerve be covered with two pieces of the fame metal, no motion will take place upon connecting thofe pieces by means of one or more different metals. After making this experiment one day, I accidentally applied the metal I had ufed as the connector, and which I ftill held in one hand, to the coating of the mufcle only, while with the other hand I touched the fimilar coating of the nerve, and was furprifed to find that the mufcle was immediately thrown into contraction. Having produced motions in this way fufficiently often to place the fact beyond doubt, I next began to confider its relations to other facts formerly known. I very foon perceived, that the immediate exciting caufe of thefe motions could not be derived from the action of the metals upon the mufcle and nerve to which they were applied; otherwife it muft have been admitted, that my body and a metal formed together a better conductor of the exciting influence than a metal alone; the contrary of which I had known, from many experiments, to be the cafe. The only fource, therefore, to which it could poffibly be referred, was the action of the metals upon my own body. It then occurred to me, that a proper opportunity now offered itfelf of determining whether animals contribute to the production of this influence by means of any other property than their moifture. With this view I employed various moift fubftances, in which there could be no fufpicion of life to conftitute, with one or more metals, different from that of the coatings of the mufcle and nerve, a connecting medium between thefe coatings, and found that they produced the fame effect as my body. A fingle drop of water was even fufficient for this purpofe; though, in general, the greater the quantity of the moifture which was ufed, the more readily and powerfully were contractions of the mufcle excited. But if the mutual operation of metals and moifture be fully adequate to the excitement of an influence capable of occafioning mufcles to contract, it follows, as an immediate confequence, that animals act by their moifture alone in giving origin to the fame influence in M. Galvani's experiments, unlefs we are to admit more caufes of an effect than what are fufficient for its production." We do not quote the above reafoning as perfectly conclufive, for it by no means appears to us to be fo; but it certainly gives fome probability to the opinion, that galvanifm is, as M. Volta fuppofes, the refult of the action of two dry conductors, which touch each other immediately on one hand, while at their other extremities they touch conductors of what he calls the fecond clafs, (that is, moifture, for all the conductors of the fecond clafs contain water), and that the bodies of animals act merely as moifture.

One of M. Humboldt's experiments related above, appears to us to ftrengthen the conclufion, that the influence difcovered by Galvani is fomething perfectly foreign to the bodies of animals. Can it be fuppofed that any fubftance which naturally refides in our bodies, fhould, in a few feconds after it is put in motion, convert the fimple ferous difcharge of a blifter into a dark coloured fluid, of a nature fo acrid as to irritate and violently inflame the fkin wherever it touches it? We do not fay that this is impoffible, for we are too little acquainted with the laws of fecretion to fay with certainty what may, or what may not, produce fuch a change; but we know no fimilar alteration produced, *in a few feconds*, by a mere change of action in the veffels themfelves.

We fhall not undertake to determine the nature of the caufe which produces fuch aftonifhing effects. We think it is certainly not the electric fluid, and probably fomething which refides or is formed in the excitatory arc; but we confider our knowledge of galvanifm as ftill in its infancy, and our ftock of facts as infinitely too fmall to admit of our forming a juft theory on the fubject. Fortunately, however, the difcovery of Galvani has attracted fo much the attention of philofophers in every part of Europe, that new facts may be expected to come to light every day; and we hope the time is not very diftant, when thefe may be fo claffed, as to entitle the fubject to be ranked among the fciences. See Torpedo in this *Suppl.* 35 The caufe which produces the galvanic effects unknown.

While this article was in the prefs, we were favoured by a friend with an account of fome German differtations on the fubject, which we are obliged to infert in this irregular manner.

Mr Creve, furgeon in Wurtzburg, had an opportunity of obferving the galvanic irritation on the leg of a boy, which had been amputated far above the knee in the hofpital of that city. Immediately after the amputation, Mr Creve laid bare the crural nerve (kniekehlnerven), and furrounded it with a flip of tinfoil. He touched at once the tinfoil and the nerve with a French crownpiece. In that inftant the moft violent convulfions took place in the leg both above and below the knee. The remainder of the thighbone bent with force toward the calf; the foot was more bent than extended. All thefe motions were made with much force and rapidity. None were produced when the tinfoil was taken away, or when a fteel pincer was ufed in place of a piece of filver, or when the tin or filver was covered with blood: but they were renewed ed when these obstacles were removed. These phenomena continued till 38 minutes after the amputation, when the limb became cold.

Dr Christopher Heinrich Pfaff (*in Dissertatione de Electricitate Animali*, Stutgardt, 1793: see also Gren's *Journal der Physik*, T. viii. p. 196, &c.) has classed the phenomena in a very orderly and perspicuous manner; and the result of the numerous experiments made by himself and others, corresponds very nearly with our inferences in the preceding pages.

I. *Phenomena of muscular contraction.*

The general form of his experiments is the same with that which we have placed at the beginning of this article; but the following varieties were observed:

The nerve being coated with tinfoil, it was always observed that the contractions were stronger when the silver first touched the muscle, and then the coating. If it touched the coating first, the effects were always, and very sensibly, weaker.

They were still stronger when the silver did not touch the muscle at all, but only the nerve and its coating.

When the contractions were weaker at the beginning, they also ceased sooner.

No contraction ensued from touching the coating only, or the nerve only, or the muscle only, with the silver.

Continuing the contact did not occasion any repetition of the contractions, except in some cases, where the silver was drawn along different parts of the coating, while its other end remained in contact with the nerve.

The contractions took place only in the muscles to which the nerve led.

Their strength and duration were greater when the surfaces of contact were greater, and when the two metals touched each other in points or sharp edges.

A ligature, with a silk thread below the coating (that is, between the coating and the muscle, or part of the nerve touched by the silver), prevented all contraction; but not if the ligature was between the coating and the brain. If the nerve was cut through below the coating, and the parts separated a quarter of an inch, no contraction followed by touching the coating and the nerve or muscle: but it took place, if the parts were brought into contact; or even if a piece of any other nerve was put between the parts.

If a considerable part of a bared nerve was insulated and coated, partly with tinfoil and partly with silver, contractions were produced in the muscle to which it led whenever the two metals were brought into contact.

If one crural nerve be coated with tin, and the other with silver, contractions are produced in both legs by bringing the metals into contact.

If the nerve be dry under the coating, or when the silver touches it, or in both places, we have no contractions; but they begin as soon as we moisten the nerve.

Dr Pfaff infers from these phenomena, that the nerve alone is subject to the irritation produced by the two metals.

If the prepared frog be immersed in water, so that the coating touches the water, contractions are produced by touching the coating above water with the silver, while another part of the silver touches the nerve, or the muscle, or even dips pretty deep in the water.

No such thing happens in oil; or, at best, the contractions are very slight.

Dr Pfaff could not produce contractions without employing two metals, or a metal and charcoal.

A very thin covering of muscular flesh on the nerve did not altogether prevent the contractions, and in many cases did not sensibly diminish them.

If a piece of silver be laid on the muscles of the breast or belly, and be brought into contact with the tin-coating on the lumbal region, only the muscles of the breast or belly are affected, but not those of the legs.

Dr Pfaff says, that the involuntary muscles are not affected by galvanism; and refers for convincing proofs to a dissertation by Dr Ludwig, shewing that the heart is not furnished with nerves, (*Scriptor. neurolog. minor. select.* vol. 2.).

II. *Irritation of the Organs of Sense.*

Here Dr Pfaff's dissertation contains nothing remarkable.

III. *Conjectures as to the Cause.*

Dr Pfaff uses the same arguments that we have employed to refute the opinion of a similarity between the animal organs and the Leyden phial, and the opinion that electricity is the agent. He mentions the opinion of those who maintain that the agent is a fluid put into motion by means of its relation to the metals only, in their action on each other, and who consider the animal as merely serving as a conductor; and also serving, by its irritability, to give us the information of the presence of such a fluid, in the same manner as another kind of irritation, somewhat analogous to it, indicates the presence and agency of the electric fluid. It may therefore be called the METALLIC IRRITATION; a term which will sufficiently distinguish it.

But Dr Pfaff seems rather to think that the agent resides in the animal, and that the metals are the conductors (See a dissertation, entitled, *Farther Contributions to the Knowledge of Animal Electricity*, in *Gren's Journal der Physik*, T. viii. p. 377.). This fluid he conceives to be intimately blended with the *principle of life*; nay, perhaps, to be the same. He mentions a thought of Professor Kielmayer, "that it may resemble the magnetic fluid in its manner of acting, giving connection to the distant particles of a nerve, as we observe a magnet give an instantaneous connection to each of a parcel of iron filings; all of which it would arrange in a certain precise manner, if they were sufficiently moveable, by giving momentary polarity to each." This somewhat resembles Newton's hypothetical whim read to the Royal Society, describing what may be done by means of an æther (See *Birche's History of the Royal Society*).

But all this is vague conjecture, and merits little attention. This will be better bestowed on an observation of M. Humboldt of Jena, "that a bit of fresh morelle (the *Helvella mitra* of Linnæus) may be substituted for a bit of nerve in the animal arc in these experiments." This is the only vegetable substance yet discovered to have this property. If the nerve be laid on the morelle, we have only to touch the morelle with the zinc, and the muscular contractions immediately follow.

GARDECAUT, or GUARD DU CORD, in a watch, is that which ſtops the fuſee when wound up, and for that end is driven up by the ſpring. Some call it Guard-cock; others Guard du Gut.

GARDEN (Francis), better known to the public by the title of *Lord Gardenſtone*, was born at Edinburgh June 24th, in the year 1721. His father was Alexander Garden of Troup; an opulent landholder in Aberdeenſhire; his mother was Jane, daughter of Sir Francis Grant of Cullen, S.C.I.

After paſſing through the uſual courſe of liberal education at the ſchool and the univerſity, he betook himſelf to the ſtudy of law for his profeſſion. In the year 1744 he was admitted a member of the Faculty of Advocates, and called to the Scottiſh bar.

In his practice as an advocate he ſoon began to be diſtinguiſhed, by a ſtrong, native rectitude of underſtanding; by that vivacity of apprehenſion and imagination which is commonly denominated *Genius;* by manly candour in argument, often more perſuaſive than ſubtlety and ſophiſtical artifice; by powers which, with diligence, might eaſily attain to the higheſt eminence of the profeſſion. But the ſame ſtrength, openneſs, and ardour of mind, which diſtinguiſhed him ſo advantageouſly among the pleaders at the bar, tended to give him a fondneſs for the gay enjoyments of convivial intercourſe, which was unfavourable to his progreſs in juridical erudition. Shining in the ſocial and convivial circle, he became leſs ſolicitouſly ambitious than he might otherwiſe have been, of the character of an eloquent advocate, or of a profound and learned lawyer. The vivacity of his genius was averſe from auſtere and plodding ſtudy, while it was captivated by the faſcinations of polite learning and of the fine arts. Nor did he always eſcape thoſe exceſſes in the purſuit of pleaſure into which the temptations of opening life are apt occaſionally to ſeduce the moſt liberal and ingenuous youth. But his cheerful conviviality, his wit, humour, taſte, good-nature, and benevolence of heart, rendered him the delight of all his acquaintance. He became his Majeſty's Solicitor July 3d, 1764.

At length the worth of his character, and his abilities as a lawyer, recommended him to the office of a Judge in the Courts of Seſſion and Juſticiary, the ſupreme judicature, civil and criminal, for Scotland. His place in the Court of Seſſion he continued to occupy till his death; but had, ſome years before, reſigned the office of a Commiſſioner of Juſticiary, and in recompence got a penſion of 200l. per annum. Clear diſcernment, ſtrong good ſenſe, conſcientious honeſty, and amiable benevolence, remarkably diſtinguiſhed all his opinions and conduct as a judge.

We not unfrequently ſee the gay young men of the preſent age, to turn, as they advance towards middle life, from the headlong purſuit of pleaſure to a ſordid and contracted ſelfiſhneſs, which excludes even thoſe few good qualities that ſeemed to accompany their firſt thoughtleſs days. Their life is divided between ſenſuality and that anxious *inhumane* avarice and ambition whoſe ultimate object is, to provide gratifications to ſenſuality and pride. The kindling light of rectitude, and the firſt ſparks of generous humanity, are extinguiſhed in their breaſts as ſoon as thoſe ebullitions of youthful paſſion and inexperience are over, by which the uſeful efficiency of their early good qualities was prevented. Hardly have they become tolerably well acquainted with mankind, when the milk of human kindneſs is turned into gall and venom in their hearts.

It was far otherwiſe with Lord Gardenſtone. As he advanced in years, humanity, taſte, public ſpirit, became ſtill more and more eminently the predominant principles in his mind.—He pitied the condition of the peaſantry, depreſſed rather by their ignorance of the moſt ſkilful modes of labour, and by their remoteneſs from the ſphere of improvement, than by any tyranny or extortion of their landlords. He admired, protected, and cultivated the polite arts He was the ardent votary of political liberty, and friendly to every thing that promiſed a feaſible amelioration of public economy, and the principles of government.

In the year 1762 he purchaſed the eſtate of Johnſton, in the county of Kincardine. Within a few years after he began to attempt a plan of the moſt liberal improvement of the value of this eſtate, by an extenſion of the village of Laurencekirk, adjoining. He offered leaſes of ſmall farms, and of ground for building upon, which were to laſt for the term of one hundred years; and of which the conditions were extremely inviting to the labourers and tradeſmen of the ſurrounding country. Theſe offers were eagerly liſtened to. More deſirous to make the attempt beneficial to the country than to derive profit from it to himſelf, he was induced, within a few years, to reduce his ground-rents to one-half of the original rate.—Weavers, joiners, ſhoemakers, and other artiſans in a conſiderable number, reſorted to ſettle in the riſing village. His Lordſhip's earneſtneſs for the ſucceſs of his project, and to promote the proſperity of the good people whom he had received under his protection, led him to engage in ſeveral undertakings; by the failure of which he incurred conſiderable loſſes. Projects of a printfield, and of manufactures of linen and of ſtockings, attempted with ſanguine hopes in the new village, and chiefly at his Lordſhip's riſk and expence, miſgave in ſuch a manner as might well have finally diſguſted a man of leſs ſteady and ardent philanthropy with every ſuch engagement. But the village ſtill continued to advance. It grew up under his Lordſhip's eye, and was the favourite object of his care. In the year 1779 he procured it to be erected into a burgh of barony; having a magiſtracy, an annual fair, and a weekly market. He provived in it a good inn for the reception of travellers; and with an uncommon attention to the entertainment of the gueſts who might reſort to it, furniſhed this inn with a library of books for their amuſement. He invited an artiſt for drawing, from the continent, to ſettle at Laurencekirk. He had the pleaſure of ſeeing a conſiderable linen manufacture at length fixed in it. A bleachfield was alſo eſtabliſhed as a natural counterpart to the linen manufacture. Before his Lordſhip's death, he ſaw his plan of improving the condition of the labourers, by the formation of a new village at Laurencekirk, crowned with ſucceſs beyond his moſt ſanguine hopes. He has acknowledged, with an amiable frankneſs, in a memoir concerning this village, "That he had tried, in ſome meaſure, a variety of the pleaſures which mankind purſue; but never reliſhed any ſo much as the pleaſure ariſing from the progreſs of his village."

In the year 1785, upon the death of his elder brother, Alexander Garden of Troup, M. P. for Aberdeenſhire, Lord Gardenſtone ſucceeded to the poſſeſſion of the family eſtates, which were very conſiderable. Until this time his Lordſhip's income had never been more than adequate to the liberal expence into which his rank, and the generoſity of his nature, unavoidably led him. But the addition of a fortune of about three thouſand pounds a-year to his former revenue, gave him the power of performing many acts of beneficence with which he could not before gratify his good heart. It was happy, likewiſe, that his ſucceſſion to this ample income, at a period when the vigour of his conſtitution was rapidly yielding to the infirmities of old age, enabled him to ſeek relief, by a partial ceſſation from buſineſs, by travel, and by other means, which could not have been eaſily compatible with the previous ſtate of his fortune.

In the month of Sept. 1786, he ſet out from London for Dover, and paſſed over into France. After viſiting Paris, he proceeded to Provence, and ſpent the winter months in the genial climate of Hieres. In the ſpring of 1787 he returned northwards, viſiting Geneva, Switzerland, the Netherlands, and the Dutch provinces, and paſſing through Germany into Italy. With a fond curioſity, attentive alike to the wonders of nature, to the noble monuments of the arts, and to the awful remains of ancient grandeur, with which Italy abounds, he viſited all its great cities, and ſurveyed almoſt every remarkable and famous ſcene that it exhibits.

His firſt object, in theſe travels, was to obtain the reſtoration of his declining health by the influence of a milder climate, by gentle, continued, and varied exerciſe; by that pleaſing exhilaration of the temper and ſpirits, which is the beſt medicine to health, and is moſt ſucceſsfully produced by frequent change of place, and of the objects of attention. But the curioſities of nature and art, in thoſe countries through which he travelled, could not fail to attract, in a powerful manner, the curioſity of a mind cultivated and ingenious as his. He, whoſe breaſt glowed with the moſt ardent philanthropy, could not view the varied works and manners of a diverſity of nations of his fellow men, without being deely intereſted by all thoſe circumſtances which might appear to mark their fortunes as happy or wretched. He eagerly collected ſpecimens of the ſpars, the ſhells, the ſtrata of rocks, and the veins of metals, in the ſeveral countries through which he paſſed. He amaſſed alſo cameos, medals, and paintings. He enquired into ſcience, literature, and local inſtitutions. He wrote down his obſervations, from time to time; not indeed with the minute care of a pedant, or the oſtentatious labour of a man travelling with a deſign to publiſh an account of his travels, but ſimply to aid memory and imagination in the future remembrance of objects uſeful or agreeable.

After an abſence of about three years he returned to his native country. The laſt years were ſpent in the diſcharge of the duties of his office as a judge; in ſocial intercourſe with his friends, among whom was the venerable Lord Monboddo, and others of the moſt reſpectable characters that our country has to boaſt of; in the performance of a thouſand generous offices of benevolence and humanity; in cheriſhing thoſe fine arts, of which he was an eminent admirer and judge; and above all, in promoting the comfort, and encouraging the induſtry of his dependants, and in lending his aid to every rational attempt at the improvement of public economy and public virtue.

St Bernard's Well, in the neighbourhood of Edinburgh, had been, long ſince, diſtinguiſhed for the medicinal virtues of its waters. But various circumſtances had alſo concurred of late to throw it into neglect. Yet its waters being ſtrongly mineralized by a ſulphurated hydrogenous gas, were, by this means, unqueſtionably qualified to operate, with highly beneficial effects, in the cure of various diſeaſes. The qualities of this mineral water falling under Lord Gardenſtone's notice, he was induced to purchaſe the property of the well, to direct it to be cleared from ſurrounding obſtacles, which contaminated the virtues of the water, or made it inacceſſible; to erect a beautiful and commodious edifice over it; and to appoint proper perſons to diſtribute the water, for a very trivial compenſation, to the public. The well lies at a diſtance from Edinbugh, which is very convenient for a ſummer morning's walk. Within the few years which have paſſed ſince Lord Gardenſtone's benevolent care brought it into notice, it has attracted many of the inhabitants of that city to viſit in the mornings of ſpring and ſummer. And, undoubtedly, the agreeable exerciſe to which they have thus been allured, and the ſalutary effects of the water, have contributed, in no mean degree, to diſpel diſeaſe, and to confirm, or re-eſtabliſh health. Such monuments are worthy to preſerve the memory of a patriotic and a good man!

As an amuſement for the laſt two or three years of his life, when his increaſing infirmities precluded him from more active exerciſe, and from mingling ſo frequently in the ſociety of his friends as was agreeable to his ſocial and convivial temper, he bethought himſelf of reviſing ſome of the *jeux d'eſprit*, and light fugitive pieces, in which he had indulged the gaiety of his fancy in his earlier days; and a ſmall volume of poems was publiſhed, in which the beſt pieces are, upon good authority, aſcribed to Lord Gardenſtone. He reviſed alſo the memorandums which he had made upon his travels, and permitted them to be ſent to preſs. The two former volumes were publiſhed one after another while his Lordſhip was yet alive; the third after his death. They met with a very favourable reception in the world, and were honoured with the high approbation of the moſt reſpectable writers of periodical criticiſm. They convey much agreeable information, and beſpeak an elegant, enlightened, and amiable mind. The laſt volume is filled chiefly with memorandums of his Lordſhip's travels in Italy; and contains many intereſting criticiſms upon ſome of the nobleſt productions of the fine arts of painting and ſculpture.

His Lordſhip's health had long been declining; and he died a bachelor on the 22d of July 1793, lamented by his relations and friends, by his tenants and humble dependants, and by all true patriots and good men to whom his merits and virtues were known.

Such is the account of Lord Gardenſtone's life, which was prefixed to the third volume of his travelling memorandums; and though it was no doubt an effuſion of fond friendſhip, we believe that the praiſe which it beſtows on his Lordſhip is not much exaggerated. In the latter years of his life, it muſt indeed be confeſſed, that he contracted intimacies with men unworthy

worthy of his regard; and that his attachment to liberty made him form expectations from the French revolution, which even the events which he faw ought to have repreffed. But his mind was by that time weakened by difeafe; and it would be very unjuft to balance the imprudencies of one or two years againft the meritorious actions of a whole life. Befides his travelling memorandums and his poems, his Lordfhip publifhed *A Letter to the Inhabitants of Laurencekirk*, the moft valuable, in our opinion, of all his publications; for it contains perhaps the moft falutary advices which were ever offered to the inhabitants of a manufacturing town, for the regulation of their conduct towards each other. That the people of Laurencekirk have followed thefe advices, it would give us pleafure to learn on good authority.

GAS. See that article, *Encycl.* and CHEMISTRY-*Index* in this *Supplement*. We have introduced the word here, to notice fome experiments made by Profeffor Jacquin of Vienna, at the defire of Dr Chladni, on the different gafes as the vehicle of founds. A glafs bell was furnifhed with a metallic ftopper cemented to a neck at the top; and in the bore of this cock, within the glafs, a fmall flute or pewter (etain) about fix inches in length was fixed. The glafs being then placed on the fhelf of the pneumatic veffel, and filled with any particular kind of gas, a bladder alfo filled with the fame gas, and provided with a cock, was adapted to the external aperture of the cock belonging to the bell-glafs. In this difpofition of the apparatus, the flute was made to found by gently preffing the bladder. Comparative experiments were made with atmofpheric air, oxygen, hydrogen, carbonic acid, and nitrous gas. The intenfity of the found did not vary; but when compared with that produced by atmofpheric air, the oxygen gas gave a found half a tone lower; azotic gas, prepared by different methods, conftantly gave a found half a tone lower; hydrogen gas gave nine or eleven tones higher; carbonic acid gas gave one-third lower, and nitrous gas alfo very nearly a third lower. A mixture of oxygen gas and azot, in the proportions of the atmofpheric air, afforded the tone of this laft; that is to fay, it was half a tone higher than each of the component parts alone. When the two gafes were not uniformly mixed, the found was abominably harfh. Chladni intends to give a fuller account of thefe interefting experiments.—*Journal de Phyfique*, Vol. IV. N. S. p. 57.

GAZONS, in fortification, turfs, or pieces of frefh earth covered with grafs, cut in form of a wedge, about a foot long, and half a foot thick, to line or face the outfide of works made of earth, to keep them up, and prevent their mouldering.

GEOCENTRIC PLACE OF A PLANET, is the place where it appears to us from the earth; or it is a point in the ecliptic, to which a planet, feen from the earth, is referred.

Geocentric Latitude of a Planet, is its latitude as feen from the earth, or the inclination of a line connecting the planet and the earth to the plane of the earth's (or true) ecliptic: Or it is the angle which the faid line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic.

Geocentric Longitude of a Planet, is the diftance meafured on the ecliptic, in the order of the figns, between the geocentric place and the firft point of Aries.

GEOMETRICAL METHOD OF THE ANCIENTS. The ancients eftablifhed the higher parts of their geometry on the fame principles as the elements of that fcience, by demonftrations of the fame kind: and they were careful not to fuppofe any thing done, till by a previous problem they had fhewn that it could be done by actually performing it. Much lefs did they fuppofe any thing to be done that cannot be conceived; fuch as a line or feries to be actually continued to infinity, or a magnitude diminifhed till it become infinitely lefs than what it is. The elements into which they refolved magnitudes were finite, and fuch as might be conceived to be real. Unbounded liberties have of late been introduced; by which geometry, which ought to be perfectly clear, is filled with myfteries.

Geometrical Solution of a problem, is when the problem is directly refolved according to the ftrict rules and principles of geometry, and by lines that are truly geometrical. This expreffion is ufed in contradiftinction to an arithmetical, or a mechanical, or inftrumental folution, the problem being refolved only by a ruler and compaffes.

The fame term is likewife ufed in oppofition to all indirect and inadequate kinds of folutions, as by approximation, infinite feries, &c. So we have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals, though there are mechanical ways, and others, by infinite feries, &c.

GEORGIUM SIDUS (fee ASTRONOMY-*Index*, *Encycl.*) has no fewer than fix fatellites revolving round it, all difcovered by Dr Herfchel. Of the two which he firft difcovered, one was found to revolve in 8 days 17 h. 1 m. 17 fec. at the diftance of 33″ from its primary; and the other in 13 d. 11 h. 5 m. 1,5 fec. at the diftance of 44″,23. The planes of their orbits form fuch large angles with that of the planet itfelf, and confequently of the ecliptic, as to be almoft perpendicular to it. To this remarkable departure from the analogy of the old planets, another ftill more fingular has been lately announced. They move in a retrograde direction! The new fatellites revolve as follows, the periodical times being inferred from their greateft elongations: The interior fatellite in 5 d. 21 h. 25 m. at the diftance of 25″,5. A fatellite intermediate between the two old ones in 10 d. 23 h. 4 m. at the diftance of 38″,57. The neareft exterior fatellite at about double the diftance of the fartheft old one, and confequently its periodical time 38 d. 1 h. 49 m. And the moft diftant fatellite full four times as far from its primary as the old fecond fatellite. Whence it will take at leaft 107 d. 16 h. 40 m. to complete its revolution. Whether the motions of thefe four be direct or retrograde, is, we fuppofe, not yet determined.

From fome obfervations of the Doctor, with an excellent feven-feet telefcope, certain appearances, refembling that of two rings furrounding the planet, and croffing each other at right angles, were feen on feveral different days. They were not altered in pofition by turning the fpeculum in its cell; but (fays Mr Nicholfon) there is little doubt that they were optical deceptions, becaufe they kept their pofition with refpect to the tube, after the relative pofition of the parallel had been

Gerard. been much changed by the earth's rotation, and because they did not appear with larger telescopes applied during the course of ten years. The disk of the Georgium Sidus is flattened. It therefore revolves with considerable rapidity on its axis. From the very faint light of the satellites, they are observed to disappear in those parts of their orbits which bring them apparently nearest the planet. This does not arise from an atmosphere; for the effect is the same, whether the satellite be within or beyond the planet.

GERARD (Alexander, D. D.), was the eldest son of the reverend Gilbert Gerard minister of Chapel Garioch, in the county of Aberdeen. He was born on the 22d of February 1728, and received the first rudiments of his education at the parish school of Foveran in the same county.

It may perhaps be proper to inform our English readers, that in every parish in Scotland there is a school where, for very small fees, the youth of the parish are not only taught to read the English language, to write, and to perform the elementary operations of arithmetic, but are also instructed in the Greek and Latin languages. Of these schools, many of the masters were, about sixty years ago, eminent for classical learning; and it seems that Mr Forbes, the master of the school of Foveran, possessed such fame as a teacher, that Mr Gerard judged it more expedient to commit his son to his care than to have him educated at the school of his own parish, and under his own immediate inspection. The attainments which that son afterwards made in literature, evince that his judgment was correct, and that the schoolmaster of Foveran deserved the fame which he enjoyed.

Young Gerard, however, did not remain long at Foveran. His father died when he was but ten years old; and his mother removing soon afterwards with her family to Aberdeen, he was of course put to the grammar school in that city: but so solid was the foundation which had been already laid, that in two years time he was deemed fit for the university, and was accordingly entered a student in Marischal college. Such rapid progress supplies the place of that testimony which we have not been able to procure, respecting his early attachment to literature.

After completing the usual academical course of four years in the study of Greek, Latin, mathematics, and philosophy, he was admitted to the degree of master of arts; and immediately afterwards commenced the study of theology, which he prosecuted in the universities of Aberdeen and Edinburgh. In 1748, when he had little more than completed his 20th year, he was licensed to preach in the church of Scotland, and two years afterwards was chosen assistant to Mr David Fordyce professor of philosophy in the Marischal college and university of Aberdeen. In this capacity he performed the duties of the absent professor till the 7th of July 1752, when he was appointed successor to Mr Fordyce, who had been drowned on the coast of Holland, as has been already related in the Encyclopædia.

At that period it was the practice in the Marischal college, as it continued to be in the King's, for the same professor to carry forward a class of students for three successive years through all the different branches of philosophy which were taught in the college. These were, LOGIC, ONTOLOGY, PNEUMATICS, MORALS, POLITICS, and NATURAL PHILOSOPHY; and Mr Gerard carried one class through this extensive course. MATHEMATICS and the GREEK language were taught by separate professors. Gerard.

About the year 1754, a very material alteration was made in the *order* of teaching philosophy in the university of Aberdeen; and in the Marischal college each professor was restricted to one department of science. The principal and professors in that college, justly observing that the public is interested in every thing which relates to education, thought it incumbent upon them to lay before that public the reasons which had determined them to deviate from the arrangement which they had hitherto observed; and they employed Professor Gerard to draw up these reasons. This task he performed in a small pamphlet, which, being printed by the appointment of the college, appears to have given very general satisfaction.

This, indeed, it could hardly fail to do; for the judicious author points out very clearly the inconveniences of the old, and the advantages of the new plan of academical study. Having observed that the philosophy which had so long kept possession of the schools, consisted, in a great measure, of verbal subtleties and theories ill-grounded, though ingeniously devised, he proceeds to contrast it with the philosophy of Bacon and Locke, and to show of how little value the former is when compared with the latter. He then enters on a brief examination of the scholastic logic, and proves, to the conviction of every impartial judge, that the art of syllogising, though a proper enough introduction to a philosophy which was built on general principles, either taken for granted, or founded on very narrow and inadequate observation, is by no means fitted to assist the mind in the cultivation of that science which is deduced by induction from particular facts. "The only basis of philosophy (says he) is now acknowledged to be an accurate and extensive history of nature, exhibiting an exact view of the various phenomena, for which philosophy is to account, and on which it is to found its reasonings. This being the reformed state of philosophy, great inconveniences must be found in prosecuting the scholastic order of the sciences. The student must make a transition at once from words and languages to philosophy, without being previously introduced to the knowledge of facts, the sole foundation of, and preparation for it; he must be hurried at the first into the most abstruse, difficult, and subtle parts of it; he must be put upon examining the nature, foundation, and different kinds of evidence and reasoning, before he is acquainted with any specimens of these kinds by which they may be illustrated. And in proportion as philosophy is more improved, and more thoroughly reformed, these inconveniences must become more sensible.

"The view of these (continues he) induced the masters of the Marischal college to think of altering the hitherto received order; and after the most mature deliberation, made them at last resolve, that their students should, after being instructed in languages and classical learning, be made acquainted with the elements of history, natural and civil, of geography and chronology, accompanied with the elements of mathematics; that they should then proceed to natural philosophy; and, last of all, to morals, politics, logic, and metaphysics."

In vindicating this arrangement, he labours with great

Gerard.

great earneſtneſs, and we think with complete ſucceſs, to ſhew the propriety of making logic the laſt branch of academical ſtudy. "All ſciences (ſays he), all departments of knowledge whatever, muſt be premiſed as a ground-work to genuine logic. Hiſtory has one kind of evidence, mathematics another, natural philoſophy one ſtill different, the philoſophy of human nature another diſtinct from all theſe; the ſubordinate branches of theſe ſeveral parts have ſtill minuter peculiarities in the evidence appropriated to them. An unprejudiced mind will in each of theſe be convinced by that ſpecies of argument which is peculiar to it, though it does not reflect *how* it comes to be convinced. By being converſant in *them*, one is prepared for the ſtudy of *logic*; for *they* ſupply him with a fund of materials; in *them* the different kinds of evidence and argument are exemplified; from *them* only thoſe illuſtrations can be taken, without which *its* rules and precepts muſt be unintelligible.

"All juſt concluſions concerning the works of nature muſt be founded on an induction of particulars. And as in *natural philoſophy* theſe particulars are ſupplied by obſervations and experiments on *natural bodies*; ſo in *logic*, the particulars, of which an induction muſt be made, are to be learned only from the body of *arts and ſciences*. Theſe are the ſubjects on which obſervations muſt be made, in order to lay down rules for inveſtigating and proving the truths of which they are made; juſt as the genuine performances of any art are what muſt be conſidered and obſerved in laying down the rules of that art. No ſolid precept can be formed in logic, except by examining arts and ſciences, and attending to the method of reaſoning uſed in them, and to the evidence that accompanies it. In proportion as they are cultivated, and no farther, logic may be improved. And what is true of the invention of logic, is true likewiſe of the ſtudy of it. It can be underſtood no farther, than the ſeveral ſciences which it reviews and criticiſes are previouſly underſtood. Accordingly we find, that all the ſyſtems of logic which have not been compiled from a careful review and examination of the ſeveral ſciences, conſiſt more of ingenious ſubtleties than of uſeful precepts aſſiſting to the mind in the various parts of knowledge. And when logic has been learned before the other ſciences, the ſubſtantial parts of it have been ſcarce attended to, or made any uſe of, in the proſecution of them; nor ſo much as underſtood, but in as far as the mind was gradually opened, and brought to recollect them in its progreſs through the ſciences.

"Logic is preciſely the ſame to *philoſophy* that works of criticiſm are to *poetry*. The rules of criticiſm are formed by an accurate ſcrutiny and examination of the beſt works of poetry. To one who had never read a poem, theſe rules would be obſcure and uſeleſs; he could not comprehend them, far leſs would he be able to form a judgment of their juſtneſs, and of the reaſons on which they are founded. If one peruſes the beſt poetical performances, he will acquire ſome degree of taſte, though he has never profeſſedly ſtudied the rules of criticiſm; and he will, at the ſame time, lay in materials, and obtain a ſtock of examples, which may render theſe rules intelligible to him, and enable him to judge whether they are juſt or not. And by afterwards ſtudying theſe rules, he improves, refines, and corrects his taſte, perceives the principles on which he has founded all his judgments, though he did not in the mean time think of them, and gains additional ſecurity againſt his judging wrong. This may illuſtrate what has been ſaid of the place which logic ought to hold among the ſciences. The obſervations made in it, both concerning the methods of invention and of probation, are founded on, and deduced from, the ſeveral ſciences in which theſe methods are uſed. Neither the obſervations themſelves, nor the reaſons on which they are built, can be fully comprehended by one abſolutely ignorant of theſe ſciences. In ſtudying the particular ſciences, reaſon will ſpontaneouſly exert itſelf: if the proper and natural method of reaſoning is uſed, the mind will, by the native force of its faculties, perceive the evidence, and be convinced by it, though it does not reflect *how* this comes to paſs, nor explicitly conſider according to what general rules the underſtanding is exerted. By afterwards ſtudying theſe rules, one will be farther fitted for proſecuting the ſeveral ſciences; the knowledge of the grounds and laws of evidence will give him the ſecurity of *reflection*, againſt employing wrong methods of proof and improper kinds of evidence, additional to that of *inſtinct* and *natural genius*. And thus logic will greatly contribute to improvement in knowledge; and more ſo, when it is uſed as a *review* of the method taken in the proſecution of ſcience, of the foundations gone upon, and of the general rules that have been obſerved, than when it is applied as an *introduction* to the elements of ſcience; for in the former caſe, its rules can be perfectly underſtood, ſufficiently illuſtrated, and put in practice as they are learned, which in the latter is quite impoſſible."

Having thus vindicated the new arrangement with reſpect to the place which it aſſigns to the ſtudy of logic, he proceeds to inquire in what order the other ſciences ſhould ſucceed each other. "Ethics (ſays he) or moral philoſophy is founded as well as logic on pneumatics, and muſt therefore come after it. The conſtitution of man, and his ſeveral active powers, muſt be explained, before his buſineſs, his duty, and his happineſs, can be diſcovered. Juriſprudence and politics, taking a more complex view of man than morals, by conſidering his various ſtates, as well as his nature and powers, cannot, with any propriety, be introduced till morals have firſt been ſtudied.

"It only remains then to determine whether natural philoſophy or pneumatology ought, in the order of teaching, to have the preference. And many conſiderations ſeem to require that the former ſhould be ſtudied firſt. If it were not, pneumatology would be too far disjoined from the practical ſciences founded on it; one of which, logic, ought, as we have ſeen, to be taught laſt of all. Beſides, we ought always to begin with the eaſieſt and moſt obvious ſubjects, and to proceed gradually to the moſt difficult; and in order to this, we ought to comply as much as poſſible with the natural openings and progreſs of the human mind. Now it is evident, that the mind receives firſt of all impreſſions and ideas of thoſe ſenſible things with which it is ſurrounded. It is not till after it has exerciſed its faculties about them that it reflects on its own operations, or acquires perceptions of them. We are from our earlieſt infancy accuſtomed to obſerve external things, though often tranſiently and inattentively; they lie

lie always in our view, they force themſelves upon us, and we cannot avoid regarding them more or leſs. But we ſeldom attend to the operations of our minds in our earlier years; it is late before we acquire diſtinct notions of them, or can eaſily and readily make them the objects of our contemplation. Farther, external ſenſation, by which bodies are perceived, is a more palpable kind of evidence than internal, from which all our knowledge of ſpirits is derived; it ſtrikes and affects us more. The philoſophy of ſpirits, as well as that of bodies, is founded ſolely on experiments and obſervations; but in the latter it is much eaſier to make theſe than in the former: we can put *bodies* in any ſituation that we pleaſe, and obſerve at leiſure their effects on one another: but the phenomena of the *mind* are of a leſs conſtant nature; we muſt catch them in an inſtant, and be content to glean them up, by obſerving their effects as they accidentally diſcover themſelves in the ſeveral circumſtances of life. The reaſonings alſo by which concluſions are deduced concerning mind are of a more abſtruſe and difficult nature than thoſe employed in the ſcience of bodies; the ideas about which they are converſant are apter to be confounded with one another, and are with greater difficulty kept diſtinct. On all theſe accounts, natural philoſophy muſt be to young minds eaſier than pneumatology, and conſequently ſhould be taught firſt."

For this long digreſſion, if ſuch it ſhall be deemed, we are perſuaded that thoſe who retain any attachment to the place where their minds were firſt imbued with the principles of ſcience, will think no apology requiſite, when they are informed, that the plan of education, which is here ſo ably defended, was about the ſame period adopted by both colleges in the univerſity of Aberdeen; that the writer of this article had his own education in the King's college; and that in the proſperity of that college he ſtill feels himſelf deeply intereſted. Let it be remembered, too, that the publication from which this extract has been made, furniſhes a proof of profeſſor Gerard's abilities, and of the eſtimation in which he was held by his colleagues at a very early period of life; and then ſurely the digreſſion will not be thought impertinent.

He was now profeſſor of moral philoſophy and logic, and of theſe ſciences alone: but though his *plan of education in the Mariſchal College* ſhews the order in which his lectures were arranged, we have not been able to learn on what foundation he built his ſyſtem of ethics. As Hutcheſon's Moral Philoſophy was then much read and admired, it will not detract from Mr Gerard's merits to ſuppoſe, that, with his predeceſſor Mr Fordyce, he was an advocate for the *moral ſenſe* of that author; for there are but three or four foundations on which a ſyſtem of ethics can be raiſed; and it may be doubted whether there be one of them which is not as old as the age of Plato. It would indeed be ridiculous in any modern (A) to aim at giving a *new* foundation to moral virtue; for virtue muſt have been practiſed upon ſome ſteady principle from the earlieſt period of human ſociety; and the moſt eminent profeſſor will find ſufficient room for the diſplay of all his learning and ingenuity in illuſtrating the principle which his own judgment has led him to adopt.

Of this profeſſor Gerard was fully ſenſible; and whilſt he was conſcientiouſly diſcharging his duty to his pupils, he neglected no opportunity of improving himſelf. He was member of a literary ſociety at Aberdeen, of which the reſpectability will not be queſtioned, when it is known that it conſiſted of ſuch men as the late Doctors Blackwel, Gregory, Reid, and Campbell, with Dr Beattie, and many others of perhaps equal talents, though not known to the world as authors (B). This ſociety met regularly during the winter, we believe once every fortnight; the members communicated their ſentiments with the utmoſt freedom; every novel opinion was ſure to be canvaſſed on all ſides with impartiality; the underſtandings of the members were thus mutually whetted; and hence originated Reid's *Inquiry into the Human Mind*, Gregory's *Comparative View*, Gerard's *Eſſay on Genius*, Beattie's *Eſſay on Truth*, and Campbell's *Philoſophy of Rhetoric.*

On the 5th of September 1759, Mr Gerard was ordained a miniſter of the Church of Scotland; on the 11th of June 1760, he was appointed profeſſor of divinity in the Mariſchal College, and miniſter of the Grayfriars church in Aberdeen; and at the ſame time, as we ſuppoſe, created doctor in divinity.

On the 18th of June 1771 he reſigned his profeſſorſhip in Mariſchal College, together with his church-living, and was preferred to the theological chair in the univerſity of King's College, then become vacant by the death of profeſſor Lumiſden. In that ſtation he continued, proſecuting his ſtudies, beloved by his colleagues, and revered by his pupils, till his birth-day 1795; when, having juſt completed his 67th year, he died without a groan. His death was occaſioned by a ſchirrous tumor, which began to appear on his face in the year 1794, but without confining him to the houſe, or, except for a very few weeks, interrupting his uſual purſuits. It impaired, however, his health, and gradually undermined his conſtitution. Of this he was very ſoon ſenſible; but he ſaw his diſſolution approaching with the utmoſt compoſure and reſignation, and preſerved to all about him ſo much of that equanimity and placidneſs of temper which had marked the whole courſe of his life, that of him may truly be ſaid,

> Multis illi multos annos precantibus
> Diri carcinomatis veneno contabuit,
> Nexibuſque vitæ paulatim reſolutis,
> E terris, meliora ſperans, emigravit.

Were we to hazard an opinion of Dr Gerard's intellectual powers, from having attentively peruſed his works,

(A) The friends of Mr Godwin, who affect to call his Political Juſtice the *new* philoſophy, will, of courſe, think this a raſh aſſertion; but were it worth while, it would be no very difficult taſk to produce, from the atheiſtical writers of antient Greece, ſomething ſimilar even to his wildeſt paradoxes. Dr Gerard was too well acquainted with the ſubject, and too warm a friend to genuine virtue, to pretend to *novelty* in moral ſcience.

(B) Such as Profeſſor Thomas Gordon, who read lectures in the King's College for 63 or 64 years, and whoſe learning was equalled only by his virtues.

Gerard.

works, we would ſay that he poſſeſſed great rectitude of judgment, rather than any remarkable vigour of mind; that he was capable, by intenſe ſtudy, of becoming maſter of almoſt any ſubject, though perhaps he had not the imagination requiſite for making diſcoveries in ſcience; and that his attainments were ſolid rather than brilliant. What he knew, he knew thoroughly; but to us his knowledge ſeems to have been the reward of labour.

By one, to whom he was well known, and who himſelf ſtands high in the republic of letters *, we are aſſured that he had improved his memory to ſuch a degree, that, in little more than an hour, he could get by heart any ſermon of ordinary length; though far from availing himſelf of this talent, as many would have done, he compoſed with care all the ſermons that he preached. In early life he made it a rule not to ſtudy after ſupper; and from that rule he never deviated, but amuſed himſelf after that time, either with the converſation of his family, or with any light reading that came in his way; and he was generally in bed by half paſt eleven. He ſeems not to have approved of early more than of late ſtudy; for though, for a few years, when as profeſſor of philoſophy he had various ſciences to teach, he roſe regularly, during winter, at five in the morning, he diſcontinued that practice as ſoon as he had it in his power, and did not enter upon ſerious ſtudy till after breakfaſt, generally about ten o'clock. He was indeed very laborious through the day, and could with difficulty be perſuaded to take any bodily exerciſe; but being remarkably temperate in eating and drinking, he enjoyed very good health, which was only occaſionally interrupted by thoſe ſtomach complaints, to which men of ſedentary lives are often ſubject.

* *Dr Beattie.*

The fruits of this inceſſant ſtudy were, beſides the lectures which he read to his different claſſes, 1*ſt*, *An Eſſay on Taſte*, to which, in 1756, was adjudged the gold medal by the Philoſophical Society of Edinburgh (See Societies, *Encycl.*), which had propoſed taſte as the ſubject for a prize. Of this eſſay there has been a ſecond, and a third edition; of which the laſt, which was publiſhed in 1780, is conſiderably enlarged and improved. 2*d*, *Diſſertations on the Genius and Evidences of Chriſtianity*, publiſhed in 1766. 3*d*, *An Eſſay on Genius*, publiſhed in 1774. 4*th*, Two volumes of *Sermons*; of which the firſt was publiſhed in 1780, and the ſecond in 1782. 5*th*, A part of his theological courſe, entitled *The Paſtoral Care*, which was publiſhed in 1799 by his ſon Dr Gilbert Gerard, who ſucceeded him as profeſſor of divinity in the King's college and univerſity of Aberdeen. Beſides theſe works Dr Gerard publiſhed many ſingle ſermons, which were preached on occaſional ſubjects.

Of this amiable and reſpectable inſtructor of youth, we have been favoured with the following character, drawn by a man of talents and virtue †, who was firſt his pupil and afterwards his friend; and though it made part of a funeral ſermon, we believe that, by thoſe who were moſt intimately acquainted with Dr Gerard, the panegyric which it contains will not be deemed extravagant.

† *The Rev. Skene Ogilvie, Old Aberdeen.*

"In domeſtic life, his conduct was amiable and exemplary. He poſſeſſed, in a high degree, that kindneſs of heart and affability of manner which intereſted him at all times in the happineſs of his dependants, preſerved good humour in his houſe, and endeared him to his family. He knew how to check improprieties without harſhneſs, and when and how to indulge without impairing his authority. His natural good ſenſe, ſteadineſs, and prudence, prevented him from being thrown into confuſion by the adverſe incidents of life; and enabled him, in preſſing emergencies, to adopt wiſe meaſures, and to adminiſter ſalutary counſel. His tender ſympathy ſoothed the troubled hour of ſorrow; his rational and friendly advice guided his family thro' the perplexities of life, and he feelingly rejoiced in all their innocent enjoyments. His attachments were not confined to his family or his relatives; he was ſuſceptible of warm friendſhip. In ſelecting the objects of it he was cautious, always preferring thoſe whoſe merits entitled them to confidence and regard. His attachment, ſlowly formed, was not to be ſhaken by every oblique inſinuation, or by every idle report to the prejudice of his friend. Steady in his profeſſions of regard, he was capable of conſiderable and diſintereſted exertions to ſerve thoſe whom he really eſteemed. To his judicious advice they had ready acceſs; and his beſt efforts to promote their good they could always command. As a member of ſociety, his houſe was ever the ſeat of hoſpitality, and his door was always open to the ſtranger. In entertaining his friends, he equally avoided the extravagance and oſtentation which did not become his character or ſuit his fortune, and the rigid economy which marks the conduct of thoſe who give with a reluctant and ſparing hand. He neither anxiouſly courted, nor affectedly ſhunned learned converſation. While he never obtruded upon company ſubjects which, by the diſplay of ſuperior knowledge or abilities, were calculated to gratify his own vanity at the expence of hurting others, he always ſtudied, as far as propriety would admit, to adapt his converſation to the temper and inclinations of his aſſociates. To pleaſe the young, and to promote their harmleſs feſtivity, was ever his delight; with cheerfulneſs he deſcended to their trivial amuſements, and in his preſence they felt no reſtraints but thoſe which virtue and decency impoſe. Though he often left for a little ſtudies in which he was keenly engaged, to enjoy the converſation of a friend, he never ſuffered his love of ſociety, one of his ſtrongeſt paſſions, to induce him to ſacrifice any important literary purſuit, or to neglect any neceſſary buſineſs.

"As a clergyman, the office which he held for ſeveral years in Mariſchal college rendered it his duty to be a daily preacher, and gave him a ſeat in the eccleſiaſtical courts. But the unavoidable labour of preparing prelections for his theological pupils, did not prevent his unremitting attention to his public exhibitions in the pulpit. Theſe were marked by that diſtinctneſs of arrangement, that juſtneſs of reaſoning, and that accuracy of compoſition, which effectually ſecured the approbation of the ableſt judges; while by their plainneſs and ſimplicity, they failed not of promoting the edification of the meaneſt capacities. To the low arts of acquiring popularity he never ſtooped: But his prudence, his good ſenſe, his exemplary conduct, and his miniſterial diligence, eſtabliſhed his reſpectability and uſefulneſs, and procured him the full confidence and eſteem of his colleagues. Poſſeſſing more than ordinary

dinary

dinary excellence, envy never led him to depreciate the merits of other preachers. Though one of the beſt of judges, he was always one of the moſt candid hearers. When by his tranſlation to the univerſity of King's college he was releaſed from the labour of conſtant preaching, far from ſhewing any averſion to diſcharge the moſt public miniſterial-duties, he was always obedient to preſbyterial appointments; and while health and ſtrength remained, willing to oblige his clerical friends by appearing in their pulpits. Nor in private life did he ever loſe ſight of the character of a clergyman. Having in a publication ably defended its reſpectability, in oppoſition to the ſcoffs and ſneers and ſophiſms of modern ſceptics; he conſidered it as his honour, in his life and converſation, to diſplay its dignity and importance; and to ſhew that the gravity of a Chriſtian paſtor is perfectly conſiſtent with the good breeding of a gentleman, and with the cheerfulneſs, affability, and eaſe of an agreeable companion.

"As a man of letters, his attainments were far above thoſe at which the generality of ſtudents arrive. In his literary purſuits, he had all the advantages of a judgment uncommonly clear and diſtinct; aided, from his earlieſt years, by the moſt indefatigable and perſevering ſtudy. The well-earned reputation with which, before he was promoted to the theological chair, he taught in Mariſchal college different ſciences, inconteſtibly proves that his powers, not confined to one ſubject, juſtly entitled him to eminence in ſeveral branches of literature. His publications, ſeveral of which have been tranſlated into other languages, promiſe fair to extend his fame, and to hand it down to generations yet unborn; and his unremitting labours promiſed ſtill a farther contribution to the general ſtock of learning.

"As a profeſſor of divinity, he will be long and gratefully remembered by his numerous pupils. This was his peculiar department, and in this he ſhone. Poſſeſſing large ſtores of theological knowledge, he was judicious in ſelecting his ſubjects, happy and ſucceſsful in his manner of communicating inſtruction. He had the merit of introducing a new, and in many reſpects a better plan of theological education, than thoſe on which it had been formerly conducted. Liberal, but not looſe, in his ſentiments, his great aim was, not to impoſe by his authority upon his pupils any favourite ſyſtem of opinions; but to impreſs them with a ſenſe of the importance of the miniſterial office, to teach them the proper manner of diſcharging all its duties, and to enable them, by the knowledge of Scripture, to form a juſt and impartial judgment on controverted ſubjects. Solicitous for their improvement, he was ever ready to encourage riſing merit by his warmeſt approbation; and reluctant to damp even unſucceſsful efforts of genius by deſerved cenſure. Having a conſtant eye to what is practically uſeful, rather than to unedifying ſpeculation, he enjoined no duty which he was unwilling to exemplify in his own conduct. Hence that ſtrict regard to the miniſterial character which he uniformly diſplayed, and hence his uncommon punctuality in attending the public ordinances of religion."

GERMINATION, among botaniſts, is a very intereſting ſubject, on which the late diſcoveries in chemiſtry have thrown much light ſince the article GERMINATION was publiſhed in the *Encyclopædia.* In the year 1793, Mr Humboldt diſcovered that ſimple metallic ſubſtances are unfavourable to the germination of plants, and that metallic oxides favour it in proportion to their degree of oxidation. This diſcovery induced him to ſearch for a ſubſtance with which oxygen might be ſo weakly combined as to be eaſily ſeparated, and he made choice of oxigenated muriatic acid gas mixed with water. Creſſes (*lepidium ſativum*) in the oxygenated muriatic acid ſhewed germs at the end of ſix hours, and in common water at the end of 32 hours. The action of the firſt fluid on the vegetable fibres is announced by an enormous quantity of air bubbles which cover the ſeeds, a phenomenon not exhibited by water till at the end of from 30 to 45 minutes. Theſe experiments, announced in Humboldt's *Flora Subterranea Fribergenſis*, and in his Aphoriſms on the chemical phyſiology of Plants, have been repeated by others (A). They were made at a temperature of from 12 to 15 Reaumur. In the ſummer of 1796, Humboldt began a new ſeries of experiments, and found that by joining the ſtimulus of caloric to that of oxygen he was enabled ſtill more to accelerate the progreſs of vegetation. He took the ſeeds of garden creſſes (*lepidium ſativum*), peas (*piſum ſativum*), French beans (*phaſeolis vulgaris*), garden lettuce (*lactuca ſativa*), mignonette (*reſeda odorata*); equal quantities of which were thrown into pure water and the oxygenated muriatic acid at a temperature of 88° F. Creſſes exhibited germs in three hours in the oxigenated muriatic acid, while none were ſeen in water till the end of 26 hours. In the muriatic, nitric (B), or ſulphuric acid, pure or mixed with water, there was no germ at all: the oxygen ſeemed there to be too intimately united with baſes of azot or ſulphur, to be diſengaged by the affinities preſented by the fibres of the vegetable. The author announces, that his diſcoveries may one day be of great benefit in the cultivation of plants. His experiments have been repeated with great induſtry and zeal by ſeveral diſtinguiſhed philoſophers. Profeſſor Pohl at Dreſden cauſed to germinate in oxygenated muriatic acid the ſeed of a new kind of *euphorbia* taken from Bocconi's collection of dried plants, 110 or 120 years old. Jacquin and Vander Schott at Vienna threw into oxygenated muriatic acid all the old ſeeds which had been kept 20 or 30 years at the botanical garden, every attempt to produce vegetation in which had

(A) See Uſlar's Fragments of Phytology, Plenck's Phyſiology, Villdenow's Dendrology, and *Dictionnaire de Phyſique* par Gehler.

(B) The nitric acid, however, diluted with a great deal of water, accelerates germination alſo, according to the experiments of Candolle, a young naturaliſt, who has applied with great ſucceſs to vegetable phyſiology. This phenomena is the more intereſting, as chemiſtry affords other analogies of the oxygenated muriatic acid and the nitric acid. Profeſſor Pfaſs at Kiel, by purſuing Humboldt's experiments, has found that frogs ſuffocated in oxygenated muriatic acid gas increaſe in irritability, while thoſe which periſh in carbonic acid gas are leſs ſenſible of galvaniſm.

had been fruitless, and the greater part of them were stimulated with success. Even the hardest seeds yielded to this agent. Among those which germinated were the yellow bonduc or nickar tree (*guilandina bonduc*), the pigeon cytisus or pigeon pea (*cytisus cajan*), the *dodonea angustifolia*, the climbing mimosa (*mimosa scandens*), and new kinds of the *homea*.—There are now shewn at Vienna very valuable plants which are entirely owing to the oxygenated muriatic acid, and which are at present from five to eight inches in height. Humboldt caused to germinate the *clusia rosea*, the seeds of which had been brought from the Bahama islands by Boose, and which before had resisted every effort to make them vegetate. For this purpose he employed a new process, which seems likely to be much easier for gardeners who have not an opportunity of procuring oxigenated muriatic acid: He formed a paste by mixing the seeds with the black oxide of manganese, and then poured over it the muriatic acid diluted with water. Three cubic inches of water were mixed with half a cubic inch of the muriatic acid. The vessel which contains this mixture must be covered, but not closely shut; else it might readily burst. At the temperature of 95° the muriatic acid becomes strongly oxidated; the oxigenated muriatic gas which is disengaged passes through the seeds; and it is during this passage that irritation of the vegetable fibres takes place.—*Philosophical Magazine.*

GESCHE EL AUBE, or GIR GIR, a species of grass growing plentifully near *Ras el Feel* on the borders of Abyssinia. It begins, says Mr Bruce, to shoot in the end of April, when it first feels the humidity of the air. It advances then speedily to its full height, which is about 3 feet 4 inches. It is ripe in the beginning of May, and decays, if not destroyed by fire, very soon afterwards.

The leaf is long, pointed, narrow, and of a feeble texture. The stock from which it shoots produces leaves in great abundance, which soon turn yellow and fall to the ground. The goats, the only cattle these miserable people have, are very fond of it, and for it abandon all other food while it is within their reach. On the leaves of some plants our author saw a very small glutinous juice, like to what we see upon the leaves of the lime or the plane, but in much less quantity; this is of the taste of sugar.

From the root of the branch arises a number of stalks, sometimes two, but never, as far as he had seen, more than three. The flower and seed are defended by a wonderful perfection and quantity of small parts. The head, when in its maturity, is of a purplish brown.

This species of grass was one of the acquisitions of our author's travels. It was not before known in Europe, nor when he published his book had the seed produced a plant any where but in the garden of the French king.

GHEYSSIQUAS, a nation of Hottentots which inhabits a district of South Africa bordering on the country of Caffraria. M. Vaillant visited a horde of this people at no great distance from Orange river, as he was returning from his last African excursion to the Cape, and was shewn by them a chain of mountains to the east, which extending to a distance was lost in the north, and which, inhabited by their principal tribes, separated them from the Caffres, or at least from the Briquas and Bremas, whom they consider as tribes of Caffres.

With respect to such characteristics as are not original and derived from nature, as the form of their dress, weapons, instruments of music, fondness for hunting and dancing, and the like, the Gheyssiquas do not differ from the surrounding nations, except in having adopted a particular colour for their ornaments. All the ornaments of the Gheyssiquas are white, and composed of the bones of a sheep's leg or foot, to which they give a dazzling whiteness by processes peculiar to themselves. Thus, as they fabricate their own necklaces and other articles of luxury, and have no occasion to purchase the materials, they have no dependence on the colonies with respect to trade, except for a few necessary articles, which they want in common with other savages. Accordingly this nation is less known and less visited than any other.

The women are well made, lively, and always ready to laugh or dance: yet, with all the gaiety of their disposition, they have the reservedness of manners to which polished nations give the names of modesty and decorum, and which, in so warm a climate, and with such ardent constitutions, appears to be a virtue of no easy attainment.

Our author says that he no where met with a nation so truly generous. Though he had nothing to give in exchange, yet during two days that he staid with them, he had bowls of milk brought to him as presents, night and morning, from every hut. The chief even obliged him to accept a lamb; and though our traveller's attendants were not destitute of provisions, he would give them also several sheep with which to regale themselves; a degree of generosity of which a proper estimate can be formed only by those who know something of savage manners and savage penury.

The practice of semi-castration prevails among the Gheyssiquas, and among them only of all the Hottentot tribes; and it prevails in all their hordes without exception. Our author convinced himself of this fact by his own eyes; for the men were so complaisant, that, if he had chosen, he might have inspected the whole horde. Many travellers have written upon the subject of this whimsical operation; but they do not agree either as to its origin, the motives that lead to its invention, or the nations by whom it is practised. Kolben, who says that it commonly consists in the extraction of the left testicle, represents it as a religious ceremony, a general and sacred law, with all the Hottentots indiscriminately; but this is unquestionably false. (See HOTTENTOTS, *Encycl.*) Others attribute it to the desire of the Gheyssiquas to render themselves more fleet in running, an effect which it surely is not calculated to produce; and some have said that its intention is to prevent the too abundant propagation of the species. Yet Kolben, though he seems inclined to this last opinion, affirms that twins are not the less common on account of the operation. According to those whom M. Vaillant questioned on the subject, it is merely a mark of distinction, which their ancestors, being at war with the neighbouring nations, invented for the purpose of knowing one another; but, as he himself admits, this is a very improbable account of the matter, as they would surely have adopted, like the Loangoes, Pomboes, and Cormantins, marks of distinction

Ghirgong. tion more eafily difcerned. Be this as it may, the operation among the Gheyffiquas is performed by the father, commonly at the birth of the child, though fometimes not till he has completed his third year.

GHIRGONG, the capital of *Afam* in Hindoftan, is, according to Mr Pennant, fituated in latitude 26° 30′ north. He does not ftate its longitude. It has four gates, and the city is encompaffed with a bound hedge of bamboos. The Rajah's palace is furrounded by a caufey, planted on each fide with a clofe hedge of bamboos, which ferves inftead of a wall. On the outfide there is a ditch, which is always full of water. The Rajah's feat is adorned with lattice work and carving. Within and without have been placed plates of brafs, fo well polifhed, that when the rays of the fun ftrike upon them they fhine like mirrors. It is an afcertained fact, that 3000 carpenters and 12,000 labourers were conftantly employed in this work during two years before it was finifhed.

Pennant's View of Hindoftan.

The Afiatic Refearches fpeak much of the wealth of Afam, and of the plenty and excellency of its natural productions, and that it abounds in all metals but tin. Gold is found in every part of the country by wafhing the fand of the rivers, and is one of the fources of revenue; 12,000, fome fay 20,000 people, are employed in that work, each of whom has from the Rajah certain wages. Its gum lac is excellent, and it is very productive of filk.

Among the fruits which this country produces are mangoes, plantains, jacks, oranges, citrons, limes, pine apples, and puniala, a fpecies of tamarind, which has fuch an excellent flavour, that every perfon who taftes it prefers it to the plum. There are alfo cocoa nut trees, pepper vines, and areca trees. The fugar cane excels in foftnefs and fweetnefs, and is of three colours, red, black, and white. There is ginger free from fibres, and betel vines. The ftrength of vegetation and fertility of the foil are fuch, that whatever feed is fown or flips planted they always thrive. The environs of Ghirgong furnifh fmall apricots, yams, and pomegranates; but as thefe articles are wild, and not affifted by cultivation and engraftment, they are very indifferent. The principal crop in this country confifts in rice and lentiles. Wheat and barley are never fown; lignum aloes is alfo a production of this country. The filks are excellent, and refemble thofe of China, but they manufacture very few more than are required for ufe. They are fuccefsful in embroidering with flowers and in weaving velvet.—One of their great forefts is inhabited by abundance of elephants: 6 or 700 may be taken in a year, but they are neglected by the natives, who have neither horfes, camels, nor affes, fuch as are brought from other countries.

According to our author, "the people of Afam are a bafe unprincipled nation, and have no fixed religion. They follow no rule but that of their own inclination, and make their own vicious minds the teft of the propriety of their actions. They do not adopt any mode of worfhip practifed either by heathens or Mahomedans, nor do they concur with any of the known fects which prevail among mankind; unlike the pagans of Hindoftan, they do not reject victuals which have been dreffed by Moflems, and they abftain from no flefh except human. They even eat animals that have died a natural death."

On this paffage, one of the ableft of our literary journalifts obferves, that in juftice to the people of Afam, we muft remark, that the above account, extracted from the memoirs of Mir Jumla's expedition into that country, was compofed by a rigid Mahomedan, at the court of that fanatical tyrant Aurengzebe. The author and his mafter faw, in the Afamefe, only idolaters; and, in idolaters, the meaneft of mankind. Their diet, though lefs reftricted than that of the Hindoos of Bengal, is by no means promifcuous; and their religion does not in any way differ from that of Hindoftan,—as might eafily be proved by their coins, infcribed with the names of Hindoo deities.

Gibbon.

GIBBON (Edward, Efq.), the celebrated hiftorian of the Decline and Fall of the Roman Empire, was born at Putney in the county of Surrey on the 27th of April 1737. He was the firft child of the marriage of Edward Gibbon, Efq; and Judith Porten, the youngeft daughter of a merchant of London.

The family of Gibbon appears to be ancient and honourable; and our author delights to trace his pedigree from John Gibbon architect to King Edward III. who poffeffed lands in the hundred and parifh of Rolvenden, in the diftrict which is now called the *Weald* of Kent. In that diftrict the elder branch of the family ftill adheres to its native foil, without much increafe or diminution of property; but the fortunes of the younger branch, from which fprung the fubject of this memoir, were fluctuating. It is not, however, with his family, but with himfelf, that we are concerned.

So feeble was his conftitution, and fo precarious his life during his childifh years, that at the baptifm of each of his brothers (and they were five in number) his father's prudence fucceffively repeated the name of Edward, that, in cafe of the death of the eldeft fon, this patronymick appellation might ftill be perpetuated in the family. His brothers and a fifter were all fnatched away in their infancy; and, in terms of affectionate gratitude, he attributes his own prefervation to the more than maternal care of a maiden aunt, his mother's eldeft fifter. "Many anxious and folitary days (fays he) did that dear and excellent woman confume in the patient trial of every mode of relief and amufement. Many wakeful nights did fhe fit by my bed-fide in trembling expectation that each hour would be my laft. Suffice it to fay, that while every practitioner from Sloane and Ward to the Chevalier Taylor was fucceffively fummoned to torture or relieve me, the care of my mind was too frequently neglected for that of my health. Compaffion always fuggefted an excufe for the indulgence of the mafter, or the idlenefs of the pupil; and the chain of my education was broken as often as I was called from the fchool of learning to the bed of ficknefs."

His education feems indeed to have been far from fyftematical. At the age of feven he was delivered into the hands of Mr John Kirby, who exercifed about eighteen months the office of his domeftic tutor, and of whom he writes in terms of refpect. This man had been an indigent curate in Cumberland, and when forced by diftrefs to leave his native country, he was introduced by his learning and his virtue to the family of Mr Gibbon, from whom he might have found at leaft a temporary fhelter, had not an act of indifcretion again driven him into the world. One day reading prayers in the parifh church, he moft unluckily forgot the name of

Gibbon. of King George; and his patron, a loyal ſubject, diſmiſſed him with ſome reluctance and a decent reward. As our author deſcribes his anceſtors as hereditary Tories, and ſome of them as Jacobites, we think it not improbable that Mr Kirby may have been accuſtomed to omit the name of the King when reading prayers in the family; for otherwiſe he would have pronounced it mechanically in the church.

Be this as it may, our author, upon the diſmiſſion of his tutor, was ſent to Kingſton upon Thames, to a ſchool of ſeventy boys kept by Dr Wooddeſon and his aſſiſtants. He does not repreſent himſelf either as happy or as having made great progreſs at that ſchool. The want of ſtrength and activity diſqualified him for the ſports of the field; his companions reviled him for the ſins of his Tory anceſtors; and his ſtudies were frequently interrupted by ſickneſs. After a real or nominal reſidence of near two years at Kingſton, he was finally recalled (Dec. 1747) by the death of his mother. By this time he was well acquainted with Pope's Homer, the Arabian Nights Entertainments, Dryden's Virgil, and a tranſlation of Ovid's Metamorphoſes; and the entertainment which he received from theſe books gave him a taſte for deſultory reading.

After living a year with his maternal aunt, during which period he read many books on religious ſubjects too deep for the comprehenſion of a boy, he was in January 1749 entered in Weſtminſter ſchool, of which Dr John Nicholl was at that time head maſter. "There (ſays he) in the ſpace of two years, interrupted by danger and debility, I painfully climbed into the third form; and my riper age was left to acquire the beauties of the Latin and the rudiments of the Greek tongue. Inſtead of audacioſly mingling in the ſports, the quarrels, and the connections of our little world, I was ſtill cheriſhed at home under the maternal wing of my aunt, who now lived in College-ſtreet; and my removal from Weſtminſter long preceded the approach of manhood."

He was firſt carried to Bath for the recovery of his health; then to Wincheſter, where he lived in the houſe of a phyſician; then to Bath again, where he read with a clergyman ſome odes of Horace and ſome epiſodes of Virgil; after which an unſucceſsful trial was made to renew his attendance at Weſtminſter ſchool. "It might now be apprehended (ſays he) that I ſhould continue for life an illiterate cripple; but as I approached my ſixteenth year, Nature diſplayed in my favour her myſterious energies: my conſtitution was fortified and fixed; and my diſorders inſtead of growing with my growth, and ſtrengthening with my ſtrength, moſt wonderfully vaniſhed." In conſequence of this he was carried to Oxford; and before he had accompliſhed his fifteenth year, was, on April 3. 1752, matriculated a gentleman commoner of Magdalen college.

For the honour of that celebrated univerſity, we would fain hope that the account which Mr Gibbon gives of Magdalen college is greatly exaggerated. He repreſents his tutors as totally regardleſs of his morals or his ſtudies. Speaking of the firſt and beſt of them, for he had two, he ſays, "No plan of ſtudy was recommended for my uſe; no exerciſes were preſcribed for his inſpection; and, at the moſt precious ſeaſon of youth, whole days and weeks were ſuffered to elapſe without labour or amuſement, without advice or account." We ſhall make no other remark on this paſſage, than that from gentlemen, who muſt have been contemporary with Mr Gibbon at Magdalen, we have received different accounts of the college; and it is ſurely a very ſingular circumſtance, that at this period of idleneſs, our author ſhould have become enamoured of Sir John Marſham's *Canon Chronicus*, and have conceived the idea of writing an *Eſſay on the age of Seſoſtris*. Such, however, was the caſe. Not only was the eſſay planned, but part of it was written; and though he never finiſhed it, he declares, that his ſolution of ſome difficulties in chronology was not devoid of ingenuity; but he goes on to vilify Oxford. "It might at leaſt be expected (ſays he), that an eccleſiaſtical ſchool ſhould inculcate the orthodox principles of religion. But our venerable mother had contrived to unite the oppoſite extremes of bigotry and indifference: an heretic, or unbeliever, was a monſter in her eyes; but ſhe was *always*, or *often*, or *ſometimes* (A), remiſs in the ſpiritual education of her own children. Without a ſingle lecture, either public or private, either Chriſtian or Proteſtant, without any academical ſubſcription, without any Epiſcopal confirmation, I was led by the dim light of my catechiſm to grope my way to the chapel and communion table, where I was admitted without a queſtion, how far, or by what means, I might be qualified to receive the ſacrament. Such almoſt incredible neglect was productive of the worſt miſchiefs. From my childhood I had been fond of religious diſputation; nor had the elaſtic ſpring been totally broken by the weight of the atmoſphere of Oxford. The blind activity of idleneſs urged me to advance without armour into the dangerous mazes of controverſy; and, at the age of ſixteen, I bewildered myſelf in the errors of the church of Rome."

Thus anxious is our author to account for his reconciliation to the Romiſh church by the negligence of the tutors of his college. This event took place on the 8th of June 1753, when, at the feet of a prieſt in London, he ſolemnly, though privately, abjured the errors of hereſy. An elaborate controverſial epiſtle, approved by his director, and addreſſed to his father, announced and juſtified the ſtep he had taken; and the old gentleman, in the firſt ſally of paſſion, divulging the ſecret, the gates of Magdalen college were ſhut againſt the convert. It was neceſſary therefore to form a new plan of education; and our young Catholic, by the advice of Mr Eliot (afterwards Lord Eliot), was ſettled, on the 30th of June, under the roof and tuition of Mr Pavilliard, a Calviniſt miniſter at Lauſanne in Switzerland.

He repreſents his ſituation there as at firſt extremely uncomfortable. He could not avoid contraſting a ſmall chamber, ill contrived and ill furniſhed, with his elegant apartment in Magdalen college; and M. Pavilliard being entruſted with the management of his expences, he felt himſelf degraded from the rank of gentleman commoner to that of a ſchool-boy. He began, however, gradually to be reconciled to his fate; and his love of reading returned, which, he ſays, had been chilled by the air of Oxford. He rapidly acquired the French language; and of his tutor he ſays, "My obligations to

(A) Surely *always* and *ſometimes* are words of very different import: why are they uſed then, in this ſentence, as ſynonymous?

Gibbon.

to the lessons of Mr Pavilliard gratitude will not suffer me to forget. He was endued with a clear head and a warm heart; his innate benevolence had assuaged the spirit of the church; he was rational, because he was moderate: in the course of his studies, he had acquired a just, though superficial knowledge of most branches of literature; by long practice he was skilled in the arts of teaching; and he laboured with assiduous patience to know the character, gain the affection, and open the mind of his English pupil."

Under the tuition of this amiable preceptor he describes his progress in the French and Latin classics, in history, geography, logic, and metaphysics, as uncommonly rapid; and he allows to the same man a handsome share of the honour of reclaiming him from the errors of popery. The various discriminating articles of the Romish creed disappeared like a dream; and, after a full conviction, on Christmas-day 1754, he received the sacrament in the church of Lausanne. Thus had our author communicated with three different societies of Christians before the completion of his eighteenth year; and as such changes from church to church are always dangerous, we need not wonder that, in a mind so ill-furnished as Mr Gibbon's then was for theological investigations, they paved the way for his last change to Deism. At present, however, he suspended his religious inquiries, acquiescing (as he says) with implicit belief in the tenets and mysteries which are adopted by the general consent of Catholics and Protestants.

He continued to prosecute his studies with ardour. Under Mr Pavilliard he learned the Greek alphabet, the grammar, and the pronunciation of the language according to the French accent, and soon made himself master of the works of Homer, Herodotus, and Xenophon. During two winters he attended the private lectures of M. de Traytorrens, who explained the elements of algebra and geometry as far as the conic sections of the Marquis de l'Hôpital; but in mathematics he was content (he says) to receive the passive impression of his professor's lectures, without any active exercise of his own powers. In the writings of Grotius and Puffendorf he studied the duties of a man, the rights of a citizen, the theory of justice, and the laws of peace and war, which have had some influence on the practice of modern Europe. "Locke's treatise on government (says he) instructed me in whig principles, which are founded rather in reason than experience; but my delight was in the frequent perusal of Montesquieu, whose energy of style and boldness of hypothesis were powerful to awaken and stimulate the genius of the age"

We have been thus minute in our account of Mr Gibbon's studies, because it furnishes perhaps the most useful lesson which can be drawn from the whole history of his life. His education had been rendered irregular, and had been often interrupted by ill-health and a feeble constitution; but as soon as he was able, and had an opportunity, he applied with ardour to the cultivation of letters, and his works bear witness that his labour was crowned with success. "This part of his story therefore (to use the words of Johnson) well deserves to be remembered. It may afford useful admonition and powerful encouragement to men whose abilities have been made, for a time, useless, and who, having lost one part of life in idleness, are tempted to throw away the remainder in despair."

In the year 1757 Voltaire arrived at Lausanne, and our young student's desire to see the man who was at once a poet, an historian, and, as he deemed himself, the prince of philosophers, was ardent, and easily gratified. He was received by the vain and arrogant Frenchman with civility as an English youth, but could not boast of any peculiar notice or distinction. "The highest gratification (says he) which I received from Voltaire's residence at Lausanne, was the uncommon circumstance of hearing a great poet declaim his own productions on the stage. His declamation was fashioned to the pomp and cadence of the old stage; and he expressed the enthusiasm of poetry rather than the feelings of Nature."

About this time Mr Gibbon became enamoured of Mademoiselle Susan Curchod, the daughter of the minister of Crasse, in the mountains which separate the Pays de Vaud from the county of Burgundy. In terms of rapture he describes this lady as possessed of every accomplishment which could adorn her sex. She listened to the voice of truth and passion; her parents honourably encouraged the connection; and our author indulged in the dream of felicity: but on his return to England, he discovered that his father would not hear of this strange connection, and that without his consent he was destitute and helpless. "After a painful struggle (says he) I yielded to my fate. I sighed as a lover, I obeyed as a son, and my wound was insensibly healed by time, absence, and the habits of a new life." The lady consoled herself by giving her hand to M. Neckar, then a rich banker of Paris, afterwards the minister, and at last one of the destroyers of the French monarchy.

In the spring of the year 1758 our author was recalled to England. On his arrival in London he hastened to the house of his aunt, Mrs Porten, who had been the guardian of his tender years; for though his father was in town awaiting his arrival, he knew not how he should be received by a parent who had parted with him in anger, and given him a stepmother in his absence. His reception was more agreeable than he expected. His father received him as a man and a friend; and the manners of Mrs Gibbon were such, that, after some reserve on his side, she and he easily adopted the tender names and genuine characters of mother and son; and, by the indulgence of these parents, he was left at liberty to consult his own taste or reason in the choice of place, of company, and of amusements. In London he had few acquaintances, and hardly any friends; and being accustomed to a very small society at Lausanne, he preferred the retirement of the country to the bustle of that over-grown metropolis, where he found hardly any entertainment but in the theatres.

Before he left Lausanne he had begun a work on the study of ancient literature, which was suggested by the desire of justifying and praising the object of a favourite pursuit. "In France (says he), to which my ideas were confined, the learning and language of Greece and Rome were neglected by a philosophic age. The guardian of those studies, the Academy of Inscriptions, was degraded to the lowest rank among the three royal societies of Paris: The new appellation of *Erudits* was contemptuously applied to the successors of Lipsius and Casaubon; and I was provoked to hear *, that the exercise of the memory, their sole merit, had been superseded by the nobler faculties of the imagination and the judgment

* *See Le Discours Preliminaire par D'Alembert à l'Encyclopédie.*

Gibbon.

judgment. I was ambitious of proving by my own example, as well as by my precepts, that all the faculties of the mind may be exercifed and difplayed by the ftudy of ancient literature." This laudable ambition continued; and in his father's houfe at Beriton in Hampfhire he finifhed his *Effai fur l' Etude de la Literature;* which, after being revifed by Mallet the poet and Dr Maty of the Britifh mufeum, was, in 1761, publifhed in a fmall 12mo volume.

The fubjects of tafte, criticifm, and philofophy, which in this work came under our young author's confideration, could hardly promife much novelty of remark. Some former obfervations, however, he appears to have placed in a new and pleafing point of view; advancing, moreover, fome ingenious conjectures, and difplaying no inconfiderable erudition. Yet, by his own account, he was at this time almoft a ftranger to the writers of Greece; and when he quotes them, it is probable that the quotations are given at fecond hand. To this effay was prefixed a dedication to his father in the Englifh language, which exhibits the author himfelf in a very amiable light; but if his reputation had depended folely upon this youthful attempt, the name of Gibbon would have been loft in oblivion. Yet he feems, even in his riper years, to have been delighted with it himfelf, and to have confidered its merits as equal to thofe of his later productions; but Milton, it is faid, preferred the Paradife Regained to the Paradife Loft.

Before the publication of this effay, the author, at his own defire, had been appointed a captain in the South Hampfhire militia, in which he ferved upwards of two years. At firft, the company of ruftic and illiterate officers, and the buftle of a military life, were extremely difagreeable to him, as they interrupted his ftudies; but he admits, that his military fervices, his bloodlefs and inglorious campaigns, as he calls them, were, on the whole, beneficial, as they brought him acquainted with Englifh manners, Englifh parties, and Englifh principles, to which his foreign education and referved temper had hitherto kept him an entire ftranger. In the camp and in quarters he had even found leifure, after the firft feven or eight months of his fervice, to read a great deal of Greek, and to plan different hiftorical works, to the compofition of which he feems to have thought that he was born with an innate propenfity. He always talks of himfelf as a philofopher; but furely a more unphilofophical perfuafion than this has feldom been admitted.

At the end of the war he went again abroad, and reached Paris on the 28th of January 1763, only 36 days after the difbanding of the militia in which he had borne the commiffion of a captain. In that metropolis he ftaid not long. He vifited palaces, churches, gardens, and theatres, and was introduced to D'Alembert and Diderot, then confidered as at the head of French fcience. From Paris he proceeded to Switzerland, and once more took up his refidence at his favourite Laufanne. Voltaire's impieties had forced him from that town to his own caftle at Ferney, where our author once vifited him, without (he fays) courting his more intimate acquaintance.

The fociety in which Mr Gibbon moft delighted during his fecond refidence at Laufanne was a very fingular one. "It confifted of fifteen or twenty unmarried ladies of genteel families; the eldeft perhaps about twenty, all agreeable, feveral handfome, and two or three of exquifite beauty. At each other's houfes they affembled almoft every day, without the controul, or even the prefence of a mother or an aunt; they were trufted to their own prudence, among a crowd of young men of every nation in Europe. They laughed, they fung, they danced, they played at cards, they acted comedies; but in the midft of this carelefs gaiety, they refpected themfelves, and were refpected by the men; the invifible line between liberty and licentioufnefs was never tranfgreffed by a gefture, a word, or a look, and their virgin chaftity was never fullied by the breath of fcandal or fufpicion."

We readily agree with our author that this fingular inftitution was expreffive of the innocent fimplicity of Swifs manners; and we only regret that he had not the fame refpect for the ladies of his own country as for thofe frolic females of Switzerland. He would not, in that cafe, have ftained fome of his moft brilliant pages with obfcene ribaldry.

We fhall not follow him in his ramble through Italy, or repeat his remarks on the towns which he vifited. It is fufficient, in fuch a fketch as this, to inform our readers, that it was at Rome on the 15th of October 1764, as he fat mufing amidft the ruins of the Capitol, that the idea of his great work firft ftarted into his mind. But his original plan was circumfcribed to the decay of the city rather than of the empire.

From carrying even this contracted plan into execution he was for fome years diverted. On the 25th of June 1765 he arrived from Italy at his father's houfe in Hampfhire, and found that he had filial duties to perform which interrupted his ftudies and difturbed his quiet. His father had involved himfelf in difficulties from which he could be extricated only by felling or mortgaging part of his eftate; and to fuch fale or mortgage our author cheerfully confented. He regrets on this occafion that he had not "embraced the lucrative purfuits of the law or of trade, the chances of civil office or India adventure, or even the fat flumbers of the church;" and it is to be hoped that, when he thought even of *flumbering* in the church, he had ftill fome faith in revealed religion. He wafted fome time in planning a hiftory of the revolutions of Switzerland, and even wrote part of it in the French language, which, by the advice of friends, he however fuppreffed. We next find him engaged with a friend in a Journal entitled *Memoires Literaires de la Grande Bretagne*, of which two volumes for the years 1767 and 1768 were publifhed, and a third almoft completed, when his friend, a native of Switzerland, was engaged, through his intereft, as travelling governor to Sir Richard Worfley, and the Journal was, of courfe, abandoned. He then entered the lifts with Warburton; whofe interpretation of the fixth book of the Æneid he attacked with great petulance and with much fuccefs. The bifhop of Glocefter was by this time in a ftate of great mental decay, which was peculiarly unfortunate for our author; for had his Lordfhip enjoyed his priftine vigour, he would probably have given Mr Gibbon fuch a chaftifement as might have made him more modeft afterwards when writing the hiftory of the Decline and Fall of the Roman Empire.

To that great work he now fat down ferioufly; and the hiftory which he gives of his preparatory ftudies fufficiently

Gibbon. ſufficiently accounts for the inaccuracy of his quotations. Through the darkneſs of the middle ages he explored his way in the annals and antiquities of Italy by the learned Muratori and other moderns; and ſeems to acknowledge that, from the beginning to the end of his work, he frequently contented himſelf with authorities furniſhed at ſecond hand.

At laſt, in 1776, the firſt volume of his hiſtory was publiſhed by Cadell the bookſeller and Strahan the printer; and the ſucceſs of it far ſurpaſſed his expectation. The encomiums laviſhed on it by Dr Robertſon and Mr Hume in letters to the author, and the fulſome compliments which thoſe three eminent hiſtorians paid to each other, are melancholy ſpecimens of lettered littleneſs and vanity. The ſecond and third volumes appeared in 1781; the fourth, fifth, and ſixth in 1787; and Mr Gibbon's fame was eſtabliſhed as a hiſtorian. The work was admired both by natives and by foreigners, and tranſlated into ſeveral of the languages of Europe. Dr Zimmerman repreſents the author as excelling perhaps Hume and Robertſon, who were hiſtorians of the firſt rank. All the dignity (he adds), all the charms of hiſtoric ſtyle, are united in Gibbon: his periods are melody itſelf, and all his thoughts have nerve and vigour." This praiſe, however, muſt not be admitted without exception. Few writers, indeed, were poſſeſſed of ſuch popular talents as our hiſtorian. The acuteneſs of his penetration, and the fertility of his genius, have been ſeldom equalled, and ſcarcely ever ſurpaſſed. He ſeizes, with ſingular felicity, on all the moſt intereſting facts and ſituations; and theſe he embelliſhes with the utmoſt luxuriance of fancy and elegance of ſtyle. His periods are full and harmonious; his language is always well choſen, and is frequently diſtinguiſhed by a new and peculiarly happy adaptation. His epithets, too, are in general beautiful and happy; but he is rather too fond of them. The uniform ſtatelineſs of his diction ſometimes imparts to his narrative a degree of obſcurity, unleſs he deſcends to the miſerable expedient of a note, to explain the minuter circumſtances. His ſtyle, on the whole, is much too artificial; and this gives a degree of monotony to his periods, which extends, we had almoſt ſaid, to the turn of his thoughts.

A more ſerious objection is his attack upon Chriſtianity; the looſe and diſreſpectful manner in which he mentions many points of morality regarded as important on the principles of natural religon; and the indecent alluſions and expreſſions which too often occur in the work.

An attack upon Chriſtianity is not cenſurable merely as ſuch; it may proceed from the pureſt and moſt virtuous motives: but, in that caſe, the attack will never be carried on in an inſidious manner, and with improper weapons, and Chriſtianity itſelf, ſo far from dreading, will invite every mode of fair and candid diſcuſſion. Our hiſtorian, it muſt be confeſſed, often makes, when he cannot readily find, an opportunity to inſult the Chriſtian religion. Such, indeed, is his eagerneſs in the cauſe, that he ſtoops to the moſt deſpicable pun, or to the moſt awkward perverſion of language, for the pleaſure of turning the ſcripture into ribaldry, or calling Jeſus an impoſtor.

Yet of the Chriſtian religion has Mr Gibbon himſelf obſerved, that it "contains a pure, benevolent, and univerſal ſyſtem of ethics, adapted to every duty and every condition of life." Such an acknowledgment, and from ſuch a writer, too, ought to have due weight with a certain claſs of readers, and of authors likewiſe, and lead them ſeriouſly to conſider, how far it is conſiſtent with the character of good citizens, to endeavour, by ſly inſinuations, oblique hints, indecent ſneer, and profane ridicule, to weaken the influence of ſo *pure* and *benevolent* a ſyſtem as that of Chriſtianity, acknowledgd to be admirably calculated for promoting the happineſs of individuals, and the welfare of ſociety.

Mr Hayley, in his poetical Eſſay on Hiſtory, after a ſplendid panegyric on the arduous labours of his friend, laments the irreligious ſpirit by which he was actuated.

Think not my verſe means blindly to engage
In raſh defence of thy profaner page!
Though keen her ſpirit, her attachment fond,
Baſe ſervice cannot ſuit with Friendſhip's bond;
Too firm from Duty's ſacred path to turn,
She breathes an honeſt ſigh of deep concern,
And pities Genius, when his wild career
Gives Faith a wound, or Innocence a tear.
Humility herſelf divinely mild,
Sublime religion's meek and modeſt child,
Like the dumb ſon of Crœſus, in the ſtrife,
Where force aſſail'd his father's ſacred life,
Breaks ſilence, and with filial duty warm,
Bids thee revere her parent's hallowed form (B)!

The part of the hiſtory which gave ſuch offence to his own friend, as well as to the friends of the Chriſtian religion in general, was the account which our hiſtorian has given of the progreſs and eſtabliſhment of Chriſtianity in the two laſt chapters of his firſt volume; in which he endeavours to prove, that the wonderful triumph of that religion over all the eſtabliſhed religions of the earth, was not owing to any miraculous atteſtations to its truth, but to five ſecondary cauſes which he enumerates; and that Chriſtianity, of courſe, could not be of divine origin. Several anſwers appeared on this occaſion, written, as we may naturally ſuppoſe, with different degrees of temper and ability (C).

One of them only, Mr Davis, who had undertaken to point out various inſtances of miſrepreſentation, inaccuracy, and even plagiariſm in his account, did our hiſtorian condeſcend particularly to anſwer, and that in a tone of proud contempt and confident ſuperiority. To this

(B) Herodotus relates, that a Perſian ſoldier, at the ſtorming of Sardis, was preparing to kill Crœſus, whoſe perſon he did not know, and who, giving up all as loſt, neglected to defend his own life. A ſon of the unfortunate monarch, who had been dumb from his infancy, and who never ſpoke afterward, found utterance in that trying moment, and preſerved his father by exclaiming, 'O kill not Crœſus!'

(C) Dr Chelſum, Dr Randolph, Dr Watſon (biſhop of Llandaff), Lord Hailes, Dr White, Mr Apthorpe, Mr Davis, and Mr Taylor, the author of 'The Letters of Ben Mordecai.'

Gibbon.

this Mr Davis replied; and it is but juſtice to obſerve, that his reply bears evident marks of learning, judgment, and critical acumen, and that he has convicted our author of ſometimes quoting inaccurately to ſerve a purpoſe. At his other anſwerers Mr Gibbon merely glanced, treating Dr Watſon, however, with particular reſpect; but his poſthumous memoirs ſhew how much he felt the attacks made on him by Lord Hailes, Dr White of Oxford, and Mr Taylor. To Dr Prieſtley, who, in his *Hiſtory of the Corruptions of Chriſtianity*, threw down his gauntlets at once to Biſhop Hurd and the hiſtorian of the Roman empire, and who preſented the latter with a copy of his book, declaring at the ſame time, that he ſent it not as a gift but as a *challenge*; he wrote in ſuch terms as produced a correſpondence, which certainly added not to the honour of the diſſenting divine.

At the beginning of the memorable conteſt between Great Britain and America, our author was returned, by the intereſt of Mr Eliot (now Lord Eliot), for the borough of Liſkeard, and ſupported, with many a ſincere and ſilent vote, the rights, though not, perhaps, the intereſt, of the mother country. "After a fleeting illuſive hope, prudence condemned me (ſays he) to acquieſce in the humble ſtation of a mute. I was not armed by Nature and education with the intrepid energy of mind and voice.

Vincentem ſtrepitus, et natum rebus agendis.

Timidity was fortified by pride; and even the ſucceſs of my pen diſcouraged the trial of my voice."

That pen, however, was uſeful to the miniſtry whom he could not ſupport by his eloquence in the houſe. At the requeſt of the Lord Chancellor and Viſcount Weymouth, then ſecretary of ſtate, he vindicated, in a very able manner, againſt the French manifeſto, the juſtice of the Britiſh arms; and his *Memoire Juſtificatif* was delivered as a ſtate paper to the courts of Europe. He was rewarded for this ſervice with the place of one of the lords commiſſioners of trade and plantations; and kept it, till the board was aboliſhed by Mr Burke's reform bill. For accepting this place he was ſeverely, but moſt unjuſtly, blamed by ſome of the leaders of the oppoſition, as if he had deſerted a party in which he had never enliſted, and to the principles of which he was rendered inimical both by family prepoſſeſſion and by his own judgment.

On the downfal of Lord North's adminiſtration, Mr Gibbon was of courſe in the oppoſition deprived of an office, without the ſalary of which he could not conveniently ſupport the expence of living in London. The coalition was indeed ſoon formed, and his friends were again in power; but having nothing to give him immediately, they could not detain him in parliament or even in England. He was tired of the buſtle of the metropolis, and ſighed once more for the retirement of Lauſanne, at which he arrived before the overthrow of the coalition miniſtry, and where he lived happily till the laſt years of his life. It was in this retreat that he wrote the fourth, fifth, and ſixth volumes of his hiſtory; and he left it only for a year to ſuperintend the publication of theſe volumes in London. This great work being concluded, he returned to the banks of the Leman lake, but found his enjoyments damped by the diſtreſs, and ſoon afterwards by the death, of his oldeſt and deareſt Swiſs friend. Lauſanne had now loſt much of its attraction; the French revolution had crowded it with unfortunate emigrants, who could not be cheerful themſelves or excite the cheerfulneſs of others; and the demons of democracy had begun to poiſon the minds of the ſober citizens with principles which Mr Gibbon had always held in abhorrence. Speaking of theſe principles and their effects in Switzerland, he adds, "I beg leave to ſubſcribe my aſſent to Mr Burke's creed on the revolution of France. I admire his eloquence, I approve his politics, I adore his chivalry, and I can almoſt excuſe his reverence for church eſtabliſhments. While the ariſtocracy of Berne protects the *happineſs*, it is ſuperfluous to inquire whether it be founded in the *rights* of men: the economy of the ſtate is liberally ſupplied without the aid of taxes; and the magiſtrates *muſt* reign with prudence and equity, ſince they are unarmed in the midſt of an armed nation."

It was againſt the beneficent and mild government of Berne that the emiſſaries of France contrived to excite the diſcontents of the people, by inſtilling into their ſimple and untutored minds their own wild notions of liberty and equality. From the effects of this Gallic frenzy, which began to be very viſible ſo early as the beginning of the year 1792, Mr Gibbon reſolved to take ſhelter in England, and to abandon, for ſome time at leaſt, what he called his paradiſe at Lauſanne. Difficulties intervened, and forced him to poſtpone his journey from week to week, and from month to month; but on receiving the accounts of Lady Sheffield's death, he haſtened to adminiſter conſolation to his friend, and arrived ſafe in London in the beginning of June 1793.

He continued in good health and ſpirits through the whole of the ſummer; but his conſtitution had ſuffered much from repeated attacks of the gout, and from an incipient dropſy in his ancles. The ſwelling of his ancles, however, ſubſided; but it was only in conſequence of the water flowing to another place: and being repeatedly tapped for a *hydrocele*, he at laſt ſunk under it, and died at his lodgings in St James's ſtreet, London, on the 16th of January 1794.

To draw a character at once general and juſt of this extraordinary man, would be difficult perhaps to one who had enjoyed the pleaſure of his acquaintance, and muſt be impoſſible to thoſe to whom his perſon was a ſtranger. Of the extent of his erudition there can be but one opinion; but various opinions may be held reſpecting the accuracy of his knowledge. Lord Sheffield, who knew him well, and loved him much, aſſures us, that his converſation was ſtill more captivating than his writings: but this could not reſult from the brilliancy of his wit; for of wit he declares himſelf that he had none. His memory was capacious and retentive, his penetration uncommon, and his colloquial eloquence ready and elegant; ſo that he could illuſtrate almoſt any topic of converſation from the copious ſtores of his own mind. From his private correſpondence, and a journal not written for the public eye, he appears to have been a dutiful ſon, a loyal ſubject, and an affectionate and ſteady friend; but it is difficult to reconcile with ſo much moral and political worth his unfair and unmanly ſneers at the religion of his country.

Gibraltar.

GIBRALTAR is a fortreſs of immenſe ſtrength, of which a very full account has been given in the *Encyclopædia.*

Gibraltar.

cyclopædia. Nothing, however, is in that article ſaid of the natural hiſtory of the mountain on which the fortreſs is built, though, to men of ſcience, that ſubject muſt be as intereſting as a detail of ſieges. This defect we are enabled to ſupply by means of Major Imrie's mineralogical deſcription of Gibraltar, which is publiſhed in the fourth volume of the Tranſactions of the Royal Society of Edinburgh; and, we are perſuaded, the following abſtract of that elegant memoir will afford rational entertainment to many of our readers.

"The form of this mountain is oblong; its ſummit a ſharp craggy ridge; its direction is nearly from north to ſouth; and its greateſt length, in that direction, falls very little ſhort of three miles. Its breadth varies with the indentations of the ſhore, but it nowhere exceeds three quarters of a mile. The line of its ridge is undulated, and the two extremes are ſomewhat higher than its centre.

"The ſummit of the Sugar Loaf, which is the point of its greateſt elevation towards the ſouth, is 1439 feet; the Rock Mortar, which is the higheſt point to the north, is 1350; and the Signal Houſe, which is nearly the central point between theſe two, is 1276 feet above the level of the ſea. The weſtern ſide of the mountain is a ſeries of rugged ſlopes, interſperſed with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the north-weſt, where what are called the Lines intervene, and a narrow paſſage of flat ground that leads to the iſthmus, and is entirely covered with fortification. The eaſtern ſide of the mountain moſtly conſiſts of a range of precipices; but a bank of ſand, riſing from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its ſouthern extremity falls, in a rapid ſlope from the ſummit of the Sugar Loaf, into a rocky flat of conſiderable extent, called Windmill Hill.

"The principal maſs of the mountain rock conſiſts of a grey, denſe (what is generally called primary) marble; the different beds of which are to be examined in a face of 1350 feet of perpendicular height, which it preſents to Spain in a conical form. Theſe beds, or ſtrata, are of various thickneſs, from 20 to upwards of 40 feet, dipping in a direction from eaſt to weſt, nearly at an angle of 35 degrees. In ſome parts of the ſolid maſs of this rock are found teſtaceous bodies entirely tranſmuted into the conſtituent matter of the rock, and their interior hollows filled up with calcareous ſpar; but theſe do not occur often in its compoſition, and its beds are not ſeparated by any intermediate ſtrata.

"The caves of Gibraltar are many, and ſome of them of great extent. That which moſt deſerves attention and examination is called St Michael's Cave, which is ſituated upon the ſouthern part of the mountain, almoſt equally diſtant from the Signal Tower and the Sugar Loaf. Its entrance is 1000 feet above the level of the ſea: This entrance is formed by a rapid ſlope of earth, which has fallen into it at various periods, and which leads to a ſpacious hall, incruſted with ſpar, and apparently ſupported in the centre by a large maſſy ſtalactitical pillar. To this ſucceeds a long ſeries of caves of difficult acceſs. In theſe cavernous receſſes, the formation and proceſs of ſtalactites is to be traced, from the flimſy quilt-like cone, ſuſpended from the roof, to the robuſt trunk of a pillar, three feet in dimeter, which riſes from the floor, and ſeems intended by Nature to ſupport the roof from which it originated.

"The only inhabitants of theſe caves are bats, ſome of which are of a large ſize. The ſoil, in general, upon the mountain of Gibraltar is but thinly ſown; and in many parts that thin covering has been waſhed off by the heavy autumnal rains, which have left the ſuperficies of the rock, for a conſiderable extent, bare and open to inſpection. In thoſe ſituations, an obſerving eye may trace the effects of the ſlow, but conſtant, decompoſition of the rock, cauſed by its expoſure to the air, and the corroſion of ſea-ſalts, which, in the heavy gales of eaſterly winds, are depoſited with the ſpray on every part of the mountain. Thoſe uncovered parts of the mountain rock alſo expoſe to the eye a phenomenon worthy of ſome attention, as it tends clearly to demonſtrate, that, however high the ſurface of this rock may now be elevated above the level of the ſea, it has once been the bed of agitated waters. This phenomenon is to be obſerved in many parts of the rock, and is conſtantly found in the beds of torrents. It conſiſts of pot-like holes, of various ſizes, hollowed out of the ſolid rock, and formed apparently by the attrition of gravel or pebbles, ſet in motion by the rapidity of rivers or currents in the ſea.

"Upon the weſt ſide of the mountain, towards its baſe, ſome ſtrata occur, which are heterogenial to the mountain rock: the firſt, or higheſt, forms the ſegment of a circle; its convex ſide is towards the mountain, and it ſlopes alſo in that direction. This ſtratum conſiſts of a number of thin beds; the outward one, being the thinneſt, is in a ſtate of decompoſition, and is mouldering down into a blackiſh brown or ferruginous coloured earth. The beds, inferior to this, progreſſively increaſe in breadth to 17 inches, where the ſtratification reſts upon a rock of an argillaceous nature.

"This laſt bed, which is 17 inches thick, conſiſts of quartz of a blackiſh blue colour, in the ſepta or cracks of which are found fine quartz cryſtals, colourleſs, and perfectly tranſparent. Theſe cryſtals are compoſed of 18 planes, diſpoſed in hexangular columns, terminated at both extremities by hexangular pyramids. The largeſt of thoſe that Major Imrie ſaw did not exceed one-fourth of an inch in length: They, in general, adhere to the rock by the ſides of the column, but are detached without difficulty. Their great degree of tranſparency has obtained them the name of *Gibraltar diamonds*."

Much has been ſaid of the foſſil bones found in the rock of Gibraltar; and the general idea which exiſts concerning them is, that they are found in a petrified ſtate, and encloſed in the ſolid calcareous rock; but this, ſays Major Imrie, is a miſtake, which could ariſe only from inaccurate obſervation and falſe deſcription.

"In the perpendicular fiſſures of the rock, and in ſome of the caverns of the mountain (all of which afford evident proofs of their former communication with the ſurface), a calcareous concretion is found, of a reddiſh brown ferruginous colour, with an earthy fracture, and conſiderable induration, encloſing the bones of various animals, ſome of which have the appearance of being human. Theſe bones are of various ſizes, and lie in all directions, intermixed with ſhells of ſnails, fragments of the calcareous rock, and particles of ſpar; all of which materials are ſtill to be ſeen in their natural uncombined ſtates, Gibraltar. ftates, partially fcattered over the furface of the mountain. Thefe having been fwept, by heavy rains at different periods, from the furface into the fituations above defcribed, and having remained for a long feries of years in thofe places of reft, expofed to the permeating action of water, have become inveloped in, and cemented by, the calcareous matter which it depofits.

"The bones, in this compofition, have not the fmalleft appearance of being petrified; and if they have undergone any change, it is more like that of calcination than that of petrifaction, as the moft folid parts of them generally admit of being cut and fcraped down with the fame eafe as chalk,

"Bones combined in fuch concretions are not peculiar to Gibraltar: they are found in fuch large quantities in the country of Dalmatia, and upon its coafts in the iflands of Cherfo and Ofero, that fome naturalifts have been induced to go fo far as to affert, that there has been a regular ftratum of fuch matter in that country, and that its prefent broken and interrupted appearance has been caufed by earthquakes, or other convulfions, experienced in that part of the globe. But, of late years, a traveller (Abbé Alberto Fortis) has given a minute defcription of the concretion in which the bones are found in that country: And by his account it appears, that with regard to fituation, compofition, and colour, it is perfectly fimilar to that found at Gibraltar. By his defcription, it alfo appears that the two mountain rocks of Gibraltar and Dalmatia confift of the fame fpecies of calcareous ftone; from which it is to be prefumed, that the concretions in both have been formed in the fame manner and about the fame periods.

"Perhaps if the fiffures and caves of the rock of Dalmatia were ftill more minutely examined, their former communications with the furface might yet be traced, as in thofe defcribed above; and, in that cafe, there would be at leaft a ftrong probability, that the materials of the concretions of that country have been brought together by the fame accidental caufe which has probably collected thofe found in the caverns of Gibraltar. Major Imrie traced, in Gibraltar, this concretion, from the loweft part of a deep perpendicular fiffure, up to the furface of the mountain. As it approached to the furface, the concretion became lefs firmly combined, and, when it had no covering of the calcareous rock, a fmall degree of adhefion only remained, which was evidently produced by the argillaceous earth, in its compofition, having been moiftened by rain and baked by the fun.

"The depth at which thefe materials had been penetrated by that proportion of ftalactitical matter, capable of giving to the concretion its greateft adhefion and folidity, he found to vary according to its fituation, and to the quantity of matter to be combined. In fiffures, narrow and contracted, he found the concretion poffeffing a great degree of hardnefs at fix feet from the furface; but in other fituations more extended: and where a larger quantity of the materials had been accumulated, he found it had not gained its greateft degree of adhefion at double that depth. In one of the caves, where the mafs of concretion is of confiderable fize, he perceived it to be divided into different beds, each bed being covered with a cruft of the ftalactitical fpar, from one inch to an inch and a half in thicknefs; which feems to indicate, that the materials have been carried in at various periods, and that thofe periods have been very remote from each other.

Gibraltar.

"At Rofia Bay, upon the weft fide of Gibraltar, this concretion is found in what has evidently been a cavern, originally formed by huge unfhapely maffes of the rock which have tumbled in together. The fiffure, or cavern formed by the difruption and fubfidence of thofe maffes, has been entirely filled up with the concretion, and is now expofed to full view by the outward mafs having dropped down in confequence of the encroachments of the fea. It is to this fpot that ftrangers are generally led to examine the phenomenon; and the compofition, having here attained to its greateft degree of hardnefs and folidity, the hafty obferver, feeing the bones inclofed in what has fo little the appearance of having been a vacuity, examines no further, but immediately adopts the idea of their being incafed in the folid rock. The communication from this former chafm to the furface from which it has received the materials of the concretion, is ftill to be traced in the face of the rock, but its opening is at prefent covered by the bafe of the line wall of the garrifon. Here bones are found that are apparently human; and thofe of them that appear to be of the legs, arms, and vertebræ of the back, are fcattered among others of various kinds and fizes, even down to the fmalleft bones of fmall birds. Major Imrie found here the complete jaw-bone of a fheep; it contained its full complement of teeth, the enamel of which was perfect, and its whitenefs and luftre in no degree impaired. In the hollow parts of fome of the large bones was contained a minute cryftallization of pure and colourlefs calcareous fpar; but, in moft, the interior part confifted of a fparry cruft of a reddifh colour, fcarcely in any degree tranfparent.

"At the northern extremity of the mountain, the concretion is generally found in perpendicular fiffures. The miners there, employed upon the fortifications in excavating one of thofe fiffures, found, at a great depth from the furface, two fkulls, which were fuppofed to be human; but, to the Major, one of them, if not both, appeared to be too fmall for the human fpecies. The bone of each was perfectly firm and folid; from which it is to be prefumed, that they were in a ftate of maturity before they were inclofed in the concretion. Had they appertained to very young children, perhaps the bone would have been more porous, and of a lefs firm texture. The probability is, that they belonged to a fpecies of monkey, which ftill continues to inhabit, in confiderable numbers, thofe parts of the rock which are to us inacceffible.

"This concretion varies, in its compofition, according to the fituation in which it is found. At the extremity of Princes Lines, high in the rock which looks towards Spain, it is found to confift only of a reddifh calcareous earth, and the bones of fmall birds cemented thereby. The rock around this fpot is inhabited by a number of hawks, that, in the breeding feafon, neftle here and rear their young; the bones in this concretion are probably the remains of the food of thofe birds. At the bafe of the rock, below King's Lines, the concretion confifts of pebbles of the prevailing calcareous rock. In this concretion, at a very confiderable depth under the furface, was found the under parts of a glafs bottle, uncommonly fhaped, and of great thicknefs; the colour of the glafs was of a dark green."

Major

Major Imrie makes an apology for giving fo minute a defcription of thefe foffil bones ; but, in our opinion, the public is indebted to him for beftowing fo much attention on a fubject which all muft admit to be curious, and which, from the ftrange inferences drawn from fimilar phenomena by modern philofophers, has become important as well as curious.

We cannot difmifs this article without noticing the fubterraneous galleries conftructed in the rock not only for the protection of the men during a fiege, but alfo for placing cannon, to annoy the enemy, in fituations inacceffible but by fuch means. The idea of forming thefe galleries was conceived by the late Lord Heathfield when governor, and by him, in fome meafure, carried into execution ; though the plan was not completed till lately by General O'Hara. Of thefe galleries we have in the *Monthly Magazine* for April 1798 an animated account, which we fhall infert in the writer's own words.

"The fubterraneous galleries are very extenfive, pierce the rock in feveral places and in various directions, and at various degrees of elevation ; all of them have a communication with each other, either by flights of fteps cut in the rock, or by wooden ftairs where the paffages are required to be very perpendicular.

"The centinels may now be relieved during a fiege from one poft to another in perfect fafety ; whereas, previoufly to the conftructing of thefe galleries, a vaft number of men were killed by the Spaniards while marching to their feveral ftations. The width of thefe galleries is about twelve feet, their height about fourteen. The rock is broken through in various places, both for the purpofe of giving light and for placing the guns to bear on the enemy. In different parts there are fpacious receffes, capable of accommodating a confiderable number of men. To thefe receffes they give names, fuch as St Patrick's Chamber, St George's Hall, &c. The whole of thefe fingular ftructures have been formed out of the folid rock by blafting with gunpowder. Through the politenefs of an officer on duty, a place called Smart's Refervoir was opened for our infpection, which is a great curiofity, and not generally permitted to be fhewn. It is a fpring at a confiderable depth in the body of the rock, and is above 700 feet above the level of the fea ; we defcended into the cavern that contains it by a rope ladder, and with the aid of lighted candles proceeded through a narrow paffage over cryftallized protuberances of the rock till we came to a hollow, which appears to have been opened by fome convulfion of Nature. Here, from a bed of gems, arifes the falutary fount, clear as the brilliant of the eaft, and cold as the icicle. We hailed the nymph of the grot, and, proftrating ourfelves, quaffed hygean nectar from her fparry urn. When reftored to the light of day, we obtained, through the medium of the fame gentleman, the key of St George's Hall, at which we arrived by a very intricate and gloomy path to the fpacious excavation, which is upwards of an hundred feet in length, its height nearly the fame. It is formed in a femicircular part of the rock ; fpacious apertures are broken through, where cannons of a very large calibre command the ifthmus, the Spanifh lines, and a great part of the bay. The top of the rock is pierced through, fo as to introduce fufficient light to enable you to view every part of it. It appears almoft incredible that fo large an excavation could be formed by gunpowder, without blowing up the whole of that part of the rock, and ftill more fo, that they fhould be able to direct the operations of fuch an inftrument, fo as to render it fubfervient to the purpofe of elegance. We found in the hall a table, placed, I fuppofe, for the conveniency of thofe who are traverfing the rock. The cloth was fpread, the wine went round, and we made the vaulted roof refound with the accents of mirth and the fongs of conviviality."

Thefe excavations are indeed very extraordinary works ; but as the whole rock abounds with caverns, we wifh that our author had inquired more particularly than he feems to have done, whether St George's Hall be wholly the work of art. From one of the paffages which we have extracted from Major Imrie's memoir, we are led to think that it is not, or at leaft, that the concretion removed had not acquired the confiftence of the more folid parts of the rock. If this was the cafe, much of the wonder will vanifh, fince the pick-axe and chifel were probably employed to give elegance to the vault, and even, in fome degree, to direct the operation of the gunpowder.

GIMBOLS, are the brafs rings by which a fea-compafs is fufpended in its box that ufually ftands in the binacle.

GIRT, in timber-meafuring, is the circumference of a tree, though fome ufe this word for the quarter or 4th part of the circumference only, on account of the great ufe that is made of it ; for the fquare of this 4th part is efteemed and ufed as equal to the area of the fection of the tree ; which fquare therefore multiplied by the length of the tree, is accounted the folid content. This content, however, is always about one-fourth part lefs than the true quantity ; being nearly equal to what this will be after the tree is hewed fquare in the ufual way : fo that it feems intended to make an allowance for the fquaring of the tree.

Girt *Line*, is a line on the common or carpenter's fliding rule, employed in cafting up the contents of trees by means of their girt.

GLASS Etching, or *Engraving upon*, is in the article Chemistry (*Encycl.*) faid to be a new art ; and as that acid which diffolves filiceous earth, and alfo glafs, was firft difcovered in the year 1771 by Scheele, one might naturally imagine that the art of etching with it upon glafs could not be older. By many others, as well as by us, it has indeed been noticed as a new invention ; yet Profeffor Beckmann, whofe laborious refearches have brought many things to light, has proved, that fo early as the year 1670 the art of etching upon glafs was difcovered by Henry Schwanhard, fon of George Schwanhard, who was a celebrated glafs-cutter, patronized by the Emperor Ferdinand III. about the middle of the laft century. At the time of his death, 1667, the father practifed his art at Prague and Ratifbon. Whether the fon followed the fame bufinefs at the fame towns, or removed to Nuremberg, is not very evident from the profeffor's hiftory ; but in the year above-mentioned, fome *aqua regia (nitro muriatic acid)* having accidentally fallen on his fpectacles, he was furprifed to find the glafs corroded by it, and become quite foft. He thus found himfelf in poffeffion of a liquid by which he could etch writing and figures upon plates of glafs.

Such is our information ; but if it be admitted (and it would difplay unreafonable fcepticifm to queftion it), Schwanhard muft either have improved the nitro-muriatic acid

acid by fome means or other unknown to us, or have confined his etchings to fome particular kinds of glafs; for the *fluoric* is the only acid, with which we are acquainted, that corrodes all glafs. (See CHEMISTRY-*Index* in this *Supplement*). M. Beckmann indeed feems to think that he had difcovered the fluoric acid itfelf; for in the year 1725 there appeared in a periodical work the following receipt for making a powerful acid, by which figures of every kind can be etched upon glafs.

"When the *fpiritus nitri per diftillationem* has paffed into the recipient, ply it with a ftrong fire, and when well dephlegmated, pour it, as it corrodes ordinary glafs, into a Weldenburg flafk. Then throw into it a pulverifed green Bohemian emerald, otherwife called *hefphorus* (which, when reduced to powder, and heated, emits in the dark a green light), and place it in warm fand for 24 hours. Take a piece of glafs well cleaned, and freed from all greafe by means of a ley; put a border of wax round it, about an inch in height, and cover it all over with the above acid. The longer you let it ftand fo much the better; and at the end of fome time the glafs will be corroded, and the figures which have been traced out with fulphur and varnifh will appear as if raifed above the pane of glafs."

That the Bohemian emerald or *hefphorus* mentioned in this receipt is green fparry fluor, cannot, fays the profeffor, be doubted; and he feems to have as little doubt of the receipt itfelf having paffed from Schwanhard and his fcholars to the periodical work of 1725, from which it has been lately inferted in the Œkonomifche Encyclopedie of Krunitz. This fuppofition certainly acquires a confiderable degree of probability from the fimilarity of Schwanhard's method of etching to that which is here recommended, and which is fo different from what is now followed. At prefent, the glafs is covered with a varnifh either of ifinglafs diffolved in water, or of turpentine oil mixed with a little white lead, through which the figures to be etched are traced as on copper; but Schwanhard, when he had drawn his figures, covered them with varnifh, and then by his liquid corroded the glafs around them. His figures, therefore, when the varnifh was removed, remained fmooth and clear, appearing raifed from a dim or dark ground; and M. Beckmann, who perfuaded fome ingenious artifts to make trial of this antient method of etching, declares, that fuch figures have a much better effect than thofe which are cut into the glafs.

Before concluding this article, it may be worth while juft to mention a propofal which has been lately made to employ glafs inftead of copper for throwing off prints in the rolling prefs. That it is poffible to ufe glafs plates of great thicknefs for this purpofe, it would be rafh to deny; but the fuperiority of fuch plates to thofe of copper we cannot conceive. If not broken in pieces in the rolling prefs, they would doubtlefs laft longer; but the expence of them at firft would probably be greater, and the engraving on them could not be fo fine.

GLOSSOCOMMON, in mechanics, is a name given by Heron to a machine compofed of divers dented wheels with pinions, ferving to raife huge weights.

GLUCINA (A), a peculiar earth difcovered by Vauquelin in the beryl and the emerald. Its general properties are as follows: 1. It is white; 2. Infipid; 3. Infoluble in water; 4. Adhefive to the tongue; 5. Infufible; 6. Soluble in the fixed alkalis; 7. Infoluble in ammoniac; 8. Soluble in the carbonat of ammoniac; 9. Soluble in almoft every one of the acids (except the carbonic and phofphoric acids), and forming falts of a faccharine tafte; 10. Fufible with borax into a tranfparent glafs; 11. Abforbs one fourth of its weight of carbonic acid; 12. Decompofes the aluminous falts; 13. Is not precipitable by well faturated hydro-fulphurets.

The fpecific characters of glucina, which are united in none of the other known earths, are: 1. Its falts are faccharine, and flightly aftringent; 2. It is very foluble in the fulphuric acid by excefs; 3. It decompofes the aluminous falts; 4. It is foluble in the carbonat of ammoniac; 5. Is completely precipitated from its folutions by ammoniac; 6. Its affinity for the acids is intermediate between magnefia and alumine.

One hundred parts of beryl contain 16 of glucina; but for the beft method of analyzing the beryl, and of courfe obtaining the earth, we muft refer our readers to the article MINERALOGY in this *Supplement*; and fhall conclude this fhort article with a valuable and judicious remark of Vauquelin's.

"It almoft always happens (fays this able chemift), in the fciences of obfervation, and even in the fpeculative fciences, that a body, a principle, or a property, formerly unknown, though it may often have been ufed, or even held in the hands, and referred to other fimple fpecies, may, when once difcovered, be afterwards found in a great variety of fituations, and be applied to many ufeful purpofes. Chemiftry affords many recent examples of this truth. Klaproth had no fooner difcovered the different fubftances with which he has enriched the fcience, but they were found in various other bodies; and if I may refer to my own proceffes, it will be feen, that after I had determined the characters of chrome, firft found in the native red lead, I eafily recognized it in the emerald and the ruby. The fame has happened with regard to the earth of the beryl. I have likewife detected it in the emerald; in which, neverthelefs, it was overlooked both by Klaproth and myfelf in our firft analyfis: fo difficult it is to be aware of the prefence of a new fubftance, particularly when it poffeffes fome properties refembling thofe already known!"

GOLD, the moft perfect of all the metals. See CHEMISTRY-*Index* in this *Supplement*.

It has been a very common opinion among metallurgifts, that tin has the property of deftroying the ductility of gold, on being melted with it even in very fmall quantities; and Dr Lewis adds, that even the vapours which arife from tin in the fire, make gold fo brittle, that it flies in pieces under the hammer. This opinion was controverted by Stanefby Alchorne, Efq; of his Majefty's mint, who made a fet of experiments, which, in his opinion, authorife a very different conclufion, viz. that though tin, like other inferior metals, will

(A) This name was given to the earth of beryl by the editors of the *Annales de Chimie*. Its moft characteriftic property being that it forms falts of a faccharine tafte, they gave it a name derived from γλυκαινω, *to render fweet*. According to this etymology, fhould not the name be *Glycina*?

Gold.

will contaminate gold in proportion to the quantity mixed with it, yet there does not appear in tin any thing fpecifically inimical to that precious metal.

As we have elfewhere (fee CHEMISTRY, nº 1091, &c. *Encycl.*) enumerated thefe experiments, and admitted the conclufion drawn from them, it becomes our duty, in this place, to ftate what has been urged againft that conclufion.

M. Tillet, being in his own mind perfuaded that tin renders gold fo brittle that it cannot be reduced to thin leaves, and far lefs be made to pafs through the wire-plate but by virtue of repeated annealing, and peculiar treatment, which gold of the ufual ductility does not require, determined, from refpect to M. Alchorne, to repeat his experiments.

His firft experiment* confifted in mixing 24 grains of fine gold with one of tin which contained no arfenic. He wrapped the grain of tin in the 24 grains of gold reduced to a very thin leaf, and placed the whole upon a piece of charcoal, fo hollowed out as to fupport the mixed metal during fufion. He even fprinkled a fmall quantity of calcined borax upon the metal, in order that the fufion might be more fudden, that the metal might flow together, and the tin unite with the gold, without allowing time for it to become calcined. This alloy was fpeedily fufed by the enameller's lamp, and reduced into a fmall button without any lofs of weight. It was then flattened carefully beneath the hammer; but, notwithftanding his utmoft precaution in this refpect, it cracked, and at laft broke into three pieces, its thicknefs then being a quarter of a line or thereabouts. He repeated this experiment with a double quantity as well of pure gold as of tin, and the refult was the fame.

* *Memoirs of the Academy of Sciences at Paris for the year* 1790.

He next alloyed 4 ounces of gold, of the finenefs of 22 carats, with 1 gros 24 grains of tin deprived of arfenic, or, in other words, with 4 pennyweights of tin; and thefe two metals being reduced into fmall pieces, were mixed together, put into a crucible, and urged by the ftrong heat of a forge with two pair of bellows. When their fufion appeared to be complete, he poured the metal into a fmall ingot mould proportioned to the quantity.

The ingot thus obtained had loft fcarcely any thing of the weight of the two metals that compofed it; which was a proof that the tin had united and incorporated with the four ounces of gold. But on attempting to bend the ingot, which was about fix inches long, and not more than two or three lines thick, he remarked, contrary to the nature of gold of 22 carats, that it was rigid, and would have required a confiderable effort to give it any degree of curvature, or bring it to the flexibility it would have poffeffed if no tin had entered into its compofition. Not fatisfied, however, with the inference naturally flowing from this circumftance, he proceeded to the proper teft by hammering, particularly with the edge of the hammer, in order that the bar might be lengthened, and by that means fubmitted to the moft decifive proof. He did not obferve, during the continuation of this procefs, till the bar was reduced to about two-thirds of its firft thicknefs, that its edges were cracked, or exhibited much of the appearance of brittlenefs; but as he was apprehenfive that this accident might happen by too long hammering, he divided the bar by cutting off the part which had been hammered out. This part was placed in the midft of lighted charcoal, in order that, by a moderate annealing, it might recover the ftate of malleability it poffeffed before it was hammered. But when he went to take it out of the fire, where it had undergone no greater heat than a cherry-red, he found it divided into two parts. After having fuffered thefe to cool, he forged them again. They were extended with confiderable eafe, though with fome cracks at the edges; but they did not yet fatisfy the whole of his enquiries. He therefore annealed one of the two laft mentioned pieces a fecond time, and referved the other in its hard-hammered ftate to be paffed between the laminating rollers. The annealed part, which might have the thicknefs of about a fhilling, broke in the fire, though the heat was very gentle, into four or five portions. The longeft of thefe portions, which beft refifted the action of the fire, bent and twifted itfelf, and fhewed, by this ftate of ftrong contraction in different directions, that it had tended to break and become divided into fmall portions, fimilar to thofe which had already feparated from it.

Satisfied by this experiment that the piece of the mixed ingot which he had kept in its hammer-hardened ftate would not bear annealing, he determined to extend it ftill more between the rollers, fetting them up very gradually, in order that the fracture, if it fhould take place, might be principally owing to the brittlenefs of the material, and not to the force of compreffion to which it was fubjected. By this management he fucceeded in extending the metal to double its length notwithftanding its hardnefs, and rendering it as thin as ftrong paper; though the edges were cracked through their whole length like the teeth of a faw. But this accident is not at all furprifing, when it is confidered that gold, though alloyed fimply with copper, whatever may be the caufe, does not poffefs its ufual ductility, particularly when it is laminated very thin, without repeated annealing as the metal becomes hard.

Aware that the fracture of the pieces of gold might be attributed to an incomplete fufion, or unequal mixture of the two metals, he melted the whole ingot over again with the utmoft precaution; but in vain. The metal was as brittle as formerly, and would not bear annealing.

He next fufed fix ounces of pure gold of 24 carats with 2 gros, or 6 penny-weights of tin, taking every poffible precaution to have the metals completely mixed. When the whole was in perfect fufion, he poured the mixture into an ingot mould, and obtained an ingot rather longer and cleaner than the two former. As foon as it was cold he forged one of its extremities with the edge of the hammer. It was lengthened without any perceptible crack; and when it was reduced to the thicknefs of one line, or thereabouts, he cut it off for feparate treatment. By moderate annealing it maintained its integrity; and, with the exception of a few cracks, it paffed the laminating rollers without breaking. As he was fearful, neverthelefs, that it might break in fome part if he continued to laminate it, he gave it a flight annealing. It had fcarcely acquired a cherry-rednefs between the charcoal, before it broke into five or fix parts, fome of which were fimply bended or twifted, and others flat as they quitted the rollers. Among the annealed pieces of this extremity

Gold.

extremity of the ingot, there was one sufficiently long, though a little curled, which he laminated a second time, with the determination of rendering it very thin without the least annealing. It acquired at least double the length it had at first without breaking; and, if we except the two sides of this plate which were cracked, the body, or main piece, was entire. It was spongy, and might be considered as if formed out of an ingot of common gold containing no tin, but not possessing the whole of its natural ductility.

"It follows, says M. Tillet, from these experiments, that gold, whether fine or alloyed, when perfectly fused with a small portion of the finest tin, acquires rigidity and hardness by the mixture; that it loses somewhat of its distinguishing colour; and that it may, indeed, by careful management, be extended to a certain degree by the hammer, or still better by the rollers; but that, as it cannot be annealed without danger of breaking, it is by this defect deprived of the essential advantage of recovering its original softness after it has been strongly hammer-hardened. It is not but by careful management in the use of the hammer, and by frequent annealing, that artists employed on works of gold and silver succeed in obtaining them without cracks, and bringing them to a state of perfection, without being obliged to have recourse to solder to repair the defects which excessive hardness under the hammer would occasion. How much, therefore, ought gold-workers, who continually have this metal in their hands, to be attentive to prevent the introduction of tin in their workshops, and never to employ such compounds of gold as are subject to break, or even to warp, while annealing? The expence of refining, which they would pay for depurating such compounds, would be of less consequence to them than the loss of time required for the careful management of such gold contaminated by tin, even if they did succeed in using it, and were not often forced to abandon, after much labour, a work nearly finished.

"If it be allowable (continues our author) to form conjectures on the cause of the fracture of plates of gold containing tin, when subjected to the annealing heat, it may be presumed, since tin very speedily melts, while gold requires a strong heat for its fusion, that the parts of the tin intermixed in a sort of proportional equality with those of the gold, tend to separate by a speedy fusion and at a very gentle degree of heat; that they remain without consistence between the parts of the gold, while the latter preserve the whole of their solidity, and do not lose it even by the annealing heat: whence it seems, that the parts of the precious metal, when ignited among the coals, having no longer the solid connection formed by the tin, but, on the contrary, having an infinite number of small cavities occupied by particles of that metal in fusion, must tend to disunion; whereas the same accident does not take place in the pieces which have resisted the annealing, and have been laminated after cooling, because the particles of tin have become solid by cooling, and have recovered their original state of union with the gold.

"This fracture of the compound does not take place with an alloy of gold and copper, for an opposite reason to that which has here been explained; namely, because these two metals require nearly the same heat for their fusion. The effect of annealing being therefore equal upon both, the metals, notwithstanding this treatment, preserve their natural consistence, even tho' the heat be carried near the point of fusion."

Gold, Goldoni.

Gold-Leaf. See *Gold-Leaf* (*Encycl.*), where a full account is given from Dr Lewis of the process of gold-beating. In that article we have said that gold-leaf ought to be prepared from the finest gold; but Mr Nicholson, who in all probability knows much more of the matter than the author from whom our account was copied, assures us that this is a mistake, and that pure gold is too ductile to be worked between the gold-beater's skin. The newest skins will work the finest gold, and make the thinnest leaf, because they are the smoothest. Old skins, being rough or foul, require coarser gold. The finer the gold, the more ductile; insomuch that pure gold, when driven out by the hammer, is too soft to force itself over the irregularities, but would pass round them, and by that means become divided into narrow slips. The finest gold for this purpose has three grains of alloy in the ounce, and the coarsest twelve grains. In general, the alloy is six grains, or one-eightieth part. That which is called pale-gold contains three pennyweights of silver in the ounce. The alloy of leaf-gold is silver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold is delivered by the master to the workman, who, if extraordinary skilful, returns two thousand leaves, or eighty books of gold, together with one ounce and six pennyweights of waste cuttings. Hence one book weighs 4.8 grains; and as the leaves measure 3.3 inches in the side, the thickness of the leaf is one two hundred and eighty-two thousandth part of an inch.

The yellow metal called Dutch gold is fine brass. It is said to be made from copperplates, by cementation with calamine, without subsequent fusion. Its thickness, compared with that of leaf gold, proved as 19 to 4, and under equal surfaces it is considerably more than twice as heavy as the gold. *Nicholson's Journal*, vol. 1st.

GOLDONI (Charles), was born at Venice in the year 1707. He gave early indications of his humourous character, as well as his invincible propensity to those studies which have rendered his name immortal. His father, perceiving that the darling amusement of his son was dramatic performances, had a small theatre erected in his own house, in which Goldoni, while yet an infant, amused himself with three or four of his companions, by acting comedies. Before he was sent to school, his genius prompted him to become an author. In the seventh and eighth years of his age, ere he had scarcely learned to read correctly, all his time was devoted to the perusing comic writers, among whom was *Cicognini*, a Florentine, little known in the dramatic commonwealth. After having well studied these, he ventured to sketch out the plan of a comedy, which needed more than one eye-witness of the greatest probity to verify its being the production of a child.

After having finished his grammatical studies at Venice, and his rhetorical studies at the Jesuit's college in Perugia, he was sent to a boarding-school at Rimini to study philosophy. The impulse of nature, however, superseded with him the study of Aristotle's works, so much in vogue in those times. He frequented the theatres with uncommon curiosity; and passing gradually

gradually from the pit to the ftage, entered into a familiar acquaintance with the actors. When the feafon of comic performances was over, and the actors were to remove to Chiozza, young Goldoni made his efcape in their company. This was the firft fault he committed, which, according to his own confeffion, drew a great many others after it. His father had intended him to be a phyfician, like himfelf: the young man, however, was wholly averfe to the ftudy. He propofed afterwards to make him an advocate, and fent him to be a practitioner in Modena. An horrid ceremony of ecclefiaftical jurifdiction, at which he was prefent, infpired him with a melancholy turn, and he determined to become a capuchin.

His father, perceiving the whimfical, inconftant humour of his fon, feigned to fecond this propofal, and promifed to go and prefent him to the guardian of the capuchins in Venice, in the hope that, after fome ftay in that extenfive and merry city, his melancholy fit would ceafe. The fcheme fucceeded; for the young man, indulging in all the fafhionable diffipation of the place, was cured of his foolifh refolution. It was however neceffary for him to be fettled in fome employment; and he was prevailed upon by his mother, after the death of his father, to exercife the profeffion of a lawyer in Venice. By a fudden reverfe of fortune he was compelled to quit at once both the bar and Venice. He then went to Milan, where he was employed by the refident of Venice in the capacity of fecretary; where becoming acquainted with the manager of the theatre, he wrote a farce, entitled *Il Gondoliere Veneziano*, the Venetian Gondolier; which was the firft comic production of his that was performed and printed. Some time after, Goldoni broke with the Venetian refident, and removed to Verona.

There was in this place, at that time, the company of comedians of the theatre of St Samuel of Venice, and among them the famous actor *Cofali*, an old acquaintance of Goldoni, who introduced him to the manager. He began therefore to work for the theatre, and became infenfibly united to the company, for which he compofed feveral pieces. Having removed along with them to Genoa, he was for the firft time feized with an ardent paffion for a lady, who foon afterwards became his wife. He returned with the company to Venice, where he difplayed, for the firft time, the powers of his genius, and executed his plan of reforming the Italian ftage. He wrote the *Momolo*, *Courtifan*, the *Squanderer*, and other pieces, which obtained univerfal admiration.

Feeling a ftrong inclination to refide fome time in Tufcany, he repaired to Florence and Pifa, where he wrote *The Footman of Two Mafters*, and *The Son of Harlequin loft and found again*. He returned to Venice, and fet about executing more and more his favourite fcheme of reform. He was now attached to the theatre of St Angelo, and employed himfelf in writing both for the company and for his own purpofes. The conftant toils he underwent in thefe engagements impaired his health. He wrote, in the courfe of twelve months, fixteen new comedies, befides forty-two pieces for the theatre; among thefe many are confidered as the beft of his productions. The firft edition of his works was publifhed in 1753, in 10 vols. 8vo. As he wrote afterwards a great number of new pieces for the theatre of St Luca, a feparate edition of thefe was publifhed, under the title of *The New Comic Theatre*: among thefe was the *Terence*, called by the author his *favourite*, and judged to be the mafter-piece of his works. He made another journey to Parma, on the invitation of Duke Philip, and from thence he paffed to Rome. He had compofed 59 other pieces fo late as the year 1761, five of which were defigned for the particular ufe of Marque Albergati Capacelli, and confequently adapted to the theatre of a private company. Here ends the literary life of Goldoni in Italy.

Through the channel of the French Ambaffador in Venice, he had received a letter from Mr Zenuzzi, the firft actor in the Italian theatre at Paris, containing a propofal for an engagement of two years in that city. He accordingly repaired to Paris, where he found a felect and numerous company of excellent performers in the Italian theatre. They were, however, chargeable with the fame faults which he had corrected in Italy; and the French fupported, and even applauded in the Italians, what they would have reprobated on their own ftage. Goldoni wifhed to extend even to that country his plan of reformation, without confidering the extreme difficulty of the undertaking. Scurrilities and jefts, which are ever accompanied by actions, geftures, and motions, are the fame in all countries, and almoft perfectly underftood even in a foreign tongue: while the beauties of fentiment and dialogue. and other things which lead to the underftanding of characters and intrigues, require a familiar acquaintance with the tongue of the writer.

The firft attempt of Goldoni towards his wifhed-for reform, was the piece called *The Father for Love*; and its bad fuccefs was a fufficient warning to him to defift from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general tafte, and publifhed twenty-four comedies; among which *The Love of Zelinda and Lindor* is reputed the beft.

The term of two years being expired, Goldoni was preparing to return to Italy, when a lady, reader to the dauphinefs, mother to the late king, introduced him at court, in the capacity of Italian mafter to the princeffes, aunts to the king. He did not live in the court, but reforted there at each fummons, in a poftchaife fent to him for the purpofe. Thefe journeys were the caufe of a diforder in the eyes, which afflicted him the reft of his life; for being accuftomed to read while in the chaife, he loft his fight on a fudden, and in fpite of the moft potent remedies, he could never afterwards recover it entirely. For about fix months lodgings were provided him in the chateau of Verfailles. The death, however, of the dauphin, changed the face of affairs. Goldoni loft his lodgings, and only, at the end of three years, received a bounty of 100 louis in a gold box, and the grant of a penfion of four thoufand livres a-year. This fettlement would not have been fufficient for him, if he had not gained, by other means, farther fums. He wrote now and then comedies for the theatres of Italy and Portugal; and, during thefe occupations, was defirous to fhew to the French that he merited a high rank among their dramatic writers. For this purpofe, he neglected nothing which could be of ufe to render himfelf mafter of the French language.

He

Goldoni, Good Hope. He heard, spoke, and conversed so much in it, that, in his 62d year, he ventured to write a comedy in French, and to have it represented in the court theatre, on the occasion of the marriage of the king.

This piece was the *Bourru Bienfaisant*; and it met with so great success, that the author received a bounty of 150 louis from the king, another gratification from the performers, and considerable sums from the booksellers who published it. He published, soon after, another comedy in French, called *L'Avare Fastueux*. After the death of Louis XV. Goldoni was appointed Italian teacher to the Princess Clotilde, the present princess of Piedmont; and after her marriage he attended the late unfortunate Princess Elizabeth in the same capacity.

The approach of old age obliged him to quit Versailles, and to live in Paris, the air of which, less sharp, was better adapted to his constitution. The last work of Goldoni was *The Volponi*, written after his retirement from court; from which time he bade a lasting adieu to writing. Unfortunately for him, he lived to see his pensions cut off at the revolution, like others, and he spent his last days in poverty and distress. He died in 1792, at a crisis when, according to the expression of a deputy in the Convention, the French nation was ready to repay him every debt of gratitude.

Goldoni is on a par with the greatest comic poets of modern times, with regard to dramatic talents, and is thought superior to them all with regard to the fertility of his genius. His works were printed at Leghorn in 1788—91, in 31 vols. 8vo. He has been generally called the Moliere of Italy; and Voltaire, in one of his letters to Marquis Albergati, styles him *The Painter of Nature*. Goldoni is one of those authors whose writings will be relished in the most remote countries, and by the latest posterity.

GOOD-HOPE, or Cape of Good Hope, was taken by the British on 17th August 1796 with very little difficulty. At this we need not be much surprised, if to the discontent which must have prevailed among the planters and townsmen with the new order of things, be added the manners of the people. M. Vaillant, who was at the Cape during the last war, when the garrison expected to be every day attacked by a British squadron, and when the people were not absolutely disgusted with their own government, represents them, however, as rendered so completely frivolous by imitating the manners of their French allies, that, though the place was strongly fortified, it could hardly be expected to hold out long against a vigorous and well conducted siege.

"The females of the Cape (says he), when I saw them for the first time, had really excited my astonishment by their dress and their elegance; but I admired in them, above all, that modesty and reserve peculiar to the Dutch manners, which nothing as yet had corrupted.

"In the course of six months, a great change had taken place. It was no longer the French modes that they copied; it was a caricature of the French. Plumes, feathers, ribbons, and tawdry ornaments heaped together, without taste, on every head, gave to the prettiest figures a grotesque air, which often provoked a smile when they appeared. This mania had extended to the neighbouring plantations, where the women could scarcely be known. A mode of dress entirely new was everywhere introduced; but so fantastical, that it would have been difficult to determine from what country it had been imported."

Good Hope. At that time a French and a Swiss regiment were in the garrison; and though the town was occupied only with warlike preparations, and though an attack from the British fleet was every moment expected, the French officers had already introduced a taste for pleasure. Employed in the morning at their exercise, the French soldiers in the evening acted plays. A part of the barracks was transformed into a theatre; and as women capable of performing female characters could not be found in the town, they assigned these parts to some of their comrades, whose youth, delicate features, and freshness of complexion, seemed best calculated to favour the deception. These heroines, of a new kind, heightened the curiosity of the spectators, and rendered the entertainment still more lively and interesting.

To add to the general pleasure, ladies of the first rank considered it as incumbent on them to lend to the military actors and actresses, their laces, jewels, rich dresses, and most valuable ornaments. But some of them had cause to repent of their condescension; for it happened more than once that the Countess of Almaviva having left in pledge at the suttling-house her borrowed decorations, the owner, to recover them, was obliged to discharge not only the bill due for brandy and tobacco, but all the other debts of the heroine.

During the intoxication and giddiness occasioned by these amusements, Love also did not fail to act his part; and certain little intrigues were, from time to time, brought to light, which gave employment to the tongue of scandal, and introduced unhappiness into families. Hymen, it is true, amidst these adventures, sometimes intervened to repair the follies of his brother; and many marriages, which restored every thing to order, were the result of his negotiations; but the complaints, though stifled, did not less exist. The watchfulness of the mother was alert. The husband, by so much the more secretly irritated as he saw himself obliged to conceal his jealousy, cursed in his heart both actors and theatre; while the matronly part of the community, less on the reserve, declaimed with bitterness against the licentiousness that prevailed, which they wholly imputed to this mode of theatrical entertainment. At last, to the great mortification of the young, but to the high satisfaction of the old women and husbands, the theatre was on a sudden shut up. The cause that affected this was altogether foreign to the complaints that were made, and of a nature that it was impossible to foresee. Two of the French actors, who, it must be remembered, were officers in the army, thought proper to imitate the paper money of the company, and to put their forged notes in circulation. The forgery was detected, and traced to its authors; the two theatrical heroes were banished from the Cape; and the company, ashamed of the adventure, dared neither seek others to supply the vacant places, nor resume their stage entertainments.

Intoxicating as were these pleasures, government meanwhile had not been inattentive to the danger which threatened the colony. As they daily expected

to

Good Hope

to be attacked by the British fleet, they had increased the means of defence, and ordered different works and new fortifications to be constructed.

At first, the business was carried on with activity and ardour; because the inhabitants, instigated by their private interest, which was then considered as involved with that of the public, had voluntarily offered their services, and mingled with the workmen. Young and old, soldiers and magistrates, sailors and planters, all solicited the honour of co-operating for the general good and common safety. To behold this heterogeneous multitude—some loaded with pick-axes, and some with spades, or other similar implements—marching out in the morning from the town, and proceeding in high spirits to the new fortifications, was a sight truly admirable.

But this patriotic fervour was of no long continuance. Under pretence of sparing their strength, and that they might not weary themselves to no purpose, they soon caused their slaves to follow them with the tools and instruments. In a little time they contented themselves with sending their slaves only; and at last these substitutes themselves, in imitation of their masters, or perhaps by their secret orders, gave over going also. Their enthusiasm, in short, from the first moment of its breaking out till the period when it was thus entirely cooled, had been the affair of something less than a fortnight.

This taste for frivolity which, almost twenty years ago, was introduced among the Dutch in Cape-town by their good friends the French, spread rapidly thro' the planters, who are thus described by M. Vaillant, who certainly had the best opportunities of knowing them.

The planters of the Cape may be divided into three classes; those who reside in the vicinity of the Cape, within a distance of five or six leagues; those who live farther off in the interior parts of the colony; and lastly, those who, more distant still, are found at the extremity of the frontiers among the Hottentots.

The first, who are opulent proprietors, and have handsome country houses, may be likened to what was formerly called in France *petits seigneurs terriers*, and differ extremely from the other planters in ease and luxury, and particularly in their manners, which are haughty and disdainful. Such is the result of wealth. The second, simple, kind, hospitable, are cultivators, who live upon the fruits of their labour. Here we have an example of the good effects of mediocrity. The last, poor enough, yet too indolent to derive subsistence from the soil, have no other resource than the produce of some cattle, which they feed as they can. Like the Beduin Arabs, they think much of the trouble of driving them from canton to canton, and from one pasturage to another. This wandering life prevents them from building any settled habitations. When their flocks oblige them to sojourn for a while in the same place, they construct, in haste, a rude kind of hut, which they cover with matts, after the manner of the Hottentots, whose customs they have adopted, and from whom they in no respect differ, but in their complexion and features. And here the evil is, that there is no precise situation in social life to which these miserable beings belong.

These sluggish tribes are held in horror by their industrious neighbours, who dread their approach, and remove as far from them as they can; because, having no property of their own, they steal without scruple that of others, and, when in want of pasturage for their cattle, conduct them secretly to the first cultivated piece of ground that comes in their way. They flatter themselves they shall not be discovered, and they remain till every thing is devoured. If detected in their thefts, squabbles and contentions ensue, and afterwards a suit at law, in which recourse is had to the magistrate, and which commonly terminates in making three men enemies, the robber, the person robbed, and the judge.

Nothing can be so mean and cringing as the conduct of the first description of planters, when they have any thing to transact with the principal officers of the company, who may have some influence over their lot; and nothing so absurdly vain and so superlatively insolent as their behaviour to persons from whom they have nothing to hope and nothing to fear. Proud of their wealth, spoiled by residing near a town, from whence they have imbibed only a luxury that has corrupted, and vices that have degraded them, it is particularly towards strangers that they exercise their surly and pitiful arrogance. Though neighbours to the planters who inhabit the interior of the country, you must not suppose they regard them as brethren; on the contrary, in the true spirit of contempt, they have given them the name of Rauw-boer, a word answering to the lowest description of clown. Accordingly, when these honest cultivators come to the town upon any kind of business, they never stop by the way at the houses of the gentry of whom we are speaking; they know too well the insulting manner in which they would be received. One might suppose them to be two inimical nations always at war, and of whom some individuals only met at distant intervals, upon business that related to their mutual interests.

What is the more disgusting in the insolence of these Africans is, that the majority of them are descended from that corrupt race of men, taken from prisons and hospitals, whom the Dutch company, desirous of forming a settlement at the Cape, sent thither to begin, at their risk and pearl, the population of the country. This shameful emigration, of which the period is not so remote but that many circumstances of it are remembered, ought to render particularly modest those who are in the most distant manner related to it. On the contrary, it is this very idea that most contributes to their arrogance; as if they flattered themselves that, under the guise of supercilious manners, they could hide the abjectness of their origin. If a stranger arrives at the Cape with the design of remaining and settling there, they conceive him to be driven from his country by the same wretched circumstances which formerly banished their fathers, and they treat him with the most sovereign contempt.

This melancholy failing is the more to be lamented as the contagion has spread through almost every residence about the Cape, which is in reality a very charming canton. Embellished by cultivation, by its numerous vineyards and pleasant country houses, it everywhere exhibits so varied and delicious a prospect, that, were it occupied by other inhabitants, it would excite no sensations but those of pleasure.

As

Good Hope

As we advance into the country, the planters are a sort of farmers; and constitute, by their manners, customs, and occupations, a class by themselves, perfectly distinct from what we have been describing. Situated farther from the Cape, and, of consequence, not having the same opportunities for disposing of their commodities, they are less rich than the first. We see among them none of those agreeable country houses, which, placed at different distances from the town, embellish the country as we pass, and afford such charming prospects. Their habitation, which is about the size of a large coach-house, is covered with thatch, and divided into three rooms by means of two partitions, which reach only to a certain height. The middle apartment, in which is the entrance to the house, serves at once both as a parlour and eating-room. It is there that the family reside during the day, and that they receive their tea and other visitors. Of the two other rooms, one forms a chamber for the male children, and the other for the females, with the father and mother. At the back of the middle apartment is a farther room serving for a kitchen. The rest of the building consists of barns and stables.

Such is the distribution which is generally followed in the interior plantations of the colony; but nearer to the frontiers, where there does not prevail the same ease of circumstances, the habitations are much less commodious. They are merely a barn, consisting of a single room, without any division, in which the whole family live together, without separating either day or night. They sleep upon sheep skins, which serve them also for covering.

The dress of these planters is simple and rustic. That of the men consists of a check shirt, a waistcoat with sleeves, a large pair of trowsers, and a hat half unlooped. The women have a petticoat, a jacket fitted to their shape, and a little round bonnet of muslin. Unless upon extraordinary occasions, neither sex wear stockings. During a part of the year, the women even walk with their feet quite naked. The occupations of the men require that theirs should have some covering; and this covering they make from a piece of the hide of an ox, applied and shaped to the foot soon after the animal is killed, and while the hide is yet fresh. These sandals are the only article of their dress which they make themselves; the rest is the business of the women, who cut out and prepare their whole wardrobe. Though the equipment we have mentioned constitute the every-day dress of the planter, he has, however, a coat of handsome blue cloth, which he wears upon days of gala and ceremony. He has then also stockings and shoes, and is dressed exactly like an European. But this finery never makes its appearance but when he goes to the Cape; and then, indeed, is not put on till he arrives at the entrance of the town.

It is commonly in these journeys that they purchase such things as they may want to refit their wardrobe. There is, at the Cape, as well as in Paris and London, a species of old-clothes-men, who deal in commodities of this sort; and who, from their enormous profits, and the extortion they practise, they have obtained the name of *Capse Smouse*, or Cape Jews. These traffickers contrive at all times to sell their goods at a dear rate; but they vary their price in proportion as their stock is great or small: of course they bear no fixed price; and the planter who comes from the desert, and who can understand but little of this fluctuation, is sure to be duped.

Good Hope

On the other hand, the regular shopkeeper, who knows the probity of these farmers, and how punctual they are in the payment of their debts, exerts every effort to prevail on them to open an account with him. He tempts them by the pretended cheap price and excellent quality of his stuffs, and offers to remit the payment till their next journey in the following year. It is seldom that these people, simple and unexperienced as they are, perceive the craft that is presented to them under this guise of kindness and civility. If they suffer themselves to be prevailed upon, they are shackled for life. Upon their return, there are new purchases to be made upon the same conditions; and thus, year after year, always in debt, always buying without prompt payment, they become the prey of an extortioner, who raises to himself a fortune out of their weakness.

It is true, these buyers, after being thus duped at the Cape, commonly return home only to make dupes of others. The cunning that has been employed to deceive them, they employ in their turn to tempt the Hottentots who are in their service. The remnants of stuff, or the frippery garments which they bring back, are sold to these unfortunate servants with so great a profit, that commonly the wages of a year are inadequate to the payment; and they find themselves, like their masters, in debt for the year that is to come. In the end, therefore, it is the poor Hottentot that pays for the extortion at the Cape.

Custom has rendered the planters insensible to the want of fruit and pulse, though the soil is admirably adapted to the cultivation of both. The facility with which they rear their cattle makes up for this privation, as their flocks afford them plenty of provision. The chief food is mutton; and their tables are loaded with such profusion as to disgust one at the sight.

From this mode of living, cattle are in the colonies, as in other places, not only a useful object, but an article of the first necessity. The planter undertakes himself the care of watching over his flocks. Every evening, when they return from the field, he stands at his door, with a stick in his hand, and counts them over one by one, in order to be sure that none of them are missing.

People who have no other employment than a little agriculture, and the superintendance of a flock, must have long intervals of idleness. It is thus with the planters, particularly those who live in the interior parts of the country, and who being unable, on account of their distance from the Cape, to dispose of their corn, never raise more than is sufficient for their own consumption. From the profound inaction in which they live, one would suppose their supreme felicity to consist in doing nothing. They sometimes, however, visit each other; and upon these occasions the day is spent in smoking, and drinking tea, and in telling, or listening to tales of romance, that are equal neither in merit nor morality to the story of Blue-beard.

As every man always carries with him, wherever he goes, both a pipe, and a tobacco-pouch made of the skin of the sea-calf, he is sure in these visits to have one source of amusement. When any one of the company

is

is desirous of lighting his pipe, he takes out his pouch, and, having filled, passes it to the rest. This is a civility that is never omitted. However numerous may be the party, every body smokes: the consequence of which is a cloud, that, rising at first to the upper part of the room, increases, by degrees, till it fills the whole house, and becomes at last so thick that it is impossible for the smokers to see one another.

When a stranger travelling through the country is received by the master of a house, he instantly becomes a member of the family. Accustomed to a domestic life, the planters delight in the ties of affinity, and consider in the light of a relative every person whom they love. Upon entering a house, the form of salutation is, to shake hands first with the master, and then with every male person in the company arrived at years of maturity. If there happens to be any one whom we do not like, the hand is refused to him; and this refusal, of so common a testimony of friendship, is looked upon as a formal declaration that the visitor considers him as his enemy. It is not the same with the females in the company. They are all embraced one after another; and to make an exception would be a signal affront. Old or young, all must be kissed. It is a benefice with the duties attached to it.

At whatever time of the day you enter the house of a planter, you are sure to find the kettle and tea-things upon the table. This practice is universal. The inhabitants never drink pure water. If a stranger presents himself, it is tea they offer him for refreshment. This is their common liquor in the interval of meals, and in one season of the year, when it often happens that they have neither beer nor wine, is their only beverage.

If a stranger arrives at dinner-time before the cloth is taken away, he shakes hands, embraces, and immediately seats himself at the table. If he wishes to pass the night, he stays without ceremony, smokes, drinks tea, asks the news, gives them all he knows in his turn; and the next day, the kissing and shaking hands being repeated, he goes on his way, to perform elsewhere the same ceremony. To offer money on these occasions would be regarded as an insult.

These particulars of a people, whose condition it is to be hoped that the generosity of the British character, and the mildness of the British government, will
1799. gradually meliorate, cannot but be acceptable to many of our readers. We shall, therefore, make no apology for the length of this article.

GOMASHTEH, in the language of Bengal, one cent.

GONIOMETRY, a method of measuring angles, so called by M. de Lagny, who gave several papers on this method in the Memoirs of the Royal Acad. anno 1724, 1725, 1729. M. de Lagny's method of goniometry consists in measuring the angles with a pair of compasses, and that without any scale whatever, except an undivided semicircle. Thus, having any angle drawn upon paper to be measured, produce one of the sides of the angle backwards behind the angular point; then with a pair of fine compasses describe a pretty large semicircle from the angular point as a centre, cutting the sides of the proposed angle, which will intercept a part of the semicircle. Take then this intercepted part very exactly between the points of the compasses, and turn them successively over upon the arc of the semicircle, to find how often it is contained in it, after which there is commonly some remainder: then take this remainder in the compasses, and, in like manner, find how often it is contained in the last of the integral parts of the first arc, with again some remainder: find, in like manner, how often this last remainder is contained in the former; and so on continually, till the remainder become too small to be taken and applied as a measure. By this means he obtains a series of quotients, or fractional parts, one of another, which being properly reduced into one fraction, give the ratio of the first arc to the semicircle, or of the proposed angle to two right angles, or 180 degrees, and consequently that angle itself in degrees and minutes.

We have given this account of goniometry from Dr Hutton, and frankly acknowledge that we had never thought of it till we perused his excellent Dictionary of Mathematics and Philosophy. To have omitted the method when pointed out to us would have been wrong; though we mistake much if mathematicians in general will not look upon it as a method of very little value.

GOTHIC ARCHITECTURE. See *Gothic ARCHITECTURE* in this *Suppl.* and ROOF, *Encycl.*

GOUVERNANTE, the Spanish name of a plant which the Indians of California use in decoction as a sudorific drink for the cure of the venerial disease. It is thus described in the third volume (English translation) of Perouse's Voyage round the World.

Calyx quadrified, egg-shaped, of the same size with the corolla; placed beneath the fruit, deciduous. Corolla polypetalous; petals four, small, entire, egg-shaped, fixed upon the receptacle. Stamina, eight, fixed to the receptacle, of the same length as the corolla: threads channelled, concave on the one side, and convex on the other; wings veiled, antheræ simple. Pistil, germ oblong, covered, with five angles, and five cells; seeds oblong; pericarpium covered with fine hairs.

This plant is a shrub of middle size; the branches are angular and knotty, and covered with an adhesive varnish; the lateral branches are alternate, and placed very near to each other: the leaves are small, petiolated, bilobed, opposite, smooth on the upper side, the under side indistinctly veined; the blossoms are axillary, sometimes terminating, pedunculated, solitary, but sometimes in pairs.

From this description, the gouvernante appears to be a new species of *daphne*.

GRAVIMETER, the name given by citizen Guyton (Morveau) to an instrument of glass, constructed in all respects on the principle of Nicholson's Hydrometer, described in the article HYDROSTATICS, n° 18. *Encycl.* It is therefore needless to give a description of this instrument here; as every artist in glass, who has seen Nicholson's hydrometer, or understands our description of it, may construct the gravimeter of Morveau; and every man who has made himself master of our article *SPECIFIC Gravity*, may apply the gravimeter to every purpose to which it is applicable. It may just be proper to observe, that Morveau, having at first loaded the small scale or bason G (Plate 240, fig. 9. *Encycl.*) with a bulb of glass containing a sufficient quantity of mercury, found it expedient afterwards to substitute in the place of this bulb a small mass of solid glass, brought to the proper form and weight by grinding. For a minute account of this instrument, if any of

Green.

of our readers can be supposed to require a minute account of it, we must refer to the third number of Nicholson's *Journal of Philosophy, Chemistry, and the Arts.*

GREEN, though one of the seven original or prismatic colours, is among dyers a compound of blue and yellow. Of the European methods of dyeing green, and of the principles on which these methods are founded, a sufficient account will be found in the *Encyclopædia*, under the articles *Colour-Making* and Dyeing, and, in this *Supplement*, under *Animal and Vegetable Substances*; but it may be worth while, in this place, to insert the method practised at Astracan, in giving to cotton yarn that beautiful green colour for which the oriental cotton is so justly admired.

The principal dye is the blue, which is employed both for cotton and silk. To prepare it, the indigo or blue dye-stuff is finely pounded, and dissolved in water by a gentle heat in large earthen jars, seven of which stand in brick-work over the fire-place, at the distance of about an ell and a half from each other. About two pounds are put into each vessel. Five pounds of soda finely pounded, together with two pounds of pure lime and one pound of clarified honey, are added to each; when these ingredients have been well mixed, the fire is strengthened; and when the whole begins to boil, the dye is stirred carefully round in all the vessels, that every thing may be completely dissolved and mixed. After the first boiling the fire is slackened, and the dye is suffered to stand over a gentle heat, while it is continually stirred round: this is continued even after the furnace is cooled, till a thick scum arises in the neck of each jar, and soon after disappears. The dye is then allowed to stand two days, until the whole is incorporated, and the dye thickens.

The dyers assert, that with this dye they can produce three shades of blue, and that, as the dyeing particles gradually diminish, they can dye also a green colour by the addition of yellow.

When a manufacturer gives cotton yarn to a blue dyer, he first boils it at home in a ley of soda (*kalakar*), then dries it, washes it, and dries it again. The blue dyer lays this yarn to steep in pure water, presses out the superfluous water with the hands, and then immediately begins to dip it in the blue jar, often wringing it till it is completely penetrated by the dye. This first tint is generally given to yarn in such jars as have had their colouring matter partly exhausted. It is then dried, rinsed, and again dried; after which, it is put into the fresh blue dye, properly saturated; and, after the colour has been sufficiently heightened, it is dried for the last time.

For a yellow dye, the dyers of Astracan employ partly saw-wort, brought from Russia, and partly the leaves of the *kislar belge* or *sumach*. The process is as follows: The yarn is first boiled for an hour in a strong ley of soda; it is then dried, afterwards rinsed and laid wet to steep for twelve hours in a solution of alum with warm water. When it has been dried in the air, it is laid to soak several times in troughs with the dye which has been boiled thick in kettles from the above-mentioned plants, till it has acquired the wished-for colour, care being taken to dry it each time it is soaked. It is then rinsed in running water, and dried for the last time.

Gregory.

On this yellow colour a green is often dyed. After the yarn has been dyed yellow, it is given out to the blue dyer, who immediately dips it in the blue jars, the dye of which has been already partly exhausted; and if the green colour is not then sufficiently high, the operation is repeated, the yarn being dried each time. See *Neue Nordische Beytrage*, by Professor Pallas; or *Philosophical Magazine*, n° 2.

GREGORY (David), was a son of the Rev. John Gregory, minister of Drumoak, in the county of Aberdeen, and elder brother to Mr James Gregory, the inventor of the most common reflecting telescope. He was born about the year 1627 or 1628; and though he possessed all the genius of the other branches of his family, he was educated by his father for trade, and served an apprenticeship to a mercantile house in Holland. Having a stronger passion, however, for knowledge than for money, he abandoned trade in 1655; and returning to his own country, he succeeded, upon the death of an elder brother, to the estate of Kinardie, situated about forty miles north from Aberdeen, where he lived many years, and where thirty-two children were born to him by two wives. Of these, three sons made a conspicuous figure in the republic of letters, being all professors of mathematics at the same time in three of the British universities, viz. David at Oxford, James at Edinburgh, and Charles at St Andrews.

Mr Gregory, the subject of this memoir, while he lived at Kinardie, was a jest among the neighbouring gentlemen for his ignorance of what was doing about his own farm, but an oracle in matters of learning and philosophy, and particularly in medicine, which he had studied for his amusement, and began to practise among his poor neighbours. He acquired such a reputation in that science, that he was employed by the nobility and gentlemen of that county, but took no fees. His hours of study were singular. Being much occupied through the day with those who applied to him as a physician, he went early to bed, rose about two or three in the morning, and, after applying to his studies for some hours, went to bed again and slept an hour or two before breakfast.

He was the first man in that country who had a barometer; and having paid great attention to the changes in it, and the corresponding changes in the weather, he was once in danger of being tried by the presbytery for witchcraft or conjuration. A deputation of that body waited upon him to enquire into the ground of certain reports that had come to their ears; but he satisfied them so far as to prevent the prosecution of a man known to be so extensively useful by his knowledge of medicine.

About the beginning of this century he removed with his family to Aberdeen, and in the time of Queen Anne's war employed his thoughts upon an improvement in artillery, in order to make the shot of great guns more destructive to the enemy, and executed a model of the engine he had conceived. Dr Reid informs us, that he conversed with a clock-maker in Aberdeen who had been employed in making this model; but having made many different pieces by direction without knowing their intention, or how they were to be put together, he could give no account of the whole. After making some experiments with this model,

del, which satisfied him, the old gentleman was so sanguine in the hope of being useful to the allies in the war against France, that he set about preparing a field equipage with a view to make a campaign in Flanders, and in the mean time sent his model to his son the Savilian professor, that he might have his and Sir Isaac Newton's opinion of it. His son shewed it to Newton, without letting him know that his own father was the inventor. Sir Isaac was much displeased with it, saying, that if it had tended as much to the preservation of mankind as to their destruction, the inventor would have deserved a great reward; but as it was contrived solely for destruction, and would soon be known by the enemy, he rather deserved to be punished, and urged the professor very strongly to destroy it, and if possible to suppress the invention. It is probable the professor followed this advice. He died soon after, and the model was never found.

If this be a just account of the matter, and Dr Reid's veracity is unquestionable, we cannot help thinking that Newton's usual sagacity had, on that occasion, forsaken him. Were the implements of war much more destructive than they are, it by no means follows that more men would be killed in battle than at present. Muskets and cannons are surely more destructive weapons than javelines and bows and arrows; and yet it is a well known fact, that since the invention of gunpowder battles are not half so bloody as they were before that period. The opposite armies now seldom come to close quarters, a few rounds of musketry and artillery commonly decide the fate of the day; and had Mr Gregory's improvement been carried into effect, still fewer rounds would have decided it than at present, and the carnage would consequently have been less.

When the rebellion broke out in 1715, the old gentleman went a second time to Holland, and returned when it was over to Aberdeen, where he died about 1720, aged 93, leaving behind him a history of his own time and country, which was never published.

Gregory (Dr David). In addition to the account given in the *Encyclopædia* of this eminent mathematician, it may be proper to add, that he was a most intimate and confidential friend of Sir Isaac Newton, and was intrusted with a manuscript copy of the *Principia*, for the purpose of making observations on it. Of these Newton availed himself in the second edition, they having come too late for his first publication, which was exceedingly hurried by Dr Halley, from fears that Newton's backwardness would not let it appear at all. There is a complete copy of these observations preserved in the library of the university of Edinburgh, presented to it by Dr James Gregory, the present professor of the practice of medicine. These contain many sublime mathematical discussions, many valuable commentaries on the *Principia*, and many interesting anecdotes. There are in it some paragraphs in the hand-writing of Huyghens relative to his Theory of Light. It would appear that this work of confidential friendship was the foundation of that system of physical and mathematical astronomy which has raised Dr Gregory to great eminence in the republic of letters.

GRINDING, in Cutlery, a well-known operation, by which edge-tools are sharpened. As commonly practised, the grinding of tools is attended with great inconveniency, arising from the production or developement of heat by friction. The fact of sparks flying from a dry grindstone when a piece of iron or steel is applied to its surface during the rotation, has been seen by every one. The heat produced during this process is such that the steel very soon becomes ignited, and hard tools are very frequently softened and spoiled, for want of care during the grinding. When a cylindrical stone is partly immersed in a trough of water, the rotation must be moderate and the work slow, otherwise the water would soon be thrown off by the centrifugal force; and when this fluid is applied by a cock from above, the quantity is too small to preserve the requisite low temperature. It is even found, that the point of a hard tool, ground under a considerable mass of water, will be softened, if it be not held so as to meet the stream; sparks being frequently afforded even under the water.

To find a remedy for this, Mr Nicholson was led, by some accounts which he received of German cutlery, to make the following experiment. He procured a Newcastle grindstone of a fine grit and ten inches in diameter, and also a block of mahogany to be used with emery on its face. Both the stone and the wooden block were mounted on an axis, to be occasionally applied between the centres of a strong lathe. In this situation both were turned truly cylindrical, and of the same diameter. The face of the wood was grooved obliquely in opposite directions, to afford a lodgement for the emery. The face of the stone was left smooth, and there was a trough of proper size applied beneath the stone to hold water. The grindstone was then used with water, and the wooden cylinder was faced with emery and oil. The instrument ground was a file, out of which it was proposed to grind all the teeth. The rotation was produced by the mechanism of the lathe; the velocity being such as to turn the grinding apparatus about five revolutions in a second. The stone operated but slowly, and the water from the trough was soon exhausted, with inconvenience to the workman, who could scarcely be defended from it but by slackening the velocity. The emery cylinder cut rather faster. But notwithstanding the friction was made to operate successively and by quick changes on the whole surface of the file, it soon became too much heated to be held with any convenience; and when a cloth was used to defend the hand, the work not only became awkward, but the heat increased to such a degree that the oil began to be decomposed, and emitted an empyreumatic smell. The stone was then suffered to dry, and the file tried upon its face. It almost immediately became blue, and soon afterwards red-hot. Both the cylinders were then covered with tallow, by applying the end of a candle to each while revolving, and emery was sprinkled upon the cylinder of wood. The same tool was then applied to the grindstone in rapid motion. At the first instant the friction was scarcely perceptible; but very speedily afterwards the zone of tallow pressed by the tool became fused, and the stone cut very fast. The tool was scarcely at all heated for a long time; and when it began to feel warm, its temperature was immediately lowered by removing

Grose.

moving it to a new zone of the cylinder. The same effect took place when the experiment was repeated with the wooden cylinder.

It is not difficult to explain this by the modern doctrine of heat. When oil was used upon the wooden cylinder, the heat developed by the friction was employed in raising the temperature of the tool and of the fluid oil: but when tallow was substituted instead of the oil, the greatest part of the heat was employed in fusing this consistent body. From the increased capacity of the tallow, when melted, this heat was absorbed, and became latent, instead of being employed to raise the temperature: and whenever, by continuing the process, the tallow already melted began to grow hot, together with the tool, it was easy to reduce the temperature again by employing the heat on another zone of consistent tallow. He used these two cylinders, with much satisfaction, in a considerable quantity of work.

This promises to be a valuable discovery; and the public is obliged to the ingenious author of the Philosophical Journal for being at so much pains on this, as well as on other occasions, to render his science subservient to the useful arts.

GROSE (Francis, Esq; F.A.S.) was born, we believe, in 1731. He was the son of Mr Francis Grose of Richmond, jeweller, who filled up the coronation crown of George II. and died 1769. By his father he was left an independent fortune, which he was not of a disposition to add to, or even to preserve. He early entered into the Surrey militia, of which he became adjutant and paymaster; but so much had dissipation taken possession of him, that in a situation which above all others required attention, he was so careless as to have for some time (as he used pleasantly to tell) only two books of accounts, viz. his right and left hand pockets. In the one he received, and from the other paid; and this too with a want of circumspection which may be readily supposed from such a mode of book-keeping. His loses on this occasion roused his latent talents. With a good classical education he united a fine taste for drawing; and encouraged by his friends, as well as prompted by his situation, he undertook the work from which he derived both profit and reputation; we mean, his Views of Antiquities in England and Wales, which he first began to publish in numbers in the year 1773, and finished in the year 1776. The next year he added two more volumes to his English Views, in which he included the islands of Guernsey and Jersey, which were completed in 1787. This work answered his most sanguine expectations; and, from the time he began it to the end of his life, he continued without intermission to publish various works (a list of which we subjoin), generally to the advantage of his literary reputation, and almost always to the benefit of his finances. His wit and good humour were the abundant source of satisfaction to himself, and entertainment to his friends. He visited almost every part of the kingdom, and was well received wherever he went. In the summer of 1789 he set out on a tour in Scotland; the result of which he began to communicate to the public in 1790 in numbers. Before he had concluded this work, he proceeded to Ireland, intending to furnish that kingdom with views and descriptions of her antiquities, in the same manner he had executed those of Great Britain; but soon after his arrival in Dublin, being at the house of Mr Horne there, he suddenly was seized at table with an apoplectic fit, on the 6th May 1791, and died immediately. He was interred in Dublin.

"His literary history (says a friend), respectable as it is, was exceeded by his good humour, conviviality, and friendship. Living much abroad, and in the best company at home, he had the easiest habits of adapting himself to all tempers; and, being a man of general knowledge, perpetually drew out some conversation that was either useful to himself or agreeable to the party. He could observe upon most things with precision and judgment; but his natural tendency was to humour, in which he excelled both by the selection of anecdotes and his manner of telling them: it may be said, too, that his figure rather assisted him, which was in fact the very title-page to a joke. He had neither the pride nor malignity of authorship: he felt the independency of his own talents, and was satisfied with them, without degrading others. His friendships were of the same cast; constant and sincere, overlooking some faults, and seeking out greater virtues. He had a good heart; and, abating those little indiscretions natural to most men, could do no wrong."

He married at Canterbury, and resided there some years, much beloved and respected for his wit and vivacity; "which (another friend observes), though he possessed in an extreme degree, was but little tinctured with the caustic spirit so prevalent among spirits of that class. His humour was of that nature which exhilarates and enlivens, without leaving behind it a sting; and though perhaps none possessed more than himself the faculty of "setting the table in a roar," it was never at the expence of virtue or good manners. Of him indeed may be said in the words of Shakespeare,

> ——— ——— a merrier man,
> Within the limits of becoming mirth,
> I never spent an hour's talk withal:
> His eye begets occasion for his wit;
> And every object that the one doth catch,
> The other turns to a mirth-moving jest.

"Of the most careless, open, and artless disposition, he was often (particularly in the early part of his life) the prey of the designing; and has more than once (it is believed) embarrassed himself by too implicit confidence in the probity of others. A tale of distress never failed to draw commiseration from his heart; and often has the tear been discovered gliding down that cheek which a moment before was flushed with jocularity."

He was father of Daniel Grose, Esq; captain of the royal regiment of artillery (who, after several campaigns in America, was appointed in 1790 deputy governor of the new settlement at Botany Bay), and some other children.

His works are as follow:

1. The Antiquities of England and Wales, 8 vols. 4to and 8vo. 2. The Antiquities of Scotland, 2 vols. 4to and 8vo. 3. The Antiquities of Ireland, 2 vols. 4to and 8vo. 4. A Treatise on ancient Armour and Weapons, 4to, 1785. 5. A Classical Dictionary of the Vulgar Tongue, 8vo, 1785. 6. Military Antiquities; being a History of the English Army from the

the Conqueſt to the preſent time, 2 vols 4to, 1786, 1788. 7. The Hiſtory of Dover Caſtle, by the Rev. William Danell, 4to, 1786. 8. A Provincial Gloſſary, with a Collection of local Proverbs and popular Superſtitions, 8vo, 1788. 9. Rules for drawing Caricatures, 8vo, 1788. 10. Supplement to the Treatiſe on Ancient Armour and Weapons, 4to, 1789. 11. A Guide to Health, Beauty, Honour, and Riches; being a collection of humorous Advertiſements, pointing out the Means to obtain thoſe bleſſings; with a ſuitable introductory Preface, 8vo. 12. The Olio; being a Collection of Eſſays in 8vo, 1793.

GUERITE, in Fortification, a centry-box; being a ſmall tower of wood, or ſtone, uſually placed on the point of a baſtion, or on the angles of the ſhoulder, to hold a centinel, who is to take care of the ditch, and watch againſt a ſurpriſe.

GUILLOTINE, a new term introduced into the languages of Europe by the mournful effects of fanaticiſm in the holy cauſe of liberty. Our readers are not ignorant that this is the name given by the National Aſſembly of France to the engine of decapitation, which thoſe uſurpers of the legiſlative authority decreed to be the ſole puniſhment of thoſe condemned to death for their crimes. This decree was iſſued on March 20th 1792.

We do not imagine that the world will derive much uſeful inſtruction from a minute deſcription of this terrible inſtrument of public juſtice; and therefore content ourſelves with giving two figures of it, ſufficiently expreſſive of its conſtruction. It is only the revival of an inſtrument uſed in former times. The earlieſt accounts that we have of it is, that it was uſed in the barony of Halyfax in Yorkſhire. It was alſo ſet up in Scotland; but we have no certain information that it has ever been uſed; and it is ſtill ſhewn as a ſort of curioſity by the name of the *Mayden*. See Maiden, *Encycl.*

Plate XXIX.

Eratoſthenes could not think of a better way of handing down his name to future ages than by burning the temple of Diana at Epheſus; Dr Guillotin, phyſician at Lyons, and member of the ſelf-named National Aſſembly of France, thought himſelf honoured by the decree which aſſociated his name with this inſtrument of popular vengeance. It was indeed propoſed by him as an inſtrument of mercy, in a ſtudied harangue, filled with that ſentimental ſlang of philanthropy, which coſts ſo little, promiſes ſo much, and has now corrupted all the languages of Europe. His invention is indeed one of the moſt expenſive ſpecimens of Gallic philanthropy, whoſe tender mercies are cruel; and was accordingly received with loud applauſes, both from the houſe and from the galleries. To proceed, however, with impoſing dignity, it was referred to the conſideration of a committee, with injunctions to aſk the opinion of able ſurgeons of its efficiency. Mr Louis, a celebrated ſurgeon of Paris, declared it well fitted for the taſk, in a long pedantic diſſertation; in which he takes occaſion to deliver, with academic coldneſs, a theory of the operation of cutting inſtruments; and ſays that he had examined the edge of the guillotine, and other ſuch inſtruments, with a microſcope, and had diſcovered that the fineſt edges were toothed like a ſaw. M. Guillotin, he ſaid, had therefore with great judgment made the axe of his engine of death with a ſloping edge, by which means *il gliſſoit d'une façon infinitment plus douce.* This diſſertation was ſo much to the taſte of the humane legiſlature, that they rewarded Mr Louis with 2000 livres, and publiſhed it in the Paris Journals. As to the inventor, he reaped all the benefit from it which he ſo kindly intended for the nation, by the trial of it on his own perſon, when he fell under the diſpleaſure of Robeſpierre.

We acknowledge, that in as far as this inſtrument leſſens the duration of the horrid conflict with the king of terrors, and probably diminiſhes the corporeal ſufferance, it may be called merciful (alas! the day!); but we queſtion much, whether the dreadful agitation of ſoul is not rather increaſed by the long train of preparatory operations. The hands of the convict are tied behind his back: he is then ſtretched along on his face on a ſtrong plank, and his preciſe poſition adjuſted to the inſtrument. When faſtened to the plank, it is puſhed forward into its place under the fatal edge, his neck adjuſted to the block, and a baſket placed juſt before his eyes (for the face of Louis XVI. was not covered) to receive his head. This muſt employ a good deal of time, and every moment is terrible.

The conſtruction has received many alterations and refinements; and has at laſt been made ſo compendious and portable, as to become part of the travelling equipage of a commiſſioner from the National Aſſembly, ſent on a provincial or ſpecial viſitation. Thus did the ſovereign people become terrible in majeſty. So ſenſible was the aſſembly of the advantages of this awful impreſſion, or ſo intoxicated with the enjoyment of irreſiſtible power, that they have thought their coins ornamented by this attribute of their ſupremacy: and as Jupiter is diſtinguiſhed by his thunderbolt, ſo the majeſty of the people is diſtinguiſhed by the no leſs fatal axe. We have ſeen a piece of ten ſous, ſtruck at Mentz in 1793, and iſſued as current money, at the very time that they were planting the tree of liberty in that illuminated city by the hands of Cuſtine and his troops. The device is the faſces and axe of ancient Rome, crowned with a red cap, and ſurrounded by a laurel wreath. The inſcription is, *Republique Françoiſe*, 1793, *an.* 2d. Fully impreſſed with the ſame ſentiments, Lequinio, the ſentimental novelliſt of France, whom Mercier compares with the tender, the heart-touching Sterne—Lequinio, now commiſſioner, ſent by the National Aſſembly to regenerate Normandy and Brittany, writes to his maſters, that "he is very ſucceſsful in converſions from ſuperſtition to ſound reaſon." He oppoſes to the Bible and the relicts of the ſaints the conſtitution and the guillotine. "And you would wonder (ſays he) at my ſucceſs—The wiſe (but they are few) give up their prejudices at once; but the multitude, the ſtupid worſhippers of *Notre Dame*, look at our lady the guillotine; are ſilent, becomes ſerious, and their doubts vaniſh;—they are converted. This is your *labarum—in hoc ſigno vinces.*"

GULA, Gueule, or Gola, in Architecture, a wavy member whoſe contour reſembles the letter S, commonly called an Ogee.

GUNPOWDER, as we have obſerved in the *Encyclopædia* under the word Gun, has been known in the eaſt, and particularly in China, from a period of very remote antiquity. No man, however, ſeems to have ſuſpected that the knowledge of it was conveyed from the eaſt into Europe; but all have agreed to allow the merits

merits of the invention both to friar Bacon and to Bartholomew Schwartz. This generally received opinion has been lately controverted by citizen Langles, who, in a memoir read in the French national institute, contends, that the knowledge of gunpowder was conveyed to us from the Arabs, on the return of the Crusaders to Europe. He assures us that the Arabs made use of it in 690 at the siege of Mecca; and he adds, that they derived it from the Indians, among whom it must have been known in the remotest ages, since their sacred books (the Vedam) forbid the use of it in war.

It is indeed extremely probable, that the composition of gunpowder was known in India at a very early period; for in whatever country nature forms nitre in the greatest plenty, there its deflagrating quality is most likely to be first observed; and a few experiments founded on that observation, will lead to the composition which produces such sudden and violent effects. "Nitre (says Sir George Staunton) is the natural and daily produce of China and India; and there accordingly the knowledge of gunpowder seems to be coeval with that of the most distant historic events. Among the Chinese, it has been applied at all times to useful purposes; such as blasting rocks, and removing great obstructions, and to those of amusement in making a vast variety of fire-works. It was also used as a defence by undermining the probable passage of the enemy, and blowing him up. But its force had not been directed through strong metallic tubes as it was by Europeans soon after they had discovered it. And though, in imitation of Europe, it has been introduced into the armies of the East, other modes of warfare are sometimes still preferred to it."

Of gunpowder manufactured by those who have manufactured it so long, it is desirable to know the composition and the qualities. It was therefore natural for the Hon. George Napier, when superintending the royal laboratory at Woolwich, and making experiments upon so necessary an implement of modern war, to procure some Chinese powder from Canton.

This he did; and analyzing two ounces of it, he found, after repeating the operation six times, that the mean result gave the following proportions *. Nitre 1 oz. 10 dwts. charcoal 6 dwts. sulphur 3 dwts. 14 grs. Here is a deficiency in weight of ten grains, which M. Napier supposes the consequence of some defect in his process; but as M. Baumé, a French chemist, made a variety of experiments to obtain a total separation of the sulphur from the charcoal of gunpowder, and was never able to effect it, one fourteenth part remaining united, three grains must be deducted from the charcoal and added to the sulphur to give the accurate proportion of the ingredients; which by turning to the article Gunpowder, *Encycl.* the reader will perceive differs somewhat from the proportion of the same ingredients in the gunpowder of Europe. This Chinese powder was usually large-grained, and not strong, but very durable. It had been made many years when our author got it; yet there was no visible symptom of decay, the grain being hard, well coloured, and though angular, it was even-sized, and in perfect preservation.

* *Transactions of the Royal Irish Academy.*

When we consider the operations in which gunpowder is employed, it is obvious that it must be an object of importance to ascertain its explosive force; and yet there is scarcely a subject concerning which the most approved writers have so much differed. Mr Robins, who has done more towards perfecting the art of gunnery than any other individual, states the explosive force of gunpowder to be 1000 times greater than the mean pressure of the atmosphere; while the celebrated Daniel Barnouilli determines it to be not less than 10,000 times this pressure. Such a difference of opinion led Count Rumford to pursue a course of experiments, of which some were published in the Transactions of the Royal Society for the year 1781, and the remainder in the Transactions of the same Society for 1797; with the view principally of determining the initial expansive force of gunpowder. By one of these experiments, it appeared, that calculating even on Mr Robins's own principles, the force of gunpowder, instead of being 1000 times, must at least be 1308 times greater than the mean pressure of the atmosphere. From this experiment, the Count thought himself warranted in concluding that the principles assumed by Mr Robins were erroneous, and that his mode of ascertaining the force of gunpowder could never satisfactorily determine it. Despairing of success in that way, he resolved to make an attempt for ascertaining this force by actual measurement; and after many unsuccessful experiments, he was at length led to conclude, that this force was at least 50,000 times greater than the mean pressure of the atmosphere.

Mr Robins apprehends that the force of fired gunpowder consists in the action of a permanently elastic fluid, similar in many respects to common atmospherical air; and this opinion has been very generally received: but Count Rumford thinks, that though the permanently elastic fluids, generated in the combustion of gunpowder, assist in producing the effects which result from its explosion, its enormous force, allowing it to be 50,000 times greater than the mean pressure of the atmosphere, cannot be explained, without supposing that it arises principally from the elasticity of the aqueous vapour generated from the powder in its combustion.

"The brilliant discoveries of modern chemists (says he) have taught us, that both the constituent parts of which water is composed, and even water itself, exist in the materials which are combined to make gunpowder; and there is much reason to believe that water is actually formed, as well as disengaged, in its combustion. M. Lavoisier, I know, imagined that the force of fired gunpowder depends in a great measure upon the expansive force of uncombined *caloric*, supposed to be let loose in great abundance during the combustion or deflagration of the powder: but it is not only dangerous to admit the action of an agent whose existence is not yet clearly demonstrated; but it appears to me that this supposition is quite unnecessary, the elastic force of the heated aqueous vapour, whose existence can hardly be doubted, being quite sufficient to account for all the phenomena. It is well known that the elasticity of aqueous vapour is incomparably more augmented by any given augmentation of temperature than that of any permanently elastic fluid whatever; and those who are acquainted with the amazing force of steam, when heated only to a few degrees above the boiling point, can easily perceive that its elasticity must be almost infinite when greatly condensed and heated to the temperature of red-hot iron; and this heat it must certainly acquire in the explosion of gunpowder. But if the force of fired gunpowder arises *principally* from the elastic force of heated aqueous vapour, a cannon is nothing more than a *steam-engine* upon a peculiar construction; and upon determining the ratio of the elasticity of this vapour to its density, and to its temperature, a law will be found to obtain very different from that assumed by Mr Robins in his Treatise on Gunnery."

In order to measure the elastic force of fired gunpowder, Count Rumford adopted a new plan; and, instead of causing the generated elastic fluid to act on a moveable body through a determined space, which he had found to be ineffectual to his purpose, he contrived an apparatus in which this fluid should be made to act, "by a determined surface, against a weight, which, by being increased at pleasure, should at last be such as would just be able to confine it, and which in that case would just counterbalance and consequently *measure* the elastic force."

Having succeeded in setting fire to the powder, without any communication with the external air, "by causing the heat employed for that purpose to pass through the solid substance of the barrel, it only remained to apply such a weight to an opening made in the barrel, as the whole force of the generated elastic fluid should not be able to lift, or displace." Many precautions were necessary. A solid block of very hard stone, four feet four inches square, was placed upon a bed of solid masonry, which descended six feet below the surface of the earth. Upon this block of stone, which served as a base to the whole machinery, was placed the small barrel, in which the explosions were made, with its opening directly upwards. This opening was closed by a solid hemisphere of hardened steel, on which the weight to be overcome by the explosion was laid. Having charged the barrel with 10 grains of powder, its whole contents being about 28 grains, and a 24 pounder, weighing 8081 lbs. avoirdupois, being placed on its cascabel so as by its weight to confine the generated elastic fluid, a heated iron ball was applied to the end of the vent tube (a small solid projection from the centre of the bottom of the barrel). In a few moments the powder took fire, though the explosion made a very feeble report; and when the weight was raised, the confined elastic vapour rushed out of the barrel. The slight effect produced by this explosion induced some of the attendants on this occasion to undervalue the importance of this experiment, and to form a very inadequate idea of the real force of the elastic fluid that had been thus almost insensibly discharged. In a second experiment, the barrel was filled with powder, and the same weight laid on as before. The barrel was made of the best hammered iron, and uncommonly strong. The charge of powder amounted to little more than $\frac{1}{10}$th of a cubic inch, which is not so much as would be required to load a small pocket-pistol, and not *one-tenth* part of the quantity frequently used for the charge of a common musket. Yet this inconsiderable quantity of powder, when set on fire, exploded with a force that burst the barrel, and with a loud report that alarmed the whole neighbourhood.

The author proceeds to make an estimate, from the known strength of iron, and the area of the fracture of the barrel in the preceding experiment, of the real force employed by the elastic vapour to burst it; and he computes that it must have been equal to the pressure of a weight of 412529 lbs.; which, by another computation, he found to be 55004 times greater than the mean pressure of the atmosphere. By another process, he investigates the strength of the iron of which the barrel was made; and he thence finds that the force required to burst it was equal to the pressure of a weight of 410624½ lbs. This weight, reduced into atmospheres, gives 54750 atmospheres for the measure of the force exerted by the elastic fluid in the present instance. This force must be considerably less than the initial force of the elastic fluid generated in the combustion of gunpowder, before it has begun to expand; "for it is more than probable (says Count Rumford) that the barrel was in fact burst before the generated elastic fluid had exerted all its force, or that this fluid would have been able to have burst a barrel still stronger than that used in the experiment."

After having shewn the extreme force of fired gunpowder, the Count adverts to an objection which may be made against his deductions. How does it happen that fire-arms and artillery of all kinds, which certainly are not calculated to withstand so enormous a force, are not always burst when they are used? Instead of answering this question, by asking how it happened that the extremely strong barrel used in his experiment could be burst by the force of gunpowder, if this force be not in fact much greater than it has ever been supposed to be, he proceeds to shew that the combustion of gunpowder, instead of being instantaneous, as Mr Robins's theory supposes, is much less rapid than has hitherto been apprehended; an observation which, if established, is certainly sufficient to answer the objection.

He remarks, that it is a well-known fact that, on the discharge of fire-arms of all kinds, there is always a considerable quantity of unconsumed grains of gunpowder blown out of them; and what is very remarkable, as it leads directly to a discovery of the cause of this effect, these unconsumed grains are not merely blown out of the muzzles of fire-arms, but come out also by their vents or touch-holes, where the fire enters to inflame the charge, as many persons who have had the misfortune to stand with their faces near the touch-hole of a musket, when it has been discharged, have found to their cost.

It appears extremely improbable to our author, if not absolutely impossible, that a grain of gunpowder actually in the chamber of the piece, and completely surrounded by flame, should, by the action of that very flame, be blown out of it without being at the same time set on fire. And, if this be true, he considers it as a most decisive proof, not only that the combustion of gunpowder is less rapid than it has generally been thought to be, but that a grain of gunpowder actually on fire, and burning with the utmost violence over the whole of its surface, may be projected with such a velocity into a cold atmosphere, as to extinguish the fire, and suffer the remains of the grain to fall to the ground unchanged, and as inflammable as before.

This extraordinary fact was ascertained beyond all possibility of doubt by the Count's experiments. Having procured from a powdermill in the neighbourhood of the city of Munich a quantity of gunpowder, all of the same mass, but formed into grains of very different sizes, fizes, fome as fmall as the grains of the fineft Battel powder, he placed a number of vertical fcreens of very thin paper, one behind another, at the diftance of 12 inches from each other; and loading a common mufket repeatedly with this powder, fometimes without and fometimes with a wad, he fired it againft the foremoft fcreen, and obferved the quantity and effects of the unconfumed grains of powder which impinged againft it. The fcreens were fo contrived, by means of double frames united by hinges, that the paper could be changed with very little trouble, and it was actually changed after every experiment.

The diftance from the muzzle of the gun to the firft fcreen was not always the fame; in fome of the experiments it was only 8 feet, in others it was 10, and in fome 12 feet.

The charge of powder was varied in a great number of different ways; but the moft interefting experiments were made with one fingle large grain of powder, propelled by fmaller and larger charges of very fine grained powder.

Thefe large grains never failed to reach the fcreen; and though they fometimes appeared to have been broken into feveral pieces by the force of the explofion, yet they frequently reached the fcreen entire; and fometimes paffed through all the fcreens (five in number) without being broken.

When they were propelled by large charges, and confequently with great velocity, they were feldom on fire when they arrived at the firft fcreen; which was evident, not only from their not fetting fire to the paper (which they fometimes did), but alfo from their being found fticking in a foft board, againft which they ftruck, after having paffed through all the five fcreens; or leaving vifible marks of their having been impinged againft it, and being broken to pieces and difperfed by the blow. Thefe pieces were often found lying on the ground; and from their forms and dimenfions, as well as from other appearances, it was often quite evident that the little globe of powder had been on fire, and that its diameter had been diminifhed by the combuftion before the fire was put out, on the globe being projected into the cold atmofphere.

That thefe globes or large grains of powder were always fet on fire by the combuftion of the charge, can hardly be doubted. This certainly happened in many of the experiments; for they arrived at the fcreens on fire, and fet fire to the paper; and in the experiments in which they were projected with fmall velocities, they were often feen to pafs through the air on fire; and when this was the cafe, no veftige was to be found. They fometimes paffed on fire through feveral of the foremoft fcreens without fetting them on fire, and fet fire to one or more of the hindmoft, and then went on and impinged againft the board which was placed at the diftance of twelve inches behind the laft fcreen.

The Count then proceeds to mention another experiment, in which the progreffive combuftion of gunpowder was fhewn in a manner ftill more ftriking, and not lefs conclufive.

A fmall piece of red hot iron being dropped down into the chamber of a common horfe piftol, and the piftol being elevated to an angle of about 45 degrees, upon dropping down into its barrel one of the fmall globes of powder (of the fize of a pea), it took fire, and was projected into the atmofphere by the elaftic fluid generated in its own combuftion, leaving a very beautiful train of light behind it, and difappearing all at once like a falling ftar. This amufing experiment was repeated very often, and with globes of different fizes. When very fmall ones were ufed fingly, they were commonly confumed entirely before they came out of the barrel of the piftol; but when feveral of them were ufed together, fome, if not all of them, were commonly projected into the atmofphere on fire.

As the flownefs of the combuftion of gunpowder is undoubtedly the caufe which has prevented its enormous and almoft incredible force from being difcovered, our author deduces, as an evident confequence, that the readieft way to increafe its effects, is to contrive matters fo as to accelerate its inflammation and combuftion. This may be done in various ways; but, in his opinion, the moft fimple and moft effectual manner of doing it would be to fet fire to the charge of powder, by fhooting (through a fmall opening) the flame of a fmaller charge into the midft of it.

He contrived an inftrument on this principle for firing cannon three or four years ago; and it was found, on repeated trials, to be ufeful, convenient in practice, and not liable to accidents. It likewife fuperfedes the neceffity of ufing priming, of vent tubes, port-fires, and matches; and on that account he imagined it might be of ufe in the Britifh navy, but it does not appear to have been received into practice.

Another infallible method of increafing very confiderably the effect of gunpowder in fire-arms of all forts and dimenfions, would be to caufe the bullet to fit the bore exactly, or without windage, in that part of the bore at leaft where the bullet refts on the charge; for when the bullet does not completely clofe the opening of the chamber, not only much of the elaftic fluid, generated in the firft moment of the combuftion of the charge, efcapes by the fide of the bullet; but what is of ftill greater importance, a confiderable part of the unconfumed powder is blown out of the chamber along with it in a ftate of actual combuftion, and, getting before the bullet, continues to burn on as it paffes through the whole length of the bore; by which the motion of the bullet is much impeded.

The lofs of force which arifes from this caufe, is in fome cafes almoft incredible; and it is by no means difficult to contrive matters fo as to render it very apparent, and alfo to prevent it.

If a common horfe-piftol be fired with a loofe ball, and fo fmall a charge of powder that the ball fhall not be able to penetrate a deal board fo deep as to ftick in it when fired againft it from the diftance of fix feet; the fame ball, difcharged from the fame piftol with the fame charge of powder, may be made to pafs quite through one deal board, and bury itfelf in a fecond placed behind it, merely by preventing the lofs of force which arifes from what is called windage, as he found more than once by actual experiment.

The Count has in his poffeffion a mufket, from which, with a common charge of powder, he fires two bullets at once with the fame velocity that a fingle bullet is difcharged from a mufket on the common conftruction with the fame quantity of powder. And, what renders the experiment ftill more ftriking, the diameter

diameter of the bore of his musket is exactly the same as that of a common musket, except only in that part of it where it joins the chamber, in which part it is just so much contracted, that the bullet, which is next to the powder, may stick fast in it. He adds, that though the bullets are of the common size, and are consequently considerably less in diameter than the bore, means are used which effectually prevent the loss of force by windage; and to this last circumstance he concludes, it is doubtless owing, in a great measure, that the charge appears to exert so great a force in propelling the bullets.

That the conical form of the lower part of the bore where it unites with the chamber has a considerable share in producing this extraordinary effect, is, however, very certain, as he has found by experiments made with a view merely to ascertain that fact.

At the close of the Count's last memoir, we have a computation, designed to shew that the force of the elastic fluid generated in the combustion of gunpowder, enormous as it is, may be satisfactorily explained on the supposition that it depends *solely* on the elasticity of watery vapour, or steam. From experiments made in France in the year 1790, it appears that the elasticity of steam is doubled by every addition of temperature equal to 30° of Fahrenheit's thermometer. As the heat generated in the combustion of gunpowder cannot be less than that of red-hot iron, it may be supposed equal to 1000° of Fahrenheit's scale:—but the elastic force of steam is just equal to the mean pressure of the atmosphere, when its temperature is equal to that of boiling water, or to 212° of Fahrenheit's thermometer; consequently $212° + 30° = 240°$ will represent the temperature, when its elasticity will be equal to the pressure of two atmospheres; and, pursuing the calculation, at 602°, or 2° above the heat of boiling linseed oil, its elasticity will be equal to the pressure of 8192 atmospheres, or above *eight times* greater than the utmost force of the fluid generated in the combustion of gunpowder, according to Mr Robins's computation: but the heat in this case is much greater than that of 602° of Fahrenheit; and therefore the elasticity of the steam generated from the water contained in the powder must be much greater than the pressure of 8192 atmospheres. At 722°, the elasticity will be equal to the pressure of 131,072 atmospheres; and this temperature is less than the heat of iron, which is visibly red-hot in day-light, by 355°:—but the flame of gunpowder has been found to melt brass, which requires a heat equal to that of 3807° of Fahrenheit; 2730° above the heat of red-hot iron, or 3805° higher than the temperature which gives to steam an elasticity equal to the pressure of 131,072 atmospheres. That there is in gunpowder water sufficient for supplying the necessary quantity of steam, the author has very satisfactorily evinced; but we must not pursue his curious investigations any farther. Those who want a fuller account of them, will find it either in the original memoirs themselves, or in a very accurate abridgment of these memoirs in the first volume of Nicholson's *Journal of Natural Philosophy*, &c.

We cannot conclude this article without mentioning a new kind of gunpowder, invented some years ago in France, in which the marine acid is substituted, in equal quantity, for nitre. Dr Hutton tried some of this new powder which was made at Woolwich, and found it of about double the strength of the ordinary sort; but it is not likely to come into common and general use, for the preparation of the acid is difficult and expensive (See CHEMISTRY-*Index* in this *Suppl.*), and the powder which is made of it catches fire and explodes from the smallest degree of heat, and without the aid of a spark. It is to this circumstance, however, that its superior strength seems to be in a great measure owing.

GUNTER's CHAIN. See GEOMETRY, *Encyclopædia*, Part II. chap. I.

GUT-TIE, a dangerous disease to which oxen and male calves are rendered liable by an improper mode of castration. In some places, and particularly in Herefordshire, the breeders of cattle, when they castrate their calves, open the *scrotum*, take hold of the testicles with their teeth, and tear them out with violence; by which means all the vessels thereto belonging are ruptured. The *vasa deferentia*, entering by the holes of the transverse and oblique muscles into the abdomen, pass over the ureters in acute angles; at which turning, by their great length and elastic force, the peritoneum is ruptured; the *vasa deferentia* are severed from the testicles, and, springing back, form a kind of bow from the urethra, where they are united, over the ureters, to the transverse and oblique muscles, and there again unite, where they first entered the abdomen; the part of the gut that is tied is the jejunum, at its turning from the left side to the right, and again from the right to the left, forming right angles under the kidney, and attached to the duplicature of the peritoneum, to which it was united, where the rupture happened. There the bow of the gut hangs over the bow of the *vasa deferentia*, which, by a sudden motion, or turn of the beast, form a hitch or tie of the string round the bow of the gut (filled with air), similar to what a carter makes on his cart line. This causes a stoppage in the bowels, and brings on a mortification, which, in two days, or four at most, proves fatal: And to this accident is the beast, when castrated as above, liable from the day that he was castrated till the time of his being slaughtered.

The symptoms of the gut-tie are the same as those of an incurable colic, *volvulus*, or mortification of the bowels. The beast affected with this complaint will kick at its belly, lie down, and groan; it has also a total stoppage in its bowels (except blood and mucus, which it will void in large quantities), and a violent fever, &c. To distinguish with certainty the gut-tie from the colic, &c. the hand and arm of the operator must be oiled, and introduced into the anus, through the rectum, beyond the os pubis, turning the hand down to the transverse and oblique muscles, where the vessels of the testicles enter the abdomen. There the string will be found united to the muscles, and is easily traced to the stricture by the hand, without pain to the beast.

From the general view of the agriculture of the county of Hereford, drawn up by Mr Clark of Builth, Breconshire, we learn that Mr Harris farmer at Wickton, near Leominster, had been uncommonly successful in the cure of the gut-tie. That gentleman informs us, that he had cut cattle for this disease from the age of three months to that of nine years; and as it is a matter of great importance, we shall state his method of operating in his own words.

"The

Gut-tie.

" The only method of cure (ſays he) that can be ſafely ventured upon is, to make a perpendicular inciſion, four inches under the third vertebra of the loins, on the left ſide, over the paunch or ſtomach, and introduce the arm to find the part affected; if poſſible, keep the beaſt ſtanding by the help of proper aſſiſtants. The knife I make uſe of to ſevere the ſtring is in the form of a large fiſh-hook, with an edge on the concave ſide; it is fixed to a ring, which fits the middle finger, which finger crooks round the back of the knife, the end of the thumb being placed on its edge. The inſtrument, by being thus held in the hand, is ſecured from wounding the ſurrounding inteſtines; with it I divide the ſtring or ſtrings, and bring out one or both, as circumſtances require. Here it is to be obſerved, that great care muſt be taken by the operator not to wound or divide the ureters, which would be certain death. I then ſew up the divided lips of the peritoneum very cloſe, with a ſurgeon's needle threaded with ſtrong thread, eight or ten double, ſufficiently waxed; I alſo ſew up the ſkin, leaving a vacancy at the top and bottom of the wound ſufficiently wide to introduce a tent of ſurgeon's tow, ſpread with common digeſtive and traumatic balſam; covering the inciſion with a plaſter made of the whites of eggs and wheat flour. The wound, thus treated, and dreſſed every day, will be well in a fortnight. The medicine I give to remove the ſtoppage in the three ſtomachs occaſioned by the tie, and to carry off the fever, is four ounces of Glauber's ſalt, two ounces of cream of tartar, and one ounce of ſenna, infuſed in two pounds of boiling water, adding half a pound of olive-oil, and working it off with plenty of gruel, mixed with a large quantity of infuſion of mallows and elder-bark. I adminiſter the gruel and infuſion for at leaſt two or three days; by which time the beaſt will be well, will eat his provender, and chew the cud, and will forever be relieved, and remain ſafe from this fatal diſorder.

Gut-tie, Guz.

" The following ſimple and eaſy method of caſtration will effectually prevent the gut-tie. Open the ſcrotum, looſen out the teſticles, and tie the ſeveral veſſels with a waxed thread or ſilk; or ſear them with a hot iron, to prevent their bleeding, as in the common way of cutting colts. This method can never diſplace the veſſels of the teſticles, bladder, kidneys, or inteſtines; all of which remain covered or attached to the peritoneum, or lining of the abdomen of the beaſt, which renders it impoſſible that there ſhould ever be a ſtricture or tie on the gut."

GUZ, an Indian meaſure, varying in different places, but which may be reckoned about an Engliſh yard. The guz of Akbar was 41 fingers.

H.

Hances || Harriot.

HANCES, Hanches, Haunches, or *Hanſes*, in architecture, are certain ſmall intermediate parts of arches between the key or crown and the ſpring at the bottom, being perhaps about one-third of the arch, and ſituated nearer the bottom than the top or crown; and are otherwiſe called the *ſpandrels*. See Arch in this *Supplement*.

HANSPIKE, or Handspec, a lever or piece of ſtrong wood, for raiſing by the hand great weights, &c. It is five or ſix feet long, cut thin and crooked at the lower end, that it may get the eaſier between things that are to be ſeparated, or under any thing that is to be raiſed. It is better than a crow of iron, becauſe its length allows a better poiſe.

HARRIOT (Thomas) was a very eminent mathematician of the 16th and 17th centuries, of whom ſome account has been given in the *Encyclopædia Britannica*. In that article it has been ſhewn, that Des Cartes had ſeen ſome improvements of Harriot's in algebra, and publiſhed them to the world as his own; but this piece of plagiariſm has been more completely proved in the Aſtronomical Ephemeris for the year 1788, by Dr Zache, aſtronomer to the Duke of Saxe-Gotha; who likewiſe ſhews that Harriot was an aſtronomer as well as an algebraiſt.

" I here preſent to the world (ſays the Doctor) a ſhort account of ſome valuable and curious manuſcripts, which I found in the year 1784 at the ſeat of the earl of Egremont, at Petworth in Suſſex.

Harriot.

" A predeceſſor of the family of lord Egremont, viz. that noble earl of Northumberland, named Henry Percy, was not only a generous favourer of all good learning, but alſo a patron and Mæcenas of the learned men of his age. Thomas Harriot, the author of the ſaid manuſcripts, Robert Hues (well known by his Treatiſe upon the Globes), and Walter Warner, all three eminent mathematicians, who were known to the earl, received from him yearly penſions; ſo that when the earl was committed priſoner to the Tower of London in the year 1606, our author, with Hues and Warner, were his conſtant companions; and were uſually called the earl of Northumberland's three Magi.

" Thomas Harriot is a known and celebrated mathematician among the learned of all nations, by his excellent work, *Artis Analyticæ Praxis, ad æquationes algebraicas nova expeditata & generali methodo, reſolvendas, Tractatus poſthumus*; London 1631: dedicated to Henry earl of Northumberland; publiſhed after his death by Walter Warner. It is remarkable, that the fame and the honour of this truly great man were conſtantly attacked by the French mathematicians, who could not endure that Harriot ſhould in any way diminiſh the fame of their Vieta and Des Cartes, eſpecially the latter, who was openly accuſed of plagiariſm from our author.

" Des Cartes publiſhed his Geometry ſix years after Harriot's work appeared, viz. in the year 1637. Sir Charles Cavendiſh, then ambaſſador at the French court

at

Harriot. at Paris, obferved to the famous geometrician Roverval, that thefe improvements in analyfis had been already made thefe fix years in England, and fhewed him afterwards Harriot's *Artis Analyticæ Praxis;* which, as Roverval was looking over, at every page he cried out, *Oui! oui! il l'a vu! Yes! yes! he has feen it!* Des Cartes had alfo been in England before Harriot's death, and had heard of his new improvements and inventions in analyfis.

"Now all this relates to Harriot the celebrated analyft; but it has not hitherto been known that Harriot was an eminent aftronomer, both theoretical and practical, which firft appears by thefe manufcripts; among which, the moft remarkable are 199 obfervations of the fun's fpots, with their drawings, calculations, and determination of the fun's rotation about his axis. There is the greateft probability that Harriot was the firft difcoverer of thefe fpots, even before either Galileo or Scheiner. The earlieft intelligence we have of the firft difcovered folar fpots is of one Joh. Fabricius Phryfius, who in the year 1611 publifhed at Wittemberg a fmall treatife, intitled, *De Maculis in Sole obfervatis & apparente eorum cum Sole converfione narratio.* Galileo, who is commonly accounted the firft difcoverer of the folar fpots, publifhed his book, *Iftoria e Dimonftrazioni intorne alle Machie Solare e loro accidente*, at Rome in the year 1613. His firft obfervation in this work is dated June 2d 1612. Angelo de Filiis, the editor of Galileo's work, who wrote the dedication and preface to it, mentions, page 3. that Galileo had not only difcovered thefe fpots in the month of April in the year 1611, at Rome, in the Quirinal Garden, but had fhewn them feveral months before (*molti mefi innanzi*) to his friends in Florence; and that the obfervations of the difguifed Apelles (the Jefuit Scheiner, a pretender to this firft difcovery) were not later than the month of October in the fame year; by which the epoch of this difcovery was fixed to the beginning of the year 1611. But a paffage in the firft letter of Galileo's works, pa. 11. gives a more precife term to this difcovery. Galileo there fays in plain terms, that he had obferved the fpots in the fun 18 months before. The date of this letter is May 24. 1612; which brings the true epoch of this difcovery to the month of November 1610. However, Galileo's firft produced obfervations are only from June 2. 1612, and thofe of father Scheiner of the month of October in the fame year. But now it appears from Harriot's manufcripts, that his firft obfervations of thefe fpots are of Dec. 8. 1610. It is not likely that Harriot could have this notice from Galileo, for I do not find this mathematician's name ever quoted in Harriot's papers: But I find him quoting book i. chap. 2. of Jofeph a Cofta's *Natural and Moral Hiftory of the Weft Indies;* in which he relates, that in Peru there are fpots to be feen in the fun which are not feen in Europe: and hence it is probable, that Harriot took the hint of looking for fuch fpots. Befides, it is not unlikely, that living with fo munificent a patron, Harriot got from Holland the new invented telefcopes much fooner than they could reach Galileo, who at that time lived at Venice. Harriot's very careful and exact obfervations of thefe fpots, fhew alfo that he was in poffeffion of the beft and moft improved telefcopes of that time; for it appears he had fome with magnifying powers of 10, 20, and 30 times. At leaft there are no earlier obfervations of the folar fpots extant than his; they run from December 8. 1610, till January 18. 1613. I compared the correfponding ones with thefe obferved by Galileo, between which I found an exact agreement. Had Harriot had any notion about Galileo's difcoveries, he certainly would have alfo known fomething about the phafes of Venus and Mercury, and efpecially about the fingular fhape of Saturn, firft difcovered by Galileo; but I find not a word in all his papers concerning the particular figure of that planet.

"I found likewife (continues Dr Zach) among the papers of Harriot a large fet of obfervations on the fatellites of Jupiter, with drawings of them, their pofitions, and calculations of their revolutions and periods. His firft obfervation of thofe difcovered fatellites, I find to be of January 16. 1610; and they go till February 26. 1612. Galileo pretends to have difcovered them January 7. 1610; fo that it is not improbable that Harriot was likewife the firft difcoverer of thefe attendants of Jupiter.

"Among his other obfervations of the moon, of eclipfes, of the planet Mars, of folftices, of refraction, of the declination of the needle, &c. there are remarkable ones of the comet of 1607, and the latter comet (for there were two) of 1618. They were all obferved with a crofs-ftaff, by meafuring their diftances from fixed ftars; whence thefe obfervations are the more valuable, as comets had before been but grofsly obferved. Kepler himfelf obferved the comet of 1607 only with the naked eye, pointing out its place by a coarfe eftimation, without the aid of an inftrument; and the elements of their orbits could, in defect of better obfervations, be only calculated by them. The obfervations of the comet of the year 1607 are of the more importance, even now for modern aftronomy, as this is the fame comet that fulfilled Dr Halley's prediction of its return in the year 1759. That prediction was only grounded upon the elements afforded him by thefe coarfe obfervations; for which reafon he only affigned the term of its return to the fpace of a year. The very intricate calculations of the perturbations of this comet, afterwards made by M. Clairaut, reduced the limits to a month's fpace. But a greater light may now be thrown upon this matter by the more accurate obfervations on this comet by Mr Harriot. In the month of October 1785, when I converfed upon the fubject of Harriot's papers, and efpecially on this comet, with the celebrated mathematician M. de la Grange, director of the Royal Academy of Sciences at Berlin, he then fuggefted to me an idea, which, if brought into execution, will clear up an important point in aftronomy. It is well known to aftronomers how difficult a matter it is to determine the mafs, or quantity of matter, in the planet Saturn; and how little fatisfactory the notions of it are that have hitherto been formed. The whole theory of the perturbations of comets depending upon this uncertain datum, feveral attempts and trials have been made towards a more exact determination of it by the moft eminent geometricians of this age, and particularly by la Grange himfelf; but never having been fatisfied with the few aud uncertain data heretofore obtained for the refolution of this problem, he thought that Harriot's obfervations on the comet of 1607, and the modern ones of the fame comet in 1759, would fuggeft a way of refolving the problem *à pofteriori;* that of determining by

Hasselquist.

by them the elements of its ellipsis. The retardation of the comet, compared to its period, may clearly be laid to the account of the attraction and perturbation it has suffered in the region of Jupiter and Saturn; and as the part of it belonging to Jupiter is very well known, the remainder must be the share which is due to Saturn; whence the mass of the latter may be inferred. In consequence of this consideration, I have already begun to reduce most of Harriot's observations of this comet, in order to calculate by them the true elements of its orbit on an elliptical hypothesis, to complete M. de la Grange's idea upon this matter.

"I forbear to mention here any more of Harriot's analytical papers, which I found in a very great number. They contain several elegant solutions of quadratic, cubic, and biquadratic equations; with some other solutions and *loca geometrica*, that shew his eminent qualifications, and will serve to vindicate them against the attacks of several French writers, who refuse him the justice due to his skill and accomplishments, merely to save Des Cartes's honour, who yet, by some impartial men of his own nation, was accused of public plagiarism."

HASSELQUIST (Frederick) was born in the province of East Gothland in 1722, and studied medicine and botany in the university of Upsal. Linnæus had in his lectures represented the extraordinary merits and great celebrity which a young student might obtain by travelling through Palestine, and by inquiring into and describing the natural history of that country, which was till then unknown, and had become of the greatest importance to interpret the bible, and to understand eastern philology. Hasselquist was fired with ambition to accomplish an object so important in itself, and so warmly recommended by his beloved master. There being no fund arising from the liberality of the crown, private collections were made, which poured in very copiously, especially from the native country of the young traveller. All the faculties of the university of Upsal also granted him a stipend.

Thus protected, he commenced his journey in the summer of 1749. By the interference of Lagerstroem, he had a free passage to Smyrna in one of the Swedish East Indiamen. He arrived there at the conclusion of the year, and was received in the most friendly manner by Mr A. Rydel, the Swedish consul. In the beginning of 1750 he set out for Egypt, and remained nine months at Cairo the capital. Hence he sent to Linnæus, and to the learned societies of his country, some specimens of his researches. They were published in the public papers, and met with the greatest approbation; and upon the proposition of Dean Baeck and Dr Wargentin, secretary of the Royal Academy of Sciences, a collection of upwards of 10,000 dollars in copper money was made for the continuance of the travels of young Hasselquist. Counsellors Lagerstroem and Nordencrantz were the most active in raising subscriptions at Stockholm and Gothenburgh. In the spring of 1751, he repaired to his destination, and passed through Jaffa to Jerusalem, Jericho, &c. He returned afterwards through Rhodus and Scio to Smyrna. Thus he fulfilled all the expectations of his country, but he was not to reap the reward of his toils. The burning heat of the sandy deserts of Arabia had affected his lungs; he reached Smyrna in a state of illness, in which he languished for some time, and died February 9. 1752, in the 30th year of his age.

Hat.

The fruits of his travels were, however, preserved through the liberality of a great princess. He had been obliged to contract debts. The Turks, therefore, seized upon all his collections, and threatened to expose them to public sale. The Swedish consul prevented it. He sent, with the intelligence of the unhappy exit of his countryman, an account of the distresses under which he died;—and at the representation of Dean Baeck, Queen Louisa Ulrica granted the sum of 14,000 dollars in copper specie to redeem all his collections. They arrived afterwards in good preservation at Stockholm; consisting of a great quantity of antiques, Arabian manuscripts, shells, birds, serpents, insects, &c. and were kept in the cabinets at Ulrichsdale and Drottningholm. The specimens of the natural curiosities of these museums being double or treble in number, Linnæus obtained some of them, and published the voyage of his ill-fated friend, and honoured his memory with a plant which he called from his name *Hasselquistia*. HASSELQUISTA, *Encycl.*

HAT-MAKING is a mechanical process, which is detailed in the *Encyclopædia* from the best information that could then be obtained. We have lately learned, however, that our detail is sometimes defective, and sometimes erroneous; and it is our duty to supply those defects, and to correct those errors. But, strangers as we are to the business of hat-making, we should not perhaps have suspected, that we had been misled by the persons whom we consulted, had we not been informed by a very intelligent writer in Nicholson's Philosophical Journal, that the account of the manufacturing of hats, which is given in the *Encyclopædia*, is far from the truth. This information induced us to look through the Journal itself for a more accurate account of the process; well convinced, that the liberal-minded author of that work would not have pointed out our mistakes without making us welcome to avail ourselves of his aid to correct them. Our readers will therefore be indebted only to Mr Nicholson and his correspondent for whatever instruction they may derive from this article; and as we wish not to deck ourselves in borrowed plumes, we shall communicate that instruction in the words of its author.

Having visited the manufactory of Messrs Collinsons, hatters in Gravel-lane, Southwark, Mr Nicholson gives the following account of their procedure:

"The materials for making hats are rabbits fur cut off from the skin, after the hairs have been plucked out, together with wool and beaver. The two former are mixed in various proportions, and of different qualities, according to the value of the article intended to be made; and the latter our author believes to be universally used for facing the finer articles, and never for the body or main stuff. Experience has shewn, that these materials cannot be evenly, and well felted together, unless all the fibres be first separated, or put into the same state with regard to each other. This is the object of the first process, called *bowing*. The material, without any previous preparation (A), is laid upon a platform of wood, or

(A) Some writers mention a partial wetting of the fur while on the skin, by lightly smearing it with a solution of nitrate of mercury to give it a curl. Messrs Collinsons do not use it, nor any other preparation.

Hat.

or of wire, somewhat more than four feet square, called a *hurdle*, which is fixed against the wall of the workshop, and is enlightened by a small window, and separated by two side partitions from other hurdles which occupy the rest of the space along the wall. The hurdle, if of wood, is made of deal planks, not quite three inches wide, disposed parallel to the wall, and at the distance of one-fortieth or one-fiftieth of an inch from each other, for the purpose of suffering the dust, and other impurities of the stuff, to pass through; a purpose still more effectually answered by the hurdle of wire.

"The workman is provided with a bow, a bow-pin, a basket, and several cloths. The bow is a pole of yellow deal wood, between seven and eight feet long, to which are fixed two bridges, somewhat like that which receives the hair in the bow of the violin (B). Over these is stretched a catgut, about one-twelfth part of an inch in thickness. The bow pin is a stick with a knob, and is used for plucking the bow-string. The basket is a square piece of ozier work, consisting of open strait bars with no crossing or interweaving. Its length across the bars may be about two feet, and its breadth eighteen inches. The sides into which the bars are fixed are slightly bended into a circular curve, so that the basket may be set upright on one of these edges near the right hand end of the hurdle, where it usually stands. The cloths are linen. Besides these implements, the workman is also provided with brown paper.

"The *bowing* commences by shovelling the material towards the right hand partition with the basket; upon which, the workman holding the bow horizontally in his left hand, and the bow-pin in his right, lightly places the bow-string, and gives it a pluck with the pin. The string, in its return, strikes part of the fur, and causes it to rise, and fly partly across the hurdle in a light open form. By repeated strokes, the whole is thus subjected to the bow; and this beating is repeated till all the original clots or masses of the filaments are perfectly opened and obliterated. The quantity thus treated at once is called a *batt*, and never exceeds half the quantity required to make one hat.

"When the batt is sufficiently bowed, it is ready for *hardening*; which term denotes the first commencement of felting. The prepared material being evenly disposed on the hurdle, is first pressed down by the convex side of the basket, then covered with a cloth, and pressed successively in its various parts by the hands of the workman. The pressure is gentle, and the hands are very slightly moved back and forwards at the same time through a space of perhaps a quarter of an inch, to favour the hardening or entangling of the fibres (See Felting in this *Suppl.*) In a very short time, indeed, the stuff acquires sufficient firmness to bear careful handling. The cloth is then taken off, and a sheet of paper, with its corners doubled in, so as to give it a triangular outline, is laid upon the batt, which last is folded over the paper as it lies, and its edges, meeting one over the other, form a conical cap. The joining is soon made good by pressure with the hands on the cloth. Another batt, ready hardened, is in the next place laid on the hurdle, and the cap here mentioned placed upon it, with the joining downwards. This last batt being also folded up, will consequently have its place of junction diametrically opposite to that of the inner felt, which it must therefore greatly tend to strengthen. The principal part of the hat is thus put together, and now requires to be worked with the hands a considerable time upon the hurdle, the cloth being also occasionally sprinkled with clear water. During the whole of this operation, which is called *basoning* (C), the article becomes firmer and firmer, and contracts in its dimensions. It may easily be understood, that the chief use of the paper is to prevent the sides from felting together.

"The basoning is followed by a still more effectual continuation of the felting, called *working* (D). This is done in another shop, at an apparatus called a *battery*, consisting of a *kettle* (containing water slightly acidulated with sulphuric acid, to which, for beaver hats, a quantity of the grounds of beer is added, or else plain water for rinsing out), and eight *planks* of wood joined together in the form of a frustum of a pyramid, and meeting in the kettle at the middle. The outer or upper edge of each plank is about two feet broad, and rises

(B) Mr Nicholson's correspondent, who is himself a hatter, says that the bow is best made of ash; that it is composed of the *stang* or handle; that the bridge at the smaller end, or that which is nearest the window in the act of bowing, is called the *cock*; and that the other bridge, which is nearer to the workman's hand, is called the *breech*.

(C) Mr Nicholson's correspondent says, that after bowing, and previous to the basoning, a *hardening skin*, that is, a large piece of skin, about four feet long and three feet broad, of leather alumed or half tanned, is pressed upon the bat, to bring it by an easier gradation to a compact appearance; after which it is basoned, being still kept upon the hurdle. This operation, the basoning, derives its name from the process or *mode of working*, being the same as that practised upon a wool hat after bowing; the last being done upon a piece of cast metal, four feet across, of a circular shape, called a *bason*: the joining of each batt is made good here by shuffling the hand, that is, by rubbing the edge of each batt folded over the other to excite the progressive motion of each of the filaments in felting, and to join the two together. Many journeymen, to hurry this work, use a quantity of vitriol (sulphuric acid), and then, to make the nap rise and flow, they kill the vitriol, and open the body again by throwing in a handful or two of oatmeal; by this means they get a great many made, though, at the same time, they leave them quite grainy from the want of labour. This, in handling the dry grey hat when made, may be in part discovered; but in part only.

(D) The intelligent writer who has been so often quoted, says, that before this operation is begun, the hat is dipped into the boiling kettle, and allowed to lie upon the plank until cold again; this is called *soaking*, that is, being perfectly saturated with the hot liquor: if they are put in too hastily in this state, for they are then only bowed and basoned, they would burst from the edges, each batt not being sufficiently felted into the other.

Hat. rifes a little more than two feet and a half above the ground; and the flope towards the kettle is confiderably rapid, fo that the whole battery is little more than fix feet in diameter. The quantity of fulphuric acid added to the liquor is not fufficient to give a four tafte, but only renders it rough to the tongue. In this liquor, heated rather higher than unpractifed hands could bear, the article is dipped from time to time, and then worked on the planks with a roller, and alfo by folding or rolling it up, and opening it again; in all which, a certain degree of care is at firft neceffary, to prevent the fides from felting together; of which, in the more advanced ftages of the operation, there is no danger. The imperfections of the work now prefent themfelves to the eye of the workman, who picks out knots and other hard fubftances with a bodkin, and adds more felt upon all fuch parts as require ftrengthening. This added felt is patted down with a wet brufh, and foon incorporates with the reft. The beaver is laid on towards the conclufion of this kind of working. Mr Nicholfon could not diftinctly learn why the beer grounds were ufed with beaver-hats. Some workmen faid, that by rendering the liquor more tenacious, the hat was enabled to hold a greater quantity of it for a longer time; but others faid, that the mere acid and water would not adhere to the beaver facing, but would roll off immediately when the article was laid on the plank. It is probable, as he obferves, that the manufacturers who now follow the eftablifhed practice, may not have tried what are the inconveniences this addition is calculated to remove."

Our author's correfpondent, however, affigns feveral reafons for the addition of thofe dregs, which, he fays, ought to be thick, and the foureft that can be got. 1. Vitriol (fulphuric acid) would harden the hat too much, which is kept mellow by the dregs. 2. The dregs are faid by the workmen to hold or fill the body, whilft a little vitriol cleanfes it of the dirt, &c. that may be on the rabbit or other wools. 3. Another advantage attending the ufe of dregs, whether of beer, porter, or wine, is, that as the boiling of the dyeing does not draw out much of the mucilage from each hat when it comes to be ftiffened, the dregs form a body within the hat, fufficiently ftrong or retentive to keep the glue from coming through amongft the nap. 4. Vitriol (fulphuric acid) alone purges or weakens the goods too much; confequently half of the quantity does better with the addition of dregs, as it allows the body to be made clofer by more work.

Of thefe four reafons for the ufe of dregs, the laft alone appears to us perfpicuous or at all fatisfactory. But be this as it may, acid of fome kind gives a roughnefs to the furface of the hair, which facilitates the mechanical action of felting; and Mr Collinfon informed Mr Nicholfon, that in a procefs, called *carotting*, they make ufe of nitrous acid. In this operation, the material is put into a mixture of the nitrous and fulphuric acids in water, and kept in the digefting heat of a ftove all night; by which means the hair acquires a ruddy or yellow colour, and lofes part of its ftrength.

"It muft be remembered, that our hat ftill poffeffes the form of a cone, and that the whole of the feveral actions it has undergone have only converted it into a foft flexible felt, capable of being extended, though with fome difficulty, in every direction. The next thing to be done is to give it the form required by the wearer. For this purpofe, the workman turns up the edge or rim to the dipth of about an inch and a half, and then returns the point back again through the centre or axis of the cap, fo far as not to take out this fold, but to produce another inner fold of the fame depth. The point being returned back again in the fame manner, produces a third fold; and thus the workman proceeds, until the whole has acquired the appearance of a flat circular piece, confifting of a number of concentric undulations or folds, with the point in the centre. This is laid upon the plank, where the workman, keeping the piece wet with the liquor, pulls out the point with his fingers, and preffes it down with his hand, at the fame time turning it round on its centre in contact with the plank, till he has, by this means, rubbed out a flat portion equal to the intended crown of the hat. In the next place, he takes a block, to the crown of which he applies the flat central portion of the felt, and by forcing a ftring down the fides of the block, he caufes the next part to affume the figure of the crown, which he continues to wet and work, until it has properly difpofed itfelf round the block. The rim now appears like a flounced or puckered appendage round the edge of the crown; but the block being fet upright on the plank, the requifite figure is foon given by working, rubbing, and extending this part. Water only is ufed in this operation of fafhioning or blocking; at the conclufion of which it is preffed out by the blunt edge of a copper implement for that purpofe.

"Previous to the dyeing, the nap of the hat is raifed or loofened out with a wire brufh, or carding inftrument. The fibres are too rotten after the dyeing to bear this operation. The dyeing materials are logwood, and a mixture of the fulphates of iron and of copper, known in the market by the names of green copperas and blue vitriol. As the time of Mr Collinfon was limited, and my attention, fays Mr Nicholfon, was more particularly directed to the mechanical proceffes, I did not go into the dye-houfe; but I have no doubt that the hats are boiled with the logwood, and afterwards immerfed in the faline folution. I particularly afked whether galls were ufed, and was anfwered in the negative.

"The dyed hats are, in the next place, taken to the ftiffening fhop. One workman, affifted by a boy, does this part of the bufinefs. He has two veffels, or boilers, the one containing the grounds of ftrong beer, which cofts feven fhillings per barrel, and the other veffel containing melted glue, a little thinner than it is ufed by carpenters. Our author particularly afked, whether this laft folution contained any other ingredient befides glue, and was affured that it did not. The beer grounds are applied in the infide of the crown to prevent the glue from coming through to the face, and alfo, as he fuppofes, to give the requifite firmnefs at a lefs expence than could be produced by glue alone. If the glue were to pafs through the hat in different places, it might, he imagines, be more difficult to produce an even glofs upon the face in the fubfequent finifhing. The glue ftiffening is applied after the beer grounds are dried, and then only upon the lower face of the flap, and the infide of the crown. For this purpofe the hat is put into another hat, called a ftiffening hat, the crown of which is notched, or flit open in various directions. Thefe are then placed in a hole in a deal board,

board, which supports the flap, and the glue is applied with a brush.

"The dry hat, after this operation, is very rigid, and its figure irregular. The last dressing is given by the application of moisture and heat, and the use of the brush and a hot iron, somewhat in the shape of that used by tailors, but shorter and broader on the face. The hat being softened by exposure to steam, is drawn upon a block, to which it is securely applied by the former method of forcing a string down from the crown to the commencement of the rim. The judgment of the workman is employed in moistening, brushing, and ironing the hat, in order to give and preserve the proper figure. When the rim of the hat is not intended to be of an equal width throughout, it is cut by means of a wooden, or perhaps metallic pattern; but as no such hats are now in fashion, Mr Nicholson saw only the tool for cutting them round. The contrivance is very ingenious and simple. A number of notches are made in one edge of a flat piece of wood for the purpose of inserting the point of a knife, and from one side or edge of this piece of wood there proceeds a straight handle, which lies parallel to the notched side, forming an angle somewhat like that of a carpenter's square. When the legs of this angle are applied to the outside of the crown, and the board lies flat on the rim of the hat, the notched edge will lie nearly in the direction of the radius, or line pointing to the centre of the hat. A knife being therefore inserted in one of the notches, it is easy to draw it round by leaning the tool against the crown, and it will cut the border very regular and true. This cut is made before the hat is quite finished, and is not carried entirely through; so that one of the last operations consists in tearing off the redundant part, which by that means leaves an edging of beaver round the external face of the flap. When the hat is completely finished, the crown is tied up in gauze paper, which is neatly ironed down. It is then ready for the subsequent operations of lining," &c.

Our author concludes his valuable memoir on the fabrication of hats, with some observations on the probable gain or loss of employing machinery in the manufacture. These observations, as they are stated in the original paper, we recommend to the serious attention of every judicious hat-maker, who carries on his business on a large scale; for he will find them not the reveries of a rash speculatist, but the cool reflections of a real philosopher, who is at the same time no stranger to the arts of life. They suggest the following subjects of inquiry: Whether carding, which is rapidly and mechanically done, be inferior to bowing, which does not promise much facility for mechanical operation? Whether a succession of batts or cardings might be thrown round a fluted cone, which rapidly revolving, in contact with three or more cylinders, might perform the hardening, and even the working, with much more precision and speed than they are now done by hand? Whether blocking or shaping be not an operation extremely well calculated for the operation of one or more machines? Whether loose weaving and subsequent felting might not produce a lighter, cheaper, and stronger article? And how far the mechanical felting, which is not confined merely to the hairs of animals, might be applied to this art?

Before we dismiss this subject, it may be worth while to state Mr Dunnage's method of making *water-proof hats*, in imitation of beaver, for which, in November 1794, he obtained a patent. It is as follows: Let a shag be woven, of such count in the reed, and cut over such sized wire, as will give the hats to be manufactured from it that degree of richness, or appearance of fur, which may be thought necessary. The materials of which this shag may be composed are various, and should be accommodated to different kinds of hats, according to the degree of beauty and durability to be given them, and the price at which they are designed to be sold; that is to say, silk, mohair, or any other hair that is capable of being spun into an end fine enough for the purpose, cotton, inkle, wool, or a mixture of any, or all the above materials, as may suit the different purposes of the manufacturer. Those answer best (says our author), which are made with two poles, either of Bergam, Piedmont, or Organzine silk, rising alternately, in a reed of about nine hundred count to eighteen inches wide, with three shoots over each wire. This method of weaving distributes the silk (as it may be put single into the harness), and prevents any ribby appearance which it might have if the silk were passed double, and the whole of the pole cut over each wire. This may be made either on a two or four thread ground of hard silk, shot with fine cotton, which he thinks preferable for shoot, to silk, inkle, or any other material, as it forms both a close and fine texture. An inferior kind of hats may be made from any of the before-mentioned materials, and with cheaper silk. This shag should be stretched on a frame, such as dyers use to rack cloth; then (having previously set the pile upright with a comb, to prevent its being injured or stuck together), go over the ground with thin size, laid on with a soft brush. For black, or dark colours, common size will do; with white, or any light colour, use isinglass, or a size made from white kid leather. These, or gum, or any other mucilaginous matter, which, without altering the colour, will prevent oil from getting through the ground so as to injure the pile, will answer the purpose. Take care not to apply more of any material, as a preparation, than may be fully saturated with oil or varnish, so that water will not discharge it from the ground. The size, or other glutinous matter, being dry, the pile must be teeseled, or carded with a fine card, till the silk is completely taken out of the twist or throwing, when it will lose its coarse shaggy look, and assume the appearance of a very fine fur. It must now be once more set upright with a comb, and you may proceed to lay on your water-proof material; this too may be varied according to circumstances. For black, or any dark colour, linseed oil well boiled with the usual driers, and thickened with a small quantity of any good drying colour, will do; for white, or very fine colours, poppy or nut oil, or copal or other varnishes, may be used. In this particular the manufacturer must judge what will best answer his purpose, taking care never to use any thing that will dry hard, or be subject to crack. Mr Dunnage has found good drying linseed oil preferable to any other thing which he has used, and, with the precaution of laying on very little the first time, it will not injure the finest colours. When the first coat of oil is dry, go over it a second and a third time, if necessary, till you are convinced the pores

Hat.

pores of the ground are fully closed up, and the stuff rendered impervious to water. It should now stand several days, till the smell is sufficiently gone off; and before it is taken from the frame, should be gone over with some ox-gall or lime-water, to take off the greasiness, which would otherwise prevent the stiffening from adhering to the oil. The material being now ready to be formed into hats, should be cut into proper shapes for that purpose. The crown should be made up over a block, with needle and silk, the oiled side outwards. The seams should then be rubbed with a piece of hard wood, bone, or ivory, to make them lie flat, and the edges of the stuff pared off very near the stitches, that no joint may appear on the right side. The seams should then be carefully gone over with the prepared oil, till every crevice or hole made by the needle is completely filled up, and the crown rendered perfectly water-proof. The crown may then be turned and stiffened, by sticking linen, leather, paper, or any other material that may be found to answer the purpose, to the inner or painted side, till it acquires about the same degree of stiffness, or resistance to the touch, as a good beaver. The mucilaginous matter which he used to attach the stiffening to the crown, and the upper and under parts of the brim to each other, was composed of one pound of gum-arabic or senega, one pound of starch, and a half a pound of glue, boiled up with as much water as reduced the whole to the consistence of a thick paste. A greater or less proportion of any of these ingredients may be used, and other glutinous and adhesive substances may answer the same purposes; or drying-oils may be made use of, instead of this or other mucilage; or any of the resinous gums dissolved in oil or spirits; only it should be observed, in this case, the hats will require more time in the preparation, as the oily matter, unless exposed to the air, will not readily dry; but he found by experience that the above mentioned composition does not dry hard or brittle, but retains that pleasant flexibility which is agreeable to the touch, while it communicates to the other materials a sufficient degree of elasticity. Before the brim is perfectly dry, care should be taken to form a neck or rising round the hole where it is to be attached to the crown, by notching it round with a pair of scissars, and then forcing it over a block something larger than you have made the hole, so that the uncut stuff may turn up, under the lower edge of the crown, about a quarter of an inch. Before you join the crown and brim together, go over the outside of the neck of the brim, and the inside of the crown, as high as the neck will come (which should be about half an inch), with the prepared oil; and when they are nearly dry, so as to adhere to the finger on touching them, put the crown over the neck of the brim, and let them be sewed strongly together, taking care to sew down as little of the pile as possible, and using the same precaution of oiling, where the needle has been through, as was observed in making up the crown. The hat is now ready for dressing; which operation may be performed over a block, with a hot iron, brush, &c. in the same manner as those commonly called felts. When putting in the lining, be very careful to let the needle only take hold of the under surface of the brim; for should it perforate the upper one, the water will find its way through, and the hat be of no value. Though we have already declared how little we are acquainted with the operation of hat-making, we cannot help suggesting the inquiry, whether these water-proof hats might not be improved both in strength and beauty, by a slight felting before the application of the size by the brush. Such of them as are composed of wool or hair, or contain a mixture of these materials, are unquestionably susceptible of felting.

Hawkins.

HAWKINS (Sir John), was the youngest son of a man who, though descended from Sir John Hawkins the memorable admiral and treasurer of the navy in the reign of Queen Elizabeth, followed at first the occupation of a house-carpenter, which he afterwards exchanged for the profession of a surveyor and builder. He was born in the city of London on the 30th day of March 1719; and after having been sent first to one school, and afterwards to a second, where he acquired a tolerable knowledge of Latin, he went through a regular course of architecture and perspective, in order to fit him for his father's profession of a surveyor. He was, however, persuaded, by a near relation, to abandon the profession of his first choice, and to embrace that of the law; and was accordingly articled to Mr John Scott an attorney and solicitor in great practice. In this situation his time was too fully employed in the actual dispatch of business to permit him, without some extraordinary means, to acquire the necessary knowledge of his profession by reading and study; besides that, his master is said to have been more anxious to render him a good copying clerk, by scrupulous attention to his hand-writing, than to qualify him by instruction to conduct business. To remedy this inconvenience, therefore, he abridged himself of his rest, and rising at four in the morning, found opportunity of reading all the necessary and most eminent law writers, and the works of our most celebrated authors on the subjects of verse and prose. By these means, before the expiration of his clerkship, he had rendered himself a very able lawyer, and had acquired a love for literature in general, but particularly for poetry and the polite arts; and the better to facilitate his improvement, he occasionally furnished to the Universal Spectator, the Westminster Journal, the Gentleman's Magazine, and other periodical publications of the time, essays and disquisitions on several subjects. The first of these is believed to have been an Essay on *Swearing*; but the exact time of its appearance, and the paper in which it was inserted, are both unknown. It was, however, re-published some years before his death (without his knowledge till he saw it in print) in one of the newspapers. His next production was an Essay on *Honesty*, inserted in the Gentleman's Magazine for March 1739; and which occasioned a controversy, continued through the Magazines for several succeeding months, between him and a Mr Calamy, a descendant of the celebrated Dr Edmund Calamy, then a fellow-clerk with him.

About the year 1741, a club having been instituted by several amateurs of music, under the name of the Madrigal Society, to meet every Wednesday evening, and his clerkship being now out, he became a member of it, and continued so many years. Pursuing his inclination for music still farther, he became also a member of the Academy of Ancient Music, which used to meet every Thursday evening at the Crown and Anchor in the Strand, but since removed to Freemasons Hall; and

Hawkins. and of this he continued a member till a few years before its removal.

Impelled by his own taste for poetry, and excited to it by his friend Foster Webb's example, who had contributed to the Gentleman's Magazine many very elegant poetical compositions, he had, before this time, himself become an occasional contributor in the same kind, as well to that as to some other publications. The earliest of his productions of this species, now known, is supposed to be a copy of verses "To Mr George Stanley, occasioned by looking over some Compositions of his lately published," which bears date 19th February 1740, and was inserted in the Daily Advertiser for February 21. 1741; but, about the year 1742, he proposed to Mr Stanley the project of publishing, in conjunction with him, six cantatas for a voice and instruments, the words to be furnished by himself, and the music by Mr Stanley. The proposal was accepted, the publication was to be at their joint expence, and for their mutual benefit; and accordingly, in 1742, six cantatas were thus published, the five first written by Mr Hawkins, the sixth and last by Foster Webb; and these having succeeded beyond the most sanguine expectations of their authors, a second set of six more, written wholly by himself, was in like manner published a few months after, and succeeded equally well.

As these compositions, by being frequently performed at Vauxhall, Ranelagh, and other public places, and at many private concerts, had become favourite entertainments, many persons, finding the author also a modest well-informed young man of unexceptionable morals, were become desirous of his acquaintance. Among these was Mr Hare of Limehouse, a brewer, who being himself a musical man, and having met him at Mr Stanley's at musical parties, gave him an invitation to his house; and, to forward him in his profession, introduced him to a friend of his, Peter Storer of Highgate, Esq; which proved the means of making his fortune.

In the winter of the year 1749, Doctor, then Mr Johnson, was induced to institute a club to meet every Tuesday evening at the King's Head, in Ivy lane, near St Paul's. It consisted only of nine persons; and Mr Hawkins was one of the first members. About this time, as it is supposed, finding his father's house, where he had hitherto resided, too small for the dispatch of his business, now very much increasing, he, in conjunction with Dr Munckley, a physician with whom he had contracted an intimacy, took a house in Clements-lane, Lombard-street. The ground-floor was occupied by him as an office, and the first floor by the Doctor as his apartment. Here he continued till the beginning of 1753, when, on occasion of his marriage with Sidney, the youngest of Mr Storer's daughters, who brought him a considerable fortune, he took a house in Austin Friars, near Broad-street, still continuing to follow his profession of an attorney.

Having received, on the death of Peter Storer, Esq; his wife's brother, in 1759, a very large addition to her fortune, he quitted business to Mr Clark, afterwards Alderman Clark, who had a short time before completed his clerkship under him, disposed of his house in Austin Friars, and purchased a house at Twickenham. Soon afterwards he bought the lease of one in Hatton-street, London, for a town residence. Hawkins.

From a very early period of his life he had entertained a strong love for the amusement of angling; and his affection for it, together with the vicinity of the river Thames, was undoubtedly his motive to a residence at this village. He had been long acquainted with Walton's Complete Angler; and had, by observation and experience, become himself a very able proficient in the art. Hearing, about this time, that Mr Moses Browne proposed to publish a new edition of that work, and being himself in possession of some material particulars respecting Walton, he, by letter, made Mr Browne an offer of writing, for his intended edition, Walton's Life. To this proposal no answer was returned, at least for some time; from which circumstance Mr Hawkins concluded, as any one reasonably would, that his offer was not accepted; and, therefore, having also learnt that Mr Browne meant not to publish the text as the author left it, but to modernize it, in order to file off the rust, as he called it, he wrote again to tell Mr Browne that he understood his intention was to sophisticate the text, and that therefore he, Mr Hawkins, would himself publish a correct edition. Such an edition, in 1760, he accordingly published in octavo with notes, adding to it a Life of Walton by himself, a Life of Cotton, the author of the second part, by the well-known Mr Oldys; and a set of cuts designed by Wale, and engraved by Ryland.

His propensity to music, manifested by his becoming a member and frequenter of the several musical societies before mentioned, and also by a regular concert at his house in Austin Friars, had led him, at the time that he was endeavouring to get together a good library of books, to be particularly solicitous for collecting the works of some of the best musical composers; and, among other acquisitions, it was his singular good fortune to become possessed by purchase of several of the most scarce and valuable theoretical treatises on the science any where extant, which had formerly been collected by Dr Pepusch. With this stock of erudition, therefore, he, about this time, at the instance of some friends, set about procuring materials for a work then very much wanted, a History of the Science and Practice of Music, which he afterwards published.

At the recommendation of the well-known Paul Whitehead, to the Duke of Newcastle, then Lord-lieutenant for Middlesex, his name was, in 1761, inserted in the commission of the peace for that county; and having, by the proper studies, and a sedulous attendance at the sessions, qualified himself for the office, he became an active and useful magistrate in the county (A). Observing, as he had frequent occasion to do in the course of his duty, the bad state of highways, and

(A) When he first began to act, he formed a resolution of taking no fees, not even the legal and authorised ones, and pursued this method for some time, till he found that it was a temptation to litigation, and that every trifling ale-house quarrel produced an application for a warrant. To check this, therefore, he altered his mode, and received his due fees, but kept them separately in a purse; and at the end of every summer, before he left the country for the winter, delivered the whole amount to the clergyman of the parish, to be by him distributed among such of the poor as he judged fit.

Hawkins. and the great defect in the laws for amending and keeping them in repair, he set himself to revise the former statutes, and drew an act of parliament consolidating all the former ones, and adding such other regulations as were necessary. His sentiments on this subject he published in octavo, in 1763, under the title of "Observations on the State of Highways, and on the Laws for amending and keeping them in Repair;" subjoining to them the draught of the act before mentioned; which bill being afterwards introduced into parliament, passed into a law, and is that under which all the highways in England are at this time kept repaired. Of this bill, it is but justice to add, that, in the experience of more than thirty years, it has never required a single amendment.

Johnson, and Sir Joshua, then Mr Reynolds, had, in the winter of this year (1763) projected the establishment of a club to meet every Monday evening at the Turk's Head, in Gerard-street; and, at Johnson's solicitation, Mr Hawkins became one of the first members.

An event of considerable importance engaged him, in the year 1764, to stand forth as the champion of the county of Middlesex, against a claim then for the first time set up, and so enormous in its amount as justly to excite resistance. The city of London finding it necessary to rebuild the gaol of Newgate, the expence of which, according to their own estimates, would amount to L.40,000, had this year applied to parliament, by a bill brought into the House of Commons, in which, on a suggestion that the county prisoners removed to Newgate for a few days previous to their trials at the Old Bailey, were as two to one to the London prisoners constantly confined there, they endeavoured to throw the burthen of two-thirds of the expence on the county, while they themselves proposed to contribute one-third only. This attempt the magistrates for Middlesex thought it their duty to oppose; and accordingly a vigorous opposition to it was commenced and supported under the conduct of Mr Hawkins, who drew a petition against the bill, and a case of the county, which was printed and distributed amongst the members of both houses of parliament. It was the subject of a day's conversation in the House of Lords; and produced such an effect in the House of Commons, that the city, by its own members, moved for leave to withdraw the bill. The success of this opposition, and the abilities and spirit with which it was conducted, naturally attracted towards Mr Hawkins the attention of his fellow-magistrates; and the chairman of the quarter sessions dying not long after, he was, on the 19th day of September 1765, elected his successor.

In the year 1771 he quitted Twickenham, and sold his house there to Mr Vaillant; and in the summer of the next year, for the purpose of obtaining, by searches in the Bodleian and other libraries, farther materials for his history of music, he made a journey to Oxford, carrying with him an engraver from London, to make drawings from the portraits in the music school.

On occasion of actual tumults or expected disturbances, he had more than once been called into service of great personal danger. When the riots at Brentford had arisen, during the time of the Middlesex election in the year 1768, he and some of his brethren attended to suppress them; and, in consequence of an expected riotous assembly of the journeymen Spitalfield weavers in Moorfields in 1769, the magistrates of Middlesex, and he at their head, with a party of guards, attended to oppose them; but the mob, on seeing them prepared, thought it prudent to disperse. In these and other instances, and particularly in his conduct as chairman, having given sufficient proof of his activity, resolution, abilities, integrity, and loyalty, he, on the 23d of October 1772, received from his majesty the honour of knighthood.

In 1773, Dr Johnson and Mr Stevens published, in 10 vols 8vo, their first joint edition of Shakespeare, to which Sir John Hawkins contributed such notes as are distinguished by his name, as he afterwards did a few more on the republication of it in 1778. An address to the king from the county of Middlesex, on occasion of the American war, having, in 1774, been judged expedient, and at his instance voted, he drew up such an address, and, together with two of his brethren, had, in the month of October in that year, the honour of presenting it.

After sixteen years labour, he, in 1776, published, in five volumes quarto, his General History of the Science and Practice of Music; which, in consequence of permission obtained in 1773, he dedicated to the king, and presented it to him at Buckingham House on the 14th of November 1776, when he was honoured with an audience of considerable length both from the king and queen.

Not long after this publication, that is to say in November 1777, he was induced, by an attempt to rob his house, which, though unsuccessful, was made three different nights with the interval of one or two only between each attempt, to quit his house in Hatton-street; and, after a temporary residence for a short time in St James's Place, he took a lease of one, formerly inhabited by the famous Admiral Vernon, in the street leading up to Queen Square, Westminster, and removed thither.

By this removal he became a constant attendant on divine worship at the parish-church of St Margaret, Westminister; and having learnt, in December 1778, that the surveyor to the board of ordnance was, in defiance of a proviso in the lease under which they claimed, carrying up a building at the east end of the church, which was likely to obscure the beautiful painted glass window over the altar there, Sir John Hawkins, with the concurrence of some of the principal inhabitants, wrote to the surveyor, and compelled him to take down two feet of the wall, which he had already carried up above the sill of the window, and to slope off the roof of his building in such a manner, as that it is not only no injury, but, on the contrary, a defence to the window.

In the month of December 1783, Dr Johnson having discovered in himself symptoms of a dropsy, sent for Sir John Hawkins, and telling him the precarious state of his health, declared his desire of making a will, and requested him to be one of his executors. Sir John accepted the office; instructed the Doctor how to make his will; and on his death undertook to be his biographer, and the guardian of his fame, by publishing a complete edition of his works.

Not three months after the commencement of this undertaking, he met with the severest loss of almost any that a literary man can sustain, short of that of his friends or relations, in the destruction, by fire, of his library; consisting of a numerous and well-chosen collection.

Hawkins. lection of books, ancient and modern, in many languages, and on most subjects, which it had been the business of above 30 years at intervals to get together. Of this loss, great as it was in pecuniary value, and comprising in books, prints, and drawings, many articles that could never be replaced, he was never heard in the smallest degree to complain; but having found a temporary reception in a large house in Orchard-street, Westminster, he continued there a short time, and then took a house in the Broad Sanctuary, Westminster.

This event, for a short time, put a stop to the progress of his literary pursuits. As soon, however, as he could sufficiently collect his thoughts, he recommenced his office of biographer of Johnson; and completed his intention by publishing, in 1787, the life and works, in eleven volumes octavo, which he dedicated to the king.

With this production he terminated his literary labours; and having for many years been more particularly sedulous in his attention to the duties of religion, and accustomed to spend all his leisure from other necessary concerns in theological and devotional studies, he now more closely addicted himself to them, and set himself to prepare for that event, which he saw could be at no great distance; and the better to accomplish this end, in the month of May 1788, he, by a will and other proper instruments, made such an arrangement of his affairs as he meant should take place after his decease.

In this manner he spent his time till about the beginning of May 1789, when, finding his appetite fail him in a greater degree than usual, he had recourse, as he had sometimes had before on the same occasion, to the waters of the Islington Spa. These he drank for a few mornings; but on the 14th of that month, while he was there, he was, it is supposed, seized with a paralytic affection, as, on his returning to the carriage which waited for him, his servants perceived a visible alteration in his face. On his arrival at home, he went to bed, but got up a few hours after, intending to receive an old friend, from whom he expected a visit in the evening. At dinner, however, his disorder returning, he was led up to bed, from which he never rose, on the 21st of the same month, about two in the morning, dying of an apoplexy. He was interred on the 28th in the cloisters of Westminster Abbey, in the north walk near the eastern door into the church, under a stone, containing, by his express injunctions, no more than the initials of his name, the date of his death, and his age; leaving behind him a high reputation for abilities and integrity, united with the well-earnt character of an active and resolute magistrate, an affectionate husband and father, a firm and zealous friend, a loyal subject, and a sincere Christian.

Such is the character of him in the Biographical Dictionary, which we have neither right no inclination to controvert. With none of his works are we acquainted but his edition of *Walton's Complete Angler*, and his *Life of Johnson*. The former is a very pleasing book; and in the latter are collected many interesting anecdotes of literature and literary men; but they are not well arranged, and the style of the composition is coarse and slovenly. Sir John, we doubt not, was a man of worth, and his reflections on the sentimental slang of Sterne and others, shew that he had successfully studied human nature; but he certainly was not a man of general taste.

Heat. HEAT. See in this Supplement, CHEMISTRY, Part I. chap. v. where we have endeavoured to establish the modern doctrine respecting *Caloric* or latent heat. In n° 309, &c. of that article, we have given an account of Count Rumford's ingenious experiments, instituted with a view to determine whether or not caloric be a substance, and have stated our reasons for dissenting from his opinion. It has been suggested to us, however, by a friend, to whose judgment we are inclined to pay great deference, that it would be proper, in this place, to give the Count's arguments at full length, and in his own words; and the propriety of this is the more apparent, that in the supplementary article ELECTRICITY, we have hinted our own suspicions of the non-existence of an *electrical fluid*. The Count then reasons from his experiments in the following words:

" By meditating on the results of all these experiments, we are naturally brought to that great question which has so often been the subject of speculation among philosophers, namely, What is heat?—Is there any such thing as an *igneous fluid?*—Is there any thing that can with propriety be called caloric?

" We have seen that a very considerable quantity of heat may be excited in the friction of two metallic surfaces, and given off in a constant stream or flux *in all directions*, without interruption or intermission, and without any signs of diminution or exhaustion.

" From whence came the heat which was continually given off in this manner in the foregoing experiments? Was it furnished by the small particles of metal detached from the larger solid masses on their being rubbed together? This, as we have already seen, could not possibly have been the case.

" Was it furnished by the air? This could not have been the case; for in three of these experiments, the machinery being kept immersed in water, the access of the air of the atmosphere was completely prevented.

" Was it furnished by the water which surrounded the machinery? That this could not have been the case is evident; *first*, because this water was continually *receiving heat* from the machinery, and could not at the same time be *giving to* and *receiving heat from* the same body; and, *secondly*, because there was no chemical decomposition of any part of this water. Had any such decomposition taken place (which indeed could not reasonably have been expected), one of its compound elastic fluids (most probably inflammable air) must at the same time have been set at liberty, and, in making its escape into the atmosphere, would have been detected; but though I frequently examined the water to see if any air bubbles rose up through it, and had even made preparations for catching them, in order to examine them if any should appear, I could perceive none; nor was there any sign of decomposition of any kind whatever, or other chemical process going on in the water.

" Is it possible the heat could have been supplied by means of the iron bar to the end of which the blunt steel borer was fixed? or by the small neck of gun-metal by which the hollow cylinder was united to the cannon? These suppositions appear more improbable even than either of those before mentioned; for heat was continually

continually going off or *out of the machinery*, by both these last passages, during the whole time the experiment lasted.

"And, in reasoning on this subject, we must not forget to consider that most remarkable circumstance, that the source of the heat generated by friction in these experiments appeared evidently to be inexhaustible.

"It is hardly necessary to add, that any thing which any *insulated* body or system of bodies can continue to furnish *without limitation*, cannot possibly be a *material substance*; and it appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of any thing capable of being excited and communicated in the manner the heat was excited and communicated in these experiments, except it be motion.

"But although the mechanism of heat should in fact be one of those mysteries of nature which are beyond the reach of human intelligence, this ought by no means to discourage us, or even lessen our ardour, in our attempts to investigate the laws of its operations. How far can we advance in any of the paths which science has opened to us, before we find ourselves enveloped in those thick mists which on every side bound the horizon of the human intellect? But how ample and interesting is the field that is given us to explore!

"Nobody, surely, in his sober senses has ever pretended to understand the mechanism of gravitation; and yet what sublime discoveries was our immortal Newton enabled to make, merely by the investigation of the laws of its action! The effects produced in the world by the agency of heat are probably *just as extensive* and quite as important, as those which are owing to the tendency of the particles of matter towards each other; and there is no doubt but its operations are in all cases determined by laws equally immutable."

HELENA, or ST HELENA. In addition to the account of this island in the *Encyclopædia*, the following particulars from Sir George Staunton deserve a place in this *Supplement*, because some of them are important in themselves, while others correct one or two mistakes into which we had fallen, by adopting, implicitly, the narrative of Forster.

The circumference of St Helena measures somewhat less than twenty-eight miles. Along the whole coast to leeward, or to the northward, ships may anchor in perfect security in all seasons of the year, but the bank shelves so abruptly afterwards, that the anchorage, being in deep water, is insecure. The tide seldom rises above three feet and a half; but the surge of the sea is sometimes tremendous; and several accidents happened in approaching or quitting the shore, until a wharf was erected lately, which renders the arrival there, and departure from it, perfectly safe. In the immediate neighbourhood of the island, storms are little known, thunder is rarely heard, and lightning is seldom perceived.

The steep eminences which intervene between the valleys, that are the chief seats of population, render the communication from one part of this little spot to another slow and difficult. Planters on the windward side of the island consider a journey to the leeward, or seat of government, as a serious undertaking. Several of them take that opportunity of paying their respects to the governor, which is called there sometimes "going to court." There are St Helena planters who have not travelled so far. At present, by order of the governor, there are signals so placed all over the island, as to give instant notice of the approach of vessels to any part of it.

In the *Encyclopædia*, it is said that peaches are the only European fruits which thrive in St Helena; but this appears to be a mistake. Several sorts of fruit trees imported into the island had been destroyed by a particular insect; but encouragement has been given for the cultivation of those which that mischievous animal is known to spare, such as the apple, for example, with all the varieties of which it is susceptible. The plantain and banana, or the two species of the *musa*, thrive also remarkably well. The ground is fertile, and in favourable seasons produces, in some instances, double crops within the year. Plantations, however, of cotton, indigo, or canes, were not found to answer: though some good coffee has been produced in it. A botanic garden has been established near the governor's country house. An intelligent gardener has been sent to take care of it by the company; and a vast variety of trees, plants, and flowers of different, and sometimes opposite climates, are already collected in it. The surrounding sea abounds in esculent fish; and seventy different species, including turtle, have been caught upon the coasts. Whales are seen in great numbers playing round the island, where it is supposed the southern whale fishery might be carried on to great national advantage.

The country is chiefly cultivated by blacks. Persons of that colour were brought in a state of slavery to it by its first European settlers; and it seldom happens that white men will submit to common work where there are black slaves to whom it may be transferred. These were for a long time under the unlimited dominion of their owners, until a representation of the abuses made of that power induced the India Company to place them under the immediate protection of the magistracy, and to enact various regulations in their favour; which have contributed to render them, in a great degree, confortable and secure. These regulations may have hurt, at first, the feelings of the owners of slaves, but not their real interest; for it appears, that before their introduction there was a loss, upon an average, of about ten in a hundred slaves every year, to be supplied at a very heavy expence; whereas, under the present system, they naturally increase. All future importation of slaves into the island is prohibited.

Besides the blacks in a state of slavery, there are some who are free. The labour of these tending to diminish the value of that of slaves, the free blacks became once obnoxious to some slave owners; who had sufficient influence, in a grand jury, to present them as without visible means of gaining a livelihood, and liable to become burdensome to the community; but upon examination, it appeared that all free blacks of age to work were actually employed; that not one of them had been tried for a crime for several years, nor had any of them been upon the parish. They are now by the humane interposition of the company placed under the immediate protection of the government, and put nearly upon a footing with the other free inhabitants, who, when accused of crimes, have the privilege of a jury, as well as in civil causes.

The principal settlement of St Helena has the peculiar advantage of uniting the shelter of a leeward situation with the coolness of windward gales. The south-east wind blows constantly down the valley, rendering a residence in it pleasant as well as healthy.

The country is so fertile, and the climate so congenial to the human feelings, that perhaps it would be difficult to find out a spot where persons, not having acquired a relish for the enjoyments of the world, or already advanced in life, and surfeited with them, could have a better chance of protracting their days in ease, health, and comfort.

HELICOID PARABOLA, or the *Parabolic Spiral*, is a curve arising from the supposition that the common or Apollonian parabola is bent or twisted, till the axis come into the periphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in the same plane.

HELISPHERICAL LINE, is the Rhumb line in Navigation; being so called, because on the globe it winds round the pole helically or spirally, coming still nearer and nearer to it.

HENIOCHAS, or HENIOCHUS, a northern constellation, the same as Auriga, which see *Encycl.*

HERSCHEL, the name by which the French, and most other European nations, call the new planet discovered by Dr Herschel in the year 1781. Its mark or character is ♅. The Italians call it Ouranos, or Urania; but the English, the Georgian Planet, or Georgium Sidus.

HETERODROMUS VECTIS, or LEVER, in Mechanics, a lever in which the fulcrum, or point of suspension, is between the weight and the power; being the same as what is otherwise called a lever of the first kind.

HINZUAN, the proper name of one of the Comora islands, which by different writers of different nations has been called *Anzuame*, *Anjuan*, *Juanny*, and *Johanna*, and which is described in the *Encyclopædia* under the name of ST JOANNA. In that article, it is observed, that an anonymous writer has censured the descriptions of this island given by the Abbé Reynal and Major Rooke, as being not only exaggerated, but erroneous; neither the country being so picturesque as the former represents it, nor the inhabitants meriting the respectable character given of them by the latter.

There was not perhaps much propriety in admitting into such a work as the *Encyclopædia Britannica*, the anonymous censure of descriptions, authenticated by the names of respectable authors; but the best reparation which we can make to those authors is, to inform our readers, that their descriptions of Hinzuan are confirmed by Sir William Jones, whose testimony, we believe, no man will controvert. That accomplished scholar, who visited the island on his voyage to India, thus describes its appearance from the bay in which the ship rode at anchor.

"Before us was a vast amphitheatre, of which you may form a general notion by picturing in your minds a multitude of hills infinitely varied in size and figure, and then supposing them to be thrown together, with a kind of artless symmetry, in all imaginable positions. The back ground was a series of mountains, one of which is pointed, near half a mile perpendicularly high from the level of the sea, and little more than three miles from the shore: all of them richly clothed with wood, chiefly fruit trees, of an exquisite verdure. I had seen many a mountain of stupendous height in Wales and Swisserland, but never saw one before, round the bosom of which the clouds were almost continually rolling, whiles it green summit rose flourishing above them, and received from them an additional brightness. Next to this distant range of hills was another tier, part of which appeared charmingly verdant, and part rather barren; but the contrast of colours changed even this nakedness into a beauty: nearer still were innumerable mountains, or rather cliffs, which brought down their verdure and fertility quite to the beach; so that every shade of green, the sweetest of colours, was displayed at one view by land and by water. But nothing conduced more to the variety of this enchanting prospect, than the many rows of palm trees, especially the tall and graceful *Arecas*, on the shores, in the valleys, and on the ridges of hills, where one might almost suppose them to have been planted regularly by design. A more beautiful appearance can scarce be conceived, than such a number of elegant palms in such a situation, with luxuriant tops, like verdant plumes, placed at just intervals, and showing between them part of the remoter landscape, while they left the rest to be supplied by the beholder's imagination. The town of *Matsamúdò* lay on our left, remarkable at a distance for the tower of the principal mosque, which was built by Halímah, a queen of the island, from whom the present king is descended: a little on our right was a small town, called *Bantáni*. Neither the territory of *Nice*, with its olives, date trees, and cypresses, nor the isles of *Hieres*, with their delightful orange groves, appeared so charming to me as the view from the road of *Hinzúàn*."

Sir William Jones, speaking of the inhabitants, takes notice of the *Lords*, *Dukes*, and *Princes*, of whom we have made mention after Major Rooke. "The frigate, (says he) was presently surrounded with canoes, and the deck soon crowded with natives of all ranks, from the high born chief, who washed linen, to the half-naked slave, who only paddled. Most of them had letters of recommendation from Englishmen, which none of them were able to read, though they spoke English intelligibly; and some appeared vain of titles, which our countrymen gave them in play, according to their supposed stations: we had *Lords*, *Dukes*, and *Princes*, on board, soliciting our custom, and importuning us for presents. In fact, they were too sensible to be proud of empty sounds, but justly imagined, that those ridiculous titles would serve as marks of distinction, and, by attracting notice, procure for them something substantial." He speaks with great respect of the king, whose name was *Ahmed*, as well as of several chiefs whom he saw, and seems to have met with no man of rank on the island whose character was contemptible, but Selim the king's eldest son. For the behaviour of that prince, the old sovereign made the best apology that he could, while he privately assured the interpreter, that he was much displeased with it, and would not fail to express his displeasure. He concluded his conversation with a long harangue on the advantage which the English might derive from sending a ship every year from Bombay to trade with his subjects, and on the wonderful cheapness of their commodities, especially of their cowries. Ridiculous as this idea might seem, it showed (says Sir William) an enlargement of mind, a desire of promoting the interest of his people, and a sense of the benefits arising from trade, which could hardly have been expected from a petty African chief, and which, if he had been sovereign of Yemen, might have been expanded into rational projects proportioned to the extent of his dominions.

The

The master of the frigate learned from one of the chiefs a few curious circumstances concerning the government of *Hinzuan;* which he found to be a monarchy limited by an aristocracy. The king, he was told, had no power of making war by his own authority; but if the assembly of nobles, who were from time to time convened by him, resolved on a war with any of the neighbouring islands, they defrayed the charges of it by voluntary contributions; in return for which, they claimed as their own all the booty and captives that might be taken. The hope of gain or the want of slaves is usually the real motive for such enterprises, and ostensible pretexts are easily found: at that very time, he understood they meditated a war, because they wanted hands for the following harvest. Their fleet consisted of sixteen or seventeen small vessels, which they manned with about two thousand five hundred islanders, armed with muskets and cutlasses, or with bows and arrows. Near two years before they had possessed themselves of two towns in *Mayáta*, which they still kept and garrisoned. The ordinary expences of the government were defrayed by a tax from two hundred villages; but the three principal towns were exempt from all taxes, except that they paid annually to the chief *Mufti* a fortieth part of the value of all their moveable property; and from that payment neither the king nor the nobles claimed an exemption. The kingly authority, by the principles of their constitution, was considered as elective, though the line of succession had not in fact been altered since the first election of a sultan.

Sir William Jones concludes his remarks on this island with some reflections; of which, though they may be considered as digressive, we are persuaded our readers will approve of our extending the circulation.

"We have lately heard of civil commotions in *Hinzuan*, which, we may venture to pronounce, were not excited by any cruelty or violence of Ahmed, but were probably occasioned by the insolence of an oligarchy naturally hostile to king and people. That the mountains in the *Comara* islands contain diamonds, and the precious metals, which are studiously concealed by the policy of the several governments, may be true, though I have no reason to believe it, and have only heard it asserted without evidence; but I hope, that neither an expectation of such treasures, nor of any other advantage, will ever induce an European power to violate the first principles of justice by assuming the sovereignty of *Hinzuan*, which cannot answer a better purpose than that of supplying our fleets with seasonable refreshment; and although the natives have an interest in receiving us with apparent cordiality, yet if we wish their attachment to be unfeigned and their dealings just, we must set them an example of strict honesty in the performance of our engagements. In truth, our nation is not cordially loved by the inhabitants of *Hinzuan*, who, as it commonly happens, form a general opinion from a few instances of violence or breach of faith. Not many years ago an European, who had been hospitably received and liberally supported at *Matsamudo*, behaved rudely to a young married woman, who, being of low degree, was walking veiled through a street in the evening; her husband ran to protect her, and resented the rudeness, probably with menaces, possibly with actual force; and the European is said to have given him a mortal wound with a knife or bayonet, which he brought, after the scuffle, from his lodging. This foul murder, which the law of nature would have justified the magistrate in punishing with death, was reported to the king, who told the governor (I use the very words of Alwi, a cousin of the king's), that "it would be wiser to hush it up." Alwi mentioned a civil case of his own, which ought not to be concealed. When he was on the coast of Africa in the dominions of a very savage prince, a small European vessel was wrecked; and the prince not only seized all that could be saved from the wreck, but claimed the captain and the crew as his slaves, and treated them with ferocious insolence. Alwi assured me, that, when he heard of the accident, he hastened to the prince, fell prostrate before him, and by tears and importunity prevailed on him to give the Europeans their liberty; that he supported them at his own expence, enabled them to build another vessel, in which they sailed to *Hinzuan*, and departed thence for Europe or India: he shewed me the captain's promissory notes for sums, which to an African trader must be a considerable object, but which were no price for liberty, safety, and, perhaps, life, which his good, though disinterested, offices had procured. I lamented that, in my situation, it was wholly out of my power to assist Alwi in obtaining justice; but he urged me to deliver an *Arabic* letter from him, inclosing the notes, to the governor general, who, as he said, knew him well; and I complied with his request. Since it is possible, that a substantial defence may be made by the person thus accused of injustice, I will not name either him or the vessel which he had commanded; but, if he be living, and if this paper should fall into his hands, he may be induced to reflect how highly it imports our national honour, that a people, whom we call savage, but who administer to our convenience, may have no just cause to reproach us with a violation of our contracts."

HIPS, in architecture, are those pieces of timber placed at the corners of a roof. These are much longer than the rafters, because of their oblique position. Hip means also the angle formed by two parts of the roof, when it rises outwards.

Hip-Roof, called also Italian roof, is one in which two parts of the roof meet in an angle, rising outwards: the same angle being called a valley, when it sinks inwards.

HIRCUS, in astronomy, a fixed star of the first magnitude, the same with capella.

Hircus is also used by some writers for a comet, encompassed as it were with a mane, seemingly rough and hairy.

HIRUDO. See *Encycl.* A new species of this insect was discovered in the South Sea by Le Martiniere, naturalist in Perouse's voyage of discovery. He found it buried about half an inch in a shark's liver, but could not conceive how it had got thither. It was something more than an inch long, of a whitish colour, and composed of several rings similar to those of the tænia. The superior part of its head was furnished with four small ciliated mamillæ, by which it took its food; under each mamilla on both sides was a small oblong pouch, in the form of a cup; and in the form of its *instrumenta cibaria*, it very nearly resembles the animal which has been supposed to be the cause of measles in swine. Both these species are referable to the genus *hirudo*, the characters of which, as given by Linnæus, stand (says Martiniere) in need of reformation.

Hirundo, Hispaniola.

HIRUNDO Esculenta (see Hirundo, *Encycl.* nº 3.), is thus described in the *Transactions of the Batavian Society in the Island of Java*, vol. iii. ; and the description confirms the sagacious conjecture of Mr Latham respecting the size of the bird, which the reader will find in our article referred to.

" The hirundo esculenta is of a blackish grey colour, inclining a little to green ; but on the back to the tail, as well as on the belly, this blackish colour gradually changes into a mouse colour. The whole length of the bird from the bill to the tail is about four inches and a half, and its height from the bill to the extremity of the middle toe three inches and a quarter. The distance from the tip of the one wing to that of the other, when extended, is ten inches and a quarter. The largest feathers of the wings are about four inches in length. The head is flat ; but, on account of the thickness of the feathers, appears round, and to be of a large size in proportion to the rest of the body. The bill is broad, and ends in a sharp extremity, bent downwards in the form of an awl. The width of it is increased by a naked piece of skin, somewhat like parchment, which, when the bill is shut, lies folded together ; but which, when the bill opens, is considerably extended, and enables the bird to catch with greater ease, while on wing, the insects that serve it for food. The eyes are black, and of a considerable size. The tongue, which is not forked, is shaped like an arrow. The ears are flat, round, naked spots, with small oblong openings, and are entirely concealed under the feathers of the head. The neck is very short, as well as the legs and the bones of the wings. The thighs are wholly covered with feathers ; and the very tender lower parts of the legs, and the feet themselves, are covered with a skin like black parchment. Each foot has four toes, three of which are before and one turned backwards. They are all detached from each other to the roots ; and the middle one, together with the claw, is fully as long as the lower part of the leg. Each toe is furnished with a black, sharp, crooked claw of a considerable length, by which the animal can with great facility attach itself to crags and rocks. The tail is fully as long as the body together with the neck and the head. When expanded it has the form of a wedge, and consists of ten large feathers. The four first on each side are long ; and, when the tail is closed, extend almost an inch beyond the rest. The other feathers decrease towards the middle of the tail, and are equal to about the length of the body."

There is a variety of this species of hirundo, with a speckled breast, and white spots on the tail feathers ; and this, though less numerous than the other, and indeed not found at all in Java, appears to have been the only hirundo esculenta known to Linnæus. For an account of the eatable nests of these birds, and the manner of collecting them, see Cap and Button in this *Supplement*.

HISPANIOLA, or St Domingo, the largest of the Antilles or Caribbee islands, has been described, as it existed prior to the French revolution, in the *Encyclopædia*. Previous to the year 1789 the government of the French part of the island was administered by an officer called the Intendant, and a Governor-General, both nominated by the crown, and invested with authority for three years. Their powers were in some cases distinct, and in others united; but though these powers were extensive and almost absolute, the attention which the old government of France paid to the character and rank of those persons whom it had placed over its foreign settlements, secured to the inhabitants of Hispaniola a very considerable share of happiness. In spite of what our restless innovators call political evils, signs of prosperity were everywhere visible; their towns were opulent, their markets plentiful, their commerce extensive, and their cultivation increasing.

Such was, in 1788, the state of the French colony, in the island of St Domingo; but in that eventful year, the flame, which had burst forth in Europe, spread itself to the West Indies. An association had been formed in France upon principles somewhat similar to those of our society for the abolition of the slave trade ; but that association, which called itself *Amis des Noirs*, had much more dangerous designs than ours. Avowing its detestation of every kind of slavery, as well as of the African trade, and condemning those abettors of liberty who dared to declare themselves possessors of men, its members kept up an intimate and clandestine connection with those rich mulattoes who resided in France for their education, and laboured to convince them that neither their colour nor their *spurious birth* should make any civil or political distinction between them and the whites who were born in *wedlock*. To co-operate, as it were, with these factious and false doctrines, the National Assembly issued its famous declaration, in which it was maintained that all mankind are born, and continue free, and equal in their rights. The consequence of this was such as might have been expected. The mulattoes of Hispaniola, instructed in the French philosophy of the rights of man, broke out into rebellion; but not acting in concert, they were quickly overpowered.

The spirit, however, which had been excited among them, still continued to ferment ; and the National Assembly of France, taking the state of the island into solemn consideration, decreed, by a great majority, that its intention had never been to intermeddle with the internal affairs of the colony ; that their internal legislation was entirely their own ; and that the legislature of the mother country would make no innovation, directly or indirectly, in the system of commerce in which the colonies were already concerned. However grateful this declaration might be to the whites of St Domingo, and in the then state of things however wise in itself, it occasioned discontent and remonstrances on the part of the factious friends of the negroes. They regarded it as an unwarrantable sanction of the African traffic, and a confession that the planters of Hispaniola were not colonists, but an independent people.

The colonists themselves, indeed, or rather their representatives, seem to have thought that by this decree they were rendered independent ; for in their general assembly they passed an act debarring the king's delegate, the governor-general, from negativing any of their future acts. This violent measure was far from giving universal satisfaction. The western parishes recalled their delegates, while those of Cape François renounced their obedience to the whole assembly, and petitioned the governor to dissolve it.

During these dissensions, the commander of a ship of the line, which lay in the harbour of Port-au-Prince, gave a sumptuous entertainment to the friends of the governor ; on which account the seamen, who declared themselves in the interest of the assembly, thought fit to mutiny ;

Hiſpaniola mutiny; and the aſſembly, in return, voted their thanks to the mutineers. Some of their partizans, ſeizing at the ſame time a powder magazine, the governor declared them adherents to traitors, and called on all officers, civil and military, to bring them to puniſhment. This was the ſignal for civil inſurrection; armed troops took the field on both ſides; and war ſeemed inevitable, when the aſſembly reſolved to repair in a body to France, and juſtify their paſt conduct.

In the mean time the *Amis des Noirs* contrived to excite the people of colour to rebellion. They initiated in the doctrine of equality and the rights of man one James Oge, then reſiding in Paris in ſome degree of affluence. They perſuaded him to go to St Domingo, put himſelf at the head of his people, and deliver them from the oppreſſion of the whites; and in order to evade the notice of government, they undertook to procure for him arms and ammunition in America. He embarked accordingly, July 1790, for New England with money and letters of credit; but notwithſtanding the caution of the *Amis des Noirs*, his deſigns were diſcovered by the French government, and his portrait was ſent out before him to St Domingo. He landed on the iſland in October, and ſix weeks afterwards publiſhed a manifeſto, declaring his intention of taking up arms, if the privileges of whites were not granted to *all perſons without diſtinction*. He was joined by about 200 men of colour; and this little army of ruffians not only maſſacred the whites wherever they fell in with them in ſmall numbers, but, by a ſtill more unjuſtifiable mode of conduct, took vengeance on thoſe of their own colour who refuſed to join their rebellious ſtandard. They were, however, ſoon overpowered by the regular troops; and their leader, after diſcloſing, it is ſaid, ſome important ſecrets, ſuffered the puniſhment due to his treaſon.

While theſe things were going on in the iſland, the members of the Colonial Aſſembly arrived at Paris, where they were received by the repreſentatives of the French people with marked ſymptoms of averſion. The reſolutions compoſing their famous decree were pronounced improper; their vote of thanks to the mutineers was declared criminal; they were themſelves perſonally arreſted; orders were given for a new aſſembly to be called; and the king was requeſted to augment the naval and military force then at St Domingo.

The National Aſſembly of France having decreed that every perſon twenty-five years old and upwards, poſſeſſing property, or having reſided two years in the colony and paid taxes, ſhould be permitted to vote in the formation of the colonial aſſembly, the people of colour very naturally concluded that this privilege was conferred upon them. Such, however, we believe, was not the meaning of the National Aſſembly; but Gregoire, with the other friends of the negroes, at laſt prevailed, and mulattoes born of free parents were pronounced to be not only worthy of chooſing their repreſentatives, but alſo eligible themſelves to ſeats in the colonial aſſemblies. This decree ſacrificed at once all the whites in the iſland to the people of colour; and the indignation which filled the minds of both the royal and the republican parties ſeemed to have united them in one common cauſe. They reſolved to reject the civic oath; to confiſcate the French property in the harbour, on which they actually laid an embargo; to pull down the national colours, and to hoiſt the Britiſh ſtandard in their ſtead. The mulattoes in the mean time collected in armed bodies, and waited with anxious expectation to ſee what meaſures the colonial aſſembly would adopt. Hiſpaniola.

During theſe diſſenſions, the negro ſlaves, into whoſe minds had been ſeduloufly inſtilled an opinion that their rights were equal to thoſe of their maſters, reſolved to recover their freedom. On the morning of the 23d of Auguſt 1791, the town of the Cape was alarmed by a confuſed report that the ſlaves in the adjoining pariſhes had revolted; and the tidings were ſoon confirmed by the arrival of thoſe who had narrowly eſcaped the maſſacre. The rebellion had broken out in the pariſh of Acul, nine miles from the city, where the whites had been butchered without diſtinction; and now the rebels proceeded from pariſh to pariſh, murdering the men, and raviſhing the unfortunate women who fell into their hands. In a ſhort time the ſword was accompanied with fire, and the cane-fields blazed in every direction. The citizens now flew to arms, and the command of the national troops was given to the governor, whilſt the women and children were put aboard the ſhips in the harbour for ſafety. In the firſt action the rebels were repulſed; but their numbers rapidly increaſing, the governor judged it expedient to act ſolely on the defenſive. In the ſpace of two months it was computed that upwards of 2000 white perſons periſhed; and of the inſurgents, who conſiſted as well of mulattoes as of negroes, not fewer than 10,000 died by famine and the ſword, and hundreds by the hands of the executioner.

When intelligence of theſe dreadful proceedings reached Paris, the Aſſembly began to be convinced that its equaliſing principles had been carried too far; and the famous decree, which put the people of colour on the ſame footing with the whites, was repealed. Three commiſſioners were likewiſe ſent to the colony to reſtore peace between the whites and the mulattoes; but two of them being men of bad character, and none of them poſſeſſing abilities for the arduous taſk of extinguiſhing the flames of a civil war, they returned to France without accompliſhing in any degree the object of their miſſion.

In the mean time the *Amis des Noirs* in the mother country had once more gained the aſcendant in the National Aſſembly; and three new commiſſioners, Santhonax, Polverel, and Ailhaud, with 6000 choſen men from the national guards, were embarked for St Domingo. It was ſtrongly ſuſpected that the object of theſe commiſſioners was to procure unqualified freedom for all the blacks in the iſland; but they ſolemnly ſwore that their ſole purpoſe was to eſtabliſh the rights of the mulattoes, as decreed by the law which had been lately repealed. The whites therefore expected that a colonial aſſembly would be convoked; but inſtead of this the commiſſioners nominated twelve perſons, of whom ſix had been members of the laſt aſſembly, and ſix were mulattoes, *Une Commiſſion Intermediaire*, with authority to raiſe contributions on the inhabitants, the application of which, however, they reſerved to themſelves. The governor finding that the commiſſioners uſurped all authority, complained that he was but a cypher in public affairs; his complaint was anſwered by an arreſt upon his perſon, and he was ſent a ſtate priſoner to France.

The tyranny of the commiſſioners did not ſtop here. They overawed the members of the commiſſion *intermediaire*, by arreſting four of their number; and diſagreeing among themſelves, Santhonax and Polverel diſmiſſed Ailhaud from their councils. War was by this time declared

declared between the mother country and Great Britain, and prudence compelled the government of France to take ſome care of the injured colony. Galbaud, therefore, a man of fair character, was appointed governor, and ordered to put the iſland in a ſtate of defence againſt foreign invaſion; but poſſeſſing Weſt India property, which it ſeems was a legal diſqualification for the office of governor, the commiſſioners diſregarded his authority, and took up arms againſt him. Finding themſelves likely to be worſted, they offered to purchaſe the aid of the rebel negroes, by the offer of a pardon for their paſt conduct, freedom in future, and the plunder of the capital. Two of the negro chiefs, more honourable than the French commiſſioners, ſpurned at the baſe propoſal; but a third, after the governor had fled to the ſhips, entered the town with 3000 revolted negroes, and began an indiſcriminate maſſacre. The miſerable inhabitants fled to the ſhore, but their retreat was ſtopped by a party of mulattoes; and for two days the ſlaughter was inceſſant. The town was half conſumed by fire; and the commiſſioners, terrified at the work of their own hands, fled for protection to a ſhip of the line, and thence iſſued a manifeſto, which, while it tried to extenuate, evinced a conſciouſneſs of their guilt.

Thus was loſt the fineſt iſland in the Weſt Indies; an iſland which produced alone as much ſugar as all the Britiſh Weſt India poſſeſſions united; not to mention the coffee and indigo, which were in immenſe quantities cultivated in Hiſpaniola. Had it not been for the reſtleſs machinations of the *Amis des Noirs*, it does not appear that ſo general a revolt would have taken place among the ſlaves; for though the ſpirit of republicaniſm had found its way into the iſland, the republicans joined with the royaliſts to keep the negroes in proper ſubjection. The unſucceſsful attempt which, at the requeſt of the more reſpectable part of the inhabitants, the Britiſh government made to ſubdue the execrable commiſſioners and their adherents, is freſh in the memory of all our readers, and need not here be detailed at length. Suffice it to ſay, that after prodigies of valour, our troops were compelled, rather by diſeaſe than by the ſwords of the enemy, to abandon the iſland. Touſſaint L'Ouverture, a black chief, converted it into an independent republic, and continued to govern it undiſturbed, till the preliminaries of peace were ſigned between Britain and France in 1801. Immediately after that event, Bonaparte diſpatched a fleet from Breſt, with the permiſſion of our government, carrying a conſiderable army under the command of general Le Clerc. Touſſaint at firſt refuſed to ſubmit. Several bloody actions were fought between the French troops and the blacks, in which the former were uniformly ſucceſsful. The open country was ſoon abandoned by the negroes: ſeveral of Touſſaint's generals ſubmitted; and at laſt he himſelf was prevailed upon, by the addreſs and the magnificent promiſes of Le Clerc, not only to throw down his arms, but to put himſelf into the power of the French general. For ſome days theſe promiſes were religiouſly obſerved; but a pretence was ſoon found for breaking them. Touſſaint was ſtript of his immenſe property, and ſent priſoner to France. Thus was the colony recovered to France in a ſtill ſhorter time than it had been loſt. Since that event, nothing has tranſpired concerning the ſtate of the iſland, or the regulations which the French find it neceſſary to make. But it is obvious, that a conſiderable period muſt elapſe before it can be reſtored to that ſtate of proſperity which it formerly enjoyed.

HOLLOW, in architecture, a concave moulding, about a quarter of a circle, by ſome called a caſement, by others an abacus.

Hollow-Tower, in fortification, is a rounding made of the remainder of two briſures, to join the curtain to the orillon, where the ſmall ſhot are played, that they may not be ſo much expoſed to the view of the enemy.

HOMODROMUS Vectis, or *Lever*, in mechanics, is a lever in which the weight and power are both on the ſame ſide of the fulcrum as in the lever of the 2d and 3d kind; being ſo called, becauſe here the weight and power move both in the ſame direction, whereas in the heterodromus they move in oppoſite directions.

HOOKE (Dr Robert) is ſaid, in the account of him which is publiſhed in the *Encyclopædia*, to have laid claim to the inventions of others, and to have boaſted of many of his own, which he never communicated. We will not preſume to ſay that this charge is entirely groundleſs; but we know that it has been greatly exaggerated, and that many diſcoveries undoubtedly made by him have been claimed by others. Of this the reader will find one conſpicuous proof under the article Watch (*Encycl.*); and perhaps the following hiſtory of the inventions to which he laid claim may furniſh another. It would be harſh to charge him with falſity in any of them; that is to ſay, to imagine that he either ſtole them from others, or did not *think*, at leaſt, that he was *an* inventor. And, with reſpect to many of them, the priority of his claim is beyond diſpute.

1656, Barometer, a weather glaſs.

1657, A ſcapement, for maintaining the vibration of a pendulum.—And not long after, the regulating or balance ſpring for watches.

1658, The double barrelled air-pump.——The conical pendulum.—His firſt employment of the conical pendulum was no leſs ingenious and ſcientific than it was original. He employed it to repreſent the mutual gravitation of the planets; a fact which he had moſt ſyſtematically announced. He had ſhewn that a force, perfectly analogous to gravity on this earth, operated on the ſurface of the moon and of Jupiter. Conſidering the numerous round pits on the ſurface of the moon, ſurrounded with a ſort of wall, and having a little eminence in the middle, as the production of volcanoes, he inferred, that the ejected matter fell back again to the moon, as ſuch matter falls back again to the earth. He ſaw Jupiter ſurrounded with an atmoſphere, which accompanied him; and therefore preſſed on him, as our air preſſes on the earth:—He inferred, that it was the ſame kind of power that maintained the ſun and other planets in a round form. He inferred a force to the ſun from the circulation round him, and he called it a *gravitation;* and ſaid that it was not the earth which deſcribed the ellipſe, but the centre of gravity of the earth and moon. He therefore made a conical pendulum, whoſe tendency to a vertical poſition repreſented the gravitation to the ſun, and which was projected at right angles to the vertical plane; and ſhewed experimentally, how the different proportions of the projectile and centripetal tendencies produced various degrees of eccentricity in the orbit. He then added another pendulum, deſcribing a cone round the firſt, while this deſcribed a cone round the vertical line, in order to ſee what point between them deſcribed the ellipſe.

Hooke. ellipse. The results of the experiment were intricate and unsatisfactory; but the thought was ingenious. He candidly acknowledged, that he had not discovered the true law of gravitation which would produce the description of an ellipse *round the focus*, owing to his want of due mathematical knowledge; and therefore left this investigation to his superiors. Sir Isaac Newton was the happy man who made the discovery, after having entertained the same notions of the forces which connected the bodies of the solar system, before he had any acquaintance with Dr Hooke, or knew of his speculations.

1660, The engine for cutting clock and watch wheels. —The chief phenomena of capillary attraction.—The freezing of water at a fixed temperature.

1663, The method of supplying air to a diving bell. —The number of vibrations made by a musical chord.

1664, His Micrographia was, by the council of the Royal Society, ordered to be printed; but in that work are many just notions respecting respiration, the composition of the atmosphere, and the nature of light, which were afterwards attributed as discoveries to Mayow and others, who, though we are far from supposing that they stole their discoveries from Dr Hooke, were certainly anticipated by him.

1666, A quadrant by reflection.

1667, The marine barometer.—The gage for sounding unfathomable depths.

1668, The measurement of a degree of the meridian, with a view to determine the figure of the earth, by means of a zenith sector.

1669, The fact of the *conservatio virium vivarum*, and that in all the productions and extinctions of motion, the accumulated forces were as the squares of the final or initial velocities. This doctrine he announces in all its generality and importance, deducing from it all the consequences which John Bernoulli values himself so highly upon, and which are the chief facts adduced by Leibnitz in support of his doctrine of the forces of bodies in motion. But Hooke was perfectly aware of their entire correspondence with the Cartesian, or common doctrine, and was one of the first in applying the celebrated 39th proposition of Newton's Principia to his former positions on this subject, as a mathematical demonstration of them.

1673, That the catenaria was the best form of an arch.

1674, Steam engine on Newcomen's principle.

1679, That the air was the sole source of heat in burning: That combustion is the solution of the inflammable vapour in air; and that in this solution the air gives out its heat and light. That nitre explodes and causes bodies to burn without air, because it consists of this air, accompanied by its heat and light in a condensed or solid state; and air supports flame, because it contains the same ingredients that gunpowder doth, that is, a nitrous spirit: That this air dissolves something in the blood while it is exposed to it in the lungs in a very expanded surface, and when saturated with it, can no longer support life nor flame; but in the act of solution, it produces animal heat: That the arterial and venal blood differ on account of this something being wanting in one of them. In short, the fundamental doctrines of modern chemistry are systematically delivered by Dr Hooke in his Micrographia, published in 1664, and his Lampas, published in 1677.

1680, He first observed the secondary vibrations of elastic bodies, and their connection with harmonic sounds. A glass containing water, and excited by a fiddlestick, threw the water into undulations, which were square, hexagonal, octagonal, &c. shewing that it made vibrations subordinate to the total vibration; and that the fundamental sound was accompanied by its octave, its twelfth, &c. Horne.

1681, He exhibited musical tones by means of toothed wheels, whirled round and rubbed with a quill, which dropped from tooth to tooth, and produced tones proportioned to the frequency of the cracks or snaps.

1684, He read a paper before the Royal Society, in which he affirms, that some years before that period, he had proposed a method of discoursing at a distance, not by sound, but by sight. He then proceeds to describe a very accurate and complete telegraph, equal, perhaps, in all respects to those now in use. But some years previous to 1684, M. Amontans had not invented his telegraph; so that, though the Marquis of Worcester unquestionably gave the first hint of this instrument, Dr Hooke appears to have first brought it to perfection. See TELEGRAPH, *Encycl.*; and a book, published 1726, entitled *Philosophical Experiments and Observations* of the late eminent Dr Robert Hooke.

We are indebted to him for many other discoveries of lesser note; such as the wheel barometer, the universal joint, the manometer, screw divided quadrant, telescopic sights for astronomical instruments, representation of a muscular fibre by a chain of bladders, experiments shewing the inflection of light, and its attraction for solid bodies, the curvilineal path of light thro' the atmosphere.

HORNE (George, D. D.), late Lord Bishop of Norwich, was a man of such amiable dispositions, primitive piety, and exemplary morals, that we wish it were in our power to do justice to his character. His life, it is true, has been already written, at considerable length, by two authors, possessed of erudition and of unquestionable integrity; but mere erudition is by no means sufficient to fit a man for discharging the duties of a biographer. It was not the learning of Johnson, but his sagacity, and intimate acquaintance with human nature, that placed him so far above his contemporaries in this department of literature.

Of Bishop Horne's biographers, one possessed, indeed, the great advantage of having lived in habits of intimacy with him from his boyish years. In the authenticity of his narrative, therefore, the fullest confidence may be placed: and that narrative we shall faithfully follow; reserving, however, to ourselves the liberty of sometimes making reflections on the various incidents recorded, widely different from those of the author.

George Horne was, in 1730, born at Otham in Kent, a village near Maidstone, giving the name to a parish, of which his father was the rector. He was the second of four sons; of whom the eldest died in very early life, and the youngest, who is still alive, succeeded his father both in the rectory of Otham and in that of Breda in the county of Sussex. He had likewise three sisters, of whose fortunes we know nothing.

Mr Horne, the father of the family, was of a temper so remarkably averse from giving pain or trouble upon any occasion, that he used to awake his son George, when an infant, by playing upon a flute, that the change from ſleeping to awaking might be gradual and pleaſant. Having been for ſome years a tutor at Oxford, he took upon himſelf the early part of the claſſical education of this favourite ſon; an office of which he was well qualified to diſcharge the duties. Uunder ſuch an inſtructor, the ſubject of this memoir led a very pleaſant life, and made a rapid progreſs in the Greek and Latin languages. By the perſuaſion of a friend, however, he was, at the age of thirteen, placed in the ſchool of Maidſtone, then under the care of a Mr Bye, eminent for his knowledge of ancient literature. And remaining with this gentleman two years, he added much to his ſtock of learning; and, among other things, a little elementary knowledge of the Hebrew tongue, which Mr Bye taught on the plan of Buxtorf. Though Dr Horne afterwards rejected that plan, he readily admitted, that the knowledge of it was of great advantage to him.

At the age of fifteen, he was removed from Maidſtone ſchool to Univerſity college Oxford, where his father had happily obtained for him a ſcholarſhip. At college his ſtudies were, in general, the ſame with thoſe of other virtuous and ingenious youths; while the vivacity of his converſation, and the propriety of his conduct, endeared him to all whoſe regard was creditable. About the time of his taking his bachelor's degree, he was choſen a fellow of Magdalen College; and ſoon afterwards, if not before, commenced author.

The hiſtory of his authorſhip is curious, and we ſhall give it at ſome length. While he was deeply engaged in the ſtudy of oratory, poetry, and every branch of polite literature, he was initiated by his faithful friend Mr Jones in the myſteries of Hutchinſonianiſm; but Mr Jones was not his preceptor. Indeed that gentleman informs us, that when he firſt communicated to Mr Horne the novelties with which his own mind was filled, he found his friend very little inclined to conſider them; and had the mortification to ſee, that he was himſelf loſing ground in Mr Horne's eſteem, even for making the attempt to convert him. At this we are not to be much ſurpriſed. Mr Horne, though, by his biographer's account, no deep Newtonian, ſaw, or thought he ſaw, the neceſſity of a *vacuum* to the poſſibility of *motion*; and as we believe that every man, who knows the meaning of the words *motion* and *vacuum*, and whoſe mind is not biaſſed in favour of a ſyſtem, ſees the ſame thing, it was not to be ſuppoſed, that a youth of ſound judgment would haſtily relinquiſh ſo natural a notion. By Mr Horne, however, it was at length relinquiſhed. Mr Jones introduced him to Mr George Watſon, a fellow of Univerſity college, whom he repreſents as a man of very ſuperior accompliſhments; and by Mr Watſon Mr Horne was made a Hutchinſonian of ſuch zeal, that at the age of nineteen, he implicitly adopted the wild opinion of the author of that ſyſtem, that Newton and Clarke had formed the deſign of bringing the Heathen *Jupiter*, or Stoical *anima mundi*, into the place of the God of the univerſe. With ſuch a conviction impreſſed upon his mind, it is not wonderful that he ſhould endeavour to diſcredit the ſyſtem of Newton. This he attempted, by publiſhing a parallel between that ſyſtem and the Heathen doctrines in the *Somnium Scipionis* of Cicero. That publication, which was anonymous, we have never ſeen; but Mr Jones himſelf admits it to have been exceptionable; and the able author ſeems to have been of the ſame opinion, for he never republiſhed it, nor, we believe, replied to the anſwers which it provoked.

He did not, however, deſert the cauſe, but publiſhed, ſoon afterwards, a mild and ſerious pamphlet, which he called *A Fair, Candid, and Impartial State of the Caſe between Sir Iſaac Newton and Mr Hutchinſon*. Even of this pamphlet we have not been able to procure a ſight; but Mr Jones aſſures us, that the author allows to Sir Iſaac the great merit of having ſettled laws and rules in natural philoſophy, and of having meaſured *forces* as a mathematician with ſovereign ſkill; whilſt he claims for Mr Hutchinſon the diſcovery of the true phyſiological cauſes, by which, under the power of the Creator, the natural world is moved and directed.

If this be a fair view of *the ſtate of the caſe*, it allows to Newton more than ever Newton claimed, or has been claimed for him by his fondeſt admirers; for the laws and rules, which he ſo faithfully followed in the ſtudy of philoſophy, were not ſettled by him, but by the illuſtrious Bacon. With reſpect to the *true* cauſes here mentioned, we have repeatedly had occaſion, during the courſe of this Work, to declare our opinion, that all men are equally ignorant of them, if they be conſidered as any thing diſtinct from the general *laws* by which the operations of nature are carried on. To the diſcovery of other phyſiological cauſes, Newton, in his greateſt work, made indeed no pretenſion; but it may be worth while, and can hardly be conſidered as a digreſſion, to conſider what are the pretenſions of Hutchinſon, to which Meſſrs Horne and Jones gave ſo decided a preference.

Mr Hutchinſon himſelf writes ſo obſcurely, that we dare not venture to tranſlate his language into common Engliſh, leſt we ſhould undeſignedly miſrepreſent his meaning; but according to Mr Jones, who has ſtudied his works with care, his diſtinguiſhing doctrine in philoſophy is, that "The forces, of which the Newtonians treat, are not the forces of nature; but that the world is carried on by the action of the elements on one another, and all under God." What is here meant by the elements, we are taught by another eminent diſciple of that ſchool. "The great agents in nature, which carry on all its operations, are certainly (ſays Mr Parkhurſt) the *fluid* of the heavens; or, in other words, the fire at the orb of the ſun, the light iſſuing from it, and the ſpirit or groſs air conſtantly ſupporting, and concurring to the actions of the other two." (See Cherubim in this *Supplement*). Mr Horne adopted this ſyſtem in preference to the Newtonian; becauſe, ſays his biographer, "It appeared to him nothing better than raving, to give active powers to matter, ſuppoſing it capable of acting where it is not; and to affirm, at the ſame time, that all matter is inert, that is, inactive; and that the *Deity* cannot act but where he is *preſent*, becauſe his *power* cannot be but where his *ſubſtance* is."

That much impious arrogance has been betrayed, not by Newtonians only, but by philoſophers of every ſchool, when treating of the *modus operandi* of the Deity, we feel not ourſelves inclined to controvert; but we never knew a well-informed Newtonian, who ſpoke of the active powers of matter but in a metaphorical ſenſe; and ſuch language is uſed, and muſt be uſed, by the

Horne.

the followers of Hutchinſon. Mr Jones ſpeaks of the *action* of the elements; and Mr Parkhurſt calls the fluid of the heavens, which, according to him, conſiſts of fire, light, and air, *agents*; but it would ſurely be uncandid to accuſe theſe two pious men of *animating* the elements, though we know that *action* and *activity*, in the literal ſenſe of the words, can be predicated only of living beings. With reſpect to giving active powers to matter, therefore, the followers of Hutchinſon rave juſt as much as thoſe of Newton; and we ſee not the raving of either in any other light than as the neceſſary conſequence of the poverty of language.

But the Newtonian makes matter act upon matter at a diſtance! No; the genuine Newtonian does not make matter *act* (in the proper ſenſe of the word) at all; but he believes, that God has ſo conſtituted matter, that the motions of different maſſes of it are affected by each other at a diſtance; and the Hutchinſonian holds the very ſame thing. As this celeſtial fluid of Mr Parkhurſt's conſiſts partly of air, we know, by the teſt of experiment, that it is elaſtic. The particles of which it is compoſed are therefore diſtant from each other; and yet they reſiſt compreſſion. How does the Hutchinſonian account for this fact? Perhaps he will ſay, that as matter is in itſelf equally indifferent to motion and reſt, God has ſo conſtituted the particles of this fluid, that though they poſſeſs no innate power or activity of their own, they are affected by each other at a diſtance, in conſequence of his fiat at the creation. This we believe to be the only ſolution of the difficulty which can be given by man; but it is the very anſwer given by the Newtonians to thoſe who object to them the abſurdity of ſuppoſing matter to be affected by matter at a diſtance. That the motions of the heavenly bodies are affected by the preſence of each other is a fact, ſay they, which appears incontrovertible. "We have aſcertained with preciſion the laws by which theſe motions are regulated; and without troubling ourſelves with the true phyſiological cauſes, have demonſtrated the agreement of the phenomena with the laws. The interpoſition of this celeſtial fluid removes not a ſingle difficulty with which our doctrine is ſuppoſed to be clogged. To have recourſe to it can therefore ſerve no purpoſe, even were the phenomena conſiſtent with the nature of an elaſtic fluid conſidered as a phyſical cauſe; but this is not the caſe. It is demonſtrable (ſee ASTRONOMY and DYNAMICS in this *Suppl.*) that the motions of the heavenly bodies are not conſiſtent with the mechaniſm of an elaſtic fluid, conſidered as the cauſe of theſe motions; and therefore, whether there be ſuch a fluid or not diffuſed through the ſolar ſyſtem, we cannot allow that it is the great agent in nature by which all its operations are carried on."

Such might be the reaſoning of a well-informed Newtonian in this controverſy; and it appears ſo concluſive againſt the objections of Hutchinſon to the Newtonian forces, as well as againſt the agents which he has ſubſtituted in their ſtead, that ſome of our readers may be diſpoſed to call in queſtion the ſoundneſs of that man's underſtanding who could become a Hutchinſonian ſo zealous as Mr Horne. But to theſe gentlemen we beg leave to reply, that the ſoundeſt and moſt upright mind is not proof againſt the influence of a ſyſtem, eſpecially if that ſyſtem has novelty to recommend it, and at the ſame time conſiſts of parts, of which, when taken ſeparately, many are valuable. Such was the ſyſtem of Hutchinſon when adopted by Mr Horne. It was then but very little known; it could be ſtudied only through the medium of Hebrew literature, not generally cultivated; and that literature, to the cultivation of which Mr Hutchinſon had given a new and a better turn, is in itſelf of the utmoſt importance. Let it be obſerved, too, that the Hutchinſonians have, for the moſt part, been men of devout minds, zealous in the cauſe of Chriſtianity, and untainted by Arianiſm, Socinianiſm, and the other hereſies which have ſo often divided the church of Chriſt:—and when all theſe circumſtances are taken into conſideration, it will not be deemed a proof of any defect in Mr Horne's underſtanding, that in early life he adopted the *whole* of a ſyſtem, of which ſome of the parts contain ſo much that is good; eſpecially when it is remembered, that at *firſt view* the agency of the celeſtial fluid appears ſo plauſible, that for a time it ſeems to have impoſed upon the mind of Newton himſelf.

But the truth is, that Mr Horne was at no period of his life a thorough-paced Hutchinſonian. It is confeſſed by Mr Jones, "that Mr Hutchinſon and his admirers laid too great a ſtreſs on the evidence of Hebrew etymology; and that ſome of them carried the matter ſo far, as to adopt a mode of ſpeaking, which had a nearer reſemblance to cant and jargon than to ſound ſenſe and ſober learning. Of this (continues he) Mr Horne was very ſoon aware; and he was in ſo little danger of following the example, that he uſed to diſplay the foibles of ſuch perſons with that mirth and good humour," which he poſſeſſed in a more exquiſite degree than moſt men. This ſeems to be complete evidence that he was never a friend to the etymological part of the ſyſtem; and the preſent writer can atteſt, that, in the year 1786, he ſeemed by his converſation to have loſt much of his conviction of the agency of the celeſtial fluid. He continued, indeed, to ſtudy the Hebrew Scriptures on the plan of Mr Hutchinſon, unincumbered with the Maſoretic points, or with rabbinical interpretations; and the fruits of his ſtudies are in the hands of the religious public, in works which, by *that* public, will be eſteemed as long as their language is underſtood.

Hitherto Mr Horne was a layman, but he intereſted himſelf in every thing connected with religion, as much as the moſt zealous dignitary of the church; and conſidering the *naturalization* of the Jews as a meaſure at leaſt indecent in a Chriſtian country, he publiſhed, in an evening paper, a ſeries of letters on that ſubject, both when the Jew-bill was depending, and after it had paſſed the houſe. The letters were anonymous; but they attracted much notice, and many groundleſs conjectures were made reſpecting their author. To the real author, the meaſure which they oppoſed was ſo very obnoxious, that he refuſed to dine at the table of a friend, only becauſe the ſon-in-law of Mr Pelham was to be there. And he was not much more friendly to the marriage-act than to the Jew-bill. If he conſidered the one as diſgraceful to religion, he probably thought that the other, with its numerous clauſes, might be made a ſnare for virtue.

The time now approached when he was to take holy orders, which to him was a very ſerious affair; and when he gave an account of his ordination to an intimate

Horne.

mate friend, he concluded the letter with the following reflections, which, even in an abstract like this, it would be unpardonable to omit :

"May he, who ordered Peter three times to *feed his lambs*, give me grace, knowledge, and skill, to watch and attend to the flock which he purchased upon the cross, and to give rest to those who are under the burden of sin and sorrow. It hath pleased God to call me to the ministry in very troublesome times indeed, when a lion and a bear have broken into the fold, and are making havoc among the sheep. With a firm, though humble confidence, do I purpose to go forth ; not in my own strength, but in the strength of the Lord God ; and may he prosper the work of my hands !" This was in the year 1753, when the pious author was hardly 23 years of age ; and he had not been many months in orders, when one of the most celebrated preachers in the metropolis pronounced, that "George Horne was, without exception, the best preacher in England."

In the year 1756, he was again involved in controversy. A pamphlet had been published at Oxford, supposed by Mr Kennicott, who afterwards gained such fame as a collector of Hebrew manuscripts, entitled *A Word to the Hutchinsonians*, in which Mr Horne was personally struck at. To this work our author replied in a small tract, called *An Apology for certain Gentlemen in the University of Oxford, Asperfed in a late Anonymous Pamphlet* ; and whatever may be thought of the question at issue, all men must admire the temper with which the apologist conducted himself under very great provocation.

But it was not about Hutchinsonianism alone that these two illustrious men were doomed to differ. Mr Horne took a decided part against Mr Kennicott's proposal for collating the text of the Hebrew bible, with such manuscripts as could be found, for the purpose of *reforming the text*, and preparing it for a new translation into the English language ; and in the year 1760, he published *A View of Mr Kennicott's Method of Correcting the Hebrew Text, with three Queries formed thereon, and humbly submitted to the Christian world.* That his alarm was on this occasion too great, experience has shewn ; but that it was not groundless, is evident from the *View*, in which the reader will find above 20 instances from Mr Kennicott's dissertations (see Kennicott, *Encycl.*), to shew what an inundation of licentious criticism was breaking in upon the sacred text. Indeed there is reason to believe, that this tract, together with another on the same side of the question by Dr Rutherford of Cambridge, contributed to repress the collector's rashness, and to make the Bible of Dr Kennicott the valuable work which we find it. Be this as it may, such was the moderation of the Drs Kennicott and Horne, that though their acquaintance commenced in hostility, they at length contracted for each other a friendship, which lasted to the end of their lives, and still subsists between their families.

In what year Mr Horne was admitted to the degree of D. D. and when he was chosen president of his college, Mr Jones has not informed us ; but, if our memory does not deceive us, he had obtained both these preferments when, in the year 1772, he gave to the public a small work, 8vo, entitled *Considerations on the Life and Death of St John the Baptist.* This tract was the substance of a course of sermons, which he had many years before, in conformity to an established custom at Magdalen College, preached before the university of Oxford. Mr Jones, speaking of it, says, that "he is persuaded there was no other man of his time, whose fancy as a writer was bright enough, whose skill as an interpreter was deep enough, and whose heart as a moralist was *pure* enough, to have made him the author of that little work." By most readers this strain of panegyric will be thought extravagant, and of course it will defeat its own purpose ; but the work is certainly a work of merit.

In the year 1776, when the author was vice-chancellor, was published, in two volumes 4to, Dr Horne's Commentary on the Psalms. It is a work of which very different opinions have been formed, though it was the result of the labour of twenty years. That it will always be a favourite companion of the devout Christian, we are as much inclined to believe as Mr Jones ; but we cannot, without belying our own judgment, say that it appears to us calculated to produce much general good in an age like the present. Granting it to be true, which we believe will not be granted without some exceptions, that Clarke, and Hoadley, and Hare, and Middleton, and Warburton, and Sherlock, and South, and William Law, and Edmund Law, had turned the public attention, of which they had got the entire command, too much to the *letter* of the Bible to the neglect of the *spirit* of it ; should not Dr Horne, after the example of St Paul, have let in the light gradually upon such weak organs as those of the public thus diseased, rather than pour it upon them at once in a flood of splendor. The apostle "fed his Corinthian converts with milk and not with meat" when he found them unable to bear the latter food ; and there is reason to suspect that the carnal followers of Warburton, and Sherlock, and South, were unable to bear, at once, such strong meat, as that which makes the fifteenth psalm a portrait of our Saviour. Indeed, we think it not improbable that the mind of Sherlock would have recoiled with horror from the very conception of the *possibility* of Jesus Christ "swearing to his neighbour and disappointing him," though that conception must have passed through a mind which was certainly as pure as his. The commentary, however, though truth thus compels us to say that, in our opinion, it is far from perfect, is certainly a work of great learning, great genius, and fervent piety, and such as the devout Christian will peruse again and again with much advantage.

Dr Horne's next work was of a different kind, and, we think, of a superior order. In the year 1776 was published a letter of Dr Adam Smith's, giving an account of the death of Mr David Hume. The object of the author was to shew that Mr Hume, notwithstanding his sceptical principles, had died with the utmost composure, and that in his life, as well as at his death, he had conducted himself as became one of the wisest and best men that ever existed. The letter is very much laboured, and yet does no honour either to the author or his friend. It could not represent Mr Hume as supporting himself under the gradual decay of nature with the hopes of a happy immortality ; but it might have represented him as taking refuge, with other infidels, in the eternal sleep of death. This, though but a gloomy prospect, would

not

Horne.

not have been childish; but the hero of the tale is exhibited as talking like a school-boy of his conferences with Charon, and his reluctance to go into the Stygian ferry-boat, and as consoling himself with the thought of leaving all his friends, and his brother's family in particular, in great prosperity!!!' The absurdities of this letter did not escape the watchful and penetrating eye of Dr Horne; and as he could not mistake its object, he held it up to the contempt and scorn of the religious world in *A Letter to Adam Smith, L. L. D. on the Life, Death, and Philosophy of his Friend David Hume, Esq; by one of the People called Christians.* The reasoning of this little tract is clear and conclusive, while its keen, though good humoured wit is inimitable; and it was, some years afterwards, followed by a series of *Letters on Infidelity*, composed on the same plan, and with much of the same spirit. This small volume, to the second edition of which the letter to Dr Smith was prefixed, is better calculated than almost any other with which we are acquainted, to guard the minds of youth against the insidious strokes of infidel ridicule, the only dangerous weapon which infidelity has to wield.

When the letters on infidelity were published, their author had for some time been Dean of Canterbury, where he was beloved by the chapter and almost adored by the citizens. He was a very frequent preacher in the cathedral and metropolitical church, where the writer of this short sketch has listened to him with delight, and seen thousands of people of very various descriptions hang with rapture on his lips. As a preacher indeed he excelled; and notwithstanding the shortness of his sight, which deprived him of some of the graces of a pulpit orator, such were the excellence of his matter, the simple elegance of his style, and the sweetness of his voice, that, when at the primary visitation of the present archbishop, he preached his admirable sermon *on the Duty of Contending for the Faith*, the attention of more than 2000 people was so completely fixed, that the smallest noise was not to be heard through the whole crowded choir. Of the importance of preaching, and of the proper mode of performing that duty, he had very just notions; and though he never had himself a parochial cure of souls, it was the desire and pleasure of his life to make himself useful in the pulpit wherever he was, whether in town or in the most obscure corner of the country. Four or five volumes of his sermons have been published since his death.

In the year 1787 he published, under the name of an undergraduate of the university of Oxford, *a letter to Dr Priestley*, in which he made that oracle of Socinianism almost as ridiculous as, in the letter to Dr Smith, he had formerly made the hero of modern scepticism.

The merits of Dr Horne, which had made him president of Magdalen College, a king's chaplain, and dean of Canterbury, raised him, we think, in the year 1790, to the see of Norwich; and he had soon an opportunity of shewing that he had not lost sight of his spiritual character in the splendour of the peer of parliament. The Scotch Episcopalians had for some time been soliciting the legislature to repeal certain penal laws of uncommon severity, under which they had groaned for upwards of forty years; but they found it a work of no little difficulty to make the equity of their claim generally understood*. In removing this difficulty no man was more assisting to them than the Dean of Canterbury, to whom their religious and political principles were well known; and he continued his assistance after he was bishop of Norwich. Indeed the whole bench shewed, on this occasion, a zeal for the interests of true religion every way becoming their character of Christian bishops; and after Dr Horne was removed to a better world, the Scotch Episcopalians found among his surviving brethren friends as zealous and active as he.

* See Scotch Episcopalians in this Supplement.

Dr Horne, though a very handsome man, was not naturally of a strong constitution; and from the disadvantage of being uncommonly near-sighted, he had not been able to increase its strength by the practice of any athletic exercise. The only amusement in which he took delight was agreeable conversation; and his life was therefore what is called sedentary. The consequence of this was, that the infirmities of age came fast upon him; and when the design was formed of making him a bishop, he felt himself little inclined to undertake the charge of so weighty an office. He was, however, prevailed upon to accept of the see of Norwich; but he enjoyed his new dignity for a very short period, if he can with truth be said to have *enjoyed* it at all. His health declined rapidly; and, in the autumn of 1791, he suffered, while on the road from Norwich to Bath, a paralytic stroke, the effects of which he never recovered. He lingered a month or two, with such apparent changes in the state of his health as sometimes gave delusive hopes to his family, till the 17th of January 1792, when he died in the 62d year of his age, with those hopes which can be excited only by the consciousness of a well spent life, and by a firm trust in the promises of the gospel.

In this short sketch of the life of bishop Horne we have taken the liberty to express our dissent from some of his opinions, and to state the reasons on which that dissent rests. By himself we know that this part of our conduct would have been applauded; but it is possible that by some of his friends it may be deemed disrespectful to his memory. To these gentlemen we beg leave to observe, that if Johnson made the praise of *Kyrl*, Pope's Man of Ross, really more solid by making it more credible, it will be difficult to persuade us that we have done any injury to Dr Horne's fame by avoiding the extravagant panegyric of those who seem to have considered him as a man exempted from error. He was first induced to favour the Hutchinsonians because he thought he perceived danger to religion in the Newtonian doctrines of attraction and repulsion; and we very readily admit that many Newtonians, not understanding the doctrines of their master, have expressed themselves in such a manner as could not render a religious man partial to their system. But from the dangers of mistake, no system, whether religious or philosophical, was ever free; and the atheistical purposes which the agency of ethers and celestial fluids has lately been made to serve, must induce every man of piety to pause before he admit such agency. Dr Horne lived to witness some of its pernicious effects; and we have reason to believe that they made a due impression on his mind; but he spent his latter years, as indeed he had spent the greater part of his life, in nobler pursuits than the study of human science; he spent them in the proper employments of a Christian, a clergyman, and a bishop. His faith was founded on a rock; and it was that genuine faith which worketh by love; for though his preferments

were

were rich, his charity kept pace with them; and it has been proved that, notwithſtanding his proper economy, he hoarded not one ſhilling of his annual income. This was an elevation of character above all literary, above all philoſophical fame. The author of this article had the honour to be known to Dr Horne, to enjoy, if he miſtook not, a ſhare in his friendſhip, and to correſpond with him regularly for many years; and there is not one of his rational admirers who more fully admits the truth of the character given of him by Dr Thurlow late biſhop of Durham when ſucceeding him in the office of proctor in the Univerſity. "As to the laſt proctor (ſaid he) I ſhall ſpeak of him but in few words, for the truth of which I can appeal to all that are here preſent. If ever virtue itſelf was viſible and dwelt upon earth, it was in the perſon who this day lays down his office."

Soon after he was advanced to the preſidentſhip of Magdalen college, this great and good man married the only daughter of Philip Burton, Eſq; a gentleman of conſiderable fortune. By this lady he had three daughters, of whom the eldeſt was married to a clergyman a ſhort time before the death of her father, and the two younger were, in 1796, reſiding with Mrs Horne in Hertfordſhire.

HOROGRAPHY, the art of making or conſtructing dials; called alſo dialing, horologiography, gnomonica, ſciatherica, photoſciatherica, &c.

HOROPTER, in optics, is a right line drawn through the point where the two optic axes meet, parallel to that which joins the centres of the two eyes, or the two pupils.

HORSE-Shoe, in fortification, is a work ſometimes of a round, ſometimes of an oval figure, incloſed with a parapet, raiſed in the ditch of a marſhy place, or in low grounds; ſometimes alſo to cover a gate; or to ſerve as a lodgment for ſoldiers, to prevent ſurpriſes, or relieve an over-tedious defence.

HOVEN is a word of the ſame import with *raiſed, ſwelled, tumefied*. It is particularly applied to black cattle and ſheep, when from eating too voraciouſly of clover, or any other ſucculent food, they become ſwollen. Such cattle are, in the language of the farmer, called

Hoven-Cattle; and the beaſt, whether bullock or ſheep, which is hoven, when left without relief, dies in half an hour. The cauſe of the diſeaſe is the extra-quantity of air taken down with that kind of food, which, in its paſſage from the paunch upwards, forces the broad leaves of the clover before it, till they cloſe up the paſſage at the entrance of the paunch, and prevent the wind from going upwards in its regular courſe. The uſual method of relief is to ſtab the animal in the paunch; an operation which is always dangerous, and has often proved fatal. It was therefore, with good reaſon, that the Society for the Encouragement of Arts, Manufactures, and Commerce, voted a bounty of fifty guineas to Mr Richard Eagar of Graſſham farm, near Guildford, for making public a very ſimple method practiſed by him for the cure of hoven-cattle. It is this; "let the grazier or farmer have always ready ſmooth knobs of wood, of different ſizes, fixed to the end of a flexible cane, which for oxen ſhould be at leaſt ſix feet long, and for ſheep three feet. When a beaſt is hoven, let one perſon take hold of him by the noſtril and one horn; let another hold his tongue faſt in one hand, putting the cane down his throat with the other. Be careful not to let the animal get the knob of the cane between his grinders: obſerve alſo to put the cane far enough down; the whole length will not injure. You will find the obſtacle at the entrance of the paunch: puſh the cane hard, and when you perceive a ſmell to come from the paunch, and the animal's body to ſink, the cure is performed, and Nature will act for itſelf."

This method, we doubt not, will prove ſucceſsful; but might not the purpoſe be as well, if not better, effected, by uſing, inſtead of the cane and knob, a piece of thick ſtiff rope, which, in many places of Scotland, is employed to force down turnips or potatoes when they ſtick in the throat of a bullock?

HOUGHTON (———) is a man to whom the ſcience of geography is ſo much indebted, that we are almoſt aſhamed to confeſs that we know not his Chriſtian name, the place where he was born, or the age at which he died. He had been a captain in the 69th regiment, and in the year 1779 had acted under General Rooke as fort-major in the iſland of Goree. Hearing, ſome time in the year 1789, or perhaps earlier, that the African aſſociation wiſhed to penetrate to the Niger by the way of Gambia, he expreſſed his willingneſs to undertake the execution of their plan. For this taſk he was peculiarly fitted. A natural intrepidity of character which ſeemed inacceſſible to fear, and an eaſy flow of conſtitutional good humour, which even the rougheſt accidents of life were not able to ſubdue, formed him for exploring the country of relentleſs ſavages; whilſt the darkneſs of his complexion was ſuch, that he ſcarcely differed in appearance from the Moors of Barbary, whoſe dreſs in travelling he intended to aſſume.

His inſtructions from the aſſociation were, to aſcertain the courſe, and, if poſſible, the riſe and termination of the Niger; and after viſiting the cities of Tombuctoo and Houssa (ſee theſe articles in this *Supplement*), to return by the way of the deſart, or by any other route which the circumſtances of his ſituation at the time might recommend to his choice.

Having left England on the 16th of October 1790, he arrived at the entrance of the Gambia on the 10th of November, and was kindly received by the king of Barra, who remembered the viſit which the major had formerly paid him from the iſland of Goree; and who now, in return for a ſmall preſent of the value of 20s. cheerfully tendered protection and aſſiſtance as far as his dominion or influence extended.

Proceedings of the African Aſſociation.

An offer from the maſter of an Engliſh veſſel employed in the trade of the river, enabled the Major, and the interpreter he had engaged on the coaſt, to proceed to Junkiconda; where he purchaſed from the natives a horſe and five aſſes, and prepared to paſs with the merchandiſe which conſtituted his travelling fund, to Medina, the capital of the ſmall kingdom of Woolli.

Fortunately for him, a few words, accidentally dropped by a negro woman in the Mandingo language, of which he had haſtily acquired a ſuperficial knowledge, excited ſuſpicions of danger; and gave him intimation of a conſpiracy which the negro miſtreſſes of the traders, who feared that the Major's expedition portended the ruin of their commerce, had formed againſt his life. Afraid, therefore, of travelling by the cuſtomary route, he availed himſelf of the opportunity which the dry ſea-

Houghton. fon and the tide of ebb afforded of fwimming his horfe and his affes acrofs the ftream; and having by thofe means avoided the parties who were fent for his deftruction, he proceeded with much difficulty on the fouthern fide of the river, to that diftrict of Cantor which is oppolite to the kingdom of Woolli. There he repaffed the Gambia, and fet a meffenger to inform the king of his arrival, and to requeft a guard for his protection.

An efcort, commanded by the king's fon, was immediately difpatched; and the Major, whofe intended prefent had been announced, was kindly received, and hofpitably entertained at Medina.

The town is fituated at the diftance of about 900 miles by water from the entrance of the Gambia; and the country adjacent abounds in corn and cattle, and, generally fpeaking, in all things that are requifite for the fupport, or effential to the comfort of life. Two different fects of religion diftinguifh rather than divide the people; the one is compofed of the profeffors of the Mahomedan faith, who are called Bufhreens; the other, and, it is faid, the more numerous, confifts of thofe who, denying the miffion of the prophet, avow themfelves deifts, and from their cuftom of drinking with freedom the liquors of which he prohibited the ufe, are denominated Sonikees or drinking men.

In a letter from Major Houghton to his wife, which a feaman preferved from the wreck of a veffel in which the difpatches to the fociety were loft, the Major indulged the reflections that naturally arofe from his paft and prefent fituations. A bilious fever had attacked him foon after his arrival in the Gambia; but his health was now unimpaired—a confpiracy had affailed his life; but the danger was paffed—the journey from Junkiconda had expofed him to innumerable hardfhips; but he was now in poffeffion of every gratification which the kindnefs of the king or the hofpitality of the people could enable him to enjoy. Delighted with the healthinefs of the country, the abundance of the game, the fecurity with which he made his excurfions on horfeback, and, above all, with the advantages that would attend the erection of a fort on the falubrious and beautiful hill of Fatetenda, where the Englifh once had a factory, he expreffes his earneft hope that his wife will hereafter accompany him to a place in which an income of ten pounds a-year will fupport them in affluence; and that fhe will participate with him in the pleafure of rapidly acquiring that vaft wealth which he imagines its commerce will afford.

While, in this manner, he indulged the dream of future profperity, and with ftill more ample fatisfaction contemplated the eclat of the difcoveries for which he was preparing, but in the purfuit of which he was retarded by the abfence of the native merchant, for whofe company he had engaged, he found himfelf fuddenly involved in unexpected and irrefiftible misfortune. A fire, the progrefs of which was accelerated by the bamboo roofs of the buildings, confumed with fuch rapidity the houfe in which he lived, and with it the greateft part of Medina, that feveral of the articles of merchandize, to which he trufted for the expences of his journey, were deftroyed; and to add to his affliction, his faithlefs interpreter, who had made an ineffectual attempt on his goods, difappeared with his horfe and three of his affes; a trade gun which he had purchafed on the river foon afterwards burft in his hands, and wounded him in the face and arm: and though the hofpitable kindnefs of the people of the neighbouring town of Barraconda, who cheerfully opened their houfes to more than a thoufand families, whofe tenements the flames had confumed, was anxioufly exerted for his relief; yet the lofs of his goods, and the confequent diminution of his travelling fund, were evils which no kindnefs could remove. Houghton.

It was in this fituation that, wearied with the fruitlefs hope of the return of the native trader, with whom he had contracted for his journey, he refolved to avail himfelf of the company of another flave merchant, who was lately arrived from the fouth, and was now on his way to his farm on the frontier of the kingdom of Bambouk. Accordingly, on the evening of the 8th of May, he proceeded by moon light and on foot, with his two affes, which the fervants of the flave merchant offered to drive with their own, and which carried the wreck of his fortune; and journeying by a north-eaft courfe, arrived on the fifth day at the uninhabited frontier which feparates the kingdoms of Woolli and Bondou.

He had now paffed the former limit of European difcovery; and while he remarked with pleafure the numerous and extenfive population of this unvifited country, he obferved, that the long black hair and copper complexion of the inhabitants announced their Arab original. They are a branch of that numerous tribe which, under the appellation of Foolies, have overfpread a confiderable part of Senegambia; and their religious diftinctions are fimilar to thofe which prevail in the kingdom of Woolli.

A journey of 150 miles, which was often interrupted by the engagements of his companion who traded in every town, conducted him to the banks of the Falemé, the fouth-weftern boundary of the kingdom of Bambouk. Its ftream was exhaufted by the advanced ftate of the dry feafon, and its bed exhibited an appearance of flate intermixed with gravel.

Bambouk is inhabited by a nation, whofe woolly hair and fable complexions befpeak them of the negro race, but whofe character feems to be varied in proportion as the country rifes from the plains of its weftern divifion to the highlands of the eaft. Diftinguifhed into fects, like the people of Woolli and Bondou, by the different tenets of Mahomedans and Deifts, they are equally at peace with each other, and mutually tolerate the refpective opinions they condemn.

Agriculture and pafturage, as in the negro ftates on the coaft of the Atlantic, are their chief occupations; but the progrefs which they have made in the manufacturing arts, is fuch as enables them to fmelt their iron ore, and to furnifh the feveral inftruments of hufbandry and war. Cloth of cotton, on the other hand, which in this part of Africa feems to be the univerfal wear, they appear to weave by a difficult and laborious procefs; and to thefe two circumftances it is probably owing, that with them the meafure of value is not, as on the coaft, a bar of iron, but a piece of cloth.

The common vegetable food of the inhabitants appears to confift of rice; their animal, of beef or mutton. A liquor, prepared from fomented honey, fupplies the want of wine, and furnifhes the means of thofe feftive entertainments that conftitute the luxury of the court of Bambouk.

On

Houghton.

On the Major's arrival at the banks of the river Falemé, he found that the war which had lately subsisted between the kings of Bondou and Bambouk was terminated by the cession to the former of the conquests he had made in the low land part of the dominions of the latter; and that the king of Bondou had taken up his residence in the territory which he had thus obtained.

The Major hastened to pay his respects to the victorious prince, and to offer a similar present to that which the kings of Barra and Woolli had cheerfully accepted; but to his great disappointment an ungracious reception, a sullen permission to leave the present, and a stern command to repair to the frontier town from which he came, were followed by an intimation that he should hear again from the king. Accordingly, on the next day, the king's son, accompanied by an armed attendance, entered the house in which the Major had taken up his temporary dwelling, and demanded a sight of all the articles he had brought. From these the prince selected whatever commodities were best calculated to gratify his avarice, or please his eye; and, to the Major's great disappointment, took from him the blue coat in which he hoped to make his appearance on the day of his introduction to the Sultan of Tombuctoo. Happily, however, a variety of articles were successfully concealed, and others of inferior value were not considered as sufficiently attractive.

The Major now waited with impatience for the performance of the promise which the slave merchant, with whom he had travelled from the Gambia, had made of proceeding with him to Tombuctoo; but as the merchant was obliged to spend a few days at his rice farm on the banks of the Falemé, the Major accepted an invitation to the hospitality of his roof. There he observed, with extreme regret, that the apprehension of a scarcity of grain had alarmed his friend; and that, dreading the consequences of leaving his family in so perilous a season to the chances of the market, he had determined on collecting, before his departure, a sufficient supply for their support. This argument for delay was too forcible to be opposed; and therefore the Major resolved to employ the interval in visiting the king of Bambouk, who resided in the town of Ferbanna, on the eastern side of the Serra Coles, or river of Gold. Unfortunately, however, by a mistake of his guide, he lost his way in one of the vast woods of the country; and as the rainy season, which commenced with the new moon on the 4th of July, and was introduced with a westerly wind, was now set in, the ground on which he passed the night was deluged with rain, while all the sky exhibited that continued blaze of lightning, which in those latitudes often accompanies the tornado. Distressed by the fever, which began to assail him, the Major continued his route at the break of day, and waded with difficulty through the river Serra Coles, which was swelled by the floods, and on the banks of which the alligators were basking in the temporary sun-shine.

Scarcely had he reached Ferbanna when his fever rose to a height that rendered him delirious; but the strength of his constitution, and the kindness of the negro family to which his guide had conducted him, surmounted the dangerous disease; and in the friendly reception which was given him y the king of Bambouk he soon forgot the hardships of his journey. The king informed him, that the losses he had lately sustained in the contest with the armies of Bondou, arose from his having exhausted his ammunition; for, as the French traders, who formerly supplied his troops, had abandoned the fort of St Joseph, and, either from the dryness of the last season, or from other causes, had deserted the navigation of the upper part of the Senegal, he had no means of replenishing his stores; whereas his enemy, the king of Bondou, continued to receive from the British, through the channel of his agents on the Gambia, a constant and adequate supply.

Major Houghton availed himself of the opportunity which this conversation afforded, to suggest to the king the advantage of encouraging the British to open a trade by the way of his dominions to the populous cities on the banks of the Niger.

Such was the state of the negociation, when all business was suspended by the arrival of the annual presents of Mead, which the people of Bambouk, at that season of the year, are accustomed to send to their king; and which are always followed by an intemperate festival of several successive days.

In the interim, the Major received, and gladly accepted, the proposal of an old and respectable merchant of Bambouk; who offered to conduct him on horseback to Tombuctoo, and to attend him back to the Gambia. A premium of L. 125, to be paid on the Major's return to the British factory at Junkiconda, was fixed by agreement as the merchant's future reward. It was further determined that the Major should be furnished with a horse in exchange for his two asses; and should convert into gold dust, as the most portable fund, the scanty remains of the goods he had brought from Great Britain.

This plan was much approved by the king, to whom the merchant was personally known; and who gave to the Major at parting, as a mark of his esteem, and a pledge of his future friendship, a present of a purse of gold. With an account of these preparations the Major closed his last dispatch, of the 24th July 1791; and the African association entertained for some time sanguine hopes of his reaching Tombuctoo. Alas! these hopes were blasted. Mr Park, who succeeded him in the arduous task of exploring that savage country, learned, that having reached Jarra (See that article in this *Supplement*), he there met with some Moors who were travelling to Tisheet (a place by the salt pits in the Great Desart, ten days journey to the northward) to purchase salt; and that the Major, at the expence of some tobacco and a musket, engaged them to convey him hither. It is impossible (says Mr Park) to form any other opinion on this determination, than that the Moors intentionally deceived him with a view to rob, and leave him in the Desart. At the end of two days he suspected their treachery, and insisted on returning to Jarra. Finding him persist in this determination, the Moors robbed him of every thing which he possessed, and went off with their camels. Being thus deserted, he returned to a watering place, in possession of the Moors, called Farra; and being by these unfeeling wretches refused food, which he had not tasted for some days, he sunk at last under his misfortunes. Whether he actually died of hunger, or was murdered outright by the savage Mahometans, Mr Park could not learn; but

Houffa.

but he was fhewn at a diftance the fpot in the woods to which his body was dragged, and where it was left a prey to corruption.

Thus perifhed, in the prime of life, Major Houghton, a man whofe travels enlarged the limits of European difcovery, and whofe accounts of the places which he vifited were ftrongly confirmed by the intelligence which the Britifh conful at Tunis collected from the Barbary merchants.

HOUSSA, the capital of an African empire, on the banks of the Niger, is a city which has excited much curiofity among men of fcience, fince it was firft mentioned to a committee of the African Affociation about the year 1790. The perfon from whom they received their information was an Arab, of the name of Shabeni; who faid that the population of Houffa, where he had refided two years, was equalled only (fo far as his knowledge extended) by that of London and Cairo: and, in his rude unlettered way, he defcribed the government as monarchical, yet not unlimited; its juftice as fevere, but directed by written laws; and the rights of landed property as guarded by the inftitutions of certain hereditary officers, whofe functions appear to be fimilar to thofe of the Canongoes of Hindoftan (fee CANONGOES in this *Suppl.*); and whofe important and complicated duties imply an unufual degree of civilization and refinement. For the probity of the merchants of Houffa, the Arab expreffed the higheft refpect; but remarked, with indignation, that the women were admitted to fociety, and that the honour of the hufband was often infecure. Of their written alphabet, he knew no more than that it is perfectly different from the Arabic and the Hebrew characters; but he reprefented the art of writing as common in Houffa. And when he defcribed the manner in which their pottery is made, he gave, unknowingly to himfelf, a reprefentation of the ancient Grecian wheel. In paffing to Houffa from Tombuctoo, in which laft city he had refided feven years, he found the banks of the Niger more numeroufly peopled than thofe of the Nile, from Alexandria to Cairo; and his mind was obvioufly impreffed with higher ideas of the wealth and grandeur of the empire of Houffa, than of thofe of any kingdom which he had feen, England alone excepted.

The exiftence of the city of Houffa, and of the empire thus defcribed by Shabeni, was ftrongly confirmed by letters which the committee received from his Majefty's confuls at Tunis and Morocco; and it has been put beyond all poffibility of doubt by Mr Park, who received from various perfons fuch concurring accounts of it, as could not be the offspring of deliberate falfehood. From a well-informed fhereeff, who had vifited Houffa, and lived fome years at Tombuctoo, he learned that the former of thefe cities was the largeft that the fhereeff had ever feen; and by comparing this man's account of its population with that of various other cities, of which Mr Park had feen one or two, we can hardly eftimate the inhabitants of Houffa at a lefs number than 100,000. Many merchants, with whom our traveller converfed, reprefented Houffa as larger, and more populous, than Tombuctoo, and the trade, police, and government, as nearly the fame in both. In that cafe, the king of Houffa and chief officers of ftate muft be Moors, and zealots for the Mahometan religion; but they cannot be fo intolerant as the fovereign of Tombuctoo and his minifters; for in Houffa, Mr Park was told that the Negroes are in greater proportion to the Moors than in Tombuctoo, and that they have likewife fome fhare in the government. According to accounts derived from Barbary merchants, the people of Houffa have the art of tempering their iron with more than European fkill; and their files, in particular, are much fuperior to thofe of Great Britain and France. The confuls at Tunis and Morocco affured the committee of the African Affociation, that at both thefe courts the eunuchs of the feraglio are brought from Houffa.

Houffa, Houzouanas.

To thofe who may ftill entertain doubts of fo much refinement being to be found in the interior parts of a country, confidered as peculiarly favage, we fhall only obferve, in the words of the committee of affociation, that it is by no means "impoffible that the Carthaginians, who do not appear to have perifhed with their cities, may have retired to the fouthern parts of Africa; and though loft to the Defart, may have carried with them to the new regions which they occupy fome portion of thofe arts and fciences, and of that commercial knowledge, for which the inhabitants of Carthage were once fo eminently famed. In Major Rennel's laft map of North Africa, Houffa is placed in 16° and about 20′ N. Lat. and 4° 30′ E. Long.

HOUZOUANAS, are a wandering people, who inhabit that part of Africa, which, in a direction from eaft to weft, extends from Caffraria to the country of the Greater Nimiquas (See NIMIQUAS in this *Suppl.*) According to the map prefixed to Vaillant's new travels, the diftrict occupied by the Houzouanas lies between 16° and 29° eaft longitude. Of its breadth from fouth to north we are ignorant, but it begins at the 23d parallel, aud ftretches northward probably a great way.

M. Vaillant is inclined to believe, that the Houzouanas are the original ftem of the various nations, inhabiting at prefent the fouthern part of Africa, and that from them all the tribes of the eaftern and weftern Hottentots are defcended. The people themfelves know nothing of their origin; but to the queftions that are put to them on the fubject, they always reply, that they inhabit the country which was inhabited by their anceftors. At the Cape M. Vaillant received the following account of them, which, though he does not warrant its authenticity, has much the appearance of being authentic.

When the Europeans firft eftablifhed themfelves at the Cape, the Houzouanas inhabited the country of Camdebo, the fnowy mountains, and the diftrict that feparates thefe mountains from Caffraria. Become neighbours to the colony, in confequence of its extending itfelf towards them, they at firft lived on peaceable terms with the planters; and, as they difplayed more intelligence and greater activity than the Hottentots, they were even employed in preference to affift in cultivating the land and in forming the fettlement. This good underftanding and harmony were, however, foon interrupted by that multitude of lawlefs banditti fent from Holland to people the country.

Thofe worthlefs profligates wifhed to enjoy the fruits of the land without the trouble of tilling it. Educated, befides, with all the prejudices of the whites, they imagined that men of a different colour were born only

to

Houzouanas.

to be their slaves. They accordingly subjected them to bondage, condemned them to the most laborious services, and repaid those services with harsh and severe treatment. The Houzouanas, incensed at such arbitrary and tyrannical conduct, refused any longer to work for them, and retired to the defiles of their mountains. The planters took up arms and pursued them; they massacred them without pity, and seized on their cattle and their country. Those who escaped their atrocities betook themselves to flight, and removed to the land which they now occupy; but, on quitting their former possessions, they swore, in their own name and that of their posterity, to exterminate those European monsters, to be revenged against whom they had so many incitements. And thus, if tradition be true, was a peaceful and industrious nation rendered warlike, vindictive, and ferocious.

This hatred has been perpetuated from generation to generation, though the Houzouanas of the present day are ignorant of the original cause of it. Bred up with an invincible aversion to the planters, they know only that they are animated to plunder and destroy them; but it is only by a vague sentiment of detestation, with the source of which they are unacquainted; and which, though it renders them cruel towards the planters, does not prevent them from being good, kind, and humane, towards each other.

The Houzouanas, being known only by their incursions and plundering, are in the colonies often confounded with the Boshmen, and distinguished by the same appellation. Sometimes, however, from their tawny colour, they are called Chinese Hottentots; and, by means of this double denomination, ill-informed travellers may easily be led into an error, of which the consequence must be, that their narratives will be replete with absurdity and falsehoods.

Their real name, and the only one which they give themselves, is that of Houzouana; and they have nothing in common with the Boshmen, who are not a distinct people, but a mere collection of fugitives and free-booters. The Houzouanas form no alliances but among themselves. Being almost always at war with the surrounding nations, they never mix with them; and, if they consent at any time to admit a stranger into their hordes, it is only after a long acquaintance, a sort of apprenticeship, during which he has given proofs of his fidelity, and established his courage. Such indeed are their courage and predatory habits, that they are the dread of all the surrounding tribes; and the Hottentots who accompanied M. Vaillant trembled at the very thought of entering the Houzouana territories. Nay, after they had lived many days among them, and had experienced their fidelity, they continued under the daily apprehension of being massacred by them. Yet one of their own countrymen, who had lived long among the Houzouanas, gave such a character of that people as should have banished those idle fears.

"The Houzouanas (said he), are by no means what you suppose them to be, murderers by profession. If they sometimes shed blood, it is not from a thirst of carnage, but to make just reprisals that they take up arms. Attacked and persecuted by surrounding nations, they have found themselves reduced to the necessity of flying to inaccessible places among the barren mountains, where no other people could exist.

"If they find antelopes and damans to kill; if the nymphs of ants are abundant; or if their good fortune brings them plenty of locusts—they remain within the precincts of their rocks; but if the provisions necessary to subsistence fail, the nations in their neighbourhood must suffer. From the summits of their mountains, they survey at a distance the countries around; and if they observe cattle, they make an incursion to carry them off, or slaughter them upon the spot, according to circumstances; but though they rob, they never kill, except to defend their lives, or by way of retaliation to revenge an ancient injury.

"It happens sometimes, however, that after very fatiguing expeditions they return without booty; either because the objects of their attack have disappeared, or because they have been repulsed and beaten. In such cases, the women, exasperated by hunger and the lamentation of their children crying for food, become almost furious with passion. Reproaches, insult, and threats, are employed; they wish to separate from such dastardly men, to quit husbands destitute of courage, and to seek others who will be more anxious to procure provision for them and their children. In short, having exhausted whatever rage and despair could suggest, they pull off their small apron of modesty, and beat their husbands about the head with it till their arms are weary of the exercise.

"Of all the affronts which they can offer, this is the most insulting. Unable to withstand it, the men in their turn become furious. They put on their war-cap, a sort of helmet made with the skin that covers the neck of the hyæna, the long hair of which forms a crest that floats over the head, and setting out like madmen, never return till they have succeeded in carrying off some cattle.

"When they come back, their wives go to meet them, and extol their courage amidst the fondest caresses. In a word, nothing is then thought of but mirth and jollity; and, till similar scenes are recalled by similar wants, past evils are forgotten."

Such was the character given of this formidable people to M. Vaillant at his first interview with them; and during the long excursions which he made in their company, they did not belie it in a single instance. In many respects they appeared to resemble the Arabs, who, being also wanderers, and like them brave and addicted to rapine, adhere with unalterable fidelity to their engagements, and defend, even to the last drop of their blood, the traveller who civilly purchases their services, and puts himself under their protection. In our author's opinion, if it be at all practicable to traverse from south to north the whole of Africa, it could only be under the conduct of the Houzouanas; and he really thinks that fifty men of their temperate, brave, and indefatigable nation, would be sufficient to protect an enterprising European through that long and hazardous journey.

Yet these people, so superior both in body and mind to the other natives of South Africa, are but of low stature; and a person five feet four inches in height is accounted among them very tall; but in their little bodies, perfectly well proportioned, are united, with surprising

Houzouanas.

prising strength and agility, a certain air of assurance, boldness, and haughtiness, which awes the beholder, and with which our author was greatly pleased. Of all the savage races, he saw none that appeared to be endowed with so active a mind, and so hardy a constitution.

Their head, though it exhibits the principal characteristics of that of the Hottentot, is, however, rounder towards the chin. They are also not so black in complexion; but have the lead colour of the Malays, distinguished at the Cape by the name of *bouguinée*. Their hair, more woolly, is so short, that he imagined at first their heads to have been shaved. The nose too is still flatter than that of the Hottentots; or, rather, they seem altogether destitute of a nose; what they have consisting only of two broad nostrils which project at most but five or six lines. From this confirmation of the nose, a Houzouana, when seen in profile, is the reverse of handsome, and considerably resembles an ape. When beheld in front, he presents, on the first view, an extraordinary appearance, as half the face seems to be forehead. The features, however, are so expressive, and the eyes so large and lively, that, notwithstanding this singularity of look, the countenance is tolerably agreeable.

As the heat of the climate in which he lives renders clothing unnecessary, he continues during the whole year almost entirely naked, having no other covering than a very small jackal skin fastened round his loins by two thongs, the extremities of which hang down to his knees. Hardened by this constant habit of nakedness, he becomes so insensible to the variations of the atmosphere, that when he removes from the burning sands of the level country to the snow and hoar-frost of his mountains, he seems indifferent to and not even to feel the cold.

His hut in nowise resembles that of the Hottentot. It appears as if cut vertically through the middle; so that the hut of a Hottentot would make two of those of the Houzouanas. During their emigrations, they leave them standing, in order that, if any other horde of the same nation pass that way, they may make use of them. When on a journey, they have nothing to repose on but a mat suspended from two sticks, and placed in an inclined position. They often even sleep on the bare ground. A projecting rock is then sufficient to shelter them; for every thing is suited to a people whose constitutions are proof against the severest fatigue. If, however, they stop anywhere to sojourn for a while, and find materials proper for constructing huts, they then form a kraal; but they abandon it on their departure, as is the case with all the huts which they erect.

This custom of labouring for others of their tribe announces a social character and a benevolent disposition. They are indeed not only affectionate husbands and good fathers, but excellent companions. When they inhabit a kraal, there is no such thing among them as private property; whatever they possess is in common. If two hordes of the same nation meet, the reception is on both sides friendly; they afford each other mutual protection, and confer reciprocal obligations. In short, they treat one another as brethren, though perhaps they are perfect strangers, and have never seen each other before.

Active and nimble by nature, the Houzouanas consider it as amusement to climb mountains, and the most elevated peaks; and they conducted M. Vaillant, his servants and cattle, over precipices, and through defiles, which he and his Hottentots would have deemed absolutely impassable. The only arms of this people are bows and arrows, in the use of which they are very expert. The arrows, which are uncommonly short, are carried on the shoulder in a quiver, about 18 inches in length, and four in diameter, made of the bark of the aloe, and covered with the skin of a large species of lizard, which these wanderers find in all their rivers, particularly on the banks of Orange and Fish River.

Nocturnal fires are a peculiar language understood and employed by almost all savage nations None, however, have carried this art so far as the Houzouanas, because none have so much need of understanding and bringing it to perfection. If it be necessary to announce a defeat or a victory, an arrival or departure, a successful plundering expedition, or the want of assistance, in a word, any intelligence whatever, they are able, either by the number of their fires or the manner in which they arrange them, to make it known in an instant. They are even so sagacious as to vary their fires from time to time, lest their enemies should become acquainted with their signals, and treacherously employ them in their turn to surprise them.

Our author says, that he is unacquainted with the principles of these signals, invented with so much ingenuity. He did not request information; because he very rationally inferred that his request would not have been granted; but he observed, that three fires kindled at the distance of twenty paces from each other, so as to form an equilateral triangle, were the signal for rallying.

Among the physical qualities which, in M. Vaillant's opinion, prove that the Houzouanas are a distinct nation, he mentions the enormous natural rump of the women, as a deformity which distinguishes them from every other people, savage or polished, which he had ever known. "I have several times (says he) had occasion to remark, that, among the female Hottentots in general, as they advance in age, the inferior part of the back swells out, and acquires a size which it greatly exceeds the proportion it bore in infancy with the other parts of the body. The Houzouana women, having in their figure some resemblance to the Hottentots, and appearing therefore to be of the same race, one might be induced to believe that their projection behind is only the Hottentot rump more swelled and extended. I observed, however, that among the former this singularity was an excrescence of slow growth, and in some measure an infirmity of old age; whereas among the latter it is a natural deformity, an original characteristic of their race. The Houzouana mothers wear on their reins, like our miners, a skin which covers this protuberance of the posteriors; but which, being thin and pliable, yields to the quivering of the flesh, and becomes agitated in the same manner. When on a journey, or when they have children too young to follow them, they place them upon their rump. I saw one of these women run in this manner with a child, about three years of age, that stood erect on its feet at her back, like a footboy behind a carriage."

If one half of what our traveller says of the activity and

Hungary-water.

and enterprising spirit of this singular people be true, might not the African Association send a second Houghton, or second Park, to make discoveries in that unexplored country, under the protection of the Houzouanas? We do not indeed think that it would be possible to traverse the whole extent of Africa from south to north, but Vaillant penetrated farther in that direction than any one had done before him; and it appears that with his intrepid Houzouanas he might have penetrated much farther.

HUNGARY-WATER, is spirit of wine distilled upon rosemary, and which therefore contains its oily and strong-scented essence (see PHARMACY, n° 365. *Encycl.*) To be really good, says Professor Beckmann, the spirit of wine ought to be very strong, and the rosemary fresh; and if that be the case, the leaves are as proper as the flowers, which, according to the prescription of some, should only be taken. It is likewise necessary that the spirit of wine be distilled several times upon the rosemary; but that process is too troublesome and expensive to admit of this water being disposed of at the low price it is usually sold for; and it is certain that the greater part of it is nothing else than common brandy united with the essence of rosemary in the simplest manner. In general, it is only mixed with a few drops of the oil. For a long time past, this article has been brought to us principally from France, where it is prepared, particularly at Beaucaire, Montpelier, and other places in Languedoc, in which that plant grows in great abundance.

Hist. of Inventions.

The name *Hungary water* seems to signify, that this water, so celebrated for its medicinal virtues, is an Hungarian invention; and we read in many books, that the receipt for preparing it was given to a queen of Hungary by a hermit; or, as others say, by an angel, who appeared to her in a garden, all entrance to which was shut, in the form of a hermit or a youth. Some call the queen St Isabella; but those who pretend to be best acquainted with the circumstance affirm, that Elizabeth, wife of Charles Robert king of Hungary, and daughter of Uladislaus II. king of Poland, who died in 1380 or 1381, was the inventress. By often washing with this spirit of rosemary, when in the 70th year of her age, she was cured, as we are told, of the gout and an universal lameness; so that she not only lived to pass 80, but became so lively and beautiful, that she was courted by the king of Poland, who was then a widower, and who wished to make her his second wife.

Hunter.

The Professor justly considers this story as a ridiculous fable (A). "It appears to me (says he) most probable, that the French name *l'eau de la reine d'Hongrie*, was chosen by those who, in latter times, prepared spirit of rosemary for sale, in order to give greater consequence and credit to their commodity; as various medicines, some years ago, were extolled in the gazettes under the title of Pompadour, though the celebrated lady, from whose name they derived their importance, certainly neither ever saw them nor used them."

HUNTER (John), the celebrated surgeon, was the youngest child of John Hunter of Kilbride, in the county of Lanark. He was born on the 14th of July 1728, at Long Calderwood, a small estate belonging to the family; and losing his father when he was about ten years of age, he was perhaps too much indulged by his mother. One consequence of this was, that at the grammar-school he made no progress in learning; and he may be said to have been almost totally illiterate when, in September 1748, he arrived in London. His brother, Dr William Hunter, of whom an account is given in the *Encyclopædia*, was then the most celebrated teacher of anatomy, and John had expressed a desire to assist him in his researches. The Doctor, who was very desirous to serve him, and anxious to form some opinion of his talents for anatomy, gave him an arm to dissect for the muscles, with the necessary directions how it was to be done; and he found the performance such as greatly exceeded his expectation.

His first essay in anatomy having thus gained him some credit, Mr Hunter was now employed in a dissection of a more difficult nature; this was an arm in which all the arteries were injected, and these, as well as the muscles, were to be exposed and preserved. The manner in which this was performed, gave Dr Hunter so much satisfaction, that he did not scruple to say that his brother would become a good anatomist, and that he should not want for employment. From this period we may consider Mr Hunter as having seriously engaged in anatomy; and under the instructions of Dr Hunter, and his assistant Mr Symonds, he had every opportunity of improvement, as all the dissections at this time carried on in London were confined to that school.

In

(A) It was first published to the world in 1659 in a posthumous work of John Prevot, who says, that in the beginning of a very old breviary, he saw a remedy for the gout, written by the queen's own hand, in the following words:

"I Elizabeth, queen of Hungary, being very infirm and much troubled with the gout in the 72d year of my age, used for a year this receipt, given to me by an ancient hermit, whom I never saw before nor since; and was not only cured, but recovered my strength, and appeared to all so remarkably beautiful, that the king of Poland asked me in marriage, he being a widower and I a widow. I, however, refused him for the love of my Lord Jesus Christ, from one of whose angels, I believe, I received the remedy. The receipt is as follows:

"℞. Take of aqua vitæ, four times distilled, three parts, and of the tops and flowers of rosemary two parts: put these together in a close vessel, let them stand in a gentle heat 50 hours, and then distil them. Take one dram of this in the morning once every week, either in your food or drink, and let your face and the diseased limb be washed with it every morning.

"It renovates the strength, brightens the spirits, purifies the marrow and nerves, restores and preserves the sight, and prolongs life." Thus far from the Breviary. Then follows a confirmation which Prevot gives from his own experience.

Hunter.

In the summer 1749, Mr Chefelden, at the requeft of Dr Hunter, permitted him to attend at Chelfea Hofpital; and he there learned the firft rudiments of furgery.

The following winter he was fo far advanced in the knowledge of human anatomy, as to inftruct the pupils in diffection, to whom Dr Hunter had very little time to pay attention. This office, therefore, fell almoft entirely upon him, and was his conftant employment during the winter feafon.

In the fummer months of 1750, Mr Hunter attended the hofpital at Chelfea; in 1751, he became a pupil at St Bartholomew's, and in the winter was prefent at operations occafionally, whenever any thing extraordinary occurred. The following fummer he went to Scotland; and in 1753 entered, it is difficult to conceive for what reafon, as a gentleman commoner at St Mary-hall, Oxford. In 1754 he became a furgeon's pupil at St George's hofpital, where he continued during the fummer months; and in 1756 was appointed houfe-furgeon.

In the winter 1755, Dr Hunter admitted him to a partnerfhip in his lectures, and a certain portion of the courfe was allotted to him; befides which, he gave lectures when the Doctor was called away to attend his patients. Making anatomical preparations was at this time a new art, and very little known; every preparation, therefore, that was fkilfully made, became an object of admiration; many were wanting for the ufe of the lectures; and the Doctor being himfelf an enthufiaft for the art, left no means untried to infufe into his brother a love for his favourite purfuits. How well he fucceeded, the collection afterwards made by Mr Hunter will fufficiently evince.

Anatomy feems to have been a purfuit for which Mr Hunter's mind was peculiarly fitted, and he applied to it with an ardour and perfeverance of which there is hardly an example. His labours were fo ufeful to his brother's collection, and fo gratifying to his difpofition, that although in many other refpects they did not agree, this fimple tie kept them together for many years.

Mr Hunter worked for ten years on human anatomy; during which period he made himfelf mafter of what was already known, as well as made fome addition to that knowledge. He traced the ramifications of the olfactory nerves upon the membranes of the nofe, and difcovered the courfe of fome of the branches of the fifth pair of nerves. In the gravid uterus, he traced the arteries of the uterus to their termination in the placenta. He was alfo the firft who difcovered the exiftence of the lymphatic veffels in birds.

Many parts of the human body being fo complex, that their ftructure could not be underftood, nor their ufes afcertained, Mr Hunter was led to examine fimilar parts in other animals, in which the ftructure was more fimple, and more within the reach of inveftigation; this carried him into a wide field, and laid the foundation of his collection in comparative anatomy.

In this new line of purfuit, this active inquirer began with the more common animals, and preferved fuch parts as appeared by their analogy, or in fome other way, to elucidate the human economy. It was not his intention to make diffections of particular animals, but to inftitute an inquiry into the various organizations by which the functions of life are performed, that he might thereby acquire fome knowledge of general principles.

So eagerly did Mr Hunter attach himfelf to comparative anatomy, that he fought by every means in his power the opportunities of profecuting it with advantage. He applied to the keeper of wild beafts in the Tower for the bodies of thofe which died there; and he made fimilar applications to the men who fhowed wild beafts. He purchafed all rare animals which came in his way; and thefe, with fuch others as were prefented to him by his friends, he entrufted to the fhowmen to keep till they died, the better to encourage them to affift him in his labours.

His health was fo much impaired by exceffive attention to his purfuits, that in the year 1760 he was advifed to go abroad, having complaints in his breaft which threatened to be confumptive. In October of that year, Mr Adair, infpector-general of hofpitals, appointed him a furgeon on the ftaff; and in the following fpring he went with the army to Bellifle, leaving Mr Hewfon to affift his brother during his abfence.

Mr Hunter ferved, while the war continued, as fenior furgeon on the ftaff, both in Bellifle and Portugal, till the year 1763; and in that period acquired his knowledge of gun-fhot wounds. On his return to England he fettled in London; where, not finding the emoluments from his half-pay and private practice fufficient to fupport him, he taught practical anatomy and operative furgery for feveral winters. He returned alfo, with unabated ardour, to comparative anatomy; and as his experiments could not be carried on in a large town, he purchafed for that purpofe, about two miles from London, a piece of ground near Brompton, at a place called Earl's Court, on which he built a houfe. In the courfe of his inquiries, this excellent anatomift afcertained the changes which animal and vegetable fubftances undergo in the ftomach when acted on by the gaftric juice; he difcovered, by means of feeding young animals with madder (which tinges growing bones red), the mode in which a bone retains its fhape during its growth; and explained the procefs of exfoliation, by which a dead piece of bone is feparated from the living.

His fondnefs for animals made him keep feveral of different kinds in his houfe, which, by attention, he rendered familiar with him, and amufed himfelf by obferving their peculiar habits and inftincts; but this familiarity was attended with confiderable rifk, and fometimes led him into fituations of danger, of which the following is a remarkable inftance:

Two leopards, which were kept chained in an outhoufe, had broken from their confinement, and got into the yard among fome dogs, which they immediately attacked; the howling this produced alarmed the whole neighbourhood; Mr Hunter ran into the yard to fee what was the matter, and found one of them getting up the wall to make his efcape, the other furrounded by the dogs; he immediately laid hold of them both, and carried them back to their den; but as foon as they were fecured, and he had time to reflect upon the rifk of his own fituation, he was fo much agitated, that he was in danger of fainting.

On the fifth of February 1767, he was chofen a fellow of the Royal Society. His desire for improvement in those branches of knowledge which might assist in his researches, led him at this time to propose to Dr George Fordyce and Mr Cumming, an eminent mechanic, that they should adjourn from the meetings of the Royal Society to some coffee-house, and discuss such subjects as were connected with science. This plan was no sooner established, than they found their numbers increased; they were joined by Sir Joseph Banks, Dr Solander, Dr Maskelyne, Sir George Shuckburgh, Sir Harry Englefield, Sir Charles Blagden, Dr Noothe, Mr Ramsden, Mr Watt of Birmingham, and many others. At these meetings discoveries and improvements in different branches of philosophy were the objects of their consideration; and the works of the members were read over and criticised before they were given to the public. It was in this year that, by an exertion in dancing, after the muscles of the leg were fatigued, he broke his tendo achillis. This accident, and the confinement in consequence of it, led him to pay attention to the subject of broken tendons, and to make a series of experiments to ascertain the mode of their union.

In the year 1768 Mr Hunter became a member of the corporation of surgeons; and in the year following, through his brother's interest, he was elected one of the surgeon's of St George's hospital. In May 1771, his Treatise on the Natural History of the Teeth was published; and in July of the same year he married Miss Home, the eldest daughter of Mr Home, surgeon to Burgoyne's regiment of light horse. The expence of his pursuits had been so great, that it was not till several years after his first engagement with this lady that his affairs could be sufficiently arranged to admit of his marrying.

Though after his marriage his private practice and professional character advanced rapidly, and though his family began to increase, he still devoted much of his time to the forming of his collection, which, as it daily became larger, was also attended with greater expence. The whole suit of the best rooms in his house were occupied by his preparations; and he dedicated his mornings, from sunrise to eight o'clock (the hour for breakfast), entirely to his pursuits. To these he added such parts of the day as were not engaged in attending his patients.

The knowledge he derived from his favourite studies he constantly applied to the improvement of the art of surgery, and omitted no opportunity of examining morbid bodies; from which he made a collection of facts which are invaluable, as they tend to explain the real causes of symptoms, which, during life, could not be exactly ascertained, the judgment of the practitioner being too frequently misled by theoretical opinions, and delusive sensations of the patients.

In the practice of surgery, where cases occurred in which the operations proved inadequate to their intention, he always investigated, with uncommon care, the causes of that want of success; and in this way detected many fallacies, as well as made some important discoveries, in the healing art. He detected the cause of failure, common to all the operations in use for the radical cure of the hydrocele, and was enabled to propose a mode of operating, in which that event can with certainty be avoided. He ascertained, by experiments and observations, that exposure to atmospherical air simply, can neither produce nor increase inflammation. He discovered in the blood so many phenomena connected with life, and not to be referred to any other cause, that he considered it as alive in its fluid state. He improved the operation for the fistula lachrymalis, by removing a circular portion of the os unguis instead of breaking it down with the point of a trochar. He also discovered that the gastric juice had a power when the stomach was dead of dissolving it; and gave to the Royal Society a paper on this subject, which is published in the Philosophical Transactions.

In the winter 1773, he formed a plan of giving a course of lectures on the theory and principles of surgery, with a view of laying before the public his own opinions upon that subject. For two winters he read his lectures *gratis* to the pupils of St George's Hospital; and in 1775, gave a course for money upon the same terms as the other teachers in the different branches of medicine and surgery. But giving lectures was always particularly unpleasant to him; so that the desire of submitting his opinions to the world, and learning their general estimation, were scarcely sufficient to overcome his natural dislike to speaking in public. He never gave the first lecture of his course without taking 30 drops of laudanum to take off the effects of his uneasiness.

Comparative anatomy may be considered as the pursuit in which Mr Hunter was constantly employed. No opportunity escaped him. In the year 1773, at the request of his friend Mr Walsh, he dissected the torpedo, and laid before the Royal Society an account of its electrical organs. A young elephant, which had been presented to the Queen by Sir Robert Barker, died, and the body was given to Dr Hunter, which afforded Mr Hunter an opportunity of examining the structure of that animal by assisting his brother in the dissection; since that time two other elephants died in the Queen's menagerie, both of which came under Mr Hunter's examination. In 1774, he published in the Philosophical Transactions an account of certain receptacles of air in birds, which communicate with the lungs, and are lodged both among the fleshy parts and hollow bones of these animals; and a paper on the Gillaroo trout, commonly called in Ireland the *Gizzard-trout*.

In 1775, several animals of that species, called the *gymnotus electricus of Surinam*, were brought alive to this country, and by their electrical properties excited very much the public attention. Mr Walsh, desirous of pursuing his investigations of animal electricity, made a number of experiments on the living animals; and to give his friend Mr Hunter an opportunity of examining them, purchased those that died. An anatomical account of their electrical organs was drawn up by Mr Hunter, and published in the Philosophical Transactions. In the same volume there is a paper of his, containing experiments on animals and vegetables respecting their power of producing heat.

In the course of his pursuits, Mr Hunter met with many parts of animals where natural appearances could not be preserved, and others, in which the minuter vessels could not be distinctly seen when kept in spirits; it was therefore necessary to have them drawn, either at the moment, or before they were put into bottles.

The

Hunter.

The expence of employing professed draughtsmen, the difficulty of procuring them, and the disadvantage which they laboured under in being ignorant of the subject they were to represent, made him desirous of having an able person in his house entirely for that purpose.

With this view he engaged an ingenious young artist to live with him for ten years; his time to be wholly employed as a draughtsman, and in making anatomical preparations. This gentleman, whose name was Bell, soon became a very good practical anatomist, and from that knowledge was enabled to give a spirited and accurate resemblance of the subjects he drew, such as is rarely to be met with in representations of anatomical subjects. By his labours Mr Hunter's collection is enriched with a considerable number of very valuable drawings, and a great variety of curious and delicate anatomical preparations.

In January 1776, Mr Hunter was appointed surgeon extraordinary to his Majesty; and in the spring he gave to the Royal Society a paper on the best mode of recovering drowned persons.

In the autumn he was taken extremely ill; and the nature of his complaints made his friends, as well as himself, consider his life to be in danger. When he reflected upon his own situation, that all his fortune had been expended in his pursuits, and that his family had no provision but what should arise from the sale of his collection, he became very solicitous to give it its full value, by leaving it in a state of arrangement. This he accomplished with the assistance of Mr Bell and his brother-in-law Mr Home.

In 1778, he published the second part of his Treatise on the Teeth, in which their diseases, and the mode of treatment are considered. This rendered his work upon that subject complete. He published also in the Philosophical Transactions a paper on the Heat of Animals and Vegetables. In 1779, he published his account of the Free Martin in the Philosophical Transactions; and in 1780, he laid before the Royal Society an account of a woman who had the small pox during pregnancy, where the disease seemed to have been communicated to the fœtus.

In 1781, he was elected a fellow of the Royal Society of Sciences and Belles Lettres at Gottenburg. And in 1782, he gave the Royal Society a paper on the Organ of Hearing in Fish. Besides the papers which he presented to that learned body, he read six Croonion lectures upon the subject of Muscular Action, for the years 1776, 1778, 1779, 1780, 1781, and 1782. In these lectures he collected all his observations, upon muscles, respecting their powers and effects, and the stimuli by which they are affected; and to these he added Comparative Observations upon the moving Powers of Plants.

These lectures were not published in the Philosophical Transactions, for they were withdrawn as soon as read, not being considered by the author as complete dissertations, but rather as materials for some future publication.

It is much to be regretted (says Mr Home) that Mr Hunter was so tardy in giving his observations to the public; but such was his turn for investigation, and so extensive the scale upon which he instituted his inquiries, that he always found something more to be accomplished, and was unwilling to publish any thing which appeared to himself unfinished. His observations on the Muscular Action of the Blood-vessels were laid before the Royal Society in 1780, and yet he delayed publishing them till his Observations on the Blood and Inflammation were arranged; and they make part of the volume which was published after his death.

Hunter.

In 1783, he was chosen into the Royal Society of Medicine and the Royal Academy of Surgery in Paris; and the same year the lease of the house which he occupied in Jermyn-street having expired, he purchased the lease of a large house on the east-side of Leicester-square, and the whole lot of ground adjoining to Castle-street, on which there was another house. In the middle space between the two houses, he erected, at the expence of L. 3000, a building for his collection; though, unfortunately for his family, the lease did not extend beyond 24 years.

In the building formed for the collection there was a room fifty-two feet long by twenty-eight feet wide, lighted from the top, and having a gallery all round, for containing his preparations. Under this were two apartments; one for his lectures, and the other, with no particular destination at first, but afterwards made use of for weekly meetings of medical friends during the winter. To this building the house in Castle-street was entirely subservient; and the rooms in it were used for the different branches of human and comparative anatomy.

About this period Mr Hunter may be considered as at the height of his chirurgical career; his mind and body were both in their full vigour. His hands were capable of performing whatever was suggested by his mind; and his judgment was matured by former experience. Some instances of his extraordinary skill may very properly be mentioned.

He removed a tumor from the side of the head and neck of a patient at St George's Hospital, as large as the head to which it was attached; and by bringing the cut edges of the skin together, the whole was nearly healed by the first intention.

He dissected out a tumor on the neck, which one of the best operating surgeons in this country had declared, rather too strongly, that no one but a fool or a madman would attempt; and the patient got perfectly well.

He discovered a new mode of performing the operation for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh, without doing any thing to the tumor in the ham. The safety and efficacy of this mode have been confirmed by many subsequent trials; and it must be allowed to stand very high among the modern improvements in surgery.

If we consider Mr Hunter at this period of his life, it will afford us a strong picture of the turn of his mind, of his desire to acquire knowledge, and his unremitting assiduity in prosecuting whatever was the object of his attention.

He was engaged in a very extensive private practice; he was surgeon to St George's Hospital; he was giving a very long course of lectures in the winter; he was carrying on his inquiries in comparative anatomy; had a school of practical human anatomy in his house; and was always employed in some experiments respecting the animal economy.

He was always solicious for some improvement in medical

Hunter.

medical education; and, with the affiftance of Dr Fordyce, inftituted a medical fociety, which he allowed to meet in his lecture rooms, and of which he was chofen one of the patrons. This fociety, called the *Lyceum Medicum Londinenfe*, under his aufpices and thofe of Dr Fordyce, has acquired confiderable reputation, both from the numbers and merits of its members.

In the year 1786, in confequence of the death of Mr Middleton, Mr Hunter was appointed deputy furgeon-general to the army. He now publifhed his work upon the Venereal Difeafe, which had been long expected by the public; and, if we may judge from the rapid fale of the firft edition, thefe expectations have not been difappointed. He alfo publifhed a work entitled, Obfervations on certain Parts of the Animal Economy. In this work he has collected feveral of his papers inferted in the Philofophical Tranfactions, which related to that fubject, having permiffion from the prefident and council of the Royal Society to reprint them; there are alfo Obfervations upon fome other parts of the Animal Economy, which had not before been publifhed. This work met with a very ready fale.

In the year 1787, he gave a paper to the Royal Society, containing an Experiment to determine the Effect of extirpating one Ovarium on the Number of Young; a paper in which the wolf, jackall, and dog, are proved to be of the fame fpecies; and a third upon the Anatomy of the Whale Tribe. Thefe papers procured him the honour of receiving Sir John Copley's annual gold medal, given as a mark of diftinguifhed abilities.

His collection, which had been the great object of his life, both as a purfuit and an amufement, was now brought into a ftate of arrangement; and gave him at length the fatisfaction of fhewing to the public a feries of anatomical facts formed into a fyftem, by which the economy of animal life was illuftrated. He fhewed it to his friends and acquaintances twice a-year, in October to medical gentlemen, and in May to noblemen and gentlemen, who were only in town during the fpring. This cuftom he continued to his death.

Upon the death of Mr Adair, which happened in the year 1792, Mr Hunter was appointed infpector-general of hofpitals, and furgeon-general to the army. He was alfo elected a member of the Royal College of Surgeons in Ireland. In the year 1791, he was fo much engaged in the duties of his office, as furgeon-general to the army, and his private practice, that he had little time to beftow upon his fcientifical objects; but his leifure time, fmall as it was, he wholly devoted to them.

In 1792, he was elected an honorary member of the Chirurgo-Phyfical Society of Edinburgh, and was chofen one of the vice-prefidents of the Veterinary College, then firft eftablifhed in London. He publifhed in the Tranfactions of the Society for the Improvement of medical and chirurgical Knowledge, of which fociety he was one of the original members and a zealous promoter, three papers on the following fubjects: Upon the Treatment of Inflamed Veins, on Introfufception, and on a Mode of conveying Food into the Stomach in Cafes of Paralyfis of the Œfophagus.

He finifhed his Obfervations on the Economy of Bees, and prefented them to the Royal Society. Thefe obfervations were made at Earl's Court, and had engaged his attention for many years; every inquiry into the economy of thefe infects had been attended by almoft unfurmountable difficulties; but thefe proved to him only an incitement, and the contrivances he made ufe of to bring the different operations of thefe indefatigable animals to view were almoft without end.

Earl's Court to Mr Hunter was a retirement from the fatigues of his profeffion; but in no refpect a retreat from his labours; there, on the contrary, they were carried on with lefs interruption, and with an unwearied perfeverance. From the year 1772 till his death, he made it his cuftom to fleep there during the autumn months, coming to town only during the hours of bufinefs in the forenoon, and returning to dinner.

It was there he carried on his experiments on digeftion, on exfoliation, on the tranfplanting of teeth into the combs of cocks, and all his other inveftigations on the animal economy, as well in health as in difeafe. The common bee was not alone the fubject of his obfervation, but the wafp, hornet, and the lefs known kinds of bees, were alfo objects of his attention. It was there he made the feries of preparations of the external and internal changes of the filk worm; alfo a feries of the incubation of the egg, with a very valuable fet of drawings of the whole feries. The growth of vegetables was alfo a favourite fubject of inquiry, and one on which he was always engaged in making experiments.

The collection of comparative anatomy which Mr Hunter has left, and which may be confidered as the great object of his life, muft be allowed to be a proof of talents, affiduity, and labour, which cannot be contemplated without furprife and admiration. It remains an unequivocal teft of his perfeverance and abilities, and an honour to the country in whofe fchools he was educated, and by the patronage of which he was enabled on fo extenfive a fcale to carry on his purfuits. In this collection we find an attempt to expofe to view the gradations of Nature, from the moft fimple ftate in which life is found to exift, up to the moft perfect and moft complex of the animal creation—man himfelf.

By the powers of his art, this collector has been enabled fo to expofe, and preferve in fpirits or in a dried ftate, the different parts of animal bodies intended for fimilar ufes, that the various links of the chain of perfection are readily followed and may be clearly underftood.

This collection of anatomical facts is arranged according to the fubjects they are intended to illuftrate, which are placed in the following order: *Firft*, Parts conftructed for motion. *Secondly*, Parts effential to animals refpecting their own internal economy. *Thirdly*, Parts fuperadded for purpofes connected with external objects. *Fourthly*, Parts for the propagation of the fpecies and maintenance or fupport of the young.

Mr Hunter was a very healthy man for the firft forty years of his life; and, if we except an inflammation of his lungs in the year 1759, occafioned moft probably by his attention to anatomical purfuits, he had no complaint of any confequence during that period. In the fpring of 1769, in his forty firft year, he had a regular fit of the gout, which returned the three following fprings, but not the fourth; and in the fpring of 1773, having met with fomething which very forcibly affected his mind, he was attacked at ten o'clock in the forenoon with a pain in the ftomach, attended with all the fymptoms of *angina pectoris*. In the life of him prefixed to his *Treatife on the Blood, Inflammation, and Gun-fhot Wounds*,

Wounds, the reader will find one of the most complete histories of that disease upon record. Suffice it, in this place, to say, that for twenty years he was subject to frequent and severe attacks of it, which however did not, till a short time before his death, either impair his judgment or render him incapable of performing operations in surgery. "In autumn 1790 (says Mr Home), and in the spring and autumn 1791, he had more severe attacks than during the other periods of the year, but of not more than a few hours duration: in the beginning of October 1792, one, at which I was present, was so violent that I thought he would have died. On October the 16th, 1793, when in his usual state of health, he went to St George's Hospital, and meeting with some things which irritated his mind, and not being perfectly master of the circumstances, he withheld his sentiments; in which state of restraint he went into the next room, and turning round to Dr Robertson, one of the physicians of the hospital, he gave a deep groan and dropt down dead; being then in his 65th year, the same age at which his brother Dr Hunter had died."

It is a curious circumstance, that the first attack of these complaints was produced by an affection of the mind, and every future return of any consequence arose from the same cause; and although bodily exercise, or distention of the stomach, brought on slighter affections, it still required the mind to be affected to render them severe; and as his mind was irritated by trifles, these produced the most violent effects on the disease. His coachman being beyond his time, or a servant not attending to his directions, brought on the spasms, while a real misfortune produced no effect.

Mr Hunter was of a short stature, uncommonly strong and active, very compactly made, and capable of great bodily exertion. His countenance was animated, open, and in the latter part of his life deeply impressed with thoughtfulness. When his print was shewn to Lavater, he said, "That man thinks for himself." In his youth he was cheerful in his disposition, and entered into youthful follies like others of the same age; but wine never agreed with his stomach; so that after some time he left it off altogether, and for the last twenty years drank nothing but water.

His temper was very warm and impatient, readily provoked, and, when irritated, not easily soothed. His disposition was candid, and free from reserve, even to a fault. He hated deceit; and as he was above every kind of artifice, he detested it in others, and too openly avowed his sentiments. His mind was uncommonly active; it was naturally formed for investigation, and that turn displayed itself on the most trivial occasions, and always with mathematical exactness. What is curious, it fatigued him to be long in a mixed company which did not admit of connected conversation; more particularly during the last ten years of his life.

He required less relaxation than most other men; seldom sleeping more than four hours in the night, but almost always nearly an hour after dinner; this, probably, arose from the natural turn of his mind being so much adapted to his own occupations, that they were in reality his amusement, and therefore did not fatigue.

In private practice he was liberal, scrupulously honest in saying what was really his opinion of the case, and ready upon all occasions to acknowledge his ignorance, whenever there was any thing which he did not understand.

In conversation, he spoke too freely, and sometimes harshly, of his contemporaries; but if he did not do justice to their undoubted merits, it arose not from envy, but from his thorough conviction that surgery was as yet in its infancy, and he himself a novice in his own art; and his anxiety to have it carried to perfection, made him think meanly and ill of every one whose exertions in that respect did not equal his own.

HUNTERS, in fortification, denote pieces of timber, about six inches square, placed at the lower end of the platform, next to the parapet, to prevent the wheels of the gun-carriages from damaging the parapet.

HYDROGRAPHICAL Charts or Maps, more usually called sea-charts, are projections of some part of the sea, or coast, for the use of navigation. In these are laid down all the rhumbs or points of the compass, the meridians, parallels, &c. with the coasts, capes, islands, rocks, shoals, shallows, &c. in their proper places, and proportions.

HYDROMETER, is an instrument, of which so much has been said in the *Encycl.* under that title, and in the article Specific *Gravity*, that we certainly should not again introduce it in this place, but to guard our readers against error, when studying the works of the French chemists. These gentlemen, who are so strongly attached to every thing which is new, as to believe that their ancestors have for ages been wandering in the mazes of ignorance, refer very frequently to the *pese-liqueur* of Baumé; and as that instrument has never been generally used in this country, it becomes our duty to describe its construction.

Instead of adopting the simpler method of immediate numerical reference to the density of water expressed by unity, as is done in all modern tables of specific gravity, he had recourse to a process similar to that of graduating the stems of thermometers from two fixed points. The first of these points was obtained by immersing his instrument, which is the common areometer, consisting of a ball, stem, and counterpoise, in pure water. At that point of the stem which was intersected by the surface of the fluid, he marked *zero*, or the commencement of his graduations. In the next place, he provided a number of solutions of pure dry common salt in water: these solutions contained respectively one, two, three, four, &c. pounds of the salt; and in each solution the quantity of water was such, as to make up the weight equal to one hundred pounds in the whole; so that in the solution containing one pound of salt, there were ninety-nine pounds of water; in the solution containing two pounds of salt, there were ninety-eight pounds of water, and so of the rest. The instrument was then plunged in the first solution, in which of course it floated with a larger portion of the stem above the fluid, than when pure water was used. The fluid, by the intersection of its surface upon the stem, indicated the place for making his first degree; the same operation repeated, with the fluid containing two pounds of salt, indicated the mark for the second degree; the solution of three pounds afforded the third degree; and in this manner his enumeration was carried as far as fifteen degrees. The first fifteen degrees afterwards, applied with the compasses repeatedly along the stem, serving to extend the graduation as far as eighty degrees, if required.

This instrument, which is applicable to the admeasurement furement of denfities exceeding that of pure water, is commonly diftinguifhed by the name of the *Hydrometer for falts*.

The hydrometer for fpirits is conftructed upon the fame principle; but in this the counterpoife is fo adjufted, that moft part of the ftem rifes above the fluid when immerfed in pure water, and the graduations to exprefs inferior denfities are continued upwards. A folution of ten parts by weight of falt in ninety parts of pure water, affords the firft point, or zero, upon the ftem; and the mark indicated by pure water is called the tenth degree; whence, by equal divifions, the remaining degrees are continued upwards upon the ftem as far as the fiftieth degree.

Thefe experiments, in both cafes, are made at the tenth degree of Reaumur, which anfwers very nearly to fifty-five of Fahrenheit.

HYDRUS, or WATER SERPENT, one of the new fouthern conftellations, including only ten ftars.

HYGROMETER, is an inftrument of fo much importance to the meteorologift, that it becomes us to give fome account of every improvement of it which has fallen under our notice. In the *Encyclopædia*, the principles upon which hygrometers are conftructed have been clearly ftated, and the defects of each kind of hygrometer pointed out.

Inftead of hairs or cat-gut, of which hygrometers of the firft kind are commonly made, Caffebois, a Benedictine monk at Mentz, propofed to make fuch hygrometers of the gut of a filk-worm. When that infect is ready to fpin, there are found in it two veffels proceeding from the head to the ftomach, to which they adhere, and then bend towards the back, where they form a great many folds. The part of thefe veffels next the ftomach is of a cylindric form, and about a line in diameter. Thefe veffels contain a gummy fort of matter from which the worm fpins its filk; and, though they are exceedingly tender, means have been devifed to extract them from the infect, and to prepare them for the above purpofe. When the worm is about to fpin, it is thrown into vinegar, and fuffered to remain there twenty-four hours; during which time the vinegar is abforbed into the body of the infect, and coagulates its juices. The worm being then opened, both the veffels, which have now acquired ftrength, are extracted; and, on account of their pliability, are capable of confiderable extenfion. That they may not, however, become too weak, they are ftretched only to the length of about fifteen or twenty inches. It is obvious that they muft be kept fufficiently extended till they are completely dry. Before they attain to that ftate, they muft be freed, by means of the nail of the finger, from a flimy fubftance which adheres to them. Such a thread will fuftain a weight of fix pounds without breaking, and may be ufed for an hygrometer in the fame manner as cat-gut; but we confefs that we do not clearly perceive its fuperiority.

To an improvement of the hygrometer conftructed on the third principle, ftated in the *Encyclopædia*, M. Hochheimer was led in the following manner:

Mr Lowitz found at Dmitriewfk in Aftracan, on the banks of the Wolga, a thin bluifh kind of flate which attracted moifture remarkably foon, but again fuffered it as foon to efcape. A plate of this flate weighed, when brought to a red heat, 175 grains, and, when faturated with water, 247: it had therefore imbibed, between complete drynefs and the point of complete moifture, 72 grains of water. Lowitz fufpended a round thin plate of this flate at the end of a very delicate balance, faftened within a wooden frame, and fufpended at the other arm a chain of filver wire, the end of which was made faft to a fliding nut that moved up and down in a fmall groove on the edge of one fide of the frame. He determined, by trial, the pofition of the nut when the balance was in equilibrio and when it had ten degrees of over-weight, and divided the fpace between thefe two points into ten equal parts, adding fuch a number more of thefe parts as might be neceffary. When the ftone was fufpended from the one arm of the balance, and at the other a weight equal to 175 grains, or the weight of the ftone when perfectly dry, the nut in the groove fhewed the excefs of weight in grains when it and the chain were fo adjufted that the balance ftood in equilibrio. A particular apparatus on the fame principles as a vernier, applied to the nut, fhewed the excefs of weight to ten parts of a grain. Lowitz remarked that this hygrometer in continued wet weather gave a moifture of more than 55 grains, and in a continued heat of 113 degrees of Fahrenheit only $1\frac{1}{2}$ degree of moifture.

The hygrometer thus invented by Lowitz was, however, attended with this fault, that it never threw off the moifture in the fame degree as the atmofphere became drier. It was alfo fometimes very deceitful, and announced moifture when it ought to have indicated that drynefs had again begun to take place in the atmofphere. To avoid thefe inconveniences, M. Hochheimer propofes the following method:

1. Take a fquare bar of fteel about two lines in thicknefs, and from ten to twelve inches in length, and form it into a kind of balance, one arm of which ends in a fcrew. On this fcrew let there be fcrewed a leaden bullet of a proper weight, inftead of the common weights that are fufpended. 2. Take a glafs plate about ten inches long, and feven inches in breadth, deftroy its polifh on both fides, free it from all moifture by rubbing it over with warm afhes, fufpend it at the other end of the balance, and bring the balance into equilibrium by fcrewing up or down the leaden bullet. 3. Mark now the place to which the leaden bullet is brought by the fcrew, as accurately as poffible, for the point of the greateft drynefs. 4. Then take away the glafs plate from the balance, dip it completely in water, give it a fhake that the drops may run off from it, and wipe them carefully from the edge. 5. Apply the glafs-plate thus moiftened again to the balance, and bring the latter into equilibrium by fcrewing the leaden bullet. Mark then the place at which the bullet ftands as the higheft degree of moifture. 6. This apparatus is to be fufpended in a fmall box of well dried wood, fufficiently large to fuffer the glafs-plate to move up and down. An opening muft be made in the lid, exactly of fuch a fize as to allow the tongue of the balance to move freely. Parallel to the tongue apply a graduated circle, divided into a number of degrees at pleafure from the higheft point of drynefs to the higheft degree of moifture. The box muft be pierced with fmall holes on all the four fides, to give a free paffage to the air; and to prevent moifture from penetrating into

Hygrometer. into the wood by rain, when it may be requisite to expose it at a window, it must either be lackered or painted. To save it at all times from rain, it may be covered, however, with a sort of roof fitted to it in the most convenient manner. But all these external appendages may be improved or altered as may be found necessary.

HYPERBOLA DEFICIENT, is a curve having only one asymptote, though two hyperbolic legs running out infinitely by the side of the asymptote, but contrary ways.

Hypotrachelion. HYPOTRACHELION, in Architecture, is used for a little frize in the Tuscan and Doric capital, between the astragal and annulets; called also the colerin and gorgerin. The word is applied by some authors in a more general sense, to the neck of any column, or that part of its capital below the astragal.

I.

Jacobins. JACOBINS, in the language of the present day, is the name assumed, at the beginning of the French revolution, by a party in Paris, which was outrageously democratical, and fanatically impious. This party, which consisted of members of the National Assembly, and of others maintaining the same opinions and pursuing the same objects, formed itself into a club, and held its meetings in the hall belonging to the Jacobin friars, where measures were secretly concerted for exciting insurrections, and over-awing at once the legislature and the king. The name of *Jacobin*, though it was derived from the hall where the club first met, has since been extended to all who are enemies to monarchy, aristocracy, and the Christian religion; and who would have every man to be his own priest and his own lawgiver. Hence it is, that we have Jacobins in Great Britain and Ireland, as well as in France.

Of the proceedings of the French Jacobins, some account has been given in the *Encyclopædia*, under the title REVOLUTION; and the subject will be resumed in this *Supplement* under the same title. The purpose of the present article is to trace the principles of the sect from their source; for these principles are not of yesterday.

"At its very first appearance (says the Abbé Barruel), this sect counted 300,000 adepts; and it was supported by two millions of men, scattered through France, armed with torches and pikes, and all the firebrands of the revolution." Such a wide spread conspiracy could not be formed in an instant; and indeed this able writer has completely proved, that this sect, with all its conspiracies, is in itself no other than "the coalition of a triple sect, of a triple conspiracy, in which, long before the revolution, the overthrow of the altar, the ruin of the throne, and the dissolution of all civil society, had been debated and determined."

It is known to every scholar, that there have been in all ages and countries men of letters and pretenders to letters, who have endeavoured to signalize themselves individually by writing against the religion of their country; but it was reserved for the philosophists (A) of France to enter into a combination for the express purpose of eradicating from the human heart every religious sentiment. The man to whom this idea first occurred was Voltaire; who, daring to be jealous of his God, and being weary, as he said himself, of hearing people repeat that twelve men were sufficient to establish Christianity, resolved to prove that one might be sufficient to overthrow it. Full of this project, he swore, before the year 1730, to dedicate his life to its accomplishment; and for some time he flattered himself that he should enjoy alone the glory of destroying the Christian religion. He found, however, that associates would be necessary; and from the numerous tribe of his admirers and disciples, he chose D'Alembert and Diderot as the most proper persons to co-operate with him in his designs. How admirably they were qualified to act the part assigned them, may be conceived from the life of DIDEROT in this *Supplement*. But Voltaire was not satisfied with their aid alone.

He contrived to embark in the same cause Frederic II. of Prussia, who wished to be thought a philosopher, and who of course deemed it expedient to talk and write against a religion which he had never studied, and into the evidence of which he had probably never deigned to inquire. This royal adept was one of the most zealous of Voltaire's coadjutors, till he discovered that the philosophists were waging war with the throne as well as with the altar. This indeed was not originally Voltaire's intention. He was vain; he loved to be caressed by the great; and, in one word, he was, from natural disposition, an aristocrate and admirer of royalty: But when he found that almost every sovereign but Frederic, disapproved of his impious projects as soon *as he perceived their issue*, he determined to oppose all the governments on earth, rather than forfeit the glory, with which he had flattered himself, of vanquishing Christ and his apostles in the field of controversy.

He now set himself, with D'Alembert and Diderot, to excite universal discontent with the established order of things. This was an employment entirely suited to their disposition; for not being in any sense *great* themselves (B), they wished to pull all men down to their own level. How effectually they contrived to convert the *Encyclopedie* into an engine to serve their purposes, has been shewn already; but it was not their only nor their most powerful engine; they formed secret societies,

(A) This term was invented by Abbé Barruel, and we have adopted it, as denoting something very different from the meaning of the word *philosopher*.

(B) We do not by this mean to insinuate that D'Alembert was not a man of science. He was perhaps the only man of science in that gang; but he was a master of no science but mathematics; and his birth being obscure, Jacobins.

ties, affumed new names, and employed an enigmatical language. Thus, Frederic is called *Luc*; D'Alembert, *Protagoras*, and fometimes *Bertrand*; Voltaire, *Raton*; and Diderot, *Platon*, or its anagram *Tonpla*; while the general term for the confpirators is *Cacouce*. In their fecret meetings they profeffed to celebrate the myfteries of *Mythra*; and their great object, as they profeffed to one another, was to confound the *wretch*, meaning J— C—. Voltaire propofed to eftablifh a colony of philofophifts at Cleves, who, protected by the king of Pruffia, might publifh their opinions without dread or danger; and Frederic was difpofed to take them under his protection, till he difcovered that their opinions were anarchical, as well as impious, when he threw them off, and even wrote againft them.

They contrived, however, to engage the minifters of the court of France in their favour, by pretending to have nothing in view but the enlargement of fcience, in works which fpoke indeed refpectfully of revelation, while every difcovery which they brought forward was meant to undermine its very foundation. When the throne was to be attacked, and even when barefaced atheifm was to be promulgated, a number of impious and licentious pamphlets were difperfed, for fome time none knew how, from a fecret fociety formed at the Hotel d'Holbach at Paris. Thefe were fold for trifles, or diftributed *gratis* to fchoolmafters, and others who were likely to circulate their contents. D'Alembert, Diderot, and Condorcet, who was now affociated with the other confpirators, flattered the ambition of every man among the great, and efpecially of the Duke d'Orleans, the richeft fubject in Europe, and a prince of the blood of France. The firft and the laft of thefe three adepts had, by their mathematical knowledge, got fuch an afcendancy in the Royal Academy of Sciences, that they could admit or exclude candidates as they knew them to be friendly or inimical to the projects of the confpirators; and they had contrived, by matchlefs addrefs and unwearied perfeverance, to fill almoft all the feminaries of education with men of their own principles.

Thus was the public mind in France completely corrupted, when the mafon lodges, over which the infamous Orleans prefided, were vifited by a delegation from the German illuminati; and nothing more was neceffary to produce the fect of *Jacobins*, by whofe intrigues and influence, France, as M. Barruel expreffes himfelf, has become a prey to every crime. It was by the machinations of this fect that its foil was ftained with the blood of its pontiffs and priefts, its rich men and nobles; with the blood of every clafs of its citizens, without regard to rank, age, or fex. Thefe difciples of Voltaire were the men who, after having made the unfortunate Louis, his queen, and fifter, drink, to the very dregs, the cup of outrage and ignominy during a long confinement, folemnly murdered them on a fcaffold, proudly menacing all the fovereigns of the earth with a fimilar fate. Yet think not, indignant reader, that the ways of Providence are unequal. The nations of Europe were ripe for chaftifement; and that chaftifement thefe villains were employed to inflict: but their own punifhment did not linger. Voltaire died in agonies of defponding remorfe, which can be exceeded only by the torments of the damned. There is reafon to believe that the end of D'Alembert and Diderot very much refembled that of their leader; while the more hardened adept, Condorcet, became his own executioner; and the other chiefs of the rebellion have regularly inflicted vengeance on each other, every alteration of the French conftitution (and thefe alterations have been many) being followed by the execution of thofe by whom the government was previoufly adminiftered.

Jaghire || Jago.

JAGHIRE, affignment made in Bengal by an Imperial grant upon the revenue of any diftrict, to defray civil or military charges, penfions, gratuities, &c.

JAGHIREDER, the holder of a Jaghire.

St JAGO, the largeft and moft populous of the Cape de Verde Iflands, of which fome account has been given in the *Encyclopædia*, is reprefented by Sir George Staunton as liable to long and exceffive droughts, for which no philofophical caufe can be affigned. When the embaffy to China touched at it in the latter end of 1792, it was in a ftate of abfolute famine. Little or no rain had fallen for about three years before. The rivers were almoft all entirely dry. The furface of the earth was, in general, naked of any herbage. The greateft part of the cattle had perifhed, not lefs through drought than want of food. Of the inhabitants many had migrated, and many were famifhed to death. Nor was this calamity peculiar to St Jago. All the iflands of Cape de Verde were faid to have experienced the fame long drought, and to be confequently in a ftate of fimilar defolation. Yet the frequent fhowers which were obferved by the firft navigators who touched at St Jago, induced them to give to the ifland the name of *Pluvialis*; and no change had been obferved in the fteady current of wind, blowing from the eaft, which is common to tropical climates.

"What were the uncommon circumftances (fays Sir George) that took place in the atmofphere of that part of Africa to which the Cape de Verde iflands lie contiguous, or in the vaft expanfe of continent extending to the eaft behind it, and from which this direful effect muft have proceeded, as they happened where no man of fcience exifted to obferve or to record them, will therefore remain unknown; nor is theory bold enough to fupply the place of obfervation. Whatever was the caufe which thus arrefted the bountiful hand of Nature, by drawing away the fources of fertility, it was obfervable, that fome few trees and plants perfevered to flourifh with a luxuriance, indicating that they ftill could extract from the arid earth whatever portion of humidity it was neceffary to derive from thence for the purpofe of vegetable life, though it was denied to others."

Befide the trees of the palm kind, which are often found verdant amidft burning fands, nothing, for example, could be more rich in flavour, or abound more with milky, though corrofive juice, than the afclepias gigantea (fee Asclepias, *Encycl.*), growing plentifully, about feveral feet high, without culture, indeed, but undifturbed, it being of no avail to cut it down in favour of plants that would be ufeful, but required the aid of more moifture from the atmofphere. The jatropha

---

fcure, if not fpurious, and abftract mathematics not furnifhing ready accefs to the great, his ideas, when compared with Voltaire's, were grovelling, and (as M. Barruel fays) he was afraid to be feen.

Jago.

pha curcas, or phyfic nut tree, which the French Weft Indians, with fome propriety, call *bois immortel*, and plant, on that account, in the boundaries of their eftates, appeared as if its perpetuity was not to be affected by any drought. Some indigo plants were ftill cultivated with fuccefs in fhaded vales, together with a few cotton fhrubs. Throughout the country fome of thofe fpecies of the mimofa, or fenfitive plant, which grow into the fize of trees, were moft common, and did not appear to languifh. In particular fpots the annona, or fugar apple tree, was in perfect verdure. The boraffus, or great fan palm, lifted, in a few places, its lofty head and fpreading leaves with undiminifhed beauty. In a bottom, about a mile and a half behind the town of Praya, was ftill growing, in a healthy ftate, what may be called for fize a phenomenon in vegetation, a tree known to botanifts by the name of adanfonia, and in Englifh called *monkey bread tree*. The natives of St Jago call it *kabifera*; others, baobab. Its trunk meafured at the bafe no lefs than 56 feet in girth; but it foon divided into two great branches, one rifing perpendicularly, and meafuring 42 feet in circumference; that of the other was about 26. By it ftood another of the fame fpecies, whofe fingle trunk, of 38 feet girth, attracted little notice from the vicinity of its huge companion.

But the annual produce of agriculture was fcarcely to be found. The plains and fields, formerly productive of corn, fugar-canes, or plaintains, nourifhed by regular falls of rain, now bore little femblance of vegetation. Yet in the fmall number of plants which furvived the drought, were fome which, from the fpecimens fent to Europe, were found to have been hitherto unknown. Vegetation quickly, indeed, revived wherever, through the foil, any moifture could be conveyed.

Sir George reprefents Praya, the refidence of the Portuguefe Viceroy, as a hamlet rather than a town. It confifts of about 100 very fmall dwellings, one ftory high, fcattered on each fide of the plain, which extended near a mile in length, and about the third of a mile in breadth; and fell off, all around, to the neighbouring valleys and to the fea. Not being commanded by any neighbouring eminence, it was a fituation capable of defence; the fort, however, or battery, was almoft in ruins; and the few guns mounted on it were moftly honey-combed, and placed on carriages which fcarcely held together.

A party belonging to the embaffy croffed the country to the ruins of St Jago, the former capital of the ifland, fituated in the bottom of a vale, through which ran a ftream, then both fmall and fluggifh. On each fide of that ftream are the remains of dwellings of confiderable folidity and fize; and the fragments of glafs luftres, ftill hanging from the ceilings of fome of the principal apartments, denote the elegance or riches that were once difplayed in this now deferted place. Not above half a dozen families remain in it at prefent; the reft abandoned it, or perifhed. Here was ftill, however, an attempt at a flight manufactory of ftripped cotton flips, the fame as are made in the other parts of the ifland, for the ufe of the Africans on the main, who pay for them in flaves, elephants teeth, and that gum which is generally called arabic.

Amidft the ruins of St Jago, the party found a Portuguefe, to whom one of them was recommended, and who received them with the moft cordial hofpitality in his houfe, and treated them with every fpecies of tropical fruits from his garden, lying on each fide the river.

He had been a navigator; and informed them that the ifle of Brava, one of the Cape de Verde's, was a fitter and fafer place for fhips to call at for water and provifions than the ifland of St Jago; that it had three harbours: one called Puerto Furno on the eaft fide of the ifland, from which veffels muft warp, or be towed out by boats; the Puerto Fajendago to the weft; and the Puerto Ferreo to the fouth, which was the beft for large fhips, and into which runs a fmall river. In another of the Cape de Verde iflands, called San Vicente, he obferved that there was alfo a large harbour on the north end, but that frefh water was at fome diftance from it: and there was likewife a good port at Bonavifta. This information of the harbours in the ifle of Brava was confirmed by accounts given by others to Sir Erafmus Gower, who recommends to make a trial of them.

Jaloffs.

JALOFFS, or YALOFFS, are an active, powerful, and warlike people, inhabiting great part of that tract of Africa which lies between the Senegal and the Mandingo ftates on the Gambia (See MANDINGOES in this *Supplement*). Their nofes, fays Mr Park, are not fo much depreffed, nor their lips fo protuberant, as thofe of the generality of Africans; and though their fkin is of the deepeft black, they are confidered by the white traders as the moft fightly negroes in that part of the continent where they live. They are divided into feveral independent ftates or kingdoms, which are frequently at war with their neighbours or with each other. In their manners, fuperftitions, and government, they have a greater refemblance to the Mandingoes than to any other nation; but excel them in the manufacture of cotton cloth, fpinning the wool to a finer thread, weaving it in a broader loom, and dyeing it of a better colour. They make very good foap, by boiling ground nuts in water, and then adding a ley of wood afhes. They likewife manufacture excellent iron, which they carry to Bondou to barter for falt. Their language is faid to be copious and fignificant, and is often learned by Europeans trading to Senegal. From the names of their numerals, as given by Mr Park, it would appear that their numeration proceeds by *fives*, as ours does by *tens*.

Our author relates the event of a religious war, which, as it difplays a generofity of character very uncommon among favages, will afford pleafure to the minds of many of our readers. Almami Abdulkader, fovereign of a Mahomedan kingdom called Foota Torra, fent to Damel, a king of the Jaloffs, an imperious meffage, commanding him and his fubjects to embrace inftantly the faith of the prophet. The ambaffador having got admiffion to the prefence of Damel, ordered fome Bufhreens (*i.e.* Mahomedan negroes) who accompanied him, to prefent the emblems of his miffion. Two knives were accordingly laid before the Jaloff prince, and the ambaffador explained himfelf as follows:

"With this knife (faid he) Abdulkader will condefcend to fhave the head of Damel, if Damel will embrace the Mahomedan faith; and with this other knife Abdulkader will cut the throat of Damel, if Damel refufes to embrace it: Take your choice."—Damel coolly told the ambaffador that he had no choice to make;

he

Jaloffs, Jarra.

he neither chose to have his head shaved, nor his throat cut. And with this answer the ambassador was civilly dismissed.

Abdulkader took his measures accordingly; and with a powerful army invaded Damel's country. The inhabitants of the towns and villages filled up their wells, destroyed their provisions, carried off their effects, and abandoned their dwellings, as he approached. By this means he was led on from place to place, until he had advanced three days journey into the country of the Jaloffs. He had, indeed, met with no opposition; but his army had suffered so much from the scarcity of water, that several of his men died by the way. This induced him to direct his march towards a watering place in the woods, where his men, having quenched their thirst, and being overcome with fatigue, lay down carelessly to sleep among the bushes. In this situation they were attacked by Damel before day-break, and completely routed. Many of them were trampled to death as they lay asleep by the Jaloffs horses; others were killed in attempting to make their escape; and a still greater number were taken prisoners. Among the latter was Abdulkader himself. This ambitious, or rather frantic prince, who, but a month before, had sent the threatening message to Damel, was now himself led into his presence as a miserable captive. The behaviour of Damel, on this occasion, is never mentioned by the singing men* but in terms of the highest approbation; and it was, indeed, so extraordinary in an African prince, that the reader may find it difficult to give credit to the recital. When his royal prisoner was brought before him in irons, and thrown upon the ground, the magnanimous Damel, instead of setting his foot upon his neck, and stabbing him with his spear, according to the custom in such cases, addressed him as follows: "Abdulkader, answer me this question. If the chance of war had placed me in your situation, and you in mine, how would you have treated me?" "I would have thrust my spear into your heart (returned Abdulkader with great firmness); and I know that a similar fate awaits me." "Not so (said Damel); my spear is indeed red with the blood of your subjects killed in battle, and I could now give it a deeper stain, by dipping it in your own; but this would not build up my towns, nor bring to life the thousands who fell in the woods. I will not therefore kill you in cold blood, but I will retain you as my slave, until I perceive that your presence in your own kingdom will be no longer dangerous to your neighbours; and then I will consider of the proper way of disposing of you." Abdulkader was accordingly retained, and worked as a slave for three months; at the end of which period, Damel listened to the solicitations of the inhabitants of Foota Torra, and restored to them their king. Strange as this story may appear, Mr Park has no doubt of the truth of it. It was told to him at Malacotta by the negroes; it was afterwards related to him by the Europeans on the Gambia; by some of the French at Goree; and confirmed by nine slaves, who were taken prisoners along with Abdulkader by the watering place in the woods, and carried in the same ship with him to the West Indies.—Such generosity as this reflects honour on human nature.

* *The historians of the country.*

JARRA, is a town of considerable extent in the Moorish kingdom of Ludamar in Africa. The houses are built of clay and stone intermixed, a kind of wall very common in many parts of Scotland, where clay is made to supply the place of mortar. The greater part of the inhabitants of Jarra are Negroes from the borders of the southern states, who prefer, says Mr Park, a precarious protection under the Moors, which they purchase by a tribute, to the being continually exposed to their predatory hostilities. The tribute which they pay is considerable; and they manifest the most unlimited obedience and submission to their Moorish superiors: by whom they are, in return, treated with the utmost indignity and contempt. The Moors in this, and the other states adjoining the country of the Negroes, resemble in their persons the Mulattoes of the West Indies, and seem to be a mixed race between the Moors, properly so called, of the north, and the Negroes of the south; possessing many of the worst qualities of both nations. Jarra is situated in 15° 5′ N. Lat. and 6° 48′ E. Long.

Ibis, Ice-house.

IBIS. Under the generic name TANTALUS (*Encycl.*), we have described, after Mr Bruce, a bird which he found in Abyssinia, and concluded to be the sacred ibis of ancient Egypt. M. Vaillant, during his last travels in Africa, found, in some lakes near the elephants river, a bird very different from Mr Bruce's, which he considered as belonging to the same species; and which he describes thus: It is three feet in height. Its head and throat, which are extremely bare, are covered with a skin of the brightest red, terminated by a band of a beautiful orange, which separates the naked part from that covered with feathers. The upper part of the wings, having broad stripes of a fine violet colour, agreeably shaded, is bordered by a white band of feathers, the thick and silky beards of which, separated from each other, have a perfect resemblance to a rich fringe. The quills of the wings and tail are of a greenish black, which, as it receives the light in a more or less oblique direction, assumes the appearance of violet or purple. The rest of the plumage is of a beautiful white. The bill, which is long and somewhat crooked, is yellow; as are the feet. This bird belongs to the genus of the ibis, of which we are already acquainted with several species.

ICE-HOUSE. See that article, *Encyclopædia*. Professor Beckmann, in the third volume of his History of Inventions, has proved clearly that the ancients were well acquainted with what served the purpose of ice-houses.

"The art (says he) of preserving snow for cooling liquors during the summer, in warm countries, was known in the earliest ages. This practice is mentioned by Solomon *, and proofs of it are so numerous in the works of the Greeks and the Romans, that it is unnecessary for me to quote them, especially as they have been collected by others. How the repositories for keeping it were constructed, we are not expressly told; but it is probable that the snow was preserved in pits or trenches.

* *Proverbs*, xxv. 15.

"When Alexander the Great besieged the city of Petra, he caused 30 trenches to be dug, and filled with snow, which was covered with oak branches; and which kept in that manner for a long time. Plutarch says, that a covering of chaff and coarse cloth is sufficient; and at present a like method is pursued in Portugal. Where the snow has been collected in a deep gulph, some fome grafs or green fods, covered with dung from the fheep pens, is thrown over it ; and under thefe it is fo well-preferved, that the whole fummer through it is fent the diftance of 60 Spanifh miles to Lifbon.

"When the ancients, therefore, wifhed to have cooling liquors, they either drank the melted fnow, or put fome of it in their wine, or they placed jars filled with wine in the fnow, and fuffered it to cool there as long as they thought proper. That ice was alfo preferved for the like purpofe, is probable from the teftimony of various authors ; but it appears not to have been ufed fo much in warm countries as in the northern. Even at prefent fnow is employed in Italy, Spain, and Portugal ; but in Perfia ice. I have never any where found an account of Grecian or Roman ice-houfes. By the writers on agriculture they are not mentioned."

ICHNOGRAPHY, in architecture, is a tranfverfe or horizontal fection of a building, exhibiting the plot of the whole edifice, and of the feveral rooms and apartments in any ftory ; together with the thicknefs of the walls and partitions ; the dimenfions of the doors, windows, and chimneys ; the projectures of the columns and piers, with every thing vifible in fuch a fection.

JEBB (John), was born in Southampton-ftreet, Covent Garden, London, on the 16th of February 1736. He was the eldeft fon of the Rev. John Jebb, dean of Cafhel, in the kingdom of Ireland. He received the elements of his education in different fchools, and was admitted, July 7, 1753, penfioner in the univerfity of Dublin, whence he removed, November the 9th 1754, to St Peter's college in Cambridge, where he was likewife a penfioner. In January 1757 he proceeded to the degree of B. A. and his place in the diftribution of academical honours was, on that occafion, fecond wrangler, the late eminent mathematician Dr Waring being the firft. In 1758 he obtained the fecond prize of fifteen guineas, annually given by the univerfity to the authors of the beft compofitions in Latin profe, being fenior or middle bachelors of arts. Dr Roberts, afterwards provoft of Eton college, obtained the firft.

In the month of June 1760, Mr Jebb was admitted probationer fellow of St Peter's college, and proceeded to the degree of Mafter of Arts at the commencement in the fame year ; and on the firft of July 1761, was confirmed fellow by Dr Mawfon, bifhop of Ely.

On the 6th of June 1762, he was ordained deacon at Bugden by Dr John Green, bifhop of Lincoln ; and on the 25th of September, 1763, he was admitted by the fame bifhop into prieft's orders.

On the 22d of Auguft, 1764, Mr Jebb was collated by Dr Matthias Mawfon, bifhop of Ely, to the fmall vicarage of Gamlingay, near Potton, in Bedfordfhire, upon the recommendation of Dr Law, mafter of Peterhoufe. On the 17th of the following October, he was elected by the univerfity into the rectory of Ovington, near Watton, in Norfolk, after a competition with the Rev. Henry Turner, then fellow of St John's college, afterwards vicar of Burwell, in Cambridgefhire. Upon cafting up the votes, there appeared to be for Mr Jebb 91, for Mr Turner 73 ; and accordingly he was inftituted into the fame the 15th of December following.

On the 29th of the fame month, (December 1764) Mr Jebb married Anne, eldeft daughter of the Rev. James Torkington, rector of Little Stukeley, in Huntingdonfhire, and of lady Dorothy Sherard, daughter of Philip, fecond earl of Harborough.

Early in the year 1765, Mr Jebb, together with the Rev. Robert Thorpe, fellow of Peterhoufe, and the Rev. George Woollton, fellow of Sidney college, publifhed, in a fmall quarto, a comment on thofe parts of Sir Ifaac Newton's *Principia* which more immediately relate to the fyftem of the world. The title of the joint work of thefe able and judicious philofophers was, "Excerpta quædam e Newtoni principiis philofophiæ naturalis, cum notis variorum." A work, of which the univerfity of Cambridge continues to bear teftimony to the excellence, by the general ufe of it in the courfe of academical education.

Mr Chappelow profeffor of Arabic, dying on the 14th of January 1768, Mr Jebb offered himfelf a candidate for the vacant chair ; but it was given to Dr Hallifax, afterwards bifhop of Gloucefter ; a man of deferved celebrity, of whom we regret that it was not in our power to give a biographical fketch.

On July 10, 1769, Mr Jebb was inftituted to the vicarage of Flixton, near Bungay, in Suffolk, on the prefentation of William Adair, Efq. of Flixton-hall ; and on the 4th of April 1770, was inftituted to the united rectories of Homersfield and St Crofs, parifhes contiguous to Flixton, upon the fame prefentation : being alfo, in the fummer of the fame year, nominated chaplain to Robert earl of Harborough. In confequence of the acceffion of thefe preferments, though not confiderable in themfelves, he refigned, fome time in the month of October 1771, the rectory of Ovington, which he had received from the univerfity ; and Mr Sheepfhanks, fellow of St John's college, was elected in his place.

Dr Hallifax fucceeding to the profefforfhip of civil law, in the month of October 1770, upon the death of Dr Ridlington, Mr Jebb once more folicited that of Arabic, which Dr Hallifax then vacated : but he had by this time difplayed fuch an innovating fpirit in religion, that the univerfity gave the vacant profefforfhip to Mr Craven, a man refpected even by Mr Jebb and his friends.

Early in the year 1771, a defign was formed of applying to parliament for relief in the matter of fubfcription to the liturgy, and thirty-nine articles of the Church of England ; and in the profecution of this defign Mr Jebb took a very active part. He attended different meetings of the difcontented clergy, held at the Feathers tavern, London, affifted in the drawing up of their petition, and wrote their circular letter, which gave to the public an account of their aims. He bufied himfelf at the fame time in making various attempts to bring about what he called a reformation of the univerfity of Cambridge : but finding them fruitlefs, he retired, on the 25th of June 1772, to Bungay, where he ftudied French and Italian, and proceeded in a plan of fome *political* or *conftitutional lectures*.

He had by this time ceafed to read the prayers of the church, though he ftill continued to preach occafionally ; and the Archdeacon of Suffolk, holding, this year, his ufual vifitation of fome neighbouring parifhes in the church of Flixton, Mr Jebb preached fuch a fermon againft fubfcription, as drew upon himfelf a public rebuke from the Archdeacon, in the prefence of the clergy. "Much altercation, (fays he) enfued ; and

and for some days I expected a summons to Norwich; but have heard no more of it. *I acted thus, with a view to call the attention of the Norwich clergy to our cause*; and have in part succeeded "

He acted much more honourably than this, when, in 1775, he resigned all his preferments in the church; which surely he ought not to have retained one day after his conscience would not permit him to read the prayers of the liturgy. He now resolved to become a physician; and after attending St Bartholomew's hospital in London for six months, as the pupil of Dr William Pitcairn, he received, on the 18th of March 1777, a diploma of Doctor of Physic from the university of St Andrews!! He did not, however, commence practice till the 5th of February 1778; and even then he continued to attend the lectures of Dr Hunter, Mr John Hunter, and Dr Higgins. On the 18th of February 1779 he was elected a fellow of the Royal Society.

Dr Jebb, at the breaking out of the American war, had shewn himself at Cambridge a warm partizan of the revolting colonies; and of course a keen advocate for what he called, and, we doubt not, thought, the civil liberties of mankind. He now signalized himself by "An address to the Freeholders of Middlesex," assembled at Free mason's tavern in Great Queen-street, on Monday, December the 20th 1779, for the purpose of establishing meetings to maintain and support the freedom of election. Upon this occasion, he communicated to James Townsend, Esq. chairman of that meeting, the above address, under the signature of "Salus Publica;" presuming, that if the sentiments appeared to be founded in reason, they would not be the less regarded on account of their being suggested by an unknown individual."

This address was immediately printed, and very soon passed through three editions, each being enlarged by the addition of fresh matter; and in 1782, followed the fourth edition corrected, which also bore our author's name in the title page.

About the end of February 1780, Dr Jebb was appointed by the committee of the county of Huntingdon, one of their deputies, to attend a meeting in London of representatives from certain other petitioning counties, in order to concert measures for the more effectual reform of the present constitution of the house of commons. Soon afterwards he became one of the most active members of "the society for constitutional information;" of which the object, according to their own account, was to diffuse throghout the kingdom, as universally as possible, a knowledge of the great principles of constitutional freedom, particularly such as respect the election and duration of the representative body. "With this view (say they), constitutional tracts, intended for the extension of this knowledge, and to communicate it to persons of all ranks, are printed and distributed gratis, at the expence of the society. Essays, and extracts from various authors, calculated to promote the same design, are also published under the direction of the society, in several of the newspapers; and it is the wish of the society to extend this knowledge throughout every part of the united kingdoms, and to convince men of all ranks, that it is their interest, as well as their duty, to support a free constitution, and to maintain and assert those common rights, which are essential to the dignity and to the happiness of human nature." Could Dr Jebb have foreseen all the mischiefs which have flowed from this institution; could he have foreseen the wonderful spawn of factious societies which have sprung from it as from a parent stock, our veneration for genius and learning will not permit us to believe, that he would have neglected the studies of his profession for the sake of taking the lead in party politics.

Dr Petit, one of the physicians of St Bartholomew's hospital, dying the 26th of May, Dr Jebb offered himself a candidate to succeed to that appointment. The election came on the 23d of June; when Dr Budd, his antagonist, succeeded by a great majority.

The opposition which was made to his election at St Bartholomew's, followed him in the winter, when he offered himself at St Thomas's hospital in the borough. Indeed he relinquished his pretensions there sooner than in the former place; but for no other reason than because he found that all his political principles were likely to be again objected to him, and to hazard his success.

In the year 1783 he concurred with others in forming "the society for promoting the knowledg of the scriptures," which met first on the 20th of September in that year, and whose meetings continued to be held, and, for ought we know to the contrary, are still held at Essex-house. The sketch of their plan was chiefly written by Dr Jebb; and their object was to propagate the doctrines of Unitarianism, for which he was as great a zealot as for civil liberty.

His health now began to decline; but during his confinement, he studied the Saxon language, the Anglo Saxon laws, English history and antiquities, with a view to examine into our criminal code, and particular points of liberty. The vigour of his mind was still equal to the furnishing himself with this fresh store of knowledge; he foresaw the advantage of such an acquisition in the investigation of the legal rights of Englishmen, and had designed to have employed it in the support of some great constitutional questions, which he considered as essential to the freedom of his country.

But as the year began to dawn, it was very observable to many of his friends that, according to every appearance, and without some very great and singular effort of nature, his increased debility would defeat every exertion of the most judicious medical assistance, and terminate the remaining sparks of human life.

In this enfeebled state, his mind was active. His "Thoughts on Prisons" were printed and circulated in the county of Suffolk in 1785, by his much valued friend Mr Lofft; and there is sufficient reason for concluding that this little tract had effect on the deliberations of the justices at Ipswich and Bury, then engaged in erecting a new gaol for the division of Ipswich, and a new house of correction for that of Bury.

The good effects of this very excellent tract, it was apprehended, would be extended by a more general publication. In this hope Dr Jebb revised and corrected it with his dying hand: and his surviving friend published it soon after his death, adding thereto "an abstract of felonies created by statute and other articles relative to the penal law.

He continued to linger till May the 2d 1786, when, about 8 o'clock in the evening, he breathed his last, leaving

leaving behind him, among men of different persuasions, very different characters. By the dissenters he is seldom mentioned but as the *Great Jebb*; by churchmen, his abilities are universally allowed, whilst regret is expressed that they were so often employed in support of faction and heresy. His moral character has never been aspersed.

JEFFERSONIA, a new plant lately discovered in Georgia by Dr Brickel of Savannah, and so named by him in compliment to the vice president of the United States. In the *Monthly Magazine* for July 1798 we have the following description of it;

JEFFERSONIA pentendria monogynia.

Calyx, below, composed of five short oval imbricated leaves; *corolla*, monophyllous, funnel-shaped on the receptacle, sub-pentangular, bearing the filaments near the base, its margin hypocrateriform, divided into five round ducts nearly equal; *style*, pitiform, shorter than the petal, but longer than the stamens; *stigma*, quadripid; *anthers*, erect, linear, sagittated; *fruit*, two univalved, carinated, polyspermous capsules, united at the base, opening on their tops and contiguous sides, having flat seeds, with a marginal wing.

Only one species is as yet discovered, *Jeffersonia sempervirens*. It is a shrub with round polished twining stems, which climb up on bushes and small trees; the petioles short, opposite; leaves oblong, narrow, entire, evergreen, acute; flowers axillary, yellow, having a sweet odour. The woods are full of this delightful shrub, which is covered with blossoms for many months in the year.

JERBOA, see Mus, *Encycl*, where descriptions are given of the jaculus or common jerboa, and of the Arabian, Egyptian, and Siberian jerboas. A variety of this animal has lately been found in Canada by Major-general Davies, F. R. S. and L. S. who says it belongs to Schreber's genus of Dipus, and may be thus characterised: DIPUS CANADENSIS *palmis tetradactylis, plantis pentadactylis, caudâ annulatâ undique setosâ, corpore longiore*. The truth, however, seems to be, that it is only a variety, if indeed a variety, of the Siberian jerboa. The beautiful figure indeed given by General Davies of the Canadian jerboa differs in some respects from our figure of the Sibericus. Its ears lie flat and farther down the neck; its belly is not so large; its toes are longer; and it has no brush at the end of the tale; but the habits of the two animals seem to be the same. This will be apparent from the following extracts of the General's letter to the Linnean Society:

"The first I was so fortunate to catch was taken in a large field near the falls of Montmorenci, and by its having strayed too far from the skirts of the wood, allowed myself, with the assistance of three other gentlemen, to surround it, and after an hour's hard chase to get it unhurt, though not before it was thoroughly fatigued; which might in a great measure accelerate its death.

"During the time the animal remained in its usual vigour, its agility was incredible for so small a creature. It always took progressive leaps of from three to four, and sometimes of five yards, although seldom above 12 or 14 inches from the surface of the grass; but I have frequently observed others in shrubby places and in the woods, amongst plants, where they chiefly reside, leap considerably higher. When found in such places, it is impossible to take them, from their wonderful agility, and their evading all pursuit by bounding into the thickest cover they can find."

That the Canadian, as well as the Siberian Jerboa, sleeps through the winter, seems evident from a specimen having been found, towards the end of May, inclosed in a ball of clay, about the size of a cricket ball, nearly an inch in thickness, perfectly smooth within, and about twenty inches under ground. It was given to the General; who proceeds thus:

"How long it had been under ground it is impossible to say; but as I never could observe these animals in any parts of the country after the beginning of September, I conceive they lay themselves up some time in that month, or beginning of October, when the frost becomes sharp: nor did I ever see them again before the last week in May, or beginning of June. From their being enveloped in balls of clay, without any appearance of food, I conceive they sleep during the winter, and remain for that term without sustenance. As soon as I conveyed this specimen to my house, I deposited it, as it was, in a small chip box, in some cotton, waiting with great anxiety for its waking; but that not taking place at the season they generally appear, I kept it until I found it begin to smell: I then stuffed it, and preserved it in its torpid position. I am led to believe, its not recovering from that state arose from the heat of my room during the time it was in the box, a fire having been constantly burning in the stove, and which, in all probability, was too great for respiration. I am led to this conception from my experience of the snow bird of that country, which always expires in a few days (after being caught, although it feeds perfectly well) if exposed to the heat of a room with a fire or stove; but being nourished with snow, and kept in a cold room or passage, will live to the middle of summer."

JETTE, the border made round the stilts under a pier, in certain old bridges, being the same with starling; consisting of a strong framing of timber filled with stones, chalk, &c. to preserve the foundations of the piers from injury.

JILLIFREE is a town on the northern bank of the river Gambia, opposite to James's island, where the English had formerly a small fort. The kingdom of Barra, in which it is situated, produces great plenty of the necessaries of life; but the chief trade of the inhabitants is in salt, which they carry up the river in canoes; and, in return, bring down Indian corn, cotton cloths, elephants teeth, small quantities of Gold dust, &c. "The number of canoes and people constantly employed in this trade, make the king of Barra (says Mr Park) more formidable to Europeans than any other chieftain on the river, and have encouraged him to establish those exorbitant duties, which traders of all nations are obliged to pay at entry, amounting nearly to L. 20 on every vessel, great and small. These duties, or customs, are generally collected in person by the alkaid or governor of Jillifree, who is attended by a numerous train of noisy and troublesome dependants, who, by their frequent intercourse with the English, have acquired a smattering of our language, and beg for every thing which they fancy with such earnestness, that traders, in order to get quit of them, are frequently obliged to grant their requests. Lat. 13° 16′. Long. 16° 10′ west from Greenwich.

Illuminati.

1 Object of the Illuminati.

ILLUMINATI is the name which was assumed by a secret society or order, founded, on the first of May 1776, by Dr Adam Weishaupt professor of canon law in the university of Ingolstadt. The real object of this order was, by clandestine arts, to overturn every government and every religion; to bring the sciences of civil life into contempt; and to reduce mankind to that imaginary state of Nature when they lived independent of each other on the spontaneous productions of the earth. Its avowed object, however, was very different. It professed to diffuse from secret societies, as from so many centres, the light of science over the world; to propagate the purest principles of virtue; and to re-instate mankind in the happiness which they enjoyed during the golden age fabled by the poets. Such an object was well adapted to make a deep impression on the ingenuous minds of youth; and to young men alone Weishaupt at first addressed himself.

It will naturally occur to the reader, that the means of attaining this glorious object should have been made as public as possible; and that the veil of secrecy thrown over the proceedings of the order was calculated to excite suspicion, and to keep even *young* men of virtue and sagacity at a distance. In any other country than Germany secrecy might perhaps have had this effect; but various circumstances conspired there to make it operate with a powerful attraction.

Ever since free-masonry had acquired such reputation throughout Europe, a multitude of petty secret societies had been formed in the universities of Germany, each having its lodge, its master, its mysteries, all modelled on those founded by masons coming from England and Scotland (A). Before the foundation of Weishaupt's order, these lodges, we believe, were in general harmless; or if they were productive of any evil, it was only by giving the youth of the universities a taste for secrecy and misticism. Of this Weishaupt availed himself; and as soon as he had conceived the outlines of his plan, and digested part of his system, he initiated two of his own pupils, to whom he gave the names of AJAX and TIBERIUS, assuming that of SPARTACUS to himself. These two disciples soon vying with their master in impiety (for it will be seen by and bye that he was most impious), he judged them worthy of being admitted to his mysteries, and conferred on them the highest degree which he had as yet invented. He called them *Areopagites*, denominated this monstrous association, THE ORDER OF ILLUMINATI, OR ILLUMINEES, and installed himself GENERAL of the order.

When public report spread the news in Germany of this new order having been founded in the university of Ingolstadt by Weishaupt, it was generally supposed to be one of those little college-lodges which could not interest the adepts after they had finished their studies. Many even thought that Weishaupt, who was at that time a sworn enemy to the Jesuits, had founded this lodge with no other view than to form a party for himself against these fathers, who after the suppression of their order had been continued in their offices of public teachers at the university of Ingolstadt; and this opinion the illuminees were at pains to propagate. His character, too, was at this time such as to remove every suspicion from the public mind. A seeming assiduity in his duty, and a great shew of zeal and erudition in expounding the laws, easily misled people to believe that his whole time and talents were engrossed with the study of them; and if we are to credit his own account, Ingolstadt had never witnessed a professor so well calculated to add new lustre to its university.

2 Art of the founder.

This seems, indeed, to have been the general opinion as well as his own; for, some time after the foundation of his order, he applied himself with such diligence and apparent candour to the duties of his office, that he was chosen what Abbé Barruel's translator calls SUPERIOR of the university. This new dignity only added to his hypocrisy, and furnished him with fresh means of carrying on his dark designs. He converted his house into one of those boarding houses where young men, perpetually under the eye of their masters, are supposed to be better preserved than anywhere else from the dangers which threaten them at that age. He solicited fathers and mothers to entrust their children to his care; and, counterbalancing in secret the lessons which he was obliged to give in public, he sent home his pupils well disposed to continue the same career of seduction which he himself carried on at Ingolstadt, Atrociously impious, we see him (says M. Barruel), in the first year of his illuminism, aping the God of Christianity, and ordering *Ajax*, in the following terms, to propagate the doctrines of his new gospel: "Did not Christ send his apostles to preach his gospel to the universe? You that are my Peter, why should you remain idle at home? Go then and preach."

These preachers had yet received no particular designation; for when his first adepts were initiated, he was far from having completed the code of his order. He knew that years and experience were necessary to perfect that gradual system of initiations and trials which, according to the plan he had conceived, his novices were to undergo; but he could not endure the idea of sacrificing years to mere theoretic projects; and he flattered himself with the hopes of supplying the deficiencies of his incomplete code by provisional regulations and private instructions, and of acquiring associates who would receive his new gospel implicitly, and cooperate with him in all his views.

3 The sect divided into classes or

At length, however, the code was completed, and the sect divided into two grand classes; and each of these again subdivided into lesser degrees, proportionate to the progress of the adepts.

The

(A) Such, we are sorry to say, is the case still. In a letter, dated the 10th of May 1799, which we received from a gentleman of learning and honour then residing in Upper Saxony, is the following account of the university of Jena: "This university contains from two to three thousand students, who are almost all republicans, and go about the country in republican uniforms. They are all formed into clubs or *secret societies*; and the quarrel of one member of a club is taken up by all. The consequence is, that the number of duels among the different clubs is inconceivable. The weapon is generally the sabre, and the duel often ends in the death of one of the combatants." Yet gentlemen of Great Britain send their sons to Germany to be educated!

Illuminati.

4 Preparation and

" The *first* class is that of PREPARATION. It contains four degrees, *viz.* those of *Novice*, of *Minerval*, of *Minor Illuminee*, or *Illuminatus Minor*, and of *Major Illuminee*, or *Illuminatus Major*. To this class belong likewise some intermediary degrees, borrowed from free-masonry, as means of propagation. Of the masonic degrees, the code of the illuminati admits the first three without *any alteration;* but it adapts more particularly to the views of the sect the degree of *Scotch Knight*, and styles it the degree of *Directing Illuminee*, or *Illuminatus dirigens*.

5 The Mysteries.

The *second* class is that of the MYSTERIES, which are subdivided into the *lesser* and *greater mysteries*. The lesser comprehend the priesthood, and administration of the sect, or the degrees of *priests*, and of *regents* or *princes*.

In the *greater mysteries* are comprehended the two degrees of *Magus* or philosopher, and of the *Man-king*. The *elect* of the latter compose *the council and degree of Areopagites*.

" In all these classes, and in every degree (says the Abbé Barruel), there is an office of the utmost consequence, and which is common to all the brethren. It is that which is occupied by him who is known in the code by the appellation of *Recruiter*, or *Brother Insinuator*. This (continues our author) is not a term of my invention: it is really to be found in the code, and is the denomination of that illuminee, whose employment is to entice members into the sect."

6 The recruiter,

As the whole strength of the order depended upon the vigilant and successful exercise of this office, some brethren were carefully instructed for it, who might afterwards visit the different towns, provinces, and kingdoms, in order to propagate the doctrines of illuminism. Weishaupt proposed to select as his apostles either weak men, who would implicitly obey his orders, or men of abilities, who would improve the office by artifices of their own. It was, however, a duty which every brother was obliged to exercise once or twice in his life, under the penalty of being for ever condemned to the lower degrees.

To stimulate the ardour of the brother insinuator, he was appointed superior over every novice whom he should convert. To assist his judgment, he was instructed in three important points concerning the description of men whom he ought to select for conversion, the means which he ought to employ for enticing them to enter the order, and the arts which he ought to study to form their character.

7 To pry into the characters of all men.

To enable the recruiter to determine whom he ought to select for conversion, he was to insinuate himself into all companies; he was to pry into the character of all whom he should meet with, whether friends, relations, strangers, or enemies; he was to write down all his remarks regularly every day; to point out their strong and weak sides, their passions and prejudices, their intimacies, their interests, and their fortune. This journal was to be transmitted twice every month to the superiors; by which means the order would learn who were friendly or hostile to their views, and who were the individuals to whom they ought to direct their arts of seduction (B).

The persons to be excluded were all such as would expose the order to suspicion or reproach. All indiscreet talkers, all who were proved violent, and difficult to be managed, all addicted to drunkenness, and all Pagans, Jews, and Jesuits, were to be rejected. As the patronage of princes would tend much to enrich and strengthen the society, it was agreed to admit them to the inferior degrees, but they were never to be initiated into the grand mysteries; they were never to rise beyond the degree of Scotch knight.

8 Persons proper for the order,

The persons to be selected were young men of all stations, from eighteen to thirty; but particularly those whose education was not completed, and consequently whose habits were not formed. " Seek me out (says Weishaupt in his directions to the insinuator) the dexterous and dashing youths. We must have adepts who are insinuating, intriguing, full of resource, bold and enterprising; they must also be flexible and tractable, obedient, docile, and sociable" In another place he says, " Above all things pay attention to the figure, and select the well made men and handsome young fellows. They are generally of engaging manners and nice feelings. When properly formed, they are the best adapted for negociations; for first appearances prepossess in their favour. It is true, they have not the depth that men of more gloomy countenances often have. *They are not the persons to be entrusted with a revolt, or the care of stirring up the people;* but it is for that very reason we must know how to choose our agents. I am particularly fond of those men whose very soul is painted in their eyes, whose foreheads are high, and whose countenances are open. Above all, examine well the eyes, for they are the very mirrors of the heart and soul. Observe the look, the gait, the voice. Every external appearance leads us to distinguish those who are fit for our school."

9 To be seduced by whatever means;

Though young men were preferred, yet persons of all ages were to be admitted if their character accorded with the principles of the order. The insinuator was desired to seek out those who were distinguished by their power, riches, or learning. " Spare no pains (says Weishaupt), spare nothing in the acquisition of such adepts. If heaven refuse its succour, conjure hell.

Flectere si nequeas superos, Acheronta moveta."

Persons were to be singled out from those professions which give men influence over others, or put them in the most favourable situation for disseminating any peculiar opinions. With this view, schoolmasters, and superintendants of ecclesiastic seminaries, were to be sought after with much care. Booksellers, post-masters, and the secretaries of post-offices, were also to be selected. Those professions which accustomed men to speak and argue, as that of counsellors and attorneys, and even physicians, were also to be courted. " They are worth having (says Weishaupt), but they are sometimes real devils, so difficult are they to be led; they are, however, worth having when they can be gained over." Every exertion was to be made to gain the officers of a prince, whether presiding over provinces or attending him in his councils. " He that has done this, has done more than if he had engaged the prince himself."

There

(B) As a specimen of the journals kept by the insinuators, and of the characters which the illuminees selected for

There was alſo another deſcription of men of whom Weiſhaupt very wiſely judged that they would be admirably fitted for the diffuſſion of his doctrines. Theſe were the diſappointed and diſſatisfied. "Select thoſe in particular (ſays he) who have met with misfortunes, not from accidents, but from ſome injuſtice; that is to ſay, in other words, the diſcontented; for ſuch men are to be called into the boſom of illuminiſm as into their proper aſylum.

10 And their characters tranſmitted to the ſuperiors.

When the inſinuator has made choice of his victim, he is required to draw from his diary a view of his character, opinions, principles, and connections. This he is to tranſmit to the ſuperiors for their examination, and that they may compare it with the diaries which they have already received, perhaps from different inſinuators. When the choice of this inſinuator is approved, the ſuperiors determine which of the inſinuators will be beſt qualified to perform the taſk of ſeducing their candidate.

Two different methods were recommended; one of which was to be employed in enticing men who were ſomewhat advanced in life or diſtinguiſhed by ſcience; the other was to be uſed in ſeducing young men whoſe character was not formed.

11 Proper methods of ſeducing men of knowledge,

With men of knowledge, who had already imbibed the principles of modern philoſophiſm (for no true philoſophers were to be attempted), the inſinuator was to aſſume the character of a philoſopher well acquainted with the myſteries of ancient times. He was to deſcant upon the importance of the ſecret doctrines tranſmitted by tradition, to quote the gymnoſophiſts of India, the prieſts of Iſis in Egypt, and thoſe of Eleuſis, with the Pythagorean ſchool in Greece. He was to learn by heart certain paſſages from Iſocrates, Cicero, and Seneca, that he might have them ready upon all occaſions. He was to throw out hints, that theſe ſecret doctrines explained the difficult queſtions concerning the origin and order of the univerſe, the Providence of God, the nature of the ſoul, its immortality and future deſtination; he was to inſpire them with the belief that the knowledge of theſe things would render life more agreeable and pain more ſupportable, and would enlarge their ideas of the majeſty of God: he was then to declare that he had been initiated into theſe myſteries. If the candidate expreſſed any curioſity to be made acquainted with them, the inſinuator was firſt to aſcertain his opinions upon ſome leading points, by propoſing to him to write a diſſertation upon certain queſtions. Should the anſwers not pleaſe the inſinuator, he was to relinquiſh his prey; but ſhould they be ſatisfactory, the candidate was to be admitted to the firſt degree.

12 And young men,

When the ſelected victim was young, and had not imbibed any of thoſe opinions which correſponded with the principles of the ſect, a different method was to be followed. "Let your firſt care (ſays the legiſlator to his inſinuators) be to gain the affection, the confidence, and the eſteem of thoſe whom you are to entice into the order. Let your whole conduct be ſuch, that they ſhall ſurmiſe ſomething more in you than you wiſh to ſhew; hint that you belong to ſome ſecret and powerful ſociety; excite by degrees, and not at once, a wiſh in your candidate to belong to a ſimilar ſociety. Certain arguments and certain books, which the inſinuator muſt have, will greatly contribute to raiſe ſuch a wiſh; ſuch, for example, are thoſe which treat of the union and ſtrength of aſſociations."

Every inſinuator muſt be provided with books of this ſort. But that their ſucceſs might not depend ſolely upon books, Weiſhaupt gave to his diſciples a ſpecimen of the artifices which they might employ. The inſinuator might begin by obſerving, that a child in the cradle, abandoned to itſelf, is entirely helpleſs; and that it is by the aſſiſtance of others that it acquires ſtrength; and that princes owe their greatneſs and their power to the union of their ſubjects. Then the inſinuator might touch on the importance of knowing mankind, and the arts of governing them; that one man of parts might eaſily lead hundreds, even thouſands, if he but knew his advantages. He was next to dwell upon the defects of civil ſociety; to mention how little relief a man can obtain even from his beſt friends; and how very neceſſary it is for individuals to ſupport one another in theſe days: to add, that men would triumph even over heaven were they but united. He was to adduce as examples, the influence of the freemaſons and of the Jeſuits. He was to aſſert, that all the great events which take place in the world depend upon hidden cauſes, which theſe ſocieties powerfully influence. He was to awake in the breaſt of his pupil the deſire of reigning in ſecret; of preparing

---

for propagating their principles, we ſhall give the character of Zwack, denominated *Cato*, as it is deſcribed in the tablet of his inſinuator Ajax (Maſſenhauſen).

"Francis Xaverius Zwack was ſon of Philip Zwack, commiſſary of the *Chambre de Comptes*, and was born at Ratiſbon; at the time of his initiation (29th May 1776) he was twenty years of age, and had finiſhed his college education.

"He was then about five feet high; his perſon emaciated with debauchery; his conſtitution bordering on melancholy; his eyes of a dirty grey, weak and languiſhing; his complexion pale and ſallow; his health weak, and much hurt by frequent diſorders; his noſe long, crooked and hooked; his hair light brown; gait precipitate; his eyes always caſt towards the ground; under the noſe, and on each ſide of the mouth, a mole.

"His heart tender and philanthropic in an extaordinary degree; but ſtoic when in a melancholy mood; otherwiſe a true friend, circumſpect, reſerved, extremely ſecret; often ſpeaking advantageouſly of himſelf; envious of other people's perfections; voluptuous; endeavouring to improve himſelf; little calculated for numerous aſſemblies; choleric and violent, but eaſily appeaſed; willingly giving his private opinions when one has the precaution to praiſe him, though contradicting him; a lover of novelties. On religion and conſcience widely differing from the received ideas; and thinking preciſely as he ought, to become a good member of the order.

"His predominant paſſions are, pride, love of glory, probity; he is eaſily provoked; has an extraordinary propenſity for myſteries; a perpetual cuſtom of ſpeaking of himſelf and of his own perfections; he is alſo a perfect maſter in the arts of diſſimulation; a proper perſon to be received into the order, as applying himſelf particularly to the ſtudy of the human heart." Such is the character of the beloved diſciple of Weiſhaupt, the incomparable Cato, and a leader of the ſect of the illuminees!

Illuminati. ring in his closet a new constitution for the world; and of governing those who think they govern others.

13 Into the noviciate. After these, or other artifices of the same kind, have been employed, if the candidate be inspired with an ardour to be initiated, and give satisfactory answers to the questions proposed to him, he is immediately admitted a novice. But should he reject all means of seduction, let him take heed to imself; "for the vengeance of secret societies is not a common vengeance; it is the hidden fire of wrath. It is irreconcileable; and scarcely ever does it cease the pursuit of its victims until it has seen them immolated."

14 Period of the noviciate. The period of the noviciate varied according to the age of the new convert to illuminism. At first it continued three years for those under 18 years of age, two years for those between 18 and 24, and one year for those who were near 30; but it was afterwards shortened,

The novice was not acquainted with any of the order except his insinuator, under whose direction he remained during his noviciate. The first lessons which he was taught respected the inviolable nature of the secrecy which every illuminee was obliged to observe. He was told that silence and secrecy were the very soul of the order; that ingenuousness was a virtue only with respect to his superiors; and that distrust and reserve were fundamental principles. He was enjoined never to speak of any circumstance relating to the order, concerning his own admission, or the degree which he had received, not even before brethren, without the strongest necessity; and was required to sign a declaration to this purpose.

15 Dictionary, geography, calendar, and cypher of the order. The novice was next taught the dictionary of the order, its geography, calendar, and cypher. To prevent the possibility of discovery, every illuminee received a new name, which was characteristic of his dispositions, or of the services which were expected of him. Thus Weishaupt, as we have observed, was called *Spartacus*, because he pretended to wage war against those oppressors who had reduced mankind to slavery; and Zwack, as we have seen, was named *Cato*, because he had written a dissertation in favour of suicide, and had once determined to commit that crime.

According to the new geography of the order, Bavaria was called *Achaia;* Munich was called *Athens;* Vienna was named *Rome;* Wurtzburg was denominated *Carthage;* and Ingolstadt, the fountain of the order, was called *Ephesus*, and by the profound adepts *Eleusis*. The novice had also to learn the Persian calendar, which the order had adopted. Their era began A. D. 630. The months received new names: May was called *Adarpahascht;* June, *Chardad;* July, *Thermeh;* August, *Merdedmeh;* and so on. The cypher consisted of numbers which corresponded to the letters of the alphabet, in this order *a*, *b*, *c*, *d*, answering to the numbers 12, 11, 10, 9.

The novice had next to study *the statutes of the illuminees*, which he was assured contained nothing injurious to the state, to religion, or to good morals. He was next desired to apply himself to acquire the morality of the order; which he was to do, not by reading the gospels, but by perusing Epictetus, Seneca, and Antoninus, and by studying the works of the modern sophists Weiland, Meiners, and Helvetius, &c. The study of man was also recommended as the most interesting of all the sciences. He was taught this study not merely as a science, but as an art. A model of a journal was given him, and he was required to insert in it observations upon the character of every person that he happened to meet with. To quicken his diligence, the insinuator occasionally examined his journal. In the mean time, the insinuator was watching him as a centinel, and noting down regularly observations upon the defects and merits of his pupil, which he always sent to his superiors.

The great object of the insinuator was to entangle the novice, and to bind him indissolubly to the order. With this view he required the novice to draw a faithful picture of himself, under the pretence that he would thus know himself better. He desired him to write down his name, his age, his country, his residence, and his employment; to give a list of the books in his library; to state his revenue; to enumerate his friends and enemies, and the cause of his enmities. He was also to give a similar account of his father and mother, his brothers and sisters, and to be very careful in pointing out their passions and prejudices, their strong and weak sides. 16 Novice obliged to draw his own character.

In the mean time, the insinuator was occupied in drawing up a new statement of every thing he had been able to discover of the character and conduct of the novice. This statement was transmitted to the superiors, compared with the former. If the novice was approved, he was then admitted to the second degree, upon his answering, in a satisfactory manner, 24 grand questions, which might enable the order to judge of his principles and the credit to which he was entitled, and would fix him down by stronger ties to the authority of the superiors. The detestable principles of the illuminees now begin to appear, as will be evident from the following questions which we have selected:

Have you seriously reflected on the importance of the step you take, in binding yourself by engagements that are unknown to you? Should you ever discover in the order any thing wicked or unjust to be done, what part would you take? Do you, moreover, grant the power of life and death to our order or society? Are you disposed, upon all occasions, to give the preference to men of our order over all other men? Do you subject yourself *to a blind obedience, without any restriction whatsoever?* 17 Power of life and death claimed by the society.

The novice having thus surrendered his conscience, his will, and his life, to the devotion of the conspirators, and thus subscribed, with his own hand, and confirmed by his oath, a resolution to become the most abject slave, was now deemed qualified to ascend to the second degree, called *Minerval*.

In the dead hour of midnight he was conducted to a retired apartment, where two of the order were waiting to receive him. The superior, or his delegate, appeared standing in a severe and threatening posture; he held a glimmering lamp in his hand, and a naked sword lay before him. The novice was asked, whether he still persisted in his intention of adhering to the order? Upon answering in the affirmative, he was ordered into a dark room, there to meditate in silence on his resolution. On his return, he was strictly and repeatedly questioned if he was determined to give implicit obedience to all the laws of the order? The insinuator became security for his pupil, and then requested for him the protection of the order, which the superior granted with great solemnity, 18 Admission to the degree of Minerval.

Illuminati. nity, protesting that nothing would be found there hurtful to religion, to morals, or to the state. Having thus said, the superior takes up the naked sword, and pointing it at the heart of the novice, threatens him with the fatal consequences of betraying the secrets of the order. The novice again takes an oath, by which he binds himself, in the most unlimited manner, to serve the order with his life, honour, and estate, and to observe an inviolable obedience and fidelity to all his superiors. He is then admitted a Minerval, and henceforth is allowed to attend the academy of the sect.

19 Minerval academy; The Minerval academy was composed of 10, 12, or 15 Minervals, and placed under the direction of a major Illuminee. It met twice every month in an inner apartment, separated from the other rooms of the mansion by an antichamber; the door of which was to be shut with care during the meeting, and strongly secured by bolts. At the commencement of every meeting, the president read and commented upon some select passages of the Bible, Seneca, Epictetus, Marcus Aurelius, or Confucius; evidently with a view of diminishing the reverence for the sacred writings, by thus placing them on a level with the heathen moralists. Then each brother was asked what books he had read since last meeting, what observations he had made, and what services he had performed for promoting the success of the order?

20 Its library. To each Minerval academy a library belonged. This was formed by the contributions of the brethren, by presents of books, and by another method very extraordinary. All Illuminees acting as librarians, or keepers of archives, were admonished to *steal* such books or manuscripts as might be useful to the order. At one time, sending a list of the books which he wished to be embezzled from the library of the Carmes, Weishaupt says, "All these would be of much greater use if they were in our hands. What do those rascals do with all these books?

Every brother at his admission was required to declare to what art or science he meant chiefly to apply; and it was expected that he should afterwards every year give an account of the discoveries or improvements which he had made. All the other brethren who were occupied in the same studies, were desired to give him every possible assistance. Thus a kind of academy was formed, to which those who could not serve it by their talents might give pecuniary contributions. That this academy might have the appearance of a literary society, prizes were annually distributed; the best discourse was published, and the profits sent to the coffers of the order.

Every month the president was to take a review of the faults which he had observed in his pupils, and examine them concerning those which they might have been conscious of in themselves; and it would be an unpardonable neglect, say the statutes, should any pupil pretend that, during the space of a whole month, he had remarked nothing reprehensible.

It is impossible to read these rules without admiring them. Were men but half as anxious, attentive, and careful, to render themselves good citizens and good men, as these men were to render themselves successful conspirators, what a blessed world should we see!

21 Admission to the degree of minor illuminee. The Minerval was rigorously scrutinized, whether he was ready to submit to every torture, or even to commit suicide, rather than give any information against the order. Suicide was reckoned not only innocent, but honourable, and was also represented as a peculiar species of voluptuousness. In order to discover the sentiments of the Minervals upon this subject, they were required to write a dissertation upon the character and death of Cato, or any similar subject. They were also desired to discuss the favourite doctrine of Weishaupt, that *the end sanctifies the means;* a principle of the most pernicious tendency, which would render calumny, assassination, sedition, and treason, laudable and excellent. Next, they were called upon to compose a dissertation, by which their opinions concerning kings and priests might be ascertained. If they performed all these tasks with the spirit of an infidel, and the desperate firmness of a conspirator, they were then judged worthy of being promoted to the degree of minor illuminee.

The minor illuminees held meetings similar to those of the Minerval academy. It was necessary that the president should be one who was raised to the degree of priest, and initiated in the mysteries; but he was required to persuade his pupils, that beyond the degree which he had attained there were no mysteries to be disclosed. The minor illuminees were to be so trained, that they might look upon themselves as the founders of the order; that by this powerful motive they might be animated to diligence and exertion. With this view, hints were scattered rather than precepts enjoined. It was insinuated, that the world was not so delightful as it ought; that the happiness for which man was made is prevented by the misfortunes of some, and the crimes of others; that the wicked have power over the good; that partial insurrection is useless; and that peace, contentment, and safety, might be easily obtained by means drawn from the greatest degree of force of which human nature is capable. Such views, it is added, actuating a secret society, would not only be innocent, but most worthy of the wise and well-disposed. 22 Minor illuminees trained for the degree of

Weishaupt had formed, with peculiar care, a code for this degree, which was intitled, *Instructions for forming useful Labourers in Illuminism.* These instructions discover an astonishing knowledge of human nature, and are drawn up with a degree of systematic coolness which perhaps no conspirator before him ever exhibited. He lays down rules, by which the character of almost any person may be ascertained. He recommends to the minor illuminees, to attend to the conduct of any person entrusted to their care, at two periods; when he is tempted to be what he ought not to be, and when, removed from the influence of every external temptation, he follows the dictates of his inclination. They were to study the peculiar habits and ruling passions of each; to kindle his ardour by descanting on the dignity of the order, and the utility of its labours; to infuse a spirit of observation, by asking questions, and applauding the wisdom of the answers; to correct the failings of their pupil, by speaking of them as if they were not his, and thus making him judge in his own cause; to instruct and advise, not by tedious declamation, but by sometimes dropping a few words to the purpose, when the mind should be in a proper state to receive them. Above all, they were directed to avail themselves of those moments when they observed a pupil discontented with the world. "It is then (says Weishaupt) you must press the swelling heart, stimulate the sensibility, and

Illuminati.

and demonſtrate how neceſſary ſecret ſocieties are for the attainment of a better order of things."

23
Scotch novice.

Having paſſed with applauſe through the ſtates of probation already deſcribed, the minor illuminee is promoted to the rank of major illuminee, or Scotch novice. As major illuminee, he is encompaſſed with more rigid chains; and as Scotch novice, he is diſpatched as a miſſionary into maſonic lodges, to convert the brethren to illuminiſm.

The candidate for this degree is ſtrictly examined, in order to diſcover what opinions he now entertains concerning the object of the ſociety; the motives that prompted him to join it; whether he is diſpoſed ſtill to co-operate with the reſt of the brethren in accompliſhing the grand object; and whether he be a member of any other ſociety; and what are the duties which it requires.

The fertile genius of Weiſhaupt is not exhauſted; he has ſtill in reſerve artifices more profound, and bonds more powerful; his reſources keep pace with the progreſs of his ſchemes. He now lays a ſnare for his pupils, from which he hopes none can eſcape, and therefore he flatters himſelf they are his for ever. He demands of every candidate for higher degrees, to write, as a proof of confidence, a minute and faithful account of his whole life, without any reſerve or diſſimulation. Reſerve or diſſimulation would indeed be vain; for the moſt ſecret circumſtances of his life are already well known to the adepts, by means of innumerable ſpies, who, by the appointment of the ſuperiors, have, unknown to him, been watching and ſcrutinizing all his actions and words, his temper, paſſions, and opinions.

24
Candidates for higher degrees ſubmit to new trials.

Now is preſented to the candidate the code of the brother ſcrutator, called by the order the *noſce te ipſum* (know thyſelf). This is a catechiſm, containing from a thouſand to fifteen hundred queſtions, concerning his perſon, his health, his education, his opinions, his inclinations, his habits, his paſſions, his prejudices, and even his weakneſſes. Queſtions are alſo propoſed reſpecting his acquaintances, his relations, friends, and enemies. The candidate is required to enumerate his favourite colours, to deſcribe his language, the nature of his converſation, his gait and geſtures. Nothing, in ſhort, is omitted that can tend to diſtinguiſh his character as an individual, or as a member of ſociety. Upon many qualities in his character, thirty, forty, or ſometimes near a hundred queſtions are propoſed. The following ſpecimen will enable the reader to judge what aſtoniſhing care Weiſhaupt employed to diſcriminate characters.

Is his *gait* ſlow, quick, or firm? Are his ſteps long, ſhort, dragging, lazy, or ſkipping? Is his *language* regular, diſorderly, or interrupted? In ſpeaking, does he agitate his hands, his head, or his body with vivacity? Does he cloſe upon the perſon he is ſpeaking to? Does he hold him by the arm, clothes, or button-hole? Is he a great talker, or is he taciturn? If ſo, why? Is it through prudence, ignorance, reſpect, or ſloth? &c. Concerning his *education,* he is queſtioned to whom does he owe it? Has he always been under the eyes of his parents? How has he been brought up? Has he any eſteem for his maſters? Has he travelled, and in what countries?

By theſe queſtions his temper and diſpoſitions might be accurately known. His leading paſſions would be diſcovered by the following queries: "When he finds himſelf with different parties, which does he adopt; the ſtrongeſt or the weakeſt; the wittieſt or the moſt ſtupid? Or does he form a third? Is he conſtant and firm in ſpite of all obſtacles? How is he to be gained? by praiſe, by flattery, or low courtſhip; by women, money, or the entreaties of his friends? Does he love ſatire; and on what does he exerciſe that talent; on religion, hypocriſy, intolerance, government, miniſters, monks?" &c.

Illuminati.

All theſe queſtions are to be anſwered and illuſtrated by facts. It is neceſſary to obſerve that the ſcrutators alſo give in written anſwers to all theſe queſtions. When the candidate has thus given a minute hiſtory of his life, and revealed all his ſecrets, his foibles, his errors, his vices, and his crimes, Weiſhaupt triumphantly exclaims, "Now I hold him; I defy him to hurt us; if he ſhould wiſh to betray us, we have alſo his ſecrets."

The adept is next introduced into a dark apartment, where he ſolemnly ſwears to keep ſecret whatever he may learn from the order. He then delivers up the hiſtory of his life, ſealed, when it is read to the lodge, and compared with the character drawn of him by the brother ſcrutators. A corner of the veil is now lifted up, ſtill, however, with extreme caution. Nothing appears palpable but the pureſt principles and moſt generous deſigns. At the ſame time many things are darkly ſuggeſted, which are incompatible with purity and generoſity; for while the utmoſt care is employed to deceive the underſtanding, nothing is neglected that can tend ſecretly to corrupt the heart. A number of queſtions are aſked; the evident intention of which is to make the adept diſcontented with the preſent moral government of the world, and to excite the deſire of attempting a great revolution. After anſwering theſe queſtions, the ſecretary opens the code of the lodge; and having informed the young illuminee that the object of the order is to diffuſe the pure truth, and to make virtue triumph, he proceeds to ſhow that this is to be accompliſhed by freeing men from their prejudices, and enlightening their underſtandings. "To attain this, (continues the ſecretary), we muſt trace the origin of all ſciences, we muſt reward oppreſſed talents, we muſt undertake the education of youth; and, forming an indiſſoluble league among the moſt powerful geniuſes, we muſt boldly, though with prudence, combate ſuperſtition, incredulity ,and folly; and at length form our people to true, juſt, and uniform principles on all ſubjects." The ſecretary adds, that in attempting to diveſt vice of its power, that the virtuous may be rewarded even in this world, the order is counteracted by *princes and prieſts, and the political conſtitutions of nations;* that, however, it was not intended to excite revolutions and oppoſe force by force, but merely to bind the hands of the protectors of diſorder, and to govern without appearing to command; that the powers of the earth muſt be encompaſſed with a legion of indefatigable men, all directing their labours towards the improvement of human nature. Were there but a certain number of ſuch men in every country, each might form two others. "Let theſe (ſays he) only be united, and nothing will be impoſſible to our order." All this is very ſpecious; it is well contrived to faſcinate the imagination of the young, and the heart of

the

Illuminati. the generous and benevolent, while, under all this pretended regard to virtue and to the happiness of mankind, is concealed a most formidable conspiracy against the peace of the world.

After this address is delivered, the major illuminee is presented with the codes of the insinuator and scrutator; for he must now inspect the pupils of the insinuators, and must exercise the office of scrutator while presiding over the Minerval academies.

25 The degree of Scotch knight.

The next degree, which is that of Scotch knight, is both intermediate and stationary. It is stationary for those who are not sufficiently imbued with the principles of the order, and intermediate for those who have imbibed the true spirit of illuminism. The Scotch knights were appointed the directors of all the preparatory degrees, and to watch over the interests of the order within their district. They were to study plans for increasing the revenues of the order, and to endeavour to promote to public offices of confidence, of power and wealth, as many of the adepts as possible; and to strive to acquire an absolute sway in the masonic lodges. They were to procure the management of the masonic funds; and while they were to persuade the brethren that these were expended according to their own orders, they were to employ them for promoting the views of the order. Thus one office of the Scotch knights was to embezzle the money that was entrusted to them, in order to diffuse truth, and to make virtue triumph.

After passing with applause through this long and tedious probation, the adept is introduced to the class of the mysteries. He is not yet, however, made acquainted with the whole secrets of the society; he must still submit to new trials; his curiosity must be farther excited, his imagination must be kept longer upon the stretch, and his principles of depravity be rendered more violent and inveterate before the vail be entirely withdrawn, which will discover to him Weishaupt and his infernal crew, plotting the destruction of the laws, sciences, and religion of mankind. The degree of epopt or priest, to which the adept was next raised, opened to view, however, so great a part of the mysteries, that the reader will be fully prepared to expect the secrets which remain to be unfolded in the other degrees.

26 Preparations for the priesthood.

Before being admitted to the degree of epopt, the adept was required to give a written answer to ten preliminary questions. The insinuations against the established order of the world, which had formerly been slightly mentioned, increase now to an indirect proposal to attempt a complete revolution. The candidate is asked, whether he thinks the world has arrived at that happy state which was intended by nature? Whether civil associations and religion attain the ends for which they were designed? Whether the sciences are conducive to real happiness? or whether they are not merely the offspring of the unnatural state in which men live, and the crude inventions of crazy brains? It is then proposed as a question, whether there did not in antient times exist an order of things more simple and happy? What are the best means for restoring mankind to that state of felicity? Should it be by public measures, by violent revolutions, *or by any means that would ensure success?* Would it not be proper, with this view, to preach to mankind a religion more perfect, and a philosophy more elevated? And, in the mean time, is it not advisable to disseminate the truth in secret societies? Illuminati.

Should the answers given to these questions accord with the sentiments of the order, on the day fixed for the initiation, the candidate is blindfolded, and, along with his introducer, is put into a carriage, the windows of which are darkened. After many windings and turnings, which it would be impossible for the adept to trace back, he is conducted to the porch of the temple of the mysteries. His guide strips him of the masonic insignia which he wore as a knight, removes the bandage from his eyes, and presents him with a drawn sword; and then having strictly enjoined him not to advance a step till he is called, leaves him to his meditations. At length he hears a voice exclaiming, "Come, enter, unhappy fugitive; the fathers wait for you; enter, and shut the door after you." He advances into the temple, where he sees a throne with a rich canopy rising above it, and before it, lying upon a table, a crown, a sceptre, a sword, some pieces of gold, and precious jewels, interlaid with chains. At the foot of the table, on a scarlet cushion, lie a white robe, a girdle, and the simple ornaments of the sacerdotal order. The candidate is required to make his choice of the attributes of royalty, or of the white robe. If he choose the white robe, which he knows it is expected he should do, the hierophant, or instructor, thus addresses him: "Health and happiness to your great and noble soul. Such was the choice we expected from you. But stop; it is not permitted you to invest yourself with that robe, until you have heard to what we now destine you." The candidate is then ordered to sit down; the book of the mysteries is opened, and the whole brethren listen in silence to the voice of the hierophant.

The exordium is long and pompous; much artifice is concealed in it, and much eloquence displayed. It expatiates on the sublime and generous views of the society; evidently with the desire of lulling asleep the suspicion of the candidate, of exciting him to admiration, and of inspiring him with enthusiasm. The hierophant then proceeds to unveil the mysteries. He launches out into a splendid description of the original state of mankind; when health was their ordinary state, when meat, and drink, and shelter, were their only wants. At that period (says he) men enjoyed the most inestimable blessings, *equality and liberty;* they enjoyed them to their utmost extent: but when the wandering life ceased, and property started into existence; when arts and sciences began to flourish; when a distinction of ranks and civil associations were established, "liberty was ruined in its foundation, and equality disappeared. The world then ceased to be a great family, to be a single empire; the great bond of nature was rent asunder." Wants now increased, and the weak imprudently submitted to the wise or the strong, that they might be protected. As the submission of one person to another arises from wants, it ceases when the wants no longer exist. Thus the power of a father is at an end when the child has acquired his strength. Every man, having attained to years of discretion, may govern himself; when a whole nation, therefore, is arrived at that period, there can exist no farther plea for keeping it in wardship.

27 Instructions previous to admission.

Such

Illuminati.

Such a ſtate as that of civil ſociety, is then repreſented as incompatible with the practice of virtue. "With the diviſion of the globe, and of its ſtates, benevolence (ſays the hierophant) was reſtrained within certain limits, beyond which it could no longer be extended. Patriotiſm was deemed a virtue; and he was ſtyled a patriot who, partial towards his countrymen, and unjuſt to others, was blind to the merits of ſtrangers, and believed the very vices of his own country to be perfections. We really beheld (continues he) patriotiſm generating localiſm, the confined ſpirit of families, and even egoiſm. Diminiſh, reject that love of country, and mankind will once more learn to know and love each other as men. Partiality being caſt aſide, a union of hearts will once more appear, which will expand itſelf over the globe."

Theſe unphiloſophical declamations, enthuſiaſtically pronounced, at length make the proſylete exclaim, in uniſon with his maſter, "Are ſuch then the conſequences of the inſtitution of ſtates, and of civil ſociety? O folly! Oh people! that you did not foreſee the fate that awaited you; that you ſhould yourſelves have ſeconded your deſpots in degrading human nature to ſervitude, and even to the condition of the brute!"

Having wrought up the proſelyte to this pitch of frenzy, and enumerated all the evils which, according to Weiſhaupt, ariſe from political aſſociation, the hierophant comes to reveal the means by which the grievances of the human race may be redreſſed. "Providence (he ſays) has tranſmitted the means to us of ſecretly meditating, and at length operating, the ſalvation of human kind. Theſe means are the ſecret ſchools of philoſophy. Theſe ſchools have been in all ages the archives of nature, and *of the rights of man.* Theſe ſchools ſhall one day retrieve the fall of human nature, and PRINCES AND NATIONS SHALL DISAPPEAR FROM THE FACE OF THE EARTH; and that without any violence. Human nature ſhall form one great family, and the earth ſhall become the habitation of the man of reaſon. *Reaſon ſhall be the only book of laws, the ſole code of man.* This is one of our *grand myſteries.* Attend to the demonſtration of it; and learn how it has been tranſmitted down to us."

This pretended demonſtration makes part of the ſame ſophiſtical harangue; and conſiſts in panegyrics on the dignity of human nature; in a baſeleſs morality; and in a ſcandalous perverſion of the Chriſtian Scriptures, with a blaſphemous account of the miniſtry of the Saviour of the world.

"What ſtrange blindneſs (continues the hierophant) can have induced men to imagine, that human nature was always to be governed as it has hitherto been? Where is the being who has condemned men, the beſt, the wiſeſt, and the moſt enlightened men, to perpetual ſlavery? Why ſhould human nature be bereft of its moſt perfect attribute, that of governing itſelf? Why are thoſe perſons to be always led who are capable of conducting themſelves? Is it then impoſſible for mankind, or at leaſt the greater part of them, to come to majority? Are we then fallen ſo low as not even to feel our chains, as to hug them, and not cheriſh the flattering hope of being able to break them, and recover our liberty? No; let us own that it is not impoſſible to attain UNIVERSAL INDEPENDENCE."

The principal means which Weiſhaupt offers to his adepts for the conqueſt of this land of promiſe, is to diminiſh the wants of the people; and accordingly the code denounces eternal war with every ſpecies of commerce. Hence the hierophant proceeds to inform the candidate, that he who wiſhes to ſubject nations to his yoke, need but to create wants, which he alone can ſatisfy. "Confer (ſays he) upon the *mercantile tribe* ſome rank or ſome authority in the government, and you will have created perhaps the moſt formidable, the moſt deſpotic of all powers. He, on the contrary, who wiſhes to render mankind free, teaches them how to refrain from the acquiſition of things which they cannot afford: he enlightens them, he infuſes into them bold and inflexible manners. If you cannot diffuſe, at the ſame inſtant, this degree of light among all men, at leaſt begin by enlightening yourſelf, and by rendering yourſelf better. The mode of diffuſing univerſal light is, not to proclaim it at once to the whole world, but to begin with yourſelf; then turn to your next neighbour: you too can enlighten a third and a fourth: let theſe in the ſame manner extend and multiply the number of the children of light, until *numbers and force ſhall throw power into your hands.* You will ſoon acquire ſufficient force to *bind the hands of your opponents, to ſubjugate them,* and to ſtifle wickedneſs in the embryo;" *i. e.* you will ſoon be able to ſtifle every principle of law, of government, of civil or political ſociety, whoſe very inſtitution, in the eyes of an illuminee, is the germ of all the vices and misfortunes of human nature.

28 The illuminees enemies to commerce.

29 Their morality;

The hierophant, continuing to inſiſt on the neceſſity of enlightening the people to operate the grand revolution, ſeems to be apprehenſive that the candidate may not yet clearly conceive the real plan of this revolution, which is in future to be the ſole object of all his inſtructions. Let your inſtructions and lights be univerſally diffuſed; ſo ſhall you render mutual ſecurity univerſal; *and ſecurity and inſtruction will enable us to live without prince or government.* The inſtruction which is to accompliſh this great end, is inſtruction in *morality,* and *morality alone*; for "*true morality* is nothing elſe than the art of teaching men to *ſhake off their wardſhip,* to attain the age of manhood; and thus to need neither princes nor governments. The morality which is to perform this miracle, is not a morality of vain ſubtleties. It is not that morality which, degrading man, renders him careleſs of the goods of this world, forbids him the enjoyment of the innocent pleaſures of life, and inſpires him with the hatred of his neighbour. *Above all,* it muſt *not* be that morality which, adding to the miſeries of the miſerable, throws them into a ſtate of puſillanimity and deſpair, *by the threats of hell and the fear of devils.* It muſt be a divine doctrine, ſuch as Jeſus taught to his diſciples, and of which he gave the real interpretation in his ſecret conferences."

30 And blaſphemies of Chriſt.

The impious hierophant then proceeds, with matchleſs blaſphemy, to repreſent the Redeemer of mankind as teaching, like the Grecian ſophiſts, an exoteric and an eſoteric doctrine. He deſcribes him as the grand maſter of the illuminees; and affirms, that the object of his *ſecret,* which is loſt to the world in general, has been preſerved in their myſteries. It was "to reinſtate mankind in their ORIGINAL EQUALITY and LIBERTY, and to prepare the means. This explains in what

what ſenſe Chriſt was the *Saviour and Redeemer of the world.* The doctrine of original ſin, of the fall of man, and of his regeneration, can now be underſtood. The ſtate of pure nature, of fallen or corrupt nature, and the ſtate of grace, will no longer be a problem. Mankind, in quitting their ſtate of *original liberty*, *fell* from the ſtate of nature, and *loſt their dignity.* In their civil ſociety, under their governments, they no longer live in the ſtate of *pure* nature, but in that of *fallen* and *corrupt* nature. If the moderating of their paſſions, and the diminution of their wants, reinſtate them in their primitive dignity, that will really conſtitute their *redemption* and their *ſtate of grace.* It is to this point that morality, and the moſt perfect of all morality, that of Jeſus, leads mankind. When at length this doctrine ſhall prevail throughout the world, the reign of the good and of the elect ſhall be eſtabliſhed."

This language (as M. Barruel obſerves) is ſurely not enigmatical; and the proſelyte who has heard it without ſhuddering, may flatter himſelf with being

31 Preparatory rites to

worthy of this Antichriſtian prieſthood. He is led back to the porch, where he is inveſted with a white tunic and broad ſcarlet belt of ſilk. The ſleeves of the tunic, which are wide, are tied in the middle and at the extremities with ribbons likewiſe of ſcarlet; and the candidate is recalled into the temple of myſteries. He is met by one of the brethren, who does not permit him to advance till he has declared "whether he perfectly underſtands the diſcourſe which has been read to him; whether he has any doubts concerning the doctrines taught in it; whether his heart is penetrated with the ſanctity of the principles of the order; whether he is ſenſible of the call, feels the ſtrength of mind, the fervent will, and all the diſintereſtedneſs requiſite to labour at the *grand undertaking;* whether he is ready to make a ſacrifice of *his will*, and to ſuffer himſelf to be *led* by the moſt *excellent ſuperiors of the order.*"

32 Initiation to the prieſthood.

The rites of the preceding degree were in impious deriſion of the ſacrament of the Lord's ſupper; thoſe of the preſent are an atrocious mimicry of ſacerdotal ordination; at which, as every one knows, the Lord's ſupper is likewiſe celebrated. A curtain is drawn, and an altar appears with a crucifix upon it. On the altar is a bible; and the ritual of the order lies on a reading deſk, with a cenſer and a phial full of oil beſide it. The dean, or preſident, who acts the part of a biſhop, bleſſes the candidate, cuts hair from the crown of his head, anoints him, clothes him in the veſtments of the prieſthood, and pronounces prayers after the faſhion of the order. He preſents him with a cap, ſaying, "Cover thyſelf with this cap; it is more precious than the royal diadem." The mock communion is then diſtributed; and it conſiſts of milk and honey, which the dean gives to the proſelyte, ſaying, "This is that which nature gives to man. Reflect how happy he would ſtill have been, if the deſire of ſuperfluities had not, by depriving him of a taſte for ſuch ſimple food, multiplied his wants, and poiſoned the balm of life" The ceremonies are terminated by delivering to the epopt that part of the code which relates to his new degree.

33 Duties of the prieſt or epopt.

Among the inſtructions which it contains, the following are more particularly worthy of notice. The epopt, ſays the code, "will take care that the writings of the members of the order ſhall be cried up, and that the trumpet of fame ſhall be ſounded in their honour. He will alſo find means of *hindering the reviewers from caſting any ſuſpicions* on the writers of the ſect." He is likewiſe inſtructed to *bribe* the common people into the intereſts of the order, and to corrupt their minds, by getting poſſeſſion of ſchools and other ſeminaries of learning. But "if it be neceſſary for us to be maſters of the ordinary ſchools (ſays the impious legiſlator), of how much more importance will it be to gain over the *Eccleſiaſtic ſeminaries and their ſuperiors!* With them we gain over the chief part of the country; we acquire *the ſupport of the greateſt enemies to innovation;* and the grand point of all is, that through *the clergy* we become *maſters of the middle and lower claſſes of the people.*"

34 Qualifications for the degree of regent.

From the degree of epopt or prieſt are choſen the *regents* or *prince-illuminees.* On making this choice, ſays the code, three things of the utmoſt conſequence are to be obſerved. "1*ſt*, The greateſt reſerve is neceſſary with reſpect to this degree: 2*dly*, Thoſe who are admitted into it, muſt be as much as poſſible *free men*, and *independent of princes:* 3*dly*, They muſt have clearly manifeſted their *hatred of the general conſtitution*, or the *actual ſtate* of mankind; and have ſhewn how evidently they wiſh for a *change in the government of the world.*" If theſe requiſites be found in an epopt who aſpires to the degree of regent, ſix preliminary queſtions are put to him; of which the obvious meaning is to diſcover, whether he deems it lawful and proper to teach ſubjects to throw off the authority of their ſovereigns, or, in other words, to deſtroy every king, miniſter, law, magiſtrate, and public authority on earth.

When theſe queſtions are anſwered to the ſatisfaction of his examiner, he is informed, "that as, in future, he is to be entruſted with papers belonging to the order of far greater importance than any which he has yet had in his poſſeſſion, it is neceſſary that the order ſhould have farther ſecurities. He is therefore commanded to make his *will*, and inſert a clauſe with reſpect to any private papers which he may leave, in caſe of ſudden death. He is to get a formal or juridical receipt for that part of his will from his family, or from the public magiſtrate; and he is to take their promiſes in writing, that they are to fulfil his intentions." This precaution being taken, and the day fix-

35 Admiſſion to this degree.

ed for his inauguration, he is admitted into an antechamber hung with black, where he ſees a ſkeleton, elevated two ſteps, with a crown and ſword lying at its feet. Having given up the written diſpoſitions, &c. reſpecting his papers, his hands are loaded with chains as if he were a ſlave, and he is left to his meditations. A dialogue then takes place between his introducer and the provincial, who is ſeated on a throne in a ſaloon adjoining. It is in a voice loud enough to be heard by the candidate, and conſiſts of various queſtions and anſwers; of which the following may ſerve for a ſpecimen:

Prov. Who has reduced him to this ſtate of ſlavery?

Anſ. by the Introd. SOCIETY, GOVERNMENTS, the SCIENCES, and falſe RELIGION.

Prov. And he wiſhes to caſt off this yoke, to become a ſeditious man and a rebel?

Anſ. No; he wiſhes to unite with us, to JOIN IN OUR

Illuminati

OUR FIGHTS AGAINST THE CONSTITUTION OF GOVERNMENTS, the corruption of morals, and the profanation of religion. He wishes, through our means, to become POWERFUL, that he may attain the GRAND ULTIMATUM.

Prov. Is he superior to *prejudices?* Does he prefer the *general interest of the universe* to that of *more limited associations?*

Ans. Such have been his promises.

Prov. Ask him, whether the skeleton which is before him be that of a *king*, a *nobleman*, or a *beggar?*

Ans. He cannot tell; all that he sees is, that this skeleton was a man like us; and the character of *man* is all that he attends to.

After a great deal of insidious mummery like this, the epopt is admitted to the degree of prince; but before his investiture with the insignia of that order, he is exhorted to be *free, i. e.* to be a man, and a man who knows how to *govern himself*; a man who knows his duty, and his *imprescriptible rights;* a man who serves the *universe alone;* whose actions are solely directed to the *general benefit* of the world and of human nature. "Every thing else (says the provincial) is INJUSTICE." A long panegyric is then made on the happiness which will be experienced by mankind, when *every father* of a family shall be *sovereign* in his tranquil cot! when he that wishes to invade these *sacred rights* shall not find an asylum on the face of the earth! when idleness shall be no longer suffered; and when *the clod of useful sciences shall be cast side* (C)!

36 Sign of the degree.

The *sign* of this degree consisted in extending out the arms to a brother with the hands open; the *gripe* was to seize the brother by the two elbows, as it were to prevent him from falling; and the *word* was REDEMPTION! The epopt was invested with his principality by receiving a buckler, boots, a cloak, and a hat; and on receiving the boots, he was desired to *fear no road* which might lead to the propagation or discovery of *happiness.* Thus decorated, the prince illuminee received the *fraternal embrace*, and heard the instructions for his new degree.

One would think that the adept had now arrived at the very acmé of profaneness and treasonable conspiracy. He has been initiated in mysteries which burlesque Christianity and its Divine Author, and at the same time vow vengeance against all government, all law, and all science: yet Weishaupt, in a letter to Cato Zwack, his incomparable man, says, that he has composed four degrees above that of regent, or prince-illuminee; with respect even to the *lowest* of which, his degree of priest will be found no more than child's play. "The ritual of these degrees, (says he), I never suffer to go out of my hands. It is of too serious an import; it is the key of the ancient and modern, the religious and political, history of the universe."

This caution of the chief conspirator has deprived us of the power to give so particular an account of these degrees as we have done of the preceding; but the Abbé Barruel assures us that they were reduced to two, viz. that of MAGUS, and that of the MAN-KING; and that these two constituted the GREATER MYSTERIES. When the adept was admitted to the degree of *magus*, he was illuminized only in philosophy and religion; when to that of *man-king*, new lights were given him respecting property, and every species of political association. The Abbé quotes a passage from *the Critical history of all the degrees of illuminism*, written by a man of honour, who had passed through them all, which will give the reader a sufficient idea of the object of these last degrees.

"With respect to the two degrees of *magus* and of *man-king* (says this writer), there is no reception, that is to say, there are no ceremonies of initiation. Even the elect are not permitted to transcribe these degrees; they only hear them read, and that is the reason why I do not publish them in this work. The first is that of Magus, called also philosopher. It contains the fundamental principles of Spinozism. Here every thing is *material;* God and the world are but one and the same thing: all religions are inconsistent, chimerical, and the invention of ambitious men."

37 Objects of the degrees of magus and man-king.

That this is the doctrine of Spinoza, and that Spinoza was an atheist, is most certain; but though nothing can be *essentially* worse than atheism, we are strongly inclined to suspect that, at the initiation of the Magus, expressions must have been used more *shocking at least to the ear* than the philosophic jargon of the apostate Jew. It is long since the philosophy of Spinoza was in Germany recommended from the press (see SPINOZA, *Encycl.*); it is but very lately that a professor in the university of Jena published a book, in which he teaches that there is *no God*, and that we absurdly give that title to *the relations of Nature* (D); and something approaching so near to atheism had been communicated to the adept when he was admitted to the priesthood, that we are persuaded Weishaupt must have alluded to *language* at least different from that in which Spinoza taught his dark doctrines, and that language, accompanied perhaps with impious and audacious gestures, when he said that, compared with his higher mysteries, his degree of priest was but child's play.

What gives some degree of probability to this conjecture, if it be nothing more, is the following fact related by the Abbé Barruel. During the French revolution (says that able and well-informed writer), a comedian appeared

(C) This will naturally surprise our readers; but it could not surprise him to whom it was addressed; for when candidate for the priesthood, he had been asked, "Do the sciences which men cultivate, furnish them with real lights? Are they conducive to real happiness? Are they not, on the contrary, the offspring of numberless wants, and of the unnatural state in which men live? Are they not the crude inventions of crazy brains?" There were, however, to be academies for the cultivation of such sciences as suited the designs of the order. Each academy was to consist of nine epopts, of whom seven were to preside respectively over so many departments of science, whilst the other two were to officiate as secretaries. One of the departments included the occult sciences, to which belonged the art of *raising the seals of the letters* of all who belonged not to the order, and of securing their own letters against similar practices!!

(D) We learned this from the letter already quoted in note (A).

appeared (E), dreſſed in the ſacerdotal robes of the illuminees, and perſonally defying Almighty God. "No! (ſaid the impious wretch) thou doſt not exiſt. If thou haſt power over the thunderbolts, graſp them; aim them at the man who dares ſet thee at defiance in the face of thy altars. But no! I blaſpheme thee, and I ſtill live. No! thou doſt not exiſt." It will be ſeen by and bye, that the chiefs of the revolution, and even numbers of their tools, were illuminized; and is it improbable that this blaſphemer, who was arrayed in the inſignia of the epopts, made uſe of the language and geſtures of the higher myſteries? Whether it be or not, M. Barruel has proved, even from the writings of Weiſhaupt himſelf, that the magi were at leaſt atheiſts of the ſchool of Spinoza.

38 Atheiſm and

"The ſecond degree of the grand myſteries, called the *Man-king*, teaches (according to the author of the Critical Hiſtory), that every inhabitant of the country or town, every father of a family, is ſovereign, as men formerly were in the times of the patriarchal life, to which mankind is once more to be carried back; that in conſequence all authority and all magiſtracy muſt be deſtroyed."

39 Savagiſm.

This may appear to be nothing more than what the adept has been already taught in the leſſer myſteries; and it is in fact nothing more than that to which he muſt have ſeen theſe myſteries tending; but the reader underſtands not the language of the illuminees, if he ſuppoſes that, by the patriarchal ſtate, they mean ſuch a ſtate as that of the patriarchs of the Old Teſtament. No! their patriarchal ſtate is the fancied ſavage ſtate of the atheiſtical philoſophers of Greece and Rome, when mankind had neither property nor fixed habitation. This is evident from one of the diſcourſes of the hierophant; in which he tells the adept, that it would have been happy for man "had he known how to preſerve himſelf in the primitive ſtate in which Nature had placed him! But ſoon the unhappy germ developed itſelf in his heart, and reſt and happineſs diſappeared. As families multiplied, the neceſſary means of ſubſiſtence began to fail. *The Nomade or roaming life ceaſed; property began; men choſe fixed habitations; agriculture brought them together;* LIBERTY WAS RUINED IN ITS FOUNDATIONS, AND EQUALITY DISAPPEARED."

To reſtore that liberty and equality, therefore, which is the ultimate object of the order, and conſtitutes the MAN-KING, all property muſt be aboliſhed, every houſe burnt, as well the cottage of the peaſant as the palace of the prince; and mankind muſt once more inhabit woods and caverns without clothes and without fire, and ſally out occaſionally to encounter their fellow-brutes, and to ſearch for food among the wild herbs of the deſart. According to Mochus the Phenician, and the Greek philoſophers of this hopeful ſchool, this was the original ſtate of man *; and to this ſtate it was the object of Weiſhaupt and his adepts to reduce man again. Hence we hear them laviſhing the moſt rapturous encomiums on the Goths and Vandals who over-ran the Roman empire, annihilated the arts, put a ſtop to agriculture, and burnt the towns and villages of civilized Europe! It was thus, according to the illuminees, that thoſe barbarians regenerated mankind: but the regeneration was not complete; for the Goths and Vandals could not preſerve themſelves from the contagion of civil life; and their fall from ſavagiſm to ſcience drew from Weiſhaupt's hierophants the moſt piteous lamentations!

* See Doig's *Letters on the Savage State.*

The laſt ſecret communicated to the moſt favoured adepts was the novelty of the order. Hitherto their zeal had been inflamed, and their reſpect demanded to an inſtitution pretended to be of the higheſt antiquity. The honour of inſtituting the myſteries had been ſucceſſively attributed to the children of the Patriarchs, to ancient philoſophers, even to Chriſt himſelf, and to the founders of the maſonic lodges (ſee MASONRY in this *Suppl.*). But now the time is come when the adept, initiated in the higher myſteries, is ſuppoſed to be ſufficiently enthuſiaſtic in his admiration of the order, to be entruſted with the hiſtory of its origin. Here then they inform him, that this ſecret ſociety, which has ſo artfully led him from myſtery to myſtery; which has, with ſuch perſevering induſtry, rooted from his heart every principle of religion, all love of his country, and affection for his family; all pretenſions to property, to the excluſive right to riches, or to the fruits of the earth;—this ſociety, which has taken ſo much pains to demonſtrate the tyranny and deſpotiſm of all laws human and divine, and of every government, whether monarchical, ariſtocratical, or republican; which has declared him free, and taught him that he has no ſovereign on earth or in heaven; no rights to reſpect in others, but thoſe of perfect equality, of ſavage liberty, and of the moſt abſolute independence; that this ſociety is not the offspring of an ignorant and ſuperſtitious antiquity, but of modern philoſophy; in one word, that the true father of illuminiſm is no other than Adam Weiſhaupt, known in the ſociety by the name of SPARTACUS! This *important* ſecret, however, remained a myſtery even to the greater part of the *magi* and the *man-kings*, being revealed only to the grand council of *areopagites*, and to a few other adepts of diſtinguiſhed merit.

40 The laſt ſecret of the order.

So zealouſly was the order bent upon propagating its execrable principles through the whole world, that ſome of the chiefs had planned an order of female adepts, in ſubſerviency to the deſigns of the men. "It will be of great ſervice, (ſays *Cato* Zwack), it will procure us both information and money, and will ſuit charmingly the taſte of ſome of our trueſt members, who are lovers of the ſex." An aſſeſſor of the Imperial chamber at Wetzlar, of the name of Dittfurt, but known among the illuminees by that of *Minos*, expreſſed even his deſpair of ever bringing men to the grand object of the order without the ſupport of female adepts; and he makes an offer of his own wife and his four daughters-in-law to be firſt initiated. This order was to be ſubdivided into two claſſes, each forming a ſeparate ſociety, and having different ſecrets. The firſt was to be compoſed of virtuous women; the ſecond of the wild, the giddy, and the voluptuous. The brethren were to conduct the firſt, by promoting the reading of good books; and to train the ſecond-

41 Propoſal for a female order,

(E) He does not ſay where this appearance was made; but the circumſtances related lead us to ſuppoſe that it was in a church.

Illuminati.

second to the arts of *secretly gratifying their passions*. The wife of an adept named Ptolemy Magus was to preside over one of the classes; which (says Minos) will become, under her management and his, a very pretty society. "You must contrive pretty degrees, and dresses, and ornaments, and elegant and decent rituals. No man must be admitted. This will make them more keen, and they will go much farther than if we were present, or than if they thought that we knew of their proceedings. Leave them to the scope of their own fancies, and they will soon invent mysteries which will put us to the blush, and mysteries which we can never equal. They will be our great apostles. Reflect on the respect, nay, the awe and terror, inspired by the female mystics of antiquity. Ptolemy's wife must direct them, and she will be instructed by Ptolemy; and my step-daughters will consult with me. We must always be at hand to prevent the introduction of any improper question. We must prepare themes for their discussion: thus we shall confess them, and inspire them with our sentiments. No man, however, must come near them. This will fire their roving fancies, and we may expect rare mysteries!"

42 Rejected by Spartacus.

But notwithstanding all the plans and zeal of this profligate wretch and others of the fraternity, it does not appear that the General *Spartacus* ever consented to the establishment of the sisterhood. He supplied, however, the want of such an institution, by secret instructions to the regents, on the means of making the influence of women over men subservient to the order, without entrusting them with any of the secrets. "The fair sex (says he) having the greatest part of the world at their disposal, no study is more worthy the adept than the *art of flattery*, in order to gain them. They are all more or less led by vanity, curiosity, pleasure, or the love of novelty. It is on that side, therefore, they are to be attacked, and by that to be rendered subservient to the order." That Weishaupt's sagacity had not on this occasion forsaken him, is very evident; since it has been proved that the German fair, who were the correspondents of the illuminees, welcomed the French invaders of their native country *. Nay, so lately as the winter of 1798, our correspondent in Saxony heard several of these illuminized ladies express a wish that the French might invade and conquer England; for then, said they, *tea and coffee would be cheaper!*

* Dr Robison's *Proofs of a Conspiracy*.

It is not enough for the founder of a sect of conspirators to have fixed the precise object of his plots. His accomplices must form but one body, animated by one spirit; its members must be moved by the same laws, under the inspection and government of the same chiefs. A full account of the government of Weishaupt's order will be found in the valuable work of Abbé Barruel; our limits permit us to give only such a general view of it as may put our readers on their guard against the secret machinations of these execrable villains, whose lodges are now recruiting, under different denominations, in every country in Europe.

43 Subordination of the illuminees.

Wherever illuminism has gained a footing, as the means of subordination, there is a general division of command as well as of locality. The *candidates* and *novices* are each under the direction of his own insinuator, who introduces him into the *Minerval lodges*; each *Minerval lodge* has a superior from among the preparatory class, under the inspection of the intermediary class. So many lodges constitute a district, under the direction of a superior, whom the order calls *dean*. The dean is subjected to the *provincial*, who has the inspection and command of all the lodges and deaneries of the province. Next in order comes the *national superior*, who has full power over all within his nation, provincials, deans, lodges, &c. Then comes the supreme council of the order, or the *areopagites*, over which presides the *general* of illuminism. Thus has the order formed within itself a supreme tribunal, to whose inquisition all nations are to be subjected. The areopagites, consisting of twelve fathers of the order, with the general at their head, form the centre of communication with all the national superiors on earth; each *national* is the centre of one particular nation; the *provincial*, of one province; the *dean*, of the lodges within his deanery; the *Minerval master*, of his academy; the *venerable*, of his masonic lodge; and the *insinuator* or *recruiter*, of his *novices* and *candidates*.

44 Their mode of correspondence;

The higher degrees (says Weishaupt in one of his instructions to the regents) must always be hidden from the lower. The simple illuminee therefore corresponds with his immediate superior, knowing perhaps no other member of the order; the latter, with his dean; and thus gradually ascending to the national superiors, who alone are acquainted with the residence of the areopagites, as they again are with the names and residence of the general. Any member, however, of the inferior degrees, may occasionally correspond with his unknown superiors, by addressing his letters *Quibus licet*; and in these letters he may mention whatever he thinks conducive to the advancement of the order. If he be a novice, he may in these letters inform his superiors how his instructor behaves to him, or may draw the character of any person whatever. When the letter of any adept contains secrets, or complaints which he chooses to conceal from his immediate superior, he directs it *Soli* or *Primo*; and then it can be opened only by the *provincial*, the *national superior*, the *areopagites*, or the *general*, according to the rank of the writer, which is by some contrivance unknown to M. Barruel, indicated on the outside of the letter. The *provincial* opens the letters of the *minor* and *major* illuminees which are directed *Soli*; the *Quibus licets* of the epopts; and the *Primos* of the novices; but he cannot open either the *Primo* of the minerval, the *Soli* of the Scotch knight, or the *Quibus licet* of the regent. He can only form a conjecture as to the persons who open his own letters, and those which he is not permitted to open himself.

45 And of giving importance to their order,

When it is considered, that by one of Weishaupt's statutes, the provincial has in each chapter or district a confidential epopt, who is his *secret censor* or *spy*; that these spies are to insinuate themselves into all companies, and collect *anecdotes of secret history*; that the historian of the province is to insert these anecdotes into a journal kept for that purpose; and that the provincials are obliged to forward the contents of these journals to the high superiors of the order—some notion may be formed of the influence of the general and areopagites in every country into which illuminism has found its way. "The means of acquiring an ascendency over men (says Weishaupt), are incalculable. Who could enumerate them all? They must vary with the disposition of the times. At one period, it is a taste

taſte for the marvellous that is to be wrought upon. At another, the lure of ſecret ſocieties is to be held out. For this reaſon, it is very proper to make your inferiors believe, without telling them the real ſtate of the caſe, that all other ſecret ſocieties, particularly that of *Freemaſonry, are ſecretly directed by us.* Or elſe, and IT IS REALLY THE FACT IN SOME STATES, THAT POTENT MONARCHS ARE GOVERNED BY OUR ORDER. When any thing remarkable or important comes to paſs, hint that it *originated with our* order. Should any perſon by his merit acquire a great reputation, let
46 it be generally underſtood that *he is one of us.*

By every means, good or bad.

"If our order cannot eſtabliſh itſelf in any particular place, with all the forms and regular progreſs of our degrees, *ſome other form muſt be aſſumed.* Always have *the object* in view; that is the eſſential point. No matter what *the cloak* be, provided you ſucceed; *a cloak,* however, *is always neceſſary,* for in *ſecrecy our ſtrength lies.* The INFERIOR LODGES OF FREEMASONRY ARE THE MOST CONVENIENT CLOAKS for our GRAND OBJECT; becauſe the world is already familiariſed with the idea, that *nothing of importance,* or *worthy of their attention, can ſpring from maſonry.*" No artifice, however, is to be left untried. "You may attend large and commercial towns during the times of fairs in different characters; as *a merchant, an officer, an abbé.* Everywhere you will perſonate an extraordinary man, having important buſineſs on your hands; but all this muſt be done with a great deal of *art and caution,* leſt you ſhould have the appearance of an adventurer. You may write your orders with a *chymical preparation of ink, which diſappears after a certain time.* Never loſe ſight of the *military ſchools,* of the *academies, printing preſſes, libraries, cathedral chapters,* or *any public eſtabliſhments* that can influence *education,* or *government.* Let our regents perpetually attend to the various means, and form plans, for MAKING US MASTERS *of all theſe eſtabliſhments.* When an author ſets forth principles true in themſelves, but which do not as yet ſuit *our general plan of education for the world,* or principles, the publication of which is premature; every effort muſt be made to *gain over the author;* but ſhould all our attempts fail, and we ſhould prove unable to entice him into the order, *let him be diſcredited by every poſſible means.*"

Of their methods of diſcrediting authors, one has come to our knowledge, which muſt be intereſting to ſome of our readers. Dr Robiſon's work, entitled *Proofs of a Conſpiracy,* &c. which firſt unmaſked theſe hypocrites in this country, found its way into Germany, and was tranſlated into the German language, and expoſed to ſale at the Leipſic fairs. The illuminees, under the diſguiſe of *merchants* and *abbés,* attended, and bought up the whole impreſſion, which they committed to the flames. A ſecond edition was publiſhed, and it ſhared the ſame fate (F). This was a more compendious way of anſwering the learned author than that which has been adopted by the Jacobin journaliſts in London; but perhaps it may convince the readers of theſe journals, that the Doctor has not ſo far miſtaken the ſenſe of the writings of *Philo* and *Spartacus,* as their illuminiſed maſters wiſh them to believe.

When theſe arts of diſſeminating the diſorganiſing and impious principles of the order are duly conſidered, and when it is remembered that its emiſſaries dare not diſobey a ſingle injunction of the high ſuperiors, without expoſing themſelves to poiſon, or to the daggers of a thouſand unſeen aſſaſſins, no man can be ſurpriſed to learn that the illuminees contributed greatly to the French 47
revolution. The philoſophers of France had indeed prepared the public mind for embracing readily the doctrines of illuminiſm; and ſo early as 1782, *Philo* and *Spartacus* had formed the plan of illuminizing that nation; but they were afraid of the vivacity and caprice of the people, and extended not their attempts, at that time, beyond Straſbourg. Already, however, there exiſted ſome adepts in the very heart of the kingdom; and the Marquis de Mirabeau, when ambaſſador at the court of Berlin, was initiated at Brunſwick by a diſciple of Philo Knigge's. On his return to France he began to introduce the new myſteries among his maſonic brethren.

Illuminiſm of France

The ſtate of free maſonry was at that time peculiarly 48
adapted to the views of the conſpirators. The French had engrafted on the old and innocent Britiſh maſonry a number of degrees, gradually riſing above each other, to the very myſteries of illuminiſm itſelf (ſee MASONRY in this *Suppl.*) Theſe were called the *philoſophical* degrees, and comprehended the *knights of the ſun,* the higher *Roſicrucians,* and the *knights Kadeſh.* At the head of all theſe ſocieties, whether ancient or modern, were three lodges at Paris, remarkable for the authority which they exerciſed over the reſt of the order, and Philip of Orleans was the grand-maſter. So early as the year 1787, France contained 282 towns, in which were to be found regular lodges, under the direction of that execrable wretch. He increaſed their number by introducing to the *maſonic* myſteries the loweſt of the rabble, as well as thoſe French guards whom he deſtined to the ſubſequent attack of the baſtile, and to the ſtorming of the palace of his near relation and royal maſter. In every country town and village lodges were opened for aſſembling the workmen and peaſantry, in hopes of heating their imaginations with the ſophiſticated ideas of equality and liberty, and the rights of man; and it was then that Mirabeau invited a deputation from the order of Weiſhaupt, which very quickly diffuſed the light of illuminiſm through the whole kingdom. Inſtead of *Spartacus* Weiſhaupt, *Cato* Zwack, and *Philo* Knigge, we find wielding the firebrands of revolution in the capital of France, *Philip of Orleans, Mirabeau, Syeyes,* and *Condorcet.* The day of general inſurrection was fixed by theſe miſcreants for the 14th of July 1789. At the ſame hour, and in all parts of France, the cries of *equality* and *liberty* reſounded from the lodges. The Jacobin clubs were formed; and hence ſprung the revolution, with all its horrors of atheiſm, murder, and maſſacre!

By means of free maſonry.

In ſupport of this account of the illuminees we have not loaded our margin with authorities; becauſe our detail has been taken wholly from the valuable works of

---

(A) This information was communicated to us by a gentleman of character, who was at Leipſic when the two impreſſions of the book were thus diſpoſed of. The Abbé Barruel's work has no doubt been anſwered in the ſame way, though we cannot ſay ſo upon the ſame authority.

Illuminati. of Abbé Barruel and Dr Robison, to which we refer our readers for much curious information that our limits do not permit us to give. We cannot, however, conclude the article, without making some remarks on that specious principle by which the conspirators have deluded numbers, who abhor their impieties, and who would not go all their length even in rebellion; we mean the maxim, "that it is our duty to love all men with an equal degree of affection, and that any partial regard for our country, or our children, is unjust."

49 Reflections on the fundamental principles of illuminism;

That this maxim is false, every *Christian* knows, because he is enjoined to "do good indeed unto all men, but *more especially* to them who are of the household of faith;" because he is told, that "if any man provide not for his *own*, and especially for those of his *own house*, he hath denied the faith, and is worse than an infidel;" because his divine master, immediately after resolving all duty into the love of God and man, delivers a parable, to shew that we neither can nor ought to love all men *equally*; and because the same Divine Person had one disciple whom he loved more than the rest. But we wish those *philosophers* who talk perpetually of *the mechanism* of the human mind, and at the same time affect to have no *partial* fondness for any individual, but to love all with the same degree of *rational* affection, to consider well whether such philanthropy be consistent with what they call (very improperly indeed) *mechanism*. If this mechanism be (as one of them says it is) nothing more than *attraction* and *repulsion*, we know that it *cannot* extend with equal force over the whole world; because the force of attraction and repulsion varies with the distance. If by this absurd phrase, they mean a set of *instinctive* propensities, or feelings, we know that among savages, who are more governed by instinct than civilized men, philanthropy is a feeling or propensity of a very limited range. If they believe all our passions to originate in self love, then is it certain that our philanthropy must be progressive; embracing first, and with strongest ardour, our relations, our friends, and our neighbours; then extending gradually through the society to which we belong; then grasping our country; and last of all the whole human race. Perhaps they may say that reason teaches us to love all men equally, because such equal love would contribute most to the sum of human happiness. This some of them indeed have actually said; but it is what no man of reflection can possibly believe. Would the sum of human happiness be increased, were a man to pay no greater attention to the education of his own children than to the education of the children of strangers? were he to do nothing more for his aged and helpless parents than for any other old person whatever? or, were he to neglect the poor in his neighbourhood, that he might relieve those at the distance of 1000 miles? These questions are too absurd to merit a serious answer.

When a man, therefore, boasts of his universal benevolence, declaring himself ready, without fee or reward, to sacrifice every thing dear to him for the benefit of strangers whom he never saw; and when he condemns, in the cant phrase of faction, that narrow policy which does not consider the whole human race as one great family—we may safely conclude him to be either a consummate hypocrite, who loves none but himself, or a philosophical fanatic, who is at once a stranger to his duty and to the workings of his own heart.

Illuminati ‖ Imperfect.

50 Exemplified in the conduct of the illuminees.

If this conclusion require any farther proof, we have it in the conduct of Weishaupt and his areopagites. In the hand-writing of *Cato* his *incomparable man*, was found the description of a strong box, which, if forced open, would blow up and *destroy its contents*; several receipts for *procuring abortion*; a composition which *blinds or kills* when spurted in the face; *tea* for procuring abortion; *Herbæ quæ habent qualitatem delateream*; a method for filling a bed-chamber with *pestilential vapours*; how to take off impressions of seals, so *as to use them afterwards as seals*; a receipt *ad excitandum furorem uterinum*; and a dissertation on *suicide*. Would genuine philanthropists have occasion for such receipts as these? No! the order which used them was founded in the most consummate villany, and by the most detestable hypocrite. The incestuous Weishaupt seduced the widow of his brother, and solicited poison and the dagger to murder the woman whom he had fondly pressed in his arms. "Execrable hypocrite (says M. Barruel), he implored, he conjured both art and friendship, to destroy the innocent victim, the child, whose birth must betray the morals of his father. The scandal from which he shrinks, is not that of his crime: it is the scandal which, publishing the depravity of his heart, would deprive him of that authority by which, under the cloak of virtue, he plunged youth into vice and error. *I am on the eve*, (says he) *of losing that reputation which gave me so great authority over our people: My sister-in-law is with child. I will hazard a desperate blow, for I neither can nor will lose my honour.*" Such is the benevolence of those who, banishing from their minds all partial affection for their children and their country, profess themselves to be members of one great family, the family of the world!

IMAGINARY Quantities, or *Impossible Quantities*, in algebra, are the even roots of negative quantities; which expressions are Imaginary, or impossible, or opposed to real quantities; as $\sqrt{-aa}$, or $\sqrt[4]{-a^4}$, &c. For as every even power of any quantity whatever, whether positive or negative, is necessarily positive, or having the sign $+$, because $+$ by $+$, or $-$ by $-$, give equally $+$; hence it follows that every even power, as the square for instance, which is negative, or having the sign $-$, has no possible root; and therefore the even roots of such powers or quantities are said to be impossible or imaginary. The mixt expressions arising from imaginary quantities joined to real ones, are also imaginary; as $a - \sqrt{-aa}$, or $b + \sqrt{-aa}$.

Imaginary Roots of an equation, are those roots or values of the unknown quantity, which contain some imaginary quantity. Thus the roots of the equation $xx + aa = 0$, are the two imaginary quantities $+\sqrt{-aa}$ and $-\sqrt{-aa}$, or $+a\sqrt{-1}$ and $-a\sqrt{-1}$.

IMPACT, the simple or single action of one body upon another to put it in motion. Point of impact is the place or point where a body acts.

IMPERFECT Number, is that whose aliquot parts, taken all together, do not make a sum that is equal to the number itself, but either exceed it, or fall short of it; being an abundant number in the former case, and a defective number in the latter. Thus, 12 is an abundant imperfect number, because the sum of all its aliquot parts, 1, 2, 3, 4, 6, makes 16, which exceeds the

the number 12. And 10 is a defective imperfect number, becauſe its aliquot parts, 1, 2, 5, taken all together, make only 8, which is leſs than the number 10 itſelf.

IMPOST, in architecture, a capital or plinth, to a pillar, or pilaſter, or pier, that ſupports an arch, &c.

Doctrine of Impulſion.

IMPULSION, is the term employed in the language of mechanical philoſophy, for expreſſing a ſuppoſed peculiar exertion of the powers of body, by which a moving body changes the motion of another body by hitting or ſtriking it. The plaineſt caſe of this action is when a body in motion hits another body at reſt, and puts it in motion by the ſtroke. The body thus put in motion is ſaid to be IMPELLED by the other: and this way of producing motion is called IMPULSION, to diſtinguiſh it from PRESSION, THRUSTING, or PROTRUSION, by which we puſh a body from its place without ſtriking. The term has been gradually extended to every *change* of motion occaſioned by the colliſion of bodies.

1 Hiſtory of it.

When ſpeculative men began to collect into general claſſes, the obſervations made during the continual exertions of our own perſonal powers on external bodies, in order to gain the purpoſes we had in view, it could not be long before they remarked, that as we, by the ſtrength of our arm, can move a body, can ſtop or any how change its motion; ſo a body already in motion produces effects of the ſame kind in another body, by hitting it. Such obſervations were almoſt as early and as intereſting as the other; and the attention was very forcibly turned to the general facts which obtained in this way of producing motion; that is, to the expiſcation of the general laws of impulſion. We do not find, however, in what remains of the phyſical ſcience of the ancients, that they had proceeded far in this claſſification. While mechanics, or the ſcience of machines, had acquired ſome form, and had been the ſubject of ſucceſsful mathematical diſcuſſion, we do not find that any thing ſimilar had been done in the ſcience of impulſe. Yet the artillery of ancient times was very ingenious and powerful. But although Vegetius, and Ammianus Marcellinus, and Hero, deſcribe the mechaniſm of theſe engines with great care, and frequently with mathematical ſkill, we ſee no attempts to aſcertain with preciſion the force of the miſſile weapon, or to ſtate the efficacy of the battering ram, by meaſures of the momentum, and compariſon of it with the reſiſtance oppoſed to it. The engineers were contented with very vague notions on theſe points.

Ariſtotle, in his 20th Mechanical Queſtion, and Galen in ſome occaſional obſervations, are the only authors of antiquity whom we recollect as treating the force of impulſe as a quantity ſuſceptible of meaſure. Their obſervations are extremely vague and trivial, chiefly directed, however, to the diſcrimination of the force of impulſe from that of preſſure.

In more modern times, great additions had already been made to the aſſiſtance we had derived from the impulſive efficacy of bodies in motion. Water-mills and wind-mills had been invented, and had been applied to ſuch a variety of purpoſes, that the engineers were faſt acquiring more diſtinct notions of the force of impulſe. Naval conſtructions was changed in ſuch a manner, that there hardly remained any thing of the ancient rigging. The oblique action of wind and water were now found even more effective than the direct; and ſhips could now ſail with almoſt any wind. All theſe things fixed the attention of the engineers and of the ſpeculatiſt on the numberleſs modifications of the force of impulſe.

But it ſoon appeared that this was a refined branch of knowledge, and required a more profound ſtudy than any other department of the ſcience of motion. At the ſame time, it was equally clear, that it was alſo of ſuperior importance. Mills worked by cattle, or by mens hands, were everywhere giving place to wind and water-mills; and a ſhip alone appeared to every intelligent mechanician to be the greateſt effort of human invention, and moſt deſerving his careful ſtudy. All theſe improvements in the arts of life derived their efficacy from the impulſe of bodies. The laws of impulſion, therefore, became the objects of ſtudy to all who pretended to philoſophical ſcience. But this is a branch of ſtudy wholly new, and derives little aſſiſtance from the mechanical ſcience already acquired; for that was confined to the determination of the circumſtances which regulated the equilibrium of forces, either in their combined action on bodies in free ſpace, or by the intervention of machines. But in the production of motion by impulſe, the equilibrium is not ſuppoſed to obtain; and therefore its rules will not ſolve the moſt important queſtion, "What will be the preciſe motion?"

Galileo, to whom we are indebted for the firſt diſcoveries in the doctrine of free motions, was alſo the firſt who attempted to bring impulſion within the pale of mathematical diſcuſſion. This he attempted, by endeavouring to ſtate what is the force or energy of a body in motion. The very obſcure reflections of Ariſtotle on this ſubject only ſerved to make the ſtudy more intricate and abſtruſe. Galileo's reflections on it are void of that luminous perſpicuity which is ſeen in all his other writings, and do not appear to have ſatisfied his own mind. He has recourſe to an experiment, in order to diſcover what preſſure was excited by impulſion. A weight was made to fall on the ſcale of a balance, the other arm of which was loaded with a conſiderable weight; and the force of the blow was eſtimated by the weight which the blow could thus ſtart from the ground. The reſults had a certain regularity, by which ſome analogy was obſerved between the weights thus ſtarted and the velocity of the impulſe; but the anomalies were great, and the analogy was ſingular and puzzling; it led to many intricate diſcuſſions, and ſcience advanced but ſlowly.

2 Laws of impulſion diſcovered by Wallis, Wrenn, and Huyghens

At laſt the three eminent mathematicians, Dr Wallis, Sir Chriſtopher Wrenn, and Huyghens, about the ſame time, and unknown to each other, diſcovered the ſimple and beautiful laws of colliſion, and communicated them to the Royal Society of London in 1668 (Phil. Tranſ. n° 43—46.). Sir Chriſtopher Wrenn alſo invented a beautiful method of demonſtrating the doctrine by experiment. The bodies which were made to ſtrike each other were ſuſpended by threads of equal length, ſo as to touch each other when at reſt. When removed from this their vertical ſituation, and then let go, they ſtruck when arrived at the loweſt points of their reſpective circles, and their velocities were proportional to the chords of the arches through which they had deſcended. Their velocities, after the ſtroke, were meaſured, Impulsion. measured, in like manner, by the chords of their arches of ascent. The experiments corresponded precisely with the theoretical doctrine.

In the mean time, this subject had keenly occupied the attention of philosophers, who found it to be of a very abstruse nature; or, which is nearer the truth, they indulged in great refinement in prosecuting the study. The first attempts to measure the impulsive force of bodies, by setting it in opposition to pressures, which had long been measured by weights, gave rise to some very refined reflections on the nature of these two kinds of forces. Aristotle had said that they were things altogether disparate. If so, there can be no proportion between them. Yet the analogy observed in the experiments above mentioned of Galileo, shewed that impulse could be gradually augumented, till it exceed any pressure. This indicates sameness in kind, according to Euclid himself. A curious experiment of Galileo's, in which the impulse of a vein of water was set in equilibrio with a weight, seemed not only to establish this identity beyond a doubt, but even to shew the origin of pressure itself. The weight in one scale is sustained as long as the stream of water continues to strike the other scale. In this experiment, therefore, pressure is equivalent to continual impulse. But *continual* impulse is not conceivable: we must consider the impulse of the stream as the *successive* impulse of the different particles of water, at intervals which are altogether indistinguishable.

From these considerations were deduced two very momentous doctrines: 1. That pressure is nothing but repeated impulse; 2. That although pressure and impulse are the same in kind, they are incomparable in magnitude. The impulse is equal to the weight of a column of water, whose length is the height necessary for communicating the velocity. Now this is incessant; and the weight is sustained during any the smallest moment of time, by the impulse, not of the whole column, but of the insensible portion of it which is then making its stroke. Impulse, therefore, is infinitely greater than pressure.

3 Impulse said to be the only cause of motion.

These abstruse speculations have a charm for certain ingenious speculative minds; and when indulged, will lead them very far. Accordingly, it was not long before some of the most ingenious philosophers of Europe taught that impulse was the sole origin of pressure. There is but one moving power (said they) in mechanical nature: This is impulse.—*Nihil movetur* (says Euler) *nisi a contiguo et moto.* Moreover, having been long and familiarly conversant with the actions of animals, and the actions of moving bodies, and conceiving, with sufficient distinctness, that impenetrable bodies cannot move without moving those with which they are surrounded and in contact, they imagined that they fully understood how all this displacement of bodies is carried on; and therefore they maintained, that any motion is fully explained when it is shewn to be a case of impulsion. But they saw many cases of motion where this impulsion could not be exhibited to the senses. Thus, the fall of heavy bodies, the mutual approach or recess of magnetic and electric bodies, exhibited no such operation. But even here their experience helped them to an explanation. Air is an invisible substance, and its very existence was for a long time known to us only by means of its impulse. As we see that pressures are generated by the impulse of water and of air, may there not be fluids still more subtle than air, by whose invisible impulse bodies are made to fall, and magnets are made to approach or avoid each other? The impossibility of this cannot be demonstrated, and the laws of impulse had not as yet been so far investigated as to shew that they were incompatible with those productions of motion. It was therefore an open field for discussion; and the philosophers, without farther hesitation, adopted, as a first truth, that ALL MOTION WHATEVER IS PRODUCED BY IMPULSION. The business of the philosopher, therefore (say they), is to investigate what combination of invisible impulsions is competent to the production of any observed motion; such as the fall of a heavy body, the elliptical motion of a planet, or the polarity of a magnetic needle. The curious disposition of iron-filings round a magnet encouraged this kind of speculation: It looks so like a stream of fluid; but it is a number of quiescent fragments of iron. This does not hinder us from *supposing* such a stream, not of iron-filings, but of a magnetic fluid, which will arrange (say the atomists) those fragments, just as we see the flote-grass in a brook arranged by a stream of water. Fluids, therefore, moving in streams, vortices, and a thousand different ways, have been supposed, in order to *explain*, that is, to bring under a general known law of mechanical Nature, all those cases of the production of motion where impulsion is not observed by the senses.

As we have gradually become better acquainted with the laws of the production of motion by impulsion, we have been able to explode many of those proffered explanations, by shewing that the genuine results of the supposed invisible motions, that is, the impulsions which they would produce, are very unlike the motions which we attempt to explain. It has been shewn that the vortices supposed by Des Cartes, or by Leibnitz, or by Huyghens, cannot exist; and they have been given up. But it is answered to all those demonstrations of futility, that still the axiom remains. Motion is produced only by impulse; but we have not yet discovered all the possibilities of impulsion; and we must not despair of discovering that precise set of invisible motions, and consequent impulsions, of which the phenomena before us is the necessary result.

But this is by no means sufficient authority for deserting the rule of philosophizing, so prudently and judiciously recommended by Sir Isaac Newton; namely, not to admit as the cause of phenomenon any thing that is not *seen* to operate in its production. The prudence of this restriction is evident; and it has also been sufficiently shewn (PHILOSOPHY, *Encycl.* n° 48. &c.), that true philosophical explanation, or extension of knowledge, is unattainable, if this rule be not strictly adhered to. We therefore require a cogent reason for a practice that opens the door to every absurdity, and that cannot give us the knowledge which we are in quest of. What, then, is the reason that always induces philosophers to have recourse to impulsion for the explanation of a phenomenon, and to rest satisfied in every case where it can be clearly proved that the phenomenon is really a case of impulsion? We say that we inquire into the reason why a body falls, and that we will be satisfied if it can be shewn us that it has received a number of impulsions downward. Do we inquire why

4 The application of this principle is hazardous.

Impulsion. a body in motion puts another body in motion by hitting it? And if we do, have we discovered the reason? We believe that none of the philosophers, who have recourse to invisible impelling fluids, ever ask a reason for motion by impulsion. Indeed they should not, otherwise it would cease to be a first principle of explanation. Other philosophers, indeed (namely, such as ask no reason for the weight of a body, but the FIAT of the ALMIGHTY), require an explanation of motion by impulse, and think that, in almost every case, they have found it out.

If the philosophers ask no reason for this production of motion, they must (that it may serve as a principle of explanation) say that impulsiveness is an original property of matter, either contingent or essential. Accordingly, we believe that this, or something like this, has been assumed as a principle by the greater part of mechanicians. It has been assumed, as we have observed in the article DYNAMICS, *Suppl.* that a *moving body* possesses the power of producing motion in another body by hitting it; and they call it the IMPULSIVE FORCE *of moving bodies*—the FORCE INHERENT *in a moving body*. The reader will have observed, in our manner of treating that article, and also in several passages of different articles of the *Encyclopædia Britannica*, that we do not consider this assumption as very clearly authorised by observation, or deducible by abstract reasoning, from the first principles of philosophy. There is no branch of natural philosophy on which so many ingenious dissertations have been written; and perhaps there is none that has been more successfully prosecuted: Yet this is the only part of the science of motion that has given rise to a serious dispute; a dispute that has divided, and still divides, the mechanicians of Europe.

Some may think it presumptuous in us, in a Work of this kind, which only aims at collecting and exhibiting in one view the *existing science* of Europe, to pretend to give new doctrines, or to decide a question which has called forth all the powers of a Leibnitz, a Bernoulli, a Jurin, a M'Laurin, &c. But we make no such pretensions; we only hope that, by separating the question from others with which it has, in every instance, been complicated, and by considering it apart, such notions may be formed, in perfect conformity to the principles adopted by all parties, that the mystery, which has gradually gathered like a cloud, may be dispelled, and all cause of difference taken away. We apprehend that this requires no very extensive knowledge, but merely a strict attention to the conceptions which we form of the actions of bodies on each other, and a precision in the use of the terms employed in the discussion.

5 Inquiry into its truth.

We trust that our philosophical readers perceive and approve of our anxiety to establish (in the article DYNAMICS, *Suppl.*) the leading principles of mechanical philosophy, from which we are to reason in future on acknowledged FACTS, or LAWS of human thought. It is not so much the question, What is the essence of material Nature, from which all the appearances in the universe proceed? as it is, What do we know of it? how do we come by this knowledge? and what use can we make of it? The tænia knows nothing of the solar system, and man is ignorant of the cause of impulsiveness. Other intelligent creatures may have senses, of which this is the proper object; and others, of a still more exalted rank, may perceive the operations of mind as clearly as we perceive those of matter, while they are equally ignorant with ourselves of the causes which connect the conjoined events in either of those operations. But "known unto GOD, and to HIM alone, are ALL His works!"

6 We learn the existence of matter chiefly by means of touch.

To accomplish this purpose, we directed the reader's attention to what passes in his own mind when he thinks on the mechanical phenomena of Nature; on what he calls body; on the perceptions which bring it into his view, and which give him all the notions that he can form of its distinguishing, its characteristic properties. How does he learn that there is matter in a particular place? He has more than one mean of information; and each of these informs him of peculiar qualities of the thing which he calls *matter*. Many appearances suggest to his mind the presence of a body. Shew a monkey or a kitten (and even sometimes a human infant) a mirror, and it will instantly grope round it to find a companion. Why does the creature grope about so? It is not contented with the first indication of matter, and nothing will satisfy it but touching or grasping what is behind the mirror. It is by our sense of touch alone that we get the irresistible conviction that matter or body is perceived by us, and it never fails to give us the perception; nay, we have the perception even in some cases where the experienced philosopher thinks himself obliged to doubt of its truth. Some sensations, arising from spasm, cannot be distinguished from the feeling of touch; and the patient insists that something presses on the diseased part, while the physician knows that it is only a nervous affection. Every person will think that a cobweb touches his face when an electrified body is brought near it, and will try to wipe it off with his hand. But the modern philosopher sees good reason for asserting, that in this instance our feeling gives us very inaccurate, if not erroneous, information. He shews that the fact, of which our feeling truly informs us, is the bending of the small hairs or down which grow on the face, and that these only have been touched; and the followers of Epinus deny that even this has been demonstrated.

7 The excitement of touch is accompanied by the feeling of exerted pressure.

The philosopher adopts this mode of perception as unquestionable, and allows that, and that alone, to be matter, which invariably produces this sensation by contiguity. But engaged in speculations which fix his attention on the external object, he neglects and overlooks the instrument of information, and its manner of producing the effect, just as the astronomer overlooks the telescope, and the union and decussation of the rays of light which form the picture by which he perceives the satellite of Jupiter travel across his disk. The philosopher finds it convenient to generalise the immense variety of touches which he feels from external bodies, and to consider them as the operations of one and the same discriminating quality, a PROPERTY inherent in the external substance BODY: and he gives it a name, by which he can excite the same notion in the minds of his hearers. It is worth while to attend to what has been done in this matter, because it gives much information concerning the first principles of mechanism. An exquisite painting has sometimes such an appearance of prominence, that one is disposed to draw the finger along it, and we expect to feel some roughness, some *obstruction*, something that prevents the finger

ger from going over the place. Perhaps we doubt, and want to be aſſured. We preſs a little cloſer; but feel no obſtruction; and we deſiſt. The very firſt appearance, therefore, which this indicating quality, viewed as the *property* of external matter, has in our conceptions, is that of an obſtruction, an obſtacle, to the exertion of one of our natural powers. The power exerted on this occaſion is familiarly and *diſtinctively* known by the name of PRESSURE. This is the name of our own exertion, our own action; and, in this inſtance, and (we think, in this alone, the word is uſed purely, primitively, and without figure. When we ſay that a ſtone preſſes on the ground, we ſpeak figuratively, as truly as when we ſay that the candleſtick ſtands, and the ſnuffers lie, on the table. It is a perſonification, authoriſed by the ſimilarity of the effects and appearances. Further, when we ſpeak of our preſſure on any thing, with the intention of being preciſe in our communication, we ſpeak only of what obtains in the touching parts of the finger and the thing preſſed, paying no attention to the long train of intermediate exertions of the mind on the nerves, the nerves on the muſcular fibre, the fibre on the articulated machine, and the machine on the touching part of the finger. And thus the exertion of the ſentient and active being is attributed to the particles of lifeleſs inactive matter at the extremity of the finger, and theſe are ſaid to preſs immediately on the touching parts of the external body. And, laſtly, as this our exertion is unqueſtionably the perceived employment of a faculty in us, which we call *force, power, ſtrength*, diſtinguiſhing it from every other faculty by theſe names; we ſay (but figuratively), that force or power is exerted at the tips of the fingers, and we call it the FORCE OF PRESSURE.

8
And preſſure is conceived or ſuppoſed in almoſt every production of motion.

By far the greateſt part of our actions on external bodies is with the intention of putting them out of their preſent ſituations; and we can hardly ſeparate the thought of exerted preſſure from the thought of motion produced by it. Therefore, almoſt at its firſt appearance in the mind, preſſure comes before us as a MOVING POWER. Nay, we apprehend, that the more we ſpeculate, and the more we aim at preciſion in our conceptions, we ſhall be the more ready to grant that we have no clear *conception* of any other moving power. No man will contend that he has any conception at all of the power exerted by the mind in moving the body. It is of importance to reflect on the manner in which this notion is extended to all other productions of motion. We think that this will ſhew, that in every caſe we ſuppoſe preſſure to be exerted.

9
Examination of the inſtances of this perception.

The philoſopher proceeds in his ſpeculations, and obſerves that one man can preſs on another, and can puſh him out of his place, in the ſame way as he removes any other body; and he cannot obſerve any difference in his own exertions and ſenſations in the two caſes. But the man who is puſhed has the ſame feelings of touch and preſſure. By withdrawing from the preſſure, he alſo withdraws from the ſenſation; by withſtanding or reſiſting it, he feels the preſſure of the other man; and what he feels is the ſame with what he feels when he preſſes on the other perſon, or on any piece of matter. The ſame ſenſations of touch are excited. He attributes them to the preſſure of the other perſon. Therefore he attributes the ſame ſenſations to the counter preſſure of any other body that excites them. Farther, he can reſiſt to ſuch a degree that he is not puſhed from his place. In this caſe, the greateſt preſſure is exerted, and is felt by both. Each feels that the more he reſiſts, the greater is the mutual preſſure. And each feels that, unleſs he *not only do not reſiſt, but alſo withdraw himſelf* from the preſſure of the other, he will be preſſed, and the other will feel counter preſſure, the ſame in kind with what is produced by his reſiſtance, though leſs in degree.

10
They are generally figurative.

All theſe things are diſtinctly and invariably felt; but they require attention, in order to be ſubjects of recollection and after-conſideration. From this, and no other ſources, are derived all our notions of corporeal preſſure, of counter preſſure, of action, re-action, of *reſiſtance*, and of *inactivity* or *inertia*. Our notions of moving power, of the mobility of matter, and of the neceſſity of this power to produce motion in matter, have the ſame origin. Our notions alſo of the reſiſtance of inanimate matter, indicated by the expenditure of actual preſſure, are formed from the ſame premiſes: the counter-preſſure, or what at leaſt produces the ſame feelings in the perſon who is the mover, is conſidered as the property of dead matter; becauſe we feel, that if *we* do not exert real force, we are diſplaced by the ſame preſſure that would diſplace a lifeleſs body of the ſame bulk.

11
We obſerve many preſſures.

Theſe direct inferences are confirmed as we extend our acquaintance with things around us. We can exert our force in bending a ſpring, and we feel its counter-preſſure, preciſely ſimilar to that of another man. We feel that we muſt continue this preſſure, in order to keep it bent; and that as we withdraw our preſſure, the ſpring follows our hand, ſtill producing ſimilar feelings in our organs of touch, and requiring ſimilar exertions of our ſtrength to keep it in any ſtate of tenſion. Theſe phenomena are interpreted as indications of preſſures actually exerted by the ſpring, and quite different from what we ſhould feel from its mere reſiſtance to being moved. This action reſembles our own exertion in every particular; it produces all the effects of preſſure; it will ſqueeze in the ſoft flexible parts of our body with which we act on it; it will compreſs any ſoft body, juſt as we do ourſelves; it will put bodies in motion. Farther, we can ſet the action of one ſpring in oppoſition to that of another, and obſerve that each is bent by bending the other; and we ſee that their touching parts exert preſſure, for they will compreſs any ſoft body placed between them.

Thus, then, in all thoſe caſes, we have the ſame notion of the power immediately exerted between the two bodies, animated or inanimated. It is always preſſure. If indeed we begin to ſpeculate about the *modus operandi* in any one of theſe inſtances, we find that we muſt ſtop ſhort. How our preſſure excites the feeling of preſſure in the other perſon, or how it produces motion, eludes even conjecture—So it is—Nay, how our intention and volition cauſes our limb to exert this preſſure, or how the ſpringineſs of a ſpring produces ſimilar effects, remains equally hid from our ken. Unwearied ſtudy has greatly advanced our knowledge of theſe ſubjects in one reſpect. It has pointed out to us a train of operations, which go on in our animal frame before the oſtenſible preſſure is produced; we have diſcovered ſomething of their kind, and of the order in which they proceed; we have gone farther, and have diſcovered, in ſome

Impulsion. ſome of the preſſures exerted by lifeleſs matter, ſimilar trains of intervening operations. In the caſe of a ſpring, we have diſcovered that there is a certain combination of the properties of all its parts neceſſary for the viſible exertion. But what is the principle which thus makes them co-operate, we cannot tell, any more than in our own exertions of preſſure. Such being the origin of our notions on theſe ſubjects, it is no wonder that all our language is alſo derived from it. Force, power, preſſurre, action, re-action, reſiſtance, impulſion, are, without any exception, words immediately expreſſive of our own exertions, and applied metaphorically to the phenomena of matter and motion.

Laſtly, when we ſee a body in motion diſplace another body by hitting it, and endeavour to form a notion of the way in which this motion is immediately produced, fixing our attention on what paſſes in the very inſtant of the change, we find ourſelves ſtill obliged to ſuppoſe the thing we call preſſure. We can have no other conception of it; and there is no violence in this act of the imagination. For we know, that if we are joſtled from our place, and forcibly driven againſt another perſon, we put that perſon in motion without any intention or action of our own; and we experience, in doing this, that the very ſame feelings of touch and preſſure are excited as in the inſtances of the ſame motions produced by exerted preſſion. We alſo ſee, that when a body ſtrikes another, and puts it in motion, it makes an impreſſion or dimple in it if ſoft, or breaks it if brittle; and, in ſhort, produces every effect of preſſure. A ball of ſoft clay makes a dimple in the ball of ſoft clay which it diſplaces, and is dimpled by it. Springy bodies compreſs each other in their colliſions, and reſile from each other. In ſhort, in every caſe of this claſs, mutual preſſure, indicated by all its ordinary effects, appears to be the intermedium by which the changes of motion are immediately produced; and the previous motion of the ſtriking body ſeems to be only the method of producing this preſſure.

12 Preſſure is the only diſtinct notion of a moving power.

From this copious induction of particulars, and careful attention to the circumſtances of each, we think it plain, that preſſure is the only clear notion that a mind, not familiar with ſcrupulous diſcuſſion, forms of moving power; and therefore that it is very ſingular to think of excluding it from the liſt, and ſaying that impulſion is the only power in nature, and the ſource of all preſſure.

It may perhaps be ſaid, that the mutual immediate action to which the vulgar, and many philoſophers, have erroneouſly given the metaphorical name preſſure, is indeed the real cauſe of motion, or change of motion; but ſtill it is now properly called impulſion, becauſe it is occaſioned only by the previous motion of the impelling body. We conceive clearly (they may ſay) how this previous motion produces the impulſion. Since matter is impenetrable, we ſee clearly that a ſolid body, or a ſolid particle, cannot proceed without diſplacing the bodies with which it comes into contact; we have notions of this as clear as thoſe of geometry; whereas, how preſſure is produced, is inconceivable by us. If we preſs a ball ever ſo ſtrongly againſt another, and remove the obſtacle which prevented its motion, it will not move an inch, unleſs we *continue* to follow it, and preſs it forward; but we ſee a moving body produce compreſſion, bend ſprings, make pits in ſoft bodies, and produce all the effects of real animal preſſure. Impulſe, therefore, is the true cauſe of motion, and the ſolicitation of gravity is nothing but the repeated impulſe of an inviſible fluid.

But, in the firſt place, let it be obſerved, that both parties profeſs to *explain* the phenomena of mechanical nature, that is, to make them eaſier conceived by the mind. Now it may be granted, that could we have any previous conviction of a fluid continually flowing toward the centre of the earth, we could have ſome notion of the production of a downward motion of bodies, but not more explanation than we have without it, becauſe impulſiveneſs is as little underſtood by us as preſſure.

13 Many preſſures are inexplicable by impulſion.

But there are thouſands of inſtances of moving forces where we cannot conceive how they can be produced by the impulſe of a body already in motion. There appear to be many moving powers in nature, independent of, and inexplicable by, any previous motion; theſe may be brought into action, or occaſions may be afforded for their action, in a variety of ways. The mere will of an animal brings ſome of them into action in the internal procedure of muſcular motion; mere vicinity brings into action powers which are almoſt irreſiſtible; and which produce moſt violent motions. Thus a little aquafortis poured on powdered chalk contained in a bombſhell, will burſt it, throwing the fragments to a great diſtance. A ſpark of fire brings them into action in a maſs of gunpowder, or other combuſtibles. And here it deſerves remark, that the greater the maſs is to which the ſpark is applied, the more violent is the motion produced. It would be juſt the contrary, if the motion were produced by impulſe. For in all caſes of impulſion, the velocity is inverſely proportional to the matter that is moved. When a ſpring is bent, and the two ends are kept together by a thread, a preſſure is excited, which continues to act as long as the thread remains entire. What contrivance of impelling fluid will *explain* this, or give us any conception of the total ceſſation of this preſſure, when the thread is broken, and the ſpring regains its quieſcent form?

14 All preſſures do not produce a ſenſible motion.

We can explain, in a moſt intelligible manner, why the hardeſt preſſure produces no ſenſible motion in the caſe referred to above. We can conceive, with ſufficient diſtinctneſs, a tube filled with ſteel wires, coiled up like cork ſcrews, and compreſſed together into $\frac{1}{10}$th of their natural length. A tube of 10 inches long will contain 100 of them. While in this ſtate, compreſſed by a plug, we can ſuppoſe each of the ſprings to be tied with a thread. Suppoſe now that the thread of the ſpring next the piſton is burnt or cut; it will preſs on the piſton, and force it out, accelerating its motion till it has advanced one inch; after this, the piſton will proceed with a uniform motion. It is plain that the velocity will be moderate, perhaps hardly ſenſible, becauſe the preſſure acted on it during a very ſhort time. But if two ſprings have been ſet at liberty at the ſame inſtant, the preſſure on the piſton will be continued through a ſpace of two inches, and the final velocity will be greater, becauſe the ſame (not a double) preſſure will be exerted through a double ſpace. Unbending four ſprings at once, will give the piſton a double velocity (See DYNAMICS, *Suppl.* n° 95.). Now the effect of the motion of the ſecond ſpring is to keep the preſſure of the firſt

Impulsion. first in action during a longer time, by following it, and keeping it in a state of compression. There is nothing supposed of this kind in the case of strong pressure alluded to; and therefore no motion is produced when the obstacle is removed, except what the insensible compression produces by accelerating the body along an insensible space. If all the 100 springs are disengaged at once, the piston will be accelerated through 100 inches, and will acquire ten times the velocity that one spring can communicate. (*N. B.* The force expended in moving the springs themselves is not considered here).

It is in this way only that the previous motion of the impelling body acts in producing a considerable motion. The whole process will be minutely considered by and bye.

15 Impulsion is not more clearly conceived than pressure.

We may now ask, how it is so clear a point, that a solid body in motion must displace other bodies? This seems to be the very point in question. Is the affirmative deduced from our notion of solidity? What is our notion of solidity, and whence is it derived? We apprehend that even this primary notion is derived from pressure. It is by handling a thing, and finding that we cannot put our hand into the place where it is without displacing it, that we know that it is material. All this is indicated to us by the feeling excited by our pressure. We feel this property always as an obstacle; and therefore say, that by this property it resists our pressure. Nay, there are cases where even the philosopher prefers this quality to impulsiveness as a test of matter. To convince another that the jar out of which he has poured the water that filled it is not empty, but full of matter, he dips the mouth of the jar into water, and shows, that although he press it down till the surrounding water is above the bottom of it, the water has hardly gotten half an inch into the jar; there is something there which keeps it out; there is matter in it. He then opens a hole in the bottom of the jar; the water immediately rises on the inside of the jar, and fills it. He says that the pressure of the water has driven the matter out by the hole; and he *confirms* the materiality of what is expelled by holding a feather above the hole. It is agitated, shewing that the expelled thing has impulsiveness, another property (he says) of matter: what filled the jar was air, and air in motion is wind. The philosopher can exhibit some new cases, where something like impulsiveness appears. A slender magnet may be set on one end, the south pole, for instance, and will stand in that tottering situation. If a person bring the north pole of a powerful magnet hastily near the upper end, it will be thrown down, just as it may be blown down by a puff of wind; therefore (says the philosopher) there may be appearances of impulsion, and I may imagine that there is impelling matter; but nothing but matter excludes all other matter from its place: this property, therefore, is the surest test of its presence.

Thus we see, that our notion of solidity or impenetrability (a name still indicating an obstacle to pressure), gives us no clearer conception of the productions of motion by impulsion than pressure does; for it is the same, or indicated by the same sensations.

16 Motion does not impel by transfusing inherent force or inherent motion.

The question now seems to be reduced to this—Since the strongest pressure of a quiescent body does not produce motion, or excite that kind of pressure which is the immediate cause of motion, while a body in motion, exciting but a very moderate pressure (as may be seen by the trifling *compression* or dimpling), produces a very considerable motion, how is the previous motion conducive to this purpose? The answer usually given is this: A body in motion (by whatever cause) perseveres in that motion by the *inherent force;* when it arrives at another body, it cannot proceed without displacing that body. The nature of the inherent force is such, that none of it is lost, and that a portion of it passes into the other body, and the two bodies instantly proceed with the same quantity of motion that was in the impelling body alone. This is an exact enough narrative of the general fact, but it gives no great *explanation* of it. If the impelling body perseveres in its motion by means of its inherent force, that force is exerted in performing its office, and can do no more. The impelled body seems as much to possess an inherent force; for the same marks and evidences of pressure on both sides are observed in the collision. If both bodies are soft or compressible, both are dimpled or compressed. We are as much entitled, therefore, to say, that part of the force by which it perseveres at rest, passes into the other body. But the rest, or quiescence of a body, is always the same; yet what passes into the impelling body is different, according to its previous velocity. We can form no conception how the half of the inherent force of the impelling body is expended by every particle, passes through the points of contact, and is distributed among the particles of the impelled body; nay, we cannot conceive this halving, or any other partition of the force. Is it a thing *sui generis*, made up of its parts, which can be detached from each other, as the particles of salt may be, and really are, when a quantity of fresh water is put into contact with a quantity of brine? We have no clear conception of this; and therefore this is no elucidation of the matter, although it may be an exact statement of the visible fact.

17 This involves absurdities.

Let us take the simplest possible case, and suppose only two particles of matter, one of which is at rest, and the other moves up to it at the rate of two feet per second. The event is supposed to be as follows: in the instant of contact, the two particles proceed with half of the former velocity. Now this instant of time, and this precise point of space, in which the contact is made, is not a part of either the time or space before collision, or of those after collision; it is the boundary between both; it is the last instant of the former time, and the first instant of the latter time; it belongs to both, and may be said to be in both. What is the state or condition of the impelling particle in this instant? In virtue of the previous motion, it has the determination, or the force, or the power, to move at the rate of two feet per second; but, in virtue of the motion after collision, it has the determination or power of moving at the rate of one foot per second. In one and the same instant, therefore, it has two determinations, or only one of them, or neither of them. And it may, in like manner, be said of the impelled body, that, in that instant, it was both at rest, and moving at the rate of one foot per second. This seems inconceivable or absurd.

18 Impulsiveness is not an intuitive property of matter.

It is not perhaps very clear and demonstrable, nor is it intuitively certain, that the moving body or particle must displace the other at all. All that we know is, that matter is moveable, and that causes of this motion

motion exist in nature. When they have produced this motion, they have performed their task, and the motion is their complete effect: the particle continues in this condition for ever, unless it be changed by some cause; but we do not see any thing in this condition that enables us to say what causes are competent to this change, and what are not. Is it either intuitive or demonstrable, that the *mere existence* of another particle is not a sufficient or adequate cause? Is it certain that the arrival at another particle is an adequate cause? or can we prove that this will not stop it altogether? The only conclusion that we can draw with any confidence is, that "two particles, or two equal bodies, meeting with equal velocities, in opposite directions, will stop." But our only reason for this conclusion is, that we cannot assign an adequate reason why either should prevail. But this form of argument never carries luminous conviction, nor does it even give a decision at all, unless a number of cases can be specified which include *every possible result*. This can hardly be affirmed in the present case.

19
But an observed fact.

We apprehend that the next case, in point of simplicity, has still less intuitive or deductive evidence; namely, when bodies meet in opposite directions with equal quantities of motion. It is by no means easy, if it be at all possible, to shew that they must stop. The proof proceeds on some notion of the manner in which the impulsion, exerted on one particle, or on a few of each body, namely, those which come into contact, is distributed among all the particles. A material atom is moved only when a moving force acts on it, and each atom gets a motion precisely commensurate to the force which actuates it. Now, it is so far from being clear, how a force impressed on one particle of a solid body occasions an equal portion of itself to pass into every particle of that body, and impel it forward in the same direction, that the very authors who assume the present proposition as an elementary truth, claim no small honour for having determined with precision the moving forces that are exerted on each particle, and the circumstances that are necessary for producing an equal progressive motion in each. It was by no means an easy problem to shew, that the motion of the body (estimated by an average taken of the motions of every particle) is precisely that which is announced by this proposition. We must also consider how this investigation is conducted. It is by assuming, that whatever force connects a particle *a* with a particle *b*, or whatever force *a* exerts on *b*, the particle *b* exerts an equal force on *a* in the opposite direction—Surely no logician will say that this is an intuitive truth. The contrary is most distinctly conceivable. It was a *discovery* of the astronomers, that every deflection toward the sun is accompanied by an equal deflection of the sun. It was a *discovery*, that a piece of iron attracts a loadstone; and it was a *discovery* (and we dare not yet affirm it to be without exception), that every action of bodies is accompanied by an equal and contrary re-action. But this is by no means a first principle. It is the expression of a most generally observed fact, a sum total of knowledge. When received on this authority, it is fully competent to solve every case of impulsion, independent of all obscure and illogical doctrines of force inherent in moving bodies, of force of inertia, of communication of motion, &c.

The impossibility of conceiving the detachment of part of the *force* inherent in A, and transferring *this* part into B, and the similar impossibility of conceiving the imparting to B some of the *motion* that was in A, should make us reject any proposition involving such conceptions, and refuse its admission as an elementary truth. Much more should we reject a proposition that obliges us to suppose that a particle of matter has two determinations, forces, motions, or call them by any other name, in one and the same instant. One of these necessarily excludes the other. Indeed this was so evident, even to the most eminent partizans of the doctrine of the transfusion of inherent force, and others consequent on it, that they found themselves obliged to deny that there was such a thing in the world as a perfectly hard body, in which the motion must be instantaneously changed into another, differing from it by any sensible quantity. The existence of perfectly hard bodies is positively denied by the celebrated mathematician of Basle, John Bernoulli, in his Dissertation on the Communication of Motion, which contended for the prize given by the Academy of Sciences at Paris 1710. His reason for this rejection is singular, and somewhat amusing. "In the collision of perfectly hard bodies, the *conservatio virium vivarum*, demonstrated by the most eminent mathematician (Mr Leibnitz), to be a law of nature, would be broken without any effect being produced. He does not observe, that it is as completely broken by elastic bodies in the instant of greatest compression. A British philosopher, *nullius addictus jurare in verba magistri*, asked, What will be the case of two encountering atoms of matter? Without calling them hard, we must conceive that they acquire their changes of motion in the instant of mutual contact, and that they acquire them *totally*, being ατομοι, indivisible. No answer has been given, or indeed can be given, but what implies the same difficulty. From all that has been said, we must conclude, that this branch of mechanical philosophy is not put, by those philosophers, into the condition of an elementary foundation of clear and demonstrative science; that the transfusion, or transference, either of force or motion, is not a thing of which we have a distinct conception; and that it necessarily leads us into very untenable doctrines. Far less does it seem safe for us to confide so much in its clearness and certainty, as to affirm, that impulsion is the sole moving force in mechanical nature, and the source of what we call pressure.

All this difficulty and obscurity has arisen from our arrogant notion, that we are competent judges of first *principles*; whereas we must acknowledge, that we can only perceive such as are properly related or accommodated to our intellectual powers: these powers, being specific and peculiar, cannot judge of principles of the first class, but of those only that are *suitably* compounded. We can never know or comprehend any essential property of matter—we can only know the *relative* properties of *such matter as we see*.

20
Therefore to be learned only by observing nature.

Therefore let us quit entirely the barren and trackless fields of abstraction, and rest satisfied with contemplating *what* the Author of Nature has exhibited to our view, and *such* as he has been pleased in his wisdom to exhibit it. We grant that there are no bodies open to our inspection which are perfectly hard, receiving finite changes of motion in an instant. It has not pleased

God

Impulsion. God to put any such within our reach. When God created matter, it was with the purpose of forming a beautiful universe of this matter. He therefore gave it properties which fitted it for this purpose. It is this matter only that he has exposed to the wondering view of man. Thanks to his bounty, he has also given us properties of mind, by which this adaptation, when perceived by us, becomes a source of dignified pleasure to the observer.—A Newton, to whom " *Jovis omnia plena*," a Daniel Bernoulli, were rapt almost into ecstacy by a single atom, when they observed how its properties, and only such properties, fitted it for making part of a world, which

> Unwearied, and from day to day,
> Should its CREATOR's power display.

Let the unhappy La Place consider these properties, which ensure the permanency of the solar system through ages of ages, as proofs of fatalism, as qualities essential to matter. But this Gallic torch effaces the bloom of life from the universe, the expression of the Supreme Mind which shines from within; and it spreads over the countenance of Nature the ghastly paleness of universal death. But let us Britons rather follow the example of our illustrious countryman, and solace ourselves with every discovery which tends to quicken our perception of Nature's *animated* charms. Let us listen to the conjectures of him who had already discovered so many, and who endeavoured to remove the veil which concealed the rest.

21 Moving powers are inherent in all matter. Newton's conjecture improved by Boscovich.

Newton, in his maturity of judgment, after having collected much information from his unwearied experiments in magnetism, in chemistry, in optics, &c. said, that " he strongly suspected, that, in the same manner as the bodies of the solar system were connected by gravitation, so the particles of sublunary bodies were connected together, and affected each other, by means of forces which acted at small, and, in many cases, insensible distances; producing the phenomena of cohesion, in all its forms of hardness, elasticity, ductility, softness, fluidity, by which their mechanical actions on each other were modified and regulated." Father Boscovich, one of the first mathematicians of Europe, was the first who gave this conjecture of Newton's the attention that it so highly deserved. Other writers indeed, such as Keill, Freind, Boerhaave, &c. took occasional notice of it, and even made some use of it in their attempts to explain some complicated phenomena of nature. But they were so careless in their employment of Newton's conjecture, so completely neglected his cautious manner of proceeding, indulged so wantonly in hypothetical assumptions, and reasoned so falsely from them, that they brought his conjecture into discredit. Boscovich, on the contrary, copied Newton with care, and secured his progress as he advanced by the aid of geometry; establishing a set of uncontrovertible propositions, which must be the inevitable results of the premises adopted by him. He then proceeded to compare these with the phenomena of nature; and he shews that the coincidence is as complete as can be desired. All this is done in his *Theoria Philosophiæ Naturalis*, first published at Vienna in 1759. We have given a very short account of it in the article BOSCOVICH, *Suppl.*; but it hardly goes beyond the enunciation of the general principles, and the indication of its applicability to the purposes intended. His application to the production of motion by the collision of bodies, is peculiarly satisfactory. But as the work is written chiefly with the view of gaining the approbation of persons well instructed in natural philosophy, it can hardly be called an elementary work, or be employed for the instruction of persons entering on the study. We shall attempt to explain this important law of mechanism in a way that will give our readers a distinct notion (and, we apprehend, a just one) of the procedure of Nature in all the cases of impulsion *that we can observe*. We hope to do this, by considering the changes of motion produced by moving bodies in a certain series of familiar cases, where the procedure of nature may be distinctly observed, and where it is uniformly conceived by every spectator; and which will gradually lead the mind to those cases where the procedure is not observed with distinctness: but the similarity to the former case is concluded by so fair analogy, that we imagine no person will controvert it. We shall begin by attending to the manner in which two magnets in motion affect each other's motions; a phenomenon that is familiarly known in the general, although, perhaps, few persons have attended to it minutely.

Plate XXIX. 22 Examination of the mutual action of magnets.

Let us, therefore, suppose two magnets, A and B (fig. 1.) equal in weight (in the first instance). Let them be made to float on water, by placing them on pieces of cork. Let them be placed with their north poles touching each other. Let A be held fast, and let B be at liberty to move. We know that it will gradually recede from A, with a motion that would continually accelerate, were it not for the resistance of the water. What is the inference drawn from this appearance? Surely this, that either a moving power, inherent in A, repels B, or that B avoids A, by an evasive power inherent in itself. It is immaterial for our purpose which opinion we adopt. Let us say that A repels B. This admits more concise language than the other. If we prevent this motion of B by means of a very slender spring applied to its remote end, we shall observe that the spring is bent back a little, just as if we were pushing away the magnet gently with the finger; and we observe, that the bending of the spring is so much the greater as B is nearer to A. We can judge of the intensity of the force by which B is actuated, by the bending of the spring.—This force is equal to the *weight* of any body that will bend the spring to the same degree. This force is analogous, therefore, to the weight, the pressure of gravity, and we may call it a pressure, and measure it by grains weight. Every force that can bend a spring will move a body. This is a well known fact. Therefore it is next to certain, that it is this force which causes B to recede from A; nay, if we compare the motion of B with what *should* result from the action of a force having this very intensity, and varying in the same manner by a change of distance from A, taking in the diminution which the resistance of the water must occasion, we shall find the motions precisely the same. All this can be discovered by DYNAMICS, n° 95, &c. Therefore we must conclude that this, and no other, is the cause of the recess of B.

If, instead of placing B in contact with A, we place it at a distance from it, and push it toward A with an initial velocity, somewhat less than it would have acquired.

Impulſion. quired in that place by its receſs from A, we ſhall find that it will approach A with a motion gradually retarded, till it ſtop at a ſmall diſtance from A; and will now recede from it again with an accelerated motion. In ſhort, we ſhall find that its whole motion to and from A is preciſely the ſame with what reſults from a ſimilar computation by n° 95 of DYNAMICS.

The whole of this phenomenon is conceived by every beholder, who has not imbibed ſome peculiar theory of a ſtream of impelling fluid, as the indication and effect of a repulſive force exerted by A on B, or of a quality of B, by which it recedes from A.

If now B be held faſt, and A be ſet at liberty, it is obſerved to be repelled by B, or to recede from B, in the ſame manner, and with the ſame force.

Thus, the two magnets appear to affect each other's motions, and are thought, and ſaid, by all to repel each other. The effect appears curious, but excites no farther thought in moſt minds: it is only the ſpeculatiſt that begins to ſuſpect that he has not conceived it properly.

Now, let us ſuppoſe that B is afloat on the ſurface of the water, and at reſt; and that A is puſhed towards it, by a ſingle ſtroke, cauſing it to move ſo moderately that it ſhall not ſtrike B, but have its motion deſtroyed by the repulſion before it reaches it; and let us farther ſuppoſe, that the initial velocity of A was exactly meaſured—the fact will be as follows. As ſoon as A comes within a certain diſtance of B, its motion begins to be affected; it gradually diminiſhes, and at length it ceaſes entirely, and A remains ever after perfectly ſtill. But it is alſo obſerved, that in the inſtant that A ſlackens its motion, B begins to move; that it gradually accelerates in its motion, and at laſt acquires the initial velocity of A, with which it proceeds, till the reſiſtance of the water brings it to reſt; perhaps at a conſiderable diſtance from A. This experiment is very amuſing, and the initial velocity of A may be increaſed in each ſucceeding trial, till at laſt it ſtrikes B. Even then the general appearance remains the ſame: A is brought to reſt and remains at reſt, neither reſiling nor advancing forward; and B moves off with the initial velocity of A. What we wiſh to be particularly noticed is, that as long as the initial velocity of A is leſs than a certain quantity (depending on the ſtrength of the magnets), the motion is communicated to B, or, to expreſs it more cautiouſly, motion is produced in B, without any thing happening that can get the name of impulſion with propriety. In the ordinary conceptions and language of mankind, impulſe always ſuppoſes actual contact; and impulſion is equivalent to a blow or a ſtroke. Both of theſe are indeed metaphorical terms, as well as impulſion. Perhaps the word "to hit," expreſſes this particular caſe more purely, and it is perhaps without any figure, and is the appropriate word. We do not ſpeak at preſent of the conception and language of philoſophers, but of perſons taking an unconcerned view of things, without any intention of ſpeculating farther about the matter.

Appearances perfectly ſimilar are obſerved in electriſied bodies. If we hang two equal bunches of very light downy feathers by two equal linen threads, ſo as to hang cloſe by each other like pendulums without touching, and if, after having electrified them ſo that Impulſion. they repel each other to ſome diſtance, we draw one of them, which we ſhall call A, conſiderably aſide from the perpendicular, and then let it go to ſwing like a pendulum; we ſhall obſerve, that inſtead of accelerating till it reach the loweſt point of its vibration, its motion will be retarded; it will ſtop entirely when its thread is perpendicular, and will remain at reſt. In the mean time, the other bunch B will acquire motion, which will gradually increaſe till it equal the motion of A in its maximum ſtate; and with this it would proceed for ever, were it not riſing like a pendulum in the arch of a circle. The general fact is the ſame as in the caſe of the magnets. The moving body is brought to reſt, in which ſtate it continues, and the quieſcent body moves off with an ultimate velocity, equal to the initial velocity of the other; and all this happens without contact or impulſion, but is produced by the mutual repulſion of the electrified bodies.

If this general fact be compared with what happens in the colliſion of two billiard balls, it will be found perfectly ſimilar in every reſpect, but that of the contact and the impulſion, properly ſo called. The impelling ball is brought to reſt, and remains at reſt; and the impelled ball moves off with the velocity of the impelling ball.

This being the caſe, it is plain that we may derive ſome information from the motion of the magnets, that muſt greatly aſſiſt us in our conceptions of what paſſes in the rapid, if not inſtantaneous, production of motion in a billiard ball, by hitting it with another. In the caſe of the magnets, we perceive, and can diſcriminate, a progreſſive train of changes, which terminate in a final change, perfectly ſimilar to the change in the impulſion of the billiard ball. This will juſtify a very minute attention to, and ſtatement of, all the circumſtances.

23 First caſe. A moving toward B at reſt.

Let us attend to the proceſs of this operation, and the production of motion in the magnet originally at reſt, and the abolition of it in the one originally in motion; and let us reflect on what paſſes in our minds when we try to explain it to ourſelves. The trials mentioned at firſt, when one magnet was held faſt, ſhew us that each magnet repels or avoids the other, and that this action is found to be equal on both ſides, producing equal compreſſion of the ſpring employed for aſcertaining the intenſity of this repulſion when the diſtances are the ſame. This is the fact. It is no leſs a fact, that equal moving forces, ſuch as equal preſſures muſt be ſuppoſed to be, produce equal changes of motion in their own direction. Therefore, as ſoon as A comes to ſuch a diſtance from B that the mutual action takes place, both magnets are affected, and equally affected; that is, equal changes of motion are produced on each, but in oppoſite directions. The motion of A is diminiſhed, perhaps $\frac{1}{100}$th part in $\frac{1}{10}$th of a ſecond, and (let it be carefully remembered) while A paſſes over a certain ſpace, ſuppoſe the 10th of an inch. During this ſmall portion of time, B acquires as much motion as A loſes. This is not the motion loſt by A. This is inconceivable; for motion is not a thing, but a condition. But it is an *equal degree* of motion. B has paſſed over a ſmall ſpace during this time, perhaps the 50th part of an inch, with an almoſt imperceptible motion,

motion, that is gradually accelerated from nothing. Since A is moving faſter than B, it muſt ſtill gain upon it; and therefore the mutual repulſion will increaſe; and in the next 10th of a ſecond this force will take another and greater portion of A's original velocity from it, and will add a greater velocity to that already acquired by B. And thus, in every ſucceeding minute portion of time, the motion of A will be more and more diminiſhed, and that of B as much increaſed, by the equal, though continually increaſing, ſimultaneous repulſions acting in oppoſite directions. It is evident, that it is poſſible that the velocity of A may be ſo much diminiſhed, and that of B ſo much increaſed, that the remaining velocity of A ſhall be juſt equal to the acquired velocity of B. Till this happens, the diſtances of the magnets have been continually diminiſhing; for A has been moving faſter than B, and gaining on it. If the operation of the mutual repulſions could be ſtopped at this inſtant, both magnets would move forward for ever with equal velocities.

24 They acquire a common velocity x;

It is of particular importance to know what this common velocity is. This is determined by our previous knowledge, that the magnets repel or avoid each other with equal forces. Theſe forces may vary by a variation of diſtance; but the force acting on A is always equal and oppoſite to the force acting at the ſame time on B. This is the uncontroverted fact (the authority for which ſhall ſoon be conſidered). Theſe equal forces muſt therefore produce equal and oppoſite changes of motion. The motion acquired by B is equal to that loſt by A. But the magnets being ſuppoſed equal, and moving with equal velocities, they have equal quantities of motion. Therefore the motion acquired by B, or that loſt by A, is equal to what remains in A; that is, A has loſt half of its motion, and therefore half of its velocity; or the common velocity is half of the primitive velocity of A.

It was for the ſake of a ſomewhat eaſier diſcuſſion that we ſuppoſed the magnets to be of equal weights. But it is almoſt equally eaſy to aſcertain what this common velocity will be in any other proportion of the quantities of matter in A and B. It is a matter of unexcepted experience, that whatever be the weight or ſtrength of two magnets, their actions on each other are always equal. Therefore the ſimultaneous force muſt always produce equal changes of motion in the two bodies. But the change of motion is expreſſed by the product of the quantity of matter and the change of velocity. Therefore let A and B repreſent the quantities of matter in the magnets; and let a be the primitive velocity of A, and x the velocity which obtains when both are moving with one velocity. The velocity loſt by A is $a - x$. Therefore we muſt have $Bx = A \times \overline{a - x}$, $= Aa - Ax$; and $Aa = Ax + Bx$, $= \overline{A + B} \times x$,

25 Namely, $x = \frac{A \times a}{A + B}$

and $x = \frac{Aa}{A + B}$. *The common velocity is therefore obtained by dividing the primitive quantity of motion by the ſum of the quantities of matter.*

This may be conceived more compendiouſly in another way. Since B acquires as much motion as A loſes, the whole quantity of motion is the ſame as before: Therefore the common velocity muſt be had by dividing this quantity of motion by the whole quantity of matter. But we wiſhed to make the reader keep his attention fixed on the ſteps of procedure, and ſee the connection of each with the cauſes.

We ſhall find that this period of the whole proceſs, namely, the moment when both bodies have acquired a common velocity, and the preciſe magnitude of this velocity, are points of peculiar importance in the doctrine of impulſion; indeed they almoſt comprehend the whole of it.

26 But this does not continue, and the magnets ſeparate.

But this is a ſtate that cannot continue for a moment in the example before us. The repulſive or evaſive forces are ſtill acting on both magnets, and ſtill diminiſh the motion of A, and equally increaſe the motion of B. Therefore the velocity of A, in the very next moment, muſt be leſs than that of B; and B has, during this moment, gained on A, or has removed farther from it. This continues; A is ſtill retarded, and B is accelerated; and therefore gains more and more upon A, or ſeparates farther and farther from it. This muſt continue as long as the mutual repulſions are ſuppoſed to act. If we ſuppoſe that the *ſenſible* action of theſe forces is limited to ſome determinate diſtance, the mutual action will ceaſe when B has got to that diſtance before A. We may call it *the inactive diſtance*. After this, A and B will proceed with the velocities which they have at that inſtant. Let us inquire into theſe final velocities; and thus complete our acquaintance with the proceſs.

27 The common velocity is attained at the inſtant of neareſt approach.

We ſee (and it is important) that the magnets are in their ſtate of greateſt proximity at the inſtant of their moving with a common velocity, and that after this they gradually ſeparate, till they are again at their inactive diſtance. During this ſeparation they attain diſtances from each other equal to what they had during the period of their mutual approach. At theſe diſtances the repulſions are the ſame as before, and act in the ſame direction. Therefore, in each moment of ſeparation, and at each diſtance, A ſuſtains the ſame diminution, and B gets the ſame augmentation of its motion, as when they were at the ſame diſtance in the period of their mutual approach. The ſums total, therefore, of theſe equal augmentations and diminutions muſt be equal to the augmentation and diminution during the approach. Therefore the whole diminution of A's motion muſt be double of the diminution ſuſtained during the approach; and the whole augmentation of B's motion muſt, in like manner, be double of that acquired during the approach of A. Hence we eaſily ſee, that when the magnets are ſuppoſed equal, A muſt be brought to reſt; for in the period of approach it had loſt half of its velocity. It muſt now have loſt the whole. For ſimilar reaſons B muſt finally acquire the primitive velocity of A; for in the inſtant of greateſt proximity, it had acquired the half of it.

28 Repulſion is a cauſe adequate to the obſerved effect.

Thus we ſee that the equal mutual repulſions are preciſely adequate to the production of the changes of motion that are really obſerved; and muſt therefore be admitted as the immediate cauſes of theſe changes.

29 Effect when the magnets are unequal.

It is equally eaſy to aſcertain the final velocities when the magnets are of unequal ſizes; for the equality of their mutual repulſions is not affected by any inequality of their magnitudes. Their ſeparations, and the changes of motion during theſe ſeparations, will be the ſame with their approaches and the correſponding changes of motion; and the whole change on each will be double of the change ſuſtained at the inſtant of greateſt

Impulſion.

greateſt proximity and common velocity. Hence we learn that the final velocity of B is $2x$, or $\frac{2Aa}{A+B}$; and the final velocity of A is $\frac{\overline{A-B}\times a}{A+B}$. For the primitive velocity of A being a, and the common velocity, in the inſtant of neareſt approach being $\frac{Aa}{A+B}$, the loſs of velocity is $a-\frac{Aa}{A+B}, =\frac{Aa+Ba-Aa}{A+B} =\frac{Ba}{A+B}$. Therefore the final loſs of velocity is $\frac{2Ba}{A+B}$, and the remaining final velocity is $a-\frac{2Ba}{A+B}, =\frac{Aa+Ba-2Ba}{A+B}, =\frac{\overline{A-B}\times a}{A+B}$.

30 II. Caſe. Both magnets in motion in one direction.

Let us, in the next place, ſee what will be the reſult when both of the magnets are in motion at the beginning of their mutual action. And, firſt, let both move in one direction. Let A, moving with the velocity a, overtake B, moving in the ſame direction with the velocity b, leſs than a. Moreover, let the velocities a and b be ſuch, that their differences $a-b$ is ſomewhat leſs than the ſum of the velocities α and β, which the mutual repulſions of the magnets would generate in them, if the magnets were placed in contact, and allowed to recede from each other till they get beyond their acting diſtance.

Theſe things being premiſed, let the magnets be ſet in motion in the ſame direction with the above-mentioned velocities a and b. The magnet A muſt gain on B, and at laſt come ſo near it, that the mutual repulſions begin to act on both. It is plain, that the motion of A will be diminiſhed, and that of B increaſed, by equal quantities, during every minute portion of the time of their mutual action. It is alſo evident, that the velocity of A may be ſo much diminiſhed, and that of B ſo much increaſed, that they ſhall be rendered equal. Alſo this will happen before the magnets touch one another; becauſe the original difference of their quantities of motion has been ſuppoſed leſs than the motion which the repulſive forces are able to generate or extinguiſh, by acting on them through the whole diſtance which gives occaſion to their action. Therefore the difference of the velocities is leſs than the ſum of the velocity α, which the mutual repulſion can take from A, and the velocity β, which it can give at the ſame time to B. The magnets will gradually approach, and the mutual repulſions, and conſequent diminution of A's, and augmentation of B's motion, will gradually increaſe, till the ſum of α and β is juſt equal to the difference of a and b; that is, till the bodies are moving with one velocity. If the mutual repulſions were annihilated at this inſtant, the bodies would move forward with this common velocity. What this is we determine with great facility, as we did in the former caſe: Becauſe the repulſions produce equal and oppoſite changes of motion in the magnets, as much is taken from $A\times a$ as is added to $B\times b$; and the ſum of $A\times a$, and $B\times b$, is equal to the ſum of $A\times x$ and $B\times x$, or $\overline{A+B}\times x = A\times a + B\times b$, and $x=\frac{Aa+Bb}{A+B}$. Therefore *the common velocity is had by dividing the ſum of the primitive quantities of motion by the ſum of the quantities of matter.*

31 Common velocity $=\frac{Aa+Bb}{A+B}$ but the magnets ſeparate, and the change is doubled in each.

But the repulſive forces continue to act as in the former caſe. The motion of A is ſtill more diminiſhed, and that of B augmented: Therefore the velocity of B muſt now exceed the velocity of A, and the magnets muſt ſeparate. Reaſoning in the ſame way as in the former caſe, it is evident that the mutual action does not ceaſe till the magnets have ſeparated to their inactive diſtance from each other, and that the whole change of motion in each is double of the change that it had ſuſtained when they were in their greateſt proximity, and moving with a common velocity. Theſe conſiderations enable us to aſcertain the final ſtate of each. The common velocity is $\frac{Aa+Ab}{A+B}$. Therefore the change made on the velocity of A, at the inſtant of greateſt proximity, is $a-\frac{Aa+Bb}{A+B}$, or $=-\frac{B\times\overline{a-b}}{A+B}$, and the final velocity of A is $a-\frac{2B\times\overline{a-b}}{A+B}$. In like manner, the change produced on the velocity of B is $=\frac{Aa+Bb}{A+B}-b$, or $=+\frac{A\times\overline{a-b}}{A+B}$, and the final velocity of B is $b+\frac{2A\times\overline{a-}}{A+B}$. We may alſo obtain the final velocity of each, by taking its initial velocity from twice the common velocity.

If, in this example of two magnets in motion, we ſuppoſe them of equal weight, we ſhall find that they will finally proceed with exchanged velocities. For when $A=B$, it is plain that $a-\frac{2B\times\overline{a-b}}{A+B}$ is $= a-1\times\overline{a-b}, = a-a+b, = b$: and $b+\frac{2A\times\overline{a-b}}{A+B}$ is $= b+1\times\overline{a-b}, = b+a-b, = a$. This caſe is eaſily ſubjected to experiment, and will be found fully confirmed, if we take into account the retardations occaſioned by the reſiſtance of the water to the motions.

31 Magnets moving in oppoſite directions.

Let us, in the next place, ſuppoſe the magnets to be moving in oppoſite directions with the velocities a and b; and (in order that the magnets may not ſtrike each other) let the ſum of a and b be leſs than the ſum of α and β, which the repulſions of the magnets would produce by repelling them from contact to their inactive diſtance.

As ſoon as the magnets arrive at their acting diſtance, their mutual and equal repulſions immediately begin to diminiſh both of their motions; and in any minute portion of the period of their approach, equal quantities of motion are taken from each. It is evident, that if the primitive quantities of motion have been equal; that is, if A and B have been moving with velocities reciprocally proportional to their quantities of matter, then, when the motion of one of them has been annihilated by their mutual repulſion, the motion of the other will be be deſtroyed at the ſame time, and both will be brought to reſt. Were the repulſions annihilated at this inſtant, they would remain at reſt. But becauſe thoſe forces continue their actions, the magnets will ſeparate again, regaining, at every diſtance, the velocity which they had, when at that diſtance, during their mutual approach; and when they have reached their inactive diſtance, they will have regained each its original momentum and velocity, but in the oppoſite direction. This needs no farther comment; but muſt be kept in mind, becauſe this caſe has a preciſe counterpart in the colliſion of ſolid bodies, meeting each other in oppoſite directions with equal momenta. But if the momentum of one exceed that of the other, thus, if $A \times a$ be greater than $B \times b$, then, when the magnet B is brought to reſt, A has ſtill a momentum remaining equal to $A a - B b$. Having therefore a certain velocity, while B has none, it muſt approach ſtill nearer to B, and a ſtill greater repulſion will be exerted on B than if A had alſo been brought to reſt, but ſtill repelling B. Since B is now acquiring motion in the direction oppoſite to its former motion, and A is ſtill loſing motion, a time muſt come when the motion of A is ſo much diminiſhed, and that of B ſo much augmented, that they are moving with a common velocity in the direction of A's primitive motion. The reaſoning employed in the foregoing examples ſhew us, that, in the preſent caſe alſo, this ſtate of common velocity is alſo the ſtate of the greateſt proximity, and that the magnets ſeparate again, till they attain their diſtance of inaction, and that the total change in each is double of what it was in their ſtate of greateſt proximity.

32 Common velocity $= \frac{A a - B b}{A + B}$ but the change is doubled by the ſubſequent ſeparation.

To find this common velocity, recollect, that when the momentum of B was extinguiſhed, that of A was ſtill $= A a - B b$. From what has been already ſaid on the other caſes, we know that when the common velocity obtains, the whole momenta are ſtill equal to $A a - B b$. Therefore the common velocity x muſt be $= \frac{A a - B b}{A + B}$.

The velocity loſt by A muſt therefore be $a - \frac{A a - B b}{A + B}, = \frac{B \times \overline{a + b}}{A + B}$, and the final velocity will be $a - \frac{2 B \times \overline{a + b}}{A + B}$. The final motion of A will be in the ſame direction as at firſt, if a be greater than $\frac{2 B \overline{a + b}}{A + B}$, otherwiſe it will be in the oppoſite direction.

In like manner, the change of velocity in B is $b + \frac{A a - B b}{A + B}$, becauſe the former velocity b is deſtroyed, and the new velocity is $\frac{A a - B b}{A + B}$ in the oppoſite direction. This is $= \frac{A \times \overline{a + b}}{A + B}$, and the final velocity of B is $= b - \frac{2 A \times \overline{a + b}}{A + B}$.

33 The changes of motion in the magnets are ſimilar to thoſe in the colliſion of bodies.

Thus we have ſhewn, in the caſe of magnets acting on each other by repulſive forces, or actuated by forces equivalent to repulſive forces, how changes of motion are produced, which have a great reſemblance to thoſe which are ſeen in the colliſion of ſolid bodies. The motions which obtain in the inſtant of greateſt proximity are preciſely ſimilar to what *are obſerved* in the colliſion of unelaſtic bodies. Their common velocity after colliſion is always $= \frac{A a + B b}{A + B}$, or $= \frac{A a - B b}{A + B}$, according as the bodies were moving in the ſame or in oppoſite directions. The final motions of the magnets are alſo preciſely ſimilar to what *are obſerved* in the colliſion of perfectly elaſtic bodies. We took the inſtance of magnets, becauſe the object is familiar; but we can ſubſtitute, in imagination, an abſtract repulſive force in place of magnetiſm, and we can aſſign it any intenſity, and any law and limits of action we pleaſe. We can imagine it ſo powerful, that although its action be limited to a very ſmall, and even inſenſible diſtance, it ſhall always reduce the meeting bodies to a common velocity before they come into actual contact; and therefore without any real impulſion, as impulſion is commonly conceived.

There are ſome farther general obſervations that may be made on thoſe motions which are of importance.

34 Theſe changes are proportional to the relative motion,

1. We ſee that the changes of motion, and conſequently the actions, are dependent on the relative motions only, whatever the abſolute motions may be: For changes are always as $a - b$ when the bodies are moving in one direction, and as $a + b$ when they are moving in oppoſite directions. Now $a \pm b$ is the relative motion.

35 And reciprocally as the quantities of matter.

2. The change of velocity in each of the two bodies is inverſely as its quantity of matter, or is proportional to the quantity of matter in the other body. The changes in A and B are $\frac{B \times \overline{a \pm b}}{A + B}$ and $\frac{A \times \overline{a \pm b}}{A + B}$. The changing forces being equal on both ſides, produce equal changes in the quantities of motion; and therefore produce changes of velocity that are inverſely as the quantities of matter.

36 Conservatio momentorum.

3. During the whole proceſs, the ſum of the momenta, or quantities of motion, remains the ſame, if the bodies are moving in one direction: if they are moving in oppoſite directions, it is the difference of momenta that remains the ſame; for in every inſtant of the proceſs equal changes of momentum are made in oppoſite directions. When the motions are in the ſame direction, as much is taken from the one as is added to the other; and therefore the *ſum* remains unchanged. When the motions are in oppoſite directions, equal quantities are taken from both; and therefore the *difference* remains unchanged. This is called the CONSERVATIO MOMENTORUM; and it is uſually enunciated by ſaying, that the quantity of motion, eſtimated in one direction, is not changed by the equal and oppoſite actions of the bodies. This is a particular caſe of a general law affirmed by Des Cartes, that the quantity of motion in the univerſe remains always the ſame when eſtimated in *any* one direction.

37 Conservatio virium vivarum.

4. When the whole proceſs is completed, the ſum of the products made by multiplying each body by the ſquare of its final velocity, is equal to the ſum of the products made by multiplying each body into the ſquare of its initial velocity. For when the proceſs is completed, the two bodies are at the ſame diſtance from each other as when the mutual action began. Therefore,

fore, during the procefs, each body has paffed over an equal fpace, and in every fimilar point it has been acted on by an equal force (although this force be different in different points of this fpace). Therefore, in every inftant, the fimultaneous products of the quantity of matter by the momentary variation of the fquare of the velocity are equal on both fides; and therefore the products of the quantity of matter by the whole change of the fquare of the velocity are alfo equal on both fides. See DYNAMICS, *Suppl.* n° 95. and 110. where $v\dot{v} = \frac{f\dot{s}}{m}$; and therefore $m v \dot{v} = f\dot{s}$, and $m \times \overline{V^2 - v^2}$, or $n \times \overline{v^2 - V^2} = \int f\dot{s}$. Now, fince thefe changes are in oppofite directions, as much is added to one product as is taken from the other, and the fum of the products of the quantities of matter by the fquares of the final velocities, is equal to the fum of the products of the fame quantities of matter by the fquares of the initial velocities.

These two theorems are not principles, but general facts.

This is a particular cafe of the famous CONSERVATIO VIRIUM VIVARUM, claimed as a mighty difcovery by the partizans of Leibnitz, and afcribed to him; but he has no claim whatever to the difcovery. It was communicated to the Royal Society of London in 1668 by Huyghens, as one of the general laws of impulfion, obtaining in what he calls *hard bodies.* Several of the Leibnitzian fchool, indeed, extended it farther than Huyghens had done; fome of them indeed very lately. The obfervation of this general law was foon applied to many excellent purpofes in the folution of very intricate problems; becaufe it often faved the trouble of tracing the intermediate fteps of a complicated procefs. Affured that thefe products were invariable, the mathematician found it an eafy matter to ftate what conditions of the queftion infured this equality of products; and thus the problem was folved. In this manner Daniel Bernoulli gives moft elegant folutions of fome, otherwife almoft intractable, problems in Hydraulics. For fuch reafons, as a mighty aid in mechanical inveftigation, the difcovery of Huyghens is extremely valuable. Its merit in this refpect is perfectly fimilar (though perhaps fomewhat greater) to Des Cartes's obfervation of the *confervatio momentorum.* It is alfo like the obfervation or difcovery of Maupertuis, which he calls *the law of fmalleft action* (indeed it is the fame under a different afpect), or La Grange's *law of virtual velocities*, or D'Alembert's *law of equilibrium of action*;—all of thefe are general facts, laws by which the changes of motion are *obferved* to proceed. But their authors have vaunted them as principles, as caufes, from which to conclude effects; whereas they are really inductions from particular inftances. We muft alfo obferve, that this law of *confervatio virium vivarum* was not deduced either by Huyghens or any of the Leibnitzian fchool, by reafoning from more general principles. It was an expifcation of famenefs in events, diverfified by other circumftances. We do not recollect any author who has given what can be called a demonftration of it, deducing it from principles or laws ftill more general. We apprehend that the prefent cafe of its truth has been fo demonftrated by us. The *principle* is, that "a moving force is to be meafured by the change of motion produced by it:" And the law to which this principle is applied is, that "the mutual repulfions of magnets are equal and oppofite;" and the application is made by means of the "39th propofition of the firft book of Newton's *Principia.*" Our principle, which is the fame with Sir Ifaac Newton's fecond law of motion, is really an axiom of human thought. The propofition is the confequence logically drawn from this axiom; and the law of magnetifm is an obferved fact. We hope to fhew, by and bye, that this propofition, which is our n° 95. of DYNAMICS, is found to obtain in *every* inftance that has been or can be given of the *confervatio virium vivarum*, and that this *confervatio* is only another way of expreffing the propofition. Having done this, we fhall not think ourfelves chargeable with vanity when we fay, that we have given the firft demonftration of this famous law. We cannot refufe ourfelves fome fatisfaction at having done this; becaufe it has been fo highly efteemed, chiefly for the fupport derived from it for the Leibnitzian meafurement of the force of moving bodies by the *fquare of the velocity* which it communicates; whereas it is the logical confequence of the force being proportional to the *fimple velocity.* We have only taken a weapon out of the hands of a plunderer, and reftored it to its lawful owner, Sir Ifaac Newton. *Non ita certandi cupidus, quam propter amorem:* For we muft fay,

Tu pater et rerum inventor, tu patria nobis
Suppeditas precepta, tuifque ex, inclute, chartis
Floriferis ut apes in faltibus omnia libant,
Omnia nos itidem depafcimur aurea dicta
Aurea, perpetuâ femper digniffima vitâ.

We truft that our reader will not think that this minute difcuffion of the mutual actions of magnets or other repelling bodies, in which we have engaged him, has been thrown away, fince it has enabled us to apprehend clearly a cafe of two fuch general laws as the *confervatio momentorum*, and the *confervatio virium vivarum.*

5. In the moment of greateft vicinity and common velocity, there is a certain determinate lofs of the *vires vivæ*, or products of the matter by the fquare of the velocity; and this lofs is proportional to the fquare of the relative motion. The *vires vivæ*, at the commencement of the mutual action, are $= Aa^2 + Bb^2$ (I.) In the moment of greateft proximity, the quantity of matter A + B is moving with the common velocity $\frac{Aa + Bb}{A + B}$; therefore the *vires vivæ* are $= \overline{A+B} \times \frac{\overline{Aa + Bb}^2}{\overline{A+B}} = \frac{\overline{Aa + Bb}^2}{A + B}, = \frac{A^2a^2 + B^2b^2 + AB \times 2ab}{A + B}$ (II.)

38 Vis vivæ loft in the collifion of unelaftic bodies.

$$\text{I.} \times \overline{A+B} = A^2a^2 + B^2b^2 + AB \times \overline{a^2 + b^2}.$$
$$\text{II.} \times \overline{A+B} = A^2a^2 + B^2b^2 + AB \times 2ab.$$
$$\text{Difference} \quad - \quad - \quad - \quad AB \times \overline{a - b}^2.$$

Lofs of *vis viva* $= \frac{AB}{A + B} \times \overline{a - b}^2$, a quantity that is proportional to $\overline{a - b}^2$, the fquare of the relative velocity $a - b$.

Had the bodies been moving in oppofite directions, then (II.) $\times \overline{A + B}$ would have been $A^2a^2 + B^2b^2 - AB \times 2ab$, and the difference from $\overline{Aa^2 + Bb^2} \times \overline{A + B}$ would have been $= AB \times \overline{a + b}^2$, proportional to the fquare of the relative velocity $a + b$.

Such

Impulſion.

Phyſical cauſe of this loſs.

Such is the fact; and we ſhall find it of importance in the great debate about the force of moving bodies. Let us inquire into the phyſical or mechanical cauſe of it. In the moment of common velocity, the bodies are nearer to each other than they are at the beginning and at the end of their mutual action. Therefore (when they are moving in one direction) the body A, which follows, has been retarded through a ſpace which is greater than the ſpace along which the preceding body B has been accelerated. But, becauſe the ſimultaneous forces acting on the bodies along theſe unequal ſpaces are always equal, the area which meaſures the diminution of the ſquare of A's velocity (Dynamics, n° 95.) muſt exceed the area which expreſſes the augmentation of the ſquare of B's velocity, and there muſt be a loſs of *vires vivæ*. Now, we learned above, that the mutual action is the ſame when the relative velocity is the ſame; and therefore the approximation, which is the occaſion of this action, muſt be the ſame. And it is demonſtrated in Dynamics, n° 95. that the area, whoſe abſciſſa is the ſpace deſcribed, and ordinates the forces, expreſſes the ſquare of the generated or extinguiſhed velocity. This is evidently the relative velocity of the bodies, becauſe they are brought to a common velocity in the inſtant of greateſt proximity; that is, their relative velocity is deſtroyed.

39
The motion of the common centre of gravity is not changed by the mutual action.

6. During the whole proceſs, the common centre of poſition or gravity (A) is moving uniformly with the velocity $\frac{Aa \pm Bb}{A+B}$. For the motion of the centre of poſition is the average of the motion of every particle of matter in both bodies. Aa is the ſum of the motions of every particle of matter in A, and Bb is the ſum of the motions of every particle in B, before the mutual actions began. Therefore $Aa + Bb$ is the whole motions when the bodies are moving in the ſame direction with their different velocities. The number of particles is $A + B$: Therefore, if the whole motions be equally divided among all the particles, the velocity of each muſt be $\frac{Aa + Bb}{A+B}$. This is the average motion, or the motion of the centre of poſition, deduced from the notion we wiſh to impreſs of the character of this centre, as the index of the poſition and motion of any aſſemblage of matter. This velocity may be deduced more eaſily from its geometrical property. It is a point ſo ſituated between A and B, that its diſtance from each is reciprocally proportional to the quantities of matter in A and B, as is well known of the centre of gravity. It is equally plain, that when the bodies are moving in oppoſite directions, the average velocity x muſt be $= \frac{Aa - Bb}{A+B}$. Thus we ſee, that the motion of the centre of poſition, before the magnets have begun to act on each other, is the ſame with its motion when their mutual repulſion is the greateſt; namely, at the moment of their greateſt vicinity. It has continued the ſame during the whole proceſs: For we have already ſeen, that the ſum or difference of the momenta, or $Aa \pm Bb$, remained always the ſame; conſequently $\frac{Aa \pm Bb}{A+B}$, or x, the motion of the centre, remains always the ſame. Therefore the propoſition is demonſtrated. It is, indeed, a truth much more general than appears in the preſent inſtance. *If any number of bodies be moving with any velocities, and in any directions, the motion of the centre of poſition is not affected by their mutual, equal, and oppoſite, actions on each other.*

40
The motions, in relation to the centre, are reciprocally as the bodies.

7. During the whole motion, the motion of the bodies relative to each other, is to the motion of one of them, relative to the centre of poſition, as the ſum of the bodies is to the other body: For when they were moving with a common velocity, this velocity was the ſame with that of the centre; and they are then at reſt, relative to each other, and relative to the centre. And becauſe their diſtances from the centre are inverſely as the bodies, their changes of diſtance, that is, their motions relative to the centre, are in the ſame proportion; and the ſum of their motions relative to the centre is the ſame with their motions relative to each other. Therefore $A + B : A = a - b$: motion of B relative to the centre. Indeed we ſaw, that in their mutual action, the change of B's motion was $= \frac{A \times \overline{a-b}}{A+B}$, and the change of A's motion was $= \frac{B \times \overline{a-b}}{A+B}$.

41
The bodies ſeparate with the ſame relative velocity which they approached.

Hence we learn, that while the centre moves uniformly, the bodies approach it, and then recede from it, with velocities reciprocally proportional to their quantities of matter. This will be found a very uſeful corollary. We may alſo ſee that their final velocity of mutual receſs is equal to that of their firſt approach, or, their relative motions are the ſame in quantity after the action is over as before it began, but in oppoſite directions.

All theſe general facts, which are diſtinctly appreciable, and very perceivable, in this example of magnets, or electrified bodies, are equally appreciable in all caſes of mutual repulſions, however ſtrong theſe may be; and although the ſpace through which they are exerted ſhould be ſo ſmall as to elude obſervation, and though the whole proceſs ſhould be completed in an inſenſible moment of time.

42
An interpoſed ſpring has the ſame effect with the mutual repulſions.

It ſcarcely needs any comment to make it clear that the very ſame changes of motion muſt take place, if a ſolid body A ſhould come up to another ſolid body B, at reſt, or moving more ſlowly in the ſame direction, or moving in the oppoſite direction; provided that there be a ſpring interpoſed between them, which may hinder

(A) See the article Position in this *Supplement*; where it will be demonſtrated, that the centre of gravity (determined in the uſual manner) is the point by whoſe ſituation and motion we eſtimate with the greateſt propriety the ſituation and motion of the aſſemblage, of which it is the centre: it is therefore called the centre of position. The reader is only deſired at preſent to recollect, that the centre of gravity, or poſition of two bodies, is ſituated in the line joining their centres; and that its diſtance from each is inverſely as their quantities of matter; and that the diſtance and motion of the centre is the medium or average of all the diſtances or motions.

Impulsion. A from ftriking B; for, as foon as A touches the fpring, it begins to prefs it againft B, and, therefore, to comprefs the fpring. It cannot carry the fpring before it, without the fpring's pufhing B before it. Preffure on B is required for this purpofe. This is fupplied by that natural power which we call elafticity, which is inherent in the fpring; whether it be in motion or at reft. It is not in *action*, but in *capacity*, *faculty*, *capability*, *power*, or by whatever name we may choofe to exprefs the poffeffion. The occafion required for its exertion is compreffion. This is furnifhed by the motion of A; for A cannot advance without compreffing it. This inherent force of the fpring is *known* to act with perfect equality at both ends, in oppofite directions. It exerts equal and oppofite preffures on A and on B; it diminifhes the motion of A, and equally augments the motion of B (if both are moving that way). A is retarded, and B is accelerated; A is ftill moving fafter than B; and therefore the compreffion and the confequent reaction of the fpring increafes, and ftill more retards A and accelerates B. After fome time, both bodies, with the fpring compreffed between them, are moving with equal velocities; the fpring, however, is ftrongly reacting on both, and muft now caufe them to feparate; ftill retarding A, and accelerating B—They muft feparate more and more, till the fpring regain its quiefcent form, and its elaftic reaction ceafe entirely. During its reftitution, its preffures are the fame as during its compreffion, therefore, the whole change produced on each of the bodies muft be double of what it was when the fpring was in its ftate of greateft compreffion, and the bodies were moving with a common velocity. In fhort, the whole procefs in this example muft be precifely fimilar to that of the magnets in every circumftance relating to the changes of motion in A and B. The common velocity muft be $= \frac{A\,a \pm B\,b}{A+B}$. The final velocity of A muft be $= a - \frac{2\,B\,\overline{a \pm b}}{A+B}$, and that of B muft be $= b + \frac{2\,A\,\overline{a \pm b}}{A+B}$. The motion of the common centre muft be unaffected by the action of the fpring, and the motion of each body, relative to the centre, muft be reciprocally as its quantity of matter, &c. &c.

43
The changes of motion are produced by the inherent forces which connect the particles.

We apprehend that this procefs can fcarcely be called impulfion; A has not ftruck B. The changes of motion can fcarcely be afcribed to forces inherent in A or B, in confequence of their being in motion. Any perfon, not already warped by a theory, will (we think) afcribe them to a force inherent in the fpring; inherent in it, whether at reft or in motion, and only requiring a *continued* compreffion as the proper opportunity for its continued exertion. This fpring may be fuppofed to make a part of B, or of A, or of both; and then, indeed, the force may be faid to be inherent in either, or in both. But it is not the peculiar force inherent in motion, or in moving bodies *only*—it is the force of *elafticity*, inherent in part of the body, but requiring a continued *compreffion* for the production of a continued *repreffion*. The effect of this reaction is modified by the very occafion of the compreffion. This may be the elafticity of another fpring. In this cafe it will only comprefs that fpring.—It may be the advance of a body in motion; the reaction produces a retardation of that motion; it may be the obftacle of a quiefcent body—it will give it motion; or, it may be the abftruction by a body moving more flowly away than the fpring is preffed forward—it will accelerate that motion. Thus, in all thefe cafes, we cannot help diftinguifhing the immediate caufe of thefe changes of motion from the fuppofed force of a moving body. Nay, the procefs of motion is fimilar, even when we fuppofe that the fpring is not a thing external to the body, although attached to it; but that the whole body, or both bodies, are fpringy, elaftic, and therefore compreffible. As foon as the bodies come into fenfible contact, compreffion *muft* begin; for we may fuppofe the bodies to be two balls, which will therefore touch only in one point. The mutual preffure, which is neceffary in order to produce the retardation of A, and the acceleration of B, is exerted only on the foremoft particle of A, and the hindmoft particle B; but no atom of matter can be put in motion, or have its motion any way changed, unlefs it be acted on by an adequate force. The force urging any individual particle, muft be precifely competent to the production of the very change of motion which obtains in that particle. Except the two particles which come into contact in the collifion, all the other particles are immediately actuated by the forces which connect them with each other; and the force acting on any one is generally compounded of many forces which connect that particle with thofe adjoining. Therefore, when A overtakes B, the foremoft particle of A is immediately retarded—the particles behind it would move forward, if their mutual connection were diffolved in that inftant; but, this remaining, they only approach nearer to the foremoft ftriking particles, and thus make a compreffion, which gives occafion for the inherent elafticity to exert itfelf, and, by its reaction, retard the following particles. Thus each ftratum (fo to conceive it), continuing in motion, makes a compreffion, which occafions the elafticity to react, and, by reacting, to retard the ftratum immediately behind it. This happens in fucceffion: the compreffion and elaftic reaction begin in the anterior ftratum, and take place in fucceffion backward, and the whole body gets into a ftate of compreffion. Things happen in the fame manner in B, but in the contrary direction, the foremoft ftrata being the laft which are compreffed. All this is done in an inftant (as we commonly, but inaccurately fpeak), that is, in a very fmall and infenfible moment of time; but in this moment there is the fame gradual compreffion, increafe of mutual action, greateft compreffion, common velocity, fubfequent reftitution, and final feparation, as in the cafe of bodies with a flender fpring interpofed, or even in the cafe of the mutually repelling magnets. In all the cafes, the changes of motion are produced by the elafticity or the repulfion, and not by the transfufion of the force of motion. The changing force is indeed inherent in the bodies, but not becaufe they are in motion; the ufe of the motion is to give occafion, by continued compreffion, for the continued operation of the inherent elafticity. The whole procefs may be very diftinctly viewed, by making ufe of bodies of fmall firmnefs, fuch as foot-balls, or blown bladders. If blown bladders are ufed, each loaded with fand, or fomething that will require more force, and

44
Internal procefs of change through the fubftance of each body.

confequently

conſequently more compreſſion to impel it forward; we ſhall obſerve the compreſſion of both to be very conſiderable, and that a very ſenſible time elapſes during the proceſs of colliſion. This may even be obſerved very diſtinctly in a foot-ball, which is always ſeen to reſt a little on the toe before it flies off by the ſtroke. When one foot-ball is ſtrongly driven againſt another, they plainly adhere together for ſome time, and then the ſtricken ball flies off.

If we return to the example of the two balls with the ſpring interpoſed, we may make ſome farther uſeful obſervations. When the ſpring is in its ſtate of greateſt compreſſion, and the balls are moving with a common velocity, we can ſuppoſe that the ſpring is arreſted in that ſituation by a catch. It is evident that the two bodies will now proceed in contact with this velocity, which we have ſhewn to be $= \frac{A\,a \pm B\,b}{A + B}$.

45 Nature of imperfect elaſticity.

Now, in the conſtitution of ſuch maſſes of tangible matter as we have the opportunity of ſubjecting to our experiments, we find a ſtate of aggregation which very much reſembles this. Some bodies are almoſt perfectly elaſtic, that is, when their ſhape is changed by external preſſure; and that preſſure is removed, they recover their former ſhape completely, and they recover it with great promptitude. Glaſs, ivory, hard ſteel, are of this kind. But moſt bodies either do not recover it completely, or they recover it very ſlowly—ſome hardly recover it at all. A rod of iron will, when conſiderably bent, not nearly recover its ſhape; a rod of lead ſtill leſs; and a rod of ſoft clay will hardly recover it in any degree. Theſe, however, are but gradations of one and the ſame quality: if the quieſcent form of a body is very little diſturbed, it will recover it again. Thus, a common ſoft iron wire of N° 6. and 12 inches long, if twiſted once round, will return completely to its original form, and will allow this to be repeated for ever; but if it be twiſted $1\frac{1}{2}$ turns, it will untwiſt only 1: and in this new form, it will twiſt and untwiſt one turn as often as we pleaſe. Even a rod of ſoft clay, $\frac{1}{10}$th of an inch in diameter, and 7 feet long, will bear one twiſt as often as we pleaſe; but if twiſted 4 times, will untwiſt itſelf only one turn, and will do this as often as we chooſe. In ſhort, it appears that the particles of bodies, uſually called unelaſtic, will admit a ſmall change of diſtance or ſituation, and will recover it again, exhibiting perfect elaſticity, in oppoſition to very ſmall forces; but if they are forced too far from this ſituation, they have no tendency to return to it completely, but find intermediate ſituations, in which they have the very ſame connections with the ſurrounding particles; and in this new ſituation, they can again exhibit the ſame perfect elaſticity, in oppoſition to very ſmall forces. Mr Coulomb conceives ſuch bodies to conſiſt of elaſtic particles: they manifeſt perfect elaſticity, ſo long as the forces employed to change their ſhape do not remove the particles from their preſent contacts; but if they are removed from theſe, they ſlide on to other ſituations, where they again exhibit the ſame appearances. To underſtand this fully, the reader may conſult the article Boscovich of this *Supplement*—The fact is ſufficient for our preſent purpoſe. Now, in this variable conſtitution, where the particles may take a thouſand different ſituations, and ſtill cohere, it is plain, that when a body has been dimpled by compreſſion, the particles have nothing to bring them back to their firſt ſituation when the compreſſing force is removed: the utmoſt elaſticity to be expected, is that which will not extend to one ſhift of ſituation; therefore, the reſtitution is altogether inſenſible. This is the caſe with all ſoft bodies, ſuch as clay—the ſame quality is manifeſted in all ductile bodies, ſuch as lead, ſoft iron and ſteel, ſoft copper, ſoft gold.

46 Effect of this colliſion.

Now let one of theſe bodies ſtrike another. The compreſſion, or the ſliding of the particles over each other, requires force, or mutual preſſure—This being accompanied by a reaction perfectly equal, muſt operate, during the compreſſion, preciſely as the equal repulſive forces did. It will take as much momentum from A as it gives to B; ſo that $A\,a \pm B\,b$ will remain invariably the ſame, and a common velocity will at laſt obtain, $= \frac{A\,a \pm B\,b}{A + B}$. The compreſſion can proceed no farther, and the two bodies muſt now proceed in contact with this velocity.

And thus we ſee, that in the caſe of compreſſible, but unelaſtic bodies, the changes of motion are produced by the coheſive forces inherent in the bodies; but not inherent in them becauſe they are in motion. We ſee clearly in this way, how the pendulum uſed by Robins and his followers gave a true meaſure of the velocity of the ball. All the while that it was penetrating into the pendulum, overcoming the coheſion as it went in, this coheſion was acting equally in both directions. While the fibre was breaking, it was pulling both ways; it was holding back the ball which was breaking it, and it was pulling forward the parts to which it ſtill adhered; and when it broke at laſt, it had produced equal effects on the ball and on the pendulum in oppoſite directions. By ſuch a proceſs, the pendulum was gradually accelerated, and acquired its utmoſt velocity when the ball had ceaſed to penetrate: Therefore, this velocity muſt be $= \frac{A\,a}{A + \text{pend}^{m}}$.

What ſhould we now expect to happen in the colliſion of bodies? Such bodies as exhibit perfect elaſticity, when examined by bending, or other ſit trials, ſhould have their motions changed preciſely like the magnets, or bodies which repel or avoid each other at ſenſible diſtances. Bodies which exhibit no elaſticity whatever, ſhould continue in contact after colliſion. The common velocity in theſe ſhould be $\frac{A\,a \pm B\,b}{A + B}$. The perfectly elaſtic bodies ſhould ſuſtain changes of motion which are preciſely double of the changes ſuſtained by unelaſtic bodies, and ſhould ſeparate after colliſion with a relative velocity of receſs or ſeparation, preciſely equal to their relative velocity of mutual approach. And bodies poſſeſſing imperfect elaſticity, ſhould ſuſtain changes of motion which differ from the changes on unelaſtic bodies, preciſely in proportion to the degree of elaſticity which they are *known* to poſſeſs. And, laſtly, if the changes of motion which obtain in the colliſion of bodies, are preciſely thoſe which would reſult from the operation of thoſe inherent forces

Impulsion forces of elasticity and cohesion, NO OTHER FORCE WHATEVER CONCURS IN THEIR PRODUCTION: For we know that those forces *do operate* the collision; we see the compression and restitution which are their effective causes, and their immediate effects. If any other force were superadded, we should see its effects also, and the motions would be different from what they are.

Now the fact is, that *we have never seen a body that is not, in some degree, compressible.* It has not pleased the Almighty Creator to make any such here below. Assuredly He has not found such to be of use for the purposes He had in view in this our sublunary world. We know of no body that is perfectly unchangeable in its shape and dimensions. It is therefore no loss whatever to us, although we should not be able to say *à priori* what their motions will be in collision. We cannot even fairly guess them, by reasoning from what we observe in other bodies: For it is just as likely that their motions may resemble those of perfectly elastic bodies as those of unelastic bodies; for we find that bodies of the most extreme hardness are generally highly elastic. Diamond, crystal, agate, quartz, and such like, are the most elastic bodies we know. Philosophers, however, rather think that the motions of perfectly hard bodies will resemble those of unelastic bodies; because elasticity supposes compression. We do not pretend to say with confidence, what would be the motion of a single atom of matter (which cannot admit of compression) which is hit by another in motion. We see all the particles of terrestrial matter connected with each other by certain modifications of the general force of cohesion, so as to produce various forms of aggregation; such as aërial fluidity, liquid fluidity, rigidity, softness, ductility, firmness or hardness; all of which are combined with more or less elasticity. These tangible forms result from certain positive properties of the material atoms of which the particles are composed; and, in all the cases which come under our observation, these properties produce pressures of one kind or another; all of which are moving forces. They are inherent in the particles and atoms: therefore when such atoms are in motion, these forces are in a condition which affords occasion for a *continuation* of this pressure that is competent to the production of motion in another particle. But what would be the event of the meeting of atoms divested of such forces, we profess not to know, or even to conceive.

47 The observed effects of collision are perfectly conformable to the propositions now established.

The fact also is, that all the changes of motion, commonly called impulsions, *which have been observed*, are precisely such as have been described. Unelastic bodies proceed in contact with the velocity $\frac{Aa \pm Bb}{A+B}$. Perfectly elastic bodies separate after collision, and each sustains double of the change that is sustained by an unelastic body. Bodies of imperfect elasticity differ from the two simple cases, precisely in the proportion of the elasticity discoverable by other trials. The mutual actions are observed to be in the proportion of their relative motions, whatever the real motions may be. For not only are the changes of progressive motion exactly in this proportion, but the compressions and changes of figure, which we consider as the immediate occasions of those actions, are also observed to be in the same proportions, *in all cases that we can observe and measure with accuracy.* All these things can be ascertained with great precision by means of the collision of pendulous bodies in the way pointed out by Sir Christopher Wren (a method attributed by the French to their countryman Mariotte, but really invented by Wren, and exhibited to the Royal Society of London the week after he communicated his theory of impulsion).

48 Extensive proof of the universality of equal action and reaction.

We must also infer from these facts, that the actions of bodies on each other are mutual, equal, and opposite. This is really an inference from the phenomena, and not an original or first principle of reasoning. The contrary is conceivable, and therefore not absurd. In the same way that we can conceive a magnet repelling iron, without imagining that the iron repels the magnet, we may conceive a golden ball capable of impelling a leaden ball before it, without conceiving that the leaden ball will impel the golden ball. We do not find this easy indeed; because the contrary is so familiar, that the one idea instantly brings the other along with it. We apprehend it to be impossible to demonstrate, that a leaden ball will not stop as soon as it hits the golden ball, or *vice versa*. But all our experience shews us, that the pressures exerted in contact are mutual, equal, and opposite. The same thing is observed in the forces which connect the parts of bodies. A quantity of sand or water balanced in a scale will remain in equilibrio in whatever way it is stirred about; its parts always exert the same pressure on the scale: so does a body suspended by a string or resting on the scale, by whatever points it is supported. This could not be if the particles did not exert mutual and equal forces; nor could the phenomena called impulsions be what they are, if the pressures occasioned between the particles by the compressions and dilatations were not mutual and equal. This law of action and reaction must be admitted as universal, though contingent, like gravity. Doubtless it results from the properties which it has pleased the great Artist to give to the matter of which He has formed this world. There is one way in which we can conceive, most distinctly, how this may be a universal property of matter. If we grant the reality of attractions and repulsions *e distanti*, and suppose that every primary atom of matter is precisely similar to every other atom in all its properties, and that this assemblage of properties constitutes it a material atom; it follows, that every atom exerts the same attractions and repulsions, or has the same uniting and evasive tendencies, and then the law of action and equal reaction follows of course. This is surely the very notion that any person is disposed to entertain of the matter. And if mechanical force and mobility are the qualities which distinguish what is material from mind or other immaterial substances, the law of equal and contrary reaction seems nearly allied to the class of first principles.

Of all the phenomena that indicate this perfect equality of action and reaction, the most susceptible of accurate examination is the sameness or equality of action when the relative motions are equal. Now there is no phenomenon more certain than this. In consequence of the rotation of the earth round its axis, and its revolution round the sun, it is plain that all our experiments and observations are on relative motions only. Now, we not only find that the actions of two bodies subjected

Impulsion. ted to experiment are equal when the relative motions are equal, but we find that all our measures of action on a single body are proportional to the apparent motions which they produce. It requires precisely the same force to impel a ball eastward, westward, south, or north, at 12, or 3, or 6, or 9 o'clock: yet the real motions are immensely different in all these cases, and it is only the relative motions that have the proportions which we observe. Another very important point deducible from our experiments is, that the same *pressure* produces the same change of motion, whatever may be the velocity. We know this by observing, that when the mutual dimpling or compression is the same, the change of motion is the same, whatever be the hour of the day. This could not be if it required a greater pressure to change the velocity 100000 into 100001, than to change the velocity 1 into the velocity 2. Yet this is one of Leibnitz's great metaphysical arguments for proving that the force accumulated, and now inherent, in a moving body, is proportional to the square of its velocity. We beg that this may be kept in remembrance.

It must be granted, that what we have already said on the subject of impulsion may be called an *explanation*; for it deduces the phenomena from general and unquestionable principles, and from acknowledged laws of Nature. The only principle used is, that a moving force is indicated, characterised, and measured, by the motion which it produces. It is an acknowledged law of Nature, that pressures are moving forces; also, that moving forces appear in cases where we observe neither pressures nor impulsions, and which we call repulsions or evasive tendencies; that these are mutual and equal: and we have shewn, how a certain set of changes of motion result from them, and have stated distinctly the whole process: we shewed, that these phenomena are similar to those of common impulsion; and we then shewed in what manner the motion of a body *gives occasion* to the exertion of various moving forces, called *elasticity*, *cohesion*, &c. and that this exertion must produce motions similar to those produced by repulsions *e distanti*; and, lastly, we inferred, from the perfect sameness of those results with the actual phenomena of impulsion, that those corpuscular forces are the immediate and *only* causes of the changes called impulsions, and commonly ascribed to a *peculiar* force inherent in a moving body.

49 Why does the philosopher *attempt* to explain gravitation, &c. by impulsion?

From a collective view of the whole, we think it clear, that the opinion that impulsion is the sole cause of motion is unwarranted. We see that the phenomena of impulsion are brought about by the *immediate* operation of pressure; and we see numberless instances of pressure, in which we cannot find the smallest trace of impulsion. It is therefore a most violent and unwarranted opinion, which ascribes to repeated unperceived impulsions all those solicitations to motion by which, or in consequence of which, the motions of bodies are affected by distant bodies, or bear an evident relation to the situation and distance of other bodies; as in the examples of planetary deflection, terrestrial gravitation, magnetical and electrical deflexions, and the like. There is nothing in the phenomenon of the pressure of gravity that seems to make impulsion more necessary or more probable than in the pressure of elasticity, whether that of a spring or of an expansive fluid. The admission of an unperceived fluid to effect those impulsions is quite unwarranted, and the explanation is therefore unphilosophical, even although we should perceive intuitively that an atom in motion will put another into motion by hitting it. We apprehend that this cannot be affirmed with any clear perception of its truth. Impulsion.

50 Impulsion is supposed to be better understood and more familiar.

On the whole, therefore, we must ascribe that contented acquiescence in the explanations of gravitation, and other attractions and repulsions, by means of impulse (if the acquiescence be not pretended), to the frequency and familiarity of impulsion, and perhaps to the personal share and interest we have in this mode of producing motion. We know that it is always objected that nothing is explained, when we say that A repels B, or that B avoids A; but we must say in return, that nothing is explained, when we say that A impels B by hitting it, or that B flies away from the stroke. Why should it not be allowed to use the term repelling power, when it is allowed to use the term impelling power, the force of impulse, inertia? All these terms only express phenomena. Does the word body express any more?

51 It is not better understood.

The maxim, that a body cannot act *where* it is not, any more than *when* it is not, is a quaint and lively expression, and therefore has considerable effect: It may be granted; for we apprehend that we understand so little about *when* and *where*, that we cannot demonstrate the affirmative or negative in either case, and that they are on a par with respect to our knowledge of them. We can have no doubt, however, of the fact, that our mind can be affected by an external object that is merely recollected. And we apprehend, that we know nothing of the difference between body and mind but what we have learned by experience. Body, for any thing that we assuredly know to the contrary, may affect, or be affected by, a distant body, as well as mind may be. It is therefore worth while to pay some farther attention to the phenomena, in order to see whether this experience is so universal and unexpected as is believed. As Mr Cotes, and many of Newton's disciples, are accused of explaining many phenomena by attraction and repulsion which their opponents affirm to be cases of impulsion; it is not impossible but that ordinary observers, who have no preconceived theories, may imagine impulsions to obtain in cases where a more accurate inspection would convince them that no impulsion has happened.

52 Enquiry into the familiarity of impulsion. Instances of a foot-ball.

When we kick away a foot-ball, we consider it as a sort of solid continuous body; yet we know that it must be filled with compressed air. It may not be impossible to have it of its round shape without being so filled: but we know that, in this condition, it would not fly away from our foot by the stroke; we should only force in the side which we kick, and the flaccid skin would lie at our feet. But when it is filled with strongly compressed air, we can form to ourselves a pretty distinct notion how it is made to move off. Our foot presses on a part of the skin: this compresses the air against the anterior part of the bag, and forces it away. If we reflect more seriously on the process, we can still conceive it clearly enough, by thinking on a row of aereal particles, reaching from the part struck by the foot to the anterior part, each touching the other, and therefore forcing the anterior part forward. The air is conceived to consist of a number of

Impulſion.

of little ſpherules in contact, each of which is compreſſible; and we think the operation illuſtrated by ſuppoſing each to be like a little veſicle or bladder. This we believe to be the uſual way of conceiving the conſtitution of expanſive fluids: But this will not agree at all with the known properties of air; for it can be ſtrictly demonſtrated, that if ſuch a collection of elaſtic veſicles be compreſſed into the half of their ordinary bulk, every veſicle will be changed from a ſphere into a perfect cube, touching the adjoining cubes in every point of its ſix ſides, and ſtrongly preſſed againſt them. It can alſo be demonſtrated, that if a leaden cube of one inch be included in the box, and placed with its ſides parallel to the ſides of the box, and the compreſſion be then made, all the little cubic veſicles will acquire the ſame poſition. If the box be now turned upſide down, it can be demonſtrated that the weight of this leaden cube will not be ſufficient for overcoming the reſiſtance of the compreſſed cubes. This compreſſed maſs will not be fluid, but will require a very conſiderable force to preſs the leaden cube through it, juſt as we find ſuch a force neceſſary for moving a body through melted glaſs: the particles no longer ſlide on each other like uncompreſſed ſpherules; each will require about half of the compreſſing force, in order to overcome the friction, or obſtruction like friction, produced in ſliding along the ſurface of the contiguous cubes. But we know that air remains perfectly fluid, although vaſtly more compreſſed than this. This, therefore, cannot be like the conſtitution or form of air. Moreover, it is well known that air has been made ten times denſer than its ordinary ſtate, and is then perfectly fluid. It has alſo been made a hundred times rarer, and it ſtill remains perfectly fluid. In this ſtate its particles muſt be ten times farther removed from each other than in the former ſtate, of a thouſand times greater denſity. Yet we know that this rare air is compreſſed with a force equal to the weight of a ſtratum of mercury $\frac{1}{3}$d of an inch in thickneſs, and that if $\frac{1}{3}$d of this preſſure be removed, it will expand till it is 150 times rarer than common air; that is, there is ſome force which puſhes the particles ſtill farther from each other. This force evidently extends beyond the tenth particle of air that is made ten times denſer than common air. Therefore the elaſticity of air does not ariſe from the contact of particles, which are elaſtic like blown up bladders, but from ſome force which extends beyond the adjoining particles. There is no greater reaſon, therefore, for ſuppoſing, that the particles of air touch each other, than for ſuppoſing that the two magnets touch each other becauſe they repel. A row of magnets floating on quickſilver, and placed with their ſimilar poles fronting each other, and very near, will tend to ſeparate, and they require to be held in by a ſtop put at each end of the canal; and if one ſtop be gradually withdrawn the magnets will all ſeparate, and exhibit the general mechanical effects of a row of aerial particles ſeparating by the removal of preſſure. There ſeems, therefore, to be the ſame neceſſity for the operation of an intervening impelling fluid for producing this ſeparation or elaſticity of the aereal maſs, as for ſeparating the magnets.

Is very doubtful. The reſult of theſe remarks ſeems to be, that the impulſion of a foot-ball is not brought about in the way that is commonly imagined, by the excitement of corporeal preſſure at the points of contact of the two foot balls. For we ſee it almoſt demonſtrated, that the progreſſive motion of the anterior part of one of the balls has been produced without contact, or, at leaſt, by the *intervention* of repulſions acting at a diſtance.—May not this obtain, even in the points in which we ſuppoſe the two balls actually to touch, in the act of impulſion?

53 Many caſes of doubtful contact.

But farther—Every perſon has obſerved the brilliant dew-drops lying on the leaves of plants. Every perſon acquainted with Newton's optical diſcoveries, muſt be convinced that the dew-drop is not in mathematical contact with the leaf; if it were, it could have no brilliancy. Moſt perſons have obſerved the rain drops of a ſummer ſhower fall on the ſurface of water, and roll about for a few ſeconds, exhibiting the greateſt brilliancy. They cannot, therefore, be in mathematical contact with the water. There muſt be a ſmall diſtance between them, and therefore ſome force which keeps them aſunder, and carries the weight, that is, counteracts the downward preſſure of the rain-drop. We know that ſome inſects with long legs can run about on the ſurface of water; and if we lift them carefully, and ſet them on glaſs, their feet do not wet it. Put a little ſpirit of wine into this water, and make it lukewarm, and the inſect inſtantly ſinks up to the belly, and cannot move about as before: Its feet will now wet a glaſs. A well-poliſhed ſteel needle, even of conſiderable ſize, if perfectly clean and dry, will float on water without being wetted: It is obſerved to make a conſiderable depreſſion on the ſurface of the water, juſt as a heavy bar of iron would make when laid on a feather-bed—the needle diſplaces a quantity of water equal to itſelf in weight, yet does not touch it, for it is not wetted. If it be previouſly wetted, it will not diſplace any water, and will not float. There is ſomething, therefore, which keeps the water at a diſtance from the feet of the inſect, and from the needle, exerting a certain upward preſſure on them. The preſſure and the reaction are indeed very ſmall; but they would produce a very ſenſible motion if continued ſufficiently long in proper circumſtances. Here would be a production of motion, which moſt perſons would call an impulſion—yet there would be no ſtroke, no contact, and therefore no true impulſion.

We now beg the reader to attend minutely to Newton's famous experiment with the object glaſſes of long teleſcopes, which we have mentioned circumſtantially in the article Optics, *Encycl.* n° 63—68.

54 Very remarkable caſe of convex lenſes falſely ſeeming to touch.

When the upper glaſs is very thin and light, no colour appears at the point of contact: but by preſſing it down with ſufficient force, we ſhall have a black or unreflecting ſpot in the middle, ſurrounded by a ſilvery ring, and then by a ſeries of rings of various colours, according to the diſtance between the parts of the glaſſes where the colours appear. Newton has counted 50 of theſe rings. He ſhews, by a careful computation from the known figure of the glaſſes, that the differences between the diſtances which exhibit theſe colours are all preciſely equal, and that each is about $\frac{1}{89000}$ of an inch. Therefore, ſuppoſing that the glaſſes are in mathematical contact where the unreflecting ſpot appears, making one continuous maſs of glaſs, their diſtance at the outermoſt ring muſt not be leſs than $\frac{50}{89000}$ of an inch, or $\frac{1}{1780}$ of an inch. Therefore, when

when one glaſs carries the other, without any appearance of colour at the middle, we muſt conclude that there is a repulſion exerted between the neareſt parts, at a diſtance not leſs than $\frac{1}{155}$ of an inch, ſufficient for ſupporting the upper glaſs. It requires an increaſe of preſſure to produce the firſt appearance of colour; and when the preſſure is ſtill more increaſed, new colours appear in the middle, and the colour formerly there is now ſeen in a ſurrounding ring; theſe multiply continually, by new ones ſpreading from a central ſpot. A great preſſure at laſt produces the unreflecting ſpot in the centre, which, unlike to all the coloured ſpots which had emerged in ſucceſſion, is ſharply defined, and never round, but ragged, and it is immediately ſurrounded by a bright ſilvery reflection. The ſhape of this ſpot depends on the figure of the ſurfaces; for, on turning the upper lens a little round its axis, the inequalities of the edge of the ſpot turn, in ſome degree, with it. This ſeemingly trifling remark will be found important by the mechanician: A ſtill farther increaſe of preſſure enlarges the unreflecting ſpot, and the dimenſions of all the rings.—When the preſſure is gradually withdrawn, the rings ſhrink in their dimenſions, the unreflecting ſpot diſappears firſt, and each ring in ſucceſſion contracts into a ſpot, and vaniſhes. Here we have, by the way, an explanation of the brilliancy of dew-drops: they come ſo near, perhaps, that the neareſt point reflects the ſilvery appearance—but they do not touch; the inſtant that they touch a wetted part, making one maſs of tranſparent matter, all brilliancy is gone.

55
They repel each other;

Here then are inconteſtible proofs of a force, be its origin what it may, which keeps the glaſſes aſunder, and even cauſes them to ſeparate; which manifeſts itſelf by withſtanding preſſure; and therefore is, itſelf, a preſſure, or equivalent to a preſſure.—It varies in its intenſity by a change of diſtance; but we have not been able to aſcertain by what law. It muſt not be meaſured by the ſimple variation of the external preſſure; for ſince we ſee that, even before any colour appears in the centre, the weight of the upper lens is ſupported, we muſt conclude that the glaſſes are exerting at leaſt an equal force all around the circumference of the outermoſt ring. It is evident, that the computation of the whole force, exerted over all the coloured ſurface, muſt be difficult, even on the ſimpleſt hypotheſis concerning the law of repulſion: we can only ſay that it increaſes by a diminution of diſtance. It is very eaſy to compute the increaſe of external preſſure, which would ſuffice if the repelling force were equal at all diſtances; or if it varied according to any ſingle power of the diſtances. We have tried the inverſe ſimple, duplicate, and triplicate ratio; but the fact deviated widely from them all. The repulſion does not change nearly ſo much as in the ſimple inverſe ratio of the diſtances, if the glaſſes be ſuppoſed to touch in the whole ſurface of the unreflecting ſpot. But we found, that if we ſuppoſe them ſeparated, though at a diſtance equal to forty times the difference of diſtance at which the colours change, that is, $\frac{1}{112}$ of an inch, the preſſures employed in the experiment accord pretty well with a repulſion inverſely as the diſtance, but ſtill with a very conſiderable deviation in the great preſſures. In the courſe of a number of experiments with a favourite pair of lenſes, we broke the uppermoſt by too ſtrong a preſſure. We then cut out of it, with a lapidary's hollow drill, a piece of $\frac{1}{4}$ of an inch in diameter, and perfectly round, and we ſqueezed it on the other by a meaſured preſſure, till we produced a colourleſs ſpot of nearly $\frac{1}{6}$th of an inch in diameter, with a ſilvery margin. Computing from this, we thought ourſelves warranted to ſay, that not leſs than 800 pounds are neceſſary for producing a black ſpot of one inch ſquare!

56
And may impel without touching

Now, what is the conſequence of all this in the doctrine of impulſion? Surely this:—If a lump of this glaſs ſtrike another lump, and put it in motion, and if the mutual preſſure in the act of colliſion do not exceed 700 pounds on the ſquare inch, the motion has been produced without mathematical contact, and the production can no more be called impulſe than the motion of the magnet in our firſt experiment. The changes of motion have been the operation of moving forces, ſimilar to the force of magnetiſm; and if a ſtream of truly impelling fluid be neceſſary for producing the motion of the magnet, it is equally neceſſary for producing the motion of the piece of glaſs.

It may be ſaid here, that we cannot compare impulſe and preſſure. A ſlight blow will ſplit a diamond which could ſupport a houſe. A ſlight blow may therefore be enough for exciting all the preſſure neceſſary for producing mathematical contact. We muſt here appeal to what every man feels on this occaſion. We doubt exceedingly whether any perſon will think that, when one piece of glaſs gives another a gentle blow, and puts it into motion, with the velocity of a few inches per ſecond, a blow which he diſtinctly hears, there has been exerted a preſſure at all approaching to 800 pounds per ſquare inch.—We have ſuſpended a pair of lenſes, by an apparatus ſo ſteady and firm, that they could touch only at the centres of each ſurface; and, having placed ourſelves properly, we could ſee, with ſufficient diſtinctneſs, the momentary appearance of the coloured ſpot at the inſtant of colliſion. We ſaw this, with the fulleſt confidence that it was of no conſiderable breadth in a moderate ſtroke, and that it was very ſenſibly broader when the ſtroke was more violent. We did not truſt our own eye alone, but ſhewed it to perſons ignorant of philoſophy, and even to children, often without telling them what to look for, but aſking them what they ſaw. From all the information that we could gather, none of the preſſures came near to what muſt have been neceſſary for producing the black ſpot. This could not be miſtaken: for although the outer rings are but faint, there are five or ſix near the centre which are abundantly vivid for affecting the eye by the momentary flaſh. Beſides, the dimenſions of the lenſes, and the weight of the metal cells in which they were fixed, were ſuch as muſt have cauſed them to ſplit before the black ſpot could be produced in the centre.

And certainly do ſo, even in violent ſtrokes.

Theſe things being maturely conſidered, we imagine that few perſons will now doubt the juſtice of our aſſertion, that in all theſe examples, the motions have been produced without mathematical (or rather geometrical) contact.—And we imagine alſo, that few will refuſe granting that this is not peculiar to glaſs, but obtains alſo in the colliſion of other bodies. We have not thought of any method for putting this beyond doubt; but we have better reaſons than mere likelihood for being of this opinion. Every one acquainted with the Newtonian

Impulsion.

Newtonian discoveries in optics, knows that this curious appearance of the coloured rings is the consequence of the action of transparent bodies on the rays of light, by which these are bent aside from their rectilineal course, and that this deflection takes place at a distance from the diaphanous body; a distance which the sagacity of the great philosopher has enabled us to measure. Now, it is known that metals and other opaque bodies produce the very same deflections of the rays, bending them toward themselves at one distance, and from them at other distances; in short, attracting or repelling them as the distance varies. Nothing but prepossession can hinder a person from ascribing similar effects to similar causes, and, therefore, thinking it almost certain that this mutual repulsion is not peculiar to glass, but common to all solid bodies.

To all this we may surely add the celebrated experiment of Mr Huyghens; in which it is evident, that a smooth plate of metal attracts another, even although there be a silk fibre interposed between them. (See *Phil. Transf.* n° 86.) Is it not highly probable, that at a smaller distance the bodies repel each other? For we observe, that metals, as well as transparent bodies, attract the rays at one distance and repel them at another.

57 Impulsion is not so familiar as is believed.

Surely our readers will now grant, that the production of motion by impulsion, as distinguished from the production by action *e distanti*, is not so familiar a phenomenon as was imagined, and that it may even be said to be rare in comparison: for the instances of moderate impulses are numberless. The claim of this mode of explaining difficult phenomena by impulsion, has therefore lost much of its force; and we see much less reason for calling in the aid of invisible fluids, in order to *explain* the action of gravity, magnetism, and electricity.

58 Still greater doubts. Observations on a soap bubble.

But we have still more important information from the optical discovery of Newton. Let the reader turn again to Optics, *Encycl.* n° 65, and read the account of the phenomena exhibited by the soap-bubble. The bubble is thinner and thinner as we approach the very uppermost point of it. It also exhibits numerous rings, which vary in their colour, in the same order as in the space between the lenses. These rings come to view in the same manner. First, a coloured spot appears in the summit of the bubble; this becomes a ring, and is succeeded by another spot, as the bubble grows thinner in that part, by the gradual subsiding of the watery film. At last a black spot appears at top, well defined, but of irregular shape, surrounded by a silvery ring. This spot, when viewed very narrowly, is observed to reflect a very minute portion of light, without *separating* the differently colorific rays of which it consists; but it *contains* them all, as may be proved by viewing it through a prism. After some little time the bubble bursts.

Surely we must infer from this, that there is a certain thickness of the transparent plate which renders it unfit for the vivid reflection of light. Does it not legitimately follow from this, that the unreflecting spot between the lenses ceases to entitle us to say, that they are in contact in that place? All that we can conclude from its appearance is, that the distance still between the glasses is too small to fit the place for the vivid reflexion of light. This conclusion is indisputable. Were it refused, we are furnished with an incontestible proof by the same bountiful hand. Newton ascribed the colours to the reflection of the plate of air between the glasses, and expected the cessation of them when the air is removed. His friend Mr Boyle had lately invented a commodious air pump. The trial was made, and young Newton found himself mistaken; for the colours still appeared, and he even thought them more brilliant. He then tried the effect of water, expecting that this would diminish their lustre. So it did; and he found that the dimensions of the rings were diminished in the proportion of 4 to 3; namely, the proportion of the refractions of glass and water. By this time Newton had discovered the curious mechanical relation between bodies and the rays of light; and his mind was wholly absorbed by the discovery, and by the revolution he was about to make in the mathematical doctrines of optics. Unfortunately for us, he did not, at that time, attend to the mighty influence which the discovery would have on the whole of mechanical philosophy, and therefore occupied himself only with such phenomena as suited his present purpose. A most important phenomenon passed unnoticed. In repeating Sir Isaac Newton's experiments, we found that the diameters of the rings decreased in the proportion of 4 to 3 only in certain circumstances. When the upper lense was pressed on the other by a heavy metal ring, so as to produce three or four coloured rings, we found that when water got between them, sometimes no colours whatever appeared; sometimes there was a ring or two, and the diameters were diminished in a much greater proportion than Newton had assigned. Well assured of the extreme nicety of all his proceedings, we were much puzzled with this discrepancy, and mentioned it to a most respectable and intelligent friend, the late Dr Reid of the university of Glasgow, a mathematician and naturalist of the first rank. He thought it not improbable that the glasses separated from each other, lifting up the weight, by attracting the water into the interstice, in the same manner that we observe wood to swell with moisture. We immediately got an apparatus which compressed the glasses by means of four screws; and now we saw Newton's proportion most strictly observed. But in prosecuting the experiment, we found that the introduction of the water *always* effaced a very small spot. This happened after precautions had been taken to prevent all separation of the glasses. As the proportion of 4 to 3 has a relation to refractive power, although we have not been able to deduce it as a necessary consequence, we nevertheless considered it as a sufficient proof that the distances of the glasses *had not changed* by introducing the water between them. Therefore we think ourselves well entitled to conclude, that the disappearance of the black spot was not owing to a separation of the glasses, which admits the water into the empty space; and we affirm, that before the entry of the water, there was room for it in the place which reflected no light; that is, that although the glasses were pressed together with a very great force, they were not in contact.

Remark.

It deserves remark, that in endeavouring to produce the black spot, when water is between the glasses, we found great and unaccountable anomalies. Sometimes a moderate increase of pressure produced it, and sometimes we were not able to produce it by any pressure.

Several

Impulsion. Several lenses were broken in the trial. We are led to think that the thickness which gives the silvery reflection is much greater than the 8900th part of an inch, and that it is not the same in all glasses. But we were interrupted in these experiments, and indeed in all active pursuits, by bad health, which has never permitted their renewal. The subject is of great importance to the curious mechanicians, and we earnestly recommend it to their attention. There is something very remarkable in the abrupt sensation of the coloured reflection. At a certain thickness *all* colours are reflected, without separation, producing the whiteness of silver. The smallest diminution of it hinders the *vivid* reflection of *all* colours, and then there seems to succeed a thickness which equally reflects a small proportion of *all* without separation. The finest polish that can be given to glass in the tool of the artist, leaves irregularities which occasion the irregular ragged figure of the spot. It is worth trying, whether smoothing the surfaces (both) by a softening heat will remove this ruggedness. If it does, without destroying the sharp termination, it will prove the abrupt passage from *esse* to *nonesse*.

The last remark to be made on this important experiment in optics is, that the distance between the glasses which is unfit for vivid reflection, cannot be determined by means of the other measurable intervals. It may be equal to many of them taken together. The same must be granted with respect to the thickness of the black spot on the top of the soap bubble. We attempted to measure this thickness by letting a drop (of a known weight) of spirit of turpentine spread on the surface of water. As it slowly enlarged in surface, it decreased in thickness, and produced, in regular order, several of the more compounded colours of the Newtonian series. But before it came to the 20th ring from the centre, it became very irregular and spotty.

59 Contact is not proved in collision. The inference to be drawn from this combination of the two optical facts is remarkable and important. It is, that we have no authority for affirming that the changes of motion by the collision of bodies is brought about by absolute contact in any instance whatever. The glasses are not in contact where there is vivid reflection; and we have no proof that they are in contact in the black spot, however great the compression may be.

60 Therefore impulsion cannot explain gravitation; It is hardly necessary now to say, that all attempts to explain gravitation, or magnetism, or electricity, or any such apparent action at a distance by the impulsions of an unseen fluid, are futile in the greatest degree. Impulsion, by absolute contact, is so far from being a familiar phenomenon, that it may justly be questioned whether we have ever observed a single instance of it. The supposition of an invisible impelling fluid is not more gratuitous than it is useless; because we have no proof that a particle of this fluid does or can come into contact with the body which we suppose impelled by it, and therefore it can give no explanation of an action that is apparently *e distanti*.

61 But impulsion may be explained by continued pressure. The general inference from the whole seems to be, that, instead of explaining pressure by impulse, we must not only derive all impulse from pressure, but must also ascribe all pressure to action from a distance; that is, to properties of matter by which its particles are moved without geometrical contact.

This collection of facts conspires, with many appearances of fluid and solid bodies, to prove that even the particles of solid, or sensibly continuous bodies, are not in contact, but are held in their respective situations by the balance of forces which we are accustomed to call attractions and repulsions. The fluidity of water under very strong compressions (which have been known to compress it $\frac{1}{18}$th of its bulk), is as inconsistent with the supposition of contact as the fluidity of air is. The shrinking of a body in all its dimensions by cold, nay, even the bending of any body, cannot be conceived without allowing that *some* of its ultimate unalterable atoms change their distances from each other. The phenomena of capillary attraction are also inexplicable, without admitting that particles act on others at a distance from them. The formation of water into drops, the coalescence of oil under water into spherical drops, or into circular spots when on the surface, shew the same thing, and are inexplicable by mere adhesion. In short, all the appearances and mutual actions of tangible matter concur in shewing, that the atoms of matter are endowed with inherent forces, which cause them to approach or to avoid each other. The opinion of Boscovich seems to be well founded; namely, that at all sensible distances, the atoms of matter tend toward each other with forces inversely as the squares of the distances, and that, in the nearest approach, they avoid each other with *insuperable* force; and, in the intermediate distances, they approach or avoid each other with forces varying and alternating by every change of distance. See the article Boscovich, *Suppl.*

From all that has been said, we learn that physical or sensible contact differs from geometrical contact, in the same manner as physical solidity differs from that of the mathematician. Euclid speaks of cones and cylinders standing on the same base, and between the same parallels. These are not material solids, one of which would press the other out of its place. Physical contact is indicated, immediately and directly, by our sense of touch; that is, by exciting a pressure on our organ of touch when it is brought sufficiently near. It is also indicated by impulsion; which is the immediate effect of the pressure occasioned by a sufficient approximation of the body impelling to the body impelled. The impulsion is the completion of the same process that we described in the example of the magnets; but the extent of space and of time in which it is completed is so small that it escapes our observation. and we imagine it to be by contact and in an instant. We now see that it is similar to all other operations of accelerating or retarding forces, and that no change of velocity is instantaneous; but as a body, in passing from one point of space to another, passes through the intermediate space; so, in changing from one velocity to another, it passes through all the intermediate degrees without the smallest *saltus*. 62 Physical contact explained.

And in this way is the whole doctrine of impulsion brought within the pale of dynamics, without the admission of any new principle of motion. It is merely the application of the general doctrines of dynamics to cases where every accelerating or retarding force is opposed by another that is equal and contrary. We have found that the opinion, that there is inherent in a moving body a peculiar force, by which it perseveres in motion, and puts another in motion by shifting into it, We thus avoid many absurdities.

Impulsion. is as useless as it is inconsistent with our notions of motion and of moving forces. The impelled body is moved by the insuperable repulsion exerted by all atoms of matter when brought sufficiently near. The retardation of the impelling body does not arise from an *inertia*, or resisting sluggishness of the body impelled, but because this body also repels any thing that is brought sufficiently near to it. We can have no doubt of the existence of such causes of motion. Springs, expansive fluids, cohering fibres, exhibit such active powers, without our being able to give them any other origin than the FIAT of the Almighty, or to comprehend, in any manner whatever, how they reside in the material atom. But once we admit their existence and agency, every thing else is deduced in the most simple manner imaginable, without involving us in any thing incomprehensible, or having any consequence that is inconsistent with the appearances. Whereas both of these obstructions to knowledge come in our way, when we suppose any thing analogous to force inherent in a moving body solely because it is in motion. It forces us to use the unmeaning language of force and motion passing out of one body into another; and to speak of force and velocity as things capable of division and actual separation into parts. The force of inertia is one of the bitter fruits of this misconception of things. It is amusing to see how metaphysicians of eminence, such as D'Alembert, endeavour to make its operations tally with acknowledged principles. In his celebrated work on dynamics, the most elaborate of all his performances, he explains how a body, whose mass is 1, moving with the velocity 2, must stop another body whose mass is 2, moving with the velocity 1, in the following manner: He supposes the velocity 2 to consist of two parts, and that, in the instant of collision, one of the parts destroys the motion of one half of the other body, and then the other part destroys the motion of the other half. These are words; but in vain shall we attempt to accompany them by clear conceptions. His distinction between the force of inertia and what he calls the active forces of bodies, such as the force of bodies which strike each other in opposite directions, is equally unsusceptible of clear conceptions. Active forces (says he) absorb a part of the motion; but when inertia takes part of the motion from the striking body, this motion passes wholly into the body that is stricken, none of it being absorbed or really destroyed. He demonstrates this by the equation $A \times \overline{a-x} = B \times \overline{x-b}$, which is a mere narration of facts, but no deduction from the nature of inertia, nor even any establishment of that nature by philosophical argument. And in attempting to give still clearer notions (being sensible that some great obscurity still hangs about it), he says, "Inertia therefore, and properly speaking, is the mean of communicating motion from one body to another. Every body resists motion; and it is by resisting that it receives it; and it receives precisely as much as it destroys in the body which acts on it." Surely almost every word of this sentence is doing violence to the common use of language. What can be more incomprehensible than that a body resists motion only when it receives it? Should a man be thought to resist being pushed out of his place when he actually allows another to displace him, and not to resist when he firmly keeps his place? All these difficulties and puzzling questions vanish when we give over speaking of inertia as something distinguishable from the active forces or causes of motion which we find in bodies, and distinguish by the names of elasticity, cohesion, magnetism, electricity, weight, &c. and which philosophers have classed under one name, accelerating or retarding force, according as its direction chances to be the same, or the opposite to that of the motion under consideration. To suppose it a *peculiar* faculty by which a body maintains its condition of motion or rest, is contrary to every conception that we can annex to the words faculty, power, force. It is frivolous in the extreme to say, that snow has the faculty of continuing white or cold; or that it resists being melted because it melts, or because heat must be employed to melt it.

63
Strongest argument for inertia is the composition of force with a previous motion.

The only argument that we know for giving the name force to the perseverance of matter in its state of motion (or rather for ascribing this perseverance to the exertion of a peculiar faculty), which appears to deserve any attention, is one that we do not recollect the express employment of for this purpose, namely, the composition of a previous motion with the motion which a known force would produce in the body at rest. We know that if a body be moving eastward at the rate of four feet per second, and a force act on it which would impel it from a state of rest at the rate of three feet per second to the south, the body will move at the rate of five feet per second in the direction E. 36° 52′ S. We know also, that if a force act on this body at rest, so as to give it a motion eastward at the rate of four feet per second, and if another force act on it at the same instant, so as to give it a motion to the south at the rate of three feet per second, the body will move at the rate of five feet per second in the direction E. 36° 52′ S. In this instance, the body previously in motion seems to possess something equivalent to what is allowed to be a moving force. Why therefore refuse it the name? The answer is easy. The term force has been applied, by all parties, to whatever produces a *change* of motion, and is measured by the *change* which accompanies its exertion. There is some difference between the parties about the way of estimating this measure; but all agree in making, not the motion, but the change of motion, the basis of the measurement. Now we shewed, at great length, in the article DYNAMICS, that the *change* of motion, in every case, is that motion which, when compounded with the former motion, constitutes the new motion. Did we take the new motion itself as the characteristic and measure of the changing force, it would be different in every different previous state of the body, and would neither agree with our general notion of force, nor with the knowledge that we have of the actual pressures and other moving forces that we know. The sole reason why the previous motion is equivalent with a force is, that the only mark or knowledge that we have of a moving force is the motion which it is conceived to produce. The force is equivalent with the previous motion, because we know nothing of it but that motion; and the name that we give it, only marks some external thing to which it has an observed relation. We call it magnetism or electricity, because we observe that a magnet or an electrified body gives *occasion* to its appearance. We never observe the resistance of *inertia*, except in cases where we know, from other circumstances, that moving forces

Answered.

forces inherent in bodies are really brought into action. The inertia of the ball which has been moved by a stroke of another, is inferred from the diminution of that other's motion. But this is occasioned precisely in the same way as the diminution of the motion of the magnet A in the first example; an event which every unprepossessed person ascribes to the repulsion of B in the opposite direction, and not to its inertia.

We trust that our readers are not displeased with this detail of the procedure of Nature in the phenomena of impulsion. It has been prolix; because we apprehend, that the too synoptical manner in which the laws of collision have always been delivered, leaves the mind in great obscurity concerning the connection of the events. General facts have been taken for philosophical principles and elementary truths; whereas they were deductions from the sum total of our knowledge. They were very proper logical principles for a synthetical discussion; but their previous establishment as general facts was necessary. We have established the two most general facts from which the result of every collision may be deduced with the utmost ease. The first is, that in the instant of greatest compression, the common velocity is $= \frac{A\,a \pm B\,b}{A + B}$; and we have shewn that this is applicable to the collision of unelastic bodies. The second is, that the change in perfectly elastic bodies is double of the change in unelastic bodies. The *conservatio momentorum*, and the *conservatio virium vivarum*, are also general facts; or rather they are the same mentioned with those above, considered in another aspect. They may all be used as the principles of a synthetic treatise of impulsion; and they have been so employed. Each has its own advantages.

64 Principle of smallest action.

Mr Maupertuis gives a treatise on the Communication of Motion, that is, of impulsion or collision, which has the appearance of being deduced from a new principle, which he calls the PRINCIPLE OF SMALLEST ACTION. He supposes that perfect Wisdom will accomplish every thing by the smallest expenditure of action; and he chanced to observe, in the equations employed in the common doctrine of impulsion, a quantity which is always a minimum. He chooses to consider this as the expression of the action.

His principle or axiom, deduced from the perfect wisdom of God, is thus expressed: "When any change happens in nature, the quantity of action necessary for it is the smallest possible." And then he adds,

"In mechanical changes, the quantity of action is the product of the quantity of matter in the body by the space passed over, and by the velocity of the motion." This is evidently the measure adopted long before by Leibnitz (see *Phil. Trans.* vol. xliii. p. 423, &c.), and it is equivalent to $m\,v^2$; because the space multiplied by the velocity is as the square of either. We refer to Dr Jurin's remarks on this passage for proof that this is by no means a just measure of action; and only observe here, that we can form no other notion of velocity than that of a certain space described in a given time. The change produced is not the actual description of a line, but the determination to that motion. It is in this respect alone that the condition of the body is changed; and therefore the product $m\,v$, and not $m\,s\,v$, is the proper measure of the action. On the authority of this maxim of divine conduct, Maupertuis investigates the results which will make this quantity a minimum, and asserts that these *must* be the laws of collision. Luckily this investigation is extremely simple, and very neat and perspicuous; and it gives very easy solutions. For example, the unelastic body A, moving with the velocity a, overtakes the unelastic body B, moving with the velocity b. Both move after the collision with the velocity x. This velocity is required. To determine this, we must make $A \times \overline{a - x}|^2 + B \times \overline{x - b}|^2$ a minimum; or $A\,a^2 - 2\,A\,a\,x + A\,x^2 + B\,x^2 - 2\,B\,b\,x + B\,b^2$ is a minimum. Therefore $-2\,A\,a\,\dot{x} + 2\,A\,x\,\dot{x} + 2\,B\,x\,\dot{x} - 2\,B\,b\,\dot{x} = 0$, or $2\,A\,a + 2\,B\,b = 2\,A\,x + 2\,B\,x$, and $x = \frac{A\,a + B\,b}{A + B}$; as we have already shewn it to be.

The amiable and worthy author grew more fond of his theory, when he saw what he imagined to be its influence extended to an immense variety of the operations of nature. Euler demonstrated, that the quantity called *action* by Maupertuis was a minimum in the planetary motions, and indeed in all curvilineal motions in free space. But all the while, this principle of least action is a mere whim, and the formula which is so generally found a minimum has no perceptible connection with the quantity of action. In many cases to which Maupertuis has applied it, the conclusions are in direct opposition to any notion that we can form of the economy of action. Nay, it is very disputable whether it does not, on the contrary, express the greatest want of economy; namely, a minimum of effect from a given expenditure of power. In the case of impulsion, this minimum is the mathematical result of the equality and opposition of action and reaction. Maupertuis might have pleased his fancy by saying, that it became the infinite wisdom of God to make every primary atom of matter alike; and this would have answered all his purpose.

65 Enquiry into the distribution of impulse from the point that is struck.

There still remains to be considered a very material circumstance in the doctrine of impulsion, which produces certain modifications of the motions that are of mighty practical importance. We have contented ourselves with merely stating the moving force that is brought into action in the points of physical contact; but have not explained how this produces the progressive motion of every particle of the impelled body, and what motion it really does produce in the remote particles. A body, besides the general progressive motion which it receives from the blow, is commonly observed to acquire also a motion of rotation, by which it whirls round an axis. It has not been shewn, that when a body has received an impulse by a blow in a particular direction on one point, it will proceed in that direction, or in what direction it will proceed. Experience shews us, that this depends on circumstances not yet considered. The billiard player knows, that by a stroke in one direction he can make his antagonist's ball move in a direction extremely different.

These are questions of great intricacy and difficulty, and would employ volumes to treat them properly. We have already enlarged this article till we fear that we have exhausted the reader's patience, and deviated from the proportion of room justly allowable to IMPULSION. We must therefore limit our attention to such things only as seem elementary, and indispensably necessary

Impulsion.

cessary for a useful application of the doctrine of impulsion.

With respect to the *direction* of the motion produced by impulsion, the very example just now borrowed from billiard playing, shews that it is important, and by no means obvious. We are sorry to say, that we have nothing to offer in solution of this question that will be received by all as demonstration. It is comprehended in the following proposition, which we bring forward merely as a matter of fact.

66
Action of bodies by contact is perpendicular to the touching surface.

The direction of the stroke or pressure exerted by two bodies in physical contact, is always perpendicular to the touching surfaces. Of this truth we have a very distinct and pretty example and proof by the billiard table. If two balls A and B (fig. 2.) are laid on the table in contact, and A is smartly struck by a third ball C in any direction C c, so that the line a A, which joins the point of contact a with the centre A, may make an obtuse angle with the line AB, joining the centres of the two balls, the ball B will always fly off in the direction ABF. The pressure on B, which produces the impulsion, is evidently exerted at the point b of contact, and the direction BF is perpendicular to the plane GbH, touching both balls in the point b. The primary stroke is at a, and acts in the direction a A, although C moved in the direction C c. Had A been alone, it would have gone off in the direction a A produced. But the force acting in the direction a A is equivalent to the two forces $a d$ and d A, of which d A presses the ball on B at b, and produces the motion. In like manner, another ball E, so laid that b Be is obtuse, will fly off in the direction ED, which may even be opposite to C c. These are matters of fact; not indeed precisely so, because billiard balls are not perfectly elastic, restoring their figure with a promptitude equal to that of their compression; and also because there is a little friction, by which the point a of the ball A is dragged a little in the direction of C's motion. This may both give a twirl to A, and diminish its pressure on B. The general result, however, is abundantly agreeable to the doctrines now delivered. But we wish to shew on what properties of tangible matter this depends; and although we dare not hope for implicit belief, we expect some credit in what we shall offer.

Demonstration.

We have evident proof, that at a distance which is not unmeasureable by its minuteness, and certainly far exceeds the 900th part of an inch, bodies repel each other with very great force. This distance also far exceeds the distance between the particles, if these are discrete. Let $m n$ (fig. 3.) be the distance at which a particle repels another, and let P be a particle situated at a less distance than $m n$ from the surface AC of a solid body. With a radius PA, equal to $m n$, describe a segment of a sphere ABC, and draw PB perpendicular to AC. It is plain that every particle of matter in the segment ABC repels the particle P, and that it is not affected by any more. Let D be any such particle. It repels P in the direction DP. But there is another particle d similarly situated on the other side of PB. This will repel P with equal force in the direction dP. Therefore the two particles D and d will produce a joint repulsion in the direction BP. The like may be said of every particle and its corresponding one on the other side of PB. Therefore the joint repulsion of all the matter in the segment will have the direction BP. It is plain, that the radius of curvature of every sensible figure may be considered as immensely great in comparison of $m n$; and therefore the proposition is manifest.

This is a proposition of very great importance to the artist and the engineer, as well as to the philosopher. In all the connections of engines and machines, the mutual action is regulated by this fact. The mutual pressure at the contacts of the teeth of wheels and pinions depend so much on it, that it is easy to make them of such a shape that they shall produce no force whatever that is of any service; and it requires a skilled attention to their forms to obtain the service we want. This will be considered with some care in the article MACHINE.

Having thus discovered the *direction* of the real impulsion, and that it may be very different from that of the force exerted, we proceed to consider what will be the direction and velocity of the motion, and whether it will be accompanied with any rotation.

67
A stroke, whose action passes through the centre of a position of solid body, impels it without rotation.

Our readers are acquainted with the elementary mechanical property of the centre of gravity. If a body be supported at this point by a force acting vertically upwards, and equal to the united weight of every particle of matter in it, it will not only remain at rest, but will have no tendency to incline to either side; that is, the upward force balances the weight of the whole body, and the mechanical momenta of all the heavy particles balance each other, like the weights in the scales of a steelyard. That this may be the case, we know that if the weight of every particle be multiplied into the horizontal lever by which it hangs (which is a line drawn from the particle perpendicular to a vertical plane passing through the centre of gravity), the sum of all the products on one side must be equal to the sum of all the products on the other side. Therefore, if we suppose the particles all equal, and represent each by unity, the sums of all the perpendiculars themselves must be equal. How is this balancing effected? Every particle tends downwards with a certain force. It must therefore be kept up by a force *precisely* equal and opposite. This must be propagated to the particle by means of the connecting corpuscular forces. The force propagated to any particle is equal and opposite to the force acting on that particle, which it balanced; and if not balanced, it would produce a motion equal and opposite to that produced by the other force. Gravity would cause every particle to descend equally; therefore the force which, by acting on one point, excites those balancing forces on each particle, would cause them to move equally upwards. And since this is true in *any* attitude of the body, it follows, that a force acting in *any* direction through the centre of gravity, will cause all the particles to move in that direction equally; that is, without rotation.

Hence we learn, that when the direction of the stroke given to any body passes through the centre of gravity, the body will move in that direction without any rotation. If the quantity of matter, or number of equal particles in the body, be m, the moving power P will impress on each particle an accelerating force f, equal to the mth part of P. Therefore $f = \frac{P}{m}$, and $P = m f$. An accelerating force is estimated by the velocity v, which

Impulsion. which it generates by acting uniformly during some time t, or $v = f\,t$, and $f = \frac{v}{t}$, and $P = m\,\frac{v}{t}$, and $v = \frac{P}{m}t$. The symbol t may be omitted, if we reckon every force by the velocity which it can produce in a second. Thus may all forces be compared with gravity, by taking 32 feet for the measure of gravity. Then $m\,v$ will express the number of pounds which give a pressure equal to the force under consideration. Thus if the force can generate the velocity 48 feet per second in 100 pounds of matter, by acting on it uniformly during a second, its pressure is equal to the weight of 150 pounds.

This is *direct* IMPULSION. When a body A, moving with the velocity a, overtakes or meets a body B, moving with the velocity b, and the line perpendicular to their touching surfaces passes through the centres of both in the direction of their motion, all the circumstances of the collision are determined by the rules already laid down. This is called DIRECT IMPULSE; and it is this which admits the application of the simple doctrines of impulsion, deduced, as we have done it, from the action of accelerating forces. All that was said of the changes of motion produced in the magnets obtain here without any farther modification.

We may just be allowed to take notice of a curious observation of Mr Huyghens on the collision of perfectly elastic bodies. Instead of impelling the elastic ball C by the stroke of the elastic ball A, we may cause A to strike an intermediate ball B (also perfectly elastic), which is lying in contact with C. In many cases, the ball B will not stir sensibly from its place, and C alone will fly off. Nay, if a long row of equal billiard balls lie in contact, and one of the extreme balls be hit by another ball in the direction of the row, only the remote ball of the row will fly off. All this is easily seen and understood, by considering them as bodies mutually repelling, and placed at the limits of their mutual action. Or even supposing them elastic balls, at a very small distance from each other: The ball employed to strike the first comes to rest, and the striken ball moves off with its velocity: It strikes the second ball of the row, and is brought to rest: The second strikes the third, and is brought to rest: And this goes on in succession to the last, which is the only one that *can* fly off. The curious observation of Mr Huyghens is, that a greater velocity will be communicated by a large ball to a small one, if we employ the intermedium of another ball of a size between the two; and that the velocity will be the greatest possible when the intermediate ball is a mean proportional (geometrical) between the two. This is also easily deduced from the similar attention to the action of the accelerating forces, or from the supposition of successive impulses. From this it also follows that a greater velocity will be produced by the intervention of two, three, or more, mean proportionals.

68 Oblique IMPULSION. But the direction of the stroke may not be the same with that of the motion. This is called OBLIQUE IMPULSE. The cases of oblique collisions are extremely different, according to the directions of the motions; and the results are, in many of them, far from being obvious. But we have not room for a particular treatment of them. We shall therefore avail ourselves of some of the general facts mentioned above, by means of which we may reduce all the varieties to some easy cases. The most serviceable general facts are: 1. That the actions of bodies on each other depend on their relative motions; and, 2. That the motion of the common centre is not changed by the collision. These enable us to reduce all to the case of a body in motion striking another at rest. We have only to determine their relative motion by the proposition in DYNAMICS, n° 67. and then to superadd the common motion, which changes the relative into the true motions. Thus if two bodies A and B (fig. 4.) meet in D, describing the lines AD, BD, the collision is the same as if B had remained at rest, and A had come against it with the motion AB. In the mean time, the common centre of position has described CD. If the bodies are unelastic, they remain united, and proceed in the line CD produced toward E, and their common velocity will be represented by DE, equal to CD, if AD and BD represented their initial velocities. If the bodies are elastic, they separate again, and they separate from the common centre in the opposite direction, and with the same velocities with which they approached it. Therefore draw a E b parallel to ACB, and make E a, E b equal to CA and CB, and then D a and D b are the paths and velocities of the bodies. All this is abundantly plain, and is a necessary deduction from the general principle, that the motion of the centre is not affected by any equal and opposite forces which connect the bodies of a system.

69 Often accompanied by rotation. But this great simplicity is not sufficient for ascertaining the results of collision which occur in many of the most important cases. It not only supposes that AD and ED are exactly proportional to the velocities of A and B, but also that they meet, so that the plane of mutual contact is perpendicular to the line AB, and that the stroke on each is directed to its centre. These circumstances will not always be combined, even in the case of spherical bodies. The consequence will be, that although the motion of the centre remains the same, that of the bodies may sometimes be different. We must therefore give a general proposition, which will, with a little trouble, enable the reader to determine all the motions which can take place, whether progressive or rotative.

70 General theorem. Let the body A (fig. 5.), moving with the velocity V, in the direction AD, strike the body B at rest. Let F be the point of mutual contact, and bFH a plane touching both bodies in F. Draw AFP perpendicular to this tangent plane, and through G, the centre of position of B, draw PGC perpendicular to FP, and GI parallel to FP. Let C, in the line PG, be the spontaneous centre of conversion (ROTATION, *Encycl.* n° 77. &c.), corresponding to the point of percussion F. Join CF. Let the direction cut the tangent plane in H, and PF in A; and let AH represent the velocity V.

The impulse is made at the point F, in the direction AF or FP, and the centre of position of the body B will advance in the direction GI, parallel to FP, the direction of the effective impulse. But because this does not pass through the centre G, the body will advance, and will also turn round an axis passing through G, perpendicular to the plane of the lines GP, PF, and the spontaneous axis of conversion will pass through some

ſome point C of the line PG, and will alſo be perpendicular to the ſame plane. All this has been demonſtrated in the article ROTATION, n° 94, &c. Complete the parallelogram AFHE. It is plain, that the motion AH is equivalent to AE and AF. By the motion AE, A only ſlides along the ſurface of B without preſſing it, or cauſing any tendency to motion in that direction, except perhaps a little ariſing from friction. It is by the motion AF alone that the impulſe is made. Therefore let v be $= V \times \frac{AF}{AH}$; and then $A \times v$ may

71 Efficient velocity. be called the *efficient impulſe* of the body A in the preſent circumſtances, and v the *efficient velocity*. This will be diminiſhed by the colliſion. Let x be the unknown velocity remaining in A after the colliſion, or rather in the inſtant of the greateſt compreſſion and common motion of the touching points of A and B, eſtimated in the direction FP. The effective momentum loſt by A muſt therefore be $A \times \overline{v-x}$: but the ſame muſt be gained by B, and its centre G muſt move in the direction GI, parallel to FP, with this momentum; and therefore with the velocity $\frac{A \times \overline{v-x}}{B}$. That this may be the caſe, the point of percuſſion F muſt yield with the velocity x, becauſe the bodies are in contact. But becauſe C is the ſpontaneous axis of converſion, every particle is *beginning* to deſcribe an arch of a circle round this axis. Therefore F is beginning to move in the direction Fg, perpendicular to the momentary radius vector CF. Let Fg be a very minute arch, deſcribed in a moment of time. Draw gf perpendicular to FP. Then Ff is the motion Fg reduced to the direction FP, and will expreſs the yielding of B in the direction of the impulſe, while G deſcribes a ſpace equal to $\frac{A \times \overline{v-x}}{B}$, and A deſcribes a ſpace x. Therefore Fg will expreſs x. Let Pp be the ſpace deſcribed in the ſame time that Fg is deſcribed. Draw pC, cutting GK in the point I. GI is the yielding of the body B to the impulſe, and muſt therefore be equal to $\frac{A \times \overline{v-x}}{B}$.

The triangles Ffg and CPF are ſimilar; for the angle CFP is the complement of Ffg to a right angle: It is alſo the complement of PCF to a right angle. Therefore Fg : Ff = FC : CP. But Fg : Pp = FC : CP; becauſe the little arches Fg, Pp have the ſame angle at C. Therefore Pp = Ff, = x. It is plain, that CG : CP = GI : Pp. Therefore CG : CP $= \frac{A \times \overline{v-x}}{B} : x$, and $x = \frac{A \times \overline{v-x} \times CP}{B \times CG}$, or x $= v \times \frac{A \times CP}{B \times CG} - x \times \frac{A \times CP}{B \times CG}$; wherefore $x \times B \times CG + x \times A \times CP = v \times A \times CP$, and $x \times \overline{B \times CG + A \times CP} = v \times A \times CP$, and $x = v \times \frac{A \times CP}{B \times CG + A \times CP}$, = the velocity remaining in A, eſtimated in the direction FP.

72 Unelaſtic bodies may ſeparate. And u, the velocity with which G will advance, is $x \frac{CG}{CP}$; for CP : CG = Pp : GI, = x : u. It is evident that A will change its direction by the colliſion: For in the inſtant of greateſt compreſſion, it was acted on by a force $= A \times \overline{v-x}$ in the direction FA. This muſt be compounded with A×V, in the direction AH, in order to obtain the new motion of A; or it may be found by compounding x, which is retained by A, with FH, which has ſuffered no change by the colliſion. The bodies will therefore ſeparate, although they be unelaſtic: If they are elaſtic, we muſt double theſe changes on each. If B was alſo in motion before the colliſion, the motion of A muſt be reſolved into two, one of which is equal and parallel to the motion of B: the other muſt be employed as we have employed the motion AH.

Expreſſions ſtill more general may be obtained for x and u; namely, by taking the formulæ for the centres of converſion and percuſſion (ROTATION, n° 96, 99.)

$$CG = \frac{\int p r^2}{B \times GP}, \text{ and } CP = \frac{\int p r^2 + B \times CP^2}{B \times GP},$$

where p ſtands for a particle of matter, and r for its diſtance from an axis paſſing through G perpendicularly to the plain of the lines GP and PF. In this way we obtain $x = v \frac{A \cdot \int p r^2 + A \cdot B \cdot GP^2}{\overline{A+B} \cdot \int p r^2 + A \cdot B \cdot GP^2}$

73 Change of progreſſive motion greateſt when the direction of the effective ſtroke paſſes thro' the centres. It is plain from this propoſition, that the progreſſive motion of the body depends, not only on the momentum of the impelling body, but alſo on the place where the other is ſtruck: For even although the original momentum of A be the ſame, and the obliquity of the ſtroke, making v the ſame, and the body (and conſequently $\int p r^2$) alſo remain the ſame, we ſee that x and u depend on the ratio of CP to CG. Now C and P are always on oppoſite ſides of G: Conſequently, by removing the direction FP of the impulſion farther from G, we diminiſh CG and increaſe CP; and therefore increaſe the value of $x = v \frac{A \cdot CP}{B \cdot CG + A \cdot CP}$; and conſequently diminiſh the value of $A \times \overline{v-x}$, to which $B \times u$ is equal. The greateſt momentum of B is produced when the direction of the impulſe paſſes through G, and no rotation is produced. Indeed we are led, by a ſort of common ſenſe, to expect this.

74 Importance of this theory to ſeamanſhip, &c. This inveſtigation is by no means a piece of mere ſpeculative curioſity. It is the ſolution of the greateſt problem in practical mechanics. It is in this way that we muſt proceed in computing the actions of the wind and water on the ſails and hull of a ſhip. Were it not that many circumſtances concur in determining ſeveral of the preparatory ſteps, it is evident that the taſk muſt be almoſt impracticable. But the preſſure and its direction are generally determined by experiment, without the trouble of computation; and we are ſeldom ſolicitous about the ſubſequent motion of the wind or water.

75 Impulſion on bodies confined to particular paths. There is another queſtion in impulſion which is of the firſt practical importance—namely, when the impulſe is exerted on the parts of a machine, where the body ſtruck is not at liberty to yield freely to the ſtroke, but muſt ſlide along ſome ſolid path, or turn round ſome axis, or take ſome other conſtrained motion. The operations of moſt engines depend on this. The operation of wedges, axes, and many cutting and piercing inſtruments, and the penetration of piles, impelled

Fig. 1.

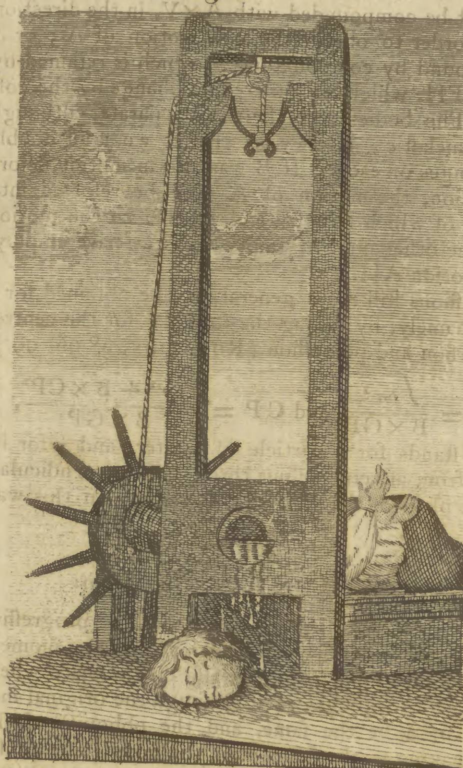

Fig. 2.

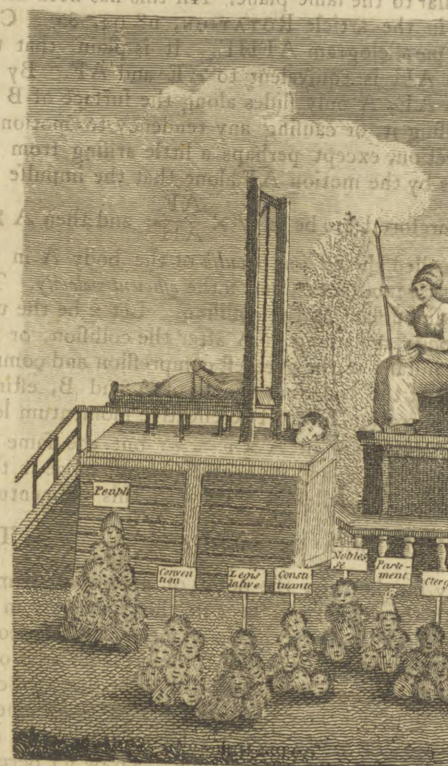

IMPULSION

Fig. 1.

Fig. 3.

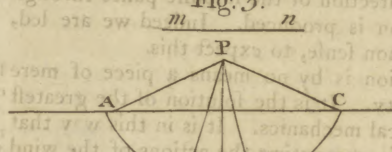

Fig. 5.

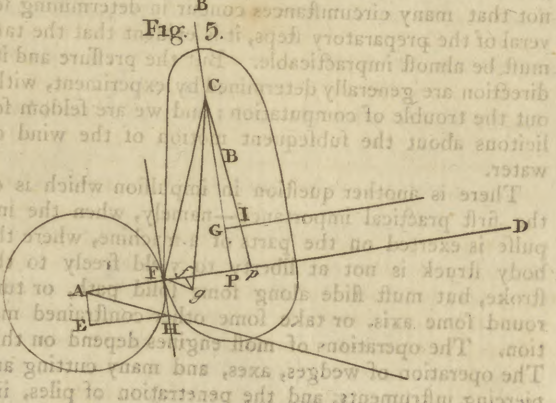

Fig. 2.

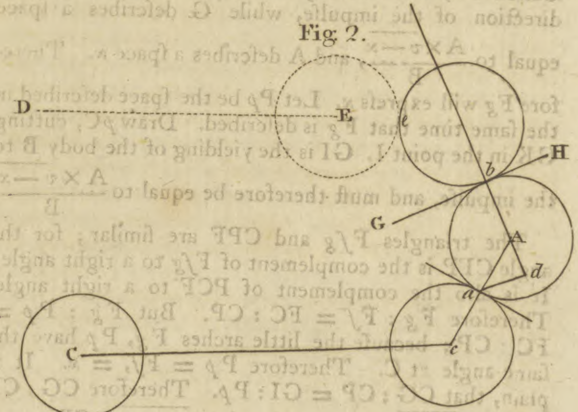

Fig. 4.

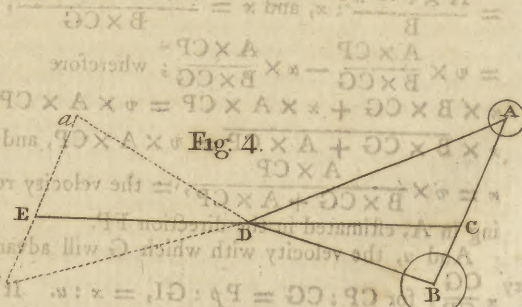

pelled by a rammer, are all ascertained by the same doctrines. But the particular applications can scarcely be elucidated by any classification that occurs to us, the circumstances of the case making such great difference in the result, both in kind and degree. For example, in the simplest case that occurs, the driving of piles, the penetration of the pile depends, in the first place, on the momentum of the rammer. If the mass of the pile be neglected, the penetration through a uniformly resisting substance will be as the square of the velocity of the rammer (DYNAMICS, *Suppl.* n° 95.), and its absolute quantity may be determined from a knowledge of the proportion of the weight of the rammer to the resistance of the earth. But when we consider that we have to put in motion the whole matter of the pile, we learn that a great diminution of the effect must take place. We still can compute what this must be, because we have the same momentum, with a velocity diminished in a certain proportion of the sum of the matter in the rammer and pile, to that in the rammer alone.—Another defalcation arises from friction, which continually increases as the pile goes deeper;—and a still greater defalcation proceeds from the nature of the pile. If it is a piece of very dry straight grained fir, it is very elastic, and acquires almost a double velocity from the stroke of a rammer of cast iron. If it is moist and soft, especially if it is oak, or other timber of an undulated fibre, it does not acquire so great velocity, and the penetration is very much diminished. It is probable that a pile, headed with moist cork, could not be driven at all. The writer of this article found a remarkable effect of the elasticity in the process of boring limestone. When the boring bit was made entirely of steel, and tempered through its whole length to a hard spring temper, the workman bored three inches, in the same time that another bored two inches with a bit made of soft iron; and he would never use any but steel bits, if they could be hindered from chipping by the hammer (which must also be of tempered steel throughout). This has hitherto baffled many attempts. A pretty large round head, like a marlin spike, has succeeded best: but even this cracks after some days use. The improvement is richly worth attention; for the workman is delighted by feeling the hammer rise in his hand after every stroke, and says that the work is not so hard by half. *N. B.* The stone cutters at Lisbon and Oporto use iron mallets.

76 **Impulsion on machines.**

The case of impulsion made on part of a machine moveable round an axis has been considered in the article ROTATION, *Encycl.* n° 72; where x is shewn to be $= v \times \frac{A \cdot CP^2}{\int p r^2 + A \cdot CP^2}$. But, in this formula, r denotes the distance of p from the point C, and not from G. $\int p r^2$ in this formula, is $B \cdot CG \cdot CP$; whereas, in the formula for a free body, where r is the distance of a particle from G, $\int p r^2$ is $= B \cdot CG \cdot GP$.

In the practical consideration of this question, the reader will do well to consider the whole of that article with attention. Many circumstances occur, which make a proper choice of the point of impulse, and the direction of the tangent plane, of the greatest consequence to the good performance of the machine; and there is nothing in which the scientific knowledge of the engineer is of more essential service to him. An engineer of great practice, and a sagacious combining mind, collects his general observations, and stores them up as rules of future practice. But it is seldom that he possesses them with that distinctness and confidence that can enable him to communicate his knowledge to others, or even secure himself against all mistakes; whereas a moderate acquaintance with these *elements* of real mechanics, may be applied with safety on all occasions, because arithmetical computations, when rightly made, afford the most certain of all results.

77 **Great loss of power by the yielding and bending of the materials.**

There is a circumstance which greatly affects the performance of machines which are actuated by impulses, namely, the yielding and bending of the parts. When the moving power acts by repeated small impulsions, it may sometimes be entirely consumed, without producing any effect whatever at the remote working point of the machine; and the engineer, who founds his constructions on the elementary theories to be had in most treatises of mechanics, will often be miserably disappointed. In the usual theories, even as delivered by writers of eminence, it is asserted, that the smallest impulse will start the greatest weight. But since impulse is only a continued pressure, and requires time for the transmission of its effect through the parts of a yielding solid, it is plain that the motion of the impelling body may be extinguished before it has produced compression enough for exciting the forces which are to raise the remote parts of a heavy body from the ground. What blow with a hammer could start a feather bed? Much oftener may we expect, that a blow, given to one arm of a long lever, will be consumed in bending the whole of its length, so as to bring the remote end into action. Therefore great stiffness, and perfect elasticity, both in the moving parts and in the points of support, are necessary for transmitting the full, or even a considerable part, of the power of the impelling body. Perhaps not the half of the blow given by the wipers of a great forge or tilting mill to the shank of the hammer is transmitted in the *proper* instant of time to the hammer-head. The hammer, while it is tossed up by the blow, is quivering as it flies. Should it reach the spring above it in the time of its downward vibration, it will not be returned with such force as if it had hit the spring a moment before or after. A quarter of an inch will produce a great effect in such cases. It is found, that the minute impulses given to the pallets of a clock or watch lose much of their force by the imperfect elasticity of the pendulum or balance. We must therefore make all the parts which transmit the blow to the regulating mass of matter as continuous, hard, elastic, and stiff, as possible. The performance of ruby pallets is very sensibly weakened by putting oil on the face of them, especially in the detached scapements, which act partly by impulse. A wheel of hard tempered steel, working on a dry ruby pallet, excels all others. The intelligent engineer, seeing that, after all his care, much impulsion is unavoidably lost, will avoid employing a first mover which acts in a subsultory manner, and will substitute one of continued pressure when it is in his power. This is one chief cause of the great superiority of overshot water wheels above the undershot.

We can now understand how it happens that Galileo, Mersennus, and others, could compare the impulse given

Impulsion. given by a falling body with the pressure of a weight in the opposite scale of a balance, and can see the reason of the immense differences, yet accompanied by a sort of regularity, in the results of the experiments. Galileo, Mersennus, and Riccioli, found them to be proofs that the forces of moving bodies are as their velocities; because the heights from which the body fell were as the squares of the weights started from the ground. Gravesande found the same thing as long as he held the same opinion; but when he adopted the Leibnitzian measure, he found many faults in the apparatus employed in his former illustrations, and altered it, till he obtained results agreeable to his new creed. But any one who examines with attention all that passes in the bending of the apparatus, and takes into account the mass of matter which must be displaced before the opposite arm rises so far as to detach the spring which gives indication of the magnitude of the stroke, must see that the agreement is purely accidental, and may be procured for any theory we please (see *Gravesande's Nat. Phil.* translated by Desaguiliers, vol. i. p. 241. &c.) The proposition, n° 95, DYNAMICS, suffices for explaining every thing that can happen in such experiments. And it will shew us, that although the motion of impulsion is produced by pressure alone, yet impulse is incomparable with mere pressure: It is not infinitely greater, but disparate. A weight (which is a pressure) bends a spring to a certain degree, and will derange to a certain degree the fibres of a body on which it presses, before it be balanced. The same weight, falling on this spring from the *smallest* height, will bend it farther, and may crush or shiver to pieces the body which would have carried it for ever. We shall make some further remarks on this subject, of great practical importance, under the word PERCUSSION.

78 Conclusion. THE method which we have pursued in considering the doctrines of impulsion, differs considerably from that which has generally been followed; but we trust that it will not be found the less instructive. Although the reader should not adopt our decided opinion, that we have no proof of pure impulsion ever being observed, and that all the phenomena which go by that name are really the effects of pressures, analogous to gravity, he perceives that our opinion does not lead to any general laws of impulsion that are different from those which are acknowledged by all. We differ only, by exhibiting the internal procedure by which they are *unquestionably* produced in a vast number of cases, and which takes place in all that we have seen, in some degree. Our method has undoubtedly this advantage, that it requires no principle but one, namely, that accelerating forces are to be estimated by the acceleration which they produce. Even this may be considered, not as a principle, but merely as a definition—We get rid of all the obscurity and perplexity that result from the introduction of inertia, considered as a power—a power of doing nothing; and we are freed from the unphilosophical fiction (adopted by all the abettors of that doctrine, and even by many others) of conceiving the space, in which motions are performed, and bodies act, to be carried along with the bodies in it.—This furnishes, indeed, in some cases, a familiar way of conceiving the thing, by supposing the experiments to be made in a ship under sail, and by appealing to the fact, that all our experiments are made on the surface of a globe that is moving with a very great velocity. But it is an absurdity in philosophy, and, when minutely or argumentatively used, it does not free us from one complication of action; for, before we can make use of this substitution, we must demonstrate, that the actions depend on the relative motions only: And this, when demonstrated, *obliges* us to measure forces by the velocity which they produce.

As no part of mechanical philosophy has been so much debated about as impulsion, it will surely be agreeable to our readers to have a notice of the different treatises which have been published on the subject:

Hermanni Phoronomia. Amst. 1716.

Discours sur les Loix de la Communication de Mouvement, par Jean Bernoulli, Paris, 1727. Jo. Bern. Oper. III.

Dynamique de D'Alembert.

Euleri Theoria Corporum solidorum seu rigidorum, 1765.

Borelli (Alphons) de Percussione.

See also M'Laurin's Fluxions, and his Account of Newton's Philosophy, for his Dissertation crowned by the Acad. des Sciences at Paris.—Also Dr Jurin's elaborate dissertations in the Phil. Transf. N° 479.—Also Gravesande's Nat. Philosophy, where there is a most laborious collection of experiments and reasonings; all of which receive a complete explanation by the 39th Prop. Princip. Neutoni I. or our n° 95. DYNAMICS. There are also many very acute philosophical observations in *Lambert's Gedanken über die Grundlehren des Gleichgewichts, und der Bewegung.* in the second part of his Gebrauch der Mathematik.—Also, in the works of Kaestner, Hamberger, and Busch. Muschenbroeck also treats the subject at great length, but not very judiciously. We do not know any work which treats it with such perspicuous brevity as M'Laurin's Account of Newton's Philosophy.

END OF THE FIRST VOLUME.

DIRECTIONS FOR PLACING THE PLATES.
