divide beings into those which are solid and extended, and those which have life or internal energy. Those beings which have life or internal energy he would again divide into such as act with consciousness, and such as act without it: the latter of which is this plastic life of nature. To prove that such an instrument is possible, or that a being may be capable of operating for ends of which it knows nothing, he instances *bees* and other animals, who are impelled by *instinct* to do many things necessary to their own preservation, without having the least notion of the purpose for which they work. (See INSTINCT). He observes, that there is an essential difference between reason and instinct, though they are both the attributes of mind or incorporeal substance: and that therefore, as we know of two kinds of mind differing so widely, there is nothing to hinder us from inferring a third, with powers differing as much from instinct as instinct differs from reason. Mankind are *conscious* of their own operations, *know* for what *purpose* they generally act, and can by the power of *reflection* take a *retrospective* view of their actions and thoughts, making as it were the mind its own object. Brutes are *conscious* of their own operations, but they are ignorant of the *purposes* for which they operate, and altogether *incapable* of *reflecting* either upon their past conduct or past thoughts. Between their intellectual powers and those of man, there is a much greater difference than there is between them and a plastic nature, which acts as an instrument of Divine Wisdom without any consciousness of its own operations. Aristotle, from whom principally the learned author takes his notion of this plastic nature, compares it, with respect to the Divine Wisdom which directs and superintends its operations, to a mere builder or mechanic working under an architect, for a purpose of which the mechanic himself knows nothing. The words of the Stagyrite are: *Τους αρχιτεκτονας περι ἑκαστον τιμιωτερους και μαλλον ειδεναι νομιζομεν των χειροτεχνων, και σοφωτερους ὁτι τας αιτιας των ποιουμενων ισασιν οἱ δ' ὡσπερ και των αψυχων ενια, ποιει μεν, ουκ ειδοτα δε ποιει, ὁιον καιει το πυρ· τα μεν ουν αψυχα φυσει τινι ποιειν τουτων ἑκαστον τους δε χειροτεχνας δι εθος* †. "We account the architects in every thing more honourable than the mere workmen, because they understand the reason of the things done; whereas the other, as some inanimate things, only work, not knowing what they do, just as the fire burns: the difference between them being only this, that inanimate things act by a certain nature in them, but the workman by habit."

† leta- ys. lib. i.). i.

200 wn to possible.

Still further to prove that a being may be endowed with some vital energy of a subordinate kind, and yet be destitute of consciousness and perception, the learned author observes, that there is no reason to think that the souls of men in sound sleep, lethargies, or apoplexies, are conscious of any thing; and still less, if possible, to suppose that the souls of embryos in the womb are from the very first moment of their arrival there intelligent and conscious beings: neither can we say, how we come to be so differently affected in our souls by the different motions made upon our bodies, nor are we conscious always of those energies by which we impress fantastic ideas on the imagination. But if it be possible for the souls of men to be for one instant void of consciousness and intelligence, it follows, that consciousness is not absolutely necessary to those energies and motions by which life is preserved. To this it may be added, upon the best authority †, "that where animal or vegetable life is concerned, there is in every case a different relation between the cause and effect, and seemingly depending upon the concurrence or influence of some farther principle of change in the subject, than what subsists in inanimate matter, or in the causes and effects that are the objects of mechanical and chemical philosophy." Now to this principle of vegetable life, without which, in a seed or in a plant, vegetation will neither begin nor continue, though light, heat, air, earth, and water, should concur in the utmost perfection, Cudworth expressly compares his plastic nature in the universe. It is so far (says he) from being the first or highest life, that it is indeed the last and lowest of all lives, being really the same thing with the vegetative.

† *Gregory's Philosophical and Literary Essays.*

201 Arguments for its truth: but

These arguments, if the phenomena of elective attractions in chemistry be added to them, demonstrate, we think, the *possibility* of such a principle: and to those who are inclined to affirm that no such thing can exist, because, according to the description of it given by Cudworth and the ancients, it is neither body nor spirit in the proper sense of the words; we beg leave to ask, in the words of Locke, "who told them that there is and can be nothing but solid beings which cannot think, and thinking beings that are not extended? which is all that they mean by the terms body and spirit." All the Greek philosophers who were not materialists, and even the inspired writers of the Old and New Testaments, constantly distinguish between the *spirit* and the *soul* of a man, calling the former sometimes *νους*, and sometimes *πνευμα*, and the latter *ψυχη*; and St Paul, who before he was a Christian, was learned in philosophy, describes the constituent parts of man as three, *πνευμα*, *ψυχη*, *σωμα*, *spirit*, *soul*, and *body*. This distinction, setting aside the *authority* with which it comes to us, seems to be well founded; for there are many operations carried on in the human body without any conscious exertion of ours, and which yet cannot be accounted for by the laws of mechanism. Of these, Cudworth instances the motion of the diaphragm and other muscles which cause respiration, and the systole and diastole of the heart; neither of which, he thinks, can be the effect of mere mechanism. But, as we are not conscious of any energy of soul from which they proceed, even while we are awake, and still less, if possible, while we are asleep; he attributes them, not to the intellect or rational mind, but to this inferior vital principle called *ψυχη* (v); which, in his opinion, acts the

(v) The existence of this plastic nature was warmly debated between Monsieur Le Clerc and Monsieur Bayle. Mosheim, who was inclined himself to admit such a principle, gives the following view of Le Clerc's sentiments from *Bibliotheque Choisie*, tom. ii. p. 113. "Respiratio, inquit, et motus cordis, actiones sunt, quorum nihil ad animam pertinet. Interim mechanice eas fieri, nullo modo probabile est. In voluntariis

Of Motion.

the same part in the system of the human body which the plastic nature acts in the system of the world.—To make the resemblance more striking, he observes, that even the voluntary motion of our limbs, though it proceeds ultimately from an energy of will, seems to be the effect of that energy employing some *instrument* which pervades the sinews, nerves, and muscles of the body; and if the human spirit or πνευμα employ the instrumentality of a plastic nature or ψυχη in moving the small machine of the body, it seems to be far from incredible that the Divine Wisdom should employ the instrumentality of a plastic nature in moving the great machine of the universe.

202 Whether it be true or not, the motions of the heavenly bodies are carried on by the constant agency of something incorporeal.

But we need not insist further on the *possibility* of such an instrument. Whatever may be thought of the arguments of Cudworth, of which some are, to say the least of them, plausible, though others appear to us to have very little strength, Dr Clarke has proved, with a force of reasoning not inferior to mathematical demonstration, that the motions of the heavenly bodies are carried on by the agency of something very different from matter, under every possible form. "For, not to say that, seeing matter is utterly incapable of obeying any *laws* in the proper sense of the word, the very original laws of motion themselves cannot continue to take place, but by something superior to matter, *continually* exerting on it a certain force or power according to such certain and determined laws: it is now evident beyond question, that the bodies of all *plants* and *animals* could not possibly have been formed by mere matter according to any general laws of motion. And not only so, but that most universal principle of *gravitation* itself, the spring of almost all the great and regular inanimate motions in the world, answering not at all the *surfaces* of bodies, by which alone they can act upon one another, but entirely to their *solid contents*, cannot possibly be the result of any motion originally impressed upon matter." For though it is true, that the most solid bodies with which we are acquainted are all very porous; and that, therefore a subtile material fluid might penetrate the bodies of the planets, and operate upon them with a force exerted internally; still it is self-evident, that the *greatest* quantities of such a fluid could not enter into those bodies which are *least* porous, and where the greatest force of *gravitation* resides: "and, therefore, this motion must of necessity be caused by something which penetrates the very *solid substance* of all bodies, and continually puts forth in them a force or power entirely different from that by which matter acts upon matter *." Which is, as the same able writer observes, an evident demonstration, not only of the world's being originally made by a supreme intelligent Cause; but moreover, that it depends every moment upon some superior Being, for the preservation of its frame; and that all the great motions in it are caused by some immaterial power *perpetually* and *actually* exerting itself every moment in every part of the corporeal universe. This preserving and governing power, whether it be the immediate power and action of the same Supreme Cause that created the world, or the action of some subordinate instruments appointed by him to direct and preside respectively over certain parts thereof, gives us equally in either way a very noble idea of Providence. We know with certainty, that *real* and *original power* can belong only to a being endowed with intelligence and will; and, therefore, if the existence of Cudworth's (W) plastic nature be admitted, (and we see not why it should be called

tariis commotionibus nesciunt animi nostri, quid facto opus sit, ut membra commoveantur: imperant illi tantum. Est vero aliud nescio quid, quod fideliter, si modo organa recte sint affecta, mandata ejus exsequitur. Quidni igitur suspicemur, esse *naturam* in corpore nostro *viventem*, præter animam nostram, cujus sit animæ præceptis et jussis morem gerere? quamquam potentia ejus ita sit definita, ut obedire nequeat animo, nisi recte sese habeant organa. Eadem forte natura, corporis nostri motibus impulsa, animam edocet, quid factum sit, ut ille possit præcipere, quæ ad conservationem corporis necessaria judicat. Anima, pergit, sit hæc vera esse putes, similis erit domino, sibimet ipsi servire nescio, nec ulla facultate alia, quam imperandi et jubendi instructo. Hæc vero natura fictrix non dissimilis erit mancipii cui nihil eorum, quæ dominus meditatur, notum est, quodque nihil aliud facit, quam ut jussis pareat, et dominum de illis rebus admoneat, quæ ad salutem ipsius pertinent." Mosheim proceeds,—Si quis huic loco sic occurrat, Hæc ratione tria fingi in homine principia; respondet vir doctus: "Nullis constares argumentis, binis tantum hominem partibus constare. Eos, qui hominem ex binis tantum partibus component, nulla ratione explicare posse naturam conjunctionis animi et corporis, nisi ipsum Deum statuant cunctis actionibus hominum intervenire: hoc vero Divina Majestate prorsus indignum esse. Definitionem accuratam mediæ hujus naturæ postulantibus sese talem dare non posse definitionem respondet: Hoc unum sese scire: esse eam naturam interiori agendi virtute instructam, quæ ex se et animam et corpus afficere queat; naturam, quæ doceat animam quid rerum geratur in corpore; naturam denique, quæ animi mandatis, quorum tamen caussas nesciat, fideliter obtemperet." Reliqua, quæ illustrandæ hujus rei caussa Clericus affert, prætereo. Satis copiosa est in illis, quæ produximus, meditandi materia. *Mosheim. ed. Syst. Intellect.* p. 173.

Such a principle actuating the universe, if it be divested of intelligence, and considered as a second or inferior cause, under the direction of the Supreme, is acknowledged by a very able judge to be a rational hypothesis; and such, if properly pursued, would certainly open a most entertaining scene of natural philosophy.—See *Jones's Answer to an Essay on Spirit.*

(W) Besides Cudworth, we have mentioned Berkeley and the author of *Ancient Metaphysics*, as holding all motion to be an effect of the immediate agency of mind or incorporeal substance. The opinion of the last of these philosophers is not essentially different from Cudworth's; and therefore it is needless to quote from him: Berkeley was better acquainted with the principles of the Newtonian philosophy, as well as an abler mathematician,

Of Motion.

called in (X) question), it can be considered only as an instrument employed by Divine Wisdom, as a chissel or a saw is employed by the wisdom of the mechanic.

203 [This] theory [is no]t inconsistent with [th]e principles of [N]ewton.

Nor let it be imagined, that this ancient theory of motion is in any degree inconsistent with the mathematical principles of Sir Isaac Newton's astronomy, or with the calculations raised from those principles. Having founded his astronomy on analogy between the phenomena of projectile and planetary motions, he assigned the same or similar *forces* existing in nature as the efficient causes of both. And indeed, both in the act of deriving his *principles* from the projectile phenomena, and afterwards for the purpose of applying them to the planetary, it was necessary to analyze the elliptical motion of the heavenly bodies into a compound of two simple motions in right lines, produced by the action of these different forces; and this might also be useful for the purposes of teaching and demonstration, just as we find it necessary, in all parts of science, to separate what in nature is inseparable, for the convenience and assistance of the understanding. The planetary motions, however, are very probably simple and uncompounded, for no experiments can be tried in those distant regions; and the astronomy of Newton, which is only the application of his mathematical principles to their mensuration from their *analogy* to projectile motions, does not at all require that the forces of gravition and projection be assigned as their real existent causes (Y). It is sufficient for the

4 L 2 *analogy*

---

matician, than either of these pupils of the ancients; and being likewise a man who on all subjects thought for himself, it may be worth while to lay before our readers a short abstract of his reasoning respecting the origin of motion. His words are: "Totum id quod novimus, cui nomen *corpus* indidimus, nihil in se continet quod motus principium seu causa efficiens esse possit. *Vis*, *gravitas*, *attractio*, et hujusmodi voces, utiles sunt ad ratiocinia et computationes de motu et corporibus motis; sed non ad intelligendam simplicem ipsius motus naturam, vel ad qualitates totidem distinctas designandas. Attractionem certe quod attinet, patet illam ab Newtono adhiberi, non tanquam qualitatem veram et physicam, sed solummodo ut hypothesin mathematicam. Quin et Leibnitius, nisum elementarem seu solicitationem ab impetu distinguens, fatetur illa entia non re ipsa inveniri in rerum natura, sed abstractione facienda esse. Similis ratio est compositionis et resolutionis virium quarumcunque directarum in quascunque obliquas, per diagonalem et latere parallelogrammi. Hæc mechanices et computationi inserviunt: sed aliud est computationi et demonstrationibus mathematicis inservire, aliud rerum naturam exhibere. Revera corpus æque perseverat in utrovis statu, vel motus vel quietis. Ista vero perseverantia non magis dicenda est actio corporis, quam existentia ejusdem actio diceretur. Cæterum resistentiam quam experimur in sistendo corpore moto, ejus actionem esse fingimus vana specie delusi. Revera enim ista resistentia quam sentimus, passio est in nobis, neque arguit corpus agere, sed nos pati: constat utique nos idem passuros fuisse, sive corpus illud a se moveatur, sive ab alio principio impellatur. Actio et reactio dicuntur esse in corporibus; nec incommode ad demonstrationes mechanicas. Sed cavendum, ne propterea supponamus virtutem aliquam realem, quæ motus causa sive principium sit, esse in iis. Etenim voces illæ eodem modo intelligendæ sunt ac vox *attractio*; et quemadmodum hac est hypothesis solummodo mathematica non autem qualitas physica; idem etiam de illis intelligi debet, et ob eandem rationem.

"Auferantur ex idea corporis extensio, soliditas, figura, remanebit nihil. Sed qualitates istæ sunt ad motum indifferentes, nec in se quidquam habent, quod motus principium dicit possit. Hoc ex ipsis ideis nostris perspicuum est. Si igitur voce *corpus* significatur id quod concipimus, plane constat inde non peti posse principium motus: pars scilicet nulla aut attributum illis causa efficiens vera est, quæ motum producat. Vocem autem proferre, et nihili concipere, id demum indignum esset philosopho.

"Præter res corporeas, alterum est genus rerum cogitantium: in iis autem potentiam inesse corpora movendi, propria experientia didicimus, quando quidem anima nostra pro lubitu possit ciere et sistere membrorum motus, quacunque tandem ratione id fiat. Hoc certe constat, corpora moveri ad nutum animæ, eamque proinde haud inepte dici posse principium motus; particulare quidem et subordinatum, quodque ipsum dependeat, a primo et universali principio.

"Ex dictis manifestum est eos qui vim activam, actionem motus principium, in corporibus revera inesse affirmant, sententiam nulla experientia fundatam amplecti, eamque terminis obscuris et generalibus adstruere nec quid sibi velint satis intelligere. E contrario, qui mentem esse principium motus volunt, sententiam propria experientia munitam preferunt, hominumque omni ævo doctissimorum suffragiis comprobatam.

"Primus Anaxagoras τον νουν introduxit, qui motum inerti materiæ imprimeret: quam quidem sententiam probat etiam Aristoteles, pluribusque confirmat, aperte pronuncians primum movens esse immobile, indivisibile, et nullum habens magnitudinem. Dicere autem, omne motivum esse mobile, recte animadvertit idem esse ac siquis dicerit, omne ædificativum esse ædificabile. Plato insuper in Timæo tradit machinam hanc corpoream, seu mundum visibilem, agitari et animari a mente, quæ sensum omnem fugiat. Et Newtonus passim nec obscure inuit, non solummodo motum ab initio a Numine profectum esse, verum adhuc systema mundanum ab eodem actu moveri. Hoc sacris literis consonum est: hoc scholasticorum calcula comprobatur."

De Motu, passim.

(X) This we say upon the received opinion, that there are things wholly incorporeal. The truth of the opinion itself will be considered in a subsequent chapter.

(Y) Indeed Sir Isaac himself is very far from positively assigning them as the *real* causes of the phenomena. The purpose for which they were introduced into his philosophy he clearly explains in the following words: "Eadem ratione qua projectile vi gravitatis in orbem flecti posset et terram totam circumire, potest et luna,

ve

Of Number.

analogy, on which the whole philosophy is founded, that the phenomena of motion are known from experiments and observations to be the *same* in *both* instances; that the *principles* or *general laws* mathematically established from the *forces* of the *one* are transferred to the *phenomena* of the *other*; and that the proofs and operations deduced from these principles in the latter case, are confirmed by *facts* and *experience*, the first and final test of truth *.

* *Tatham's Chart and Scale of Truth.*

Chap. VI. *Of* Number.

204 Unity, as an idea, cannot be abstracted from every individual.

"Amongst all the ideas that we have, as there is none (says Mr Locke†) suggested to the mind by more ways, so there is none more simple, than that of unity or *one*. It has no shadow of variety or composition in it. Every object our senses are employed about, every idea in our understandings, every thought of our minds, brings this idea along with it: and therefore it is the most intimate to our thoughts, as well as it is, in its agreement to all other things, the most universal idea we have; or number applies itself to men, angels, actions, thoughts, every thing that either doth exist or can be imagined." He seems likewise to be of opinion that we have the idea of *unity* before that of *many*; and that it is by repeating the simple idea of unity in our own minds that we come by the *complex ideas* of *two*, *three*, &c. In this opinion he is joined by Pere Buffier *; who observes that it is impossible to explain the nature of *unity*, because it is the most simple idea, and that which perhaps *first* occurred to the mind.

† *Essay*, book ii. chap. xvi.

* *First Truths.*

205 That *unity* is a simple idea, must be granted; but it certainly did not first occur to the mind, nor can it be abstracted from all individuals, and apprehended in Locke's sense of the word as a *general idea*. Let any man look into his own mind, and then say whether he has a general idea of *one* or *unity* as abstracted from every individual object mental and corporeal. In particular, when he thinks he has completely abstracted it from body and mind, sensations, ideas, actions, and passions, &c. let him be sure, before he pronounce it a general *abstract* idea, that he is not all the while contemplating the idea of its *name*, or of that numerical *figure*, by which it is marked in the operations of arithmetic. Both these ideas are in themselves particular; and become general in their import, only as representing every individual object to which unity is in any sense applicable. But in the chapter *of Abstraction*, we have said enough to convince every person capable of conviction that they are used as signs for whole classes of objets.

Instead of being an abstract general idea, *unity*, as the basis of number, is in fact nothing but a mere *relation*, which cannot be conceived without the related objects; and so far is it from being the *first* idea that occurred to the mind, that it is certainly the result of a comparison, made by the intellect, of two or more objects. The ideas which first occur to the mind are, beyond all doubt, those which are called *ideas of sensation*; and many such ideas every child receives before he is capable of comparing objects and forming to himself notions of number. *Unity*, or the idea of *one*, is indeed the element of the science of *arithmetic*, just as a mathematical *point* is the element of the science of *geometry*; but accurate notions of these elements are, in the progress of knowledge, subsequent to ideas of *many* and of *surfaces*. There is reason to believe that persons totally illiterate have no notion at all of *mathematical points*; and we think it possible to conceive an intelligent and conscious being in such a situation as that he could not acquire a notion of *unity* or *one*. Were a child never to see or feel two objects of the *same kind*, we doubt if he would think of numbering them, or of making such a comparison of the one with the other as would suggest to his mind the relations of *one* and *two*; for these relations imply both a sameness and a difference of the objects beyond the power of a child to ascertain. The difference indeed would be perceptible to the senses, but the senses would perceive no sameness or agreement. A guinea, a shilling, and a ball of lead, impress upon the mind different sensations; and therefore a child undoubtedly distinguishes these objects from one another: but what could make him derive from this his first idea of the relation of number? A guinea, a shilling, and a ball of lead, are not *one*, *two*, *three*, in any sense which a child can comprehend. To be convinced of this, let any man throw a guinea, a shilling, and a ball of lead upon a table, and ask a *clown* what is their number. From being accustomed to retail the *names* of number as signs, without affixing to them any idea of the things signified, he will probably answer with quickness *three*, or perhaps *one*, *two*, *three*: but if he be further asked in what *respect* they are *one*, *two*, *three*, we believe his answer will not be so ready: They are not *one*, *two*, *three guineas*, or *shillings*, or *balls of lead*. A philosopher knows them to be three pieces of the same first matter under different forms, and can therefore apply to them the relation of number with truth and propriety; but of the first matter a *clown* is entirely ignorant, and of course cannot call them *one*, *two*, *three*, in any sense which is at once true and to him intelligible.

208 Unity, a particular relation.

To make it still more evident, that it is only by comparing together things of the *same kind* that our *first* ideas of unity and number are formed, let us suppose no created being to have hitherto existed except the animated and intelligent globe mentioned in the last chapter, and we think it will be granted that such a being in solitude could never acquire the idea of *unity*. Let

---

vel vi gravitatis, *si modo gravis sit*, vel alia quacunque vi qua in terram urgeatur, retrahi semper a cursu rectilineo terram versus et in orbem suum flecti: et absque tali vi luna in orbe suo retineri non potest. Hæc vis, si *justo minor* esset, non satis flecteret lunam a cursu rectilineo: si *justo major*, plus satis flecteret, ac de orbe terram versus deduceret. Requiritur quippe ut sit *justæ magnitudinis*: et mathematicorum est invenire vim, qua corpus in dato quovis orbe data cum velocitate accurate retineri possit; et vicissim invenire viam curvilineam, in quam corpus e dato quovis loco data cum velocitate egressum data vi flectatur."——*Principia Mathem.* Def. V.

Of [Num]ber.

Let us next suppose a *cubical* body to be created and exhibited to the senses of this spherical man; the consequence would be a *sensation* or feeling entirely new: but that feeling would not be of *unity*; for, as the author of *Ancient Metaphysics* has somewhere well observed, unity is no object of sensation. The sensation would be of colour, hardness, softness, roughness or smoothness, &c. for beyond these the empire of the senses does not reach. Again, Let another body be created of a colour and figure totally different from the colour and figure of the cube, and the spherical man would then experience new sensations having no agreement with those which he had formerly felt. These different kinds of sensations might be compared together; but the result of the comparison would not be the ideas which are denoted by the words *one* and *two*, but merely that which is expressed by *difference* or *dissimilarity*. Were another cube, however, of exactly the same size and colour with the former to be brought into existence, and both to be at once presented to the view of the spherical man, the rudiments of the idea of number would then be generated in his mind, because he could not but perceive the cubes to be in one respect different and in another the same; different as being distinct from each other, and agreeing in their effects upon the organs of sensation.

[20]7 must made pro- in ing s ac- ng to ra and es be- they ired notion umber.

It appears, therefore, that mankind must have made some progress in classing things according to their genera and species, before they acquired any correct ideas of the relation of number, or thought of using numerical names or figures as general and discriminating signs: for we say *one*, *two*, *three*, &c. only with respect to the species or genus of which each of the things denoted by these numbers is an individual; and if there be any thing which has no genus or species, neither number nor unity can, in the original sense of the words, be predicated of it (z). We say indeed, that there is *one* God; but perhaps we do not always attend to the meaning of the expression. Language was formed to answer the common purposes of life; and those purposes are best answered by denoting individuals by the name of the species or genus to which they belong: but *God* belongs to no species or genus, unless he be said improperly (A) to be of the universal genus of *Being*; and therefore, the true meaning of the word *one*, when joined to the verb *is*, and transferred from the creature to the Creator, in such a sentence as—"there *is one* God"—seems to be nothing more than an affirmation that God exists, and that to him the relation of number cannot be applied. In a word, *unity* and *number* are merely relations between the individuals of the same species or genus of being; and men acquire ideas of these relations at the same time and by the same means that they are led to class things into species and genera. As to the processes of addition and subtraction, and the various purposes to which number is applied, these things belong to the science of arithmetic, and fall not under the province of the metaphysician, whose sole object is to ascertain the real nature and causes of things. It may, however, be worth while to observe, that Locke, whose notions of number seem to have been different from ours, owns, that a man can hardly have any ideas of numbers of which his language does not furnish him with names. But if units were either real things, or even positive ideas, we see not how *names* could be necessary to their existence; whereas, if they be nothing more than mere relations, it is obvious that they cannot be conceived but as relative either to beings actually existing, or to names which are the signs of actual beings.

Chap. VII. *Of* Time.

208 Time, a mode of duration in contradistinction to eternity.

When St Augustine was asked what time is? he replied, "*Si non roges, intelligo.*" An answer from which it may be inferred, that he thought the nature of *time* could not be explained by a logical definition. *Time* and *eternity* are commonly considered as the two modes of *duration*; and if duration be taken in what Locke thinks its true and original sense, to denote permanence of existence, with a kind of resistance to any destructive force, the distinction seems to be sufficiently proper. It is indeed the best that we can make or comprehend; for *duration*, *time*, and *eternity*, are subjects which have perplexed philosophical minds in all ages, and of which, if we have adequate notions, it is very difficult to express these notions in language. Instead of attempting it by previous definitions, the method in which the ancients generally began their inquiries, we shall pursue the better course of induction recommended by Lord Bacon, and endeavour to show by what means we acquire the notion of that mode of duration which is called *time* in contradistinction to

---

(z) We are happy to find our notions on this subject confirmed by an authority so respectable as that of Professor Stewart. "Without the power of attending separately to things which our senses present to us in a state of union, we never (says this able writer) could have had any idea of *number*: for before we can consider different objects as forming a multitude, it is necessary that we should be able to apply to all of them one common name; or, in other words, that we should reduce them all to the same genus. The various objects, for example, animate and inanimate, which are at this moment before me, I may class and number in a variety of different ways, according to the view of them that I choose to take. I may reckon successively the number of sheep, of cows, of horses, of elms, of oaks, of beeches; or I may first reckon the number of animals, and then the number of trees; or, I may at once reckon the number of all the organized substances which my senses present to me. But whatever be the principles on which my classification proceeds, it is evident that the objects numbered together must be considered in those respects only in which they agree with each other; and that if I had no power of separating the combinations of sense, I could never have conceived them as forming a plurality." *Elements of the Philosophy of the Human Mind*, chap. iv.

(A) We say *improperly*, because beings which were *created* can have nothing in *common* with that Being which is *self-existent*, and upon whose *will* and *power* all other things depend.

to *eternity*. We begin with time; because we ourselves exist in it, and it is in some sense familiar to us. If we be able to trace our notions of this mode of duration to their source, we may then give a definition of it founded on fact and universal experience, and afterwards proceed to consider the other mode in conjunction with infinity, to which it is nearly allied.

It has been already observed (see N° 92 of this article), that every man, while awake, has a train of sensations and ideas constantly passing through his mind in such a manner, as that the one succeeds the other in a regular order. It is not possible, either, by detaining in the mind one idea to the exclusion of all others, to stop the course of this succession entirely; or, by hurrying some ideas off the stage, and calling others in their place, to quicken its progress beyond a certain degree. One man indeed has naturally a quicker succession of ideas than another; and all men can, by great exertions, accelerate or retard in a small degree the natural flow of their thoughts. A studious man lays hold, as it were of a particular idea, which he wishes to contemplate, and detains it in the imagination, to the exclusion of all others; a

209 Whilst the mind is occupied by one idea or notion, there is no perception of time; which

man of wit calls remote ideas into view with a rapidity of which a cool and phlegmatic reasoner can form no conception; and a forcible *sensation* takes full possession of the mind, to the exclusion of all *ideas* whatever. Whilst the attention is wholly occupied by one idea, or by one sensation, the mind has no notion whatever of time; and were it possible to detain such idea or sensation alone in the mind till the hand of a clock should move from the number of one hour to that of another, the hour, as marked on the dial-plate and measured by the motion of the hand, would appear but as one instant absolutely void of duration. For the truth of this assertion we appeal to the experience of our readers. Such of them as have ever been engaged in deep study must often have had their attention so fixed upon one object, that large portions of time, as measured by the clock, have passed away wholly unheeded; and every man who has seen a very striking and uncommon object, must remember, that when the sensation was first impressed upon his mind, all other objects, ideas, and notions, and among the rest the notion of time, were for a while excluded.

210 arises from comparing the succession of our ideas with the permanence of other objects.

No sensation, however, keeps possession of the whole mind after it has ceased to be new; nor can the most vigorous exertions long preserve any one idea from being driven off the stage by the succeeding train. Now this succession of ideas appearing and disappearing in their turns, is that which, when compared with the permanency of ourselves and other things, gives us our first and justest notion of time: for whilst we are thinking, or whilst a series of ideas is successively passing through our minds and vanishing, we know that we ourselves and the things around us exist; and this existence, or continuation of existence, commensurate with the train of our fleeting ideas, is what we call the *duration* of ourselves and the things around us.

We are aware that the first notions of time have been often said to be derived from *motion* as perceived by our senses in the objects around us. It is observed by Euclid, that "if there were no *motion*, there could be no sound, nor any sense of hearing." "He might have added (says the author of Ancient Metaphysics), nor any other perception of sense. Further, Without motion there would have been no visible world, nor generation or production of any kind here below; and, among other things, *time* could have had no existence." All this is certainly true; but that corporeal motion, though the original source of all our ideas, is not that which *immediately* suggests to us the notion of time, will be readily granted by him who considers that motion itself is perceived by us only when it excites or accompanies a constant succession of perceptions and ideas. Motion, when equable and very slow, such as that of the hour hand of a common watch, is not perceived by us in its course; nor can we discover that the thing has moved at all, till after we have been sensible of the lapse of a considerable portion of what is commonly called *time*; when we discover that the hand of the watch has changed its place with respect to other objects which we know to be fixed. The same is true of motion remarkably quick: "Let a cannon ball (says Locke) pass through a room, and in its way take with it any limb or fleshy parts of a man; it is as clear as any demonstration can be, that it must strike successively the two sides of the room; it is also evident that it must touch one part of the flesh first, and another after, and so in succession: and yet I believe nobody who ever felt the pain of such a shot, or heard the blow against the two distant walls, could perceive any succession either in the pain or sound of so swift a stroke."

Of these two phenomena a satisfactory account may be easily given; from which we think it will at the same time be apparent, that the succession of the train of ideas in the mind is the measure and standard of all other successions. We know that the energy of 211

The succession of ideas the measure of all other successions.

mind which reviews a train of sensible ideas is of the very same kind with that which attends to a series of passing sensations (See N° 68.); and therefore it is natural to suppose that we can pay attention to sensations and ideas passing with nearly equal velocities. But it has been shown, that every sensation remains in the mind or sensorium, for a very short space after the object which excited it is taken away: whence it follows, that a body communicating to the organs of sense a series of similar impressions succeeding each other with remarkable rapidity, cannot excite a train of similar and distinct sensations; because the effects of the first and second impressions not having vanished when those of the third and fourth arrive, the whole train of effects must necessarily coalesce into one uniform sensation. This reasoning is confirmed by experience. Similar sounds succeeding each other at considerable intervals, are all distinctly perceived; and if the motion be accelerated gradually, it may be carried to a great degree of velocity before the sounds be confounded and coalesce into one. "Mr Herschel having, by means of a clock, produced sounds or clicking noises, which succeeded each other with such rapidity that the intervals between them were, as far as could be judged, the smallest possible, found that he could evidently distinguish one hundred and sixty of them in a second of time; but beyond that he could by no effort of attention distinguish one sound from another. The same philosopher tried another experiment on visible sensations. By means of the same handle and work of the clock, he caused a wheel in it to turn till

Of Time.

till it acquired the velocity of once in a second. He continued to increase the velocity, and observed it while revolving at the rate of twenty times round in thirteen seconds, and could still distinguish the teeth and spaces from each other; whence it appears (by a computation given at length), that he had two hundred and forty-six distinct visible sensations generated by equable motion in a second of time. The teeth of the wheel, he owns, were not so far visible as to show their shape distinctly, much less could they have been counted: but he very plainly distinguished the circumference to be divided into teeth and spaces; and he supposes that the same division might still have been seen though the motion had been a little faster, as far perhaps as two turns in a second, equal to three hundred and twenty sensations *." The reason that the division could not be seen whilst the wheel moved more rapidly than twice round in a second of time, was doubtless the continuance of that agitation in the brain from which each sensation proceeded, until a new impression caused a new agitation which coalesced with the former and removed all distinction Hence it is plain, that no external succession can be perceived which moves with a greater velocity than that of which the internal train of sensations and ideas is capable. On the other hand, an external succession which moves with less rapidity than that to which the internal flow of ideas may be reduced, either has not sufficient force to generate sensations at all, or the successive impressions from which the sensations proceed follow one another at such distances as to permit the natural train of ideas to intervene between them, and thus destroy the perception of the succession entirely.

* [Wat]tson's Tr[eat]ise on Ti[me].

To us, therefore, it seems evident, that the constant and regular succession of ideas in the mind of a waking man, is the measure and standard of all other successions; of which, if any one either exceeds the pace of which our ideas are capable, or falls short of it, the sense of a constant and continued succession is lost, and we perceive it not but with certain intervals of rest between. So that it is not motion, but the constant train of ideas in our minds, that suggests to us our first notion of time; of which motion no otherwise gives us any conception, than as it causes in our minds a constant succession of sensations: and we have as clear a notion of time by attending to the train of ideas succeeding each other in our minds, as by a train of sensations excited by constant and perceptible motion.

That it is merely by comparing the permanent existence of things with the fleeting succession of ideas in our own minds that we acquire our notions of time, may perhaps be still more evident from the following narrative quoted by Dr Beattie †, from *L'Histoire de l'Academie Royale des Sciences pour l'année* 1719. "A nobleman of Lausanne, as he was giving orders to a servant, suddenly lost his speech and all his senses. Different remedies were tried without effect. At last, after some chirurgical operations, at the end of six months, during all which time he had appeared to be in a deep sleep or delirium, his speech and senses were suddenly restored. When he recovered, the servant to whom he had been giving orders when he was first seized with the distemper, happening to be in the room, he asked whether he had executed his commission, not being sensible, it seems, that any interval of time, except perhaps a very short one, had elapsed during his illness." If this story be true, here was a man, who, by the train of ideas vanishing at once from his mind, lost the perception of what was to others six months of time: and had all mankind been in his state, the same portion of time would have been irrecoverably lost even to the annals of chronology.

† [Ess]ay on Tr[ut]h.

We are aware of an objection to any inference which may be drawn respecting the present question from the case of this nobleman. It may be said that he had lost, together with the perception of time, the perception of every thing besides; and that, therefore, motion may still be the cause from which a waking man derives his notions of time. But in reply to this objection, we beg leave to ask, Whether if a ball had been put in motion on a table, and the nobleman had been told, that a body moved with the velocity of that ball would have been carried over so many thousand miles of distance during the time that he lay in a state of insensibility, he could from such information alone have formed any tolerable notion of the length of time in which he was insensible? He certainly could not, for want of a standard by which to measure the rapidity of the motion. He would, indeed, have known instantly that he had been insensible for a considerable length of time, because he had the evidence of former experience that a body carried by perceptible motion over a great extent of distance would have generated in his mind a vast train of successive sensations; but till he had attended this ball during part of its course, and compared with the permanency of other objects the series of sensations which it generated in his mind, he would not have been able to guess with any thing near to accuracy the length of time it would take to pass over a thousand miles.—The same insensibility of duration happens to every man in sound sleep. From having notions of time, such as they are, formed in our minds, we never indeed suppose, however soundly we have slept, that the moment at which we awake in the morning is contiguous to that in which we fell asleep at night. The reason is obvious; every man has been awake whilst others were sleeping, and has known by experience, that if they had been awake likewise a train of ideas would have passed through their minds which must have suggested to them the notions of time. Most men, too, have been frequently awake whole nights, and have thus acquired a notion of time as going on incessantly, whether perceived by them or not; and this motion being closely associated with our ideas of night and morning, we inevitably suppose a portion of time to have elapsed between them, though unperceived by us in our sleep. But were a man to sleep without dreaming from Sunday night till Tuesday morning, and then to awake at his usual hour as marked on the clock, there are numberless instances on record to convince us, that he would not of himself suppose, nor perhaps be very easily persuaded, that more than one night had elapsed between his falling asleep and the moment at which he awoke.

It being thus evident, that our notion of time is suggested by that comparison which we inevitably make of the existence of things permanent with the train

Of Time. train of ideas incessantly passing through our minds; we may now perhaps be able to answer the question, "What is time?" It must of necessity be one of three things, viz. either the ideal succession itself; a certain quality inherent in all objects; or merely the relation of coexistence between things that are permanent and the trains of fleeting ideas which succeed each other on the theatre of the imagination. It is not the first of these; for in every train of thought, the appearance of any one idea in the mind occupies no more of the extension of time, than a mathematical point occupies of the extension of distance. Ten thousand mathematical points added together would make no part of a line; and ten thousand ideas made to coalesce, if that were possible, would occupy no part of that mode of duration which is called *time*. A point is the boundary of a line, but no part of it: the appearance of an idea in the mind is instantaneous; and an instant is the boundary, but no part of time. Hence it follows, that were every thing instantaneous like ideas in a train, there could be no such thing as time, since nothing could be said to have in that sense of the word any duration. That time is not a quality inherent in all objects, is likewise plain; for we have seen, that were *ideas* as permanent as objects, the notion of time could never have been acquired. Succession, though it does not itself constitute time, is essential to its existence; and were all motion to cease, and the attention of men to be immoveably fixed upon one invariable object or cluster of objects, *time* would cease likewise. It remains, therefore, that time can be nothing else than the relation of coexistence apprehended between things that are permanent and those trains of fleeting ideas which incessantly succeed each other on the theatre of the imagination. Thus whilst a man is steadily looking at one object, which, from its being common, does not occupy his whole mind, he may be conscious of a thousand ideas starting up in his imagination, and each in its turn vanishing the instant in which it appeared. Every one of these ideas had an existence as well as the object at which he is looking; but the existence of each of them was instantaneous and in succession, while the existence of the external object is permanent. The object, therefore, as contrasted with a train of ideas, is said to endure or to exist in time, whilst each idea is destitute of duration, and exists in no time.

212 Time a mere relation of coexistence.

213 Objections answered.

To this theory some objections occur, which it will be incumbent upon us to obviate. It may be said, that though each idea considered by itself is instantaneous, and occupies no time; yet the whole train when taken together, without being compared with any thing external, is perceived to occupy a considerable portion of that mode of duration; and that, therefore, time itself must be something more than a mere relation between a fleeting succession of ideas and objects of more permanent existence. But how, we beg leave to ask, is the whole train perceived to occupy any portion of time? Is it not by being compared with our own existence? A man whilst a train of ideas is passing through his mind may be suddenly deprived of all his external senses, and then indeed it will be impossible for him to compare the fleeting existence of this internal succession with the more permanent existence of external things; but, whilst he thinks at all, he must be conscious of his *own* existence, and cannot avoid perceiving, that whilst his ideas pass in constant succession, each making an instantaneous appearance in his mind, he himself remains unchanged. Now, what is it that this perception suggests to the mind? Evidently nothing more than the relation of coexistence between a fleeting succession and a permanent object; for were it possible that the man could be deprived of memory as well as of his senses, and still have ideas succeeding each other in his mind, he would then think all objects equally fleeting; he would indeed be himself a mere succession of instantaneous distinct persons, and could have no notion whatever of time. His existence, though it should seem to endure half a century as estimated by others, must to himself appear to pass away like a flash of lightning.

It may be still further objected to our theory, that time is measured by motion; and that it seems very absurd to talk of measuring a relation, especially a mere *ideal* relation, by a real external thing. In answer to this objection, which at first sight appears formidable, we beg leave to observe, that all relations are equally ideal; and that yet many of them may be said to be measured by real external things, with as much propriety as time can be said to be measured by motion. When a man wishes to ascertain the relation of quantity which one body bears to another, though he knows that such a relation has no other than an ideal existence, and cannot be conceived but in conjunction with the related bodies, he applies to them successively some commom standard; and having discovered the relation which each bears to that, he compares the one relation with the other, and thus ascertains the relation sought. Just so it is with respect to motion measuring time. That which to each individual constitutes real time, is the relation of coexistence between the fleeting succession of his own ideas and other things of a more permanent nature. But a man has often occasion to ascertain the time of things external which fall not under the inspection of his senses; and in society all men have transactions with one another to be performed in some determinate portion of time, though there are not, perhaps, two men existing whose ordinary trains of thought flow with precisely the same rapidity. To remedy these inconveniences, it was necessary to invent some common standard, by means of which men might ascertain the duration of actions performed at a distance, and be able to keep appointments made with each other. The only standard proper for these purposes is such a constant and equable motion as has suggested a flux of perceptions common to all men in all ages and countries; and hence the motions of the heavenly bodies have been universally made use of for the common regulators of time. These motions, however, do not constitute real and natural time, any more than a foot or a yard applied to two distant bodies constitutes the relation of quantity which these bodies bear to each other. They are merely stated measures, to be differently applied according to the different purposes which we have in view.

Thus, if a man in Europe wishes to know what would to him have been the *real* and *natural* time of an action performed in the East Indies, he has only to be told that it was co-existent, we shall suppose, with

Time. with a diurnal revolution of the earth; and by comparing this common measure with his usual flow of thought, he can form some notion of the extent of that train of ideas, which, had he been present, would to him have been successively co-existent with the action in question. But when persons have an appointment to keep, this common measure of motion must be differently, or rather partially, applied. In such cases, it is no part of their intention to compare their own existence with that of the whole train of ideas which may pass in the mind of each; for the result of such a comparison, which alone constitutes true and natural time, would not be the same in perhaps any two men: but their purpose is, to compare their own permanent existence only with that train of sensations which shall be excited in the mind by the perceptible motion of the sun, or any other body fixed upon which moves equably; and such a train must consist of an equal number of instants in all men. Neither the sun, nor the hour hand of a common watch, moves with such apparent rapidity as to keep pace with the internal flow of thought of which the most phlegmatic man is conscious. That these bodies move at all, is known only by their visible change of place during the lapse of a considerable portion of real time; and as there is in their course a certain number of places distinctly marked, to which alone it is agreed that the attention is to be turned, it is impossible that of time so computed two men can have different notions. Such time, however, is but partial; and the method of ascertaining it, when compared with that by which we ascertain real time, has a striking resemblance to that by which we ascertain the relation of partial quantity between two distant bodies. When it is our purpose to ascertain the relation of real quantity which one body bears to another, we apply the common standard to each in every dimension of length, breadth, and depth; but when we have no other view than to ascertain the relation of length which the one bears to the other, we apply the common standard to each in that dimension only. Just so it is with regard to real and partial time. When an individual wishes to ascertain what would to him have been the duration of any action which he did not see performed, he applies the common standard to the existence of that action, and to the usual flow of his own thoughts: but when two men talk of the duration of any action, or agree to meet on such a day, they compare the existence of the action, or the distance intervening between the present moment and the day of meeting, only with that partial train of sensations which by the common standard is generated in an equal number, and in the same order, in the minds of both.

214 [Ti]me must [have] had a [begin]ning.

It will be said, that if time be nothing more than a mere relation subsisting between trains of ideas or other fleeting objects, and things of a more permanent existence; and if the universe had a beginning; either time must have had a beginning likewise, or the Deity cannot be immutable. We allow the force of the argument; but instead of an objection, we consider it as a confirmation of the truth of our theory. The Deity, who is immutable, exists not in time, but in eternity; and that these, though from the poverty of language they are both called modes of duration, are yet very different from each other, we shall endeavour to prove in the next chapter. Of Infinity and Eternity.

Chap. VIII. *Of* Infinity *and* Eternity.

215 Why we treat of infinity and eternity among the adjuncts of body.

As corporeal substance is certainly not infinite, and as the present material system has in itself every evidence of its not being eternal, it may seem strange, perhaps, to the reader, that we should treat of infinity and eternity among the adjuncts of body. But in modern metaphysics these words are used in a vague sense to denote the extent of space and time; and in this chapter it is our intention to do little more than ascertain their meaning, and to show, in opposition to some celebrated names, of what subjects they may not be predicated. There is a mathematical and a metaphysical infinity, which, though often confounded, ought to be kept distinct. In mathematics, extension is said to be divisible *ad infinitum*, and number is sometimes considered as infinite: but in metaphysics these modes of expression are extremely improper. A positive and metaphysical infinite is that which has no limits, and to which no addition can be made; but it is obvious that there is no number which may not be enlarged, nor any positive idea of extension which has not limits, and which may not be either increased or diminished. The infinity of the mathematician is termed *infinity of power*, and that of the metaphysician *absolute infinity*. The first consists in this, that a being, however great or small it be supposed, may still be conceived to possess more greatness or minuteness than we can form an idea of, even after the utmost stretch of human thought. Thus when it is said, that all extension as such is infinitely divisible, it is not meant that every extended substance contains an infinite number of *real parts*: for then the parts of an inch would be equal to those of a league: but the meaning is, that in ideal extension we can never reach the end of ideal division and subdivision. In like manner, when it is said that number is infinite, the meaning is not that any positive number is without limits, or the possibility of increase, but that we might go on for ever, adding unit to unit, without approaching nearer to the end of the process. If, therefore, the mathematician would speak properly, and without the affectation of paradox, he ought to say that all extension as such is *indefinitely* divisible, and that unit might be added to unit without end; but these phrases suggest notions very different from that of a metaphysical infinite, which is something positive to which nothing can be added (B).

216 Space and time supposed to be, the one infinite, and the other eternal:

That there is something positively infinite, has been very seldom questioned; but it has been warmly disputed among metaphysicians what subjects are infinite.

(B) 'Ου γαρ ὀυ μηδεν ἐξω αλλ ὀυ αει το ἐξω ἐσλι, τουλο απειρον ἐσλι. *Arist. Phys. Auscult.* lib. ix. cap. 9. page 492. tom. i. *Oper.*

Of Infinity and Eternity.

Dr Clarke and his adherents have contended that space and time are real things; that they are bodies of necessary existence; that the former impresses us with the idea of its infinity, and that the latter is positively eternal. "Time and space (says the doctor *) are the *sine qua non* of all other *things*, and of all other *ideas*. To suppose either of them *finite*, is an express *contradiction* in the idea itself. No man *does* or *can* possibly *imagine* either of them to be finite; but only either by *non-attention* or by *choice* he attends perhaps to *part* of his *idea*, and *forbears attending to* the remainder. They who suppose *space* to be nothing but a *relation between two bodies* are guilty of the absurdity of supposing that which is *nothing* to have *real qualities*: *For the space which is between two bodies* is always unalterably just what it was, and has the very same dimensions, quantity, and figure, whether *these* or any *other bodies* be there or any where else, or not at *all*. Just as *time* or *duration* is the same, whether you turn your *hour-glass* or no, or whether the sun moves or stands still, or whether there *was* or *was not any sun*, or any *material world* at all. To set *bounds* to space is to suppose it *bounded* by something which itself *takes up space*, and that is a *contradiction*; or else that it is *bounded by nothing*, which is another contradiction. To suppose space *removed*, *destroyed*, or *taken away*, amounts to the absurd supposition of removing a thing away *from itself*; that is, if in your *imagination* you *annihilate* the *whole of infinite space*, the whole of *infinite space* will still remain; and if you annihilate any *part* of it, *that part* will still *necessarily* remain, as appears by the unmoved situation of the *rest*; and to suppose it *divided* or *divisible* amounts to the same contradiction."

** Demonstration of the Being and Attributes of God, and Correspondence with a Gentleman of Gloucestershire.*

The absurdity of considering space as a real external thing has been already evinced in Chap. IV. p. 624. where it was shown how we acquire the notion, and what kind of notion it is. Space, as was there observed, may be conceived either as the mere absence and possibility of body; or as ideal extension, united to, and inhering in, an ideal substratum. Taken in the former sense, it is an object of pure intellect; in the latter, it is an *idea* or *form* in the imagination. That the absence of body or matter is the *sine qua non* of all other things, and all other ideas, Dr Clarke was not dis-

217 but improperly.

posed to affirm, when he made the divine substance to pervade every material atom in the universe: and to talk of the absence of body being infinite is a palpable contradiction, unless Berkeley's doctrine be true, that the material world has no existence. To say that the *possibility* of matter is infinite, is to use language which has no other meaning than that, however far the material world be on all sides extended, its extension may still be conceived greater and greater *ad infinitum*. This is a position which no philosopher ancient or modern has ever denied; but it is so far from implying that we have a positive idea of the infinity of the material world, or of any adjunct of the material world, that it is absolutely inconsistent with such infinity. Whatever is capable of perpetual increase must certainly have limits, and every new addition is the limit of that to which the addition was made.

218 Neither space nor

Taken in the second acceptation as an ideal extension united with an ideal *substratum*, space is so far from being infinite in any sense of the word, that we will venture to assert no man ever contemplated such a *form* in his own imagination, without conceiving it to be bounded. Of this, at least we are certain, that when we have attempted to frame a positive idea of pure space, it has not been in our power to divest that idea of limits. Those who can frame in their minds real and positive ideas wholly abstracted from every individual object, may indeed perform in this way many feats above our abilities; but as we possess no such powers of abstraction, every thing which we can call an idea is limited in the same manner that the object itself is limited from which the idea was derived.—Thus, the largest expansion that ever we beheld is the concave hemisphere; and when we try to form the largest positive idea of pure space, all that we can do is to figure to ourselves that concave empty of body. We may, indeed, suppose its diameter to be either a million or ten thousand millions of miles; and we may go on enlarging it *ad infinitum*: but when we return from this process of intellect to the contemplation of the ideal forms of the imagination, none of these forms appear to us larger or more extended than the hemisphere, which is the object of sense, and they all appear to be bounded, and bounded in the very same way.

With respect to the eternity of time, we think Dr Clarke equally mistaken as with respect to the infinity of space. Of time, indeed, we cannot, properly speaking, have any *idea* or mental *form*. Time, as we have seen, is a mere relation, and is in itself the creature of the mind which has no external *idiatum*. It is suggested, however, by the fleeting succession of our ideas, compared with the more permanent existence of other objects: and therefore succession is essential to it. But nothing which has parts, whether coexistent or in succession, can be positively infinite. For, "in an infinite series of successive generations of men, for instance, there will be several infinites that are parts of one another; and by consequence one greater than another: which (as has been well argued *) is an express contradiction, since the greater must necessarily bound the less, and exceed its limits by so much as it is greater than it; that is, must make it not infinite. Infinite generations contain an infinitely greater infinity of particular men. An infinite number of men must have twice as many hands, and ten times as many fingers, and so on. Infinite time has an infinity of ages; these a much greater infinity of years, days, hours, &c. Space likewise (according to Dr Clarke) has three dimensions, all infinite. It must therefore, contain an infinity of surfaces, an infinitely greater infinity of lines, and a still infinitely greater infinity of physical points. The case is the same in number itself, which, if we suppose it to contain an absolute infinity of thousands (and we may as well do that as imagine it to comprehend an infinity of units), it will contain ten times as many hundreds, fifty times as many scores, and so on. All this is only the *indefiniteness* of number, which we in vain attempt to turn into a positive infinite with which it is totally incompatible. For let us add *one* to any of these infinite series of generations, ages, lines, or numbers, which we know to be always in our power, and if it was absolutely infinite before, here is one more than infinite. If it only becomes infinite now, then one finite added to another finite makes infinity. If it be no larger after

219 time ca[n be] positive[ly] infinite; and wh[...]

Of Infinity and Eternity.

ter the addition than it was before, then one part added to another adds nothing; all which are absurdities. The same will appear, if we subtract a part from this supposed absolute infinite, which may be done in any of the forementioned subjects, as well as in every thing which admits of parts, or may be taken in pieces by the mind."

220 The usual answer to the foregoing reasoning shown

To this kind of reasoning Dr Clarke replies as follows: "To endeavour to prove that there cannot possibly be any such thing as *infinite time* or *space*, from the impossibility of an addition of finite parts ever composing or exhausting an infinite; or from the imaginary inequality of the number of years, days, and hours, that would be contained in the one; or of the miles, yards, and feet, that would be contained in the other, is supposing infinites to be made up of numbers of finites; that is, it is supposing finite quantities to be *aliquot* or *constituent parts* of infinite, when indeed they are not so, but do all *equally*, whether *great* or *small*, whether *many* or *few*, bear the very same proportion to an infinite, as mathematical points do to a line, or lines to a superficies, or as moments do to time, that is, none at all. No given number or quantity can be any *aliquot* or *constituent* part of infinite, or be compared at all with it, or bear any kind of proportion to it, or be the foundation of any argument in any question concerning it."

If it be indeed true, and it is that for which we contend, that no given number or quantity can be any aliquot or constituent part of infinite, or be compared at all with it; then it undeniably follows, not that miles, yards, and feet, are no constituent parts of space; or years, days, and hours constituent parts of time; but that space and time cannot possibly be positive infinites. This, we say, follows undeniably: for nothing is more evident, than that all quantities of the same kind, from the largest to the least, bear a certain proportion to each other; and upon the supposition that space is a real extending thing, miles, yards, and feet are included in it, and bear to it the relation of parts to a whole. The same is true of time, days, and hours. To affirm (for no proof is offered), that all finite quantities, whether great or small, whether many or few, do equally bear the very same proportion to an infinite, as mathematical points do to a line, or as moments do to time, is plainly to beg the question—

221 ...e a petitio principii.

"that *space* considered as a real extended thing is *infinite*;" and to beg it, too, in opposition to the common sense and reason of mankind. Mathematical points we all know to be nothing real, but merely negations of extension; but supposing space to be something real and extended, can any man persuade himself that a mile or a million of miles of this space is likewise a mere negation of extension? With him who can bring himself to this persuasion, we pretend not to argue. He is possessed of faculties, whether true or false, of which we are destitute.

That finite quantities, whether great or small, do all equally bear the same proportion to an *infinite in power*, is indeed true; but it is no great discovery: for such an infinite, as we have seen, is nothing but the continued possibility of repeating the same mental process of addition or multiplication; and he who can go on for ever adding, in his own imagination, foot to foot, or hour to hour, will find it equally easy to add, in the same manner, league to league, or age to age. If he can perform the one operation, he must likewise have power to perform the other; and he cannot but perceive that it is as impossible to come to an end, of adding league to league, or age to age, as of adding foot to foot, or hour to hour; but then he must know that these leagues, feet, ages, and hours, are not real external things, but mere ideas and notions in his mind. If such powers of ideal multiplication and addition be what Dr Clarke means by the ideas of space and time, it is indeed a contradiction to suppose either of them limited; for that is to suppose our powers different from what we know them to be by consciousness and experience. But to confound *powers* with the *objects* of those powers, is certainly very inaccurate; and to suppose, because we can go on for ever adding one portion of ideal space or time to another, that therefore our ideas of space and time are in themselves positively infinite, is a contradiction: for to an idea positively infinite, it is obvious that nothing can be added. Either, therefore, space and time do not impress us with the ideas of their positive infinity; or we cannot have the power of adding league to league, and age to age, without end.

"But (says the doctor) to suppose space removed, destroyed, or taken wholly away, amounts to the absurd supposition of removing a thing from itself; that is, if in your imagination you remove the whole of space, the whole of space will still remain." True, every man has ideas of space treasured up in his imagination, which the sound of the very word space will at all times bring into his immediate view; and whilst he has such ideas, it is impossible that he should not have them: which is all the mystery of the matter, and amounts to nothing more than that a thing cannot be and not be at the same instant. When the doctor affirms, that if "you annihilate any part of space, that part will necessarily remain, as appears by the unmoved situation of the rest," we are not certain that we perfectly understand him. A man may surely think of a cubical inch without thinking of a foot or a yard; and he may suppose the inch taken away from the foot or the yard, and these ideal quantities so much lessened by the subtraction. But if the doctor be here again confounding the powers of the mind with the positive ideas of space, the sentence when explained will be seen to contain nothing to his purpose. Every man has the power of contemplating in idea millions of miles, and millions of ages, and of adding mile to mile, and age to age, without end; and if he try to deprive himself of any part of this power, or to fix a limit to the mental process of addition, he will find that in spite of himself his imagination will ramble beyond the limit assigned, and that he has attempted an impossibility. This, however, is so far from being a proof that his ideas of space and time are positively infinite, that, as we have already observed, it is a proof of the contrary.

222 Space and time are said to be the *sine qua non* of all other things; but

But (says this great man and his followers) "space and time are the *sine qua non* of all other things and all other ideas. The supposal of the existence of *any thing whatever* includes necessarily a *presupposition* of the existence of *space* and *time*;" and, therefore, if there be any thing infinite and eternal, space and time must likewise be so.

To

Of Infinity and Eternity.

To every corporeal substance, and every idea of such substance, space and time are indeed necessary: for every body has extension and duration; and every idea of a particular body, being nothing but a secondary perception in the imagination or memory, must have the same relation to imaginary extension, that the object from which it was derived has to extension which is real. Every idea, too, which remains in the imagination whilst a train of other ideas passes successively in view, or whilst external things are perceived to change, has real time. But will any man say that *consciousness*, our notion of *power*, our acts of *willing*, or even *tastes*, *sounds*, and *smells*, are extended, or that the supposal of their existence necessarily implies a presupposition of the existence of space? We acquire our ideas of extension and space by means of our senses of touch and sight; and we learn from experience, that things external and extended are the causes of our sensations of taste, sound, and smell. The effects are in our minds closely associated with the ideas of their causes; and it is not perhaps easy to think of a particular sound, taste, or smell, without at the same time thinking of the object by which it was first excited in the mind; but had we been originally formed with the powers of consciousness, thinking, and willing, and with no other senses than those of tasting, smelling, and hearing, it is obvious that we never could have had the idea of *space*; and therefore, that idea cannot possibly be necessary to the presupposition of every thing else. To consciousness, thinking, and willing, space is so far from being necessary, that we cannot perceive any the most distant relation between them. It is not more difficult to conceive a part greater than the whole, than it is to conceive an ell of *consciousness*, of *thought*, or of *will*; nor is it in the power of any man to make *space* and *sweetness* coalesce in his mind so as to form of the two simple ideas one complex conception. The very reverse is the case with respect to the objects of sight and touch. The idea of every thing which we see and handle necessarily coalesces in the mind with the idea or space, nor can we possibly separate the one from the other; but the things which we see and handle are neither infinite nor capable of infinity.

223 there are things which have no relation whatever to space, or

224 to time.

With respect to time, the same observations will be found to be just as with respect to space. Whatever is liable to change, exists in time and cannot be eternal; but if there be any being immutable, and who views at once all things which to us are past, present, and to come, the existence of that being is not commensurable with time. That such a being is possible no man can doubt, who reflects, that if we had one permanent idea invariably in the mind, we should never have acquired the *notion* of succession or of time; and that if there were *actually* no *change* in nature there could not possibly in nature be any such *thing as time*. Every man, therefore, who can conceive existence without change, must be convinced, that "the supposal of the existence of any thing whatever does *not* necessarily include the presupposition of the existence of time; and that there may be an eternity distinct from time, as well as an infinity distinct from space; nay, that nothing which is properly infinite and eternal can possibly occupy either space or time.

225 Infinity and eternity, what they are.

If it be asked, What kind of infinity and eternity they are which have no relation to space and time? Cudworth, treading in the footsteps of the ancients, has long ago answered, That they are "absolute perfection, and necessary existence. For (says he), *infinite understanding* and *knowledge* is nothing else but *perfect* knowledge, which hath in it no defect or mixture of ignorance, but knows whatsoever is knowable. In like manner, *infinite power* is nothing else but *perfect* power, which hath in it no defect or mixture of impotency—a power which can do every thing which is possible or conceivable. Lastly, *Infinity of duration*, or *eternity*, is really nothing else but *perfection*, as including in it *necessary existence* and *immutability*; so that it is a contradiction to suppose such a being to have had a beginning, to cease to be, or to suffer or be affected by any change whatever. And because infinity is perfection, therefore nothing which includes in its idea or essence any thing of *imperfection*, as every positive idea of number, corporeal magnitude, and successive duration, evidently does, can be truly and properly infinite *."

* *Intellectual System.*

It must indeed be confessed, that the idea of succession so insinuates itself into our usual ideas of existence, and is so closely connected with the existence of all finite beings, that we find it extremely difficult to imagine the eternal existence of God, any otherwise than as an eternally continued series or succession. Our constant conversation with material objects, and the associations thence arising, make it almost impossible for us to consider things abstracted from time and space; yet we have the evidence of experience and consciousness, that an idea may be conceived without relation to space and time, and that space and time cannot be made to coalesce with some of our notions. The same must be true with respect to infinity and eternity; for we have seen that neither space, time, nor any thing else which consists of parts, whether continuous or successive, can be supposed to be positively infinite, as the supposition implies the most palpable contradiction. But that there may be perfect power, perfect knowledge, and permanent invariable existence, is so far from implying any contradiction, that even we, whose faculties are so very narrow, can yet make some advances towards the conception of such perfections. Thus, every man of common understanding knows that some things are in themselves possible, and others impossible, to be performed by any power. Of these possibilities and impossibilities a philosopher knows more than an illiterate man; and one philosopher knows more than another. An intellect more perfect knows more of them than any man; and that intellect which knows them all must be absolutely perfect, and incapable of improvement, because it knows every thing which is to be known. The same is true of perfect power:—but we shall treat of real infinity and eternity more at large when we come to demonstrate the being and attributes of God. At present it is sufficient to have shown that nothing can be positively infinite but a being absolutely perfect; which never was not, which can produce all things possible and conceivable, and upon which all other things must depend.

PART

PART III. OF MINDS AND THEIR POWERS.

Chap. I. *Of* Mind *in* General.

THE science of metaphysics comprehends every thing, into the existence, nature, or causes of which any inquiry may be made. But all things of which we have any notion or idea may be divided into mind and body, with their various powers, qualities, and adjuncts. By body is meant that which is solid, extended, inert, and divisible; and its several adjuncts are space, motion, number, and time. The only mind with which we are *intimately* acquainted is our own; and we know that it is possessed of the powers of sensation, perception, retention, consciousness, reflection, reason, and will. These are totally different from extension, solidity, divisibility, and motion; and therefore it is proper to distinguish the being of which they are powers by another name than that of body.

226 Mind distinguished from body.

227 Probably kinds of different minds.

Of bodies there are various kinds possessing various sensible qualities; and from analogy it is reasonable to conclude, that there may be various classes of minds endowed with different kinds or degrees of power. For this indeed we have stronger evidence than that of analogy. Brute animals evidently possess the powers of perception and spontaneity with some degree of consciousness; but as they appear not to reflect upon their own conduct, or to have their actions influenced by motives, their minds are inferior to ours, though still perfectly distinct from mere extended, inert, and divisible substances. Mind, therefore, considered with respect to its powers, is evidently different from body considered with respect to its qualities. This is indeed a truth which has seldom if ever been controverted; but it has been long and warmly disputed, Whether mind and body be not both composed of the same first matter?

228 The absurd hypothesis of Hobbes respecting mind.

Hobbes supposed that every material atom is endowed with the faculty of sensation (c); but that for want of memory each sensation is momentaneous, being instantly and wholly effaced as soon as its cause is removed. Though this hypothesis is too absurd to require a formal and laboured confutation, it may not be improper to observe, that, if it were true, the hairs of a man's head would feel extreme pain when pinched by the hot iron of the hair-dresser; and that the nails of his fingers would be severely tortured when under the operation of the knife or the rasp.

229 Other hypotheses.

Others have supposed that each atom of matter has a *tendency towards* sensation and perception; and that when a sufficient number of these atoms are brought together in a certain order, the *united tendencies* produce the *actual* powers which distinguish mind from gross body. This supposition is if possible more absurd than that of Hobbes. Sensation and perception are of such a nature, that a mere *tendency towards* them is inconceivable. A thing must either be sensible and percipient, or insensible and inert: there is evidently no medium. Or if we could suppose each individual atom to have a *tendency* towards sensation, it would by no means follow that a number of such atoms brought together in any possible order would become one sentient, thinking, and active being. A number of bodies laid upon an inclined plane have each a *tendency* to roll downwards; but if the declivity of the plane be not such as that their separate tendencies may overcome the resistance opposed to each individual body by friction, the *united tendencies* of all the bodies when brought together will not be able to overpower the resistance of their united frictions. Just so is it with respect to sensation and perception: If the tendency of one atom cannot overcome one degree of inertness, the tendency of a thousand atoms will not overcome a thousand degrees of the same inertness. 230

Only two opinions at present on the subject.

We have just mentioned these absurd suppositions that our article might be complete: but it is proper to inform the reader, that, so far as we know, neither of them has for these many years been maintained by any philosopher of eminence either at home or abroad. The opinions on this subject, which at present divide the republic of letters, are two; and these alone are worthy of examination. One party maintains, That perception, memory, reason, and will, &c. are the powers of a being which must be immaterial and indivisible: The other alleges, That as we know nothing of these powers but from our own consciousness, and as we can trace them in ourselves to the brain and no farther, we have no reason to suppose that they are the powers of any substance distinct from matter. Both parties, however, distinguish that which in man is the subject of thought from his external organs of sense, and agree to call it by the name of *mind;* though the one considers it as composed of the same first matter with the dust of the ground; whilst the other believes it to have no property whatever in common with that matter.

Were we to adopt some of the ancient methods of philosophizing, this important question might be soon decided. A most respectable writer, who has laboured to restore the metaphysics of Plato and Aristotle, hopes to confute the materialists, by laying down what they must think arbitrary definitions of mind and matter, and then showing that the one is not the other. "In

(c) Scio fuisse philosophos quosdam, eosdemque *viros doctos*, qui corpora omnia sensu prædita esse sustinuerunt: *Nec video*, si natura sensionis in reactione sola collocaretur QUOMODO *refutari possint*. Sed etsi ex reactione etiam corporum aliorum, phantasma aliquod nasceretur; illud tamen, remoto objecto, statim cessaret. Nam nisi ad retinendum motum impressum, etiam remoto objecto, apta habeant organa, ut habent animalia; ita tantum sentient, ut nunquam sensisse se recordentur. Sensioni ergo, quæ vulgo ita appellatur, necessario adhæret memoria aliqua. *Hobbes's Physic*, cap. xxv. sect. 5.

Of Mind in general.

"In all the parts of the material world (says he) there is a perpetual *motion*: For the celestial bodies move constantly in one respect or another; and all here below is in a continual vicissitude of generation and corruption, which cannot be without *motion*. Now, where there is *motion*, there must be something that *moves*: What is *moved* I call *body*: what moves I call *mind*." From this definition he undertakes to prove, that mind must be immaterial. "That there is a relation between *moving* and *being moved* (says he) nobody can deny; and the relation is no other than that of *action* and *passion*. But the nature of relation is such, that it must necessarily be between two things at least; and it is further necessary, that the two things related should exist together. Hence, if there be that which *moves*, there must be a different thing that *is moved*; and wherever the one is, the other must necessarily be; so that nothing can move itself. This being established, I say that what *moves* must be either material or immaterial: for the one of these being the negation of the other, there can be no middle betwixt them; because a thing must necessarily *be*, or not *be*. If then it be immaterial, there is an end of the question: but if it be said to be material, then I say that it must be *moved* itself before it can move any thing else; for it is only in that way that body can move body. If then it must be first moved itself, but cannot itself move itself, what is it that moves itself? If it be answered, That it is another material mover, then I repeat the same question, to which the same answer must be given: and so we have an infinite series of *material movers*, without any beginning or *principle* of *motion*. Now this is absurd, and contradictory to this first principle of natural philosophy, admitted by all philosophers ancient and modern, That *nothing can be produced without a cause**.

* *Ancient Metaphysics.*

For the immateriality of the human mind, and of every being endowed with the powers of perception and thought, the learned writer has better arguments; but it is upon this chiefly that he rests his persuasion, that mind is the only *mover* in the universe. It is needless to observe, that in the very definitions and axioms upon which this reasoning is built, the thing to be proved is taken for granted: for if it be self-evident, that what *moves* is, in the author's sense of the word, *mind*, that what is *moved* is *body*, and that *nothing can move itself*, all reasoning on the subject is superfluous. This, however, is so far from being self-evident, that a materialist may reply, "every animal moves itself, and yet every animal is nothing more than a system of matter." This position, whether true or false, can neither be proved nor confuted by arguments *à priori* founded on general definitions. That animals move themselves, and that to the senses they appear to be nothing else than systems of matter, are facts which cannot be controverted. If we would know whether they have in them a principle of motion which is not material, we must submit to the laws of induction (see LOGIC); and by investigating the essential qualities of matter, endeavour to ascertain whether a material system can be rendered active. That we ourselves have active powers, we know by the most complete of all evidence, viz. consciousness of their energies; and it has been already shown, that such powers as we experience in ourselves cannot exist but in a subject possessed of will and understanding. The question therefore to be first decided between the materialists and immaterialists is, Whether the powers of consciousness, understanding, and will, can result from the particular organization of a system of matter? If they can, we have no reason to attribute them in man to any other source: If these powers appear necessarily to require an immaterial principle for their support, it will probably be granted, that an immaterial principle is the source of every power and every motion in the universe; and the doctrine of *mind*, in the strictest sense of the word, will be sufficiently established.

Of the Substance of the Human Mind.

231 The proper method of investigating the nature of mind.

CHAP. II. *Of the* SUBSTANCE *of the* HUMAN MIND.

232 Argument for the immateriality of the human mind.

THE most celebrated materialist of this or perhaps of any other age is Dr Priestley; who having in his own imagination divested matter of solidity, and reduced it to mere centres of attraction and repulsion, observes, that "if one *kind of substance* be capable of supporting all the known *properties* of man; that is, if those properties have nothing in them that is absolutely incompatible with one another; we shall be obliged to conclude (unless we openly violate the rules of philosophizing, which will not authorize us to *multiply causes* or kinds of substance *without necessity*), that no other kind of substance enters into his composition; the supposition being manifestly *unnecessary*, in order to account for any appearance whatever.—All the properties that have hitherto been attributed to matter, may be comprised under those of attraction and repulsion. Besides these, man is possessed of the powers of *sensation* or *perception*, and *thought*. But if, without giving the reins to our imaginations, we suffer ourselves to be guided in our inquiries by the simple rules of philosophizing above mentioned, we must necessarily conclude, that these powers also may belong to the same substance that has also the properties of attraction, repulsion, and *extension* (D), which I as well as others call by the name of *matter*. The reason of the conclusion is simply this, that the powers of sensation or perception and thought, as belonging to man, have never been found but in conjunction with a certain *organized system of matter*; and therefore that those powers necessarily exist in and depend upon such a system. This at least must be our conclusion, till it can be shown that these powers are incompatible with the

(D) When Dr Priestley mentions the *extension* of corporeal substance, it must be remembered that he does not mean the extension of any real thing possessed of an independent existence. The extension belongs wholly to the *sphere* or the *combination* of spheres of *attraction* and *repulsion*. The centre itself, which attracts and repels, he repeatedly affirms not to have the dimensions even of a physical point; and he sometimes seems to entertain a doubt whether it be any thing more than a mere relative notion.

Of the Substance of the Human Mind.

the other known properties of the same substance; and for this I see no sort of pretence."

This is what Dr Priestley calls the proper and direct proof that the sentient principle in man is the material substance of the brain; and he enforces it by the following observations: "Had we formed a judgment concerning the necessary seat of thought by the circumstances that *universally accompany it*, which is our rule in all other cases, we could not but have concluded that in man it is a property of the *nervous system*, or rather of the brain; because, as far as we can judge, the faculty of thinking, and a certain state of the brain, always accompany and correspond to one another; which is the very reason why we believe that any property is inherent in any substance whatever. There is no instance of any man retaining the faculty of thinking when his brain was destroyed; and whenever that faculty is impeded or injured, there is sufficient reason to believe that the brain is disordered in proportion: and therefore we are necessarily led to consider the latter as the seat of the former. Moreover, as the faculty of thinking in general ripens and comes to maturity with the body, it is also observed to decay with it; and if, in some cases, the mental faculties continue vigorous when the body in general is enfeebled, it is evidently because in those particular cases the *brain* is not much affected by the general cause of weakness. But, on the other hand, if the brain alone be affected, as by a blow on the head, by actual pressure within the skull, by sleep, or by inflammation, the mental faculties are universally affected in proportion. Likewise, As the mind is affected in consequence of the affections of the body and brain, so the body is liable to be reciprocally affected by the affections of the mind, as is evident in the visible effects of all strong passions, hope or fear, love or anger, joy or sorrow, exultation or despair. These are certainly irrefragable arguments, that it is properly no other *than one and the same thing* that is subject to these affections, and that they are necessarily dependent upon one another. In fact, there is just the same reason to conclude, that the powers of sensation and thought are the necessary result of a particular organization, as that sound is the necessary result of a particular concussion of the air. For in both cases equally the one constantly accompanies the other; and there is not in nature a stronger argument for a necessary connexion of any cause and any effect. To adopt an opinion different from this, is to form an hypothesis without a single fact to support it*."

Disquisitions on Matter and Spirit.

Though the ingenious author thinks, that if there be any foundation for the established rules of philosophizing, this reasoning ought to be conclusive, he yet subjoins, for the greater satisfaction of his readers, some additional arguments, or rather, as he says, distinct illustrations of the great argument. They are as follow:

1. "That the faculty of thinking necessarily depends, for its *exercise* at least, upon a stock of ideas, about which it is always conversant, will hardly be questioned by any person. But there is not a single idea of which the mind is possessed but what may be proved to have come to it from the bodily senses, or to have been consequent upon the perceptions of sense. The notion, therefore, of the *possibility* of thinking in man, without an organized body, is not only destitute of all evidence from actual appearances, but is directly contrary to them; and yet these appearances ought alone to guide the judgment of philosophers.

2. "The only reason why it has been so earnestly contended for, that there is some principle in man that is not material, is, that it might subsist, and be capable of sensation and action, when the body is dead. But if the mind was naturally so independent of the body, as to be capable of subsisting by itself, and even of appearing to more advantage, after the death of the body; it might be expected to discover some signs of its independence before death, and especially when the organs of the body were obstructed, so as to leave the soul more at liberty to exert itself; as in a state of *sleep* or *swooning*, which must resemble the state of death; in which it is pretended that the soul is most of all alive, most active, and vigorous. But judging by appearances, the reverse of all this is the case.

3. "If the mental principle was, in its own nature, immaterial and immortal, all its particular faculties would be so too; whereas we see that every faculty of the mind without exception is liable to be impaired, and even to become wholly extinct, before death. Since, therefore, all the faculties of the mind, separately taken, appear to be mortal, the substance or principle in which they exist must be pronounced to be mortal too.

4. "If the sentient principle in man be immaterial, it can have no *extension*; it can neither have length, breadth, nor thickness; and consequently every thing within it, or properly belonging to it, must be *simple* and *indivisible*. Let us now consider how this notion agrees with the phenomena of sensation and ideas. It will not be denied, but that sensations or ideas properly exist *in the soul*, because it could not otherwise retain them, so as to continue to perceive and think after its separation from the body. Now, whatever ideas are in themselves, they are evidently produced by external objects, and must therefore correspond to them; and since many of the objects or archetypes of ideas are divisible, it necessarily follows, that the ideas themselves are divisible also. But, how is it possible that a thing (be the nature of it what it may) that is *divisible*, should be contained in a substance, be the nature of *it* likewise what it may, that is *indivisible*? If the archetypes of ideas have extension, the ideas which are expressive of them, and are actually produced by them according to certain mechanical laws, must have extension likewise: and therefore the mind in which they exist, whether it be material or immaterial, must have extension also. But how any thing can have extension and yet be immaterial, without coinciding with our idea of mere empty *space*, I know not."

To the argument, which is here chiefly insisted on as being agreeable to the established rules of philosophizing, a very able reply has been made, which we shall give in the words of its elegant and spirited author. But before we attempt to dig up the foundation of the doctor's system, it may not be improper to demolish, if possible, the additional buttresses by which it is strengthened. An experienced general, before he storm a citadel which he knows to be strongly

Of the Substance of the Human Mind.

ly fortified and skilfully defended, will take care to raze every less important redoubt from which the enemy might annoy him in his rear.

233 Answered.

Because the faculty of thinking in general ripens, comes to maturity, and decays with the body, and the body on the other hand is affected by the affections of the mind, the doctor affirms that we have the same reason to conclude, that the powers of sensation and thought are the necessary result of a particular organization, as that sound is the necessary result of a particular concussion of the air. This argument is conclusive only upon the supposition that there is no *positive* evidence whatever of the immateriality of the being which is the subject of thought. If the other reasonings for the materiality or immateriality of the mind be of equal weight, this argument ought doubtless to turn the balance; but if there be the smallest preponderancy in behalf of the immaterialists, it is a mere begging of the question to attempt to counteract it by any inference which can be drawn from the mutual affections of the body and mind. If two such heterogeneous beings as an immaterial mind and an organized body can be supposed united in one person, they must necessarily affect each other; and to affirm on account of this reciprocal affection, that they are *one and the same*, is equally absurd as to say that an electrician and his apparatus are *one and the same*. Dr Priestley himself did not at first perform his electrical experiments with so much ease as after he had acquired facility by long practice, nor could he even yet perform them so neatly with a bad as with a good apparatus.

That which the doctor calls the first illustration of his argument might be admitted, and the force of the argument itself be consistently denied. Some kind of organized body may be necessary to the mind as an instrument without which it could not exert its faculties; but it would certainly be rash to infer that the mind must *therefore* be a system of matter. An anvil and a hammer are necessary to the exercise of the blacksmith's art; but what would be thought of him who should from this fact conclude, that the blacksmith himself must be a system of iron! This, therefore, instead of illustrating the great argument, seems to be wholly foreign from the question in debate; and it has in fact been admitted by Dr Price *, and thousands of others who reject the doctrine of materialism, as an impious absurdity. The second illustration, however, is more to the purpose; and as it is not new, we shall give it an old answer.

* *Correspondence with Dr Priestley.*

Why do not we perceive external objects in our *sleep* or in a *swoon*? "Because (says Mr Wollaston †), the *passages* are become impracticable, the *windows* shut, and the *nerves* being obstructed, or somehow rendered for the time useless, can transmit no information to it. Why, however, does it not reason and think about *something or other*? Because, all the *marks* by which things are remembered, being for the present choked up or disordered, the remembrance of those *objects* about which it is wont to employ itself, and even of the words (or other signs) in which it uses to reason, and to preserve the deductions and conclusions it makes, is all suspended at least for the time: and so its tables being covered, its books closed, and its tools locked up, the requisites for reasoning are wanting, and no subject offers itself to exercise its thoughts, it having yet had little or no opportunity to take in *higher objects* and more *refined matter* for contemplation. And, to conclude, if it be demanded, Why any one should imagine that the *soul* may think, perceive, act, *after death*, when it doth not do this in sleep, &c.? the answer is, Because those *enclosures* and *impediments* which occasioned the forementioned intermissions, and those great limitations under which it labours at all times, will be removed with its enlargement out of the body. When it shall in its *proper vehicle* be let go, and take its flight into the open fields of heaven, it will then be bare to the immediate impressions of objects: And why should not those impressions which affected the *nerves*, that moved and affected the vehicle and soul in it, *affect the vehicle immediately* when they are immediately made upon it, without the interposition of the nerves? The hand which feels an object at the end of a *staff*, may certainly be allowed to feel the same much better by *immediate contact* without the staff."

† *Religion of Nature Delineated.*

The opinion, that the soul is united to some fine vehicle, which dwells with it in the brain, and goes off with it at death, was not peculiar to Mr Wollaston. It was thought extremely probable by Dr Hartley, and shall be shown afterwards to have been a very ancient opinion; but we do not quote it at present as either well or ill founded, but only as sufficient, in conjunction with the reasoning of its author, to obviate the force of Dr Priestley's second illustration of his argument for the materiality of mind, provided the argument itself be not more powerful than any which the immaterialists can bring against it.

The doctor's third illustration we have already obviated, when we accounted for the mind and the body mutually affecting each other; and we might refer to Dr Price's answer (E) to the fourth, as being, in our opinion, a full confutation of it. But as that author's notions of *mind* and *ideas* differ in some respects from our own, we shall examine this objection to the doctrine of the immaterialists upon principles which we believe Dr Priestley more inclined to admit.

That the sentient principle in man, if it be immaterial,

(E) In *Disquisitions*, p. 37 and 102, it is asserted, that ideas are certainly divisible. "This seems to me very absurd. It would be as proper to assert ideas to be hard or round. The idea of an object is the apprehension, view, or notion of it; and how can this be divisible? Perception is a single and indivisible act. The object perceived may be divisible; but the *perception* of it by the mind cannot be so. It is said in page 95, *that if ideas are not things distinct from the mind, a mind with ideas and a mind without ideas would be the same.*—I maintain that ideas are not distinct from the mind, but its conceptions; or not *things* themselves, but *notions* of things. How does it follow from hence, that a mind with or without ideas is the same? It would seem that this follows much more from the contrary assertion." *Correspondence between Dr Price and Dr Priestley.*

Of the Substance of the Human Mind.

terial, can have no extension, is a truth which we think cannot be controverted; and if so, every thing in that principle must be *simple* and *indivisible*. Thus far we agree with Dr Priestley; but with respect to what follows we differ from him entirely. The agitation in the brain, which is the immediate cause of sensation, must indeed correspond to the impression *ab extra* by which it is produced, and therefore must have the property of extension; but that agitation, whatever it be, is not itself sensation, any more than a bludgeon is a blow, or a sword is a wound. Dr Priestley, indeed, in answer to Dr Price, affirms, that, according to Hartley's theory, ideas are only *vibrations in the brain*; but whoever shall take the trouble to examine that theory himself, will not find that its author ever advances such an opinion, or considers vibrations as any thing more than the instruments by which sensations and ideas are excited in the sentient principle. A real and proper idea, as we have often repeated, is nothing else than a fainter sensation: but no sensation, from whatever cause it may proceed, is itself extended; nor could we, without memory, the reasoning faculty, and the power of local motion, have acquired from mere sense any notion of extension at all: (see sect. 3. Chap. 1. Part I.). Sensations and ideas are those *appearances* (if we may so say), which vibrations or some other motion in the brain excite in the mind; but a *half* appearance is an absurdity. A man may view *half a tree* with his eyes, and he may contemplate the idea of *half a tree* in his mind; but he cannot have *half a view* or *half an idea* of any thing. Sensations and ideas result from the mutual agency of the brain and sentient principle upon each other; and if the agency of the brain be vibration, more of it may vibrate at one time than at another: but surely the mere relation between its agency at any time and the agency of the mind, can neither have extension nor be divisible; for who ever thought of extending or dividing relations? On this subject it is extremely difficult to write with perspicuity and precision; and what we have said may very possibly be misunderstood. Our notion is to ourselves clear and determinate; but language, which was not invented by metaphysicians, wants words in which it may be properly expressed. Perhaps the reader may understand what we mean, when we say that a sensation or an idea is the instantaneous effect of the mutual agency of the brain and sentient principle. Of this we think every man, by a little attention, may be perfectly convinced, though it may be impossible ever to discover the precise nature of this agency; and if so, it is plain that sensations and ideas cannot be divided, for no instantaneous effect of any kind is divisible. A sensation, and of course a simple and original idea, neither has extension itself, nor suggests the notion of extension *ab extra*. By running the hand or any other member along a solid body, we feel continued resistance: this feeling, or the idea of this feeling, becomes in time so closely associated with all our sensations of touch and sight, that the one cannot be separated from the other; and these associations are what Dr Priestley calls *extended ideas*. Upon the whole then, we think it apparent, that our sensations, and the relicks of our sensations, are unextended and indivisible (E); and that though they suggest

(F) We affirm this only of *human* sensations and ideas, because these are the only sensations and ideas of which we are conscious, and about which we can reason. Other animals are sentient as well as man, and appear to have their sensations excited by impressions *ab extra*; but whether in every species of animals a single impression excites but one sensation common to the whole animal, or different sensations which are felt each by a different faculty or sentient principle, is a question which we are not able to answer. We make this remark, because from the phenomena of sensation in the earthworm and other reptiles, some philosophers of eminence having supposed, that in these creatures the sentient faculty belongs to the material system, and is divisible with it; have thence concluded, we think rashly, that all arguments for the immateriality of the human mind are founded merely on our ignorance. We call this conclusion rash; because, though we know perfectly what a human sensation is, we have so little knowledge of the nature of sensation in worms, that what may be true of the one *principle* of sensation may be false of the other. Indeed, if we are to judge from the phenomena, this is actually the case. It appears from experiments made by Abbe Spallanzani and others, that if a certain number of rings be cut off either from the anterior or posterior part of a worm, or even from both, the remainder will not only continue to live and be sentient, but will also regenerate a new head and a new tail, and become again a complete worm. Nothing like this takes place in man or in the higher orders of animals; and therefore, were it certain that the sentient principle in the worm is diffused through the whole system, and divisible with it, we could not infer that the principle of such sensations as we are conscious of, is likewise extended and divisible. It is, however, so far from being certain that the sentient principle is diffused through the whole worm, that nothing necessarily follows from this fact, but that its seat is at some distance from either extremity. Nay, were it true, as perhaps it is, that a worm may be so divided, as that each of the two sections shall retain life, sensation, and this reproductive power, we would not therefore be authorized to conclude that the sentient principle is *one* coextended and divisible with the material system. The earthworm, like many other reptiles, being an hermaphrodite, which unites in itself both sexes, may possibly consist of two animated systems; which though united by some bond of connexion, by which sensation is communicated from the one to the other, are yet in themselves perfectly distinct. Should this, upon proper investigation, be found to be the case; and should it likewise be found, that when a worm is divided into three or more parts, only one or two of these parts continue to live, there would be no room whatever for supposing that even in these creatures the principle of sensation is extended and divisible. In the mere power of reproducing amputated parts, when that power is considered by itself, there is nothing more wonderful than in the growing of the nails of our fingers, or the hairs

Of the Substance of the Human Mind.

gest to us the existence of extended things *ab extra*, the sentient being *may* be unextended and indivisible.

Having thus examined Dr Priestley's auxiliary arguments for the materiality of mind, we now proceed to consider his main and direct proof. To this, as we have observed, so able a reply has been made, that it would be injustice to our readers not to lay it before them, in the words of its author. "I readily acknowledge (says this spirited essayist*) that the power of sensation or perception never having been found but in conjunction with a certain organized system of matter, we ought, as philosophers, to conclude that this power necessarily exists in, and results from, that organized system, unless it can be shown to be incompatible with other known properties of the same substance. On the other hand, it must be admitted, that constant conjunction implies *necessary* connexions only when reasons cannot be discovered to prove the conjunction to be accidental and arbitrary. In the present instance, it is alleged, that discerptibility is a property of matter absolutely incompatible with the property of sensation or perception; or in other words, that sensation is a power or property incapable of division. But as the power of the entire system is clearly nothing more than the sum or aggregate of the powers of all the parts, it necessarily follows, that the primary particles of which the system is composed must, upon the material hypothesis, possess distinct powers of sensation; and that those powers combined constitute the indivisible power of sensation belonging to the system; or, in other words, that the *indivisible* power of sensation is a *divisible* power, nay, an infinitely divisible power, if matter be, as philosophers in general allow, an infinitely divisible substance—a conclusion obviously and grossly ridiculous. We are then compelled to acknowledge, that sensation or perception is not the property of a material substance; i. e. if the common mode of expression be retained, it is the property of an immaterial substance; or, to avoid verbal contention, it is a property not resulting from, or necessarily connected with, the organical system, but a property wholly foreign, superinduced, and adventitious (G).

234
Direct proof that the sentient principle in man cannot be a system of matter.

"In

* *Essays, Philosophical, Historical, and Literary*, vol. ii.

---

hairs of our heads. The only thing which seems to militate against the simplicity of the principle of sensation in worms, is the continuance of life, &c. with both parts of a worm when cut into two by a knife or pair of scissars; but if a worm be found to have two seats of sensation analogous to the brain in higher animals, and if it be likewise found that life continues only in such sections as retain at least one seat of sensation, the sentient principle in the worm may be as simple and indivisible as in any animal whatever. We neither wish nor expect much stress to be laid upon these hints and conjectures. Should they induce any of our physiological readers, who have leisure, and are at the same time skilled in philosophy, properly so called, to institute a set of experiments upon worms and such reptiles, and to trace apparent effects to their higher causes, they might eventually lead to important discoveries. In the mean time, it is sufficient for our purpose to observe, that whatever be the sentient principle or principles in the earthworm, it is obvious that the whole animal cannot in any case be conscious, as man undoubtedly is, of *one individual sensation;* and that therefore no arguments built upon the phenomena accompanying sensation in worms, can be of any importance in the controversy about the materiality or immateriality of the human mind.

(G) This argument is not new. It was long ago urged by Dr Clarke against Mr Dodwell; and some of our readers may not be ill pleased to see it stated by so masterly a reasoner: "That the soul cannot possibly be *material*, is demonstrable from the single consideration of bare sense or consciousness. For matter being a divisible substance, consisting always of separable, nay of actually separate and distinct parts, it is plain that unless it were essentially conscious, in which case every particle of matter must consist of innumerable separate and distinct consciousnesses, no system of it, in any possible composition or division, can be an individual conscious being. For suppose three or three hundred particles of matter, at a mile or any given distance one from another, is it possible that all these separate parts should in that state be one individual conscious being? Suppose then all these particles brought together into one system, so as to touch one another, will they thereby, or by any motion or composition whatsoever, become one whit less truly distinct beings than they were when at the greatest distance? How then can their being disposed in any possible system make them one individual conscious being? If you will suppose God by his infinite power superadding consciousness to the united particles, yet still these particles being really and necessarily as distinct beings as ever, cannot be *themselves* the *subject* in which that individual consciousness inheres; but the consciousness can only be superadded by the addition of something, which in all the particles must still itself be but one individual being. The soul, therefore, whose power of thinking is undeniably one individual consciousness, cannot possibly be a material substance." *Clarke's Letter to Mr Dodwell*, 2d edition.

That the same mode of reasoning was known to the ancients, Cudworth has shown by numerous quotations; and as an argument certainly loses nothing by antiquity, or by having occurred to thinking men in distant ages, we shall lay before our readers two passages from Plotinus, of which the extract from Clarke's letter (though we are persuaded it was not borrowed by the author) must be considered as little more than a paraphrastical translation.——*τι τοινυν φησουσιν, οἱ την ψυχην σωμα ειναι λεγοντες, πρωτον μεν περι ἑκαστου μερους της ψυχης της εν τω αυτω σωματι, ποτερον ἑκαστον ψυχην, οἱα εστι και ἡ ὁλη; και παλιν του μερους το μερος; ουδεν αρα το μεγεθος συνεβαλλετο τη ουσια αυτης· καιτοι εδει γε ποσου τινος οντος· αλλα και ὁλον πολλαχη, οπερ σωμασι παρειναι αδυνατον, εν πλειοσι το αυτο ὁλον ειναι, και το μερος ὁ περ το ὁλον, ὑπαρχειν· εν δε ἑκαστον των μερων, ου ψυχην φησουσιν, εξ αψυχων ψυχη αυτοις υπαρξει.* *En.* IV. *Lib.* vii. *Cap.* 5.

The same argument is elsewhere stated thus: *ει δε ἑκαστον ζωην εχοι, και εν αρκει· ει δε μηδενος αυτων ζωην εχοντος ἡ συνοδος πεποιηκε ζωην, ατοπον· μαλλον δε αδυνατον συμφορησιν σωματων ζωην εργαζεσθαι, και νουν γενναν τα ανοητα.* *En.* IV. *Lib.* ii. *Cap.* 2.

The Substance of the Human Mind.

"In opposition to this reasoning, the materialists affirm, that entire systems may possess, and they think themselves warranted to pronounce that organized systems of matter actually do possess, powers essentially different from those which inhere in the several parts. Amongst various familiar though striking illustrations of this truth, it has been said, that a rose possesses the property of sweetness or fragrance, a globe the property of sphericity, a harpsichord the property or power of producing harmony, *aqua regia* the property of dissolving gold, &c. though the component particles of these different organized systems are themselves totally destitute of the powers and properties here enumerated.

"The immaterialists, in reply, assert, that it is not only false in fact, but a direct contradiction, and an absolute impossibility in the nature of things, that a system should possess any property which does not inhere in its component parts. To assert that the power of the whole is the sum or aggregate of the powers of all the parts, is an identical and self-evident proposition, the whole and all the parts being terms precisely synonymous. Whoever, therefore, calls in question the truth of this axiom, must maintain that the power of the whole is something different from the power of all the parts, i. e. that the power of the whole is *not* the power of the whole.

"It will be easy to demonstrate the correspondence of facts with this plain and simple theory. For this purpose, it is necessary to observe, that the properties of matter, or what are generally denominated such, may be divided into real and nominal, which Locke and others have called primary and secondary qualities. Figure, magnitude, and motion, are qualities really inherent in matter; but figure, magnitude, and motion, eternally varied, can produce only different combinations of figure, magnitude, and motion. There are also powers, or qualities, vulgarly considered as inherent properties of matter organically disposed, which are really and truly qualities or affections of the mental or percipient principle, and have no existence when not perceived. Thus the sweetness or fragrance of the rose, considered as mere sweetness and fragrance, can be nothing but an affection of the mind; considered as a quality of the rose, they can mean nothing more than a certain arrangement, configuration, and motion of parts, which in some inexplicable manner produces the sensation of sweetness. In this instance, therefore, the power of the whole is plainly the aggregate of the powers residing in the parts, by the motion and organization of which a certain effect is produced upon a foreign and percipient substance.

"But a globe, we are told, possesses the property of sphericity, though not a single particle amongst that infinite number of which the globe is constituted is itself of a spherical form. The fallacy of this illustration is, however, as easily demonstrable as that of the former. The sphericity of a globe is evidently the sum or aggregate of the curvilinear or convex parts which compose its surface; and the property of the whole is neither more nor less than the combined properties of all its parts. No one doubts, that by new compositions or arrangement of material particles possessing magnitude, figure, and motion, an endless diversity of phenomena may be produced, to which it may be necessary to apply new names. New names, however, do not constitute new properties; and though we give to a globe the appellation of an entire system, and ascribe to it the property of sphericity, we know at the same time that it is really nothing more than a collection of thousands of millions of particles, actually separate and distinct, arranged in that particular form which we denominate spherical. But this can never be regarded as in the remotest manner analogous to the *creation* of the power of perception, in consequence of a certain organical arrangement or disposition of impercipient particles. Though sphericity is, indeed, the property of the entire sphere, yet every part of the sphere, if divided, possesses its share of sphericity. But if the percipient principle be divided, what would become of the power of perception? A sphere equally divided becomes two hemispheres; Does a perception, when divided in like manner, become two demi-perceptions?

"The same reasonings may easily be transferred, and applied to the harpsichord. Can any one be absurd enough to affirm that the power of harmony resides in the harpsichord, as the power of perception does in the mind? After the utmost skill of the artificer has been exerted, we discover nothing more in the harpsichord than new modifications of the old properties of figure, magnitude, and motion, by means of which certain vibrations are communicated to the air, which, conveyed by the medium of the auditory nerves to the sensorium, produce the sensation of harmonic sounds. These new modifications are therefore attended, indeed, with new and very wonderful effects; but then those effects are produced upon, and are themselves modifications of, the sentient or percipient faculty. And though it is wholly incomprehensible to us in what manner these effects, that is, these *sensations*, are produced, we well know, and perfectly comprehend, that they are not new powers belonging to any organized system of matter; that they have no existence but in a mind perceiving them; and that they are far from militating against that grand and universal axiom, that the power of the whole is nothing more than the united powers of all the parts.

"As to the last instance adduced, of the power of *aqua regia* to dissolve gold, though neither the spirit of salt, nor the spirit of nitre of which it is compounded, separately possesses that power, it is plain, that from the union of these two substances, certain new modes of configuration and motion result; and the solution of gold is the consequence of this new arrangement and motion of the parts. But the particles of which the menstruum is composed were always possessed of the properties of figure and motion; and what is styled a new property, is clearly nothing more than a new effect of the old properties differently modified. In a word, the advocates for materialism may safely be challenged to produce, in the whole compass of nature, a case which bears the least analogy to that which these instances are most unphilosophically adduced to prove and to illustrate. It is an absurdity which transubstantiation itself does not exceed, to maintain that a whole is in reality any thing different from its component parts: and all nature rises up in confutation of an assertion so monstrous and extravagant. To affirm that perception can arise from any combination of impercipient particles, is as truly ridiculous, as to affirm that

Of the Substance of the Human Mind.

that a combination of the seven primary colours with the four cardinal virtues may constitute a planet. It is equivalent to an assertion, that an epic poem might be composed of parallelograms, cones, and triangles. In a word, it is an absurdity not less real, and a little less obvious, than that of the blind man who thought that the idea of a scarlet colour resembled the sound of a trumpet."

If matter be taken in the common acceptation, to be a solid, extended, and inert substance, this reasoning for the immateriality of the sentient principle in man appears to us to have the force of demonstration, which no difficulties or partial objections, arising from our inability to conceive the band of union between two such heterogeneous substances as mind and body, can ever weaken, and far less overturn. But the modern materialists deny that matter is either solid or inert. "All those facts (say they) which led philosophers to suppose that matter is impenetrable to other matter, later and more accurate observations have shown to be owing to *something else* than solidity and impenetrability, viz. a *power of repulsion*, which for that reason they would substitute in its place. The property of *attraction* or repulsion (says Dr Priestley) appears to me not to be properly what is *imparted* to matter, but what really *makes it to be what it is;* insomuch, that without it, it would be nothing at all; and as other philosophers have said,—'Take away solidity, and matter vanishes,' so I say, 'Take away attraction and repulsion, and matter vanishes." If this be admitted, the ingenious author hopes that we shall not consider matter with that contempt and disgust with which it has generally been treated, there being nothing in its real nature that can justify such sentiments respecting it.

235 Reply by the materialists shown

236 to be absurd.

We know not why, upon any hypothesis, matter should be viewed with contempt and disgust.—Whether penetrable or impenetrable, every consistent theist considers it as one of the creatures of God, perfectly fitted to answer all the purposes for which it was intended: but were it really destitute of solidity, and endowed with the powers of attraction and repulsion, we should still be obliged to consider it as incapable of the powers of sensation and thought. If we have any notion at all of what is meant by centres of attraction and repulsion (of which indeed we are far from being confident), it appears to us to be intuitively certain, that nothing can be the result of any possible combination of such centres, but new and more enlarged spheres of attraction and repulsion. But surely consciousness, sensation, and will, are as different from attraction and repulsion, as a cube is from the sound of a trumpet, or as the sensations of a felon in the agonies of death are from the attraction of the rope by which he is hanged. If this be admitted, and we are persuaded it will be denied by no man whose understanding is not clouded by an undue attachment to paradoxes, the sentient principle cannot possibly be matter; for if, when the powers of attraction and repulsion are taken away, matter vanishes; and if consciousness and sensation are not attraction and repulsion; it is not more evident that three and two are not nine, than that the substance which attracts and repels cannot be that which is conscious and percipient.

237 Locke's opinion hasty and ill-founded,

Locke, who was certainly no materialist, as he repeatedly affirmed, and indeed demonstrated, that thought could never be the result of any combinations of figure, magnitude, and motion, was yet of opinion, that God by his almighty power might endow some systems of matter with the faculties of thinking and willing. It is always with reluctance that we controvert the opinions of so great a man; and it is with some degree of horror that we venture in any case to call in question the power of Omnipotence.—But Omnipotence itself cannot work contradictions; and it appears to us nothing short of a contradiction, to suppose the individual power of perception inhering in a system which is itself extended and made up of a number of separate and distinct substances. For let us suppose such a system to be six feet long, three feet broad, and two feet deep (and we may as well suppose a system of these dimensions to be percipient, as one that is smaller) then it is plain, that every idea must be extended, and that part of it must be in one place, and part in another. If so, the idea of a square inch will be six feet long, three feet broad, and two feet deep; and what is still harder to be digested, the several parts of this idea will be at a great distance from each other, without any bond of union among them. The being which apprehends one extremity of the idea, is, by the supposition, six feet distant from the being which apprehends the other extremity; and though these two distinct beings belong to one system, they are not only separable, but actually separated from each other as all the particles of matter are. What is it then that apprehends as *one* the whole of this extended idea? Part of it may be apprehended by one particle of matter, and part of it by another; and there is nothing which apprehends or can apprehend, the whole. Perhaps it will be said, the power of apprehension is not divided into parts, but is the power of the one system, and therefore apprehends at once the whole idea. But a power or faculty cannot be separated from its subject, power which inheres in nothing being confessedly impossible; and a material system is not *one subject* in which any individual power or faculty can inhere. There must, therefore, be united to the system some *one* being, which is the subject of thought, and which is unextended as well as indivisible. This, we say, follows undeniably. For, let us suppose, that an extended being without separate parts is possible, and that such a being is percipient; it is obvious, that the whole of any one of its perceptions could not be in one place. Now, though we should grant to Dr Priestley and other materialists, that every idea of an extended substance has itself three dimensions, and is incorporated and commensurate with the whole percipient system; what, upon this supposition, shall we think of consciousness and of the perception of truth? Is consciousness or truth extended? If so, one side or superficies of consciousness, or of a truth, may be greater or less than another, above or below, to the right or to the left; and it will be very proper and philosophical to speak of the length, breadth, and depth, of consciousness or of truth. But surely to talk of the place or the extension of these things, is as absurd as to talk of the colour of sound, or the sound of a triangle; and we might as well say, that consciousness is green or red, as that it is an ell or an inch long;

long; and that truth is blue, as that it has three dimensions.

This reasoning is somewhat differently stated by Cudworth; who observes, that if the soul be an extended substance, "it must of necessity be either a physical point (i. e. the least extension possible, if there be any such least extension), or else it must consist of more such physical points joined together. As for the former of these, it is impossible that *one single atom*, or *smallest point* of extension, should be able to perceive distinctly all the *variety* of things, i. e. take notice of all the *distinct* and *different* parts of an *extended object*, and have a *description* or *delineation* of the whole of them upon itself (for that would be to make it the least, and not the least, possible extension at the same time: Besides, to suppose every soul to be but one *physical point*, or the smallest *possible extension*, is to suppose such an essential difference in matter or extension, as that some of the *points* thereof should be *naturally* devoid of all *life*, *sense*, and *understanding;* and others again, naturally *sensitive* and *rational*. And even should this absurdity be admitted, it would yet be utterly inconceivable how there should be *one*, and *but* one, *sensitive* and *rational* atom in every man; how this atom of so *small* dimension, should actuate the whole system; and how it should constantly remain the same from infancy to old age, whilst all the other parts of the system transpire perpetually, and are succeeded by new matter (H).

Of the Substance of the Human Mind.

"But if, according to the second hypothesis, souls be extended substances consisting of many points one without another, and all concurring in every sensation; then must every one of these points perceive either a *point* only of the object, or else the *whole*. Now, if every *point* of the *extended soul* perceives only a *point* of the *object*, then there is no *one thing* in us that perceives the whole, or that can compare one part of the object with another. On the other hand, if every *point* of the *extended soul* perceive the *whole object* at once, then would there be *innumerable perceptions* of the same object in every sensation; as many, indeed, as there are points in the extended soul.—And from both these suppositions it would alike follow, that no man is *one single percipient* or person, but that in every man there are innumerable distinct *percipients* or *persons*; a conclusion directly contrary to the infallible evidence of consciousness (I)."

Cogent as these arguments for the immateriality of

(H) Should it be said, that this essential difference between the atoms of matter is not fortuitous; that some of them are created intelligent for the express purpose of animating systems of others which are unintelligent: and that these intelligent atoms do not operate upon the systems with which they are united, by the *vis inertiæ*, *solidity*, or *extension*, of matter, but by the energies of understanding and will: Should this (we say) be alleged, surely it may be asked, for what purpose they are conceived to have the quality of extension? It is evidently of no use; and it has been already shown, and shall be more fully shown afterwards, that by our notions of consciousness and understanding, we are so far from being led to suppose the subject of these powers extended, that we cannot suppose any relation whatever between them and extension. But if these intelligent atoms be divested of their quality of extension, they will be transformed from matter to mind, and become the very things for the existence of which we plead.

(I) As the materialists endeavour to prejudice the public against the notion of an unextended soul, by representing it as a fiction of *Des Cartes*, altogether unknown to the ancients, it may not be improper to give our readers an opportunity of judging for themselves how far this representation is just.—*Plotinus*, reasoning about the nature of the soul from its energies of sensation, expresses himself in these words:—ειτι μελλει αισθανεσθαι τινος, ἑν αυτο δει ειναι, και τω αυτω παντος αντιλαμβανεσθαι και ει δια πολλων αισθητηριων πλειω τα εισιοντα, ἡ πολλαι περι ἑν ποιοτητης και δι ἑνος ποικιλον, ὁιον προσωπον· ου γαρ αλλο μεν ρινος αλλο δε οφθαλμων, αλλα ταυτον ὁμου παντωνι και ει το μεν δι ομματων το δε δι ακοης, εν τι δει ειναι εις ὁ αμφω· ἡ πως αν ειποι ὁτι ἑτερα ταυτα, μη εις το αυτο ὁμου των αισθησεων ελθοντων. "That which perceives in us, must of necessity be one thing, and by one and the same indivisible perceive all; and that whether they be more things entering through several organs of sense, as the many qualities of one substance, or one various and multiform thing, entering through the same organ, as the countenance and picture of a man. For it is not one thing in us that perceives the nose, and another thing the eyes; but it is one and the self-same thing that perceiveth all. And when one thing enters through the eyes, another through the ears, both these also must of necessity come at last to one indivisible; otherwise they could not be compared together, nor one of them be affirmed to be different from the other, the several ideas of them meeting nowhere in one place." Pursuing the same argument, and having observed, that if what perceiveth in us be extended, then one of these three things must of necessity be affirmed, that either every part of this extended soul perceives a part only of the object, or every part of it the whole object; or else, that all comes to some one point, which alone perceives both the several parts of the object and the whole: he observes of the first of these suppositions,—μεγεθει οντι τουτω, ζυμμεριζοιτο αν· ωστε αλλο αλλου μερος, και μηδενα ἡμων ὁλου του αισθητου αντιληψιν εχειν· ὡσπερ αν ει εγω μεν αλλου· συ δε αλλου αισθοιο: "If the soul be a magnitude, then must it be divided, together with the sensible object, so that one part of the soul must perceive one part of the object, and another another; and nothing in it, the whole sensible; just as I should have the sense of one thing, and you of another." Of the second supposition he writes in this manner: ει δε ὁτιουν παντος αισθησεται· εις απειρα διαιρεισθαι του μεγεθους πεφυκοτος απειρους και αισθησεις καθ' εκαστον αισθητον συμβησεται γιγνεσθαι ἑκαστω ὁιον του αυτου απειρους εν τω ἑγεμονουντι ἡμων εικονας: "But if every part of the extended soul perceive the whole sensible object, since magnitude is infinitely divisible, there must be in every man infinite sensations and images of one object."—And as for the third and last part of this disjunction, Plotinus by asserting the infinite divisibility of body, here shows that the supposition of any one physical point is in itself an absurdity. But if it were not, he agrees with Aristotle

Of the Substance of the Human Mind.

of the sentient principle appear to be, they have been lately treated with the most sovereign contempt by a writer who professes to be a disciple of Dr Priestley's, but who seems not to have learned the modesty or the candour of his master. Dr Priestley labours to prove, that to account for the phenomena of perception and volition, &c. it is not necessary to suppose an immaterial principle in man. Mr Cooper with greater boldness affirms, and undertakes to demonstrate with all the parade of mathematical precision*, that such a principle is impossible. Though the authority of this philosopher in such inquiries as depend not immediately upon the retort and the furnace, is certainly not great, he yet utters his dogmas with such confidence, that it may not be improper to examine the chief arguments upon which they rest.

* Tracts Ethical, Theological, and Political, vol. i.

239 An attempt to prove the impossibility of immaterial substance.

"Suppose (says he) the soul to have no common property with matter; then, no thing can act upon any other but by means of some common property. Of this we have not only all the proof that induction of known and acknowledged cases can furnish, but that additional proof also which arises from the impossibility of conceiving how the opposite proposition *can* be true. But by the supposition, the soul has no property in common with matter; and therefore the soul cannot act upon matter. But by the supposition of every system of immaterialism (except those of Malebranche, Berkeley, and Leibnitz), it is deemed an essential property of the soul, that it acts upon the body, or upon matter; therefore the soul can and cannot act upon matter at the same time, and in the same respect. But this is a contradiction in terms; and as two contradictions cannot both be true at the same time, the supposition of the existence of an immaterial soul cannot be true; that is, the soul does not exist."

240 shown to be futile.

This reasoning, the reader will observe, is carried on with all the pomp of mode and figure. The propositions hang upon each other like the several steps of an algebraic process: but as in such processes one error unwarily admitted produces a false result, so in demonstrative reasonings one unsound argument admitted into the premises is necessarily productive of error in the conclusion. When the author affirms, "that no thing can act upon any other but by means of some common property," he affirms without the shadow of proof what is certainly not self-evident. He says, indeed, that of this we have all the proof that induction of known and acknowledged cases can furnish; but unless consciousness be calculated to deceive us, this is unquestionably a mistake. Matter, he repeatedly affirms, has no other properties than those of attraction and repulsion: but a man moves his arm by a mere energy of will; and therefore, according to this demonstrator, an energy of will must be either material attraction or material repulsion. If so, it is reasonable to conclude, that when a man draws his hand towards his head, the centre of his brain exerts its power of *attraction*; and that when he extends his arm at full length before him, the same centre exerts its power of *repulsion*. We beg pardon of our readers for detaining them one moment upon such absurdities as these: yet we cannot dismiss the argument without taking the liberty to ask our all-knowing author, How it comes to pass that the same centre sometimes attracts and sometimes repels the same substance at the same distance; nay, that it both attracts and repels substances of the same kind, at equal distances, and at the very same instant of time? This must be the case, when a man puts one hand to his head, and thrusts another from him; and therefore, if these operations be the effect of attraction and repulsion, it must be of attraction and repulsion to which induction of known and acknowledged cases furnishes nothing similar or analogous, i. e. of such attraction and repulsion as, according to Mr Cooper's mode of reasoning, does not exist. The truth is, that we are not more certain that we ourselves exist, than that an energy of will is neither attraction nor repulsion; and therefore, unless all matter be endued with will, it is undeniable, that, whatever be the substance of the soul, one thing acts upon another by a property not common to them both. In what *manner* it thus acts, we pretend not to know: but our ignorance of the *manner* of any operation is no argument against the *reality* of the *operation itself*, when we have for it the evidence of consciousness and daily experience; and when the author shall have explained to general satisfaction how material centres attract and repel each other at a distance, we shall undertake to explain how one thing acts upon another with which it has no common properties.

241 A second attempt of the same kind.

Suspicious, as it should seem, that this reasoning has not the complete force of mathematical demonstration, the author supports his opinion by other arguments. "Whatever we know (says he), we know by means of its properties, nor do we in any case whatever certainly know any thing but these; and we infer in all cases the existence of any thing which we suppose to exist from the existence of its properties. In short, our idea of any thing is made up of a combination of our ideas of its properties. Gold is heavy, ductile, tenacious, opaque, yellow, soluble in *aqua regia*, &c. Now, let any one suppose for an instant that gold is deprived of all these, and becomes neither heavy, ductile, tenacious, opaque, yellow, soluble, &c. what remains, will it be gold? Certainly not. If it have other properties, it is another substance. It it have no properties remaining, it is nothing. For nothing is that which hath no properties. Therefore, if any thing lose all its properties, it becomes nothing; that is, it loses its existence. Now, the existence of the soul is inferred, like, the existence of every thing else, from its supposed properties, which are the phenomena of thinking, such as perception, recollection, judgment, and volition. But in all cases of *perfect* sleep, of the operation of a strong narcotic, of apoplexy, of swooning, of drowning where the vital powers are not extinguished, of the effects of a violent blow on the back

Aristotle in asking πως τω αμιξει το μεγιστον.—thereby plainly indicating, that the sentient principle is totally separated from extension, and can neither be considered as extended like a superficies or solid, nor unextended as a physical point.

back part of the head, and all other leipothymic affections, there is neither perception, recollection, judgement, nor volition; that is, all the properties of the soul are gone, are extinguished. Therefore, the soul itself loses its existence for the time. If any man shall say, that these properties are only *suspended* for the time, I would desire him to examine what idea he annexes to this suspension; whether it be not neither more nor less than that *they are made not to exist for the time.* Either no more is meant, or it is contradictory to matter of fact; and moreover, if more *be* meant, it may easily be perceived to involve the archetypal existence of abstract ideas, and to contradict the axiom *impossibile est idem esse et non esse.*"

42 sh n to be ually w.

For the benefit of short-sighted inquirers, it is to be wished that the author had favoured the public with this *proof* which might have been so easily brought; for we can discern no connexion whatever between the suspension of the exercise of the powers of the mind, and the archetypal existence of abstract ideas, or the absurd proposition that it is *possible for the same thing to be and not to be.* We think, however, that we understand enough of this reasoning which he has given us to be able to pronounce with some confidence that it is nothing to the purpose. For, in the *first* place, We beg leave to observe, that between the properties of gold and the powers of thinking, &c. there is no similarity; and that what may be true when affirmed of the one, may be false when affirmed of the other. The powers of the mind are all more or less active; the enumerated properties of gold are all passive. We know by the most complete of all evidence, that the exercise of power *may be* suspended, and the power itself remain unimpaired; but to talk of the suspension of the energies of what was never energetic, if it be not to contradict the axiom *impossibile est idem esse et non esse*, is certainly to employ words which have no meaning. Yet even this argument from the properties of gold might have led the author to suspect that something else may be meant by the suspension of the exercise of powers, than that *those powers are made not to exist for the time.* In a room perfectly dark gold is not yellow; but does it lose any of its essential properties, and become a different substance, merely by being carried from light to darkness? Is a man while in a dark room deprived of the faculty of sight, and one of the powers of his mind made not to exist for the time? The author will not affirm that either of these events takes place. He will tell us that gold exhibits not its yellow appearance, merely because the proper medium of light passes not from it to the eye of the percipient, and that it is only for want of the same medium that nothing is seen by us in perfect darkness. Here, then, by his own confession, is a power of the mind, and a property of an external object, both suspended in their energies, without being annihilated; and no proof has yet been brought that all the powers of the mind may not in the same manner be suspended in their energies without being made not to exist. As light is necessary to vision, but is not itself either the thing which sees or the thing which is seen; so may the brain be necessary to the phenomena of thinking, without being either that which thinks, or that which is thought upon: and as actual vision ceases when light is withdrawn, though the eye and the object both continue to exist; so may the *energy* of thinking cease when the brain is rendered unfit for its usual office, though the being which thinks, and the power of thought, continue to exist, and to exist unimpaired. That this is actually the case every man must be convinced who believes that in thinking he exerts the same powers to-day that he exerted yesterday; and therefore our author's second demonstration of the nonexistence of mind is, like his first, founded upon assertions which cannot be granted.

243 A third attempt of the same kind

Another of these pretended demonstrations is as follows: "If the soul exist at all, it must exist somewhere; for it is impossible to frame to one's self an idea of any thing existing, which exists nowhere. But if the soul exist somewhere, by the terms it occupies space, and therefore is extended; but whatever has extension, has figure in consequence thereof. The soul then, if it exist, hath the properties of extension and figure in common with matter. Moreover, by the supposition of every immaterial hypothesis (except those of Malebranche, Berkeley, and Leibnitz), it acts upon body, i. e. upon matter; that is, it attracts and repels, and is attracted and repelled, for there is no conceivable affection of matter but what is founded on its properties of attraction and repulsion; and if it be attracted and repelled, its reaction must be attraction and repulsion. The soul then has the properties of extension, figure, attraction and repulsion, or solidity. But these comprise every property which matter, as such, has ever been supposed to possess. Therefore the soul is matter, or material. But by the supposition it is immaterial; therefore it does not exist. For nothing can exist whose existence implies a contradiction."

244 shown to confute itself.

Mr Cooper, we see, still proceeds in the direct road of mathematical demonstration; but in the present instance we beg leave to stop him in the very beginning of his course, and to ask *where* the universe exists? When he shall have given such an answer to this question as men of common sense may be able to comprehend, we may perhaps attempt to tell him where an unextended soul exists. If this demonstration be not a collection of words without meaning, the existence of space as a real thing is taken for granted. Space, therefore, has extension, and of course figure; but we believe Mr Cooper will find some difficulty in ascertaining the figure of infinite space. The mind certainly acts upon body. For this we have the evidence of consciousness and experience; but we have no evidence whatever that it must therefore attract and repel, and be attracted and repelled. It has been already observed, that the mind, whatever be its substance, acts upon the body by energies of will. What these are every man knows with the utmost certainty and precision; whilst we may venture to assert, that no man knows precisely what corpuscular attraction and repulsion are, supposing the existence of such powers to be possible. When we speak of attraction and repulsion, we have some obscure notion of bodies acting upon each other at a distance; and this is all that we know of the matter. But when we think of an energy of the human will, the idea of distance neither enters nor can enter into our notion of such an energy. These are facts which we pretend not to prove by a mathematical or a chemical process. Every man must be convinced

Of the Substance of the Human Mind.

convinced of their truth by evidence more complete than any proof, viz. immediate consciousness of his own thoughts and volitions. This being the case, we may turn Mr Cooper's artillery against himself, and because mind acts upon body by powers different from attraction and repulsion, argue that body neither attracts nor repels; and were it true, as it is certainly false, that no thing could act upon another but by means of some property common to both, we might infer that every atom of matter is endowed with the powers of volition and intelligence, and by consequence that every man is not one but ten thousand conscious beings, a conclusion which our philosopher seems not inclined to admit.

245 Objections to the doctrine of immaterialism stated and answered.

Having finished his *demonstrations*, the author states other objections to the doctrine of immaterialism which, as they are not his own nor new, have greater weight. "It appears no more than reasonable (says he), that if the doctrine of materialism be rejected as inadequate to explain the phenomena, these latter should at least be explained in some manner or other better upon the *substituted* than the *rejected* hypothesis; so that it is reasonable to require of an immaterialist that his supposition of a distinct soul should explain the *rationale* of the phenomena of thinking. But, strange to say, so far from attempting to explain these phenomena on the immaterial hypothesis, it is acknowledged on all hands that even on this hypothesis the phenomena are inexplicable." This objection it would certainly be no difficult task to obviate; but from that trouble, small as it is, we are happily exempted by the objector. "I would have it understood (says he), that no materialist ever undertook to say *how* perception results from our organization. What a materialist undertakes to assert is, that perception, *whatever* it be, or *however* it results from, does actually result from our organization." According to Mr Cooper, then, the *rationale* of thinking is equally inexplicable by materialists and immaterialists; and the truth is, that we know the *rationale* of hardly any one operation in nature. We see that the stroke of a racket produces motion in a billiard ball; but how it does so, we believe no man can say. Of the fact, however, we are certain; and know that the motion is produced by some power, about the effects of which we can reason with precision. In like manner we know with the utmost certainty, that we ourselves have the powers of perception and volition; and that these powers cannot be conceived as either an ell or an inch long. How they result from the mutual agency of an immaterial and material substance upon each other, we are indeed profoundly ignorant; but that such is the fact, and that they are not the result of mere organization, we must necessarily believe, so long as it is true that the power of the entire system is nothing more than the sum or aggregate of the powers of all its parts. The immaterial hypothesis contains in it something inexplicable by man: The material hypothesis likewise contains, by the confession of its advocates something that is equally inexplicable; and is over and above burdened with this contradiction, that the whole is something different from all its parts. It is therefore *no* "singular phenomenon in literary history, that one hypothesis should be rejected as inadequate to account for appearances, and that the hypothesis substituted should, even by the acknowledgment of its abettors, be such as not only not to explain the *rationale* of the appearances, but from the nature of it, to preclude all hopes of such an explanation." This is exactly the case with respect to a *vacuum* in astronomy. That hypothesis does not in the least tend to explain the rationale of the motions of the planets; but yet it must be admitted in preference to a *plenum*, because upon this last hypothesis motion is impossible.

246 Whether as many things may be asserted of the soul as of the body.

"Supposing the existence of the soul, it is an unfortunate circumstance (says Mr Cooper), that we cannot properly assert positively any thing of it at all." Were this the case, it would indeed be a very unfortunate circumstance; but can we not assert positively as many things of the soul as we can of the body? Can we not say with as much propriety and certainty, that the soul has the powers of perception and volition, &c. as that the body is solid and extended, or as that matter has the powers of attraction and repulsion? We know perfectly what perception and volition are, though we cannot have *ideas* or mental images of them; and if our author knows what attraction and repulsion are, we believe he will not pretend to have of them ideas entirely abstracted from their objects. "But granting the soul's existence, it may be asked (says he), Of what use is an hypothesis of which no more can be asserted than its existence?" We have just observed that much more can be asserted of the soul than its existence, viz. that it is something of which perception and will are properties; and he himself asserts nothing of matter but that it is something of which attraction and repulsion are properties.

"This soul, of which these gentlemen (the immaterialists) are conscious, is immaterial essentially. Now I deny (says our author), that we can have any idea at all of a substance purely immaterial." He elsewhere says, that nothing can exist which is not extended, or that extension is inseparable from our notions of existence. Taking the word *idea* in its proper sense, to denote that appearance which external objects make in the imagination, it is certainly true that we can have no *idea* of an immaterial substance; but neither have we, in that sense, any idea of matter abstracted from its qualities. Has Mr Cooper any *idea* of that which attracts and repels, or of attraction and repulsion, abstracted from their objects? He may perhaps, have, though we have not, very adequate ideas of bodies acting upon each other at a distance; but as he takes the liberty to substitute assertions for arguments, we beg leave in our turn to assert, that those ideas neither are, nor can be, more clear and adequate than our notion of perception, consciousness, and will, united in one being.

247 Extension not inseparable from all notion of existence.

That extension is no otherwise inseparable from our notions of existence than by the power of an early and perpetual association, is evident from this circumstance, that, had we never possessed the senses of sight and touch, we never could have acquired any idea at all of extension. No man, who has thought on the subject, will venture to affirm, that it is absolutely impossible for an intelligent being to exist with no other senses than those of smell, taste, and hearing. Now it is obvious that such a being must acquire some notion of existence

Of the Substance of the Human Mind.

istence from his own consciousness: but into that notion extension could not possibly enter; for neither sounds, tastes, smells, nor consciousness, are extended; and it is a fundamental article of the materialists creed, that all our ideas are relicks of sensation. Since then existence may be conceived without extension, it may be inferred that they are not inseparable from each other; and since cogitation cannot be conceived with extension, we may reasonably conclude, that the being which thinks is not extended.

Mr Cooper indeed, with his master, talks of extended ideas and extended thoughts: but we must assert, in the words of Cudworth, that "we cannot conceive a *thought* to be of such a certain *length*, *breadth*, and *thickness*, measurable by *inches*, *feet*, and *yards;* that we cannot conceive the *half*, or *third*, or *twentieth* part of a thought; and that we cannot conceive every thought to be of some determinate *figure*, such as *round* or *angular*, *spherical*, *cubical*, *cylindrical*, or the like. Whereas if extension were inseparable from existence, *thoughts* must either be mere *nonentities*, or extended into *length*, *breadth*, and *thickness;* and consequently all truths in us (being nothing but complex thoughts) must be long, broad, and thick, and of some determinate figure. The same must likewise be affirmed of volitions, appetites, and passions, and of all other things belonging to cogitative beings; such as knowledge and ignorance, wisdom and folly, virtue and vice, &c. that these are either all of them absolute *nonentities*, or else extended into three dimensions, and measurable not only by *inches* and *feet*, but also by solid measures, such as *pints* and *quarts*. But if this be absurd, and if these things belonging to soul and mind (though doubtless as great realities at least as the things which belong to body) be *unextended*, then must the substances of souls or minds be themselves unextended, according to that of Plotinus, νους ου διαστας αφ ἑαυτου, and therefore the human soul cannot be material."

248 That the human soul cannot exert its faculties but in union with some corporeal system, an opinion probable and

Mr Cooper employs many other arguments to prove the materiality of the sentient principle in man; but the force of them extends no farther than to make it in the highest degree probable, that the mind cannot exert its faculties but in union with some organized corporeal system. This is an opinion which we feel not ourselves inclined to controvert; and therefore we shall not make any particular remarks upon that part of our author's reasonings. That an immaterial and indiscerptible being, such as the soul, is not liable to be *dissolved* with the body, is a fact which cannot be controverted: for what has no parts can perish only by *annihilation;* and of annihilation the annals of the world afford no instance. That an immaterial being, endowed with the powers of perception and volition, &c. *may be capable* of exerting these powers in a state of separation from all body, and that at least one immaterial Being does actually so exert them, or other powers analogous to them, are truths which no man whose arrogance does not surpass his judgment will venture to deny; but the question at present between the most rigid immaterialists and their opponents, is, whether there be ground to think that the human soul is such a being?

Now, when Mr Baxter and his followers confidently affirm, that human perception must *necessarily* subsist after the dissolution of the present mortal and perishable system; and that the soul, when disencumbered of *all body*, will have its faculties greatly *enlarged;* they affirm what to us appears incapable of proof. That a disembodied soul *may* perceive, and think, and act, and that its powers of intellection *may* have a wider range than when they were circumscribed by a corporeal system, which permitted their action upon external objects only through five organs of sense, is certainly *possible;* and the argument by which the materialists pretend to prove it *not* possible, is one of the most contemptible sophisms that ever disgraced the page of philosophy. To affirm, that because our intellectual powers, in their embodied state, seem to decay with the system to which they are united, the mind, when set free, must therefore have no such powers at all, is equally absurd as to say, that because a man shut up in a room which has but one window sees objects less and less distinctly as the glass becomes more and more dimmed, he must in the open air be deprived of the power of vision. But because the human soul *may*, for any thing that we see to the contrary, subsist, and think, and act, in a separate state, it does not therefore necessarily follow that it *will* do so; and every thing that we know of its nature and its energies leads us to think, that without some kind of body by which to act as by an instrument, all its powers would continue dormant. There is not the shadow of a reason to suppose that it existed and was conscious in a prior state; and as its memory at present, unquestionably depends upon the state of the brain, there is all the evidence of which the case will admit, that if it should subsist in a future state divested of all body, though it might be endowed with new and enlarged powers of *perception*, it could have no *recollection* of what it did and suffered in *this world*, and therefore would not be a fit object either of reward or of punishment. This consideration has compelled many thinking men, both Pagans and Christians, to suppose that at death the soul carries with it a fine material vehicle, which is its immediate sensorium in this world, and continues to be the seat of its recollection in the next. Such, as we have seen, was the opinion of Mr Wollaston and Dr Hartley; it was likewise the opinion of Cudworth and Locke, who held that the Supreme Being alone is the only mind wholly separated from matter; and it is an opinion which even Dr Clarke, one of the ablest advocates for immaterialism, would not venture positively to deny.

249 ancient.

Nor is this opinion peculiar to a few moderns. Cudworth, after giving a vast number of quotations from Pythagoreans and Platonists, which prove to a demonstration that they held the Deity to be the only mind which perceives and acts without the instrumentality of matter, observes, "from what hath been said, it appeareth, that the most ancient assertors of the incorporeity and immortality of the human soul, yet supposed it to be always conjoined with some body." Thus *Hierocles* plainly: ἡ λογικη ουσια συμφυες εχουσα σωμα. ὁυλω παρα του δημιουργου εις το ειναι παρηλθεν, ως μητε το σωμα ειναι αυλην, μητε ανευ σωματος· αλλ αυλην μεν ασωματον, αποπερα τουσθαι δε εις σωμα το ὁλον αυλης ειδος. *The rational nature having always a kindred body, so proceeded from the demiurgus, as that neither itself is body, nor yet can it be without body; but though itself be incorporeal, yet its whole form is terminated in a body.*

Of the Substance of the Human Mind.

body. Agreeably to this the definition which he gives of a man is, ψυχη λογικη μετα συμφυους αθανατου σωματος, *a rational soul, together with a kindred immortal body;* and he affirms, that our present animated terrestrial body, or mortal man, is nothing but ἔιδωλον ανθρωπου, *the image of the true man*, or an accession from which it may be separated. Neither does he affirm this only of human souls, but also of all other rational beings whatsoever below the Supreme Deity, that they always naturally actuate some body. Wherefore a demon or angel (which by *Hierocles* are used as synonymous words), is also defined by him after the same manner, ψυχη λογικη μετα φωτεινου σωματος, *a rational soul, together with a lucid body.* And accordingly *Proclus* upon *Plato's Timæus affirmeth*, παντα δαιμονα των ημετερων κρειττονα ψυχων, και νοεραν εχειν, ψυχην, και οχημα αιθεριον: *That every demon, superior to human souls, hath both an intellectual soul and an ethereal vehicle, the entireness thereof being made up or compounded of these two things.* So that there is hardly any other difference between demons or angels, and men, according to these philosophers, but only this, that the former are lapsable into aërial bodies only, and no further; but the latter into terrestrial also. Now, *Hierocles* positively affirms this to have been the true cabala, and genuine doctrine of the ancient Pythagoreans, entertained afterwards by Plato: και τουτο των Πυθαγορειων ἠν δογμα, ὁ δε Πλατων υστερον εξεφηνεν, απεικασας ξυμφυτω δυναμει υποπτερου ξευγους τε και ἡνιοχου; πασαν θειαν τε και ανθρωπινην ψυχην. *And this was the doctrine of the Pythagoreans, which Plato afterwards declared; he resembling every both human and divine soul* (i. e. in our modern language, every created rational being) *to a winged chariot, and a driver or charioteer both together*: meaning by the chariot, an animated body; and by the charioteer, the incorporeal soul actuating it.

That this Pythagorean opinion of the Deity's being the only mind which thinks and acts without material organs was very generally received by the ancient Christians, might be proved by a thousand quotations: We shall content ourselves with producing two from the learned *Origen*. "Solius Dei (saith this philosophic father of the church), id est, Patris, Filii, et Spiritus Sancti, naturæ id proprium est, ut sine materiali substantia, et absque ulla corporeæ adjectionis societate, intelligatur subsistere *." "Materialem substantiam opinione quidem et intellectu solum separari, a naturis rationalibus, et pro ipsis, vel post ipsas affectam videri; sed nunquam sine ipsa eas vel vixisse, vel vivere: Solius namque Trinitatis incorporea vita existere putabitur †." Should Mr Cooper and his friends ask, What is the use of a soul which cannot act without the instrumentality of matter? or why we should suppose the existence of such a substance? we beg leave, in our turn, to ask these gentlemen, What is the use of a brain which cannot see without eyes? and why they should suppose all our sensations to terminate in such an internal system, since the vulgar certainly suppose their sensations to subsist in their respective organs? How this ancient notion, which makes body so essential a part of man, is consistent with the immortality of the human soul, we shall inquire in a subsequent chapter; in which we shall endeavour to ascertain what kind of immortality we have reason to expect, and upon what evidence our expectation must rest. Previous to this inquiry, however, it is necessary to enter upon another, which is of the first importance, and which every materialist has endeavoured to perplex; we mean that which concerns *personal identity*: for if, as has been often said, no man is the same person two days successively, it is of no importance to us whether the soul be mortal or immortal.

* *Peri Archon* lib. 1. cap. 6.

† Lib. 2. cap. 2.

Of Personal Identity.

Chap. III. *Of* Personal Identity.

250 Personal identity,

Whether we are to live in a future state, as it is the most important question which can possibly be asked, so it is the most intelligible one which can be expressed in language. Yet strange perplexities have been raised about the meaning of that identity or sameness of person, which is implied in the notion of our living now and hereafter, or indeed in any two successive moments; and the solution of these difficulties hath been stranger than the difficulties themselves. To repeat all that has been said on the subject would swell this chapter to a disproportionate bulk. We shall therefore content ourselves with laying before our readers the sentiments of Bishop Butler, and the fancies and demonstrations of the philosopher of Manchester. We are induced to adopt this course, because we think the illustrious bishop of Durham has exhausted the subject, by stating fairly the opinions which he controverts, and by establishing his own upon a foundation which cannot be shaken, and which are certainly not injured, by the objections of Mr Cooper.

251 though it cannot be defined, easily understood and ascertained by consciousness and memory.

"When it is asked (says this philosophical prelate*) in what personal identity consists? the answer should be the same as if it were asked in what consists similitude or equality?—that all attempts to define would but perplex it. Yet there is no difficulty at all in ascertaining the idea or notion: For as, upon two triangles being compared or viewed together, there arises to the mind the notion of similitude; or, upon twice two and four, the notion of equality: so likewise, upon comparing the consciousness of one's self or one's own existence in any two moments, there as immediately arises to the mind the notion of personal identity. And as the two former comparisons not only give us the notions of similitude and equality, but also show us that two triangles are similar, and that twice two and four are equal; so the latter comparison not only gives us the notion of personal identity, but also shows us the identity of ourselves in these two moments—the present, suppose, and that immediately past, or the present and that a month, a year, or twenty years past. In other words, by reflecting upon that which is myself now, and that which was myself twenty years ago, I discern they are not two, but one and the same self.

* *Dissertation* 1st, *subjoined to the Analogy of Religion*, &c.

252 These, however, do not make personal identity.

"But though consciousness of what is present and remembrance of what is past do thus ascertain our personal identity to ourselves; yet, to say that remembrance makes personal identity, or is necessary to our being the same persons, is to say that a person has not existed a single moment, nor done one action, but what he can remember; indeed none but what he reflects upon. And one should really think it self-evident, that consciousness of personal identity presupposes and therefore

Of personal identity.

fore cannot constitute personal identity; any more than knowledge, in any other case, can constitute truth, which it presupposes.

"The inquiry, what makes vegetables the same in the common acceptation of the word, does not appear to have any relation to this of personal identity; because the word *same*, when applied to them and to person, is not only applied to different subjects, but is also used in different senses. When a man swears to the same tree, as having stood fifty years in the same place, he means only the same as to all the purposes of property and uses of common life, and not that the tree has been all that time the same in the strict philosophical sense of the word: For he does not know whether any one particle of the present tree be the same with any one particle of the tree which stood in the same place fifty years ago. And if they have not one common particle of matter they cannot be the same tree in the proper and philosophic sense of the word *same;* it being evidently a contradiction in terms to say they are, when no part of their substance and no one of their properties is the same; no part of their substance, by the supposition; no one of their properties, because it is allowed that the same property cannot be transferred from one substance to another: And, therefore, when we say that the identity or sameness of a plant consists in a continuation of the same life, communicated under the same organization to a number of particles of matter, whether the same or not; the word *same*, when applied to life and to organization, cannot possibly be understood to signify what it signifies in this very sentence, when applied to matter. In a loose and popular sense, then, the life, and the organization, and the plant, are justly said to be the same, notwithstanding the perpetual change of the parts. But, in a strict and philosophical manner of speech, no man, no being, no mode of being, no any thing, can be the same with that with which it has indeed nothing the same. Now sameness is used in this latter sense when applied to persons. The identity of these, therefore, cannot subsist with diversity of substance.

253
What it is.

"The thing here considered, and demonstratively, as I think, determined, is proposed by Mr Locke in these words: *Whether it* (i. e. the same self or person) *be the same identical substance?* And he has suggested what is a much better answer to the question than that which he gives it in form: For he defines a person *a thinking intelligent being*, &c. and personal identity, *the sameness of a rational being;* and then the question is, Whether the same rational being is the same substance? which needs no answer; because being and substance are in this place synonymous terms. The ground of the doubt, whether the same person be the same substance, is said to be this, that the consciousness of our own existence in youth and in old age, or in any two joint successive moments, is not *the same individual action*, i. e. not the same consciousness, but different succesive consciousnesses. Now it is strange that this should have occasioned such perplexities: for it is surely conceivable that a person may have a capacity of knowing some object or other to be the same now which it was when he contemplated it formerly; yet in this case, where, by the supposition, the object is perceived to be the same, the perception of it in any two moments cannot be one and the same perception. And thus, though the successive consciousnesses which we have of our own existence are not the same, yet are they consciousnesses of one and the same thing or object; of the same person, self, or living agent. The person of whose existence the consciousness is felt now, and was felt an hour or a year ago, is discerned to be, not two persons, but one and the same person; and therefore is one and the same.

254
False notions of personal identity

"Mr Locke's observations upon this subject appear hasty; and he seems to profess himself dissatisfied with suppositions which he has made relating to it. But some of those hasty observations have been carried to a strange length by others; whose notion, when traced and examined to the bottom, amounts, I think, to this: 'That personality is not a permanent but a transient thing: That it lives and dies, begins and ends, continually: That no one can any more remain one and the same person two moments together, than two successive moments can be one and the same moment: That our substance is indeed continually changing: but whether this be so or not, is, it seems, nothing to the purpose; since it is not substance, but consciousness alone, which constitutes personality; which consciousness, being successive, cannot be the same in any two moments, nor consequently the personality constituted by it*." Hence it must follow, that it is a fallacy upon ourselves to charge our present selves with any thing we did, or to imagine our present selves interested in any thing which befel us yesterday; or that our present self will be interested in what will befal us to-morrow; since our present self is not in reality the same with the self of yesterday, but another self or person coming in its room, and mistaken for it; to which another self will succeed to-morrow. This, I say, must follow: for if the self or person of to-day and that of to-morrow are not the same, but only like persons; the person of to-day is really no more interested in what will befal the person of to-morrow, than in what will befal any other person. It may be thought, perhaps, that this is not a just representation of the opinion we are speaking of; because those who maintain it allow that a person is the same as far back as his remembrance reaches: And indeed they do use the words *identity* and *same* person; nor will language permit these words to be laid aside. But they cannot, consistently with themselves, mean that the person is really the same: For it is self-evident, that the personality cannot be really the same, if, as they expressly assert, that in which it consists is not the same. And as, consistently with themselves, they cannot, so I think it appears they do not, mean that the person is *really* the same, but only that he is so in a fictitious sense, in such a sense only as they assert: for this they do assert, that any number of persons whatever may be the same person. The bare unfolding this notion, and laying it thus naked and open, seems the best confutation of it. However, since great stress is said to be put upon it, I add the following things:

* *Answer to Dr Clarke's third Defence of his Letter to Mr Dodwell*, 2d edit. p. 44. 56, &c.

255
overthrown.

"*First*, This notion is absolutely contradictory to that certain conviction, which necessarily and every moment rises within us, when we turn our thoughts upon ourselves, when we reflect upon what is past, and look forward to what is to come. All imagination, of a daily change of that living agent which each man calls himself

Of Personal Identity.

self for another, or of any such change throughout our whole present life, is entirely borne down by our natural sense of things. Nor is it possible for a person in his wits to alter his conduct with regard to his health or affairs, from a suspicion that though he should live to-morrow he should not however be the same person he is to-day.

" *Secondly*, It is not an *idea* or abstract *notion*, or quality, but a being only, which is capable of life and action, of happiness and misery. Now all beings confessedly continue the same during the whole time of their existence. Consider then a living being now existing, and which has existed for any time alive: this living being must have done, and suffered, and enjoyed, what it has done, and suffered, and enjoyed, formerly (this living being, I say, and not another), as really as it does, and suffers, and enjoys, what it does, and suffers, and enjoys, this instant. All these successive actions, sufferings, and enjoyments, are actions, enjoyments, and sufferings, of the same living being; and they are so prior to all considerations of its remembering or forgetting, since remembering or forgetting can make no alteration in the truth of past matter of fact. And suppose this being endued with limited powers of knowledge and memory, there is no more difficulty in conceiving it to have a power of knowing itself to be the same being which it was some time ago, of remembering some of its actions, sufferings, and enjoyments, and forgetting others, than in conceiving it to know, or remember, or forget, any thing else.

" *Thirdly*, Every person is conscious that he is now the same person or self he was as far back as his remembrance reaches: since when any one reflects upon a past action of his own, he is just as certain of the person who did that action, namely himself (the person who now reflects upon it), as he is certain that the action was at all done. Nay, very often a person's assurance of an action having been done, of which he is absolutely assured, arises wholly from the consciousness that he himself did it: and this he, person or self, must either be a substance or the property of some substance. If *he*, if person, be a substance; then consciousness that he is the same person, is consciousness that he is the same substance. If the person, or *he*, be the property of a substance, still consciousness that he is the same property is as certain a proof that his substance remains the same, as consciousness that he remains the same substance would be; since the same property cannot be transferred from one substance to another.

" But though we are thus certain that we are the same agents, living beings, or substances, now, which we were as far back as our remembrance reaches; yet it is asked, Whether we may not possibly be deceived in it? And this question may be asked at the end of any demonstration whatever; because it is a question concerning the truth of perception by memory: and he who can doubt whether perception by memory can in this case be depended upon, may doubt also whether perception by deduction and reasoning, which also include memory, or indeed whether intuitive perception itself, can be depended upon. Here then we can go no farther: for it is ridiculous to attempt to prove the truth of our faculties, which can no otherwise be proved than by the use or means of those suspected faculties themselves."

Of Personal Identity.

256 Objection to the foregoing reasoning.

This reasoning, which we believe will to most men appear unanswerable, Mr Cooper hopes to overturn by the following observations *: " If all imagination of a daily change in us be borne down by our natural sense of things, then (says he) does our natural sense of things positively contradict known fact; for a daily, a momentaneous, change in us, i. e. in our bodies, does actually take place." True, a daily change in our bodies does take place, and so likewise does a daily change in our clothes; but surely no man was ever led by his natural sense of things to suppose, that his limbs or external organs were the seats of sensation and will, any more than that his coat or his shoes were any real parts of his trunk or of his feet. But it is only that which thinks and wills that any man considers in this case, as himself or his person; and if our natural sense of things, or consciousness, tell us, that what thinks and wills has continued the same from a distance of time as far back as we can remember, it is certain, that whether it be material or immaterial, it has continued from that period, otherwise we can be certain of nothing. " But (says our philosopher) other known and ascertained facts are frequently borne down by our natural sense of things: for how many thousand years before the days of *Copernicus* was the motion of the earth round the sun entirely borne down by our natural sense of things, which made us give full credit to the motion of the sun round the earth? Do not the generality of mankind believe, upon the evidence of their natural sense of things, that every part of their body remains exactly the same to-day as it was yesterday?"

* *Tracts*, &c.

257 Answered.

To the former of these questions we answer positively, that before the days of *Copernicus* the motion of the earth round the sun was *not* borne down by our *natural sense* of things, but by ill-founded hypotheses and inconclusive reasonings. By the natural sense of things, nothing can be meant, in this place, but the evidence of consciousness or of external sensation; but the *actual motion* either of the sun or of the earth is not perceived either by consciousness or by sensation. Of consciousness nothing is the object but the internal energies and feelings of our own minds; and with regard to the motion of the sun or of the earth, nothing is perceived by the sense of sight but that, after considerable intervals of time, these two great bodies have repeatedly changed their places in the heavens with respect to each other. This is all that on this subject our *natural sense of things* leads us to believe; and is not this infallibly true? Afterwards indeed, by taking for granted the truth of proposisions, for which neither sense nor consciousness affords the shadow of evidence; the vulgar now, and all mankind formerly, reasoned themselves into the opinion, that the earth stands still, and that the sun moves round it. In vulgar philosophy it is taken for granted, that in the universe there is not a *relative* but an *absolute upwards* and an *absolute downwards*; that our heads are absolutely upward, and our feet downward; and that were the earth to revolve round its axis; these positions would be reversed, that our heads would be placed beneath our feet, and that we ourselves would fall from the earth into

Of Personal Identity.

into empty space. Upon these false hypotheses the vulgar reason correctly. They know that bodies cannot change their place without motion; they know that in the time of their remembrance the sun and the earth have been perpetually varying their places with respect to each other; they know that they themselves have never fallen, nor had a tendency to fall, into empty space; and hence they infer that it is the sun and not the earth that moves (K). But will any man say that the absurd suppositions from which this conclusion is logically deduced, have the evidence either of sensation or of consciousness, as the permanency of that living agent which each man calls himself has?

To our author's second question we likewise reply with confidence, that the generality of mankind do *not* believe, upon their natural sense of things, that every part of their body remains exactly the same to-day as it was yesterday. It would be strange indeed if they did, after having repeatedly experienced the waste of increased perspiration or sweating; after having witnessed men emaciated by sickness, and again restored to plumpness in health; and after having perhaps lost whole limbs, which certainly their natural sense of things teaches them to consider as parts of their body. In all these cases, the generality of mankind are as sensible of changes having taken place in their bodies as he who has attended ever so closely to physiological inquiries, though not one of them has the least imagination of a change having taken place in the living agent which each man calls himself.

Bishop Butler observes, that if the living agent be perpetually changing, it is a fallacy upon ourselves to charge our present selves with any thing we did, to imagine our present selves interested in any thing which befel us yesterday, or that our present self will be interested in what will befal us to-morrow. To this judicious observation our daring philosopher replies, "that as the man of to-morrow, though not in all points the same with, yet depends for his existence upon, the man of to-day, there is sufficient reason to care about him." Could he have said that as the man of to-day depends for his existence on the man of to-morrow, there is sufficient reason for the present man to care about the future man; or that as the man of to-morrow depends for his existence on the man of to-day, there is to-day sufficient reason for the future man to care about the present man; we should in either case, if the anachronism had been kept out of sight, have seen the force of his argument. Every man has sufficient reason to care about the ox upon which he is to be fed; but we cannot so clearly perceive what reason the ox has to care about the man.

Not satisfied, it would seem, with this reply, our author proceeds to affirm, "that the man of to-morrow, possessing a reminiscence of the actions of the man of to-day, and knowing that these actions will be referred to him both by himself and others (which is certainly knowing that both himself and others are most iniquitous wretches), they cannot be indifferent to the man of to-day, who looks forward to the properties of the man of to-morrow;" i. e. the reminiscence and knowledge of a future man constitute all the relation that subsist between a present man and his actions; a discovery worthy of an original genius. But as on the subject of personal identity we pretend to no originality, we shall leave this proposition to the meditation of our readers, and take the liberty to ask our author a question or two respecting this same reminiscence, which he is graciously pleased to acknowledge for a property.

He defines identity, "the continued existence of any being unaltered in substance or in properties;" and he repeatedly acknowledges that no identical quality or property can be transferred from one subject to another. Let us now suppose, that a man has a reminiscence of an individual action performed a month ago, and that this reminiscence is accompanied with a consciousness that the action was performed by himself. This supposition, whether true or false, may certainly be made; for it implies nothing more than what every man firmly believes of himself in every act of remembrance. Let us again suppose, that, at the distance of ten or twenty years, the man known by the same name has a reminiscence of the same action, with a consciousness that he himself performed it. Is this reminiscence the same with the former? or is it a different reminiscence? If it be the same, either the person remembering at the distance of ten or twenty years is the same with him who remembered at the distance of a month, or there is an identical quality transferred from one substance to another, which is admitted to be impossible. If reminiscence be itself a real and immediate quality of any substance, and not the mere energy of a power, and if the one reminiscence be different from the other, the subjects in which these two different qualities inhere must likewise be different. Yet the man who has the reminiscence at the distance of a month, has the evidence of consciousness that the action was performed by him; and the man who has the reminiscence at the distance of ten or twenty years, has likewise the evidence of consciousness that the same action was performed by him and not by another. By the confession of Hume and of all philosophers, consciousness never deceives; but here is the evidence of one consciousness in direct opposition to another; and therefore, as two contradictory propositions cannot both be true, either the one reminiscence is the same with the other, or reminiscence is no real quality. That one act of reminiscence should be numerically the same with another, which followed it at the distance of twenty years, is plainly impossible; whence it should seem, that reminiscence itself is no real and immediate quality of any substance. But if this be so, what is reminiscence? We answer, it is plainly neither more nor less than the *energy* of a power, which

(K) This inference too has been so often drawn, that it comes in time to coalesce in the mind with the *sensations*, from which the motion either of the sun or of the earth is deduced with infallible certainty; and hence it is considered as part of that truth which sensation immediately discovers. *See our chapter of Association.*

Of Personal Identity.

which though dormant between its energies, remains unchanged from the one to the other, and which being itself the real and immediate quality of a subject, that subject must likewise remain unchanged. That powers may remain dormant, and yet unchanged, every man must be convinced; who having struck any thing with his hand, knows that he has power to repeat the stroke, and yet does not actually repeat it. Two blows with the hand immediately following each other are numerically different, so that the one cannot with truth be said to be the other; but we have the evidence of external sense, that they are both struck by the same member. In like manner, two energies of reminiscence directed to the same object, and succeeding each other at any interval of time, cannot possibly be one and the same energy; but as the latter energy may include in it the former as well as the object remembered by both, we have the evidence of consciousness that both are energies of the same power; and we have seen, that to suppose them any thing else, may be demonstrated to involve the grossest absurdities and contradictions.

Mr Cooper has other arguments to obviate the force of Bishop Burnet's demonstration of personal identity; such as, that a "high degree of *similarity* between the two succeeding men is sufficient to make the one care about the other; and, that "a good man, knowing that a future being will be punished or rewarded as the actions of the present man deserve, will have a sufficient motive to do right and to abstain from wrong." But if there be any one of our readers who can suffer himself to be persuaded by such assertions as these, that the living agent which he calls himself is perpetually changing, and at the same time that such change is consistent with the expectation of future rewards and punishments, he would not be reclaimed from his error by any reasoning of ours. We shall therefore trust such trifling with every man's judgment, and proceed to examine our author's *demonstration*, that personal identity has no existence. But here it is no part of our purpose to accompany him through his long chemical ramble, or to controvert his arguments for the nonidentity of vegetable and animal bodies. The only thing to which, after Bishop Butler, we have ascribed identity, is that which in man is sentient and conscious; and the nonidentity of this thing, whatever it be, Mr Cooper undertakes to demonstrate from the known properties of sensations and ideas.

258 A pretended demonstration that personal identity is impossible.

This demonstration sets out with a very ominous circumstance. The author, after conducting impressions *ab extra*, from the extremities of the nerves to the brain, affirms, that *sensations* and *ideas* are nothing but "motions in the brain perceived;" i. e. when a man thinks he is looking at a mountain, not only at rest, but to appearance immoveable, he is grossly deceived: for he perceives nothing all the while but *motion in his brain!* Were not the desire of advancing novelties and paradoxes invincible in some minds, we should be astonished at finding such an assertion as this fall from the pen of any man who had paid the slightest attention to the different energies of his own intellect. Motions in the brain, as we have repeatedly observed, are the immediate causes of our sensations; but is it conceivable, is it possible, that any thing should be the cause of itself? The motion of a sword through the heart of a man, is the immediate cause of that man's death; but is the sword or its motion *death* itself, or can they be conceived as being the *sensations* of the *man* in the *agonies* of *dying*? But sensations and ideas, whatever they be, exist in succession; and therefore, argues our demonstrator, no two sensations or ideas can be one and the same sensation or idea. The conclusion is logically inferred; but what purpose can it possibly serve? What purpose! why it seems "sensations and ideas are the only *existences whose existence* we certainly know (a charming phrase, the *existence* of *existences*, and as original as the theory in which it makes its appearance); and, therefore, from the nature of sensations and ideas there is no such thing as permanent identity." Indeed! what then, we may be permitted to ask, is the import of the word *we* in this sentence? Does it denote a series of sensations and ideas, and does each sensation and each idea certainly know not only itself, but all its ancestors and all its descendants? Unless this be admitted, we are afraid that some other existence besides sensations and ideas must be allowed to be certainly known, and even to have something of a permanent identity. Nay, we think it has been already demonstrated (see Chapter of TIME), that were there not something permanent, there could be no time, and of course no notion of a first and last, or indeed of succession, whether of sensations or ideas. And therefore, if we have such a notion, which the author here takes for granted, and upon which indeed his demonstration rests, it follows undeniably that there is something permanent, and that we *know* there is something permanent, which observes the succession of sensations and ideas.

259 Shown to be absurd and ridiculous.

All this, indeed, Mr Cooper in effect grants; for he is not much startled at the appearance of contradictions in his theory. "I find (says he), by perpetually repeated impressions which I perceive, that my hands, body, limbs, &c. are connected, are parts of one whole. I find, by perpetually repeated perceptions also, that the sensations excited by them are constantly similar, and constantly different from the sensations excited by others." He has then repeated perceptions: but how can this be possible, if *he* be not different from the perceptions, and if *he* do not *remain unchanged* while the perceptions succeed each other at greater or less intervals of time? A striking object passing with rapidity before the eyes of a number of men placed beside each other in a line of battle, would undoubtedly excite a succession of sensations; but surely that succession would not take place in the mind of *any individual* in the line, nor could any *single man* in this case say with truth that he had *repeated* perceptions of the object. In like manner, were that which is sentient perpetually changing, no man could possibly say or suppose that he had repeated perceptions of any thing; for upon this supposition, the man of to-day would have no more connexion with the man who bore his name yesterday, or twenty years ago, than the man in the line had with the first.

Upon the whole, we cannot help thinking that Bishop Butler's demonstration of personal identity remains unshaken by the batteries of Mr Cooper.—It rests, indeed,

Of Personal Identity.

deed, upon the solid basis of consciousness and memory; and if implicit credit be not given to the evidence of these faculties, we cannot proceed a single step in any inquiry whatever, nor be certain of the truth even of a mathematical demonstration.

260 A difficulty removed.

But as we have ourselves supposed, that to sensation, reminiscence, and every actual energy of the mind of man, the instrumentality of some material system is necessary, it may perhaps be thought incumbent on us to show how the perpetual flux of the particles of matter which compose the brain, as well as all the other parts of the body, can consist with the identity of the person who perceives, remembers, and is conscious. If this cannot be done, our hypothesis, ancient and plausible as it is, must be given up; for of personal identity it is impossible to doubt. In this case, however, we perceive no difficulty; for if there be united to the brain an immaterial being, which is the subject of sensation, consciousness, and will, &c. it is obvious, that all the *intellectual powers* which properly constitute the person, must be inherent in that being. The material system, therefore, can be necessary only as an instrument to excite the energies of those powers; and since the powers themselves remain unchanged, why should we suppose that their energies may not be continually exerted by successive instruments of the same kind, as well as by one permanent instrument? the powers of perception and volition are not in the material system, any more than the sensation of seeing is in the rays of light, or the energy of the blacksmith in the hammer with which he beats the anvil. Let us suppose a man to keep his eye for an hour steadily fixed upon one object. It will not surely be denied, that if this could be done, he would have one uninterrupted and unvaried perception of an hour's duration, as measured by the clock. Yet it is certain that the rays of light which alone could occasion that perception would be perpetually changing. In like manner, a blacksmith, whilst he continues to beat his anvil, continues to exert the same power whether he uses one hammer all the time, or a different hammer at each stroke. The reason is obvious; the eye, with all its connexions of brain and mind in the one case, and the person of the smith in the other, remain unchanged; and in them alone reside the faculty of sensation and the power of beating, though neither the faculty nor the power can be exerted without material instruments. But were it possible that millions of men could in the space of an hour take their turns in rotation with each new ray of light, it is self-evident, that in this case, there would be nothing permanent in sensation; and therefore, there could not be one uninterrupted and unvaried perception, but millions of perceptions, during the hour, totally distinct from and unconnected with each other. Let us now suppose a man to fix his eye upon an object for the space of a minute, and at the distance of a day or a month to fix it upon the same object a second time. He could not indeed, in this case have one uninterrupted and unvaried perception, but he would be conscious of the energy of the very same faculty the second time as at the first. Whereas were one man to view an object to-day, and another to view the same object to-morrow, it is obvious, that he who should be last in the succession could know nothing of the energy of that faculty by which the object was perceived the first day, because there would be nothing common to the two perceptions.

Of the Immortality of the Soul.

Thus then we see, that *personal identity* may with truth be predicted of a compound being, though the material part be in a perpetual flux, provided the immaterial part remain unchanged; and that of such a being only is a resurrection from the dead possible.—For since the motions of the brain do nothing more than excite to energy the permanent powers of the mind, it is of no sort of consequence to that energy whether these motions be continued by the same numerical atoms, or by a perpetual succession of atoms arranged and combined in the very same manner. We shall, therefore, be the same persons at the resurrection as at present, whether the mind be united to a particular system composed of any of the numberless atoms which have in succession made parts of our present bodies, or to a system composed of totally different atoms, provided that new system be organized in exactly the same manner with the brain or material vehicle, which is at present the immediate instrument of perception. This (we say) is self-evident; but were the immaterial part to change with the changing body, a resurrection of the same persons would be plainly impossible.

Chap. IV. *Of the* Immortality *of the* Soul.

261 The immortality of the soul the general belief in all nations.

Wherever men have been in any degree civilized, and in some nations where they have been in the most savage state, it has been the general persuasion, that the mind or soul subsists after the dissolution of the body. The origin of this persuasion, about which disputes have been raised, no Christian hesitates to attribute to revelation. The Egyptians, from whom the Greeks derived many of their theological and philosophical principles, appear to have taught the immortality of the soul, not as a truth discovered by the exertions of human reason, but as a dogma derived to them from the earliest ages by tradition. This indeed may be confidently inferred from the character and conduct of their first Greek disciples. Those early wise men who fetched their philosophy immediately from Egypt, brought it home as they found it, in detached and independent placits. Afterwards, when schools were formed, and when man began to philosophize by hypothesis and system, it was eagerly inquired upon what foundation in *nature* the belief of the soul's immortality could rest; and this inquiry gave rise to the various disquisitions concerning the *substance* of the soul, which have continued to exercise the ingenuity of the learned to the present day. It was clearly perceived, that if consciousness, thought, and volition, be the result of any particular modification of matter and motion, the living and thinking agent must perish with the dissolution of the system; and it was no less evident, that if the being which perceives, thinks, and wills, be not material, the mind of man *may* subsist after the resolution of the body into its component particles. The discovery of the immateriality of the mind was therefore one *step towards* the proof of its immortality; and in the opinion of many philosophers, whose hopes ought to rest on a surer basis, it was alone a complete proof.—"They who hold sensitive perception in brutes (says a pious writer)

Of the Immortality of the Soul.

writer *) to be an argument for the immateriality of their souls, find themselves under the necessity of allowing those souls to be immortal."

* See the Procedure, Extent, and Limits of the Understanding.

262 The philosophers of ancient Greece believed likewise in its pre-existence

The philosophers of ancient Greece, however, felt not themselves under any such necessity. Whatever were their opinions respecting the souls of brutes, they clearly perceived that nothing which had a beginning of existence could be naturally immortal, whether its substance were material or immaterial.—" There never was any of the ancients before Christianity (says the accurate Cudworth), that held the soul's future permanency after death, who did not likewise assert its pre-existence; they clearly perceiving, that if it were once granted that the soul was generated, it could never be proved but that it might be also corrupted. And, therefore, the assertors of the soul's immortality commonly began here, first to prove its pre-existence, proceeding thence to establish its permanency after death. This is the method of proof used in Plato: Ην που ἡμων ἡ ψυχη πριν εν τω δε τω ανθρωπινω ειδει γενεσθαι, ὡστε και ταυτη αθανατον τι εοικεν ἡ ψυχη ειναι. *Our soul was somewhere before it came to exist in this human form, and thence it appears to be immortal, and as such will subsist after death.*

263 and absolute eternity.

To give this argument for immortality any strength, it must be taken for granted, not only that the soul existed in a *prior* state, but that it existed from all *eternity*; for it is obvious, that if it had a beginning in any state, it may have an end either in that state or in another. Accordingly, Plato asserts in plain terms its eternity and self-existence, which, as we learn from Cicero, he infers from its being the principle of motion in man. " Quin etiam cæteris, quæ moventur, hic fons, hoc principium est movendi. *Principii autem nulla est origo.* Nam ex principio oriuntur omnia: ipsum autem nulla ex re alia nasci potest: nec enim esset id principium, quod gigneretur aliunde †." This, it must be acknowledged, is very contemptible reasoning; but the opinion which it was intended to prove was held by all the philosophers. They were unanimous in maintaining the *substance* of the soul, though not its *personality*, to be eternal *à parte ante* as well as *ad partem post*; and Cicero, where he tells us that this opinion passed from *Pherecydes Syrus* to Pythagoras, and from Pythagoras to *Plato*, expresses their notion of the soul's duration by the word *sempiternus* ‡, which, in its original and proper sense, is applicable only to that which has neither beginning nor end.

† *Tuscul.* lib. i. cap. 23.

‡ *Tuscul.* lib. i.

Indeed none of the philosophers of ancient Greece appear to have believed a creation (see CREATION) possible: for it was a maxim universally received among them, *De nihilo nihil fit, in nihilum nil posse reverti*; that *nothing can come from nonentity, or go to nonentity.* This maxim, as held by the theistical philosophers, the learned Cudworth labours to interpret in a sense agreeable to our notions of the origin of the world; but the quotations urged by himself must convince every competent reader that on this occasion he labours in vain. For instance, when Aristotle writes of Parmenides and Melissus, that ουδεν ουδε γινεσθαι φασιν ουδε φθειρεσθαι των οντων, *they say that no real entity is either made or destroyed*; what can be his meaning, but that those philosophers taught that nothing could be either created or annihilated? He testifies the same thing of *Xenophanes* and *Zeno*, when he says that it was a fundamental principle of their philosophy—μη ενδεχεσθαι γινεσθαι μηδεν εκ μηδενος—*that it is impossible that any thing should be made out of nothing.* And of Empedocles, when he relates απαντα ταυτα κακεινος ὁμολογει ὁτι εκ τε μη οντος αμηχανον εστι γινεσθαι το τε ον εξολλυσθαι ανηνυστον και αρρηκτον—*That he acknowledges the very same thing with other philosophers*, viz. *that it is impossible that any thing should be made out of nothing, or perish into nothing.* But it is needless to multiply quotations respecting the opinions of single philosophers. Of all the physiologers before himself and Plato, Aristotle says, without exception, περι ταυτης ὁμογνωμονουσι της δοξης οἱ περι φυσεως, ὁτι το γιγνομενον εκ μη οντων γιγνεσθαι αδυνατον †—*That they agree in this opinion, that it is impossible that any thing should be made out of nothing*: and he calls this the common principle of naturalists; plainly intimating, that they considered it as the greatest absurdity to suppose that any real entity in nature could either be brought from nothing or reduced to nothing.

† *Physic.* lib. i. cap. 5.

The author of the *Intellectual System*, in order, perhaps, to hide the impiety of this principle, endeavours to persuade his readers, that it was urged only against the hypothesis of forms and qualities of bodies considered as real entities, distinct from matter. But how it could be supposed to militate against that particular opinion, and not against the possibility of all creation, is to us perfectly inconceivable. The father of the school which analyzed body into matter and form, together with by far the greater part of his followers, taught the eternity of both these principles (L); and therefore maintained, as strenuously as any atomist, the universal maxim, *De nihilo nihil fit.* Even Plato himself, whose doctrine of *ideas* is supposed to wear a more favourable aspect than Aristotle's *forms* to the truths of revealed religion, taught the *eternity* of *matter*; but whether as a self-existing substance, or only as an emanation from the Deity, is a question which has

Mosheim's edition of Cudworth's Intellectual System, lib. i. cap. 3. sect. 33. note 60. On this subject see also *Ancient Metaphysics.*

has been disputed. That he admitted no proper creation, may be confidently inferred from Plutarch; who, writing upon the generation of animals, according to the doctrine laid down in the *Timæus*, has the following passage: Βελτιον ουν, Πλατωνι πειθομενους τον μεν κοσμον ὑπο θεου γεγονεναι λεγειν και αδειν· ὁ μεν γαρ καλλιςος των γεγονοτων ὁιδε αριςος των αιτιων την δε ΟΥΣΙΑΝ και ΥΛΗΝ εξ ης γεγονεν ου γενομενην, αλλα ὑποκειμενην αει τω δημιουργω εις διαθεσιν και ταξιν αυτης, και προς εξομοιωσιν, ὡς δυνατον ην παρασχειν· ου γαρ εκ του μη οντος ἡ γενεσις, αλλ' εκ του μη καλως, μηδ' ικανως εχοντος, ὡς οικιας και ἱματιον, και ανδριαντος *. *It is therefore better for us to follow Plato, and to say and sing that the world was made by God. For as the world is the best of all works, so is God the best of all causes. Nevertheless, the* SUBSTANCE OR MATTER *out of which the world was made, was* NOT *itself made, but was always ready at hand, and subject to the artificer, to be ordered and disposed by him. For the making of the world was not the production of it out of nothing, but out of an antecedent bad and disorderly state, like the making of a house, garment, or statue.*

The Immortality of the Soul.

* Plut. Op. t. ii. p. 1014.

If, then, this be a fair representation of the sentiments of Plato, and surely the author understood those sentiments better than the most accomplished modern scholar can pretend to do, nothing is more evident, than that the founder of the academy admitted of no proper creation, but only taught that the matter which had existed from eternity in a chaotic state, was in *time* reduced to order by the *Demiurgus* or Supreme Being. And if such were the sentiments of the divine Plato, we cannot hesitate to adopt the opinion of the excellent Mosheim, which the reader will probably be pleased to have in his own words: "Si à Judæis discedas, nescio an ullus antiquorum philosophorum mundum negaverit æternum esse. Omnes mihi æternum professi videntur esse mundum: hoc uno vero disjunguntur, quod nonnulli ut *Aristoteles*, *formam* et *materiam* simul hujus orbis, alii vero, quorum princeps facile Plato, *materiam* tantum *æternam*, formam vero, à Deo comparatam, dixerunt †."

† Notes on Cudworth's Intellectual System.

Now, it is a fact so generally known, as not to stand in need of being proved by quotations, that there was not among them a single man who believed in the existence of mind as a being more excellent than matter, and essentially different from it, who did not hold the superior of at least equal antiquity with the inferior substance. So true is this, that Synesius, though a Christian, yet having been educated in one of the schools of philosophy, could not, by the hopes of a bishopric, be induced to dissemble this sentiment: αμελει την ψυχην ουκ αξιωσω ποτε σωματος ὑςερογενη νομιζειν ‡. —*I shall never be persuaded to think my soul younger than my body.* This man probably believed, upon the authority of the scriptures, that the matter of the visible world was created in time; but he certainly held with his philosophic masters, that his own soul was as old as any atom of it, and that it had consequently existed in a prior state before it animated his present body.

‡ Epist. 105.

264 They supposed all souls to be emanations from the first mind;

Those who maintained that the world was uncreated, maintained upon the same principle that their souls were uncreated likewise; and as they conceived all bodies to be formed of one first matter, so they conceived all souls to be either emanations from the one first Mind, or discerpted parts of it. Aristotle, who distinguishes between the intellectual and sensitive souls, says expressly of the former, that it "enters from without, and is DIVINE;" adding this reason for his opinion, that "its energy is not blended with that of the body—λειπεται δε τον νουν μονον θυραθεν επεισιεναι, και θειον ειναι μονον· ουδε γαρ αυτου τη ενεργεια κοινωνει σωματικη ενεργεια *. As to the Stoics, *Cleanthes* held (as Stobæus informs us †), that "every thing was made out of one, and would be again resolved into one." But let Seneca speak for them all: "Quid est autem, cur non existimes in eo *divini* aliquid existere, qui DEI PARS est? Totum hoc, quo continemur, et unum est, et Deus: et socii ejus sumus, et membra ‡—*Why should you not believe something to be divine in him, who is indeed* PART OF GOD? *That* WHOLE *in which we are contained is* ONE, *and that one is* GOD; *we being his companions and* MEMBERS. Epictetus says, *The souls of men have the nearest relation to God, as being* PARTS OR FRAGMENTS *of him,* DISCERPTED *and* TORN *from his* SUBSTANCE; συναφεις τω θεω, ἁτε αυτου μορια ουσαι και αποσπασματα. Plato writes to the very same purpose, when, without any softening, he frequently calls the soul *God*, and *part of God*. And Plutarch says, that "Pythagoras and Plato held the soul to be immortal; for that, launching out into the soul of the universe, it returns to its parent and original—Πυθαγορας, Πλατων, ἀφθαρτον ειναι την ψυχην· εξιουσαν γαρ εις την του παντος ψυχην, αναχωρειν προς το ομογενες ||." Plutarch declares his own opinion to be, that "the soul is not so much the work and production of God, as a PART of him; nor is it made BY him, but FROM him, and OUT of him: ἡ δε ψυχη ουκ εργον εςι μονον, αλλα και μερος· ουδ' ΥΠ' αυτου, αλλ' ΑΠ' αυτου, και ΕΞ αυτου γεγονεν §." But it is needless to multiply quotations. Cicero delivers the common sentiments of his Greek masters on this head, when he says ¶, "A natura deorum, ut doctissimis sapientissimisque placuit, HAUSTOS animos et LIBATOS habemus." And again: "Humanus autem animus DECERPTUS EX MENTE DIVINA: cum alio nullo, nisi cum ipso Deo (si hoc fas est dictu), comparari potest."

Of the Immortality of the Soul.

§ Plato Quæst.

¶ De Divinatione, lib. i. cap. 49.

265 But differed in opinion as to the mode of their separation.

Whilst the philosophers were thus unanimous in maintaining the soul to be a part of the self-existent Substance, they differed in opinion, or at least expressed themselves differently, as to the mode of its separation from its divine parent. Cicero and the Stoics talk as if the Supreme Mind were extended, and as if the human soul were a part literally torn from that mind, as a limb can be torn from the body. The Pythagoreans and Platonists seem to have considered all souls as emanations from the divine Substance rather than as parts torn from it, much in the same way as rays of light are emanations from the sun. Plato, in particular, believed in two self-existent principles, God and matter. The former he considered as the supreme Intelligence, incorporeal, without beginning, end, or change; and distinguished it by the appellation of το αγαθον, *the Good*. Matter, as subsisting from eternity, he considered as without any one *form* or *quality* whatever, and as having a natural tendency to disorder. Of this chaotic mass God formed a perfect world, after the eternal pattern in his own mind, and endowed it with a soul or emanation from himself. In the language of Plato, therefore, the universe being animated by a soul which proceeds from God, is called the *son of God*; and

Of the Immortality of the Soul.

and several parts of nature, particularly the heavenly bodies, are *gods*. The human soul, according to him, is derived by emanation from God, through the intervention of this soul of the world; and receding farther from the first intelligence, it is inferior in perfection to the soul of the world, though even that soul is debased by some material admixture. To account more fully for the origin and present state of human souls, Plato supposes *, that "when God formed the universe, he separated from the soul of the world inferior souls, equal in number to the stars, and assigned to each its proper celestial abode; but that those souls, (by what means, or for what reason, does not appear), were sent down to the earth into human bodies, as into sepulchres or prisons." He ascribes to this cause the depravity and misery to which human nature is liable; and maintains, that it "is only by disengaging itself from all animal passions, and rising above sensible objects, to the contemplation of the world of intelligence, that the soul of man can be prepared to return to its original state." Not inconsistently with this doctrine, our philosopher frequently speaks of the soul of man as consisting of three parts: or rather he seems to have thought that man has three souls; the first the principle of intelligence, the second of passion, and the third of appetite (M); and to each he assigns its proper place in the human body. But it was only the intellectual soul that he considered as immortal.

* *Enfield's Abridgement of Brucker's History of Philosophy.*

Aristotle taught, in terms equally express, that the human soul is a part of God, and of course that its substance is of eternal and necessary existence. Some of his followers, indeed, although they acknowledged *two first principles*, the active and the passive, yet held, with the Stoics, but *one substance* in the universe; and to reconcile these two contradictory propositions, they were obliged to suppose matter to be both active and passive. Their doctrine on this subject is thus delivered by Cicero: "De natura ita dicebant, ut eam dividerent in res duas, ut altera esset efficiens, altera autem quasi huic se præbens, ea quæ efficeretur aliquid. In eo, quod efficeret, vim esse censebant; in eo autem quod efficeretur, materiam quandam; in UTROQUE TAMEN UTRUMQUE. Neque enim materiam ipsam cohærere potuisse, si nulla vi contineretur, neque VIM SINE ALIQUA MATERIA; nihil est enim, quod non alicubi esse cogatur †." *They divided nature into two things, as the first principles; one whereof is the efficient or artificer, the other that which offers itself to him for things to be made out of it. In the efficient principle, they acknowledged active force; in the passive, a certain matter; but so, that in* EACH BOTH OF THESE WERE TOGETHER: *forasmuch as neither the matter could cohere together unless it were contained by some active force, nor* THE ACTIVE FORCE SUBSIST OF ITSELF WITHOUT MATTER; *because that is nothing which may not be compelled to be somewhere.* Agreeably to this strange doctrine, Arrian, the interpreter of Epictetus, says of himself, ειμι ανθρωπος, μερος των παντων, ὡς ὡρα ἡμερας, "I am a man (a part of the το παν or *universe*), as an hour is part of the day."

† *Academicum*, lib. 1. cap. 6.

Aristotle himself is generally supposed to have believed in the eternal existence of two substances, *mind* and *matter*; but treating of the generation of animals, he says, ενδε το παντι θερμοτης ψυχικη, ως τροπον τινα παντα ψυχης ειναι πληρη διο συνισταται ταχεως ὁποταν εμπεριληφθη ‡. *In the universe there is a certain animal heat, so as that after a manner all things are full of mind; wherefore they are quickly completed (or made complete animals) when they have received a portion of that heat.* This *heat*, from which, according to Cicero ||, the Stagyrite derived all souls, has, it must be confessed, a very material appearance; insomuch that the learned Mosheim seems to have been doubtful whether he admitted of any immaterial principle in man; but for this doubt there appears to us to be no solid foundation. Aristotle expressly declares, that *this heat is not fire* nor any *such power, but a spirit which is in the seeds* or *elementary principles of bodies*; τουτο δε ου πυρ, ουδε τοιαυτη δυναμις εστιν, αλλα το εμπεριλαμβανομενον εν τω σπερματι και εν τω αφρωδει πνευμα §. And as the excellent person himself acknowledges (N), that Aristotle taught the existence of two principles, God and matter, not indeed subsisting

‡ *De Generatione Animalium*, lib. iii. cap. 11.

|| *Tuscul.* lib. i. c. 3.

§ *De Generatione Animalium*, lib. ii. c. 3.

(M) "Plato triplicem finxit animam; cujus principatum, id est, rationem, in capite, sicut in arce, posuit: et duas partes separare voluit, iram et cupiditatem, quas locis disclusit; iram in pectore, cupiditatem subter præcordia locavit." *Ciceronis Tusc. Quest.* lib. i. cap. 10.

This hypothesis has been adopted by the learned author of Ancient Metaphysics: but it cannot be proved by argument, and is in direct opposition to consciousness. Were there three distinct minds in each man—the principles of intelligence, of passion, and of appetite, it is obvious that *each man* would be *three persons*, and that *none* of these persons could know any thing of the powers and properties of the *other two*. The intelligent person could not reason about *passion* or *appetite*: nor could the persons who know nothing but passion and appetite reason about *intelligence*, or indeed about any thing else. The very question at issue, therefore, furnishes the most complete proof possible, that the same individual which each man calls himself, is the principle of intelligence, of passion, and of appetite; for if the Platonic hypothesis were true, that question could never have been started, as no one individual of the human race could have understood all its terms. It may be just worth while to mention, that the author of Ancient Metaphysics, attributing all motion, and even the coherence of the minute particles of body, to the immediate agency of mind, of course furnishes every human body with at least *four minds*. This fourth mind differs not from the *plastic nature* of Cudworth, and is likewise a Platonic notion apparently better founded. That there are in our bodies motions perpetually carried on by the agency of something which is not the principle of either our intelligence, our passions, or our appetites, is a fact which cannot be denied; but if those motions proceed immediately from mind, it must either be from the *supreme* mind, or from some *subordinate* mind, acting under the supreme, but wholly *distinct from and independent* of that which each man calls himself.

(N) "Non cum illis componi prorsus potest ARISTOTELES, qui bina rerum separataque statuunt principia, Deum ne Im-mortality of the Soul.

ing separately, but eternally linked together by the closest union; we think it follows undeniably, that this heat, from which he derived all souls, must be that mind which he called *God*, and which he considered as the actuating soul of the universe.

Upon these principles neither Aristotle nor the Stoics could believe with Plato, that in the order of nature there was first an emanation from the Supreme Mind to animate the universe, and then through this universal soul other emanations to animate mankind. The Stagyrite believed, that the Supreme Mind himself is the soul of the world, and that human souls are immediately derived from him. The genuine Stoics, acknowledging but one substance, of necessity considered both the souls and bodies of men as portions of that substance, which they called *το εν*; though still they affected to make some unintelligible distinction between body and mind. But however the various schools differed as to those points, they were unanimous as to the soul's being a part of the self-existing Substance; and Cicero gives their whole system from Pacuvianus in words which cannot be misunderstood:

> Quicquid est hoc, omnia animat, format, alit, auget, creat,
> Sepelit, recipitque in sese omnia, omniumque idem est Pater:
> Indidemque eadem, quæ oriuntur de integro, atque eodem occidunt.

266 On these principles maintained the necessary existence of the soul;

To these verses he immediately subjoins the following query: "Quid est igitur, cur, cum domus sit omnium una, eaque communis, cumque *animi hominum* SEMPER FUERINT, FUTURIQUE SINT, cur ii, quid ex quoque eveniat, et quid quamque rem significet, perspicere non possint *?" And upon the same principle he elsewhere argues, not merely for the immortality, but for the *eternity* and *necessary existence* of the soul: "Animorum nulla in terris origo inveniri potest: His enim in naturis nihil inest, quod vim memoriæ mentis, cogitationis habeat; quod et præterita teneat, et futura provideat, et complecti possit præsentia; quæ sola divina sunt. Nec invenietur unquam, unde ad hominem venire possint, nisi à Deo. Ita quicquid est illud, quod sentit, quod sapit, quod vult, quod viget, cæleste et divinum est; OB EAMQUE REM ÆTERNUM SIT NECESSE EST †." This was indeed securing the future permanency of the soul in the most effectual manner; for it is obvious, that what had not a beginning can never have an end, but must be of eternal and necessary existence.

* De Divinatione, i. p. 57.

† Frag. de Consolatione.

267 but not in distinct and personal capacity.

But when the ancients attributed a proper eternity to the soul, we must not suppose that they understood it to be eternal in its *distinct* and *personal existence*. They believed that it proceeded or was *discerpted* in *time* from the substance of God, and would *in time* be again *resolved* into that substance. This they explained by a close vessel filled with sea water, which swimming a while upon the ocean, does, on the vessel's breaking, flow in again, and mingle with the common mass. They only differed about the time of this reunion; the greater part holding it to be at death; but the Pythagoreans not till after many transmigrations. The Platonists went between these two opinions; and rejoined pure and unpolluted souls immediately to the Universal Spirit; but those which had contracted much defilement, were sent into a succession of other bodies, to be purged and purified, before they returned to their parent substance *."

* Warburton's Divine Legation.

268 A similar doctrine held by the Bramins.

A doctrine similar to this of Plato has been held from time immemorial by the Bramins in India, whose sacred books teach, "That intellect is a PORTION of the GREAT SOUL of the universe, breathed into all creatures, to animate them for a certain time; that after death it animates other bodies, or returns like a *drop* into that *unbounded ocean* from which it first arose; that the souls of men are distinguished from those of other animals, by being endowed with reason and with a consciousness of right and wrong; and that the soul of him who adheres to right as far as his powers extend, is at death ABSORBED INTO THAT DIVINE ESSENCE, never more to re-animate flesh. On the other hand, the souls of those who do evil, are not at death disengaged from all the elements; but are immediately clothed with a body of fire, air, and *akash* (a kind of celestial element, through which the planets move, and which makes no resistance) in which they are for a time punished in hell. After the season of their grief is over, they reanimate other bodies: and when they arrive through these transmigrations at a state of purity, they are absorbed into God, where all PASSIONS are UTTERLY UNKNOWN, and where CONSCIOUSNESS IS LOST IN BLISS †."

† See *Preliminary Dissertation to Dow's History of Indostan.*

269 This doctrine incompatible with a future state of rewards and punishments, and

Whether the Greeks derived their notions of the divinity and transmigration of souls from the east, or whether both they and the Bramins brought the same doctrines at different periods from Egypt, it is foreign from the purpose of this article to inquire. Certain it is, that the philosophers of Greece and India argued in the very same manner, and upon the very same principles, for the *natural* immortality of the soul; and that the immortality which they taught was wholly incompatible with God's moral government of the world, and with a future state of rewards and punishments. That this is true of the doctrine of the Bramins, is evident from the last-quoted sentence: for if the soul when absorbed into the Divine essence, loses all consciousness of what it did and suffered in the body, it cannot possibly be rewarded for its virtues practised upon earth. That the philosophers of Greece taught the same cessation of consciousness, might be inferred with the utmost certainty, even though we had not Aristotle's express declaration to that purpose: For as they all believed their souls to have existed before they were infused into their bodies, and as each must have been conscious that he remembered nothing of his former state (o), it was impossible to avoid concluding,

Deum et materiam. Arctissime enim utrumque hoc initium conjunxit Stagyrita, atque ipsa naturæ necessitate Deum cohærere cum mole hac corporea putavit." *Cudworth's Intellectual System*, Book i. Chap. iv. Sect. 6. note 3.

(o) This is expressly acknowledged by Cicero, though he held with his Greek masters the eternity of the soul. In cluding, that in the future state of his soul as little would be remembered of the present. Accordingly Aristotle teaches, that "the agent intellect only is immortal and eternal, but the passive corruptible,"—τουτο μονον αθανατον και αιδιον ὁ δε παθητικος νους φθαρτος *. Cudworth thinks this a very doubtful and obscure passage; but Warburton, whose natural acuteness often discovered the sense of ancient authors when it had escaped the sagacity of abler scholars, has completely proved, that by the *agent intellect* is meant the *substance* of the soul, and by the *passive* its *particular perceptions*. It appears therefore that the Stagyrite, from the common principle of the soul's being a part of the Divine substance, draws a conclusion against a future state of rewards and punishments; which though all the philosophers (except Socrates) embraced, yet all were not so forward to avow.

270
Grossly absurd in itself;

That the hypothesis of the soul's being a part of the Divine substance is a gross absurdity, we surely need not spend time in proving. The argument long ago urged against it by St Austin must ere now have occurred to every reader. In the days of that learned father of the church, it was not wholly given up by the philosophers; and in his excellent work of the *City of God*, he thus exposes its *extravagance* and impiety: "Quid infelicius credi potest, quam Dei partem vapulare, cum puer vapulat? Jam vero *partes Dei* fieri *lascivas*, *iniquas*, *impias*, atque omnino *damnabiles*, quis ferre potest nisi qui prorsus insanit?

271
yet the only principle from which the soul can be inferred to be essentially immortal.

But though this hypothesis be in the highest degree absurd and wholly untenable, we apprehend it to be the only principle from which the *natural* or *essential* immortality of the soul can possibly be inferred. If the soul had a *beginning* it *may* have an *end;* for nothing can be more evident than that the being which had not existence of itself, cannot of itself have perpetuity of existence. Human works, indeed, continue in being after the power of the workman is withdrawn from them; but between human works and the Divine there is this immense difference, that the former receive from the artist nothing but their form; whereas the latter receive from the Creator both their form and their substance. Forms are nothing but modifications of substance; and as substances depend upon God and not upon man, human works are continued in being by that fiat of the Creator, which made the substances of which they are composed susceptible of different forms, and of such a nature as to retain for a time whatever form may be impressed upon them. Human works therefore are continued in being by a power different from that by which they are finished; but the works of God depend wholly upon that power by which they were originally brought into existence; and were the Creator to withdraw his supporting energy, the whole creation would sink into nothing.

272
Baxter's argument for the natural or essential immortality of the soul.

Self-evident as this truth certainly is, some eminent philosophers *seem* to have questioned it. "No substance or being (says Mr Baxter *) can have a natural tendency to annihilation, or to become nothing. That a being which once exists should cease to exist is a real effect, and must be produced by a real cause: But this cause could not be planted in the nature of any substance or *being* to become a tendency of its nature; *for it could not be a free cause*, otherwise it must be a *being* itself, the subject of the *attribute freedom*, and therefore not the property of another *being; nor a necessary cause*, for such a cause is only the effect of something imposing that necessity, and so no cause at all."

273
Inconclusive,

That the author's meaning in this argument is good, cannot, we think, be controverted; but he has not expressed himself with his usual accuracy. He seems to confound *causes* with the *absence* of causes, and the *effects* of the *former* with the *consequences* of the *latter*. The visible world was brought into existence by the actual energy of the power of God; and as the visible world had nothing of itself, it can *remain* in existence only by a *continuance* of the *same energy*. This energy therefore is at the present moment as *real a cause* as it was six thousand years ago, or at any period when it may have been first exerted; and the visible world is its *real and permanent effect*. But would the ceasing of this energy be likewise a *cause?* It would certainly be followed with the annihilation of the visible world, just as the withdrawing of the sun-beams would be followed with darkness on the earth. Yet as no one has ever supposed that darkness, a nonentity, is a *positive effect* of the sun or of his beams, but only a mere negative consequence of their absence; so, we think, no one who believes in creation can consider that destruction which would inevitably follow the withdrawing of the energy by which all things are supplied, as the *positive effect* of a contrary energy, or as any thing more than a *negative consequence* of the ceasing of that volition or energy of power by which God at first brought things into existence. For "where the *foundation* of existence lies *wholly* in the power of an infinite Being *producing*, the *ground* of the *continuance* of that existence must be wholly in the same power *conserving;* which, has therefore, with as much truth as frequency, been styled a continued creation (P)."

274
and in effect given up by himself.

The force of this reasoning Mr Baxter certainly saw, when he said, that "a tendency to persevere in the same state of nature, and a tendency to change it, are contradictories, and impossible to be planted in the same subject at once: or, not to urge the contradiction, if the last prevailed, the remaining in the same state for any given time would be impossible. We forget the true cause of all these tendencies, *the will of God*, which it is absurd to suppose contrary to itself. The tendency in matter to persevere in the same state of rest or motion, is nothing but *the will of the Creator*, who preserves all things in their existence and manner of existence: nor can we have recourse to any other cause

---

* *De Anima*, lib. iii. cap. 6.

* *Inquiry into the Nature of the Human Soul*, vol. i. sect. 3.

In answer to some very foolish assertions concerning the evil of death, he says, "Ita, qui nondum nati sunt, miseri jam sunt, quia non sunt: et nos ipsi, si post mortem miseri futuri sumus, miseri fuimus antequam nati. Ego autem *non commemini*, *antequam sum natus*, *me miserum*. *Tuscul.* lib. i. cap. 6.

(P) See Stillingfleet's *Origines Sacræ*, where this question is treated in a very masterly manner by one of the ablest metaphysicians of the 17th century. See also our article PROVIDENCE.

Of the Immortality of the Soul.

cause for the preservation of immaterial substance in its existence. Therefore these tendencies are to be ascribed to the will of God, and it is absurd to suppose them contrary."

275 Analogical evidence of the immortality of the soul, and a moral proof of a future state of rewards and punishments.

All this is unquestionably true. The existence or nonexistence of matter and of created spirits depends wholly upon the will of God; and we cannot suppose him to be willing to-day the reverse of what he willed yesterday, because we know that all his volitions are directed by unerring wisdom. We have likewise the evidence of experience, that nothing is ever suffered to perish but particular systems, which perish only *as systems* by a decomposition of their parts. A being, which like the soul has no parts, can suffer no decomposition; and therefore, if it perish, it must perish by annihilation. But of annihilation there has not hitherto been a single instance; nor can we look for a single instance without supposing the volitions of God to partake of that unsteadiness which is characteristic of man. Corporeal systems, when they have served their purpose, are indeed resolved into their component parts; but the matter of which they were composed so far from being *lost*, becomes the matter of *other systems* in endless succession. Analogy, therefore, leads us to conclude, that when the human body is dissolved, the immaterial principle by which it was animated continues to think and act, either in a state of separation from all body, or in some material vehicle to which it is intimately united, and which goes off with it at death; or else that it is preserved by the Father of spirits, for the purpose of animating a body in some future state. When we consider the different states through which that living and thinking *individual*, which each man calls himself, goes, from the moment that it first animates an embryo in the womb, to the dissolution of the man of fourscore; and when we reflect likewise on the wisdom and *immutability* of God, together with the various dissolutions of corporeal systems, in which we know that a single atom of matter has never been lost; the presumption is certainly strong, that the soul shall subsist after the dissolution of the body. But when we take into the consideration the *moral* attributes of God—his justice and goodness, together with the unequal distribution of happiness and misery in the present world; this presumption from analogy amounts to a *complete moral proof* that there shall be a future state of rewards and punishments (Q) (see MORAL *Philosophy* and RELIGION): and if we estimate the duration of the rewards by the benevolence of Him by whom they are to be conferred, we cannot imagine them shorter than eternity.

CHAP. V. *Of* NECESSITY *and* LIBERTY.

276 Freedom of agency implied in accountableness.

IN the preceding chapter we have adverted to that great *moral proof* for a future state, and the immortality of the soul, arising from the relation in which man, as a being accountable for his conduct, stands to a God of almighty power, infinite wisdom, and perfect justice. But the circumstance of accountableness implies freedom of agency; for it is contrary to all our notions of right and wrong (see MORAL *Philosophy*), that a man should be either rewarded or punished for actions which he was necessitated or compelled to perform.

Of Necessity and Liberty.

277 Every man has power to do what he wills:

Human actions are of three kinds: one, where we act by instinct, without any view to consequences; one, where we act by will, in order to obtain some end; and one, where we act against will. It is the second kind of actions only which confers upon the agent merit or demerit. With respect to the first, he acts blindly (see INSTINCT), without deliberation or choice; and the external act follows from the instinctive impulse, no less necessarily than a stone by its gravity falls to the ground. With respect to the last, he is rather an instrument than an agent; and it is universally allowed, that were a strong man to put a sword into the hand of one who is weaker, and then to force it through the body of a third person, he who held the sword would be as guiltless of the murder as the sword itself. To be entitled to rewards, or liable to punishment, a man must act voluntarily; or in other words, his actions must proceed from that energy of mind which is termed *volition;* and, we believe, it has never been denied, that all men have power to do whatsoever they *will*, both with respect to the operations of their minds and the motions of their bodies, uncontrouled by any foreign principle or cause. "Every man (says Priestley) is at liberty to turn his thoughts to whatever subject he pleases, to consider the reasons for or against any scheme or proposition, and to reflect upon them as long as he shall think proper; as well as to walk wherever he pleases, and to do whatever his hands and other limbs are capable of doing." Without such liberty as this, morality is inconceivable.

278 But different opinions entertained of the freedom of volition.

But though philosophers have in general agreed with respect to the power which a man has to perform such actions as he wills, they have differed widely in opinion respecting the nature of his volitions. That these are the result of motives, has seldom if ever been questioned; but whether that result be necessary so as that the agent has no self-determining power to decide between different motives, has been warmly disputed by men equally candid, impartial, and intelligent. The principal writers on the side of necessity are, Hobbes, Collins, Hume, Leibnitz, Lord Kames, Hartley, Edwards, Priestley, and perhaps Locke. On the other side are Clarke, King, Law, Reid, Butler, Price, Bryant, Wollaston, Horsley, Beattie, and Gregory,

(Q) It was by such arguments that Socrates reasoned himself into the belief of a future state of rewards and punishments. He was singular, as we have already observed, in this belief; and he was as singular in confining himself to the study of morality. "What could be the cause of this belief, but this restraint, of which his belief was a natural consequence? For having confined himself to morals, he had nothing to mislead him; whereas the rest of the philosophers, applying themselves with a kind of fanaticism to *physics* and *metaphysics*, had drawn a number of absurd, though subtle, conclusions, which directly opposed the consequences of those moral arguments."
Warburton s Div. Leg. vol. ii.

Of Necessity and Liberty.

gory, &c. To give a short view of this celebrated question, is all that our limits will permit; and as we do not think ourselves competent to settle the dispute, it were perhaps a thing desirable to give the opposite reasonings in the words of those eminent authors themselves. It must, however, be obvious to the reader, that the style and manner of so many different writers are extremely various, and that to introduce them all into our abstract, would make the whole a mass of confusion. We shall, therefore, select one writer to plead the cause of necessity, supplying his defects from those who, though inferior to him on the whole, may yet have argued more ably on some particular points which the question involves; and to this combined reasoning we shall subjoin such answers as to us appear most conclusive. Hartley, Hume, and Priestley, are perhaps the most profound reasoners on the side of necessity; but there is so much more perspicuity in the arguments of Lord Kames, that we cannot help preferring them, as being on the whole better calculated to give the ordinary reader a fair view of the subject.

279
Scheme of necessity, according to Lord Kames.

"Into actions done with a view to an end (says his lordship*), desire and will enter: desire to accomplish the end goes first; the will to act, in order to accomplish the end, is next; and the external act follows of course. It is the will then, that governs every external act done as a mean to accomplish an end; and it is desire to accomplish the end that puts the will in motion; desire, in this view, being commonly termed the *motive* to act. But what is it that raises desire? The answer is ready: It is the prospect of attaining some agreeable end, or of evading one that is disagreeable. And if it be inquired, what makes an object agreeable or disagreeable? the answer is equally ready: It is our nature that makes it so. Certain visible objects are agreeable, certain sounds, and certain smells: other objects of these senses are disagreeable. But there we must stop; for we are far from being so intimately acquainted with our own nature as to assign the causes.

* *Sketches of the History of Man*, Book iii. Sketch 2. part 1. sect. 8.

"With respect to instinctive actions, no person, I presume, thinks that there is any freedom. With respect to voluntary actions, done in order to produce some effect, the necessity is the same, though less apparent at first view. The external action is determined by the will: the will is determined by desire; and desire by what is agreeable or disagreeable. Here is a chain of causes and effects, not one link of which is arbitrary, or under command of the agent: he cannot will but according to his desire; he cannot desire, but according to what is agreeable or disagreeable in the objects perceived: nor do these qualities depend on his inclination or fancy; he has no power to make a beautiful woman ugly, nor to make a rotten carcase smell sweetly.

"Many good men, apprehending danger to morality from holding our actions to be necessary, endeavour to break the chain of causes and effects above mentioned; maintaining, that whatever influence desire or motives may have, it is the agent himself who is the cause of every action; that desire may advise, but cannot command; and, therefore, that a man is still free to act in contradiction to desire and to the strongest motives.

"That a being may exist which in every case acts blindly and arbitrarily, without having any end in view, I can make a shift to conceive: but it is difficult for me even to imagine a thinking and rational being, that has affections and passions, that has a desirable end in view, that can easily accomplish this end; and yet after all can fly off or remain at rest, without any cause, reason, or motive, to sway it. If such a whimsical being can possibly exist, I am certain that man is not that being. There is not, perhaps, a person above the condition of a changeling, but can say *why* he did so and so, what moved him, what he intended. Nor is a single fact stated to make us believe that ever a man acted against his own will or desire, who was not compelled by external force.—On the contrary, constant and universal experience proves, that human actions are governed by certain inflexible laws; and that a man cannot exert his self-motive power but in pursuance of some desire or motive.

"Had a motive always the same influence, actions proceeding from it would appear no less necessary than the actions of matter. The various degrees of influence that motives have on different men at the same time, and on the same man at different times, occasion a doubt, by suggesting a notion of chance. Some motives, however, have such influence as to leave no doubt: a timid female has a physical power to throw herself into the mouth of a lion roaring for food; but she is withheld by terror no less effectually than by cords: if she should rush upon a lion, would not every one conclude that she was frantic? A man, though in a deep sleep, retains a physical power to act, but he cannot exert it. A man, though desperately in love, retains a physical power to refuse the hand of his mistress; but he cannot exert that power in contradiction to his own ardent desire, more than if he were fast asleep. Now, if a strong motive have a necessary influence, there is no reason for doubting, but that a weak motive must also have its influence, the same in kind, though not in degree. Some actions indeed are strangely irregular; but let the wildest actions be scrutinized, there will always be discovered some motive or desire, which, however, whimsical or capricious, was what influenced the person to act. Of two contending motives, is it not natural to expect that the stronger will prevail, however little its excess may be? If there be any doubt, it must arise from a supposition, that a weak motive may be resisted arbitrarily. Where then are we to fix the boundary between a weak and a strong motive? If a weak motive can be resisted, why not one a little stronger, and why not the strongest? Between two motives opposing each other, however nearly balanced, a man has not an arbitrary choice, but must yield to the stronger. The mind, indeed, fluctuates for some time, and finds itself in a measure loose: at last, however, it is determined by the more powerful motive, as a balance is by the greater weight after many vibrations.

"Such, then, are the laws that govern our voluntary actions. A man is absolutely free to act according to his own will; greater freedom than which is not conceivable. At the same time, as man is made accountable for his conduct to his Maker, to his fellow

low creatures, and to himself, he is not left to act arbitrarily; for at that rate he would be altogether unaccountable: his will is regulated by desire; and desire by what pleases or displeases him.—Thus, with regard to human conduct, there is a chain of laws established by nature; no one link of which is left arbitrary. By that wise system, man is made accountable; by it he is made a fit subject for divine and human government: by it persons of sagacity foresee the conduct of others; and by it the prescience of the Deity with respect to human actions is clearly established."

Of the doctrine of necessity, a more perspicuous or plausible view than this is not to be found in any work with which we are acquainted. It is indeed defective, perhaps, as his lordship only *hints* at the *nature* of that relation which subsists between motive and action; but from his comparing the fluctuations of the mind between two contending motives, to the vibrations of a balance with different weights in the opposite scales, there is no room to doubt but that he agreed exactly in opinion with Mr Hume and Dr Priestley. Now, both these writers hold, that the relation of motives to volition and action, is the very same with that which subsists between cause and effect in physics, as far as they are both known to us.

280 Hume, Inquiry concerning Human Understanding, sect. 8.

"It is universally allowed (says Mr Hume *), that matter, in all its operations, is actuated by a necessary force; and that every natural effect is so precisely determined by the energy of its cause, that no other effect, in such particular circumstances, could possibly have resulted from it. The degree and direction of every motion is, by the laws of nature, prescribed with such exactness, that a living creature may as soon arise from the shock of two bodies, as motion in any other degree or direction than what is actually produced by it. Would we, therefore, form a just and precise idea of *necessity*, we must consider whence that idea arises, when we apply it to the operation of bodies. But our idea of this kind of necessity and causation arises entirely from the uniformity observable in the operations of nature, where similar objects are constantly conjoined together, and the mind is determined by custom to infer the one from the appearance of the other. These two circumstances form the whole of that necessity which we ascribe to matter. Beyond the *constant conjunction* of similar objects, and the consequent *inference* from one to the other, we have no notion of any necessity or connexion." He then gives a pretty long detail to prove a great uniformity among the actions of men in all nations and ages; and concludes that part of his argument with affirming, "not only that the conjunction between motives and voluntary actions is as regular and uniform as that between the cause and effect in any part of nature; but also, that this regular conjunction has been universally acknowledged among mankind, and has never been the subject of dispute either in philosophy or common life." He afterwards observes, "That men begin at the wrong end of this question concerning liberty and necessity, when they enter upon it by examining the faculties of the soul, the influence of the understanding, and the operations of the will. Let them first discuss a more simple question, namely, the operations of body, and of brute unintelligent matter, and try whether they can there form any idea of causation and necessity, except that of a constant conjunction of objects, and subsequent inference of the mind from one to another. If these circumstances form in reality the whole of that necessity which we conceive in matter, and if these circumstances be also universally acknowledged to take place in the operations of the mind, the dispute is at an end; at least must be owned to be thenceforth merely verbal. When we consider how aptly *natural* and *moral* evidence link together, and form only one chain of argument, we shall make no scruple to allow that they are of the same nature, and derived from the same principles.—Between a connected chain of natural causes and voluntary actions, the mind feels no difference in passing from one link to another; nor is less certain of a future event which depends upon motives and volitions, than if it were connected with the objects present to the memory and senses by a train of causes, cemented together by what we are pleased to call a *physical* necessity. The same experienced union has the same effect on the mind, whether the united objects be motives, volition and action, or figure and motion. We may change the names of things, but their nature and their operation on the understanding never change."

Dr Priestley, in words a little different, teaches the very same doctrine which was taught by Mr Hume.— 281 Dr Priestley.
"In every determination of the mind (says he *), or in cases where volition and choice are concerned, all the previous circumstances to be considered are the *state of mind* (including *every thing belonging to the will itself*), and the *views of things* presented to it; the latter of which is generally called the *motive*, though under this term some writers comprehend them both. To distinguish the *manner* in which events depending upon *will* and *choice* are produced, from those in which no volition is concerned, the former are said to be produced *voluntarily*, and the latter *mechanically*. But the same general maxims apply to them both. We may not be able to determine *à priori* how a man will act in any particular case; but it is because we are not particularly acquainted with his *disposition of mind, precise situation*, and *views of things*. But neither can we tell in which way the wind will blow to-morrow, though the *air* is certainly subject to no other than necessary laws of motion.

* *The Doctrine of Philosophical Necessity illustrated.*

"It is universally acknowledged, that there can be no effect without an adequate cause. This is even the foundation on which the only proper argument for the being of a God rests. And the necessarian asserts, that if, in any given state of mind, with respect both to *disposition* and *motives*, two different determinations or volitions be possible, it can be so on no other principle, than that one of them shall come under the description of an *effect without a cause*; just as the beam of a balance might incline either way, though loaded with equal weights. It is acknowledged, that the mechanism of the balance is of one kind, and that of the mind of another; and, therefore, it may be convenient to denominate them by different words; as, for instance, that of the balance may be termed a *physical*, and that of the mind a *moral* mechanism. But still, if there be a *real mechanism* in both cases, so that there can be only one result

Of Necessity and Liberty.

result from the same previous circumstances, there will be a *real necessity*, enforcing an absolute certainty in the event. For it must be understood, that all that is ever meant by *necessity in a cause*, is that which produces *certainty in the effect*."

Such is the nature of human volitions, according to every necessarian of eminence who has written on the subject since the days of Hobbes: and if this theory be just, if there be a constant and inseparable conjunction of motives and actions similar to that of cause and effect in physics, it is obvious, that in volition the mind is as inert as body is in motion.

282 View of human liberty.

This consequence is indeed avowed and insisted upon by Hume, Priestley, and their adherents; whilst the advocates for human liberty, on the other hand, contend for an absolute exemption of the will from all internal *necessity*, arising from its own frame and constitution, the impulse of superior beings, or the operations of objects, reasons, or motives, &c. By this they do not mean, that between motives and volitions there is no relations whatever, or that a man can ever choose evil as evil, or refuse good as good. Such an assertion would be contrary to consciousness and universal experience. But what they endeavour to prove is, that the conjunction of motive and volition is not inseparable, like that of cause and effect in physics; that a man may in most cases choose according to any one of two or more motives presented to his view; that by choosing any thing, he may make it in some measure agreeable by his own act, or, to speak more properly, may bend his desire to it; that in volition, the mind is not enert; and that, therefore, we are under no *necessity* to act in a particular manner in any given case whatever.

That the conjunction of motive and action is not constant like that of cause and effect in physics, and that by consequence the mind in forming volitions is not inert, has been evinced by Dr Gregory with the force and precision of mathematical demonstration.—Former writers on the side of liberty had often observed, that upon the supposition of the *inertia* of mind, a man, with equal and opposite motives presented at once to his view, would, during their continuance, remain perfectly at rest, like a balance equally loaded in both scales. The observation is admitted to be just by all the advocates for necessity; but they contrive to evade its consequences, by denying that in any given case a man can be at once assailed by two equal and opposite motives. Thus, when it is said that a porter, standing with his face due north, must remain in that position at perfect rest, as long as equal motives shall at once be offered to him for travelling eastward and westward, the necessarians admit the force of the argument; but when it is added that a guinea, offered for every mile that he should travel in each of these opposite directions, ought therefore to fix him at rest till one of the offers be withdrawn, they deny that the desire of gaining the guineas is the *whole* of the motives which operate upon his mind. He may have, say they, some secret reason which we cannot discern for preferring the one direction to the other; and that reason, added to the guinea, will make him go eastward or westward, just as an ounce thrown into either scale of a balance poised by equal weights will make that scale preponderate. Though we think that this solution of the difficulty can satisfy no man who is not already biassed to the necessarian system; and though, even were it to be admitted, it seems to militate against the constant conjunction of motives and actions, unless it can be proved that the porter must travel the road which he has been necessitated to choose with reluctance and a heavy heart; yet as it may admit of endless quibbling upon ambiguous words, the philosophical world is much indebted to Dr Gregory † for an argument which, in our opinion can neither be overturned nor evaded, and which demonstrates that the conjunction of motive and action cannot be constant and inseparable, like that of cause and effect in physics.

† *Essay on the Relation between Motive and Action.*

283 Demonstration that the conjunction of motive and action is not constant.

His reasoning is to this purpose: Suppose a porter to be offered a guinea for every mile that he shall travel directly eastward. If there be no physical cause or moral motive to keep him at rest, or to induce him to move in another direction, there cannot be a doubt, upon either hypothesis, but he will gladly embrace the proposal, and travel in the direction pointed out to him, till he shall have gained as much money as to satisfy his most avaricious desires. The same thing would have happened, if a guinea had been offered for every mile that he should travel due south. In these two cases taken separately, the relation between the man's motions and his actions would be strikingly analogous to that between a single impulse and motion in physics. Let us now suppose the two offers to be made at the same instant, and the man to be assured that if he travel eastward he can have no part of the reward promised for his travelling to the south, and that if he travel southward he can have no part of the reward promised for his travelling to the east. What is he to do in this case? If his mind be inert in volition, and if the two motives operate upon him with the same necessity that causes operate in physics, it is obvious that the man could travel neither towards the east nor towards the south, but in a diagonal direction from north-west to south-east; and this he must do *willingly*, although perfectly satisfied that he could gain nothing by his journey. As this inference is contrary to fact and universal experience, the doctor very justly concludes that the premises, from which it is deduced by mathematical reasoning, must be false and absurd; or, in other words, that the relation between motive and action cannot be that of constant conjunction, like the relation between cause and effect in physics.

He uses many arguments of the same kind, and equally convincing, to prove the absurdity of supposing the inertness of mind, and only an occasional conjunction of motives and actions; but we forbear to quote them, both because we wish his book to be read, and because we think the single argument which we have borrowed from him sufficient to demolish the theory of Priestley and Hume, which rests wholly upon the hypothesis of the *constant* conjunction of motive and action.

But is it then not really true, that the external action is determined by the will, the will by desire, and desire by what is agreeable or disagreeable? That the external action is universally determined by the will, is certainly true; but that the will is necessitated and universally determined by the desire is as certainly false. If Potiphar's

Potiphar's wife was handsome, and made her proposals to Joseph with any degree of female address; and if his constitution was like that of other young men; there cannot be a doubt but that he felt a *desire* to do what she requested of him: yet we know that he *willed* to do otherwise, and in direct opposition to his *desire* fled from the room. Perhaps it may be said, that his volition to flee was the effect of a contrary and stronger *desire* not to sin against God; but this is confounding the reader, by calling two energies of mind, between which there is little or no similarity, by the same name. He perceived, or knew, that to comply with his mistress's request would be to sin against God; he knew that he ought not to sin against God, and therefore he chose or determined himself not to do it. We can easily conceive how the presence, attitudes, and address, of the lady might be agreeable to him, and excite desire. There may very possibly be more than one of our readers, who, during the course of their lives, have experienced something of the same kind: but could abstract truth be in the same way agreeable, so as to excite in his mind a *desire* of virtue sufficient to annihilate or banish the *desire* of the woman? As well may it be said that one sensation can annihilate another, that the beautiful colours of the rainbow can remove the sensation of stench from the mind of him who is plunged into the midst of a dunghill, or that the smell of a rose can make a man insensible to the pain of a stroke inflicted by a bludgeon. Sensitive desire, and the perception of duty, are things so totally different, that to consider them as operating against each other, like different weights in the opposite scales of a balance, is as absurd as to suppose that sound can operate against colour, or colour against smell. A man may prefer sound to colour, or colour to smell, and act accordingly; but the determination must be wholly his own, unless these two sensations be themselves either agents or physical causes of the *same kind*, like the weights in the opposite scales of the balance.

284 ...n do always ...ermine ...mselves the ...ngest ...tive.

The advocates for liberty do not pretend, that in matters of importance a man ever acts without some motive or reason for his conduct. All that they insist upon is, that between two or more motives of different kinds he has a liberty of choice, and that he does not always determine himself by that which he knows to be the greatest. Without such freedom, they think men might be often brought into situations where they could not act at all, and where inaction would at the same time be in the highest degree absurd. Thus, were two bags of gold containing each a thousand or ten thousand guineas, to be placed on the same table, before a man whose family is perishing for want, and were the man to be told that he might take either of them, but not both, is it conceivable that he would be held in perpetual suspense between the two? No; he would instantly and with alacrity take up one of them, without feeling the least regret for the want of the other. This action would, indeed, be the consequence of a very powerful motive, the desire to obtain honestly that wealth of which he and his family stood so much in need. That motive, however, being general, would draw him equally to both bags; and it remains with the necessarians to say by what else than a self-determining power he could take either the one or the other. When it is affirmed, that such self-determination would be an effect without a cause, the advocates for liberty cannot help thinking that their antagonists are guilty of advancing as an argument a *petitio principii*; for the affirmation is true, only if the mind in volition be inert, and the *inertia* of the mind is the sole question at issue. If the mind be not inert, it is plain, that in consequence of a man's self-determination, no effect would be produced without a sufficient cause. At any rate, motives cannot be causes. In the proper sense of the word, a cause is that which produces an effect; but the production of an effect requires active power; and power being a quality, must be the quality of some being by whom it may be exerted. Power may be dormant, and therefore power without will produces no effect. Are motives, then, real beings endowed with power and will? No; they are only views of things or mental conceptions, which in the strictest sense of the word are passive; and between two motives the mind determines itself, without receiving an impulse from either.

Nor is it only between motives of equal force that men have the power of determining themselves. Whoever believes in a future state of rewards and punishments, and yet acts in a manner which he knows to be offensive to Him who is to be the future and final judge, unquestionably prefers to the strongest of all motives, another which even to himself appears to have comparatively but very little strength. Whether there be men who occasionally act in this manner, is a question which can be decided only by an appeal to every one's consciousness. That there are, we can have no doubt; for we never met with a single individual, not biassed by system, who was not ready to acknowledge, that during the course of his life he had done many things, which at the time of action he clearly perceived to be contrary to his true interest. Without a self-determining power in the mind, this could never be the case. Did motives operate with the necessity of physical causes, it is obvious that in every possible situation the strongest must constantly prevail; and that he who in certain circumstances had in time past done any particular thing, would on a return of the same circumstances do the very same thing in every time future. Dr Priestley, indeed, wishes to persuade his readers that this is actually the case. "In every determination of the mind (says he), or in cases where volition and choice are concerned, all the previous circumstances to be considered are the *state of mind* (including) *every thing belonging to the will itself*), and the various views of things presented to it;" and he affirms, that "whenever the same precise circumstances occur twice, the very same determination or choice will certainly be made the second time that was made the first." This is an assertion of which no man can controvert the truth; for it is an identical proposition. If in the circumstances previous to the determination of the mind, *every thing* belonging to the *will itself* must be included, it is self-evident that he who in any given circumstances has acted a particular part, will on a return of these circumstances act the same part a second time; for this is only saying, that he who on two different occasions shall exert volitions of the same tendency, will not on these occasions exert volitions of which the tendencies are different. But the question

Of Necessity and Liberty.

to be decided is, Whether a man, in the same general state of mind, possessed of the same degree of health, and conscious of the same appetites, must, in external circumstances perfectly alike, necessarily exert at all times the same volitions. That the human mind is under no such necessity, we think every man's consciousness and experience may abundantly satisfy him; for there are, perhaps, but very few who have not at one time resisted temptations, to which at another they have chosen to yield.

285
If they did, folly as well as merit and demerit would be banished from the world.

That there is a relation between motives and actions, must be confessed; but that relation is neither *necessity*, nor constant conjunction. If it were, all actions would be perfectly rational; and folly, as well as merit and demerit, would be banished from the conduct of men. What is the particular nature of that relation which subsists between the voluntary actions of men, and the motives from which they proceed, can be known to every individual only by an attentive and unbiassed reflection on the operations of his own mind. Without this reflection, no man can be made to understand it by the reasonings of philosophers, and with it no man can need the aid of those reasonings. That a self-determining power, such as that for which we plead, contributes to the sum of human happiness, has been shown by Archbishop King and his ingenious translator; who have proved, with the force of demonstration, that the mind can take pleasure in the object of its choice, though that object be in itself neither agreeable nor disagreeable to our natural appetites; and that if it could not, it would be in vain in such a world as ours to hope for any portion of felicity. Into that detail our limits will not permit us to enter: but to the reader who wishes for further information, we beg leave to recommend the last edition of King's Origin of Evil, by Dr Law late bishop of Carlisle; without, however, vouching for the truth of all the opinions advanced by either of those learned writers.

Before we conclude this chapter, it may be proper to observe, that it is only in volition that we are conscious of any original active power in ourselves, and that without such consciousness we could never have acquired the *notion* of active power. In our desires and appetites, we neither are active nor suppose ourselves active. Lord Kames, and most necessarians, confound desire with volition; but that they are perfectly distinct is plain from this circumstance, that we daily *desire* many things which we know to be wholly *out* of our own power *, whereas no man ever *willed* what he did not believe to be *in* his own power. We all *desire* or wish that our children may be virtuous, wise, and happy; and though we are conscious that it is not in our power to make them so, we cannot banish the desire from our breasts. But madmen only have ever *willed* virtue, wisdom, and happiness, to any person; and if there was ever a man so extravagantly mad as to exert such a volition as this, he has at the time fancied himself a divinity, and therefore believed that the object of his volition depended upon himself. When the astronomer, whose character is so admirably drawn by our great master of moral wisdom †, fancied himself the regulator of the weather and the distributor of the seasons, he might *will* either *rain* or *sunshine* as he thought proper, because he considered the object of his volition as depending upon a power imparted to him from heaven; but though he might *desire* he could not *will*, the rising or the falling of *winds*, for these he confessed were not subjected to his authority. In a word, without freedom in volition power is inconceivable; and therefore it is as certain that we are free agents, as that we have any notion of active powers.

* *Reid's Essays on the Active Powers of Man.*

† *Rasselas Prince of Abyssinia.*

Chap. VI. *Of the* Being *and* Attributes *of* God.

Of the Being and Attributes of God.

It has been already observed, that as of bodies there are various kinds, endowed with various properties; so the probability is, that of minds endowed with different powers, or different degrees of power, the variety may be as great, or perhaps greater. The existence and powers of our own minds are made known to us by consciousness and reflection; and from our dependent state, and the mutability of the objects around us, we are necessarily led to infer the existence of another mind, which is independent, unchangeable, eternal, and the cause of all things which have a beginning of existence. Between that mind and our own, we can hardly avoid believing that there are many orders of "thrones, dominations, princedoms, virtues, powers;" but as we have no intuitive knowledge of such intermediate beings, and cannot from any thing which we perceive discern the *necessity* of their existence, they are not properly the object of science. The existence however, and many of the attributes, of One First Cause, are capable of the strictest demonstration; "for the invisible things of him from the creation of the world are clearly seen, being understood by the things which are made."

286
The existence of God capable of demonstration.

Of this great truth, the most important by far which can occupy the mind of man, many demonstrations have been given both by divines and by philosophers. We shall lay before our readers such a one as to us appears perfectly conclusive, being founded on the intuitive knowledge which we have of our own existence, and therefore independent of all theories about the nature and reality of the material world.

287
Some one independent Being has existed from eternity.

Every man, whether he adopt the common theory or that of Berkeley respecting matter, is conscious that he *himself* exists, and must therefore grant that *something now* exists. But, if any thing exists *now* *, then must something have *always* existed; otherwise that thing which *now* exists, must either have been created by *nothing*, i. e. have been *caused by no cause*, or else it must have *created itself*, acting before it existed. Both these suppositions are so palpably absurd, that no atheist has avowed them, either among the ancients or the moderns. We must therefore admit, either that there is some one *independent* being, which now exists, and always has existed; or that the things which we know to exist at present (every man's *self* for instance), were produced by *something* which had its *existence* from *something else*, which also depended upon *some other cause*, and so on in an *infinite series of caused* or *successive beings*. But this last supposition, though it has been often made, is as grossly absurd as either of the two former. For of this infinite series, either *some one* part has *not* been successive to any other, or

* See Notes to King's Origin of Evil.

the Be- and At- butes of God.

or else *all* the several parts of it have been successive. If some one part of it was *not successive*, then it had a *first part*; which destroys the supposition of its infinity (R). If *all* the several parts of it have been successive, then have they all once been *future*; but if they have *all* been future, a time may be conceived when none of them had existence: and if so, then it follows, either that all the *parts*, and consequently the *whole* of this infinite series, must have arisen from *nothing*, which is absurd; or else that there must be something in the *whole* besides what is contained in *all the parts*, which is also absurd.

As the possibility or impossibility of an infinite series of dependent beings is the main question at issue between the atheists and us, we shall state the preceding reasoning in a manner somewhat different. For this purpose, let us suppose some one to affirm, that the course of generation has had no beginning, and consequently that the number of successive births has been infinite. We would ask such a person, Whether before the birth of Abraham, for example *, there had past an infinite series of generations or not? If not, the course of generation must have had a beginning, which is the conclusion for which we contend. But if the series past was infinite, then at the birth of Joseph the great-grandson of Abraham, it is evident, that more generations were past, and that the number then was greater than that which was supposed to be infinite; so that upon this supposition we have a number that is both infinite and not infinite, which is a manifest contradiction. Should it be said that the number of generations was infinite, as well at the birth of Abraham as at the birth of Joseph; it will then follow, that one infinite may be greater than another of the very same kind; and consequently that an infinite may be bounded, i. e. be finite. But should it be alleged, that the number of births at Abraham's was finite, and became infinite when it reached to Joseph's, it will then follow, that one finite number added to another may make an infinite number, which is directly contrary to every possible notion of infinity. We might argue in the same manner against an infinite series of every kind, the very supposition of which involves the most palpable contradictions. See Chap. *Of* INFINITY *and* ETERNITY.

* See an Essay towards an ...iction of Attributes of God, by ...h Ward Printed Oxford, 55.

288 ...ose duration is not commensurate with succession, and

From the impossibility of an infinite series it necessarily follows, that there exists, and must have existed from eternity, some one independent being, whose duration cannot be commensurate with succession, and to whom the relation of time is not applicable. Here will some atheists presently imagine, that by the same mode of reasoning they may disprove the existence of God: for do not they who thus destroy the eternity of the world, destroy at the same time the eternity of the Creator? If time itself be not eternal, how can the Deity or any thing else be so?

In urging these questions, it must be taken for granted that time is essential to all existence, and that God cannot be eternal otherwise than by a successive flux of infinite time. But it has been already shown (N° 224.), that successive duration is not essential to existence; that we can even *conceive* existence without succession; and it may here be added, that if we suppose a perfect being alone in nature, we shall find it impossible to imagine any *succession of ideas*, any *flux of moments*, or any *alteration* or *increase* whatever in his knowledge and essence. Such duration as we are acquainted with can have no relation to an immutable Being, while supposed to exist alone; but as soon as he determined to exercise his several attributes in the production of something distinct from himself, then, and not till then, have we reason to think that *time*, *succession*, and *increase*, began. These atheistical questions, therefore, instead of containing an objection to the existence of a Deity, afford a plain demonstration of it: for since it is not more evident that something now exists than that something must have existed from eternity; and since it has been shown, that neither the world in its present state, nor time, nor any thing capable of change or succession, can possibly be eternal; it follows, that there must necessarily be some Being who, in the order of nature, is before time, and who, in the stability and immutable perfection of his own intelligence, comprehends at once his *yesterday*, *to-day*, and *for ever*. "The atheists (says the excellent Cudworth *) can here only smile, or make wry faces, and show their little wit in quibbling upon *nunc-stans*, or a *standing now of eternity*; as if that *standing eternity* of the *Deity* (which with so much reason hath been contended for by the ancient *genuine theists*) were nothing but a *pitiful small moment of time standing still*, and as if the duration of all beings whatsoever must needs be like our own: whereas the duration of every thing must of necessity be agreeable to its nature; and therefore, as that whose *imperfect nature* is ever *flowing* like a river, and consists in *continual motion* and *changes* one after another, must needs have accordingly a *successive* and *flowing duration* sliding perpetually from *present* into *past*, and always hasting on towards the *future*, expecting something of itself which is not yet in being; so must that whose perfect nature is *essentially immutable* have *permanent and unchanging duration*, never losing any thing of itself once present, nor yet running forward to meet something of itself which is not yet in being."

* *Intellectual System*, book i. chap. 5.

289 who is self-existent, and

From the eternity of the Supreme Being we necessarily infer his independence or self-existence; for that which never had a *beginning* of existence cannot possibly have any cause of that existence, or in any manner depend upon any other being, but must exist of itself, or be *self-existent*.

290 cannot cease to be.

Eternity *ad partem post*, or *necessary existence*, or the impossibility of ever ceasing to be, follows from independence: For to the nature of that which exists without any cause, existence must be essential. But a being whose eixstence is of itself and essential to its nature, cannot be *indifferent* to existence or nonexistence, but must exist *necessarily*. And here it may be proper to observe, that the word *necessity*, when applied to existence, may be taken in two acceptations very different from each other †; either as it arises from the relation which the existence of that being, of which it is affirmed, has to the existence of *other things*; or from the relation which the *actual* existence of that thing has to the *manner* of its *own* existence.

† *Notes to King on Evil*, and *Law's Inquiry into the Ideas of Space*, &c.

In

(R) Των απειρων ουκ εστι ουδεν πρωτον, *Arist. Phys.* lib. viii. cap. 5. sect. 4.

Of the Being and Attributes of God.

In the former sense, when necessity of existence has relation to the existence of other things, it denotes that the supposition of the *non*-existence of that thing of which necessity is affirmed, implies the non-existence of things which we *know to exist*. Thus, some inde-

291 What is meant by necessary existence.

pendent being does *necessarily exist;* because, to suppose *no independent* being, implies that there are *no dependent beings;* the contrary of which we know to be true.

In the second sense, when the necessity of existence arises from the relation which the actual existence of any thing has to the *manner* of its own existence, necessity means, that the thing, of which it is affirmed, exists after such a manner as that it never could in *time past* have *been nonexistent*, or can in *time future cease to be*. Thus, *every independent being*, as it exists without a cause, *is necessarily* existing; because existence is *essential* to such a being; so that it never could *begin* to exist, and never can *cease to be:* For to suppose a being to begin to exist, or to lose its existence, is to suppose a *change* from nonentity to entity, or *vice versa;* and to suppose such a change is to suppose a cause upon which that being depends. Every being, therefore, which is independent, i. e. which had no cause of its existence, must exist *necessarily*, and cannot possibly have begun to exist in time past, or cease to be in time future.

292 Only one necessarily existent being in the former sense; and

These two kinds of necessity as applied to existence, though they have been often confounded, are in themselves perfectly distinct: For though a being cannot be necessarily existent in the *former* sense without being so in the latter also; yet may it be necessarily existent in the latter sense without being so in the former. For any thing that we know to the contrary, there may be two or more beings existing *necessarily* in the latter sense of the word *necessity*, i. e. with regard to *independence* and the *manner* of their own existence: but in the former sense of the word, i. e. in relation to *this system*, there can be but *one necessarily* existent being; for it is obvious that no more are necessary to account for the production of the *dependent* beings which we know to exist. To suppose the non-existence of all *independent* beings, implies the non-existence of all dependent beings, ourselves, and every thing else; but to suppose the non-existence of all independent beings except *one*, involves in the supposition no such absurdity.

293 though there might be more than one in the latter, they would be no gods to us.

Thus the phenomena of nature lead us, by the strictest reasoning, to one first cause, which is sufficient for their production; and therefore none but *one* first cause can in this sense of the word be *necessary:* And though several more *independent* beings might possibly exist, yet they would be no gods to us: they would have no relation to us demonstrable by reason, nor we any thing to do with them. For if the supposition of their existence were not requisite to the production of this system, which it obviously would not be, we could *perceive* no necessity for it at all; we could never discover it by our own faculties, and therefore it could be nothing to us. And though two or three such beings should exist, and act in the formation and government of their *respective* systems, or *agree in one;* yet till their existence and operations were made known to us, and a natural relation discovered, nothing would be due from us to them. They would have no *religious* or *moral* relations to us; and we should have no reason to call more than one of them *our* creator, preserver and governor, which is the proper sense of the word *God*.

To show in this manner that there is only *one* eternal self-existent Being which bears the relation of *God to us*, seems to be going as far as is necessary, or as

294 Impossible to demonstrate that there can be but one self-existent Being

natural light will lead us. Those who endeavour to *demonstrate* that there *cannot possibly* be *more than one* self-existent Being, either reason in a circle, or proceed upon principles which their antagonists cannot be compelled to grant. When they deduce the Divine unity from independence or omnipotence, they evidently presuppose it in their definition of these attributes: and when they infer it from the nature of space and duration, which they consider as modes of the self-existent Being, they take it for granted, that space and duration have a real existence, independent of us and our thoughts; and that the one is infinite and the other eternal, contrary to what has been already proved, we think, with the force of demonstration. The celebrated Dr Clarke made much use of space and duration in his attempt to demonstrate that there can be but one self-existent Being; but he argues for the same thing from the nature of necessity as applied to existence.

295 Dr Clarke's first demonstration of the unity

"Necessity (says he *), absolute in itself, is *simple* and *uniform* and *universal*, without any possible *difference*, *difformity*, or *variety*, whatsoever: and all *variety* or *difference* of *existence* must needs arise from some *external* cause, and be *dependent upon it*, and *proportionable* to the efficiency of that *cause*, whatsoever it be. *Absolute necessity*, in which there can be *no variation* in *any kind* or *degree*, cannot be the *ground* of existence of a *number* of beings, however *similar* and *agreeing:* because, without any *other difference*, even *number* is itself a manifest *difformity* or *inequality* (if I may so speak) of *efficiency* or *causality*."

* *Demonstration of the Being and Attributes of God*, Prop. 7.

296 examined and shown to be inconclusive

Such is this great man's first argument from necessity, to prove that there cannot be more than one self-existent Being. But what is this *necessity* which proves so much? It is the ground of existence (he says) of that which exists of itself; and if so, it must, in the order of nature, and in our conceptions, be antecedent to that being of whose existence it is the ground. Concerning such *a* principle, there are but three suppositions which can possibly be made; and all of them may be shown to be absurd and contradictory. We may suppose either the *substance* itself, some *property* of that substance, or something *extrinsic* to both, to be this *antecedent ground* of existence prior in the order of nature to *the first cause*.

One would think, from the turn of the argument which here represents this antecedent necessity as *efficient* and *causal*, that it were considered as something *extrinsic* to the first cause †. Indeed if the words have any meaning in them at all, or any *force* of argument, they must be so understood, just as we understand them of any external cause producing its effect. But as an *extrinsic* principle is absurd in itself, and is besides rejected by Dr Clarke, who says expressly, that "of the thing which derives not its being from any other thing, this *necessity* or ground of existence must be *in* the thing itself," we need not say a word more of the last of these suppositions.

† *Dissertation on the Argument à priori*, added to *Law's Inquiry into the Ideas of Space, Time, Immensity*, &c.

Let

Of the Being and Attributes of God.

Let us then consider the first; let us take the *substance* itself, and try whether *it* can be conceived as *prior* or *antecedent* to itself in our conceptions or in the order of nature. Surely we need not observe that nothing can be more absurd or contradictory than such a supposition. Dr Clarke himself repeatedly affirms, and it would be strange indeed if he did not affirm, that no *being*, no *thing* whatever, can be conceived as in any respect prior to the first cause.

The only remaining supposition is, that some *attribute* or *property* of the self-existent Being may be conceived as in the order of nature *antecedent* to that being. But this, if possible, is more absurd than either of the two preceding suppositions. An *attribute* is *attributed* to its *subject* as its ground or support, and *not* the *subject* to its *attribute*. A *property*, in the very notion of it, is *proper* to the substance to which it belongs, and *subsequent* to it both in our conceptions and in the order of nature. An *antecedent* attribute, or *antecedent* property, is a solecism as great, and a contradiction as flat, as an *antecedent subsequent* or *subsequent antecedent*, understood in the same sense and in the same syllogism. Every property or attribute, as such, presupposes its subject; and cannot otherwise be understood. This is a truth so obvious and so forcible, that it sometimes extorts the assent even of those who upon other occasions labour to obscure it. It is confessed by Dr Clarke *, that "the scholastic way of proving the *existence* of the self-existent Being from the absolute perfection of his nature, is ὑστερον προτερον. For all or any perfections (says he) presuppose existence; which is a *petitio principii*." If therefore properties, modes, or attributes in God, be considered as perfections (and it is impossible to consider them as any thing else), then, by this confession of the great author himself, they must all or any of them *presuppose* existence. It is indeed immediately added in the same place, "that bare necessity of existence does not presuppose, but infer existence;" which is true only if such necessity be supposed to be a principle *extrinsic*, the absurdity of which has been already shown, and is indeed universally confessed. If it be a *mode* or a *property*, it must *presuppose* the existence of its subject, as certainly and as evidently as it is a *mode* or a *property*. It might perhaps *à posteriori* infer the existence of its subject, as effects may infer a cause; but that it should infer in the other way *à priori* is altogether as impossible as that a *triangle* should be a *square*, or a *globe* a *parallelogram*.

* *Answer to the Sixth Letter.*

297 Second demonstration of the same author.

Doubtful, as it would seem, of the force of his first argument, which even those who pretend to be convinced by it acknowledge to be obscure, the doctor gives a second, which we must confess appears to us to be still more obscure, and if possible less conclusive. "To suppose two or more *distinct beings* existing *of themselves* necessarily and *independent* of each other, implies (he says) this *contradiction*, that *each* of them being independent from the other, they may either of them be supposed to exist *alone*; so that it will be no contradiction to suppose the other not to exist; and consequently *neither of them* will be necessarily existing. Whatsoever therefore exists necessarily is the one simple essence of the self-existent Being; and whatsoever differs from that is not necessarily existing, because in absolute necessity there can be no *difference* or *diversity* of existence.

"Necessity is used here in two different senses *, both as *absolute* and *relative*. In the former, neither of the two beings can exist without the other, i. e. without our supposing the other to exist also, since that is equally necessary. In the latter, either of them may exist alone, i. e. as without the help of the other, or without the supposition of the other as requisite to its own existence. The consequence, therefore, that either of them may exist alone, and so neither of them is necessary, is a mere *equivocation* on *necessity*, using it both in an absolute and relative sense at the same time." But as this is a question of the highest importance, and as the author was a man of great worth, we shall consider his argument upon the supposition that the word *necessity* has from the beginning to the end of it the same invariable meaning.

* *Law's Inquiry into the Ideas of Space*, &c. chap. 6.

298 examined, and shown to be equally inconclusive.

It has been already observed, that there are only two senses in which that word can be applied to the existence of any being; and whether it be here used in the one or the other of these senses, the reasoning, if resolved into a syllogism, will appear to be inconclusive. If the word be taken in that sense of necessity which arises from the relation that dependent beings which we know to exist bear to some one independent Being, the argument will stand thus:

> From a known effect no more causes can be *necessarily* inferred than what are sufficient to account for that effect; but
>
> *One* self-existent and independent Being is sufficient to account for all the phenomena of nature; therefore, from the phenomena, &c.
>
> *No more* than *one* such Being can be *necessarily* inferred to exist.

But though no more than *one* independent being can in this sense of the word *necessarily* exist, it by no means follows from this syllogism, that two or more such beings may not *possibly* exist. It is, indeed, a plain contradiction to say, that two or more self-existent beings are in this sense *necessary*; but surely there is no contradiction in saying, that two or twenty such beings are *possible*. We could not, therefore, by this argument convict a person of absurdity, who should affirm that two or more independent beings *actually* exist. We might, indeed, deny the existence of them all but *one*, because one is sufficient to account for those phenomena, from which alone we know that *any* independent being exists; but because one of them might be supposed to exist *alone*, so that it would be no contradiction to suppose the other not to exist; we know not how the doctor came to affirm, in direct opposition to his own demonstration, that *not one* of them would be necessarily existing.

Necessity, as applied to existence, in the other sense of the word, arises, as we have seen, from the relation which the *actual* existence of the being, of which it may be affirmed, has to the *manner* of that being's existence. It is the same necessity, we are told †, with that which is the cause of the unalterable proportion between two and four; and it is considered as the *formal* cause or *ground* of the existence of an independent being. Were it not for the strange expressions *formal cause* and *ground* of *existence*, we should have no objection to this account of that *necessity* by which a being independent undoubtedly exists: but this kind

† *Answer to the Sixth Letter* from a Gentleman in Gloucestershire.

of

of necessity is a principle which will not support the superstructure which the learned author labours to raise upon it. The same *necessity* which is the cause of the unalterable proportion between *two* and *four*, is likewise the cause of the unalterable proportion between *three* and *six*, between *four* and *eight*, and between *five* and *ten*, &c. But if it can be the cause of so many different proportions of the same kind, why may it not be the *formal cause* or *ground* of existence to as *many independent beings* of the same kind as well as to *one*? The following syllogism, we apprehend, to be legitimate both in mode and figure, and its conclusion is directly contrary to the proposition which the doctor deduces from the same notion of necessity.

> If necessity, considered as a *formal cause* or *ground of existence*, be in *one instance* of its causality the formal cause or ground of existence to *many things* of the same kind, it *may* likewise in *every other instance* of its causality, be the formal cause or ground of existence to many things of the same kind.
>
> But such necessity, in that instance of its causality where it is the formal cause or ground of existence to the unalterable proportion between two and four, *is* the formal cause or ground of existence to *many proportions* of the same kind.
>
> Therefore, the same necessity in that other instance of its causality, where it is said to be the formal cause or ground of existence to *one* independent being, undoubtedly *may be* the formal cause or ground of existence to *many independent beings* of the same kind.

299 Necessity, a dangerous principle.

Thus it appears, that *necessity*, in any sense in which it can be properly affirmed of existence, cannot be the foundation of any argument to prove the impossibility of more than one self-existent being. It is indeed a principle from which we apprehend that no positive conclusion whatever can be deduced by reasoning *à priori*. That necessity of existence may be predicated of a being which is independent and uncreated, is self-evident; because to the *nature* of such a being, existence is essential. But whilst *that nature* itself remains wholly *incomprehensible* by us, it is impossible that we should discover, by our own unassisted reason, whether it can be the nature of *only one*, or of *more than one*, independent being. To argue from necessity, as if it were the cause or ground of existence to such a being, is certainly absurd, if it be not impious; for if that to which existence is essential, does not exist without any cause efficient or formal, we shall be obliged to inquire after a cause or ground of this cause, and thus be involved in all the absurdities and contradictions of an infinite series. We have insisted the longer on this point, because *necessity*, as the foundation of the argument *à priori*, has sometimes been employed to very bad purposes. Attempts have been made from the notion of *necessary* existence, to prove that the Supreme Being cannot be a free agent, and to set the first principles of the religion of nature at variance with those which are revealed in the Scriptures.

300 The unity of God highly probable.

But though we are firmly persuaded that the divine unity cannot be *demonstrated à priori*, we are far from thinking it incapable of any *proof*. On the contrary, the common arguments *à posteriori*, drawn from the *order* and *harmony* of the world, have always satisfied us, and in our opinion must satisfy every person capable of proportioning his assent to evidence, that the Creator and Preserver of such a system has but *one will* and *one intelligence*, and therefore is himself but *one being*. But *proof* is one thing, and *demonstration* is, in the proper sense of the word, another (G). And if we cannot arrive at *absolute* certainty concerning this important truth by the light of nature, we ought to be the more thankful for that revelation, which has put the unity of God past dispute to all who believe the holy Scriptures.

301 God omnipotent.

The being which is self-existent and independent must be also *omnipotent*. That such a being has *active power in some degree*, is shown at the same time and by the same medium that we prove his existence; and since he depends upon no cause for his existence or his power, he cannot depend upon any for the exertion of that power, and consequently no *limits* can be applied to it. Limitation is an *effect* of some *superior cause*, which in the present instance there cannot be: consequently to suppose *limits* where there can be no *limiter*, is to suppose an *effect* without a *cause*. For a being to be *limited* or *deficient* in any respect *, is to be *dependent* in that respect on some *other* being which gave it just so much and no more; consequently that being which in *no respect* depends upon any other is in *no respect* limited or deficient. In all beings capable of increase or diminution, and consequently incapable of *perfection* or *absolute infinity*, *limitation* or *defect* is indeed a necessary consequence of existence, and

* *Notes to King on Evil.*

(G) John Gerhard and John Vossius both cite *Gabriel Biel* as acknowledging the unity of God to be incapable of rigid demonstration; and with the sentiments of that schoolman, those two learned divines profess their own to agree.

Sed Biel (1 Sent. Dist. 2. Q. 10. Art. 3.), statuit "quod tantum *unum* esse Deum, sit *creditum* et *non demonstratum* ratione naturali nobis in via possibili." Id nos ita interpretamur; etiamsi ex *naturæ libro* rationes *non contemnendæ* pro *unitate* divinæ essentiæ asserenda erui possint, eas tamen ad fidei πληροφορίαν cordibus nostris ingenerandum, non satis efficaces esse. Ergo mens prius confirmanda est ex *verbo Dei*, et illustribus testimoniis in quibus se Deus generi humano patefecit: Postea utiliter potest addi consideratio philosophicarum demonstrationum. *Gerhard. Loc. Comm.* tom. i. p. 106.

Dissentit *Gabriel Biel*, qui ante annos hosce 140 *Tubingensi* Gymnasio præfuit. Is censet *probabiles* magis rationes esse quam *evidentes* et *certas*.—Verum esto sane, ut solæ non sint αποδεικτικαι: At magnum iis pondus addit *traditio* vetus; tum autem quod argumenta isthæc, si non prorsus αποδεικτικα, saltem usque adeo *probabilia* sint, ut της πολυθειας patroni nihil ullius momenti adferre valeant; cur plusquam unum statuere deum potius conveniat. *Voss. de Idolatria*, lib. i. c. 2.

f the Being and Attributes of God.

and is only a *negation* of that perfection which is wholly incompatible with their nature; and therefore in these beings it requires no further cause. But in a being *naturally capable* of *perfection* or absolute *infinity*, all *imperfection* or *finiteness*, as it cannot flow from the *nature* of that being, seems to require some *ground* or *reason;* which reason, as it is foreign from the being itself, must be the effect of some other external cause, and consequently cannot have place in the *first cause.* That the self-existent being is *capable* of perfection or absolute infinity must be granted, because he is manifestly the subject of one infinite or perfect attribute, viz. *eternity*, or absolute invariable existence. In this respect his existence has been shown to be perfect, and therefore it *may* be perfect in every other respect also. Now that which is the subject of one finite attribute or perfection, must have all its attributes infinitely or in perfection; since to have any perfections in a finite limited manner, when the subject and these perfections are both *capable* of strict *infinity*, would be the forementioned absurdity of positive limitation without a cause. To suppose this eternal and independent being limited *in* or *by* its own *nature*, is to suppose some *antecedent nature* or *limiting quality* superior to that being, to the existence of which no *thing*, no *quality*, is in any respect *antecedent* or *superior.* And to suppose that there is no such thing as *active power* in a being which is evidently the fountain of all power, is the grossest of all absurdities. The same method of reasoning will prove knowledge and every other perfection to be *infinite* in the Deity, when once we have proved that perfection to belong to him at all; at least it will show, that to suppose it limited is unreasonable, since we can find no manner of *ground* for limitation in any respect; and this is as far as we need go, or perhaps as natural light will lead us.

302 mnipotence can every thing which does not imply a contradiction.

Of the omnipotence of the supreme Being some philosophers as well theists as atheists, have talked very absurdly. *Hobbes* *, with a view to make this attribute appear impossible and ridiculous, affirms "that God by his omnipotence or infinite power could turn a tree into a syllogism." And *Des Cartes* †, though certainly no atheist, childishly asserts, that all things whatever, even abstract truth and falsehood, do so depend upon the arbitrary will and power of God, as that if he had pleased, "twice two should not have been four, nor the three angles of a plain triangle equal to two right ones." But the true motion of Omnipotence, so far from implying a power to turn a tree into a syllogism, or to make twice two not equal to four, implies only that the being possessed of it can actually perform whatever can be conceived by the most perfect understanding; conception in this case being the measure of possibility. Now every thing may be conceived by a mind sufficiently enlarged which does not involve in it a direct contradiction; but what we clearly discern to imply a contradiction, such as that a thing may be and not be at the same instant, cannot be conceived by any intellect, or made to exist by any power.

* *Leviath.* cap. 3.

† *Respons.* ad *Objectiones Sextas*, § 6.

And thus has this attribute of the Divinity been always stated, not only by the wiser Christians, but also by most of the ancient philosophers themselves, who expressly admit that "nothing is exempted from the divine power, but only to make that which hath been done to be undone (H)."

303 Creation possible to Omnipotence.

And here it may be asked, Whether creation, in the proper sense of the word (see CREATION), be within the compass of infinite power. All the ancient philosophers, who were unenlightened by the rays of divine revelation, held that it is not *; grounding their opinion upon this maxim, *Ex nihilo nihil fit.* But the maxim will support no such conclusion.—The ancients, or at least the Peripatetic school, with the metaphysics of which we are best acquainted, considered four kinds of causes, the *efficient*, the *material*, the *formal*, and the *final;* and though they extended the maxim to the first *two*, if not to all these causes, it is a self-evident truth only when applied to the *efficient cause.* Without the actual exertion of *power*, it is indeed most certain that nothing could be brought into existence; but it is so far from being clear that pre-existent matter, or, as Aristotle chose to express himself, a *material cause*, must be supposed for infinite power to operate upon, that, we think, every man may find complete evidence of the contrary in himself. That sensation, intelligence, consciousness, and volition, are not the result of any modifications of figure and motion, is a truth as evident as that consciousness is not swift, nor volition square. If then these be the powers or properties of a being distinct from matter, which we think capable of the completest proof, every man who does not believe that his mind has existed and been conscious from eternity, must be convinced that the power of creation has been exerted in himself. If it be denied that there is any immaterial *substance* in man, still it must be confessed, that, as matter is not essentially conscious, and cannot be made so by any particular organization, there is some real *thing* or *entity*, call it what you please, which has either existed and been conscious from eternity, or been in time brought from non-entity into existence by an exertion of infinite power.

* See *Mosheim's Dissertation on this Subject, in his Edition of Cudworth's Intellectual System.*

To this perhaps some one may object, that upon our own supposition of the inability of the human mind to exert its faculties but in union with some material and organized system, the mind of every man may have existed from eternity without being conscious of its own existence; and that, therefore, we have in ourselves no evidence of *creation*, but only of the union of two self-existent substances, which, in their prior state, had been distinct and separate from each other. But such an objection as this, we beg leave to reply, can arise from nothing but misapprehension of our hypothesis, and of the reasons by which we think it supported. We suppose, that to the exertion of the human faculties, a body of some kind or other may be necessary as an instrument, not merely from what we observe of the dependence of perception

(H) Το δε γεγονος ουκ ενδεχεται μη γενεσθαι· διο αγαθως Αγαθων.
Μονου γαρ αυτου και θεος στερισκεται,
Αγενητα ποιειν, ἁττ' αν ἠ πεπραγμενα. *Arist. ad Licomach.* lib. vi. cap. 2.

Of the Being and Attributes of God.

tion and memory on the state of the brain, but because we cannot conceive a Creator of infinite wisdom and goodness to immerse in systems of matter, minds to which he knows that such systems must be always useless and often hurtful. We believe, therefore, that our souls and bodies were created and formed for each other; but as our present adversaries admit not of a Creator, we must ask them, How their self-existent souls have been disposed of from eternity, and by what power they have all in due succession been united each to its proper body? As before the union they were not conscious, they could not unite themselves; and to suppose them united by some superior intelligence, is to suppose them in some respects dependent on that intelligence, which seems not to accord with their self-existence. Whatever is self-existent and eternal must be independent; and if possessed of any power, cannot be conceived to have that power limited.—We repeat, therefore, that every man has in himself sufficient evidence that creation is possible; for if infinite power can create an immaterial and percipient being, it may surely be supposed capable of creating dead and unintelligent matter.

But the creation of the material system may be shown to be in the highest degree probable by other arguments. The same reasoning which proves the impossibility of an infinite series and of eternal time, proves that the universe cannot have existed from eternity in its present state. But if it has not existed from eternity in its present state, it belongs to the opponents of creation to say what was its former. We talk indeed of *chaos;* but such language, when a Creator is not admitted, is most unphilosophical trifling. It appears from the most accurate inquiries that have been made into the substance and essence of body *, that the atoms of which each mass is composed are held together by a foreign force. If by chaos be meant matter, when this force is supposed to be removed, we must beg leave to say, that of such a substance we have neither idea nor notion, and cannot distinguish it from nonentity. The original atoms of matter, we believe indeed to require no other agency to keep each entire than that *fiat* by which it was created; but still, as those atoms are conceived to be solid and extended, they must be capable of division by infinite power; and if that *fiat* or influence which makes them solid and extended were removed, they would lose solidity and extension, and of course become nothing. So far is it, therefore, from being true, that the creation of matter appears to be impossible, that we are compelled by every thing that we know of it to believe that matter cannot possibly be self-existent.

* *Baxter's Inquiry into the Nature of the Human Soul.*

"Because it is undeniably certain, concerning ourselves (says Cudworth †), and all imperfect beings, that none of these can create any *new substance*, men are apt to measure all things by their own scantling, and to suppose it universally impossible for any power whatever thus to create. But since it is certain, that imperfect beings can themselves produce *some things* out of nothing pre-existing, as *new cogitations*, *new local motion*, and *new modifications* of things corporeal, it is surely reasonable to think that an absolutely perfect Being can do *something more*, i. e. create *new substances*, or give them their whole being. And it may well be thought as easy for God or an Omnipotent Being, to make a whole world, matter and all, ἐξ οὐκ ὄντων, as it is for us to create *a thought* or to move a finger, or for the sun to send out rays, or a candle light; or lastly, for an opaque body to produce an image of itself in a glass or water, or to project a shadow: all these imperfect things being but the *energies*, *rays*, *images*, or *shadows*, of the Deity. For a substance to be made out of nothing by *God*, or a *Being infinitely perfect*, is not for it to be made out of nothing in the impossible sense, because it comes from him who is *all*. Nor can it be said to be impossible for any thing whatever to be made by that which hath not only *infinitely greater perfection*, but also *infinite active power*. It is indeed true, that infinite power itself cannot do things in their own nature impossible; and, therefore, those who deny creation, ought to prove, that it is absolutely impossible for a *substance*, though not for an *accident* or *modification*, to be brought from non-existence into *being*. But nothing is in itself impossible, which does not imply a contradiction: and though it be a contradiction for a thing to be and not to be at the same time, there is surely no contradiction in conceiving an imperfect being, which before was not, afterwards to be." To call in question the possibility of creation, because we have no *adequate conception* how a thing can be brought into existence, would be in the highest degree absurd; for it may be doubted, whether we have *adequate* conceptions of any thing except our own ideas and their various relations (1).

† *Intellectual System*, Book i. chap. 5.

304 God a free agent; but

That Being which is self-existent, omnipotent, and omniscient, is not a *necessary*, but a *free* agent; for *active*

(1) "Ridicula foret et inepta ejus temeritas, qui corporum ideo creationem sibi duceret negandum esse, quod ejus creationis *claram et perspicuam notionem* effingere cogitatione nobis haud licet. Infinita enim est rerum copia, quarum perspicuis et apertis caremus notionibus. Et si omnia neganda continuo nobis essent, quorum confusam tantum et imperfectam consequi possumus notionem, omnia fere nobis essent neganda, exceptis *relationibus*, quas inter notiones quasdam abstractas esse intelligimus. Quis interiorem sibi naturam rerum, tam corporum, quam spirituum, cognitam esse dixerit? Et esse tamen has naturas, omni plane dubitatione vacat. Quis quemadmodum altera harum naturarum agat in alteram, sese scire, affirmet? Quis causas sibi patere, propter quas hi vel illi effectus, quos videmus quotidie contingere, à certis veniant corporibus, jure glorietur? Nec tamen quisquam est, qui vel illam animæ in corpus operationem, vel hos effectus in dubium revocare ausit. Teneamus igitur ea, quæ certo novimus, nec idcirco nos ab illis dimoveri patiamur, quod multa rursus sunt, quorum naturam ignoramus; contra multa nos fugere et cognitionem nostram superare, æquo at tranquillo feramus animo. *Joannis Clerici contra eos qui negant, ex nihilo ulla ratione fieri posse aliquid, observationes; in Moshemii edit. Intellec. Syst.*

Of the Being and Attributes of God.

tive power implies *freedom*, and *infinite* power *infinite* freedom. What, therefore, hath no bounds set to its power, what can have no opposition made to its will, nor restraint laid on its actions, must both will and act freely. "If the Supreme Cause were not a being endowed with liberty and choice, but a mere necessary agent, then would it follow, as Dr Clarke well observes *, that nothing which is not, could *possibly* have been; and that nothing which is, could *possibly* not have been; and that no mode or circumstance of the existence of any thing could *possibly* have been in any respect otherwise than it now actually is. All which being evidently most false and absurd; it follows, on the contrary, that the Supreme Cause is not a mere necessary agent, but a Being endued with liberty and choice."

Demonstration of the Being and Attributes of God.

Cooper's Tracts.

To this reasoning it has been lately replied †, that "Clarke must have known, that all those who contend against the free agency of the Deity, do of course acknowledge, that nothing could have happened, or does happen, or will happen, but what actually has happened, or doth happen, or will happen; and that it is most false and absurd to deny it." It is, therefore, according to the necessarians, absolutely impossible, that at present there could exist upon this earth more or fewer persons than are now actually alive; that the earth could move in any other direction than from west to east; or that there could be more or fewer planets in the solar system. Yet is it most certain, that there *have been fewer persons* on the earth than there are now; that there is not a cultivated country in Europe which could not contain *more* people than now inhabit it; that the comets move in very different directions from that of west to east; and that as, till very lately, we *conceived* only six primary planets in the system, it is evidently *possible* that the system *might contain* no more. Upon the supposition, therefore, that the Supreme Being acts under a physical necessity, the same things are possible and not possible at the same time, which is the grossest of all absurdities. It might have been objected with much more plausibility, that the First Cause cannot possibly be free, because he must needs do always what is best in the whole; but it will be seen by and by, that among different created systems, there is no reason for supposing any one absolutely *best*.

305 Himself unchangeable.

But though this Being be *free*, and as such the author of *change* in other beings, yet he must himself *be unchangeable*; for all changes have a beginning, and consequently are effects of some *prior causes*. But there can be nothing prior to the existence of this Being, as he is *eternal*; neither any *cause* of it, as he is *independent*; nor consequently any *change* in it, except we could suppose him to *change himself*, which is the same absurdity as to *produce* himself, i. e. to be at *the same time both effect* and *cause*.

306 Omniscience, &c. proved in a different manner. Notes to ...ing on ...il.

Omniscience, as well as some of the foregoing attributes of the Supreme Being, may perhaps be more easily deduced thus ‡. We find in ourselves such qualities as *thought* and *intelligence*, *power* and *freedom*, &c. for which we have the evidence of consciousness as much as for our own existence. Indeed it is only by our consciousness of these that our existence is known to ourselves. We know likewise that these are *perfections*, and that to have them is better than to be without them. We find also that they have not been in us from eternity. They must, therefore, have had a *beginning*, and consequently some *cause*, for the very same reason that a *being* beginning to exist in time requires a cause. Now this cause, as it must be *superior* to its *effect*, must have those perfections in a *superior* degree; and if it be the *first cause*, it must have them in an *infinite* or *unlimited* degree, since *bounds*, or *limitation* without a limiter, would, as we have already shown, be an *effect* without a *cause*.

It is indeed obvious, that the *omniscience* of the Supreme Being is implied in his very existence. "For all things being not only present to him, but also entirely *depending* upon him, and having *received* both their *being* itself and all their powers and faculties *from him*, it is manifest that as he knows all things that are, and penetrates every part of their substance with his all-seeing eye, so must he likewise know *all possibilities* of things, that is, all effects that *can* be. For, being alone self-existent, and having alone given to all things all the powers and faculties with which they are endued, it is evident that he must of necessity know perfectly what all and each of these powers and faculties, *which are derived wholly from himself*, can possibly produce. And seeing at one boundless view, or more properly in his own ideas, all the possible compositions and divisions, variations and changes, circumstances and dependencies of things, all their possible relations one to another, and their dispositions or fitnesses to certain and respective ends, he must without possibility of error know exactly what is best and properest in every one of the numberless possible cases, or methods of disposing things; and understand perfectly how to order and direct the respective means to bring about what he so knows to be in its kind, or on the whole, the best and fittest in the end. This is what is meant by infinite wisdom, or omniscience *;" and it has been readily admitted by every man who has believed in the existence of a God, as the creator and preserver of all things.

* *Clarke's Demonstration*, &c.

307 God foreknows the actions of free agents.

Doubts, however, have been entertained by theists, and pious theists, whether omniscience itself can certainly foreknow what are called contingent events, such as the actions of free agents; and some few there are professing to be even Christians, who have boldly pronounced such knowledge to be impossible. That we have no adequate notion *how* events, which are called contingent, can be certainly foreknown, must indeed be granted; but we are not, therefore, authorized to say that such knowledge is impossible, unless it can be clearly shown to imply a contradiction. They who suppose that it implies a contradiction, must likewise suppose, that, where there is not a chain of necessary causes, there can be no certainty of any future event; but this is evidently a mistake. "For let us suppose that there is in man a power of beginning motion, and of acting with what has been of late called *philosophical* freedom; and let us suppose farther that the actions of such a man cannot possibly be foreknown; will there not yet be in the nature of things, notwithstanding this supposition, the same *certainty of event* in every one of the man's actions, as if they were ever so fatal and necessary? For instance, suppose the man, by an internal principle of motion, and an absolute freedom of mind, to do some particular action *to-day*, and suppose it was

Of the Being and Attributes of God.

was not possible that this action should have been foreseen *yesterday*, was there not nevertheless the same *certainty of event* as if it had been foreseen, and absolutely necessary? That is, would it not have been as *certain a truth* yesterday, and from eternity, that this action was in event *to be performed to-day*, notwithstanding the supposed freedom, as it is now a *certain and infallible truth* that it is performed? Mere *certainty of event*, therefore, does not in any measure imply *necessity* *." And surely it implies no contradiction to suppose, that every future event which in the nature of things is *now certain*, may *now be certainly known* by that intelligence which is omniscient. The *manner* how God can foreknow future events, without a *chain of necessary causes*, it is indeed impossible for us to explain: yet some sort of *general notion* of it we may conceive. "For, as a man who has no influence over another person's actions, can yet often perceive beforehand what that other will do; and a wiser and more experienced man, with still *greater probability* will foresee what another, with whose disposition he is perfectly acquainted, will in certain circumstances do; and an angel, with still *less degrees of error*, may have a further prospect into men's future actions: so it is very reasonable to conceive, that God, without influencing men's wills by his power, or subjecting them to a chain of necessary causes, cannot but have a knowledge of future free events, as much *more certain* than men or angels can possibly have, as the *perfection* of *his* nature is greater than that of *theirs*. *The distinct manner how* he foresees these things we cannot, indeed, explain; but neither can we explain the *manner* of numberless other things, of the reality of which, however, no man entertains a doubt †." We must therefore admit, so long as we perceive no contradiction in it, that God always knows all the free actions of men, and all other beings endued with liberty; otherwise he would know many things now of which he was once ignorant, and consequently his *omniscience* would receive addition from events, which has been already shown to be contrary to the true notion of infinity.—In a being incapable of change, knowledge has nothing to do with *before* or *after*. To every purpose of knowledge and power, all things are to him equally present. He knows perfectly every thing that is, and what to us is future he knows in the very same manner as he knows what to us is present.

* *Clarke's Demonstration.*

† *Clarke's Demonstration, &c.*

308 God infinitely perfect, all-sufficient, and omnipresent.

Thus have we demonstrated the necessary existence of a being who is *eternal*, *independent*, *unchangeable*, *omnipotent*, *free in his actions*, and *omniscient*; and this is the being whom we worship as GOD. *Eternity*, *independence*, *immutability*, *omnipotence*, *liberty*, and *omniscience*, which seem to be all the *natural* attributes which we can discover in the divine nature, as they are conceived to be differently combined, make us speak of him in different terms. His enjoying in an absolute manner every conceivable power or perception, makes us call him a Being *infinitely perfect*. His being capable of no want, defect, or unhappiness of any kind, denotes him to be *all sufficient in himself;* and the unlimited exercise of his knowledge and power, demonstrates him to be *omnipresent*. That such a Being must be incomprehensible by us, and by every creature, is a truth self-evident; and yet in all ages men of the best intentions have been vainly attempting this impossibility. The manner of his omniscience, for instance, has been the subject of much disputation among those who ought to have reflected that they know not how their own minds were present to their own bodies.—The celebrated Dr Clarke and his adherents, who considered space as the *sine qua non* of all other things, insisted, that God must be infinitely extended; and that, as wherever his substance is, there his attributes must be, it is thus that his knowledge and power are present with every creature. But this notion labours under insuperable difficulties.

309 The manner of the divine omnipresence incomprehensible.

For "if the Divine substance be infinitely extended, then will there be part of it in this place and part in that. It must be commensurate with all particular beings, so that some will occupy more and some less of its dimensions. By this account it will be very proper and philosophical to say, that God is not in *heaven*, but only a *part* of him: and that an *elephant* or a *mountain*, a *whale* or a wicked *giant*, have more of the essence or presence of God with them, than the *holiest* or *best* man in the world, unless he be of equal size: all which, as has been well observed *, are at least harsh and grating expressions. As the attributes of the Divine Being must be considered in the same manner with his substance, we shall likewise, upon this notion of omnipresence, have a part of his knowledge and power in this place, and a part of them in that; and of these parts the one must be greater or less than the other, according to the dimensions of the place with which it is commensurate; which is a supposition that appears to us harsher, if possible, than even the former.

* *Watt's Essays*, and *Law's Inquiry into the Ideas of Space, Time, Immensity*, &c.

"Should it be said that the divine attributes are not to be considered as having parts (though we see not how they can be considered otherwise than as their subject), they must then exist *completely* in every point of this immense expansion. Be it so; and what follows? Why, every point of this infinitely expanded being will be omniscient and omnipotent by himself; an inch of it will have as much wisdom and power as a yard, a mile, or the whole; and, instead of one infinite wisdom and power, we shall have millions: For as these parts of the substance are conceived *distinctly*, and one individual part is not another, so must the attributes be likewise conceived, and the individual power and knowledge of one part be distinct from that of another." And if so, it follows, that one point of this expanded being has equal power and intelligence with the whole; so that the notion of extension being *necessary* to God's presence with every creature, involves in it the most palpable contradiction. That God is at all times and in all places so present with every creature as to have an absolute knowledge of and power over it, is indeed capable of the strictest demonstration; but we think it great presumption to assign the particular *mode* of his presence, especially such a one as is neither agreeable to the nature of an absolutely perfect Being, nor in the least necessary to the exercise of any one perfection which he can be proved to possess. Philosophers and divines have offered several names for the manner in which God is present with his works; but we choose rather to confess, that the *manner* of his presence is to us, and probably to every creature, wholly incomprehensible. Nor need we be surprised or staggered at this, when we reflect that the manner in which our own minds are present

Of the Being and Attributes of God.

present with our bodies is to us as incomprehensible as the manner in which the supreme Mind is present with every thing in the universe. That our minds have a power over our limbs, we know by experience: but that they are not extended or substantially diffused through them, is certain; because men daily lose arms and legs, without losing any part of their understanding, or feeling their energies of volition in the smallest degree weakened. But we need pursue this subject no farther. It has been confessed by one of the most strenuous advocates* for the extension of the Deity and all minds, that "there is an incomprehensibleness in the *manner* of every thing, about which no controversy can or ought to be concerned."

* Mr Jackson's Existence and Unity, &c. page 110.

310 God's moral attributes result from his natural perfections.

The moral attributes of God may be deduced from his natural ones, and are immediate consequences of them when exercised on other beings. They may be termed his *secondary relative* attributes, as they seem to be the perfection of his *external acts* rather than any *new internal* perfections. And though the existence of any moral quality or action is not capable of strict *demonstration*, because every moral action or quality, as such, depends upon the *will* of the agent, which must be absolutely free; yet we have as great assurance that there are moral qualities in God, and that he will always act according to these qualities, as the nature of the thing admits; and may be as well satisfied of it, as if it were capable of the most rigid demonstration. This important point, however, cannot be so clearly or so firmly established by abstract reasoning as by taking a scientific view of the works of creation, which evince the goodness, holiness, and justice of their Author, as well as his perfect wisdom and infinite power. The consideration, therefore, of the moral attributes of God, together with his providence, and the duties thence incumbent on man, is the proper business of other articles (see RELIGION, THEOLOGY, and MORAL *Philosophy*.

311 How they ought to be conceived.

At present we shall only observe, that by reasoning *à priori* from his existence and his natural perfections, we must necessarily infer that his actions are the result of unmixed benevolence. Every wise agent has some end in view in all his actions; it being the very essence of folly to act for no end: but there cannot be an end of action which is not either selfish or benevolent. Selfishness is the offspring of want and imperfection, and is therefore the source of most *human* actions; because men are weak and imperfect beings, capable of daily additions to their happiness. When the thief plunders a house at midnight, when the highwayman robs a traveller on the road, and even when the assassin murders the man who never injured him; it will be found that their actions spring not from an innate desire to inflict misery upon others, but from a prospect of reaping advantage to themselves. The object of the thief and the robber is obvious: it is to gain money, which is the mean of procuring the comforts of life. Even the assassin has always the same selfish end in view: either he is *bribed* to commit the murder, or he fancies that his horrid deed will remove an *obstacle* from the way to his own happiness. But they are not vicious men *only* who act from selfish considerations: much of human *virtue*, when traced to its source, will be found to have its origin in the desire of happiness. When a man gives his money to feed the hungry and to clothe the naked, he believes that he is acting agreeably to the will of Him to whom he and the poor stand in the same relation; and he looks for a future and eternal reward. By continuing the practice, he soon acquires the habit of benevolence; after which, indeed, he looks for no further reward, when performing particular actions, than the immediate pleasure of doing good. This selfishness of man is the necessary consequence of his progressive state. But the Being who is independent, omnipotent, omniscient, and, in a word, possessed of every possible perfection, is incapable of progression, or of having any accession whatever made to his happiness. He is immutable; and must of necessity have been as happy from eternity, when existing alone, as after the creation of ten thousand worlds. When, therefore, he willed the existence of other beings, he could have nothing in view but to communicate some resemblance of his own perfections and happiness. That he had *some* end in view, follows undeniably from his infinite wisdom. That he could not have a *selfish* end, follows with equal certainty from his own infinite perfections; and as there is no medium, in the actions of a wise Being, between selfishness and benevolence, we must necessarily conclude, that the creation was the result of unmixed benevolence or perfect goodness. The other moral attributes of the Deity, his justice, mercy and truth, ought therefore only to be considered as so many different views of the same *goodness* in the *Creator*, and various sources of *happiness* to the *creature*. These are always *subordinate* to and *regulated* by this one principal perfection and brightest ray of the Divinity.

"Thus we conceive his *justice* to be exerted on any being no farther than his goodness necessarily requires, in order to make that being, or others, *sensible* of the *heinous nature* and *pernicious effects of sin* *, and thereby to bring them to as great a degree of happiness as their several natures are capable of. His *holiness* hates and abhors all wickedness, only as its necessary consequences are absolute and unavoidable misery; and his veracity or faithfulness seems to be concerned for truth, only because it is connected with and productive of the happiness of all rational beings; to provide the properest means for attaining which great end, is the exercise of his *wisdom*." Such is the view of God's moral attributes, which the abstract contemplation of his natural perfections necessarily gives; and whether this way of conceiving them be not attended with less difficulty than the common manner of treating them under the notion of two infinites *diametrically opposite*, must be left to the judgment of the reader.

* *Notes to King on Evil.*

312 The origin of evil.

But if the Creator and supreme Governor of all things be a Being of infinite power, perfect wisdom, and pure benevolence, how came evil into the works of creation? This is a question which has employed the speculative mind from the first dawning of philosophy, and will continue to employ it till our faculties be enlarged in a future state, when philosophy shall give place to more perfect knowledge. To these meditations, as has been well observed ‡, humanity is not equal. Volumes have been written on the subject; but we believe that the following extract from Dr

‡ *Johnson's Review of a free Inquiry into the Origin of Evil.*

Dr Clarke contains all that can be advanced with certainty, and all that is necessary to vindicate the ways of God to man.

"All that we call evil (says that able reasoner †), is either an *evil of imperfection*, as the want of certain faculties and excellencies which other creatures have; or *natural evil*, as pain, death, and the like; or *moral evil*, as all kinds of vice. The *first* of these is not properly an evil: for every power, faculty, or perfection, which any creature enjoys, being the free gift of God, which he was no more obliged to bestow than he was to confer being or existence itself, it is plain, that the want of any certain faculty or perfection in any kind of creatures, which never belonged to their nature, is no more an evil to them, than their never having been created or brought into being at all could properly be called an evil." To this we may add, that as no created being can be self-existent and independent, imperfection is unavoidable in the creation, so that the evil of defect (as it is most absurdly called) must have been admitted, or nothing could ever have existed but God. "The *second* kind of evil, which we call *natural* evil, is either a necessary consequence of the former, as *death* to a creature on whose nature immortality was never conferred; and then it is no more properly an evil than the former: Or else it is counterpoised in the whole with as great or greater good, as the *afflictions and sufferings of good men*: and then also it is properly no evil. Or else it is a *punishment*; and then it is a necessary consequence of the *third* and last sort of evil, viz. *moral evil*. And *this* arises wholly from the abuse of *liberty*, which God gave to his creatures for other purposes, and which it was reasonable and fit to give them for the perfection and order of the whole creation: only they, contrary to God's intention and command, have abused what was necessary for the perfection of the whole, to the corruption and depravation of themselves. And thus have all sorts of evils entered into the world, without any diminution to the infinite goodness of its Creator and Governor."

† *Demonstration of the Being and Attributes of God.*

313
Whether the present be the best system possible.

But though evil could not be totally excluded from the universe, are we not authorized to infer, from the infinite power, wisdom, and goodness of the Creator, that the present system is upon the whole the very best system possible? Undoubtedly we are, if of possible systems there *can be a best*: but this is so far from being evident, that we think it implies a contradiction. A best of beings there is, viz. God, who is possessed of infinite perfections; but there cannot be a best of creatures or of created systems. To prove this, we need only reflect, that wherever creation stops, it must stop infinitely short of infinity; and that how perfect soever we conceive any creature or system of creatures to be, yet the distance between that and God is not lessened but continues infinite. Hence it follows that the nature of God and his omnipotence is such, that whatever number of creatures he has made, he may still add to that number; and that however good or perfect the system may be on the whole, he might still make others equally good and perfect.

314
Origin of that question.

The dispute, whether a being of infinite power, wisdom, and benevolence, must be supposed to have created the *best possible system*, and the embarrassment of men's understandings about it, seem to have arisen from their taking the words *good*, *better*, and *best*, for absolute qualities inherent in the nature of things, whereas in truth they are only relations arising from certain appetites. They have indeed a foundation, as all relations have, in something absolute, and denote the thing in which they are founded; but yet they themselves imply nothing more than a relation of congruity between some appetite and its objects. This is evident; because the same object, when applied to an appetite to which it has a congruity, is good; and bad, when applied to an appetite to which it has no congruity. Thus, the earth and air to terrestrial animals are good elements, and necessary to their preservation: to those animals the water is bad, which yet affords the best receptacle to fishes. *Good*, therefore, being relative to appetite, that must be reckoned the best creature by us which has the strongest appetites, and the surest means of satisfying them all, and securing its own permanent happiness. And though the *substance* of creatures is chiefly to be regarded as contributing to their perfection, yet we have no way of measuring the perfection of different substances but by their qualities, *i. e.* by their appetites by which they are sensible of good and evil, and by their powers to procure those objects from which they receive that sense of things which makes them happy.

315
No system absolutely best.

It is plain, therefore, that whatever system we suppose in nature, God might have made another equal to it; his infinite wisdom and power being able to make other creatures equal in every respect to any that we know or can conceive, and to give them equal or stronger appetites, and as certain or more certain ways of satisfying them. We see in many cases, that very different means will answer the same end. A certain number of regular pyramids will fill a space; and yet irregular ones will do it as well, if what we take from the one be added to another; and the same thing may be done by bodies of the most irregular and different figures in the same manner: and therefore we may very well conceive, that the answering of appetites, which is all the *natural good* that is in the world, may as well be obtained in another system as in this; provided we suppose, that where the appetites of the sentient beings are changed, the objects are also suited to them, and an equal congruity among the parts of the whole introduced. This is so easily conceived, that in an indefinite number of possible worlds, we do not see why it may not be done in numberless ways by infinite power and wisdom.

316
God not necessitated by his goodness to create the present in preference to all other worlds.

If then it be plain, that there might have been many other worlds, or even but one, equal to this in all respects as to goodness, there could be no necessity, either physical or moral, that God should create the one rather than the other; because nothing could make the one better, or to him more agreeable, than the other, but his own free choice. Either, therefore, God must be possessed of absolute freedom, or, among a number of possibilities equally perfect, he could not have made a choice, and so nothing would ever have been created. It is not, then, as Leibnitz and others argue, the natural and necessary goodness of some particular things, *represented by the divine ideas*, which determines God to prefer them to all others, if understood of his *first* act of producing them; but it is is his own free choice which, among many equal *potential* goods, makes some things *actually* good, and determines them into existence. When those are once supposed to exist, every thing or action becomes good which tends to their happiness and preservation; and to suppose their all-perfect Author to have any other end in view than their preservation and happiness, is the same absurdity as to suppose that knowledge may produce ignorance; power, weakness; or wisdom folly.

We have now finished what we proposed under the article Metaphysics. It has swelled in our hands to a large extent; and yet it can be considered as little more than an introduction to that science, which comprehends within its wide grasp every thing existing. The reader who wishes to pursue these interesting speculations, should study diligently the authors whom we have consulted, and to whom we have been careful to refer in the margin. Were we to make a selection, we should without hesitation recommend Aristotle and Plato among the ancients; and Cudworth, Locke, Hartley, and Reid, among the moderns. These philosophers, indeed, on many points, differ exceedingly from one another; but he who wishes not to adopt opinions at random, should know what can be said on both sides of every question.

METAPLASMUS, in *Grammar*, a transmutation or change made in a word, by adding, retrenching, or altering a syllable or letter thereof.

METAPONTUM, or METAPONTIUM, in *Ancient Geography*, a town of Lucania, on the Sinus Tarentinus, to the west of Tarentum; built by the Pylians who returned from Troy; and where Pythagoras is said to have taught in the time of Servius Tullius. *Metapontini*, the people; who pretended to show in a temple of Minerva, the tools with which Epeus built the wooden horse, (Justin). Now a tower, called *Torre di Mare*, in the Basilicata of Naples.

METASTASIO, L'ABBE PIERRE BONAVENTURE, a celebrated Italian poet, whose real name was *Trapassi*, was born at Assise, on January 3d, 1698. His talent for poetry was first unfolded by the reading of Tasso; and he began to compose verses at ten years of age. " A prodigy of this nature (says Metastasio) made such an impression on my master, the celebrated Gravina, that he thenceforth considered me as a plant worthy of being cultivated by his own hands." Metastasio was only fourteen years of age when he composed his tragedy entitled *Il Giustino;* in which he appears too close and scrupulous an imitator of the Grecian drama. Our young poet unfortunately lost his patron in 1717; who left him his heir, " as being a young man of the most promising abilities." Metastasio, at the age of nineteen, being, in consequence of this inheritance, superior to those wants which repress the exertions of genius, and to which men of abilities are too often subject, gave full scope to his inclination for poetry. He began his dramatic career with the *Didonne Abandonnata*, which was acted at Naples in 1724; the music was composed by Sarro. He soon acquired such celebrity, that in 1729 he was invited to Vienna by the emperor Charles VI.; who appointed him imperial poet, and granted him a pension of 4000 florins. From that time some of his works were presented at every court festival; and notwithstanding the extreme magnificence of these entertainments, they would now be forgotten were it not for the verses which he composed upon the occasion. The courts of Vienna and Madrid vied with each other in the presents which they conferred upon him. From Maria Theresa he received a snuff-box and a port-folio set with diamonds, and a golden candlestick with a screen. Ferdinand VI. king of Spain, informed of the great merit of Metastasio by Farinelli, of whom he was a passionate admirer, sent him a present of a casket mounted with gold, and furnished with the different implements of writing. This favourite of kings and of the muses was of a cheerful temper, and was exceedingly temperate: to this he was probably indebted for the uninterrupted health which he enjoyed, and for the entire possession of his senses and faculties to the most advanced period of old age. He took his meals, arose, and went to bed, always at stated hours. This exactness and order were scrupulously observed even in the most trifling actions of his life. He used to say in jest, that he dreaded hell for no other reason but because it was a place *ubi nullus ordo, sed sempiternus horror inhabitat*. He had even his stated hours for making verses; to which he scrupulously adhered, without waiting for the moment of poetical enthusiasm. He was equally regular in the duties of the Christian as in the labours of the scholar. His behaviour was that of a true philosopher: his ambition extended no farther than the attainment of literary fame; and he despised every civil mark of distinction. When Charles VI. offered him the title of *Count* or of *Baron*, which add no real worth or dignity to the possessor, but frequently make him appear in a more ridiculous light, he instantly begged the favour that he would allow him still to continue *Metastasio*. The empress Maria Theresa afterwards wished to bestow upon him the small cross of St Stephen; but he excused himself on account of his age, which would prevent him from assisting at the festivals of the order. He was attacked by a fever on the 2d of April 1782; and he died on the 12th of the same month, at the age of 84. Before his death he received the sacrament according to the form of the Romish church; and Pius VI. who was then at Vienna, sent him his apostolical benediction *in articulo mortis*. He left about 150,000 florins. He composed a great number of tragic operas, and several small dramatic pieces which have been set to music. We have different editions of them in 4to, 8vo, and 12mo; and M. Richelet has published a translation of them into French, in 12 vols. small 12mo.

The greatest part of Metastasio's writings will confer immortality on their author. His dialogue is natural,

tural, simple, and easy; his style is always pure and elegant, and sometimes sublime and pathetic. His subjects are noble, interesting, and excellently adapted for representation. He was perfectly acquainted with the resources of his art, and has subjected the opera to rules. He stripped it of its machinery, and of the marvellous, which was fitted to excite the gaze of astonishment, but which gave no instruction to the understanding, and made no impression on the heart. His descriptions are copied from nature; the situations of his characters never fail to raise an interest in the reader, and often excite the tear of pity. His fables are celebrated; his characters are noble and well supported; his plots are excellently conducted, and happily unravelled. "There are scenes (says Voltaire) worthy of Corneille when he does not declaim, and of Racine when he is not feeble." His operas, in point of the pathetic, may be compared with our finest tragedies; and may be read with great pleasure, independent of the charms of the music. We must not, however, expect to find in Metastasio that exact regularity, and that fertile simplicity, which constitutes the excellence of some of our tragic poets: But though he sometimes transgresses the unities of time and place, he always preserves the unity of interest. Notwithstanding all these advantages, some critics will not allow him the merit of invention, which is the first qualification of a poet. They consider him only as a successful imitator of the French tragic writers, from whom a great part of his beauties are borrowed, and place him at the head of the finest wits in Italy, but deny that he possessed genius. He was a fond admirer of the ancients; and this admiration, increasing with the solidity of his understanding, continued to the last period of his life. He recommended reading them, as he himself had done, in a chronological order. His memory was excellent, and continued unimpaired even in old age. Horace was his favourite author, and he could repeat almost the whole of his verses. Metastasio, who, as we have observed, was the pupil of the celebrated Gravina, added a gentleness of character peculiar to himself to the accuracy of thinking and great erudition of his master. His abilities and fame were respected by the critics in general; and whereas the life of most men of letters is one continued warfare, his days happily glided away in tranquillity and peace. The circumstance which occasioned the change of his name is thus related in a late anecdote: "Gravina's barber, who, like most of his profession, was a great talker, one day informed him, that in the *Place de la Valicella*, where he had his shop, a young boy came every evening, and sung extempore verses of his own composition, so harmonious and elegant that all the passengers stopped to listen to them. Gravina, upon this information, added one to the number of the young poet's audience, and found the verses so superior to the idea which he had formed of them from the account of the barber, and so much above the capacity of a child of ten or eleven years of age, that he instantly determined to undertake the cultivation of so promising a plant. His first care was to put the young *Trapassi* (which was the boy's name) to school; but apprehending that the ordinary methods of education might check the progress of so uncommon talents, he took him home to his own house, and changed his name into *Metastasio*, which signifies the same thing in Greek. In short, by a plan of education and by instructions suited to his genius, Gravina laid the foundation of that reputation which he predicted, and which Metastasio now enjoys." *Vies des Hommes Illustres d'Italie*, tom. i. p. 187.

METASTASIS, in *Medicine*, a transposition or settlement of some humour or disease in some other part; and sometimes it signifies such an alteration of a disease as is succeeded by a solution.

METATARSUS (μετα, *beyond*, and ταρσος, *the tarsus*), in anatomy, that part of the human skeleton containing the middle of the foot. See ANATOMY *Index*.

METATHESIS, in *Grammar*, a species of the metaplasmus; being a figure whereby the letters or syllables of a word are transposed, or shifted out of their usual situations, as *pistris* for *pristis*, *Lybia* for *Libya*, &c.

This word is, by physicians, used with respect to morbific causes, which when they cannot be evacuated, are removed to places where they are less injurious.

METELIN, the modern name of the island of Lesbos. See LESBOS and MITYLENE.

In the Irish Philosophical Transactions for 1789, we have a description of this island by the earl of Charlemont, in which he speaks with raptures of its beauties. "The mountains, whose rugged tops exhibit a pleasing interspersion of rocks and fine groves, have their green sides, for many miles along the coast, covered with olives, whose less agreeable verdure is corrected, embellished, and brightened by a lively mixture of bays and laurels aspiring to the height of forest trees, of myrtles and pomegranates, of arbutes rich at once in blossom and in berry, of mulberries growing wild and laden with fruit, &c. Winter is here unknown, the verdure is perpetual, and the frequency of evergreens gives to December the colour of June. The parching heat of summer is never felt; the thick shade of trees, and thousands of crystal springs which everywhere arise and form themselves into unnumbered rivulets, joined to the refreshing sea breeze, the constant corrective and companion of noontide heat, qualify the burning air, and render the year a never-ending May. The houses are constructed in such a manner as to have the best view of these natural beauties. Each is a square tower neatly built of hewn stone, so high as to overtop the trees, and to command a view of the sea and neighbouring islands. The lower stories are granaries and storehouses; and the habitable apartments are all at the top, to which you ascend by a stone stair, built for the most part on the outside, and surrounding the tower; so that from the apartment the trees are overlooked, and the whole country is seen; while the habitations themselves, which are very numerous, peering above the groves, add life and variety to the enchanting prospect, and give an air of human population to these woodlands, which might otherwise be supposed the region of Dryads, of Naiads, and of Satyrs."

The most remarkable thing, however, in this island is a custom by which the women have here openly usurped those rights of sovereignty which in other countries

countries are supposed to belong essentially to the men. "Contrary (says his lordship) to the usage of all other countries, the eldest daughter here inherits; and the sons, like daughters everywhere else, are portioned off with small dowers, or, which is still worse, turned out pennyless to seek their fortune. If a man have two daughters, the eldest, at her marriage, is entitled to all her mother's possessions, which are by far the greater part of the family estate, as the mother, keeping up her prerogative, never parts with the power over any portion of what she has brought into the family, until she is forced into it by the marriage of her daughter; and the father also is compelled to ruin himself by adding whatever he may have scraped together by his industry. The second daughter inherits nothing, and is condemned to perpetual celibacy. She is styled a *calogria*, which signifies properly a religious woman or nun, and is in effect a menial servant to her sister, being employed by her in any office she may think fit to impose, frequently serving her as waitingmaid, as cook, and often in employments still more degrading. She wears a habit peculiar to her situation, which she can never change; a sort of monastic dress, coarse, and of a dark brown. One advantage, however, she enjoys over her sister, that whereas the elder, before marriage, is never allowed to go abroad, or to see any man, her nearest relations only excepted, the calogria, except when employed in domestic toil, is in this respect at perfect liberty. But when the sister is married, the situation of the poor calogria becomes desperate indeed, and is rendered still more humiliating by the comparison between her condition and that of her happy mistress. The married sister enjoys every sort of liberty; the whole family fortune is hers, and she spends it as she pleases; her husband is her obsequious servant, her father and mother are dependent upon her, she dresses in a most magnificent manner, covered all over, according to the fashion of the island, with pearls and with pieces of gold, which are commonly sequins; thus continually carrying about her the enviable marks of affluence and superiority, while the wretched calogria follows her as a servant, arrayed in simple homespun brown, and without the most distant hope of ever changing her condition. Such a disparity may seem intolerable, but what will not custom reconcile? Neither are the misfortunes of the family yet at an end. The father and mother, with what little is left them, contrive by their industry to accumulate a second little fortune; and this, if they should have a third daughter, they are obliged to give to her upon her marriage; and the fourth, if there should be one, becomes her calogria, and so on through all the daughters alternately. Whenever the daughter is marriageable, she can by custom compel the father to procure her a husband; and the mother, such is the power of habit, is foolish enough to join her in teasing him into an immediate compliance, though its consequences must be equally fatal and ruinous to both of them. From hence it happens, that nothing is more common than to see the old father and mother reduced to the utmost indigence, and even begging about the streets, while their unnatural daughters are in affluence; and we ourselves have frequently been shown the eldest daughter parading it through the town in the greatest splendour, while her mother and sister followed her as servants, and made a melancholy part of her attendant train.

"The sons, as soon as they are of an age to gain a livelihood, are turned out of the family, sometimes with a small present or portion, but more frequently without any thing to support them; and thus reduced, they either endeavour to live by their labour, or, which is more usual, go on board some trading vessel as sailors or as servants, remaining abroad till they have got together some competency, and then return home to marry and to be henpecked. Some few there are who, taking advantage of the Turkish law, break through this whimsical custom, who marry their calogrias, and retain to themselves a competent provision: but these are accounted men of a singular and even criminal disposition, and are hated and despised as conformists to Turkish manners, and deserters of their native customs; so that we may suppose they are few indeed who have the boldness to depart from the manners of their country to adopt the customs of their detested masters, and to brave the contempt, the derision, and the hatred, of their neighbours and fellow-citizens.

"Of all these extraordinary particulars I was informed by the French consul, a man of sense and of indisputable veracity, who had resided in this island for several years, and who solemnly assured me that every circumstance was true: but indeed our own observation left us without the least room for doubt, and the singular appearance and deportment of the ladies fully evinced the truth of our friend's relation. In walking through the town, it is easy to perceive, from the whimsical manners of the female passengers, that the women, according to the vulgar phrase, *wear the breeches*. They frequently stopped us in the streets, examined our dress, interrogated us with a bold and manly air, laughed at our foreign garb and appearance; and showed so little attention to that decent modesty which is or ought to be the true characteristic of the sex, that there is every reason to suppose they would, in spite of their haughtiness, be the kindest ladies upon earth, if they were not strictly watched by the Turks, who are here very numerous, and would be ready to punish any transgression of their ungallant laws with arbitrary fines. But nature and native manners will often baffle the efforts even of tyranny. In all their customs these manly ladies seem to have changed sexes with the men. The woman rides astride, the man sits sideways upon the horse; nay, I have been assured that the husband's distinguishing appellation is his wife's family name. The women have town and country houses, in the management of which the husband never dares interfere. Their gardens, their servants, are all their own; and the husband, from every circumstance of his behaviour, appears to be no other than his wife's first domestic, perpetually bound to her service, and slave to her caprice. Hence it is that a tradition obtains in the country, that this island was formerly inhabited by Amazons; a tradition, however, founded upon no ancient history that I know of. Sappho indeed, the most renowned female that this island has ever produced, is said to have had manly inclinations; in which, as Lucian informs us, she did but conform with the singular manners of her countrywomen: but I do not find that the mode in which she

Metelin.

she chose to show these inclinations is imitated by the present female inhabitants, who seem perfectly content with the dear prerogative of absolute sway, without endeavouring in any other particular to change the course of nature; yet will this circumstance serve to show, that the women of Lesbos had always something peculiar, and even peculiarly masculine, in their manners and propensities. But be this as it may, it is certain that no country whatsoever can afford a more perfect idea of an Amazonian commonwealth, or better serve to render probable those ancient relations which our manners would induce us to esteem incredible, than this island of Metelin. These lordly ladies are for the most part very handsome in spite of their dress, which is singular and disadvantageous. Down to the girdle, which as in the old Grecian garb is raised far above what we usually call the waist, they wear nothing but a shift of thin and transparent gauze, red, green, or brown, through which every thing is visible, their breasts only excepted, which they cover with a sort of handkerchief; and this, as we are informed, the Turks have obliged them to wear, while they look upon it as an encumbrance, and as no inconsiderable portion of Turkish tyranny. Long sleeves of the same thin material perfectly show their arms even to the shoulder. Their principal ornaments are chains of pearl, to which they hang small pieces of gold coin. Their eyes are large and fine; and the nose, which we term Grecian, usually prevails among them, as it does indeed among the women of all these islands. Their complexions are naturally fine; but they spoil them by paint, of which they make abundant use; and they disfigure their pretty faces by shaving the hinder part of the eyebrow, and replacing it with a straight line of hair neatly applied with some sort of gum, the brow being thus continued in a straight and narrow line till it joins the hair on each side of their face. They are well made, of the middle size, and for the most part plump; but they are distinguished by nothing so much and so universally as by a haughty, disdainful, and supercilious air, with which they seem to look down upon all mankind as creatures of an inferior nature, born for their service, and doomed to be their slaves; neither does this peculiarity of countenance in any degree diminish their natural beauty, but rather adds to it that sort of bewitching attraction which the French call *piquant*."

His lordship has been at great pains to investigate the origin of such a singular custom; but is unable to find any other example in history than that of the Lycians, who called themselves by the names of their mothers, and not of their fathers. When asked by their neighbours who they were? they described themselves by their maternal genealogy. If a gentlewoman should marry a slave, the children by that marriage were accounted noble; but should the first man among them marry a foreign woman, the children would be accounted ignoble. This custom is mentioned by several ancient authors. A difficulty of no little magnitude occurs, however, in accounting for the derivation of the inhabitants of Lesbos from the Lycians. This is solved in the following manner: In times of the most remote antiquity, the island of Lesbos was peopled by the Pelasgi, who, under their leader Xanthus, the son of Trioppas king of Argos, first inhabited Lesbos: previous to that time they had dwelt in a certain part of Lycia which they had conquered; and in this country we may suppose they had learned the custom in question.

Metellus || Metempsychosis.

METELLUS, the surname of the family of the Cæcilii at Rome, the most known of whom were ——A general who defeated the Achæans, took Thebes and invaded Macedonia, &c.—Q. Cæcilius, who rendered himself illustrious by his successes against Jugurtha the Numidian king, from which he was surnamed Numidicus. Another who saved from the flames the palladium, when Vesta's temple was on fire. He was then high priest. He lost his sight and one of his arms in the action; and the senate, to reward his zeal and piety, permitted him always to be drawn to the senate house in a chariot, an honour which no one had ever before enjoyed. He also gained a great victory over the Carthaginians, &c.—Q. Cæcilius Celer, another who distinguished himself by his spirited exertions against Catiline. He married the sister of Clodius, who disgraced him by her incontinence and lasciviousness. He died 57 years before Christ. He was greatly lamented by Cicero, who shed tears at the loss of one of his most faithful and valuable friends. L. Cæcilius, a tribune in the civil wars of J. Cæsar and Pompey. He favoured the cause of Pompey, and opposed Cæsar when he entered Rome with a victorious army. He refused to open the gates of Saturn's temple, in which were deposited great treasures; upon which they were broke open by Cæsar, and Metellus retired when threatened with death. Q. Cæcilius, a warlike general who conquered Crete and Macedonia, and was surnamed *Macedonicus*. He had four sons, of whom three were consuls, and the other obtained a triumph, all during their father's lifetime. A general of the Roman armies against the Sicilians and Carthaginians. Before he marched, he offered sacrifices to all the gods except Vesta; for which neglect the goddess was so incensed, that she demanded the blood of his daughter Metella. When Metella was going to be immolated, the goddess placed a heifer in her place, and carried her to a temple at Lanuvium, of which she became the priestess. Another surnamed *Dalmaticus* from his conquest over Dalmatia, A. U. C. 634.—Cimber, one of the conspirators against J. Cæsar. It was he who gave the signal to attack and murder the dictator in the senate house. —Pius, a general in Spain against Sertorius, on whose head he set a price of 100 talents and 20,000 acres of land.

METEMPSYCHOSIS, (formed of μετα, "beyond," and εμψυχω, "I animate or enliven"), in the ancient philosophy, the passage or transmigration of the soul of a man, after death, into the body of some other animal.

Pythagoras and his followers held, that after death men's souls passed into other bodies, of this or that kind, according to the manner of life they had led. If they had been vicious, they were imprisoned in the bodies of miserable beasts, there to do penance for several ages: at the expiration whereof, they returned afresh to animate men. But, if they lived virtuously, some happier brute, or even a human creature, was to be their lot.

What led Pythagoras into this opinion was, the persuasion

persuasion he had that the soul was not of a perishable nature: whence he concluded that it must remove into some other body upon its abandoning this. Lucan treats this doctrine as a kind of officious lie, contrived to mitigate the apprehension of death, by persuading men that they only changed their lodging, and only ceased to live to begin a new life.

Reuchlin denies this doctrine; and maintains that the metempsychosis of Pythagoras implied nothing more than a similitude of manners, desires, and studies, formerly existing in some person deceased, and now revived in another alive. Thus when it was said that Euphorbus was revived in Pythagoras, no more was meant than that the martial virtue which had shone in Euphorbus at the time of the Trojan war, was now, in some measure, revived in Pythagoras, by reason of the great respect he bore the *athletæ*. For those people wondering how a philosopher should be so much taken with men of the sword, he palliated the matter, by saying, that the soul of Euphorbus, i. e. his genius, disposition, and inclinations, were revived in him. And this gave occasion to the report, that Euphorbus's soul, who perished in the Trojan war, had transmigrated into Pythagoras.

Ficinus asserts, that what Plato speaks of the migration of a human soul into a brute, is intended allegorically, and is to be understood only of the manners, affections, and habits, degenerated into a beastly nature by vice. Serranus, though he allows some force to this interpretation, yet inclines rather to understand the metempsychosis of a resurrection.

Pythagoras is said to have borrowed the notion of a metempsychosis from the Egyptians; others say, from the ancient Brachmans. It is still retained among the Banians and other idolaters of India and China; and makes the principal foundation of their religion. So extremely are they bigotted to it, that they not only forbear eating any thing that has life, but many of them even refuse to defend themselves from wild beasts. They burn no wood, lest some little animalcule should be in it: and are so very charitable, that they will redeem from the hands of strangers any animals that they find ready to be killed. See PYTHAGOREANS.

METEMPTOSIS (from μετα, *post*, and πιπτω, *cado*, "I fall,") a term in chronology, expressing the solar equation, necessary to prevent the new moon from happening a day too late. By which it stands contradistinguished from *proemptosis*, which signifies the lunar equation, necessary to prevent the new moon from happening a day too soon.

The new moons running a little backwards, that is, coming a day too soon at the end of 312 years and a half; by the proemptosis, a day is added every 300 years, and another every 2400 years: on the other hand, by the metemptosis, a bissextile is suppressed each 134 years; that is, three times in 400 years. These alterations are never made but at the end of each century; that period being very remarkable, and rendering the practice of the calendar easy.

There are three rules for making this addition or suppression of the bissextile day, and, by consequence, for changing the index of the epacts. 1. When there is a metemptosis without a proemptosis, the next following or lower index must be taken. 2. When there is a proemptosis without a metemptosis, the next preceding or superior index is to be taken. 3. When there are both a metemptosis and a proemptosis, or when there is neither the one nor the other, the same index is preserved. Thus, in 1600, we had D: in 1700, by reason of the metemptosis, C was taken: in 1800, there was both a proemptosis, and a metemptosis; so the same index was retained. In 1900, there will be a metemptosis again, when B will be taken: which will be preserved in 2000, because there will then be neither the one nor the other. This is as far as we need compute for it: But Clavius has calculated a cycle of 301,800 years; at the end of which period, the same indices return in the same order. See EPACT.

METEOR, (by the Greeks called μετεωρα, q. d. *sublima* or "high raised;" by the Latins *impressiones*, as making signs or impressions in the air), commonly denotes any bodies in the air that are of a transitory nature. Hence it is extended to the phenomena of hail, rain, snow, thunder, &c.; but is most commonly confined to those unusual and fiery appearances named *falling stars*, *ignes fatui*, *auroræ boreales*, &c. See METEOROLOGY.

METEOROLITE. This term is derived from the Greek μετεωρα, a *meteor*, and λιθος, a *stone;* and denotes a stony substance, exhibiting peculiar characters, and whose descent to the earth is usually accompanied by the appearance and explosion of a fire-ball.

Luminous meteors have, in all ages, been observed in the atmosphere. It is also well known that their disappearance has frequently been attended with a loud noise; but that they should moreover terminate in the fall of one or more solid bodies to the earth's surface, is a position so repugnant to our ordinary conceptions of the tenor of physical events, that we cannot admit it as a fact on slight or scanty evidence. With due deference, however, to some philosophers of name, we are not prepared to assert, that it implies impossibility. For who has explored the higher regions of the atmosphere? or who knows what may take place beyond its precincts? If a solid result from the combination of two aeriform substances, as muriatic acid and ammoniacal gases; if oxygen, the properties of which are most familiar to us in the state of gas, can undergo fixation, and if fluids can pass into crystalline forms, is it too bold to presume, that the same, or similar processes, effected in the grand laboratory of the atmosphere, may be within the range of possible occurrences? At all events, the same Being who called into existence those sublime and countless masses of matter which revolve in space, may, to serve purposes unknown to us, create bodies of dimensions infinitely smaller, and destined to impinge on some planetary orb. The reasoning of an angel may not convince us, that a part is greater than the whole, or that the value of two and two is equivalent to six; but a very ordinary logician may prove to our satisfaction, that the contact of particles of matter in portions of space which lie beyond our globe, is no chimerical supposition. Every thing around us proclaims, that matter is subject to incessant change. New forms and new modifications are ever springing into being: and can we doubt, that the same particles, as they may happen to be affected or influenced by various circumstances, may exist in the state of gas, of aqueous vapour, or of a concrete mass?

Again, it surely will not be seriously maintained, that, from the rarity of a phenomenon, we are warranted to infer its non-existence. The appearance of a comet is a rare, but not a fictitious, occurrence. Nay, we may safely advance a step farther, and assert, without fear of confutation, that the existence of a phenomenon, if otherwise well attested, cannot be disproved by our inability to explain it. How multiplied, in fact, are the subjects, even of our daily and hourly observation, which we cannot satisfactorily expound? We cannot say why a small seed should gradually unfold into a large tree, why flame should produce heat, why the hand should act in immediate subserviency to the will, or why a contusion of the brain should induce stupor, alienation of mind, or death. It is one thing to prove a fact, and it is another to account for it.

From these premises it follows in course, that we are not entitled to reject the existence of meteoric stones, provided it be established by valid testimony. Should the historical evidence, on a fair and dispassionate review, be deemed conclusive, we may afterwards examine the theories which have been proposed for the solution of the appearance.

From the Scriptures of the Old Testament we are not aware that any passage can be cited in direct corroboration of the descent of stones from the atmosphere. The ingenious and fanciful Mr Edward King, indeed, in his "Remarks concerning stones said to have fallen from the clouds, both in these days, and in ancient times," adverts to the 13th verse of the 18th Psalm.—"The Lord also thundered out of heaven, and the Highest gave his thunder: hail-stones and *coals of fire*." This last expression has, no doubt, been conjectured to denote real hard bodies, in a state of ignition; and the term ανθρακες, employed by the cautious Seventy, rather favours such an interpretation. The same expression, however, occurs in the preceding verse, without admitting this interpretation; and the phrase seems to be only a figurative mode of describing lightning. In the sober latitudes of the north, and even in colloquial language, we talk of *balls of fire* and *thunderbolts*, without any reference to solid matter. Mr King likewise quotes the 11th verse of the 10th chapter of Joshua.—"And it came to pass, as they fled from before Israel, and were in the going down to Beth-horon, that the Lord cast down *great stones* from heaven upon them unto Azekah, and they died: there were more which died with hail-stones, than they whom the children of Israel slew with the sword." Here, the expression, *great stones* is less equivocal than *coals of fire*; yet the context hardly allows us to doubt, that the great stones were really hail-stones, or rather, perhaps, lumps of ice, consolidated in the atmosphere, such as occasionally fall in hot countries, and such as alarmed the whole of Paris and its neighbourhood in 1788. At any rate, the slaughter of the Canaanites is represented as resulting from the special interposition of divine power; and the consideration of miracles is irrelevant to our present purpose.

If from sacred, we turn to the early period of profane history, we shall find the annals of public events very copiously interspersed with notices of strange appearances, many of which may be safely ascribed to the ascendency which superstition long obtained over the human mind. The scepticism of the learned is, however, sometimes not less injudicious and indiscriminate than the credulity of the savage; and he who should resolve every extraordinary event, which is recorded by the writers of Greece and Rome, into a "cunningly devised fable," would not be less reprehensible for want of candour, than the untutored rustic, who yields his assent to every alleged miracle, is to be taxed with want of discernment.

Although these general positions can scarcely admit of dispute, it becomes extremely difficult, after a lapse of many ages, and in the collation of marvellous records, to separate truth from falsehood. In our attempts to prosecute this analytical process, we may sometimes advance a certain length with perfect security, without being able to trace uniformly the precise lines of demarcation. Thus, in regard to the topic of our present discussion, we know, that in various periods of the world the vulgar have ascribed a celestial origin to stones of a peculiar configuration, as to certain modifications of pyrites, to belemnites, orthoceratites, &c. which the subsequent observations of naturalists have proved to be of mineral formation, and to the heads of arrows and sharpened flints, which have been fashioned by the hand of man, and which, accordingly we are authorized to exclude from the ex-terrestrial catalogue. But when substances dissimilar from these, and coinciding in any one character or circumstance with modern specimens of atmospheric stone, are reported by the ancients to have fallen from the clouds, the distance of ages and the lameness of the documents may powerfully affect our appreciation of the reputed evidence.

When, therefore, we shortly touch on a few of the many instances which might be quoted from the annals of antiquity, we mean not to vouch for the truth even of these particular instances; but merely to admit their probability, and the weight which the mention of them may be considered to add to that of subsequent and recent narrations.

Through the midst of fable which envelopes the history of the *bætuli*, we discern some characters which correspond with those of meteorolites. Thus, in the Λιθικα, a poem falsely ascribed to Orpheus, the σιδηριτης, which M. Falconet properly classes with the bætuli, is said to be *rough*, *heavy*, and *black*. Damascius, in an extract of his life of Isidorus, preserved by Photius, relates that the bætuli fell on Mount Libanus, in *a globe of fire*. A fragment of Sanchoniathon, preserved in Eusebius, (Præpar. Evangel. i. 10.), moreover informs us, that these stones were fabricated by the god *Uranus* (or *Heaven*), one of whose four sons was named *Bætul*. May not this mythological genealogy be regarded as merely emblematical of their descent from the upper regions of the atmosphere? In the same chapter we are told that Astarte found a *star* which had *fallen from heaven*, and honoured it with consecration in the city of Tyre. The stone denominated "the mother of the gods," if we can believe Appian, Herodian, and Marcellinus, *fell from heaven*. Aristodemus, cited by the Greek scholiast on Pindar, asserts that it *fell encircled by fire*, on a hill, at the feet of the Theban bard. It is said to have been of a *black* colour, and of an *irregular* shape. Herodian (lib. v.) expressly declares, that the Phœnicians had no statue of the sun, polished by the hand; but only a certain stone, circular below, and terminated

terminated acutely above, in the form of a cone, of a *black* colour, and that, according to report, it *fell from heaven*, and was regarded as the image of the sun.

Among various instances which might be selected from Livy, is that of a shower of stones on Mount Alba, in the reign of Tullus Hostilius, or about six hundred and fifty-two years before the birth of Christ. When the senate were told, that it had *rained stones*, they doubted the fact, and deputed commissioners to inquire into the particulars. They were then assured, that stones had really fallen, *haud aliter quam quum grandinem venti glomeratam in terras agunt*. On this occasion, the historian mentions, that similar events were celebrated by a festival of nine days. *Mansit solenne, ut quandocunque idem prodigium nuntiaretur, feriæ per novem dies agerentur*.

But one of the most remarkable cases which occurs in the records of antiquity, is that which is mentioned in the 58th chapter of the second book of Pliny's Natural History, of a large stone which fell near Ægospotamos, in Thrace, in the second year of the seventy-eighth Olympiad, or, according to our chronology, about four hundred and sixty-seven years before the Christian era. Pliny assures us, that this extraordinary mass was still shown in his day; and that it was as large as a cart, and of a *burnt colour*. The Greeks pretended that it had *fallen from the sun*, and that Anaxagoras had predicted the day of its arrival on the earth's surface. According to Plutarch, in the life of Lysander, the inhabitants of the Chersonesus held the Thracian stone in great veneration, and exhibited it as a public show. His account of its first appearance is chiefly extracted from the relation of Daimachus of Platææ, and may be thus translated. "During seventy-five successive days before the stone fell, a large fiery body, like a cloud of flame, was observed in the heavens, not fixed to one point, but wandering about with a broken irregular motion. By its violent agitation, several fiery fragments were forced from it, impelled in various directions, and darted with the velocity and brightness of so many shooting stars. After this body had fallen on the Chersonesus, and the people had assembled to examine it, they could find no inflammable matter, nor the slightest trace of combustion, but a real stone, which, though large, by no means corresponded to the dimension of the flaming globe which they had seen in the sky, but seemed to be only a piece detached from it." Daimachus, it is true, may, on this occasion, have given way to his reputed love of the marvellous; and we can easily believe that the *seventy-five continuous days* are either an error of the copyist, or an original exaggeration; yet, from the marked coincidence of some of the circumstances with those more fully detailed in the sequel, there arises the presumption that a meteorolite really fell at the place and period above assigned.

From this period till near the close of the fifteenth century, any historical notices which we have been enabled to collect, are so vague and scanty, that, in this abridged view of the subject, we may pass them over in silence.

Professor Bantenschoen, of the central school of Colmar, first directed the attention of naturalists to some of the old chronicles, which commemorate with much *naivete*, and in the true spirit of the times, the fall of the celebrated stone of Ensisheim. The following account accompanied this very singular mass, when it was suspended in the church.

"In the year of the Lord 1492, on Wednesday, which was Martinmas eve, the 7th of November, there happened a singular miracle: for, between eleven o'clock and noon, there was a loud peal of thunder, and a prolonged confused noise, which was heard to a great distance, and a stone fell from the air, in the jurisdiction of Ensisheim, which weighed 260 pounds, and the confused noise was, moreover, much louder than here. There a child saw it strike on a field, situated in the upper jurisdiction, towards the Rhine and Inn, near the district of Gisgard, which was sown with wheat, and did it no harm, except that it made a hole there: and then they conveyed it from that spot; and many pieces were broken from it, which the landvogt forbade. They, therefore, caused it to be placed in the church, with the intention of suspending it as a miracle; and many people came hither to see this stone. So there were remarkable conversations about this stone: but the learned said, that they knew not what it was; for it was beyond the ordinary course of nature, that such a large mass should smite the earth from the height of the air; but that it was really a miracle of God; for, before that time, never any thing was heard like it, nor seen, nor described. When the people found that stone, it had entered into the earth, to the depth of a man's stature, which every body explained to be the will of God, that it should be found, and the noise of it was heard at Lucerne, at Villing, and in many other places, so loud, that it was believed that houses had been overturned: And as the king (Maximilian) was here, the Monday after St Catherine's day, of the same year, his royal excellence ordered the stone which had fallen to be brought to the castle, and after having conversed a long time about it with the noblemen, he said the people of Ensisheim should take it, and order it to be hung up in the church, and not allow any body to take any thing from it. However, his excellency took two pieces of it, of which he kept one, and sent the other to the duke Sigismund of Austria: and they spoke a great deal about this stone, which they suspended in the choir, where it still is; and a great many people came to see it."

Trithemius, in his Hirsaugiensian Annals, employs language to this effect.—"In the same year, on the 7th day of November, in the village of Suntgaw, near the townlet of Ensisheim, not far from Basil, a city of Germany, a stone, called a thunder-stone, of a prodigious size, for we know from eye-witnesses that it weighed 255 pounds, fell from the heavens. Its fall was so violent, that it broke into two pieces. The most considerable is still exhibited at the door of the church of Ensisheim, suspended by an iron chain, as a proof of the fact which we have mentioned, and to preserve it in the public recollection."—We learn also from Paul Lang that there arose a furious storm on the 7th of November 1492, and that while the thunder roared, and the heavens appeared all on fire, a stone of enormous size fell near Ensisheim. Its form was that of the Greek delta, with a triangular point. They still show it at Ensisheim as an astonishing phenomenon."

It is worthy of observation, that these chroniclers lived at the period which they assign to the descent of the

Meteorolite.

the stone; and that, though their names are hastening to oblivion, Trithemius yielded to few of his contemporaries in labour and learning; while Lang, a German Benedictine as he was, travelled in search of historical monuments, arraigned the license of the catholic clergy, and applauded the independence of Luther and Melancthon.

Of the Ensisheim stone, which has been transported to the national library at Colmar, and which, notwithstanding various *dilapidations*, stills weighs 150 pounds, some interesting specimens may now be seen in the cabinets of the curious. Robert Ferguson, Esq. younger of Raith, has, in the most polite and obliging manner, gratified us with the sight of a small fragment, which belongs to his valuable collection of minerals at Raith house in Fifeshire, Scotland.

We are fully aware, that M. Barthold has laboured to convince his readers (Journal de Physique, Ventose, year 8.) that the far-famed mass of Ensisheim is merely argillo-ferrugineous, of secondary formation, detached from an adjacent mountain, and conveyed to the spot on which it was found by some torrent or land-flood. In this opinion, we might partially acquiesce, did not the artlessness of contemporary and concurring records militate against it, and had not the more accurate analysis of Vauquelin detected the same constituent parts as in the other stony and metalline substances denominated meteoric. "It is certainly composed of silica," observes this celebrated chemist, "of magnesia, of iron, of nickel, of sulphur, and of a small quantity of lime.—Particular trials have convinced me of the presence of sulphur and nickel in the grains of malleable iron, and in the pyrites, though in different proportions. This stone, then, in every respect, resembles others which have fallen from the atmosphere."

In the Commentary of Surius, a Carthusian monk of Cologne, mention is made of a shower of large stones in Lombardy, in 1510. These stones were harder than flint, and smelled of sulphur. The heaviest weighed 120 pounds. The same event is more particularly related by Cardan, in his work intitled *de Rerum Varietate* (lib. xiv. c. 72.). According to this author, near the river Adda, not far from Milan, and at five oclock in the evening, about 1120 stones fell from the air, one of them weighing 120 pounds and another 60 pounds. Many were presented to the French governor, and his deputy. At three o'clock P. M. the sky appeared as if in a general blaze; and the passage, though somewhat ambiguous, would lead us to infer, that the meteor was visible for two hours. Like many of the learned and unlearned of his day, Cardan instantly connects the extraordinary appearance with the political transactions of his district.

We next pass to an interesting extract from the memoirs of the emperor Jehangire, written in Persian, by himself, and translated by Colonel Kirkpatrick.

"*A. H.* 1030, *or 16th year of the reign.*—The following is among the extraordinary occurrences of this period.

"Early on the 30th of Furverdeen of the present year (1620), and in the eastern quarter of the heavens, there arose in one of the villages of the purgunnah of Jalindher, such a great and tremendous noise, as had nearly, by its dreadful nature, deprived the inhabitants of the place of their senses. During this noise, a luminous body was observed to fall from above, on the earth, suggesting to the beholders the idea that the firmament was raining fire. In a short time, the noise having subsided, and the inhabitants having recovered from their alarm, a courier was dispatched to *Mahommed Syeed*, the aumul of the aforesaid purgunnah, to advertise him of this event. The aumil, instantly mounting his horse, proceeded to the spot. Here he perceived the earth, to the extent of a dozen of yards in length and breadth, to be burned to such a degree, that not the least trace of verdure, or a blade of grass remained; nor had the heat yet subsided entirely.

"*Mahommed Syeed* hereupon directed the aforesaid space of ground to be dug up; when the deeper it was dug, the greater was the heat of it found to be. At length a lump of iron made its appearance, the heat of which was so violent, that one might have supposed it to have been taken from a furnace. After some time it became cold: when the aumil conveyed it to his own habitation, from whence he afterwards dispatched it in a sealed bag to court.

"Here I had this substance weighed in my presence. Its weight was 160 tolahs (A). I committed it to a skilful artisan, with orders to make of it a sabre, a knife, and a dagger. The workman reported, that the substance was not malleable, but shivered into pieces under the hammer.

"Upon this I ordered it to be mixed with other iron. Conformably to my orders, three parts of the *iron of lightning* (B) were mixed with one part of common iron; and from the mixture were made two sabres, one knife, and one dagger."

Our limits will not permit us to give the whole of the extract, nor the remarks of the Right Hon. Charles Greville and Colonel Kirkpatrick, which were read before the Royal Society of London, on the 27th January, 1803. We feel, however, no hesitation in attaching to this document something very nearly approaching to direct evidence of the fact in question.

The celebrated Gassendi relates, that, on the 27th of November, 1627, about 10 o'clock A. M. during a very clear sky, he saw a flaming stone, of the apparent diameter of four feet, fall on Mount *Vaision*, an eminence situated between the small towns of Perne and Guillaumes, in Provence. This stone was surrounded by a luminous circle of different colours, nearly resembling the rainbow, and its fall was accompanied with a noise like the discharge of artillery. It weighed 59 pounds; and its specific gravity was to that of common marble as 14 to 11. It was of a dark metallic colour, and extremely hard. Though it was not subjected to chemical analysis, and is not now to be found, the circumstances which have been stated by the philosopher are sufficiently

(A) A tolah is about 180 grains, Troy weight.
(B) This expression is equivalent to our term *thunder-bolt*.

sufficiently minute to operate on the conviction of those who are willing to be convinced.

From a curious book printed at Paris in 1672, and now become very scarce, entitled *Conversations tirées de l'Académie de M. l'Abbe Bourdelot, contenant diverses recherches et observations physiques, par le Sieur Legallois*, we make the ensuing extract.

"A member presents a fragment of two stones which fell near Verona, one of which weighed 300, and the other 200 pounds. These stones," says he, "fell during the night, when the weather was perfectly mild and serene. They seemed to be all on fire, and came from above, but in a slanting direction, and with a tremendous noise. This prodigy terribly alarmed 300 or 400 eye-witnesses, who were at a loss what to think of it. These stones fell with such rapidity, that they formed a ditch, in which, after the noise had ceased, the spectators ventured to approach them, and examine them more closely. They then sent them to Verona, where they were deposited in the Academy, and that learned body sent fragments of them to different places." That which accompanied the above intimation was of a yellowish hue, very easily pulverised, and smelled of sulphur.—In the course of examining one of these stones, M. Laugier, professor of pharmacy at Paris, has recently detected the presence of chrome, by means of the caustic alkali.—The date of the Verona phenomenon, if we have been correctly informed, is 1663.

In the Bornian collection there is a substance which is designated *Ferrum retractorium, granulis nitentibus matrice virescenti immixtis* (*Ferrum virens Lin.*), *cujus fragmenta ab unius ad viginti usque librarum pondus, cortice nigro scoriacco circumdata, ad Plann, prope Tabor, circuli Bechinensis Bohemiæ, passim reperiuntur.* The following note is subjoined. (*Quæ fragmenta 3 Julii anni 1753, inter tonitrua, è cælo pluisse creduliores quidam asserunt*). The expression *crcduliores quidam*, it may be alleged, at once destroys the evidence of this memorandum. It deserves, however, to be noted, that, in regard to our present subject, what was formerly accounted the credulity of the vulgar, may now, on several occasions, be construed into probability, if not into matter of fact; and that Mr Greville has found the identical fragment to have the same composition with other meteoric stones. Hence, we are compelled either to admit its ex-terrestrial origin, or the existence of a substance, originally belonging to the earth, and yet agreeing in character with those deemed atmospheric. The former part of the alternative is perfectly consonant with well-authenticated facts; whereas of the latter, we are not warranted to pronounce, that a single case has hitherto been established to the satisfaction of any chemist or mineralogist.

But we have now to turn our attention to a report of M. de la Lande, inserted in the Historical Almanack of Bresse, for 1756.

In the month of September 1753, about one o'clock P. M. when the weather was very hot, and very serene, without the least appearance of a cloud, a very loud noise, like the discharge of two or three cannons, was heard within the circumference of six leagues, but was of very short duration. This noise was loudest in the neighbourhood of Pont-de-Vesle; and at Liponas, a village three leagues from the last-mentioned place, it was even accompanied with a hissing, like that of a cracker. On the same evening there were found at Liponas and at Pin, two blackish masses, of a form nearly circular, but very uneven, which had fallen on ploughed ground, and sunk, by their own weight, to half a foot below the surface. One of them weighed about twenty pounds; and a fragment of one of them weighing $11\frac{1}{2}$lb. was preserved in the cabinet of M. Varenne de Beost, at Dijon. The basis of these masses resembled a grayish whinstone, and was very refractory; and some ferrugineous particles were disseminated in grains, filaments, or minute masses, through the substance of the stone, especially in its fissures. This iron, when subjected to a red heat, became obedient to the magnet. The black coating on the surface, M. de la Lande ascribes to fusion, induced by violent heat. This gentleman's acknowledged respectability and accuracy of observation, combined with the circumstances which he has adduced, circumstances, too, which, if misstated, lay so open to public investigation, powerfully plead in favour of his testimony.

On the 15th of September 1760, according to the abbé Bachclay, about half past four o'clock P. M. there appeared near the chateau de Chevabrie, in the neighbourhood of Luce, a small town of the province of Maine, a stormy cloud, from which proceeded a loud peal of thunder, like the discharge of cannon, and followed by a noise which was mistaken by several people for the lowing of oxen. This sound was heard over a space of about two leagues and a half, but unaccompanied by any perceptible flame. The reapers in the parish of Perigué, about three leagues from Luce, on hearing the same noise, looked up, and saw an opake body, which described a curve, and fell on soft turf, on the high road from Mons, near which they were at work. They all quickly ran up to it, and found a sort of stone, nearly half of which was buried in the earth, and the whole so hot that it could not be touched. At first they ran away in a panic; but on returning to the spot some time after, they found the stone precisely in the same situation, and sufficiently cooled to admit of being handled, and narrowly examined. It weighed seven ounces and a half, and was of a triangular form, presenting, as it were, three rounded horns, one of which, at the moment of the fall, had entered into the ground, and was of a gray or ash colour, while the rest, which was exposed to the air, was very black. When the abbé presented this stone to the academy, that body appointed three of its number, namely, Messieurs Lavoisier, Fougeroux, and Cadet, to examine and analyse it. This task they performed with more care and accuracy than M. de la Lande had done on the preceding occasion; but their trial was confined to an integral part of the whole, considered as a homogeneous substance, in place of being repeated on each of the constituent parts. The substance was of a pale cinereous hue, speckled with an infinite number of small and shining metallic points, visible through a magnifying glass. That part of the outer surface which remained above ground was incrusted with a thin black coating, which seemed to have undergone fusion, and which gave a few sparks when struck with steel. The specific gravity of the mass was 3535.—Two other stones, nearly of the same characters, the one reported to have fallen at Aire, in Artois, and the

Meteorolite.

the other in the Cotentin, in Normandy, were presented to the academy in the course of the same year by M. Gurson de Boyaval, honorary lieutenant-general of the bailliage of Aire, and the younger M. Morand. According to the academical report, these three stones, when compared, presented no difference to the eye, were of the same colour, and nearly of the same grain, exhibiting metallic and pyritous particles, and covered with a black and ferrugineous incrustation. Although the coincidence of facts and circumstances, in three places so remote from one another, did not convince the academy that these stones had been conveyed to the earth by lightning, yet it induced them to invite naturalists to prosecute the examination of the subject.

On the 20th of November 1768, a stone fell at Mauerkircken near the Inn, in Bavaria, that weighed 38lb. was of a triangular form, and only eight inches in thickness. Its fall was accompanied by a hissing noise, and great darkness in the atmosphere. This meteorolite penetrated two feet and a half into the soil. Part of it is in the cabinet of the right honourable Charles Greville, which is now in the British Museum; and a fragment may be seen in Mr Ferguson's collection quoted above.

The next remarkable case on record occurred on the 20th of August 1789, at Barbotan, near Roquefort, in the *Landes* of Bourdeaux, and is thus related by Citizen Lomet, who was known to several members of the Institute, and happened to be at Agen when the meteor appeared.

"It was a very bright fire-ball, luminous as the sun, of the size of an ordinary balloon, and, after inspiring the inhabitants with consternation, burst and disappeared. A few days after, some peasants brought stones, which they said fell from the meteor; but the philosophers to whom they offered them laughed at their assertions as fabulous. The peasants would have now more reason to laugh at the philosophers."—One of these stones broke through the roof of a cottage, and killed a herdsman and some cattle. Vauquelin, who received a *proces-verbal* of the circumstances, also examined one of the specimens. The fragment procured by Mr Ferguson has visibly all the characters of a genuine meteorolite.

A much more remarkable phenomenon, however, of the same description, occurred near Agen, on the 24th of July 1790. An inhabitant of St Severe communicates the following particulars to M. Darcet the chemist, who was then resident at Paris.

"Our towns-people were yesterday very much alarmed. About a quarter past nine o'clock, in the evening, there suddenly appeared in the air a fire-ball, dragging a long train, which diffused a very vivid light over the horizon. This meteor soon disappeared, and seemed to fall at one hundred paces from us. It was quickly followed by an explosion louder than that of a cannon or of thunder. Every body dreaded being buried under the ruins of his house, which seemed to give way from the concussion. The same phenomenon was seen, and the report heard, in the neighbouring towns, as Mont de Marsan, Tartas, and Dax. The weather in other respects was very calm, without a breath of wind or a cloud, and the moon shone in all her brightness."

M. Darcet's brother, a clergyman in that part of the country, sent him a small stone, which was picked up on the morning after the explosion, and the history of which he was scrupulously anxious to investigate. Being satisfied with respect to all the particulars, he at length dispatched it to Paris, accompanied with some curious remarks. "When these stones fell," says he, "they had not their present degree of hardness. Some of them fell on straw, bits of which stuck to the stones, and incorporated with them. I have seen one in this predicament. It is at present at La Bastide; but I cannot persuade the owner to part with it***. Those which fell on the houses produced a noise, not like that of stones, but rather of a substance which had not yet acquired compactness."

We subjoin the *proces-verbal*—a simple but authentic document.

"In the year one thousand seven hundred and ninety, and the 30th day of the month of August, we, the Sieur Jean Duby, mayor, and Louis Maullon, procurator of the commune of the municipality of La Grange de Juillac, and Jean Darmite, resident in the parish of La Grange de Juillac, certify in truth and verity, that, on Saturday the 24th of July last, between nine and ten o'clock in the evening, there passed a great fire, and after it we heard in the air a very loud and extraordinary noise; and, about two minutes after, there fell stones from heaven, but fortunately there fell only a very few, and they fell about ten paces from one another in some places, and in others nearer, and finally, in some other places, farther, and falling, most of them, of the weight of about half a quarter of a pound each; some of about half a pound, like that found in our parish of La Grange; and on the borders of the parish of Creon, they were found of a pound weight; and in falling they seemed not to be inflamed, but very hard and black without, and within of the colour of steel; and, thank God, they occasioned no harm to the people, nor the trees, but only to some trees which were broken on the houses; and most of them fell gently, and others fell quickly, with a hissing noise; and some were found which had entered into the earth, but very few. In witness whereof we have written and signed these presents. (Signed) Duby, Mayor—Darmite."

Monsieur Baudin mentions, that, as M. Carris of Barbotan and he were walking in the court of the castle of Mormes about half past nine o'clock, in the evening of the 24th of July 1790, when the air was perfectly calm, and the sky cloudless, they found themselves suddenly surrounded by a pale clear light, which obscured that of the moon, though the latter was nearly full. On looking up, they observed, almost in their zenith, a fire-ball of a larger apparent diameter than that of the moon, dragging a tail, which seemed to be five or six times longer than the diameter of its body, and which gradually tapered to a point, the latter approaching to blood-red, though the rest of the meteor was of a pale white. This luminous body proceeded with great velocity from south to north, and in two seconds split into portions of considerable size, like the fragments of a bursting bomb. These fragments became extinguished in the air, and some of them, as they fell, assumed that deep red colour, which had been observed at the point of the tail. Two or three minutes after M. Baudin and his friend heard a dreadful explosion, like the simultaneous firing of several pieces of ordnance; but they were not sensible of any tremulous motion under their feet, though the concussion

sion of the atmosphere shook the windows in their frames, and threw down kitchen utensils from their shelves. When these gentlemen removed to the garden, the noise still continued, and seemed to be directly over their heads. Some time after it had ceased, they heard a hollow sound rolling, in echoes, for fifty miles, along the chain of the Pyrenees, and at the end of about four minutes gradually dying away in distance. At the same time, a strong sulphureous odour was diffused in the atmosphere. The interval which occurred between the disruption of the meteor, and the loud report, induced M. Baudin to conjecture, that this fireball must have been at least eight miles from the earth's surface, and that it fell about four miles from Mormes. "The latter part of my conjecture, says he, was soon confirmed by an account which we received of a great many stones having fallen from the atmosphere at Juillac and in the neighbourhood of Barbotan." It appears, indeed, from the concurring testimony of intelligent persons worthy of credit, that the meteor really exploded at a little distance from Juillac, and that its fragments were found lying in an almost circular space, of nearly two miles in diameter. Some of them weighed eighteen or twenty, and a few, it is alleged, even fifty pounds. M. de Carris procured one of 18 lbs. which he transmitted to the Parisian Academy of Sciences. That examined by M. Baudin was small, but heavy in proportion to its size, black on the outside, grayish within, and interspersed with many minute, shining, metallic particles. These last circumstances perfectly accord with the fragment of a Barbotan stone preserved in Mr Ferguson's collection.

In one of his letters to Professor St Amand, M. Goyon d'Arzas remarks, that these stones, though generally smooth on the outside, presented some longitudinal cracks, or fissures, while their interior parts exhibited symptoms of metallic veins, especially of a ferrugineous complexion. When yet red hot, and scattered in various directions, they formed that magnificent fire-work, that shower of flame, which enlightened the horizon over a large tract of country; for this extraordinary meteor was seen at Bayonne, Auch, Pau, Tarbes, and even at Bourdeaux and Toulouse. At the last-mentioned place it excited little attention, on account of its great distance, and its appearing only a little brighter than a shooting star. It, moreover, deserves to be noted, that the meteorolites in question were found on a bare moor, of an extremely thin soil, on which no such stones, or indeed stones of any description, had been observed in the memory of man. They who are solicitous of additional information on this part of our subject, may consult N°. 23 and 24 of the *Journal des Sciences Utiles* of Montpelier, for 1790, and the *Decade Philosophique* for February 1796.

When all the circumstances of the case are duly considered, we need not be surprised, that they should produce conviction on the minds of many men of science, who, till then, possessed "an evil heart of unbelief." M. de St Amand ingenuously confessed to M. Pictet of Geneva, that he had treated this novel topic with unmerited contempt, and that the evidence deduced from the similar characters of the stones should not be rashly rejected. The learned and the unlearned of the district in which the phenomenon is stated to have occurred, attest its existence; the professor of natural history in the central school of Agen renounces his former scepticism; Vauquelin analyses a specimen, and finds it to contain the same chemical substances as other meteorolites, and in nearly the same proportions; and shall we be so unreasonable as to withhold our assent, merely because we have not *ocular demonstration* of the alleged particulars?

Our chronological series of cases has now brought us to the fall of several meteorolites near Sienna, the particulars of which, as reported by the late earl of Bristol and Sir William Hamilton, are recorded in the first part of the Philosophical Transactions for 1795 (page 103). Mr King, likewise in the tract which we have already quoted, communicates some interesting circumstances relative to this phenomenon, chiefly extracted from an account of it published by Professor Soldani. While we refer our readers to these details, we cannot omit mentioning that, in regard to aspect and composition, the Sienna stones are perfectly analogous to others already noticed, and very different from any that occur in Tuscany. As the meteor from which they were discharged appeared on the morning after a violent eruption of Vesuvius, they were at first supposed to be volcanic, till cool reflection and examination betrayed the extravagance of such a hypothesis. The precise number of stones which were collected on this occasion is not specified, but many of them were small, weighing from a quarter of an ounce to two ounces. A pretty entire specimen occurs in Mr Ferguson's collection.—The date of the Sienna meteor is the 16th of June, 1794.

On the 13th of December of the following year, about three o'clock in the afternoon, another of these singular stones, weighing 56 pounds, fell near the country house of Captain Topham, in Yorkshire. The captain's report, which is inserted in the Gentleman's Magazine for 1796, is distinct and satisfactory; while the chemical examination of the mass, detailed in Mr Howard's paper, in the Philosophical Transactions for 1802, affords a still more decisive proof of its atmospheric origin. M. de Drée, also found it to correspond exactly in aspect and character, with fragments of meteor stones from Benares and Ville-franche. The original mass is in the possession of Mr Sowerby author of English Botany, &c. It is larger than a man's head.

Mr Southey, in his letters from Spain and Portugal, transcribes the authenticated relation of another instance of the descent of a stone from the clouds on the 19th of February 1796. But we pass to some of the most important details relative to the stone which is affirmed to have fallen near Ville-franche, in the department of the Rhone, on the 12th of March, 1798. When it was transmitted to Professor Sage, member of the National Institute, he considered it at first, as only a pyritous and magnetical ore of iron, although it bore no resemblance to any known species of ore of that metal, since it contained nickel, silica, magnesia, and native iron, which shone like steel when polished. "It is of an ash gray colour, says M. Sage, granulated and speckled with gray, shining, and pyritous metallic points. One of its surfaces is covered with a dingy black enamel, about the third of a line in thickness. This stone acts very powerfully on the magnetic needle. When the senator Chasset transmitted it to me, it was

Meteorolite.

was accompanied with an historical notice of similar import with that of M. Delievre, of Ville-franche, who saw and described the phenomenon on the spot."

At six o'clock in the evening, a round body, which diffused the most vivid light, was observed in the vicinity of Ville-franche, moving westward, and producing a hissing, like that of a bomb which traverses the air. This luminous body, which was seen at the same time at Lyons and on Mont-Cenis, marked its path by a red track of fire, and exploded, about 200 toises from the earth with a tremendous report and concussion. One of the flaming fragments fell on the vineyard of Peter Crepier, an inhabitant of Sales. On the spot where this portion of the meteor was seen to fall, and in a fresh opening of about 20 inches in depth, and 18 in width, was found a black mass, 15 inches in diameter, and rounded on one side.

An account of the same meteor was published in the Journal de Physique, for Floreal, year 11, by M. de Drée. From his minute and deliberate investigation, it appears that the fire-ball had scarcely fixed the attention of the inhabitants of Sales and the adjacent villages, when its rapid approach, accompanied by a terrible whizzing noise, like that of an irregular hollow body, traversing the air with unusual velocity, inspired the whole commune with alarm, especially when they observed it passing over their heads, at an inconsiderable elevation. It left behind a long train of light, and emitted, with an almost unceasing craekling, small vivid flames, like little stars. Its fall was remarked, at the distance of only 50 paces, by three labourers, one of whom, named Montillard, let fall his coat and bundle of sticks that he might run the faster, while the other two, Chardon and Lapoces, fled with equal precipitation to Sales, where the alarm had become general.—These three witnesses attest the astonishing rapidity of the meteor's motion, and the hissing which proceeded from the spot where it fell. So terrified was Crepier at the explosion, that he locked himself up with his family, first in his cellar, and then in his private apartment, nor ventured abroad till next morning, when, in the company of M. Blandel, Chardon, Lapoccs, and many others, he repaired to the opening which had been made by the fire ball. At the bottom of this opening, which was 18 inches deep, including the entire thickness of the mould, they found a large black mass, of an irregularly ovoid form, having a fanciful resemblance to a calf's head. Though no longer hot, it smelled of gun-powder and was cracked in several places. When the observers broke it, and discovered nothing but stone, indifference succeeded to curiosity, and they coolly ascribed its appearance to causes more or less whimsical and supernatural.

The original weight of this stone was about twenty pounds. Its black vitrified surface gave fire with steel. Its interior was hard, earthy, ash-coloured, of a granular texture, presenting different substances scattered through it, namely, iron in grains, from the smallest size to a line or even more in diameter, somewhat malleable, but harder and whiter than forged iron; white pyrites, both lamellated and granular, and in colour approaching to nickel; some gray globules, which seemed to present the characters of trapp, and a very few and small particles of steatites, inclining to an olive hue. On account of its heterogeneous composition, its specific gravity could not be easily ascertained. One hundred parts of the mass gave, according to Vauquelin, 46 of silica, 38 oxide of iron, 15 magnesia, 2 nickel, and 2 lime. The excess of this result was ascribed to the absorption of oxygen by the native iron during the process. A small specimen of this mass belongs to Mr Ferguson's collection.

On the 19th of December 1798, about eight o'clock in the evening, the inhabitants of Benares and its neighbourhood observed in the heavens a very luminous meteor, in the form of a large ball of fire, which exploded with a loud noise, and from which a number of stones were precipitated near Krakhut, a village about fourteen miles from the city of Benares. Mr Davis, the judge and magistrate of the district affirmed that its brilliancy equalled the brightest moonlight. Both he and Mr Erskine, the assistant collector, were induced to send persons in whom they could confide to the spot where this shower of stones was asserted to have taken place, and thus obtained additional evidence of the phenomenon, and several of the stones, which had penetrated about six inches into fields recently watered. Mr Maclane, a gentleman who resided near Krakhut, presented Mr Howard with part of a stone, which had been brought to him the morning after its descent, by the watchman who was on duty at his house, and through the roof of whose hut it had passed, and buried itself several inches in the floor, which was of consolidated earth. Before it was broken, it must have weighed upwards of two pounds.

At the time that this meteor appeared, the sky was perfectly serene; not the smallest vestige of a cloud had been seen since the 11th of the month, nor was any observed for many days after.

" Of these stones (says Mr Howard), I have seen eight nearly perfect, besides parts of several others, which had been broken by the possessors, to distribute among their friends. The form of the more perfect ones appeared to be that of an irregular cube, rounded off at the edges; but the angles were to be observed on most of them. They were of various sizes, from about three to upwards of four inches in their largest diameter; one of them, measuring four inches and a quarter, weighed two pounds twelve ounces. In appearance they were exactly similar; externally they were covered with a hard black coat, or incrustation, which in some parts had the appearance of varnish or bitumen; and on most of them were fractures, which, from their being covered with a matter similar to that of the coat, seemed to have been made in the fall, by the stones striking against each other, and to have passed through some medium, probably an intense heat, previous to their reaching the earth. Internally they consisted of a number of small spherical bodies, of a slate colour, imbedded in a whitish gritty substance, interspersed with bright shining spiculæ, of a metallic or pyritical nature. The spherical bodies were much harder than the rest of the stone: the white gritty part readily crumbled, on being rubbed with a hard body; and on being broken, a quantity attached itself to the magnet, but more particularly the outside coat or crust, which appeared almost wholly attractable by it."

Here we are furnished with another circumstantial and authenticated narrative, by individuals above the rank

Meteorolite.

rank of suspicion, and who were prompted solely by motives of curiosity, to examine with due deliberation the particulars which they have reported.

The history of the extraordinary shower of stones which fell near l'Aigle, in Normandy, on the 26th of April 1803, first appeared in the ensuing artless letter, addressed by M. Marais, an inhabitant of the place, to his friend in Paris.

"*At l'Aigle, the 13th Floréal*, 11.

"An astonishing miracle has just occurred in our district. Here it is, without alteration, addition, or diminution. It is certain, that it is the truth itself.

"On Friday last, 6th Floréal (26th April), between one and two o'clock in the afternoon, we were roused by a murmuring noise like thunder, On going out we were suprised to see the sky pretty clear, with the exception of some small clouds. We took it for the noise of a carriage, or of fire in the neighbourhood. We were then in the meadow, to examine whence the noise proceeded, when we observed all the inhabitants of the Pont de Pierre at their windows, and in gardens, inquiring concerning a cloud, which passed in the direction of from south to north, and from whence the noise issued, although that cloud presented nothing extraordinary in its appearance. But great was our astonishment when we learned, that many and large stones had fallen from it, some of them weighing ten, eleven, and even seventeen pounds, in the space between the house of the Buat family (half a league to the north-north-east of l'Aigle) and Glos, passing by St Nicolas, St Pierre, &c. which struck us at first as a fable, but which was afterwards found to be true.

"The following is the explanation given of this extraordinary event by all who witnessed it.

"They heard a noise like that of a cannon, then a double report still louder than the preceding, followed by a rumbling noise, which lasted about ten minutes, the same which we also heard, accompanied with hissings, caused by these stones, which were counteracted in their fall by the different currents of air, which is very natural in the case of such a sudden expansion. Nothing more was heard; but it is remarkable, that previously to the explosion, the domestic fowls were alarmed, and the cows bellowed in an unusual manner. All the country-folks were much dismayed, especially the women, who believed that the end of the world was at hand. A labourer at la Sapée fell prostrate on the ground, exclaiming, 'Good God! is it possible that thou canst make me perish thus? Pardon, I beseech thee, all the faults I have committed,' &c. The most trifling objects in fact, might create alarm, for it is not improbable, that history offers no example of such a shower of stones as this. The piece which I send was detached from a large one, weighing eleven pounds, which was found between the house of the Buats and le Fertey. It is said, that a collector of curiosities purchased one of seventeen pounds weight, that he might send it to Paris. Every body in this part of the country is desirous of possessing a whole stone, or a fragment of one, as an object of curiosity. The largest were darted with such violence that they entered at least a foot into the earth. They are black on the outside, and grayish, as you see, within, seeming to contain some species of metal and nitre. If you know before us of what ingredients they are composed, you will inform us. One fell near M. Bois de la Ville, who lives near Glos. He was much afraid, and took shelter under a tree. He has found a great number of them of different sizes, in his court-yard, his wheat field, &c. without reckoning all those which the peasants have found elsewhere. Numberless stories, more or less absurd, have been circulated among the people. You know that our country is fertile in such tales. Cousin Moutardier sends one of these stones to Mademoiselle Hébert; and he is not less eager than we are, to know how these substances can be compressed and petrified in the air. Do try to explain the process.

"The person who gave me the largest stone which I send to you, went to take it at the moment that it fell, but it was so hot that it burned him. Several of his neighbours shared the same fate in attempting to lift it.

"The elder Buat has just arrived, and desires us to add, that a fire-ball was observed to hover over the meadow. Perhaps it was wild-fire."

At the sitting of the Institute, on the 9th of May, Fourcroy read a letter, addressed from l'Aigle to Vauquelin, and which sufficiently corroborates the preceding statements. But we pass to the substance of M. Biot's letter, addressed to the minister of the interior, and published in the *Journal des Débats*, (14th Thermidor, year 11.). The writer who is advantageously known for his scientific attainments, was deputed by government to repair to the spot, and collect all the authentic facts. The contents of his letter have been since expanded into the form of a memoir, which manifests the caution and good sense which guided his inquiries, and which we are surprised to learn, has not appeared in an English translation.

M. Biot left Paris on the 25th of June, and in place of proceeding directly to l'Aigle, went first to Alençon, which lies fifteen leagues to the west-south-west of it. He was informed on his way, that a globe of fire had been observed moving towards the north, and that its appearance was followed by a violent explosion. From Alençon he journeyed through various villages to l'Aigle, being directed in his progress by the accounts of the inhabitants, who had all heard the explosion on the day and at the hour specified. Almost all the inhabitants of twenty hamlets, scattered over an extent of upwards of two leagues square affirmed that they were eye-witnesses of a dreadful shower of stones which was darted from the meteor. The following is his summary of the whole evidence.

"On Tuesday, 6th Floréal, year 11, about one o'clock P. M. the weather being serene, there was observed from Caen, Pont d'Audemer, and the environs of Alençon, Falaise, and Verneuil, a fiery globe, of a very brilliant splendour, and which moved in the atmosphere with great rapidity. Some moments after, there was heard at l'Aigle, and in the environs of that town, in the extent of more than thirty leagues in every direction, a violent explosion, which lasted five or six minutes. At first there were three or four reports, like those of cannon, followed by a kind of discharge which resembled the firing of musketry; after which there was heard a dreadful rumbling like the

the beating of a drum. The air was calm, and the sky serene, except a few clouds, such as are frequently observed.

"This noise proceeded from a small cloud which had a rectangular form, the largest side being in a direction from east to west. It appeared motionless all the time that the phenomenon lasted; but the vapours of which it was composed, were projected momentarily from different sides, by the effect of the successive explosions. This cloud was about half a league to the north-north-west of the town of l'Aigle. It was at a great elevation in the atmosphere, for the inhabitants of two hamlets, a league distant from each other, saw it at the same time above their heads. In the whole canton over which this cloud was suspended, there was heard a hissing noise like that of a stone discharged from a sling, and a great many mineral masses exactly similar to those distinguished by the name of *meteor-stones* were seen to fall.

"The district in which these masses were projected, forms an elliptical extent of about two leagues and a half in length, and nearly one in breadth, the greatest dimension being in a direction from south-east to north-west, forming a declination of about 22 degrees. This direction, which the meteor must have followed, is exactly that of the magnetic meridian, which is a remarkable result. The greatest of these stones fell at the south-eastern extremity of the large axis of the ellipse, the middle-sized in the centre, and the smaller at the other extremity. Hence it appears that the largest fell first, as might naturally be supposed. The largest of all those that fell weighs seventeen pounds and a half. The smallest which I have seen weighs about two *gros* (a thousandth part of the last). The number of all those which fell is certainly above two or three thousand."

As we cannot make room for an analysis of M. Biot's more extended communication, we shall be contented to select only two facts.

The *curé* of St Michael declared, that he observed one of the stones fall, with a hissing noise, at the feet of his niece, in the court-yard of his parsonage, and that it rebounded upwards of a foot from the pavement. He instantly requested his niece to fetch it to him; but as she was too much alarmed, a woman who happened also to be on the spot, took it up; and it was found in every respect to resemble the others.

As one *Piche*, a wire-manufacturer belonging to the village of *Armées*, was working with his men in the open air, a stone grazed his arm, and fell at his feet; but it was so hot, that, on attempting to take it up, he instantly let it fall again.

He who compares the various accounts of the l'Aigle meteor, with a critical eye, may detect some apparent contradictions, which, however, on reflection, are found to be strictly conformable to truth. Thus, according to some, the meteor had a rapid motion, others believed it stationary; some saw a very luminous ball of fire, others only an ordinary cloud. Spectators, in fact, viewed it in different positions with respect to its direction. They who happened to be in its line of march, would see it stationary, for the same reason, that we fancy a ship under full sail to be motionless, when we are placed in its wake, or when we view it from the harbour to which it is approaching in a straight line. They, on the other hand, who had a side view of the meteor, would reckon its progress the more rapid, in proportion as their position approached to a right angle with its line of passage. They, again, who saw it from behind, as the inhabitants of l'Aigle, would perceive only the cloud of vapour, which it left in its train, and which, in the dark, would figure like a blazing tail, in the same manner as the smoke of a volcano appears black during the day and red at night. Lastly, they who were placed in front of the meteor, would reckon it stationary, but brilliant and cloudless.

It deserves to be remarked, that the l'Aigle stones were very friable for some days after their descent, that they gradually acquired hardness, and that after they had lost the sulphureous odour on their surface, they still retained it in their substances, as was found by breaking them. Professor Sage submitted them to several comparative trials with those of Ville-franche; and, though the l'Aigle specimens present some globules of the size of a small coriander seed, of a darker gray than the mass, and not attractable by the magnet, yet, in respect of granular texture and general aspect, the coincidence was so striking as to lead one to suppose that they were all parts of the same mass.

The l'Aigle stones, according to Fourcroy, are generally irregular, polygonal, often cuboid, sometimes subcuneiform, and exceedingly various in their diameter and weight. All are covered with a black gravelly crust, consisting of a fused matter, and filled with small agglutinated grains of iron. The greater part of them are broken at the corners, either by their shock against each other, or by falling on hard bodies. The internal parts resemble those of all the stones analyzed by Messrs Howard and Vauquelin, being gray, a little varied in their shades, granulated, and as it were scaly, split in many parts, and filled with brilliant metallic points, exactly of the same aspect as those of other stones of a like description. The proportions of their constituent materials are stated as nearly, 54 silex, 36 oxidated iron, 9 magnesia, 3 nickel, 2 sulphur, and 1 lime, the five per cent. of increase, arising from the oxidation of the metals produced by the analysis.

Of the two specimens which M. Biot presented to the celebrated Patrin, one was less compact, and of a lighter gray than the other, and likewise presented small patches of a rust colour. When immersed in water, it gave a hissing sound, like the humming of a fly, which is held by one wing. As it began to dry, it was observed to be marked by curvilinear and parallel layers. The more compact specimens, when moistened, presented no such appearances, but assumed the aspect of a gray porphyry, with a base of trap, mottled with small white spots, and speckled with metallic points.

Two fine specimens of the l'Aigle stone, one of them nearly entire, may be seen in Mr Ferguson's collection, which we have already repeatedly quoted.

Previously to the explosion of the 26th of April 1803, no meteorolites had been found by the inhabitants of the l'Aigle district, nor in the mineralogical collections of the department; nor the slightest mention of them made in the geological documents of this portion of Normandy: the mines, founderies, and forges, had produced nothing similar, in the form of dross or ore, nor had the country exhibited any trace of volcanoes.

canoes. The meteor at once appears, and a multitude of stones of the peculiar character noted above are seen scattered on a determined space of ground, in a manner, and accompanied with circumstances, which could not formerly have escaped observation. Let us likewise reflect, that the young and the old, simple peasants dwelling at a distance from one another, sagacious and rational workmen, respectable ecclesiastics, young soldiers devoid of timidity, individuals, in short, of various manners, professions, and opinions, united by no common ties, all agree in attesting a fact, which contributed neither directly nor indirectly to promote their own interest, and they all assign the manifestation of this fact to the same day and hour. They, moreover, point to existing vestiges of the descent of solid substances, and they declare, in terms unsusceptible of misconstruction or ambiguity, that they saw the masses in question roll down on roofs, break branches of trees, rebound from the pavement, and produce smoke where they fell. These recitals, and these vestiges, are limited to a tract of territory which has been accurately defined; while beyond the precincts of this tract, not a single particle of a meteorolite has been found, nor a single individual who pretends that he saw a stone fall.

Having now, we presume, advanced ample and satisfactory evidence of the existence of meteorolites, we shall forbear to enlarge this article by dwelling on instances of inferior notoriety to those which we have recounted, and shall merely note the dates of subsequent examples.

On the 4th of July 1803, a fire-ball struck the White Bull Inn at East-Norton, and left behind it several meteoric fragments.—On the 13th of December of the same year, a similar phenomenon occurred at the village of St Nicholas, in Bavaria.—At Possil, near Glasgow in Scotland, a meteor-stone fell, with a loud and hissing noise, on the 5th April 1804.—The next instance which we have to mention occurred near Apt, in the department of Vaucluse, on the 6th of October of the same year: and the last which has come to our knowledge happened at half past five o'clock in the evening of the 15th March 1806, near Alais in Languedoc.

It seems reasonable, however, to suppose, that the fall of meteoric substances takes place more frequently than is commonly supposed, since several foreign collections of fossils contain specimens of reputed celestial origin, and exhibiting the genuine atmospheric physiognomy. It is likewise worthy of remark, that many relations of the phenomenon may have sunk into oblivion, from the contempt with which they were heard by the learned, and that on a fair computation of chances, meteors may have sometimes exploded on desert tracts of land, and still more frequently over the pathless expanse of the water.

That some of the relations to which we have alluded are vague and unsatisfactory, cannot be denied, but the circumstantial testimony conveyed by others is more pointed and positive; and the whole mass of historical proof, especially when combined with the argument deduced from the identity of the physical and chemical constitution of the stones, appears to us to be altogether irresistible.

In the course of our inquiry into this novel and interesting subject, we have ascertained a variety of circumstances which render it highly probable, if not indubitable, that those detached masses of native iron, whose history has so often staggered and perplexed the geologist, are only modifications of meteoric depositions. The Tartars, for example, ascribe the descent of the Siberian mass described by Chladni, Pallas, Patrin, &c. to a period that is lost in the remoteness of antiquity; and while tradition thus favours our hypothesis, the analogy which is obviously observable in point of texture and chemical characters with those of other solid bodies, whose fall is no longer questioned, strengthens tradition. According to the discoveries of Proust and Klaproth, native iron, reputed meteoric, differs from that which occurs in a fossil state by the presence of nickel. The former of these celebrated analysts obtained 50 grains of sulphate of nickel from 100 of the South American mass, and his results are corroborated by Mr Howard and the Count de Bournon.

Of the two pieces of Siberian iron possessed by Mr Greville, one, which was transmitted by Dr Pallas, weighs several pounds; and another presents a cellular and ramified texture, analogous to that of some very light and porous volcanic scoriæ. When attentively examined, there may be perceived in it not only empty cells, but also impressions or cavities of greater or less depth, and in some of which there remains a transparent substance, of a yellowish green colour. The iron itself is very malleable; and may be easily cut with a knife, or flattened under the hammer. The specific gravity is 6487, which is obviously inferior to that of unforged iron that has undergone fusion, and may be partly owing to the oxidizement of the surface of the iron, and partly to the many minute cavities in its substance, which are often rendered visible by fracture, and which have their surface also oxidized. The fracture is shining and silvery, like that of white cast iron; but its grain is much smoother and finer; and it is much more malleable when cold. The heavier specimen is more solid and compact, exhibiting no cavities or pores, though its surface is ramified and cellular. So blended and incorporated is its compact part with the yellowish-green substance mentioned above, that if the whole of the latter could be subtracted, the remainder would consist of iron in the metallic state, and would display the same cellular appearance as the preceding specimen, or as the superficial portion of that now described. This stony part of the composition usually assumes the appearance of small nodules, generally of an irregular shape, but sometimes nearly globular, with a smooth, shining, and glassy surface. This substance, which is always more or less transparent, is hard enough to cut glass, but makes no impression on quartz. It becomes electric by friction, is very refractory, and varies in specific gravity from 3263 to 3300. Of all substances hitherto known, it approaches most to the peridot, or Wernerian chrysolite, which yielded to Klaproth nearly the same results which this substance did to Howard. In the mass of iron, it is liable to decomposition, changing to an opake white, and crumbling into a gritty dry powder, when lightly pressed or squeezed between the fingers.—"I cannot help observing (says the count de Bournon), that there appears to exist a very interesting analogy between these transparent nodules and the globules I described as making part of the stones said to to have fallen on the earth. This analogy, though not a very strong one, may lead us to suppose, that the two substances are similar in their nature, but that the globules are less pure, and contain a greater quantity of iron."

The native iron from Bohemia is compact, like the large specimen from Siberia, in Mr Greville's collection, and like it contains nodules, but not so numerous. They are besides quite opake, and very much resemble the globules in atmospheric stones. This iron contains nearly five per cent. of nickel. Between five and six per cent. of the same metal seems to exist in a piece of native iron brought from Senegal.

Though our limits will not permit us to dwell with minuteness on the physical and chemical characters of meteorolites, we shall shortly state those which the count de Bournon found to appertain to the specimens from Benares, and which may serve as no unfair standard of the aspect and composition of the others.

Like all of the same origin which were subjected to the count's examination, the Benares stones are covered over the whole extent of their surface, with a thin crust, of a deep black colour, sprinkled over with small asperities, which make it feel somewhat like shagreen or fish skin. Their fracture exhibits a grayish colour, and a granulated texture, like that of coarse grit-stone. By help of a lens, they are perceived to be composed of four different substances. One of these occurs in great abundance, in the form of small bodies, some of which are perfectly globular, others rather elongated or elliptical, and all, of various sizes, from that of a small pin's head to that of a pea, or nearly so. These small globules are usually gray, sometimes inclining much to brown, and always opake; they are easily broken in any direction, have a conchoidal fracture, and a fine, smooth, compact grain, with a slight degree of lustre, approaching to enamel; lastly, they can destroy the polish of glass without being able to cut it, and sparkle faintly when struck with steel. Another of these substances is martial pyrites, of an indeterminate form, and reddish yellow colour, slightly verging to the nickel tint, or to that of artificial pyrites; of a somewhat loosely granulated texture, and irregularly distinguished in the mass, being black when reduced to powder, and not attractable by the magnet. The third of these substances consists of small particles of iron, in a perfectly metallic state, so that they may be easily flattened or extended under the hammer. Though in a much smaller proportion than the pyrites just mentioned, they impart the magnetic attraction to the stone. When a piece of the latter was pulverized, and the particles of iron separated from it as accurately as possible, by means of a magnet, they appeared to compose about 200 parts of the weight of the stone. These three substances are united by means of a fourth, which is nearly of an earthy consistency, and of a whitish gray colour.—The black crust, or outward coating, though of very inconsiderable thickness, emits bright sparks when struck with steel, may be broken by the hammer, and seems to possess the same properties with the black oxide of iron, though, like the substance of the stone, it is occasionally intermixed with small particles of iron in the metallic state. These are easily distinguished, by passing a file over the crust, which reveals their lustre. The specific gravity of the Benares stones is 3352.

None of them, when breathed on, emit the argillaceous odour.

In consequence of various experiments, M. Sage, infers that meteorolites are composed of native iron, sulphuret of nickel, quartz or silica, alumina, and magnesia; that the proportions of iron and nickel vary; that the quartz seems to form at least the half of the stone, the alumina and magnesia the sixth, and the sulphur the 30th part. These general results pretty nearly accord with the more special reports of Howard and Vauquelin, except that the latter makes no mention of alumina, the existence of which in atmospheric stones is by no means distinctly ascertained.

We shall only beg leave to add, on this part of our subject, that Laugier, an ingenious chemist, by employing the caustic alkali, has detected a small portion of chrome. The results of his experiments, which are stated in the 58th volume of the *Annales de Chimie*, are 1st, That the five stones from Verona, Barbotan, Ensisheim, l'Aigle, and the neighbourhood of Apt, besides the principles already recognized, contain about one per cent. of chrome. 2dly, That it is very probable that all meteorolites contain this principle, since they all resemble one another in their physical and chemical properties, and have all, apparently, the same origin; and, 3dly, That in many cases, the perfection of chemical analysis requires, that the same substance should be treated both by acids and alkalies, since experience has shown, that a principle which eluded the former method, has been revealed by the latter.

Having now, as we apprehend, sufficiently established the existence and nature of meteorolites, we hope our readers will excuse us from enlarging on the various causes which have been assigned for their origin, as these seem to lie beyond the reach of our present state of knowledge. After a candid and patient review of the principal theories, we conceive that they are at best gratuitous, and that most of them are open to many and formidable objections.

The *terrestrial* hypotheses, we believe, begin already to be generally abandoned, as untenable. Until the phenomenon of exploding meteors had been distinctly observed and recorded, Lemery and others could maintain, with some degree of plausibility, that lightning might tear up the ground, and convert soil into a compact mass. But the appearances of a thunder storm and of a fire-ball are now ascertained to differ in various important respects. Spectators worthy of credit have seen the latter terminate in the fall of solid bodies; and the composition of these solid bodies has been found to differ from that of all the known fossil substances on the surface of the globe. It is in vain, then, to allege, that they are formed on the ground by common lightning, which has often produced very extraordinary effects, but which never generated thousands of stones in fine calm weather. The supposition, that such stones have been projected from some of our volcanoes, is hardly less conceivable. The ashes which accompany a violent eruption of Ætna or Vesuvius have, from their levity, been carried te a very considerable distance; but we are totally unacquainted with any projectile force which could dart solid masses many hundred miles, through such a dense medium as the atmosphere. The compact lavas of burning mountains are never found

found remote from the scene of their formation, and none of them present the characters and aspect of the stones which we have described. M. Bory de St Vincent, indeed, in his *Voyage dans les quatre Principales Isles des Mers d'Afrique*, very pompously expounds a doctrine, which, in our opinion, carries its confutation along with it. According to this writer, meteorolites were projected from immense depths, in an early stage of the earth's existence, when ignivomous mountains were endued with propelling forces sufficient to drive masses of matter into the regions of space, where they were constrained to obey, for ages, the combined laws of impulse and gravitation, until, in the progress of time, their spiral revolutions at length terminated on the surface of their native earth. Before we can adopt such an extravagant hypothesis, we must be convinced, that at one period of the history of our globe, the agency of subterraneous fire was adequate to communicate planetary motion to splinters of rock, without heaving up the rocks themselves, and that the rotatory movement, though once established, must gradually diminish and cease. The demonstration of these positions is surely not less arduous than the explanation of the phenomenon which they are intended to solve.

Of those who contend for the *atmospherical* formation of meteorolites, scarcely any two agree in regard to the manner by which such formation is effected. Patrin, who is solicitous to extend and illustrate his darling theory of volcanoes, labours at great length to maintain the existence of a regular circulation of gaseous fluids between the primitive schistose strata of the globe, and its surrounding atmosphere, and, from this fancied circulation, which he flatters himself he has *demonstrated*, he deduces, quite at his ease, the occasional ignition and concretion of portions of these fluids in the higher regions of the air. This ingenious mineralogist and geologist is so extremely tenacious of these ideas that we shall not attempt to disturb his self-complacency; but he will excuse us if we refuse to assent to results which rest on imaginary foundations. The celebrated Muschenbroeck, in one part of his writings, ascribes the descent of stones from the air to earthquakes and volcanic eruptions, an opinion which later observations have disproved. In other passages, however, he seems to incline to a modification of the atmospherical hypothesis, and endeavours to trace the origin of shooting stars to an accumulation of the volatile matters which are suspended in the air. It is extremely probable, that shooting stars and fiery meteors have an intimate relation to one another, if they are not identical appearances; but it is certain that the former move at a much greater distance from our earth than fire-balls, and only occasion a transient luminous appearance in their passage through the upper regions of the atmosphere. Perhaps they are analogous to those telescopic sparks of light which were observed by M. Schröter. Muschenbroeck, however, adopts the vulgar notion of their falling to the earth, and seems to confound their residue with *tremella nostoc*. M. Salverte has given extension to the theory of formation from vapours, by having recourse to the agency of hydrogen gas. According to him, in consequence of the decomposition of water, which is constantly going on at the surface of the earth, immense quantities of hydrogen gas are continually rising into the atmosphere, and ascending to its higher regions. As this gas is capable of dissolving metals, it carries along with it a portion of iron and nickel. During thunder-storms this gas is kindled by electricity; the metals are deposited, reduced, melted, and vitrified; in other words, meteors are produced and stones formed. This hypothesis is scarcely more satisfactory than the others. It does not account for the presence of magnesia and silica, nor does it explain why the stones are always composed of the same materials. Besides, the existence of hydrogen gas in the atmosphere has not been proved, far less that it forms a separate atmosphere, which is contrary to all experience; and it is well known, that a little hydrogen, mixed with a large portion of atmospheric air, cannot be fired by electricity. In general, we may observe, that if the origin of meteorolites be really atmospherical, the matters of which they are composed must have existed in one of two states, namely, in very attenuated particles or concretions of the matters themselves volatilized and held in solution in the air, or only in the *elements* of these matters. In the first case, when abandoned by their menstruum to their reciprocal tendencies, they would unite by aggregation only; in the second, by chemical combination. Now, we can hardly suppose that disengagement of light and violent detonation should result from the mere affinity of aggregation, whereas they are strictly symptomatic of the affinity of composition. This, and various other considerations which might be stated, if we could make room for them, induce us to regard the doctrine of combination as the most plausible. M. Izarn, who has published a treatise on *Atmospheric Lithology*, has entered into a tedious and somewhat obscure exposition of his own theory, founded on this principle. We shall give the summary, as nearly as we can, in his own words.

"Gaseous substances, arranged in spherical masses in the upper regions of the air, being admitted, the various agitations of the atmosphere should naturally waft some of these masses from their insulating medium into one capable of combining with them. If the combination begins, the disengagement of light is explained. In proportion as the combination advances, the specific gravities are changed; and, consequently, a change of place will commence, and that in the quarter which presents least resistance, or where the medium is most rarefied, in course rather towards the south than the north. Hence, most fire-balls are observed to move from north to south, or from north-east to south-west. Motion being once impressed, the mass traverses other media, capable of supplying new principles, which still increasing the weight, determine the curve; and when at length the principles which are at work, and which issue in all directions, have attained the requisite proportion for extinguishing the elements in the birth of the compound, the grand operation is announced by the explosion, and the product takes its place among the solids."—That the stones in question are produced by chemical combination in the higher regions of the atmosphere, and that they are thus formed from their own elements, are suppositions fully as probable as any that have been advanced on the subject; but whether the union of their parts be effected in the manner detailed by M. Izarn, we are unable to determine, both because we are uncertain if we perfectly comprehend his

Meteorolite.

his meaning, and because our range of data is as yet too circumscribed, to warrant any specific or decisive conclusions.

A much bolder theory has been suggested, and its *possibility* demonstrated by the celebrated French astronomer, La Place, who shews, that meteorolites *may be* the products of lunar volcanoes. As this romantic view of the subject has obtained the suffrages of some men of science, and has excited the ridicule of others, we shall present the reasoning on which it is founded in the popular and perspicuous language of Dr Hutton of Woolwich.

"As the attraction of gravitation extends through the whole planetary system, a body placed at the surface of the moon is affected chiefly by two forces, one drawing it toward the centre of the earth, and another drawing it toward that of the moon. The latter of these forces, however, near the moon's surface is incomparably the greater. But as we recede from the moon, and approach toward the earth, this force decreases while the other augments; till at last a point of station is found between the two planets, where these forces are exactly equal, so that a body placed there must remain at rest; but if it be removed still nearer to the earth, then this planet would have the superior attraction, and the body must fall towards it. If a body then be projected from the moon towards the earth, with a force sufficient to carry it beyond the point of equal attraction, it must necessarily fall on the earth. Such then is the idea of the manner in which the bodies must be made to pass from the moon to the earth, if that can be done, the *possibility* of which is now necessary to be considered

"Now, supposing a mass to be projected from the moon, in a direct line towards the earth, by a volcano, or by the production of steam by subterranean heat; and supposing for the present these two planets to remain at rest; then it has been demonstrated, on the Newtonian estimation of the moon's mass, that a force projecting the body with a velocity of 12,000 feet in a second, would be sufficient to carry it beyond the point of equal attraction. But this estimate of the moon's mass is now allowed to be much above the truth; and on M. la Place's calculation, it appears that a force of little more than half the above power would be sufficient to produce the effect, that is, a force capable of projecting a body with a velocity of less than a mile and a half per second. But we have known cannon balls projected by the force of gunpowder, with a velocity of 2500 feet per second or upwards, that is, about half a mile. It follows, therefore, that a projectile force, communicating a velocity about three times that of a cannon ball, would be sufficient to throw the body from the moon beyond the point of equal attraction, and cause it to reach the earth. Now there can be little doubt that a force equal to that is exerted by volcanoes on the earth, as well as by the production of steam by subterranean heat, when we consider the huge masses of rock, so many times larger than cannon balls, thrown on such occasions to heights also so much greater. We may easily imagine, too, such cause of motion to exist in the moon as well as in the earth, and that in a superior degree, if we may judge from the supposed symptoms of volcanoes recently observed in the moon by the powerful tubes of Dr Herschel; and still more, if we consider that all projections from the earth suffer an enormous resistance and diminution, by the dense atmosphere of this planet; while it has been rendered probable, from optical considerations, that the motion has little or no atmosphere at all, to give any such resistance to projectiles.

"Thus then we are fully authorized in concluding, that the case of *possibility* is completely made out; that a known power exists in nature, capable of producing the foregoing effect, of detaching a mass of matter from the moon, and transferring it to the earth in the form of a flaming meteor, or burning stone: at the same time we are utterly ignorant of any other process in nature by which the same phenomenon can be produced. Having thus discovered a way in which it is possible to produce those appearances, we shall now endeavour to show, from all the concomitant circumstances, that these accord exceedingly well with the natural effects of the supposed cause, and thence give it a very high degree of *probability*.

"This important desideratum will perhaps be best attained, by examining the consequences of a substance supposed to be projected by a volcano from the moon into the sphere of the earth's superior attraction; and then comparing those with the known and visible phenomena of the blazing meteors or burning stones that fall through the air on the earth. And if in this comparison a striking coincidence or resemblance shall always or mostly be found, it will be difficult for the human mind to resist the persuasion that the assumed cause involves a degree of probability but little short of certainty itself. Now the chief phenomena attending these blazing meteors or burning stones, are these: 1. That they appear or blaze out suddenly. 2. That they move with a surprising rapid motion, nearly horizontal, but a little inclined downwards. 3. That they move in several different directions with respect to the points of the compass. 4. That in their flight they yield a loud whizzing sound. 5. That they commonly burst with a violent explosion and report. 6. That they fall on the earth with great force in a sloping direction. 7. That they are very hot at first, remain hot a considerable time, and exhibit visible tokens of fusion on their surface. 8. That the fallen stony masses have all the same external appearance and contexture, as well as internally the same nature and composition. 9. That they are totally different from all our terrestrial bodies, both natural and artificial.

"Now these phenomena will naturally compare with the circumstances of a substance projected by a lunar volcano, and in the order in which they are here enumerated. And first, with respect to the leading circumstance, that of a sudden blazing meteoric appearance, which is not that of a small bright spark, first seen at at immense distance, and then gradually increasing with the diminution of its distance. And this circumstance appears very naturally to result from the assumed cause. For, the body being projected from a lunar volcano, may well be supposed in an ignited state, like inflamed matter thrown upon by our terrestrial volcanoes, which passing through the comparatively vacuum, in the space between the moon and the earth's sensible atmosphere, it will probably enter the superior parts of this atmosphere with but little diminution of its original

nal heat; from which circumstance, united with that of its violent motion, this being 10 or 12 times that of a cannon ball, and through a part of the atmosphere probably consisting chiefly of the inflammable gas rising from the earth to the top of the atmosphere, the body may well be supposed to be suddenly inflamed, as the natural effect of these circumstances; indeed it would be surprising if it did not. From whence it appears, that the sudden inflammation of the body, on entering the earth's atmosphere, is exactly what might be expected to happen.

"2. To trace the body through the earth's atmosphere; we are to observe that it enters the top of it with the great velocity acquired by descending from the point of equal attraction, which is such as would carry the body to the earth's surface in a very few additional seconds of time if it met with no obstruction. But as it enters deeper in the atmosphere, it meets with still more and more resistance from the increasing density of the air, by which the great velocity of six miles per second must soon be greatly reduced to one that will be uniform, and only a small part of its former great velocity. This remaining part of its motion will be various in different bodies, being more or less as the body is larger or smaller; and as it is more or less specifically heavy; but, for a particular instance, if the body were a globe of 12 inches diameter, and of the same gravity as the atmospheric stones, the motion would decrease so as to be little more than a quarter of a mile per second of perpendicular descent. Now while the body is thus descending, the earth itself is affected by a twofold motion, both the diurnal and the annual one, with both of which the descent of the body is to be compounded. The earth's motion of rotation at the equator is about 17 miles in a minute, or two-sevenths of a mile in a second; but in the middle latitudes of Europe little more than the half of that, or little above half a quarter of a mile in a second; and if we compound this motion with that of the descending body, as in mechanics, this may cause the body to appear to descend obliquely, though but a little, the motion being nearer the perpendicular than the horizontal direction. But the other motion of the earth, or that in its annual course, is about 20 miles in a second, which is 80 times greater than the perpendicular descent in the instance above mentioned; so that, if this motion be compounded with the descending one of the body, it must necessarily give it the appearance of a very rapid motion, in a direction nearly parallel to the horizon, but a little declining downwards. A circumstance which exactly agrees with the appearances of these meteoric bodies, as stated in the second article of the enumerated phenomena.

"3. Again, with regard to the apparent direction of the body; this will evidently be various, being that compounded of the body's descent and the direction of the earth's annual motion at the time of the fall, which is itself various in the different seasons of the year, according to the direction of the several points of the ecliptic to the earth's meridian or axis. Usually, however, from the great excess of the earth's motion above that of the falling body, the direction of this must appear to be nearly opposite to that of the former. And in fact this exactly agrees with a remark made by Dr Halley, in his account of the meteors in his paper above given, where he says that the direction of the meteor's motion was exactly opposite to that of the earth in her orbit. And if this shall generally be found to be the case, it will prove a powerful confirmation of this theory of the lunar substances. Unfortunately, however, the observations on this point are very few, and mostly inaccurate; the angle or direction of the fallen stones has not been recorded; and that of the flying meteor commonly mistaken, all the various observers giving it a different course, some even directly the reverse of others. In future, it will be very advisable that the observers of fallen stones, observe and record the direction or bearing of the perforation made by the body in the earth, which will give us perhaps the course of the path nearer than any other observation.

"4. In the flight of these meteoric stones, it is commonly observed, that they yield a loud whizzing sound. Indeed it would be surprising if they did not. For if the like sound be given by the smooth and regularly formed cannon ball, and heard at a considerable distance, how exceedingly great must be that of a body so much larger, which is of an irregular form and surface too, and striking the air with 50 or 100 times the velocity.

"5. That they commonly burst and fly in pieces in their rapid flight, is a circumstance exceedingly likely to happen, both from the violent state of fusion on their surface, and from the extreme rapidity of their motion through the air. If a grinding stone, from its quick rotation, be sometimes burst and fly in pieces, and if the same thing happen to cannon balls when made of stone and discharged with considerable velocity, merely by the friction and resistance of the air; how much more is the same to be expected to happen to the atmospheric stones, moving with more than 50 times the velocity, and when their surface may well be supposed to be partly loosened or dissolved by the extremity of the heat there.

"6. That the stones strike the ground with a great force, and penetrate to a considerable depth, as is usually observed, is a circumstance only to be expected from the extreme rapidity of their motion, and their great weight, when we consider that a cannon ball, or a mortar shell, will often bury itself many inches, or even some feet in the earth.

"7. That these stones, when soon sought after and found, are hot, and exhibit the marks of recent fusion, are also the natural consequences of the extreme degree of inflammation in which their surface had been put during their flight through the air.

"8. That these stony masses have all the same external appearance and contexture, as well as internally the same nature and composition, are circumstances that strongly point out an identity of origin, whatever may be the cause to which they owe so generally uniform a conformation. And when it is considered,

"9. That in those respects they differ totally from all terrestrial compositions hitherto known or discovered, they lead the mind strongly to ascribe them to some other origin than the earth we inhabit; and none so likely as coming from our neighbouring planet.

"Upon the whole then (continues Dr Hutton), it appears

appears highly probable, that the flaming meteors, and the burning stones, that fall on the earth, are one and the same thing. It also appears impossible, or in the extremest degree improbable, to ascribe these either to a formation in the superior parts of the atmosphere, or to the eruptions of terrestrial volcanoes, or to the generation by lightning striking the earth. But, on the other hand, that it is possible for such masses to be projected from the moon so as to reach the earth; and that all the phenomena of these meteors or falling stones, having a surprising conformity with the circumstances of masses that may be expelled from the moon by natural causes, unite in forming a body of strong evidence, that this is in all probability and actually the case.

M. Poisson, an ingenious French mathematician, has shown by an algebraical calculation, the possibility of a projectile reaching our planet from the moon. His calculation, however, which may be found in the work of Izarn, quoted above, (p. 238. et seq.) proceeds on the supposition that our satellite has no atmosphere, or next to none. There are, no doubt, appearances which seem to favour this supposition, but they do not amount to positive proof of the fact. Even could the latter be established, the combustion of a volcano, without the presence of atmospheric air, would remain to be explained. But, granting this difficulty too to be surmounted, there are other circumstances which we cannot easily reconcile to the lunar hypothesis. The occasional arrival of fragments of lava on the earth's surface, would argue, on a fair computation of chances, such a copious discharge of volcanic matters, that the moon, by this time, would consist of hardly any thing else. Again, if we may be allowed to reason from analogy, the volcanic productions of the moon should exhibit varieties of aspect and composition like those with which we are acquainted, and not a definite and precise number of the same ingredients. We may also remark, that the soft and incoherent state of several of the recent specimens of meteorolites can ill accord with their supposed passage through any considerable portion of space; and that the l'Aigle phenomenon, which is so distinctly recorded, evidently suggests the notion of instantaneous formation in the atmosphere. And, though this view of the subject may be regarded by some as inexplicable, we cannot conceive that it is more so than the doctrine of crystallization, or than many of the results of chemical combination, whose existence it is impossible to deny. These and other arguments may, we apprehend, be fairly urged against any theory which attempts to explain the history of meteors by the agency of lunar volcanoes.

The hypothesis of Dr Chladni, which likewise boasts of its advocates, though still more extravagant than the preceding, deserves to be stated. As earthy, metallic, and other particles form the principal component parts of our planet, among which iron is the prevailing part, other planetary bodies, he affirms, may consist of similar, or, perhaps, the same component parts, though combined and modified in a very different manner. There may also be dense matters accumulated in smaller masses, without being in immediate connexion with the larger planetary bodies, dispersed throughout infinite space, and which, being impelled either by some projecting power or attraction, continue to move until they approach the earth, or some other body; when, being overcome by attractive force, they immediately fall down. By their exceeding great velocity, still increased by the attraction of the earth and the violent friction in the atmosphere, a strong electricity and heat must necessarily be excited, by which means they are reduced to a flaming and melted condition, and great quantities of vapour and different kinds of gases are thus disengaged, which distend the liquid mass to a monstrous size, till, by a still farther expansion of these elastic fluids, they must at length displode. That portions of cosmical matter are allowed to revolve in space, and to terminate their career on the surface of a planet, is a position too gratuitous and vague, to be readily admitted, but the belief of which involves no principle of atheism or impiety, as some of Dr Chladni's antagonists have very unhandsomely insinuated. If worlds disappear and others spring into existence, a sportive imagination may be permitted to indulge in the innocent supposition, that fragments of their materials are detached from their fractured masses, and obey those laws of attraction which seem to extend their influence to the remotest corners of the universe.

Such of our readers as are solicitous of obtaining more ample information on the subject of this article, may consult *Izarn's Lithologie Atmospherique; Biot's Relation d'un Voyage fait dans le departement de l'Orne, pour constater la réalité d'un Météore observè à l'Aigle; Böttiger's Observations on the Accounts given by ancient authors of Stones said to have fallen from the Clouds; Fulda's Memoir on Fire-balls; Cavallo's Elements of Natural Philosophy; Klaproth on Meteoric Stones; Soldani's Account of the Tuscan Meteor; Chladni's Treatise on the Siberian Mass of Iron; Mr Edward King's Remarks concerning Stones said to have fallen from the Clouds;* and several of the more recent transactions of learned societies and periodical scientific communications, as those of the Royal Society of London, of the Institute at Paris, the Journal de Physique, Annales de Chimie, Bibliotheque Britannique, Decade Philosophique, Journal des Mines, Philosophical Magazine, Nicholson's Journal, &c. &c.

METEOROLOGICAL, something belonging to meteors.

METEOROLOGICAL Journal, is a table recording the daily state of the air, exhibited by the barometer, thermometer, hygrometer, anemometer, and other meteorological instruments. We have many journals of this kind, kept at the house of the Royal Society, and by different observers in other places, in the Philosophical Transactions, the Memoirs of the Academy of Sciences, and similar publications.

METEOROLOGY.

INTRODUCTION.

1 bject of eteoro- gy.

METEOROLOGY is that part of natural science which treats of the changes that take place in our atmosphere, as they are perceptible to our senses, or as they are indicated by certain instruments which the ingenuity of man or accident has discovered to answer that purpose. In as far as it describes the phenomena produced by such changes, meteorology is a department of natural history; but in its attempts to account for the appearances, it is almost entirely dependent on NATURAL PHILOSOPHY and CHEMISTRY.

2 s connec- on with emistry.

The connection of METEOROLOGY with CHEMISTRY is sufficiently evident to those who take only a superficial view of the subject, though it has only of late attracted the notice of philosophers. That the air is sometimes hotter and sometimes colder than usual; that it is at one time much rarefied, and at another greatly condensed; now uncommonly dry, and now surcharged with moisture—are circumstances that daily meet the senses of the most casual observer, as they are circumstances that powerfully, and often unpleasantly, arrest his attention. That these changes are the result of decompositions and combinations that are continually going on in the atmosphere, and of new modifications of its component principles, is manifest to him who is acquainted merely with the first elements of modern chemistry.

3

Indeed to modern chemistry this science is indebted for the progress it has made within the last 50 years; a period which may be considered as the second epoch of meteorology. In fact, this science is still in its infancy; but from the ardour with which it is now cultivated, from the abilities of the philosophers who are engaged in the study, and from the progress that is daily making in the kindred sciences, we may reasonably look forward to a period, at no great distance, when it shall please the great Author of nature to unveil many of those wonders which are now involved in darkness and obscurity, and permit us to controul the jarring elements, as he has allowed us to exercise dominion over the beasts of the earth, the fowls of the air, and the fishes of the sea.

4 Ieans of nproving ieteoro- gy.

A late ingenious writer on the climate of Britain has suggested some useful hints for the improvement of meteorology, which we shall here extract. "With this view, our first step must be *that* recommended by Mr Kirwan and others, to establish corresponding societies in different parts of the world; these societies must be furnished with similar apparatus, equally adjusted, and graduated in their construction, for making observations on the weather. In our own island it will be necessary to procure registers, carefully kept, from the different parts of the sea coast, and from those parts of the country situated in the interior. The various states of the barometer, thermometer, hygrometer, and electroscope, should be carefully noted; with the variations and the degrees of wind, as well as the diurnal and nocturnal aspect of the heavens discriminately marked; the appearance of the sky; and in familiar language, such as might be understood by the respective and distant observers; for instance, whether the sun is totally or partially obcured by vapour;—whether the clouds are mottled, or fleaky;—whether they assume the appearance of horizontal streaks, or appear in radii apparently from a centre—or in masses of dense vapour—or loose and fleecy—or those familiarly known by the name of *mare-tail* clouds—with any other new or accustomed phenomena. The common terms *fair*, *cloudy*, or *wet*, are insufficient for forming a judgment of the weather; as the term fair is generally at present expressed only in opposition to *rain*, without distinguishing whether the atmosphere is obscure, dull, or bright. The appearance of the stratum of air on the earth's surface, *that is, the space between the clouds and the earth*, should be always accurately described. Is there a blue haze, white mist, and dense fog? or is the air transparent? which is the case when distant objects appear more than commonly distinct and near to the eye of the observer: the temperature of the ocean at *full tide* should be frequently ascertained, as it will be found to have considerable influence in these respects on an insular country. By the remarks of observers, stationed in various parts of our coasts, we should soon be enabled to discover when vapour is wafted in from the sea, or generated by the aqueous and vegetable surface of our island. During a north-west wind, which is frequently attended with storms of hail and rain, and usually experienced in the spring, an observer stationed on the coast of Sligo in Ireland, or Denbighshire in Wales, might ascertain whether the disposition of the atmosphere to storm and cloud came in with the air from the Atlantic ocean, or was generated by the vapours of our own island. It would be desirable also again, that the temperature and blue hazy appearance of the atmosphere during the north-east winds, so common in May and June, should be noticed by observers on the north-east coast, in the counties of York, Lincoln, Essex, and Kent; and by others, on the opposite western coasts of Pembroke, Devon, and Cornwall, so as to determine what changes in temperature this wind undergoes in its passage over the island; and whether or not the degree of haze increases or diminishes by its progress from either quarter; and whether the vapour is more or less disposed to produce storms?

By such comparative observations on the coast, conjoined with those made by others in the central parts of the kingdom, we might rapidly proceed in meteorological science, or, as it is commonly called, a knowledge of the weather. The observations made in the interior of the country would enable us at all times to trace the origin and progress of storms: in situations where tillage or pasturage is most attended to, the effects of spring frosts and blights should be particularly noticed, as well as the first appearance of the aphis and coccus, the caterpillar and larvæ of other insects, on fruit trees, and particularly those peculiar to the *hop plantations*. The first opening of the vernal foliage on trees and hedges in the spring, should likewise be remarked, and compared with the starting up grass on the highly

Introduction.

highly manured pastures in the neighbourhood of towns, and on those also assisted with manure, as well as the natural herbage on the commons and wastes. Some attention should be paid to the effects of thunder storms, in destroying the aphis and other destructive insects, the pest of fruit and hop plantations; and the first appearance of the mildew or rust on wheat should be particularly observed, and remarks made to ascertain, whether or not the moisture, which occasions the disease in its commencement was attended with wind and rain, or a close damp state of the air. The different kinds of soil, where the crops, from the disease, suffered most, should be noticed, and the situation of the land for ventilation, with the height of the fences, size of inclosures, and vicinity to coppices, trees, or hedge-rows*."

* *Williams on the Climate of Britain.*

Importance of the science.

The importance of the study of meteorology requires little elucidation. In climates where the succession of seasons is nearly stated and regular, where the periods of parching drought or deluging torrents, of the tempestuous hurricane or the refreshing breeze, are fixed and ascertained, mankind has little to do, but expect the dreaded changes, and provide against their devastations; but in countries like our own, where all the vicissitudes of seasons may take place in the course of a few hours, it is of the highest consequence to investigate the nature of the change, and the circumstances that precede or accompany it. To the farmer, the mariner, the traveller, the physician, meteorology is in some measure a study of necessity; to the philosopher it is a study of interest and delight; and to the observer of nature it affords objects of grandeur and sublimity not to be found in any other department of his favourite science. Surely nothing can contribute more to elevate the mind of man, to raise it "from nature up to nature's God," than the contemplation of the sweeping whirlwind, the dazzling lightning, or the awful thunder.

Our limits will not admit of our entering into a historical detail of the progress of meteorology; but it may be proper in this place to enumerate the principal writers on this science both in our own country and on the continent.

6 Writers on meteorology.

In this country, we may reckon Dr Kirwan, (in his "Estimate of the Temperature of different Climates"), his "Essay on the Variations of the Atmosphere," and in the Irish Transactions," Mr John Dalton (chiefly in the "Manchester Memoirs"), Col. Capper (in his "Observations on the Winds and Monsoons"), Mr Williams (in his "Climate of Great Britain"), and Mr Luke Howard (in the Philosophical Magazine), as the principal cultivators of meteorological knowledge; and on the continent, the names of Cotte ("*Traite de Metcorologie*," and *Journal de Physique*), Saussure ("*Essai sur l'Hygrometrie*," and *Voyage aux Alpes*"), De Luc (A) ("*Recherches sur les Modifications de l'Atmosphere*," "*Idees sur la Meteorologie*," and other works), and Lamarck (see *Journ. de Phys.* passim) stand most conspicuous in this branch of natural science. The names of some of the more recent writers are mentioned in the article METEOROLOGY, SUPPLEMENT, which see.

7 In considering the subject of meteorology, we may properly divide it into seven general heads: 1. Of the changes which take place in the gravity of the air; 2. Of the changes of the temperature of the air; 3. Of the changes produced by evaporation and rain; 4. Of the changes produced by winds; 5. Of atmospherical electricity; 6. Of meteors, or those visible phenomena accompanied with light, which take place in the atmosphere or near the surface of the earth; and, 7. The application of the principles of meteorology to the useful purposes of life. Of these heads, the fifth has been already fully considered under ELECTRICITY, and much of the sixth has been exhausted under METEOROLITE. The remaining circumstances will form the subjects of the following chapters.

CHAP. I. *Of the Changes which take place in the Gravity of the Air.*

MANY of the facts relating to this part of our subject have been already anticipated under the article BAROMETER, and several circumstances fall to be considered more properly under PNEUMATICS than in this place. We shall here confine ourselves to a general view of the changes in the gravity of the atmosphere, as indicated by the barometer, in various situations on or near the surface of the earth, and briefly examine the conclusions that may be drawn from them.

8 Mercury stands highest at the level of the sea.

The most general fact indicated by the barometer is, that this instrument shews us the weight of a column of air

(A) In again mentioning the name of a philosopher so respectable as M. de Luc, we embrace the first opportunity of doing him justice, and of vindicating his character against an unfortunate misconception of the late Professor Robison, a mistake which we have inadvertently contributed to disseminate, by quoting Dr Robison's statement in our account of Dr Black, where M. de Luc is accused of having arrogated to himself Dr Black's discovery of *latent heat*.

M. de Luc's vindication of himself (as printed in the 12th number of the Edinburgh Review) is before the public. We owe it to candour and justice to acknowledge our conviction that Dr Robison was too hasty in his assertion, and that M. de Luc, so far from arrogating to himself the doctrine of *latent heat*, has, in various parts of his numerous writings, expressly mentioned Dr Black as the author of that doctrine. This will appear from the following citations. In his "Introduction à la Physique terrestre," p. 102, M. de Luc thus expresses himself. "Ne connoissant point le *feu latent*, dans la vapeur à toute temperature, *dont la premiere decouverte est due au* Dr Black, &c. Again, p. 232. of the same work. "Ce qui developpoit l'idée de *chaleur latente par laquelle le Dr Black avoit designé ce phénomêne*,"—and at p. 385, "Le Dr Black ayant découvert qu'une certaine quantité de chaleur disparoit quand la vapeur de l'eau bouillante se forme, *nomma ce phénoméne chaleur latente* dans la vapeur."

We trust that these quotations, with M. de Luc's own justification of himself above referred to, will be sufficient to exculpate him from the charge of *literary felony* so warmly brought against him by Professor Robison; and we have no doubt the Professor himself, were he still alive, would under such evidence retract his accusation.

Gravity of the Air.

air whose base is equal to the diameter of the mercury in the tube, and whose height is equal to the extent of the atmosphere above the place of observation. As the height of this column must vary in different situations, and must, *cæteris paribus*, be greatest at the level of the sea, the mercury in the tube will, under the same circumstances, stand highest in such a situation.

9 Medium height 30 inches.

The medium height of the barometer at the level of the sea is 30 inches, as has been found by observations in the British channel, and in the Mediterranean sea, at the temperatures of 55° and 60°; on the coast of Peru at the temperature of 84°, and in latitude 80°. As we ascend above the surface of the earth, the medium height of the mercury diminishes; and some late observations made in balloons at a considerable distance above the tops of the highest mountains, have shewn that in the higher regions of the air, the column of mercury is very considerably shortened. This fact, as we have seen (see BAROMETER), has been usefully applied to the measuring of heights and depths that cannot be ascertained by the usual geometrical methods. As the absolute gravity of the atmosphere is constantly varying even in the same place, the column of air pressing on the surface of the mercury without the tube, must press with more or less force, in proportion as these changes are greater; and hence the barometer points out these variations, falling when the atmosphere is lighter, and rising when it is heavier than usual. For an account of the observations that were made on the rise and fall of the barometer by the earlier philosophers, and the attempts which were made by them to explain these phenomena, see BAROMETER.

It will be of advantage here to consider the variations of the barometer, as they take place in different situations, in order, if possible, to point out the cause by which these variations are produced, as this cause must have considerable influence on the changes of the weather.

10 [V]ariation [in] the baro[m]eter be[tw]een the [tr]opics very [sm]all.

It is found, that between the tropics the variations of the barometer are exceedingly small, and it is remarkable, that in that part of the world it does not descend above half as much for every 200 feet of elevation as it does beyond the tropics *. In the torrid zone, too, the barometer is elevated about $\frac{2}{3}$ of a line twice every day; and this elevation happens at the same time with the tides of the sea †.

As the latitude advances towards the poles, the range of the barometer gradually increases, till at last it amounts to two or three inches. This gradual increase will appear from the following table.

Table of the Range of the Barometer.

** Edin. [Tr]ans. vol. p. 229.

There is, however, some exception to this general rule, as in North America the range of the barometer is much less than in the corresponding European latitudes.

The range of the barometer is greater at the level of the sea than on mountains, and in the same degree of latitude the extent of the range is in the inverse ratio of the height of the place above the level of the sea.

It appears probable that the barometer has a tendency to rise during the day from morning to evening, and that this tendency is greatest between 2 and 9 P. M. the greatest elevation being at this last period. The elevation at 2 differs from that at 9 by $\frac{4}{12}$, while that at 2 differs from the morning elevation only by $\frac{1}{12}$; and that in certain climates the greatest elevation takes place at 2 o'clock *.

The range of the barometer is greater in winter than in summer, as appears from some observations made at Kendal during five years; the mean range from October to March being 7.982, and that from April to September being only 5.447 †.

* Jour. de Phys. 1790. p. 11.

† Manchest. Mem. vol. iv. p. 547.

When the atmosphere is serene and settled the mercury is generally high; and in calm weather, when it is inclined to rain, the mercury is low. On the approach of high winds it sinks, as it does with a southerly wind, but rises very high on the approach of easterly and northerly winds. It is found, however, that at Calcutta the mercury is highest with north-westerly and northerly, and lowest with south-easterly winds.

The mercury suddenly falls on the approach of tempests, and during their continuance undergoes great oscillations.

To these general facts that have been observed on the rise and fall of the barometer, we shall annex the following axioms by M. Cotte. 12

Cotte's axioms on the barometer.

1. The greatest changes of the barometer commonly take place during clear weather, with a north wind; and the small risings during cloudy, rainy, or windy weather, with a south, or nearly south wind.

2. The state of the mercury changes more in the winter than in the summer months; so that its greatest rising and falling takes place in winter; but its mean elevation is greater in summer than in winter.

3. The changes of the state of the barometer are nearly null at the equator, and become greater the more one removes from it towards the poles.

4. They are more considerable in valleys than on mountains.

5. The more variable the wind, the more changeable the state of the barometer.

6. It is lower at midnight and noon than at other periods of the day; its greatest daily height is towards evening.

7. Between 10 at night and 2 in the morning, and also in the day, the rising and falling of the mercury are less; the contrary is the case between 6 and 10 in the morning and evening.

8. Between 2 and 6 in the morning and evening it rises as often as it falls; but in such a manner that it oftener rises about that time in the winter months, and falls oftener in the summer months.

9. The oscillations are less in summer, greater in winter, and very great at the equinoxes.

10. They

Gravity of the Air.

10. They are greater also in the daytime than during the night.

11. The higher the sun rises above the horizon, the less are the oscillations; they increase as he approaches the western side of the horizon, and are exceedingly great when he comes opposite to the eastern part of the horizon.

12. They are, to a certain degree, independent of the changes of temperature.

13. The mercury generally rises between the new and the full moon, and falls between the latter and the new moon.

14. It rises more in the apogee than the perigee; it usually rises between the northern lunistice and the southern, and falls between the southern lunistice and the northern.

15. In general, a comparison of the variations of the mercury with the positions of the moon gives nothing certain; the results of N° 13. and 14. are the most constant.

16. In the neighbourhood of Paris the barometer never continues 24 hours without changing.

17. The barometers in the western districts rise and fall sooner than those in the more eastern.

18. When the sun passes the meridian, the mercury, if falling, continues to fall, and its fall is often hastened.

19. When the mercury at the same period is rising, it falls, remains stationary, or rises more slowly.

20. When the mercury, under the same circumstances, is stationary, it falls, unless, before or after it becomes stationary, it has been in the act of rising.

21. The above changes commonly take place between 11 in the morning and 1 in the afternoon, but oftener before than after noon.

22. Before high tides there is almost always a great fall of the mercury; this takes place oftener at the full than the new moon.

Such is a general view of the variations in the gravity of the air, as far as they have been observed by the barometer; and we shall now endeavour to give some plausible theory of them.

13 Atmosphere forms two inclined planes meeting at the equator.

It is evident that the density of the atmosphere is least at the equator, and greatest at the poles; for at the equator the centrifugal force, the distance from the centre of the earth, and the heat (all of which tend to diminish the density of the air), are at their maximum, while at the poles they are at their minimum. The mean height of the barometer at the level of the sea, all over the globe, is 30 inches; the weight of the atmosphere, therefore, is the same all over the globe. This weight depends on the density and height of the air; where the density is greatest, its height must be least; and on the contrary, where its density is least, its height must be greatest. The height of the atmosphere, therefore, must be greatest at the equator, and least at the poles; and it must decrease gradually between the equator and the poles, so that its upper surface will resemble two inclined planes, meeting above the equator their highest parts *.

During summer, when the sun is in our hemisphere, the mean heat between the equator and the pole does not differ so much as in winter. Hence the rarity of the atmosphere at the pole, and consequently its height, will be increased. The upper surface of the atmosphere, therefore, in the northern hemisphere, will be less inclined; while that of the southern hemisphere, from contrary causes, will be much more inclined. The reverse will take place during our winter.

The density of the atmosphere depends in a great measure on the pressure of the superincumbent column, and therefore decreases according to the height, as the pressure of the superincumbent column constantly decreases. But the density of the atmosphere in the torrid zone will not decrease so fast as in the temperate and frigid zones, because its column is larger, and because there is a greater proportion of air in the higher part of this column. This accounts for the observation of Mr Casson, that the barometer sinks only half as much for every 200 feet of elevation in the torrid as in the temperate zones. The density of the atmosphere at the equator, therefore, though at the surface of the earth it is less, must at a certain height equal, and at a still greater must exceed, the density of the atmosphere in the temperate zones and at the poles.

14 Why the mercury is highest in winter in northern latitudes.

We shall presently endeavour to prove, that a quantity of air is constantly ascending at the equator, and that part of it at least reaches and continues in the higher parts of the atmosphere. From the fluidity of air it is evident that it cannot accumulate above the equator, but must roll down the inclined plane which the upper surface of the atmosphere assumes towards the poles. As the surface of the atmosphere of the northern hemisphere is more inclined during our winter than that of the southern hemisphere, a greater quantity of the equatorial current of air must flow over upon the northern than upon the southern hemisphere; so that the quantity of our atmosphere will be greater during winter than that of the southern hemisphere; but during summer the reverse will take place. Hence the greatest mercurial heights take place during winter, and the range of the barometer is less in summer than in winter.

The density of the atmosphere is in a great measure regulated by the heat of the place; wherever the cold is greatest, there the density of the atmosphere will be greatest, and its column shortest. High countries, and ranges of lofty mountains, the tops of which are covered with snow the greatest part of the year, must be much colder than other places situated in the same degree of latitude, and consequently the column of air over them much shorter. The current of superior air will linger and accumulate over these places in its passage towards the poles, and thus occasion an irregularity in its motion, which will produce a similar irregularity in the barometer. Such accumulations will be formed over the north-western parts of Asia, and over North America; hence the barometer usually stands higher, and varies less there, than in Europe. Accumulations also are formed upon the Pyrenees, the Alps, the mountains of Africa, Turkey in Europe, Tartary, and Tibet. When these accumulations have gone on for some time, the density of the air becomes too great to be balanced by the surrounding atmosphere; it rushes down on the neighbouring countries, and produces cold winds which raise the barometer. Hence the rise of the barometer which generally attends north-east winds in Europe, as they proceed from accumulations in the north-west of Asia, or about the pole; hence, too, the north-west wind from the mountains of Tibet raises the barometer at Calcutta.

* *Irish Trans* vol. ii. p. 43, &c.

We

ravity of he Air. We shall presently endeavour to shew, that considerable quantities of air are occasionally destroyed in the north polar regions. When this happens, the atmosphere to the south rushes in to supply the deficiency. Hence south-west winds take place, and the barometer falls.

As the mean heat of our hemisphere differs in different years, the density of the atmosphere, and consequently the quantity of equatorial air which flows towards the poles, must also be variable. Does this range correspond to the mean annual heat; that is to say, Is the range greatest when the heat is least, and least when the heat is greatest? In some years greater accumulations than usual take place in the mountainous parts of the south of Europe and Asia, owing, perhaps, to earlier falls of snow or to the rays of the sun having been excluded by long-continued fogs. When this takes place, the atmosphere in the polar regions will be proportionably lighter. Hence the prevalence of southerly winds during some winters more than others.

As the heat in the torrid zone never differs much, the density, and consequently the height, of the atmosphere, will not vary much. Hence the range of the barometer within the tropics is comparatively small; and it increases gradually as we approach the poles, because the difference of the temperature, and consequently of the density, of the atmosphere, increases with the latitude.

The diurnal elevation of the barometer in the torrid zone corresponding to the tides, observed by Mr Casson and others, must be owing to the influence of the moon on the atmosphere. This influence, notwithstanding the ingenious attempts of D'Alembert and several other philosophers, seem altogether inadequate to account for the various phenomena of the winds. It is not so easy to account for the tendency which the barometer has to rise as the day advances. Perhaps it may be accounted for by the additional quantity of vapour added to the atmosphere, which by increasing the quantity of the atmosphere, may possibly be adequate to produce the effect.

The falls of the barometer which precede, and the oscillations which accompany, violent storms and hurricanes, shew us that these phenomena are produced by very great rarefactions, or perhaps destructions of air, in particular parts of the atmosphere. The falls of the barometer, too, that accompany winds, proceed from the same cause. The observation made by Mr Copland, that a high barometer is accompanied by a temperature above the mean, will be easily accounted for by every one acquainted with Dr Black's theory of latent heat. The higher the mercury stands, the denser the atmosphere must be; and the denser it becomes, the more latent heat it must give out. It is well known that air evolves heat when condensed artificially. The falling of the barometer, which generally precedes rain, remains still to be accounted for; but we know too little about the causes by which rain is produced, to be able to account for it in a satisfactory manner.

It has been for some time suspected that the variation of the barometer is affected by the changes of the moon. The theory of lunar influence has been discussed on the continent chiefly by Lamarck and Cotte, (see Journal de Physique, *passim*); and in this country by Mr Luke Howard. Mr Howard's suspicions of this influence on the barometer were first conceived, in consequence of the printed charts, of which he made use in keeping a register of the barometer, having the phases of the moon marked on them, and of his observing a remarkable coincidence between these and certain states of the mercury. This coincidence consists in the depression of the barometrical line on the approach of the new and full moon, and its elevation on that of the quarters. In above 30 out of the 50 lunar weeks in the year 1798, the barometer was found to have changed its general direction once in each week, in such a manner as to be either rising or at its *maximum*, for the week preceding and following, about the time of each quarter; and to be either falling or at its *minimum*, for the two weeks, about the new and full. It is remarkable, that the point of greatest depression during the year, viz. to 28.67, was found about 12 hours after the new moon on the 8th of November; and, that at its greatest and extraordinary elevation to 30.89, on the 7th of February, at the time of the last quarter. Moreover, this coincidence appeared to take place most regularly in fair and moderate weather; and, in general, when the barometer fell, during the interval between the new or full moon and the quarters, an evident perturbation in the atmosphere accompanied; of which may be instanced February 15. to 23. when the barometer, after an uncommon rise, continued to fall rapidly after the new moon, with severe cold, which ended suddenly in stormy and wet weather: again, June 13. to 20. when two weeks of fair weather ended in a thunder storm. In the greater part of December the usual coincidence disappeared, and the converse took place; the barometer being low at the quarter and high at the full, amidst continual alternations of rain, frost, and snow, and, for part of the time, high winds. On the two days preceding the last quarter, the barometer rose rapidly, and rain followed.

Gravity of the Air.

On the whole, Mr Howard thought there appeared sufficient ground, on the evidence of the year 1798, to suppose that the gravity of our atmosphere, as indicated by the barometer, may be subject to certain periodical changes, effected by a cause more steady and regular than either change of temperature, currents, or solution and precipitation of water, to which he believes the whole variation has been heretofore attributed.

The mean of the register at large appeared to be 29.89, whence it appears that the depression at the new and full moon either amounted to more, on the whole, than the elevations at the quarters, or that they fell out nearer to the time. He was quite satisfied, in passing through this register, that if he had allowed himself to choose the higher rotations about the quarters, and the lower about the new and full, with a latitude of 24 or 36 hours, it would have made the results as much more favourable to his conclusions as in the former case.

Now, to omit the consideration of other proofs for the present, it appeared to him evident, that the atmosphere is subject to a periodical change of gravity, whereby the barometer, on a mean of ten years, is depressed at least one-tenth of an inch while the moon is passing from the quarters to the full and new; and elevated, in the same proportion, during the return to the quarter. To what causes shall we attribute this periodical change, other than the attraction of the sun and moon for the matter composing the atmosphere?

The atmosphere is a gravitating fluid, differing, in a physical

Temperature of the Air.

physical sense, from the water, chiefly in possessing less gravity; and it is demonstrated *à priori* on the principles of the Newtonian philosophy, that it ought to have its tides as well as the ocean, although in a degree as much less perceptible as is its gravity.

He supposes, therefore, that the joint attractions of the sun and moon at the new moon, and the attraction of the moon predominating over the sun's weaker attraction at the full, tend to depress the barometer, by taking off from the gravity of the atmosphere, as they produce a high tide in the waters, by taking off from their gravity; and, again, that the attraction of the moon being diminished by that of the sun at her quarters, this diminution tends to make a high barometer, together with a low tide, by permitting each fluid to press with additional gravity upon the earth *.

* *Phil. Mag.* vol. vii. p. 355.

Chap. II. *Of the Changes which take place in the Temperature of the Air.*

It is obvious to the most careless observer, that the temperature of the air varies considerably even in the same place, and at the same season. This constant variation must be attributed to the reflected rays of the sun, which communicate heat from the surface of the earth to the surrounding atmosphere. As from this cause the heat of those places which are so situated as to be most warmed by the sun's rays is always greatest, and as this temperature varies in every place with the season of the year, and diminishes according to the height of the air above the surface; and as the earth at the equator is exposed to the most perpendicular rays of the sun, the earth is there hottest, and its heat diminishes gradually from the equator to the poles. Of course, the temperature of the air must vary in the same manner, being hottest over the equator, and diminishing in temperature towards the poles, where it is coldest. Though it is hottest at the equator, its heat, as in all other situations, gradually diminishes there, as we ascend above the surface of the earth.

Temperature of the Air.

Though there is a considerable difference in every part of the world between the temperature of the atmosphere in summer and in winter; though in the same season the temperature of almost every day, and even every hour, differs from that which precedes and follows it; though the heat varies continually in the most irregular and seemingly capricious manner—still there is a certain mean temperature in every climate, which the atmosphere has always a tendency to observe, and which it neither exceeds nor comes short of beyond a certain number of degrees. What this temperature is, may be known by taking the mean of tables of observations kept for a number of years; and our knowledge of it must be the more accurate the greater the number of observations is.

15 Mean annual temperature greatest at the equator.

The mean annual temperature is greatest at the equator (or at least a degree or two on the north side of it), and it diminishes gradually towards the poles, where it is least. This diminution takes place in arithmetical progression, or, to speak more properly, the annual temperatures of all the latitudes are arithmetical means between the mean annual temperature of the equator and that of the pole. This was first ascertained by Mr Meyer; and Dr Kirwan, improving on Meyer's hint, has calculated in the following table the mean annual temperature of every latitude between the equator and the pole. It must be remarked, however, that this table is calculated only for a particular part of the earth's surface, viz. that part of the Atlantic ocean which lies between the 80° of northern, and the 45° of southern latitude, extending westward as far as the Gulf stream, and to within a few leagues of the coast of America, and for all that part of the Pacific ocean that reaches from 45° of north latitude to 40° of south latitude, and extending between the 20th and 275th degree of longitude east from London. This part of the ocean is called by Dr Kirwan the standard, and was best suited to his purpose, as the rest of the ocean is subject to irregularities, which will be noticed presently (D). See the Article Climate, Supplement.

Dr

(D) In calculating this table, Dr Kirwan proceeded on the following principle. Let the mean annual heat at the equator be m and at the pole $m-n$; but φ for any other latitude; the mean annual temperature of that latitude will be $m - n \times \sin.\ \varphi^2$. If, therefore, the temperature of any two latitudes be known, the value of m and n may be found. Now, the temperature of north latitude 40° has been found by the best observations to be 62.1°,

and

Dr Kirwan has also calculated in the following table the mean monthly temperature of the same standard (E).

Latit.

and that of latitude 50°, 52.9°. The square of the sine of 40° is nearly 0.419, and the square of the sine of 50° is nearly 0.586. Therefore,

$$m - 0.41\ n = 62.1, \text{ and}$$
$$m - 0.58\ n = 52.9; \text{ therefore,}$$
$$62.1 + 0.41\ n = 52.9 + 058\ n,$$

as each of them, from the two first equations, is equal to m. From this last equation the value of n is found to be nearly 53; and m is nearly equal to 84. The mean temperature of the equator, therefore, is 84°, and that of the pole 31°. To find the mean temperature for every other latitude we have only to find 88 arithmetical means between 84 and 31.

(E) In calculating the table of mean monthly temperature, Dr Kirwan proceeded on the following principles. The mean temperature of April seems to approach very nearly to the mean temperature of the whole year, and as far as heat depends on the action of the solar rays, the mean heat of each month may be considered as propor-

tional

Temperature of the Air.

16 It appears from the above table that January is the coldest month in every latitude; that July is the warmest month in all latitudes above 48°; that in lower latitudes August is generally the warmest month; that the difference between the hottest and coldest months increases according to the distance of the place from the equator. All habitable latitudes are found to enjoy a medium heat of 60° for at least 2 months, which is a very favourable circumstance, as probably no corn could be produced under a lower medium temperature. The temperatures within 10° of the poles differ very little, nor do they differ much within 10° of the equator. Hence it was unnecessary to note these latitudes in the table. The temperatures of different years vary but little near the equator, but this difference increases more and more as the latitudes approach the poles.

17 Temperature decreases as we ascend in the air.

It is well known that the temperature of the atmosphere gradually diminishes according to the height of the place above the level of the sea. It was found by Dr Hutton of Edinburgh, that a thermometer kept on the top of Arthur's seat, a height of about 800 feet, usually stood 3° lower than one kept at the foot of this hill; and Bouguer observed that on the top of Pinchincha, a height of about 15564 feet, a thermometer stood 54° lower than it did at the level of the sea in the same latitude.

We are indebted to Dr Kirwan for a very ingenious method of determining the rate of the diminution in the temperature in particular cases, having the temperature of the surface of the earth given. The temperature of the atmosphere constantly diminishing as we rise above the level of the sea, we must at a certain height arrive at a point where a perpetual congelation takes place. This point must vary in height according to the latitude, being highest at the equator, and coming gradually nearer the earth as we approach the poles; it must vary also with the season, being highest in summer, and lowest in winter. The cold on the top of Pinchincha was found by M. Bouguer to extend from 7° to 9° below the freezing point every morning just before sunrise; hence he concluded that between the tropics the medium height of the term of congelation (where it freezes at some part of the day all the year round) should be fixed at 15577 feet above the level of the sea; but in latitude 28°, and during the summer, at 13440 feet. If we take the difference between the temperature at the equator, and the freezing point, this difference will bear the same proportion to the term of congelation at the equator, that the difference between the medium temperature at any other latitude and the freezing point bears to the term of congelation at that latitude. Suppose the medium heat at the equator to be 84°, the difference between which and 32° is 52°; and suppose the medium heat of latitude 28° to be $72\frac{3}{10}$°, the difference between which and 32° is $40\frac{3}{10}$°. Then by the following proportion, $52° : 15577 = 40\frac{3}{10} : 12{,}72°$ gives us the term of congelation at 28°. In this way Dr Kirwan proceeded in calculating the following table.

18 Term of perpetual congelation.

Lat.

tional to the mean altitude of the sun, or rather to the sine of that altitude. If, therefore, we have the mean heat of April, and the sine of the sun's altitude given, the mean heat of May may be found by the following proportion:

As the sine of the sun's mean altitude in April : the mean heat of April = the sine of the sun's mean altitude in May : mean heat of May.

In the same manner the mean heat of June, July, and August may be found; but for the temperature of the succeeding months we must take into consideration another circumstance, since the above rule would make the temperature of these months too low, as it does not take in the heat derived from the earth, which is nearly equal to the mean annual temperature. The real mean heats of these months must be considered as an arithmetical mean between the astronomical and terrestrial heats. Thus, for latitude 51°, the astronomical heat of September being 44.6°, and the mean annual heat 52.4°, the real heat of September ought to be $\frac{44.6+52.4}{2} = 48.5$. Dr Kirwan, however, after going through a tedious calculation, found the results to correspond so little with actual observation, that he drew up the table partly from calculating from principles, and partly from an examination of several sea journals.

Temperature of the Air.

40	9016		

This last height of 120 feet M. Bouger called the lower term of congelation. He also distinguished another term of congelation above which no visible vapour rises, and this he called the upper term of congelation. This line is considered by Kirwan as much less variable during the summer months than the lower line, and it has therefore been adopted by him to determine the rate of diminution in the temperature as we ascend into the atmosphere. He has calculated its height for every degree of north latitude in the following table.

N. Lat.	Feet.	N. Lat.	Feet.	N. Lat	Feet.	N. Lat	Feet.

Temperature of the Air.

From the modes of estimating the diminution of temperature now given, which agree extremely well with observation, we find that the temperature diminishes in arithmetical progression, and hence we infer that the temperature of the air at a distance from the earth is owing to the conducting power of the air, and not to the ascent of hot air from the surface of the earth.

19 Temperature of the air above the earth owing to the conducting power of the air.

It is however found that in winter the upper strata of the air are often warmer than the lower; and this superior heat, almost constantly observed in winter, is attributed by Dr Kirwan to a current of warm air from the equator, rolling towards the north pole during our winter *.

We have now given the general method of finding the medium annual temperature all over the globe; but there are several exceptions to our general inferences which must be particularly mentioned.

* Irish Trans. vol. viii. p. 375.

20 Temperature of the North Pacific ocean.

That part of the Pacific ocean which lies between north latitude 52° and 60° is no broader at its northern extremity than 42 miles, and at its southern extremity its breadth scarcely exceeds 1300 miles: it is reasonable to suppose, therefore, that its temperature will be considerably influenced by the surrounding land, which consists of ranges of mountains, covered a great part of the year with snow; and there are besides a great many high, and consequently cold, islands scattered through it. For these reasons Dr Kirwan concludes, that its temperature is at least 4° or 5° below the standard. But we are not yet furnished with a sufficient number of observations to determine this with accuracy.

21 Of the southern hemisphere.

It is the general opinion, that the southern hemisphere beyond the 40° of latitude is considerably colder than the corresponding parts of the northern hemisphere. See America.

22 Of small seas.

Small seas surrounded with land, at least in temperate and cold climates, are generally warmer in summer and colder in winter than the standard ocean, because they are much influenced by the temperature of the land. The gulf of Bothnia, for instance, is for the most part frozen in winter; but in summer it is sometimes heated to 70°, a degree of heat never to be found in the opposite part of the Atlantic. The German sea is above 3° colder in winter, and 5° warmer in summer, than the Atlantic. The Mediterranean sea is, for the greater part of its extent, warmer both in summer and winter than the Atlantic, which therefore flows into it. The Black sea is colder than the Mediterranean, and flows into it.

The eastern parts of North America are much colder than the opposite coast of Europe, and fall short of the standard

(F) Dr Kirwan has given us the following rule for ascertaining the temperature at any required height, supposing we know the temperature of the surface of the earth.

For the temperature observed at the surface of the earth, put m; for the given height h, and t for the height of the upper term of congelation at the given latitude; then $\dfrac{m-32}{\dfrac{t}{100}-1}=$ the diminution of temperature for every 100 feet of elevation; or it is the common difference of the terms of the progression required. Let this common difference thus found be denoted by c; then $c \times \dfrac{h}{100}$ gives us the whole diminution of temperature from the surface of the earth to the given height. Let this diminution be denoted by d, then $m-d$ is obviously the

Temperature of the Air.

standard by about 10° or 12°, as appears from American meteorological tables. The causes of this remarkable difference are many. The highest part of North America lies between 40° and 50° of north latitude, and 100° and 110° of longitude west from London, for there the greatest rivers originate. The very height, therefore, makes this spot colder than it would otherwise be. It is covered with immense forests, and abounds with large swamps and morasses, which render it incapable of receiving any great degree of heat; so that the rigour of winter is much less tempered by the heat of the earth than in the old continent. To the east lie a number of very large lakes, and farther north, Hudson's bay; about 50 miles on the south of which there is a range of mountains which prevent its receiving any heat from that quarter. The bay is bounded on the east by the mountainous country of Labrador and by a number of islands. Hence the coldness of the north-west winds and the lowness of the temperature. But as the cultivated parts of North America are now much warmer than formerly, there is reason to expect that the climate will become still milder when the country is better cleared of woods, though perhaps it will never equal the temperature of the old continent.

23 Of islands.

Islands are warmer than continents in the same degree of latitude; and countries lying to the windward of extensive mountains or forests are warmer than those lying to the leeward. Stones or sand have a less capacity for heat than earth has, which is always somewhat moist; they heat or cool, therefore, more rapidly and to a greater degree. Hence the violent heat of Arabia and Africa, and the intense cold of Terra del Fuego. Living vegetables alter their temperature very slowly, but their evaporation is great; and if they be tall and close, as in forests, they exclude the sun's rays from the earth, and shelter the winter snow from the wind and the sun. Woody countries, therefore, are much colder than those which are cultivated.

We shall conclude this chapter with a series of meteorological axioms respecting the temperature of the air, by M. Cotte.

24 Cotte's axioms respecting temperature.

1. The extreme degrees of heat are almost every where the same; this, however, is not the case in regard to the extreme degrees of cold.

2. The thermometer rises to its extreme height oftener in the temperate zones than in the torrid zone.

3. It changes very little between the tropics; its variations, like those of the barometer, are greater the more one proceeds from the equator towards the poles.

4. It rises higher in the plains than on mountains.

5. It does not fall so much in the neighbourhood of the sea as in inland parts.

6. The wind has no influence on its motions.

7. Moisture has a peculiar influence on it, if followed by a wind which disperses it.

8. The greatest heat, and the greatest cold, take place about six weeks after the northern or southern solstice.

9. The thermometer changes more in summer than in winter.

10. The coldest period of the day is before sunrise.

11. The greatest heat in the sun and the shade seldom takes place on the same day.

12. The heat decreases with far more rapidity from September and October, than it increased from July to September.

13. It is not true, that a very cold winter is the prognostic of a very hot summer.

Chap. III. *Of the Changes which take place in the Air with respect to Evaporation and Rain.*

Evaporation and Rain.

25 Qualities of vapour.

There seems no reason to doubt that water exists in the atmosphere in an intermediate state between that of a fluid and that of absolute steam. This is the state of vapour, of the qualities of which it is proper that we should here take a general view.

We are indebted to the experiments of Saussure and de Luc for much of our knowledge of the qualities of vapour. It is an elastic invisible fluid like common air, but lighter; being to common air, according to Saussure, as 10 to 14, or, according to Kirwan, as 10 to 12; it cannot pass beyond a certain maximum of density, otherwise the particles of water which compose it unite together, and form small, hollow, visible vesicles, called *vesicular vapour;* which is of the same specific gravity with atmospherical air. It is of this vapour that clouds and fogs are composed. This maximum increases with the temperature; and at the heat of boiling water is so great, that steam can resist the whole pressure of the air, and exist in the atmosphere in any quantity.

After what has been stated under Chemistry with respect to the nature and properties of vapour, we have nothing here to add on that subject, except to give the result of observations that have been made on the state of vapour in the atmosphere.

26 Evaporation confined to the surface.

It is found that the evaporation of water into the air is confined entirely to the surface, and hence it is always proportional to the surface exposed to the action of the air. Accordingly, observation shows that in maritime countries, and in marshy situations in the neighbourhood of lakes, rivers, &c. the evaporation is much greater than in inland countries and dry situations.

27 Proportional to the temperature of the air.

It is found that evaporation is greatest in hot weather; whence it must depend, in some degree, on the temperature

---

the temperature required. An example will make this rule sufficiently obvious. In latitude 56° the heat below being 54°; required the temperature of the air at the height of 803 feet?

$$\text{Here } m=54,\ t=5533,\ \frac{m-32}{\frac{t}{100}-1}=\frac{22}{54.33}=0404=c, \text{ and } c\times\frac{h}{100}=0.404\times 8.03=3.24=d, \text{ and } m-d=$$

$54-3.24=50.75$. Hence we see that the temperature of the air at the height of 803 feet above the surface is 50°.75.

ture of the air. This was ascertained by Mr Dalton from actual experiments, the result of which was, that the quantity evaporated per minute from a given surface of water at a given temperature, is to the quantity evaporated from the surface at 212°, as the force of vapour at the given temperature is to the force of vapour at 212°. By means of the table expressing the force of vapour at various temperatures given under CHEMISTRY, p. 468, we may discover by the above rule the quantity of water at a given temperature lost by evaporation.

There are several circumstances that affect the quantity of vapour rising from water, even at the same temperature. Thus, we find that evaporation is least in calm weather, increases when there is wind, and is greater in proportion as the wind is stronger. This evidently arises from the agitation of the water, by which a new surface is perpetually exposed to the action of the air.

We shall here insert a table by Mr Dalton, expressing the quantity of vapour raised in various atmospheric temperatures, from a circular surface six inches in diameter.

Temperature.	Force of vapour in inches.	Evaporating force in grains.			Temperature.	Force of vapour in inches.	Evaporating force in grain.

The first column of the above table expresses the temperature; the second, the corresponding force of vapour; the other three columns give the number of grains of water that would be evaporated from a surface of six inches in diameter in the respective temperatures, on the supposition of there being previously no aqueous vapour in the atmosphere. These columns present the extremes and the mean of evaporation likely to be noticed, or nearly such; for the first is calculated upon the supposition of 35 grains loss per minute from the vessel of three inches and a quarter in diameter; the second 45, and the third 55 grains per minute.

As yet we have stated only the degree of evaporation that would take place under various circumstances, provided that the atmosphere were, at the time, entirely free from moisture; but as this can scarcely happen, it becomes necessary to ascertain the rate of evaporation when qualified by the vapour already existing in the atmosphere. This is readily done by first finding the force of the vapour already in the atmosphere, as above directed, and subtracting it from the force of vapour at the given temperature. The remainder is the actual force of evaporation, from which, by the last table, we find the required rate of evaporation.

Evaporation and Rain.

tion. Suppose, for instance, it be required to know the rate of evaporation at the temperature of 59°. From the last table we see that the force of vapour at 59° is about 0.5 or $\frac{1}{60}$ its force at 212°. Now, suppose that by trials we find the force of the vapour which already exists in the atmosphere to be 0.25 or $\frac{1}{120}=\frac{1}{2}$ of $\frac{1}{60}$. Subtracting the latter from the former, we have for a remainder 0.25=the force of evaporation required, which is therefore just the half of what it would be if the atmosphere were entirely free from vapour.

The force of vapour existing in the atmosphere is scarcely ever equal to the force of vapour of the temperature of the atmosphere. Hence evaporation may, with a few exceptions, be considered as going on without intermission. Attempts have been made to ascertain the quantity of evaporation that takes place in the course of a year; but the investigation of this problem is so difficult, that these attempts have succeeded only in obtaining approximations towards the truth. Mr Dobson of Liverpool, from a course of experiments made in 1772, 1773, 1774, and 1775, concludes that the mean annual evaporation from the surface of water, amounted to 36.78 inches. The proportions for each month are as follows.

	Inches.		Inches.
January	1.50	July	5.11
February	1.77	August	5.01
March	2.64	September	3.18
April	3.30	October	2.51
May	4.34	November	1.51
June	4.41	December	1.49

The experiments of Mr Dalton shew that the evaporation from the surface of water in a very dry and hot summer day, was rather more than two tenths of an inch.

28 Evaporation from land.

Several experiments have been made on the quantity of evaporation from land, especially by Mr Williams in America, and Dr Watson, Mr Dalton and Mr Hoyle in Britain.

Mr Williams's experiments appear to shew that the evaporation from the surface of such land as is covered with trees and other vegetables is about one-third greater than the evaporation from the surface of water, though much reliance is not laid on these experiments.

From an experiment made by Dr Watson during summer, when the earth had been parched by a month's drought, it appeared that 1600 gallons of water were evaporated from a single acre in 12 hours*. Dr Watson's experiment, however, was of a nature that did not admit of great precision.

29 Experiments by Dalton and Hoyle.

The experiments made by Mr Dalton and Mr Hoyle in the years 1796, 1797, and 1798, are the most exact that have been made on this subject, and we shall therefore consider them more at large. They were made with the following apparatus. Having procured a cylindrical vessel made of tin plate, three feet deep and ten inches in diameter, they inserted into it two pipes directed downwards, so that water might pass through them into two bottles. One pipe was fixed near the bottom of the vessel, and the other about an inch from the top. The vessel was filled up for a few inches with gravel and sand, and all the rest with good fresh soil. It was then put into a hole in the ground, and the space around filled up with earth except on one side, for the convenience of putting bottles to the two pipes; then some water was poured on the earth to sadden it, and all that would drain off was suffered to escape. Hence the earth may be considered as saturated with moisture. The soil was kept for some weeks above the level of the upper pipe, but after that it was constantly allowed to be a little below it, thus preventing any water from running off through that pipe. The top of the soil for the first year was bare; but for the two last years it was covered with grass like other turf. The apparatus being thus prepared, a correct register was kept of the quantity of rain water which ran off from the surface of the earth by the upper pipe, as long as that was below the earth, and also of the quantity of water which passed through the three feet of earth, and ran off by the lower pipe; and a rain gauge of an equal diameter with the cylinder was kept near it, for the purpose of measuring the quantity of rain which fell in any corresponding time. Then, by subtracting the quantity of water which passed through the pipes from that in the rain gauge, the remainder was considered as equal to the quantity evaporated from the surface of the earth in the cylinder. The mean annual result of these experiments is shewn in the following table.

* Watson's *Chemical Essays*, vol. iii. 54.

Evaporation and Rain.

It appears from these experiments, that at Manchester the mean annual evaporation of water is above 25 inches; and if we add to this with Mr Dalton 5 inches for the dew which falls, the whole quantity evaporated in a year will be 30 inches. On the whole, we may perhaps estimate the mean annual evaporation from the whole surface of the globe at 35 inches from every square inch of surface, making the whole water annually evaporated over the whole globe equal to 94.450 cubic miles.

31 Mean annual evaporation over the globe.

Were this prodigious mass of water all to subsist in the atmosphere at once, it would increase its mass by about $\frac{1}{12}$, and raise the barometer nearly 3 inches. But this never happens; no day passes without rain in some part of the earth; so that part of the evaporated water is continually precipitated again. Indeed it would be impossible for the whole of the evaporated water to subsist in the atmosphere at once, at least in the state of vapour.

The higher regions of the atmosphere contain less vapour than the strata near the surface of the earth. This was observed both by M. de Saussure and M. de Luc.

32 At some height above the tops of mountains the atmosphere is probably still drier, for it was observed by Saussure, that on the tops of mountains the moisture of the air was rather less during the night than the day. And there can be little doubt that every stratum of air descends a little lower during the night than it was during the day, owing to the cooling and condensing of the stratum nearest the earth. Vapours, however, must ascend very high, for we see clouds forming far above the tops of the highest mountains.

Rain never begins to fall while the air is transparent; the invisible vapours first pass their maximum, and are changed into vesicular vapours; clouds are formed, and these clouds gradually dissolve in rain. Clouds, however, are not formed in all parts of the horizon at once; the formation begins in one particular spot, while the rest of the air remains clear as before; this cloud rapidly increases till it overspreads the whole horizon, and then the rain begins.

33 Clouds always form at some height.

It is remarkable, that though the greatest quantity of vapour exists in the lower strata of the atmosphere, clouds never begin to form there, but always at some considerable height. It is remarkable, too, that the part of the atmosphere at which they form has not arrived at the point of extreme moisture, nor near that point, even a moment before their formation. They are not formed then because a greater quantity of vapour had got into the atmosphere than could remain there without passing its maximum. It is still more remarkable, that when clouds are formed, the temperature of the spot in which they are formed is not always lowered, though this may sometimes be the case. On the contrary, the heat of the clouds themselves is sometimes greater than that of the surrounding air*. Nor is the formation of clouds owing to the capacity of the air for combining with moisture being lessened by cold; so far from that, we often see clouds which had remained in the atmosphere during the heat of the day, disappear in the night, after the heat of the air was diminished.

* De Luc a Meteorol. vol. ii. 00.

34 The formation of clouds and rain as yet unexplained.

The formation of clouds and rain cannot be accounted for by a single principle with which we are acquainted. It is neither owing to the saturation of the atmosphere, nor the diminution of the heat; nor the mixture of airs of different temperatures, as Dr Hutton supposes: for clouds are often formed without any wind at all either above or below them; and even if this mixture constantly took place, the precipitation, instead of accounting for rain, would be almost imperceptible.

It is a very remarkable fact, that evaporation often goes on for a month together in hot weather without any rain. This sometimes happens in this country; it happens every year in the torrid zone. Thus at Calcutta, during January 1785, it never rained at all; the mean of the thermometer for the whole month was $66\frac{1}{2}°$; there was no high wind, and indeed during great part of the month little wind at all.

The quantity of water evaporated during such a drought must be very great; yet the moisture of the air, instead of being increased, is constantly diminishing, and at last disappears almost entirely. For the dew, which is at first copious, diminishes every night; and if Dr Watson's experiment formerly mentioned be attended to, it will not be objected that the quantity of evaporation is also very much diminished. Of the very dry state to which the atmosphere is reduced during long droughts, the violent thunder-storms with which they often conclude is a very decisive proof. Now what becomes of all this moisture? It is not accumulated in the atmosphere above the country from which it was evaporated, otherwise the whole atmosphere would in a much less period than a month be perfectly saturated with moisture. If it be carried up daily through the different strata of the atmosphere, and wafted to other regions by superior currents of air, how is it possible to account for the different electrical state of the clouds situated between different strata, which often produces the most violent thunder-storms? They could not have remained in the lower strata of the atmosphere, and been daily carried off by winds to other countries; for there are often no winds at all during several days to perform this office; nor in that case would the dews diminish, nor could their presence fail to be indicated by the hygrometer.

It is impossible for us to account for this remarkable fact upon any principle with which we are acquainted. The water can neither remain in the atmosphere, nor pass through it in the state of vapour. It must therefore assume some other form; but what that form is, or how it assumes it, we know not. There are, therefore, two steps of the process which takes place between evaporation and rain, with which we are entirely unacquainted; first, the state of the vapour after it enters into the atmosphere, and second, the cause by which it is made to lay aside the new form which it assumed, return to its state of vapour, and descend in form of rain. Several theories have been contrived to account for this phenomenon, but they are all untenable on the present known laws of chemical action.

The mean annual quantity of rain is greatest at the equator, and decreases gradually as we approach the poles. Thus at Granada, Antilles, 12° N. Lat. it is 126 inches.

Cape François, St Domingo	19°	46′	120

On

Evaporation and Rain.

On the contrary, the number of rainy days is smallest at the equator, and increases in proportion to the distance from it. From N. Lat. 12° to 43° the mean number of rainy days is 78; from 43° to 46° the mean number is 103; from 46° to 50° it is 134; from 51° to 60°, 161 days.

35 Rainy days often more numerous in winter.

The number of rainy days is often greater in winter than in summer; but the quantity of rain is greater in summer than in winter. At Petersburgh, the number of rainy or snowy days during winter is 84, and the quantity which falls is only about 5 inches; during summer the number of rainy days is nearly the same, but the quantity which falls is about 11 inches.

More rain falls in mountainous countries than in plains. Among the Andes it is said to rain almost perpetually, while in Egypt it scarcely ever rains at all. If a rain-gauge be placed on the ground, and another at some height perpendicularly above it, more rain will be collected into the lower than into the higher; a proof that the quantity of rain increases as it descends, owing perhaps to the drops attracting vapour during their passage through the lower strata of the atmosphere where the greatest quantity resides. This, however, is not always the case, as Mr Copland of Dumfries discovered in the course of his experiments. He observed also, that when the quantity of rain collected in the lower gauge was greatest, the rain commonly continued for some time; and that the greatest quantity was collected in the higher gauge only either at the end of great rains, or during rains which did not last long. These observations are important, and may, if followed out, give us new knowledge of the causes of rain. They seem to shew, that during rain the atmosphere is somehow or other brought into a state which induces it to part with its moisture; and that the rain continues as long as this state continues. Were a sufficient number of observations made on this subject in different places, and were the atmosphere carefully analysed during dry weather, during rain, and immediately after rain, we might soon perhaps discover the true theory of rain.

36 More rain falls in the day than in the night.

Rain falls in all seasons of the year, at all times of the day, and during the night as well as the day; though, according to M. Toaldo, a greater quantity falls during the day than the night. The cause of rain, then, whatever it may be, must be something which operates at all times and seasons. Rain falls also during the continuance of every wind, but oftenest when the wind blows from the south. Falls of rain often happen likewise during perfect calms.

37 Mean annual quantity of rain in Great Britain.

It appears from a paper published by M. Cotte in the *Journal de Physique* for October 1791, containing the mean quantity of rain falling at 147 places, situated between N. Lat. 11° and 60°, deduced from tables kept at these places, that the mean annual quantity of rain falling in all these places in 34.7 inches. Let us suppose then (which cannot be very far from the truth), that the mean annual quantity of rain for the whole is 34 inches. The superficies of the globe consists of 170,981,012 square miles, or 686,401,498,471,475,200 square inches. The quantity of rain, therefore, falling annually will amount to 23,337,650,812,030,156,800 cubic inches, or somewhat more than 91,751 cubic miles of water. This is 16,191 cubic miles of water less than the quantity of water evaporated. It seems probable therefore, if the imperfection of our data warrant any conclusion, that some of the vapour is actually decomposed in the atmosphere, and converted into oxygen and hydrogen gas.

The dry land amounts to 52,745,253 square miles: the quantity of rain falling on it annually therefore will amount to 30,960 cubic miles. The quantity of water running annually into the sea is 13,140 cubic miles; a quantity of water equal to which must be supplied by evaporation from the sea, otherwise the land would soon be completely drained of its moisture.

The quantity of rain falling annually in Great Britain may be seen from the following table:

Years of observation.	Places.	Rain in Inches.

Mr Dalton has estimated the quantity of rain that falls in England at 21 inches; but as no account is taken of what falls in Wales and Scotland, this estimate probably falls much short of the real annual quantity. In this country it generally rains less in March than in November, in the proportion at a medium of 7 to 12. It generally rains less in April than October, in the proportion of 1 to 2 nearly at a medium. It generally rains less in May than September; the chances that it does so are at least as 4 to 3: but when it rains plentifully in May, it generally rains but little in September; and when it rains one inch or less in May, it rains plentifully in September.

The degree of moisture that is present in the atmosphere at any given time, is measured by the hygrometer. Under the article HYGROMETER we have amply described several of the most important instruments of that kind; but there is one hygrometer, viz. that of Mr Leslie, which remains to be described in this place. Figures of the instrument are given in Plate CCLXXVI. fig. 13, 14.

The principal part of the instrument is composed of two glass tubes terminated by hollow balls, one transparent and the other opaque. The tubes are selected, as regular as possible, from 4 to 8 inches long, and about $\frac{3}{20}$ of an inch thick, or as slender as those employed for 38 Leslie's hygrometer.

vapora-on and Rain.

for thermometers, but with a much wider bore. This, in one tube, must be from $\frac{1}{40}$ to the $\frac{1}{60}$ of an inch in diameter, and an exact calibre, at least not differing by $\frac{1}{50}$ between both its extremities. To the end of it a small piece of black enamel is attached, and blown into an opaque ball, from 4 to $\frac{1}{16}$ of an inch diameter. The corresponding tube may have its bore of the same, or rather a greater width, but its uniformity is not at all essential. Near the extremity it is swelled out into a thin cylinder, almost $\frac{1}{10}$ of an inch wide, and from $\frac{3}{10}$ to $\frac{6}{10}$ long; the inner cavity only being enlarged, without altering the exterior regularity of the tube. The short bit of glass where this cylinder terminates, is now blown into a thin pellucid ball, as nearly of the size of the former as the eye can judge. The exact equality of the balls would be unattainable, and fortunately the theory of the instrument does not require it. When a dark and a bright object are viewed together, the latter, from an optical deception, appears always larger than the reality; and for this reason, says Mr Leslie, I prefer making the clear ball a slight degree smaller than the black one. In the mean time a coloured liquor is prepared by dissolving carmine in concentrated sulphuric acid, in a phial with a ground stopper, taking care to avoid heat, as by this the colouring-matter would be charred, and the beauty of the liquor destroyed.

The tubes are now cut to nearly equal lengths, and the end of each swelled out a little, to facilitate their junction. Close to the black ball, the tube is bent by the flame of a candle into a shoulder, such, that the root of the ball shall come into a line with the inner edge of the tube. This ball, being then warmed, the end of the tube is dipt into the acid liquor, and as much of it allowed to rise and flow into the cavity, as may be guessed sufficient to fill both tubes, excepting the cylinder. The two tubes are then, by the help of a blow-pipe, solidly joined together in one straight piece, without having any knot or protuberance. About half an inch from the joining, and nearer the cylinder, it is gently bent round by the flame of a candle, till the clear ball is brought to touch the tube $\frac{1}{4}$ inch directly below the black one. The instrument is now to be graduated; and the scale chosen by Mr Leslie is that which corresponds to the centigrade thermometer. Mr Leslie thus describes the mode of graduating the instrument.—The instrument is held in an oblique position, that the coloured liquor may collect at the bottom of the black ball, into which a few minute portions of air must, from time to time, be forced over, by heating the opposite ball with the hand. In this way, the interposed liquid will gradually be made to descend into the tube, and assume its proper place; and it should remain for a week or two in an inclined position, to let every particle drain out of the black ball. If any trace of fluid collects in rings within the bore, they are easily dispelled with a little dexterity and manipulation, which, though it would be difficult to describe, is most readily learnt and practised. The small cavity at the joining facilitates the rectification, by affording the means of sending a globule of air in either direction. In fixing the zero of the scale, Mr Leslie set the instrument in a remote corner of the room, or partly closed the window-shutters. When completely adjusted, the top of the coloured liquor, if held upright, should stand nearly opposite to the middle of the cylindrical reservoir.

Evaporation and Rain.

In this state of preparation, the instrument is ready for being graduated. The clear ball and the contiguous part of the parallel tube are therefore covered with two or three folds of thin bibulous paper, moistened with pure water, to make it act as a hygrometer; and there is attached to the same tube a temporary scale, by means of a soft cement composed of bees-wax and rosin. A flat round piece of wood being provided with four or five pillars that screw into it, the instrument is fixed to one of them in an erect position, and on each side is disposed a fine corresponding thermometer, inverted, and at the same height, the one having its bulb covered with wet bibulous paper. Then half a yard of flannel is dried as much as possible without singeing, before a good fire, and rolling it up like a sleeve, it is lapped loosely round the lower part of the pillars, and the whole is inclosed under a large bell-glass. The flannel powerfully absorbs moisture from the confined air, and creates an artificial dryness of 80 or 100 degrees. In the space of a quarter or half an hour, the full effect is produced, and the quantities being noted at two or three separate times, the mean results are adopted. The descent, measured by the temporary scale, being then augmented in the proportion of ten to the difference of the two thermometers, will give the length that corresponds to 100°. After the standard instrument is constructed, others are thence graduated with the utmost ease; the first being planted in the centre, and the rest, with their temporary scales, stuck to the encircling pillars. For greater accuracy, the observation should be made in a room without a fire, or a screen ought to be interposed between the fire and the apparatus.

The slips of ivory intended for the scales are divided into equal parts, and should contain from 100° to 150°. The edges are filed down and chamfered, to fit easily between the parallel tubes; and they are secured in their place by a strong solution of isinglass. The lower ball and its annexed cylinder, are covered with thin silk of the same colour as the upper ball, and a few threads are likewise lapped about that part of the tube which it touches. The instrument is lastly cemented into a piece of wood, either end of which admits a cylindrical case that serves equally to protect or to hold it. On other occasions, the hygrometer is inserted into the socket of a round bottom-piece where it stands vertical.

The above description refers particularly to fig. 14. Fig. 13. differs from this, only in having the balls of an equal height, and bended in opposite directions, which Mr Leslie considers as more convenient for some purposes to which the instrument is applied, to be mentioned hereafter, but which renders the instrument less portable.

39 Theory of the instrument.

The action of this hygrometer depends on the following principle; *That the cold produced by evaporation will accurately denote the degree of dryness of the air, or its distance from the point of saturation.* To discover the dryness or humidity of the air, therefore, we have only to find the change of temperature induced in a body of water insulated, or exposed on all sides to evaporation. The steps which led Mr Leslie from these simple

Evaporation and Rrain.

simple principles to the construction of the present ingenious instrument, are detailed by him in a paper published in Nicholson's Journal for January 1800, to which we must refer our readers for the particulars, contenting ourselves with the following summary view.

If two thermometers be filled with any expansible fluid, and having the bulb of the one wet and the other dry, they will, by their difference, denote the state of the air in respect to humidity. Mr Leslie's object was to combine two such instruments, so that they should indicate merely their difference of temperature; and this object he has completely attained by the present instrument. In ordinary cases, the intermediate liquor would continue stationary; for the air in both balls having the same temperature, and consequently the same elasticity, the opposite pressures would precisely counteract each other; but if, from the action of the external air on the moistened surface, one ball became colder, it is manifest the liquor would be pushed towards it by the superior elasticity of the air included in the other ball, so as to mark, by the space of its approach, the depression of temperature induced by evaporation.

This instrument does not merely point out the dryness of the air; it enables us to determine the *absolute quantity* of moisture which it is capable of imbibing; for the conversion of water into steam is found to consume 524° of the centigrade division; and evaporation, analogous in its effects, may be presumed to occasion the same waste of heat. If, therefore, air had the same capacity as water, for each degree of the hygrometer it would deposit as much heat as it would abstract by dissolving the $\frac{1}{3240}$ part of its weight of humidity. But the capacity of air is to that of water as 11 to six, and consequently it would require in that proportion a greater evaporation to produce the same effect. We may hence conclude, that, for each hygrometric degree, the air would require $\frac{11}{6} \times \frac{1}{3240}$ or $\frac{1}{1858}$ part by weight of water to effect saturation.

Strictly speaking, the degrees marked by this hygrometer do not measure the dryness of the air at its actual temperature, but only its state of dryness when cooled down to the standard of the wet ball. The law, however, being known of the dissolving power of air as affected by heat, it is easy, from the disposition of the air with respect to humidity at one temperature to derive that at any other. It will suffice to mention the result of a number of careful experiments:—Supposing air at the freezing point to be capable of holding 50 parts of moisture; at 10° centigrade, it will hold 100; at 20°, 200; at 30°, 400; thus doubling at each increase of 10°. Hence a table may be constructed by which these conversions will be easily made.

To omit nothing that tends to elucidate the theory of the instrument, we must observe that the air in its contact with the humid surface is not absolutely cooled to the same temperature; the air and water really meet each other at an intermediate point determined by their compounded density and capacity. Consequently the indications of the hygrometer ought to be augmented by the $\frac{1}{464}$ part, or $\frac{11}{6} + \frac{1}{850}$. But this quantity is too small in any case to be regarded. See HYGROMETRY, SUPPLEMENT.

Winds.

CHAP. IV. *Of the Changes produced in the Air by Winds.*

IN considering the subject of winds, we shall first briefly detail their natural history, so far as it has not been already anticipated, and shall then endeavour to trace the laws by which they are regulated, or explain the manner in which their varieties are produced. As the direction of the winds is of the greatest consequence, especially in a commercial view, we shall first point out the direction of the most prevalent winds in various quarters of the world. 40

41 Trade-winds.

Between the tropics the winds are the most regular. In those parts of the Pacific and Atlantic oceans which lie nearest the equator, there is a regular wind during the whole year called the *trade-wind*. On the north side of the equator it blows from the north-east, varying frequently a point or two towards the north or east; and on the south side of it, from the south-east, changing sometimes in the same manner towards the south or east. The space included between the second and fifth degrees of north latitude is the internal limit of these two winds. There the winds can neither be said to blow from the north nor the south; calms and violent storms are frequent. This space varies a little in latitude as the sun approaches either of the tropics. In the Atlantic ocean the trade-winds extend farther north on the American than on the African coast; and as we advance westward, they become gradually more easterly, and decrease in strength. Their force diminishes likewise as we approach their utmost boundaries. It has been remarked also, that as the sun approaches the tropic of cancer, the south-east winds become gradually more southerly, and the north-east winds more easterly: exactly the contrary takes place when the sun is approaching the tropic of capricorn.

42 Monsoons.

The trade-wind blows constantly in the Indian ocean from 10° south latitude to near 30°; but to the northward of this the winds change every six months, and blow directly opposite to their former course. These regular winds are called *monsoons*, from the Malay word *moossin*, which signifies a season. When they shift their direction, variable winds and violent storms succeed, which last for a month, and frequently longer; and during that time it is dangerous for vessels to continue at sea.

The monsoons in the Indian ocean may be reduced to two; one on the north and another on the south side of the equator; which extend from Africa to the longitude of New Holland and the east coast of China, and which suffer partial changes in particular places from the situation and inflection of the neighbouring countries.

Between 3° and 10° of south latitude the south-east trade-wind continues from April to October; but during the rest of the year the wind blows from the north-west. Between Sumatra and New Holland this monsoon blows from the south during our summer months, approaching gradually to the south-east as we advance towards the coast of New Holland; it changes about the end of September, and continues in the opposite direction till April. Between Africa and Madagascar its direction is influenced by the coast; for it blows

Winds. blows from the north-east from October to April, and during the rest of the year from the south-west.

43 Direction of the trade-winds throughout the year. Over all the Indian ocean to the northward of the third degree of south latitude, the north-east trade-wind blows from October to April, and a south-west wind from April to October. From Borneo, along the coast of Malacca and as far as China, this monsoon in summer blows nearly from the south, and in winter from the north by east. Near the coast of Africa, between Mozambique and Cape Guardafeu, the winds are irregular during the whole year, owing to the different monsoons which surround that particular place.—Monsoons are likewise regular in the Red sea; between April and October they blow from the north-west, and during the other months from the south-east, keeping constantly parallel to the coast of Arabia.

44 Of monsoons. Monsoons are not altogether confined to the Indian ocean; on the coast of Brazil, between Cape St Augustine and the island of St Catharine, the wind blows between September and April from the east or north-east, and between April and September from the south-west. The bay of Panama is the only place on the west side of a great continent where the wind shifts regularly at different seasons: there it is easterly between September and March; but between March and September it blows chiefly from the south and south-west.

Such in general is the direction of the winds in the torrid zone all over the Atlantic, Pacific, and Indian oceans; but they are subject to particular exceptions, which we shall now endeavour to enumerate. On the coast of Africa, from Cape Bayador to Cape Verde, the winds are generally north-west; from thence to the island of St Thomas near the equator they blow almost perpendicular to the shore, bending gradually as we advance southwards, first to the west and then to the south-west. On the coast of New Spain likewise, from California to the bay of Panama, the winds blow almost constantly from the west or south-west, except during May, June, and July, when land-winds prevail, called by the Spaniards *Popogayos*. On the coast of Chili and Peru, from 20° to 30° south latitude, to the equator, and on the parallel coast of Africa, the wind blows during the whole year from the south, varying according to the direction of the land towards which it inclines, and extending much farther out to sea on the American than the African coast. The trade-winds are also interrupted sometimes by westerly winds in the bay of Campeachy and the bay of Honduras.

As to the countries between the tropics, we are too little acquainted with them to be able to give a satisfactory history of their winds.

45 Of sea and land breezes. In all maritime countries between the tropics, of any extent, the wind blows during a certain number of hours every day from the sea, and during a certain number towards the sea from the land; these winds are called the *sea and land breezes*. The sea breeze generally sets in about 10 in the forenoon, and blows till six in the evening; at seven the land breeze begins and continues till eight in the morning, when it dies away. During summer the sea breeze is very perceptible on all the coasts of the Mediterranean sea, and even sometimes as far north as Norway.

In the island of St Lewis on the coast of Africa, in 16° north latitude, and 16° west longitude, the wind during the rainy season, which lasts from the middle of July to the middle of October, is generally between the south and the east: during the rest of the year it is for the most part east or north-east in the morning; but as the sun rises, the wind approaches gradually towards the north, till about noon it gets to the west of north, and is called a *sea breeze*. Sometimes it shifts to the east as the sun descends, and continues there during the whole night. In February, March, April, May and June, it blows almost constantly between the north and west. In the island of Bulama, which likewise lies on the west coast of Africa, in 11° north latitude, the wind during nine months of the year blows from the south-west; but in November and December, a very cold wind blows from the north-east.

In the kingdom of Bornou, which lies between 16° and 20° north latitude, the warm season is introduced about the middle of April by sultry winds from the south-east, which bring along with them a deluge of rain. In Fezzan, in 25° north latitude, and 35° east longitude, the wind from May to August blows from the east south-east, or south-west, and is intensely hot.

In Abyssinia the winds generally blow from the west, north-west, north, and north-east. During the months of June, July, August, September and October, the north and north-east winds blow almost constantly, especially in the morning and evening; and during the rest of the year they are much more frequent than any other winds. 46 Winds in Abyssinia.

At Calcutta, in the province of Bengal, the wind blows during January and February from the south-west and south; in March, April, and May from the south; in June, July, August, and September, from the south and south-east; in October, November, and December, from the north-west. At Madras the most frequent winds are the north and north-east.—At Tivoli in St Domingo, and the isles des Vaches, the wind blows oftenest from the south and south-east. From these facts it appears, that in most tropical countries with which we are acquainted, the wind generally blows from the nearest ocean, except during the coldest months, when it blows towards it. 47 At Calcutta.

In the temperate zones the direction of the wind is by no means so regular as between the tropics. Even in the same degree of latitude, we find them often blowing in different directions at the same time, while their changes are often so sudden and capricious, that to account for them has been hitherto found impossible. When winds are violent and continue long, they generally extend over a large tract of country; and this is more certainly the case when they blow from the north-east, than from any other points. By the multiplication and comparison of meteorological tables, some regular connection between the changes of the atmosphere in different places may in time be observed, which will at last lead to a satisfactory theory of the winds. It is from such tables chiefly that the following facts have been collected. 48 In the temperate zones.

In Virginia, the prevailing winds are between the *south-west*, *west*, *north*, and *north-west*; the most frequent is the *south-west*; which blows more constantly in June, July, and August, than at any other season. The north-west winds blow most constantly in Novem- 49 In Virginia.

 ber,

Winds.

ber, December, January, and February. At Ipswich in New England, the prevailing winds are also between the south-west, west, north, and north-east; the most frequent is the north-west. But at Cambridge, in the same province, the most frequent wind is the south-east. The predominant winds at New York are the north and west. In Nova Scotia north-west winds blow for three-fourths of the year. The same wind blows most frequently at Montreal in Canada, but at Quebec the wind generally follows the direction of the river St Lawrence, blowing either from the north-east or south-west. At Hudson's bay westerly winds blow for three-fourths of the year; the north-west wind occasions the greatest cold; but the north and north-east are the vehicles of snow.

It appears from these facts, that westerly winds are most frequent over the whole eastern coast of North America; that in the southern provinces south-west winds predominate, and that the north-west become gradually more frequent as we approach the frigid zone.

50 In Egypt.

In Egypt, during part of May, and during June, July, August, and September, the wind blows almost constantly from the *north*, varying sometimes in June to the west, and in July to the west and the east; during part of September, and in October and November, the winds are variable, but blow more regularly from the east than any other quarter; in December, January, and February, they blow from the north, north-west, and west; towards the end of February they change to the south, in which quarter they continue till near the end of March; during the last days of March and in April they blow from the south-east, south, and south-west, and at last from the east; and in this direction they continue during a part of May.

51 In the Mediterranean.

In the Mediterranean the wind blows nearly three-fourths of the year from the north; about the equinoxes there is always an easterly wind in that sea, which is generally more constant in spring than in autumn. These observations do not apply to the gut of Gibraltar, where there are seldom any winds except the east and the west. At Bastia, in the island of Corsica, the prevailing wind is the south-west.

52 In Syria.

In Syria the north wind blows from the autumnal equinox to November; during December, January, and February, the winds blow from the west and south-west; in March they blow from the south, in May from the east, and in June from the north. From this month to the autumnal equinox the wind changes gradually as the sun approaches the equator; first to the east, then to the south, and lastly to the west. At Bagdad the most frequent winds are the south-west and north-west; at Pekin, the north and the south; at Kamtschatka, on the north-east coast of Asia, the prevailing winds blow from the west.

53 In Italy.

In Italy the prevailing winds differ considerably according to the situation of the places where the observations have been made. At Rome and Padua they are northerly, at Milan easterly. All that we have been able to learn respecting Spain and Portugal is, that on the west coast of these countries the west is by far the most common wind, particularly in summer; and that at Madrid the wind is north-east for the greatest part of the summer, blowing almost constantly from the Pyrenean mountains. At Berne in Switzerland, the prevailing winds are the north and west; at St Gothard, the north-east; at Lausanne the north-west and south-west.

54 Result of M Cotte's observations on the direction of the winds in France.

M. Cotte has given us the result of observations made at 86 different places of France, from which it appears, that along the whole south coast of that empire the wind blows most frequently from the north, north-west, and north-east: on the west coast, from the west, south-west, and north-west; and on the north coast from the south-west. That in the interior parts of France the south west wind blows most frequently in 18 places; the west wind in 14; the north in 13; the south in 6: the north-east in 4; the south-east in 2; the east and north-west each of them in one. On the west coast of the Netherlands, as far north as Rotterdam, the prevailing winds are probably the south-west; at least this is the case at Dunkirk and Rotterdam. It is probable also, that along the rest of this coast, from the Hague to Hamburgh, the prevailing winds are the north-west, at least these winds are most frequent at the Hague and at Franeker. The prevailing wind at Delft is the south-east, and at Breda the north and the east.

55 Direction of the winds in Germany.

In Germany the east wind is most frequent at Gottingen, Munich, Weissemburg, Dusseldorff, Saganum, Erford, and at Buda in Hungary; the south-east at Prague and Wirtsburg; the north-east at Ratisbon, and the west at Manheim and Berlin.

56 At London.

From an average of 10 years of the register kept by order of the Royal Society, it appears, that at London the winds blow in the following order:

Winds.	*Days.*	*Winds.*	*Days.*
South-west	112	South-east	32
North-east	58	East	26
North-west	50	South	18
West	53	North	16

It appears from the same register, that the south-west wind blows at an average more frequently than any other wind during every month of the year, and that it blows longest in July and August; that the north-east blows most constantly during January, March, April, May, and June, and most seldom during February, July, September, and December; and that the north-west wind blows oftener from November to March, and more seldom during September and October, than any other months. The south-west winds are also most frequent at Bristol, and next to them are the north-east.

57 Table of winds at Lancaster.

The following table of the winds at Lancaster has been drawn up from a register kept for seven years at that place.

Winds.	*Days.*	*Winds.*	*Days.*
South-west	92	South-east	35
North-east	67	North	30
South	51	North-west	26
West	41	East	17

58 At Dumfries.

The following table is an abstract of nine years observations made at Dumfries by Mr Copland.

Winds.	*Days.*	*Winds.*	*Days.*
South	$82\frac{1}{2}$	North	$36\frac{1}{2}$
West	69	North-west	$25\frac{1}{2}$
East	68	South-east	$18\frac{1}{2}$
South-west	$50\frac{1}{2}$	North-east	$14\frac{1}{2}$

The

Winds.

59 At Cambuslang. The following table is an abstract of seven years observations, made by Dr Meek at Cambuslang, near Glasgow.

Winds.	*Days.*	*Winds.*	*Days.*
South-west	174	North-east	104
North-west	40	South-east	47

It appears from the register from which this table was extracted, that the north-east wind blows much more frequently in April, May, and June, and the south-west in July, August, and September, than at any other period. We learn from the Statistical Account of Scotland, that the south-west is by far the most frequent wind all over that kingdom, especially on the west coast. At Saltcoats in Ayrshire, for instance, it blows three-fourths of the year; and along the whole coast of Murray on the north-east side of Scotland, it blows for two-thirds of the year. East winds are common over all Great Britain during April and May; but their influence is felt most severely on the eastern coast.

The following table exhibits a view of the number of days during which the westerly and easterly winds blow in a year, at different parts of the island. Under the term westerly are included the north-west, west, south-west, and south; the term easterly is taken in the same latitude.

Years of observation.	Places.	Wind. Westerly	Wind. Easterly
10	London	233	132
7	Lancaster	216	149
51	Liverpool	190	175
9	Dumfries	227.5	137.5
10	Branxholm	232	133
7	Cambuslang	214	151
8	Hawkhill near Edin.	229.5	135.5
	Medium	220.3	144.7

60 Direction of the winds in Ireland. In Ireland, the south-west and west are the grand trade-winds, blowing most in summer, autumn, and winter, and least in spring. The north-east blows most in spring, and nearly double to what it does in autumn and winter. The south-west and north-west are nearly equal, and are most frequent after the south-west and west.

61 At Copenhagen, and in Russia. At Copenhagen the prevailing winds are the east and south-east; at Stockholm, the west and north. In Russia, from an average of a register of 16 years, the winds blow from November to April in the following order.

	W.	N.W.	E.	S.W.	S.	NE.	N.	SE.
Days	45	26	23	22	20	19	14	12

And during the other six months,

	W.	N.W.	E.	S.W.	S.	N.E.	N.	S.E.
Days	27	27	19	24	22	15	32	18

The west wind blows during the whole year 72 days; the north-west 53, the south-west and north 46 days each. During summer it is calm for 41 days, and during winter for 21. In Norway the most frequent winds are the south, and south-west and south-east. The wind at Bergen is seldom directly west, but generally south-west or south-east; a north-west, and especially a north-east wind, are but little known there.

From the whole of these facts, it appears that the most frequent winds on the south coasts of Europe are the north, the north-east and north-west, and on the western coast the south-west; that in the interior parts which lie most contiguous to the Atlantic ocean, south-west winds are also most frequent; but that easterly winds prevail in Germany. Westerly winds are also most frequent on the north-east coast of Asia.

It is probable that the winds are more constant in the south temperate zone, which is in a great measure covered with water, than in the north temperate zones, where their direction must be frequently interrupted and altered by mountains and other causes.

M. de la Bailie, who was sent thither by the French king to make astronomical observations, informs us, that at the Cape of Good Hope the main winds are the south-east and north-west; that other winds seldom last longer than a few hours; and that the east and north-east winds blow very seldom. The south-east wind blows in most months of the year, but chiefly from October to April; the north-west prevails during the other six months, bringing along with it rain, and tempests, and hurricanes. Between the Cape of Good Hope and New Holland the winds are commonly westerly, and blow in the following order: north-west, south-west, west, north. 62 Main winds at the Cape of Good Hope.

In the great South sea, from latitude 30° to 40° south, the south-east trade-winds blow most frequently, especially when the sun approaches the tropic of Capricorn; the wind next to it in frequency is the north-west, and next to that is the south-west. 63 In the Pacific ocean.

Thus it appears that the trade-winds sometimes extend farther into the south temperate zone than their usual limits, particularly during summer; that beyond their influence the winds are commonly westerly, and that they blow in the following order: north-west, south-west, west.

We have now considered pretty much at large the direction of the winds in different parts of the earth's surface. Another very curious part of the history of the winds relates to their violence, and the effects with which they are attended, or to the history of hurricanes, whirlwinds, tornadoes, &c. Of some of these we have already treated under the articles Hurricane and Harmattan; and the confined limits of this article oblige us to refer our readers for more particulars to Capper's Observations on the Winds and Monsoons. 64 Theory of the winds.

As to the velocity of the wind, its variations are almost infinite, from the gentlest breeze, to the hurricane which tears up trees and blows down houses. Our most violent winds take place when neither the heat nor the cold is greatest; violent winds generally extend over a large tract of country, and they are accompanied with sudden and great falls in the mercury of the barometer. The wind is sometimes very violent at a distance from the earth, while it is quite calm at its surface. On one occasion Lunardi went at the rate of 70 miles an hour in his balloon, though it was quite calm at Edinburgh when he ascended, and continued so during his whole voyage. 65 Velocity of the winds almost infinitely various.

Winds.

66 Velocity of the winds.

A pretty good idea of the velocity of the wind, under different circumstances, may be formed from the following table, which was drawn up by Mr Smeaton.

Miles per Hour	Feet per Second.	Perpendicular force on one square foot, in Avoirdupois pounds and parts.	
1	1.47	.005	Hardly perceptible.
2	2.93	.020	Just perceptible.
3	4.4	.044	
4	5.87	.079	Gently pleasant.
5	7.33	.123	
10	14.67	.492	Pleasant, brisk.
15	22.	1.107	
20	29.34	1.968	Very brisk.
25	36.67	3.075	
30	44.01	4.429	High wind.
35	51.34	6.027	
40	58.68	7.873	Very high wind.
45	66.01	9.963	
50	73.35	12.300	Storm or tempest.
60	88.02	17.715	Great storm.
80	117.36	31.490	Hurricane.
100	146.7	49.200	Hurricane that tears up trees and carries buildings before it.

For the means of ascertaining the velocity of the winds, see ANEMOMETER and ANEMOSCOPE.

We shall now endeavour to explain the phenomena that we have been describing, or to form a plausible theory of the winds.

The atmosphere is a fluid surrounding the earth, and extending to an unknown height. Now all fluids tend invariably to a level: if a quantity of water be taken out of any part of a vessel, the surrounding water will immediately flow in to supply its place, and the surface will become level as before; or if an additional quantity of water be poured into any part of the vessel, it will not remain there, but diffuse itself equally over the whole. Such exactly would be the case with the atmosphere. Whatever therefore destroys the equilibrium of this fluid, either by increasing or diminishing its bulk in any particular place, must at the same time occasion a wind.

67 Air, besides its qualities in common with other fluids, is also capable of being dilated and compressed. Suppose a vessel filled with air: if half the quantity which it contains be drawn out by means of an air-pump, the remainder will still fill the vessel completely; or if twice or three times the original quantity be forced in by a condenser, the vessel will still be capable of holding it.

Rarefied air is lighter, and condensed air heavier than common air. When fluids of unequal specific gravities are mixed together, the heavier always descend and the lighter ascend. Were quicksilver, water, and oil, thrown into the same vessel together, the quicksilver would uniformly occupy the bottom; the water the middle, and the oil the top. Were water to be thrown into a vessel of oil, it would immediately descend, because it is heavier than oil. Exactly the same thing takes place in the atmosphere. Were a quantity of air, for instance, to be suddenly condensed at a distance from the surface of the earth, being now heavier than before, it would descend till it came to air of its own density; or, were a portion of the atmosphere at the surface of the earth to be suddenly rarefied, being now lighter than the surrounding air, it would immediately ascend.

Winds.

68 Cause of the trade-winds.

If a bladder half filled with air be exposed to the heat of the fire, the air within will soon expand, and distend the bladder; if it be now removed to a cold place, it will soon become flaccid as before. This shews that heat rarefies, and that cold condenses air. The surface of the torrid zone is much more heated by the rays of the sun than the frozen or temperate zones, because the rays fall upon it much more perpendicularly. This heat is communicated to the air near the surface of the torrid zone, which being thereby rarefied, ascends, and its place is supplied by colder air, which rushes in from the north and south.

The diurnal motion of the earth is greatest at the equator, and diminishes gradually as we approach the poles, where it ceases altogether. Every spot of the earth's surface at the equator moves at the rate of 15 geographical miles in a minute; at 40° of latitude it moves at about 11 miles and a half in a minute, and at the 30° at nearly 13 miles. The atmosphere, by moving continually round along with the earth, has acquired the same degree of motion, so that those parts of it which are above the equator move faster than those which are at a distance. Were a portion of the atmosphere to be transported in an instant from latitude 30° to the equator, it would not immediately acquire the velocity of the equator; the eminences of the earth, therefore, would strike against it, and it would assume the appearance of an east wind. This is the case in a smaller degree with the air that flows towards the equator, to supply the place of the rarefied air which is continually ascending; and this, when combined with its real motion from north to south, must cause it to assume the appearance of a north-easterly wind on this side the equator, and of a south-easterly beyond it.

The motion westward occasioned by this difference in celerity alone, would be very small; but it is increased by another circumstance. Since the rarefaction of the air in the torrid zone is owing to the heat derived from the contiguous earth, and since this heat is owing to the perpendicular rays of the sun, those parts must be hottest where the sun is actually vertical; and consequently the air above them must be most rarefied; the contiguous parts of the atmosphere will therefore be drawn most forcibly to that particular spot. Now, since the diurnal motion of the earth is from east to west, this hottest spot will be continually shifting westwards, and this will occasion a current of the atmosphere in that direction. That this cause really operates, appears from a circumstance already mentioned: When the sun approaches either of the tropics, the trade-wind on the same side of the equator assumes a more easterly direction, evidently from the cause here mentioned, while the opposite trade-wind being deprived of this additional impulse, blows in a direction more perpendicular to the equator.

69 What increases the westerly direction of the trade-wind.

The westerly direction of the trade-wind is still farther increased by another cause. Since the attraction of the sun and moon produces so remarkable an effect

Winds. effect upon the ocean, we cannot but suppose that an effect equally great, at least, is produced upon the atmosphere. Indeed as the atmosphere is nearer the moon than the sea is, the effects produced by attraction upon it ought to be greater. When we add to this the elasticity of the air, or that disposition which it has to dilate itself when freed from any of its pressure, we cannot but conclude, that the tides in the atmosphere are considerable. Now since the apparent diurnal motion of the moon is from east to west, the tides must follow it in the same manner, and consequently produce a constant motion in the atmosphere from east to west. This reasoning is confirmed by the observations of several philosophers, particularly of M. Casson, that in the torrid zone the barometer is always two-thirds of a line higher twice every 24 hours than during the rest of the day; and that the time of this rise always corresponds with the tides of the sea; a proof that it proceeds from the same cause.

All these different causes probably combine in the production of the trade-winds; and from their being sometimes united, and sometimes distinct or opposite, arise all those little irregularities which take place in the direction and force of the trade-winds.

Since the great cause of these winds is the rarefaction of the atmosphere by the heat of the sun, its ascension and the consequent rushing in of colder air from the north and south, the internal boundary of the trade-winds must be that parallel of the torrid zone which is hottest, because there the ascension of the rarefied air must take place. Now since the sun does not remain stationary, but is constantly shifting from one tropic to the other, we ought naturally to expect that this boundary would vary together with its exciting cause; that therefore, when the sun is perpendicular to the tropic of Cancer, the north-east trade-wind would extend no farther south than north latitude 23° 30′; that the south-east wind would extend as far north; and that, when the sun was in the tropic of Capricorn, the very contrary would take place. We have seen, however, that though this boundary be subject to considerable changes from this very cause, it may in general be considered as fixed between the second and fifth degrees of north latitude.

Though the sun be perpendicular to each of the tropics during part of the year, he is for one-half of it at a considerable distance, so that the heat which they acquire, while he is present, is more than lost during his absence. But the sun is perpendicular to the equator twice in a year, and never farther distant from it than $23\frac{1}{2}$°; being therefore twice every year as much heated, and never so much cooled as the tropics, its mean heat must be greater, and the atmosphere in consequence generally most rarefied at that place. Why then, it will be asked, is not the equator the boundary of the two trade-winds? To speak more accurately than we have hitherto done, the internal limit of these winds must be that parallel where the mean heat of the earth is greatest. This would be the equator, were it not for a reason that shall now be explained.

It has been shewn by astronomers, that the orbit of the earth is an ellipsis, and that the sun is placed in one of the foci. Were this orbit to be divided into two parts by a straight line perpendicular to the transverse axis, and passing through the centre of the sun, one of these parts would be less than the other; and the earth during its passage through the small part of its orbit, would constantly be nearer the sun than while it moved through the other portion. The celerity of the earth's motion in any part of its orbit is always proportioned to its distance from the sun; the nearer it is to the sun it moves the faster; the farther distant, the slower. The earth passes over the smaller portion of its orbit during our winter, which must therefore be shorter than our summer, both on account of this part of the orbit being smaller than the other, and on account of the increased celerity of the earth's motion. The difference, according to Cassini, is 7 days, 23 hours, 53 minutes. While it is winter in the northern, it is summer in the southern hemisphere; wherefore the summer in the southern hemisphere must be just as much shorter than the winter, as our winter is shorter than our summer. The difference, therefore, between the length of the summer in the two hemispheres is almost 16 days. The summer in the northern hemisphere consists of $190\frac{1}{2}$ days, while in the southern it consists only of $174\frac{1}{2}$. They are to one another nearly in the proportion of 14 to 12.8; and the heat of the two hemispheres may probably have nearly the same proportion to one another. The internal limit of the trade-winds ought to be that parallel where the mean heat of the globe is greatest; this would be the equator, if both hemispheres were equally hot; but since the northern hemisphere is the hottest, that parallel ought to be situated somewhere in it; and since the difference between the heat of the two hemispheres is not great, the parallel ought not to be so far distant from the equator.

The trade-wind would blow regularly round the whole globe if the torrid zone were all covered with water. If the Indian ocean were not bounded by land on the north, it would blow there in the same manner as it does in the Atlantic and Pacific oceans. The rays of light pass through a transparent body without communicating any, or at least but a small degree of heat. If a piece of wood be inclosed in a glass vessel, and the focus of a burning-glass directed upon it, the wood will burn to ashes, while the glass through which all the rays passed is not even heated. When an opaque body is exposed to the sun's rays, it is heated in proportion to its opacity. If the bulb of a thermometer be exposed to the sun, the mercury will not rise so high as it would do if this bulb were painted black. Land is much more opaque than water; it becomes therefore much warmer when both are equally exposed to the influence of the sun. For this reason, when the sun approaches the tropic of Cancer, India, China, and the adjacent countries, become much hotter than the ocean which washes their southern coasts. The air over them becomes rarefied, and ascends, while colder air rushes in from the Indian ocean to supply its place. As this current of air moves from the equator northward, it must, for a reason already explained, assume the appearance of a south-west wind; and this tendency eastward is increased by the situation of the countries to which it flows. This is the cause of the south-west monsoon, which blows during summer in the northern parts of the Indian ocean. Between Borneo and the coast of China, its direction is almost due north, because

Winds.

cause the country to which the current is directed lies rather to the west of north; a circumstance which counteracts its greater velocity.

In winter, when the sun is on the south side of the equator, these countries become cool, and the north-east trade-wind resumes its course, which, had it not been for the interference of these countries, would have continued the whole year.

As the sun approaches the tropic of Capricorn, it becomes almost perpendicular to New Holland; that continent is heated in its turn, the air over it is rarefied, and colder air rushes in from the north and west to supply its place. This is the cause of the north-west monsoon, which blows from October to April, from 3° to 10° south latitude. Near Sumatra its direction is regulated by the coast: this is the case also between Africa and Madagascar.

The same cause which occasions the monsoons, gives rise to the winds which blow on the west coasts of Africa and America. The air above the land is hotter and rarer, and consequently lighter than the air above the sea; the sea air, therefore, flows in, and forces the lighter land atmosphere to ascend.

The same thing will account for the phenomena of the sea and land breezes. During the day, the cool air of the sea, loaded with vapours, flows in upon the land, and takes the place of the rarefied land air. As the sun declines, the rarefaction of the land air is diminished; thus an equilibrium is restored. As the sea is not so much heated during the day as the land, neither is it so much cooled during the night, because it is constantly exposing a new surface to the atmosphere. As the night approaches, therefore, the cooler and denser air of the hills (for where there are no hills there are no sea and land breezes) falls down upon the plains, and pressing upon the now comparatively lighter air of the sea, causes the land breeze.

The rarefied air which ascends between 2° and 5° north latitude, has been shewn to be the principal cause of the trade-winds. As this air ascends, it must become gradually colder, and consequently heavier; it would therefore descend again if it were not buoyed up by the constant ascent of new rarefied air. It must therefore spread itself to the north and south, and gradually mix in its passage with the lower air; and the greater part of it probably does not reach far beyond 30°, which is the external limit of the trade-wind. Thus there is a constant circulation of the atmosphere in the torrid zone; it ascends near the equator, diffuses itself towards the north and south, descends gradually as it approaches 30°, and, returning again towards the equator, performs the same circuit. It has been the opinion of the greater part of those who have considered this subject, that the whole of the rarefied air which ascends near the equator, advances towards the poles and descends there. But if this were the case, a constant wind would blow from both poles towards the equator, and the trade winds would extend over the whole earth; for otherwise the ascent of air in the torrid zone would very soon cease. A little reflection must convince us that it cannot be true. Rarefied air differs in nothing from the common air, except in containing a greater quantity of heat. As it ascends, it gradually loses this superfluous heat. What then should hinder it from descending, and mixing with the atmosphere below? That there is a constant current of superior air, however, towards the poles, cannot be doubted; but it consists principally of hydrogen gas. We shall immediately attempt to assign the reason why its accumulation at the pole is not always attended with a north wind.

If the attraction of the moon and the diurnal motion of the sun have any effect upon the atmosphere, and that they have some effect can hardly be disputed, there must be a real motion of the air westwards within the limits of the trade-winds. When this body of air reaches America, its further passage westwards is stopt by the mountains which extend from one extremity of that continent to the other. From the momentum of this air, when it strikes against the sides of these mountains, and from its elasticity, it must acquire from them a considerable velocity, in a direction contrary to the first, and would therefore return eastwards again if this were not prevented by the trade-winds. It must therefore rush forwards in that direction where it meets with the least resistance: that is, towards the north and south. As air is nearly a perfectly elastic body, when it strikes against the sides of the American mountains, its velocity will not be perceptibly diminished, though its direction be changed. Continuing to move, therefore, with the velocity of the equator, when it arrives at the temperate zones it will assume the appearance of a north-east or south-east wind. To this is to be ascribed the frequency of south-west winds over the Atlantic ocean and western parts of Europe. Whether these winds are equally frequent in the northern Pacific ocean, we have not been able to ascertain; but it is probable that the mountains in Asia produce the same effect as those in America.

It is not impossible that another circumstance may also contribute to the production of these winds. The oxygen, which is rather heavier than common air, may mix with the atmosphere; but the hydrogen (a cubic foot of which weighs only 41.41 grains, while a cubic foot of oxygen weighs 593.32 grains) may ascend to the higher regions of the atmosphere.

By what means the decomposition is accomplished (if it takes place at all) we cannot tell. There are probably a thousand causes in nature of which we are entirely ignorant. Whether heat and light, when long applied to vapours, may not be able to decompound them, by uniting with the hydrogen, which seems to have a greater attraction for heat than oxygen has, or whether the electrical fluid may not be capable of producing this effect, are questions which future observations and experiments must determine. Dr Franklin filled a glass tube with water, and passed an electrical shock through it; the tube was broken in pieces, and the whole water disappeared. He repeated the experiment with ink instead of water, and placed the tube upon white paper: the same effects followed, and the ink, though it disappeared completely, left no stain on the paper. Whether the water in these cases was decomposed or not, it is impossible to say; but the supposition that it was, is not improbable. An experiment might easily be contrived to determine the point.

This decomposition would account for the frequency of south-west winds, particularly in summer; for this new air is furnished to supply the place of that which is forced northwards by the causes already explained.

Perhaps

Winds. Perhaps it may be a confirmation of this conjecture, that the south-west winds generally extend over a greater tract of country than most other winds which blow in the temperate zones. What has been said of south-west winds holds equally with regard to north-west winds in the south temperate zone.

After south-west winds have blown for some time, a great quantity of air will be accumulated at the pole, at least if they extend over all the northern hemisphere; and it appears, from comparing the tables kept by some of our late navigators in the northern Pacific ocean with similar tables kept in this island, that this is sometimes the case so far as relates to the Atlantic and Pacific oceans. When this accumulation becomes great, it must, from the nature of fluids, and from the elasticity of the air, press with a considerable and increasing force on the advancing air; so that in time it becomes stronger than the south-west wind. This will occasion at first a calm, and afterwards a north wind, which will become gradually easterly as it advances southwards, from its not assuming immediately the velocity of the earth. The mass of the atmosphere will be increased in all those places over which this north-east wind blows; this is confirmed by the almost constant rise of the barometer during a north-east wind.

Whatever tends to increase the bulk of the atmosphere near the pole, must tend also to increase the frequency of north-east winds; and if there be any season when this increase takes place more particularly, that season will be most liable to these winds. During winter the northern parts of Europe are covered with snow, which is melted in the beginning of summer, when the heat of the sun becomes more powerful. Great quantities of vapour are during that time raised, which will augment both the bulk and weight of the atmosphere, especially if the conjecture about the conversion of vapour into air has any foundation. Hence north-east winds are most prevalent during May and June.

But it will be said, if this hypothesis were true, the south-west and north-east winds ought to blow alternately, and continue each of them for a stated time; whereas the south-west wind blows sometimes longer and sometimes shorter, neither is it always followed by a north-east wind.

If the conjecture about the decomposition of vapour in the torrid zone be true, the hydrogen which formed a part of it will ascend from its lightness, and form a stratum above the atmospherical air, and gradually extend itself, as additional hydrogen rises, towards the north and south, till at last it reaches the poles. The lightness of hydrogen is owing to the great quantity of heat which it contains; as it approaches the poles it must lose a great part of this heat, and may in consequence become heavy enough to mix with the atmosphere below. Oxygen makes a part of the atmosphere; and its proportion near the poles may sometimes be greater than ordinary, on account of the additional quantity brought thither from the torrid zone. Mr Cavendish mixed oxygen and hydrogen together in a glass jar; and upon making an electrical spark pass through them, they immediately combined and formed water.

That there is electric matter at the poles, cannot be doubted. The abbé Chappe informs us, that he saw thunder and lightning much more frequently at Tobolski and other parts of Siberia, than in any other part of the world. In the north of Europe, the air, during very cold weather, is exceedingly electric; sparks can be drawn from a person's hands and face, by combing his hair, or even powdering him with a puff. Æpinus was an eye-witness to this fact, and to still more astonishing proofs of the electricity of the atmosphere during great colds.

May not the appearance of the aurora borealis be owing to the union of oxygen and hydrogen by the intervention of the electric fluid? That it is an electrical phenomenon, at least, can hardly be doubted. Artificial electricity is much strengthened during an aurora, as M. Volta and Mr Canton have observed; and the magnetic needle moves with the same irregularity during an aurora that has been observed in other electrical phenomena. This fact we learn from Bergman and De la Lande. Many philosophers have attempted to demonstrate that auroræ boreales are beyond the earth's atmosphere; but the very different results of their calculations evidently prove that they were not possessed of sufficient data.

If this conjecture be true, part of the atmosphere near the poles must at times be converted into water. This would account for the long continuance of south-west winds at particular times; when they do so, a decomposition of the atmosphere is going on at the pole. It would render this conjecture more probable, if the barometer fell always when a south-west wind continues long.

70 South-west winds very common after auroræ boreales.

If this hypothesis be true, a south-west wind ought always to blow after auroræ boreales; and we are informed by Mr Winn, that this is actually the case. This he found never to fail in 23 instances. He observed also, that when the aurora was bright, the gale came on within 24 hours, but did not last long: but if it was faint and dull, the gale was longer in beginning, and less violent, but it continued longer. This looks like a confirmation of our conjecture. Bright auroræ are probably nearer than those which are dull. Now, if the aurora borealis be attended with a decomposition of a quantity of air, that part of the atmosphere which is nearest must first rush in to supply the distant parts. Just as if a hole were bored in the end of a long vessel filled with water, the water nearest the hole would flow out immediately, and it would be some time before the water at the other end of the vessel began to move. The nearer we are to the place of precipitation, the sooner will we feel the south-west wind. It ought therefore to begin sooner after a bright aurora, because it is nearer than a dull and faint one. Precipitations of the atmosphere at a distance from the pole cannot be so great as those which take place near it; because the cold will not be sufficient to condense so great a quantity of hydrogen; south-west winds, therefore, ought not to last so long after bright as after dull auroræ. Winds are more violent after bright auroræ, because they are nearer the place of precipitation; just as the water near the hole of the vessel runs swifter than that which is at a considerable distance.

71 Probable causes of south-west winds.

If these conjectures have any foundation in nature, there are two sources of south-west winds; the first has its origin in the trade winds, the second in precipitations of the atmosphere near the pole. When they originate from the first cause, they will blow in countries farther

Winds.

farther south for some time before they are felt in those which are farther north; but the contrary will take place when they are owing to the second cause. In this last case, too, the barometer will sink considerably; and it actually does so constantly after auroræ, as we are informed by Mr Madison, who paid particular attention to this subject. By keeping accurate meteorological tables in different latitudes, it might easily be discovered whether these consequences be true, and of course whether the above conjectures be well or ill grounded.

72 Winds commonly begin at the place towards which they blow.

It appears that winds generally commence at that point towards which they blow; and hence they must arise from a rarefaction and consequent displacing of the air in some particular place, by the action of heat, or some other cause. Perhaps, according to the idea of Mr Williams, this cause may be an increased precipitation of the superior strata of air, rendered unusually dense from its being surcharged with moisture in the place where the wind begins to blow, or from an increased evaporation from a humid surface in the opposite direction.

Hurricanes are constantly preceded by a great depression of the thermometer; and in these cases the wind often seems to blow from every direction towards the quarter where this fall of the barometer is observed.

Violent winds from the north-east have repeatedly been observed to begin at the quarter towards which they blow. In 1740 Dr Franklin was prevented from observing an eclipse of the moon at Philadelphia by a north-east storm, which came on about seven o'clock in the evening. He was surprised to find afterwards that it had not come on at Boston till near 11 o'clock; and, upon comparing all the accounts which he received from the several colonies of the beginning of this and other storms of the same kind, he found it to be always an hour later the farther north-east, for every 100 miles. "From hence (says he) I formed an idea of the course of the storm, which I will explain by a familiar instance. I suppose a long canal of water stopped at the end by a gate. The water is at rest till the gate is opened; then it begins to move out through the gate, and the water next the gate is first in motion, and moves on towards the gate, and so on successively, till the water at the head of the canal is in motion, which it is last of all. In this case the water moves indeed towards the gate; but the successive times of beginning the motion are in the contrary way, viz. from the gate back to the head of the canal. Thus to produce a north-east storm, I suppose some great rarefaction of the air in or near the gulf of Mexico; the air arising thence has its place supplied by the next more northern, cooler, and therefore denser and heavier air; a successive current is formed, to which our coast and inland mountains give a north-east direction."

Several instances of a similar kind have occurred. In 1802, Dr Mitchell observed a storm which began at Charlestown on the 21st of February, at two o'clock P. M. but was not observed at Washington, several hundred miles to the north-east, till five o'clock; at New-York till 10, nor at Albany till daybreak of the following morning. Hence it appears that it must have moved at the rate of 1100 miles in 11 hours, or 100 miles an hour.

A remarkable storm of this kind, in which the wind was easterly, and attended with a heavy fall of snow, was observed in Scotland on the 8th of February 1799; but the motion of the wind was much slower. It began to snow at Falkirk on the 7th of February at six in the evening, but in Edinburgh not till one o'clock A. M. on the 8th; and the snow was not observed at Dunbar till seven hours after. The storm continued 11 hours, during which time it did not travel more than 100 miles.

Currents of air from the poles naturally assume a north-east direction as they advance southwards, because their diurnal motion becomes less than that of the earth. Various circumstances, however, may change this direction, and cause them to become north, or even north-west winds. The south-west winds themselves may often prove sufficient for this; and violent rains, or great heat, by lessening or rarefying the atmosphere in any country, will produce the same effect in countries to the westwards, when north winds happen to be blowing.

In North America, the north-west winds become gradually more frequent as we advance northwards. The east coast of this continent, where the observations were made from which this conclusion was drawn, is alone cultivated; the rest of the country is covered with wood. Now cultivated countries are generally considered as warmer than those which are uncultivated, though Mr Williams is of a different opinion; and on this circumstance founds his hypothesis of the climate of Britain being much deteriorated during the last 50 years. The air, therefore, in the interior parts of the country should be constantly colder than the east coast. This difference will scarcely be perceptible in the southern parts, because there the influence of the sun is very powerful; but it will become gradually greater as we advance northwards, because the influence of the sun diminishes, and the continent becomes broader. Hence north-west winds ought to become more frequent upon the east coast as we advance northwards; and they will probably cease to blow so often as soon as the whole continent of North America becomes cultivated.

73 Different currents often appear in the atmosphere at the same time.

There is one curious circumstance which deserves attention: One current of air is often observed to blow at the surface of the earth, while a current in the contrary direction is flowing in a superior part of the atmosphere. Dr Thomson on one occasion observed three currents of this kind blowing all at the same time in contrary directions. It has been affirmed that changes of weather commonly commence in the upper strata, and that they are gradually extended by the current of air that commences above, proceeding towards the lower parts of the atmosphere.

74 Partial winds.

Besides these more general winds, there are others which extend only over a very small part of the earth. These originate from many different causes. The atmosphere is principally composed of three different kinds of air, oxygen, azote, and carbonic acid, to which may be added water. Great quantities of each of these ingredients are constantly changing their aërial form, and combining with various substances: or they are separating from other bodies, assuming the form of air, and mixing with the atmosphere. Partial deficiencies, therefore, and partial accumulations, must be continually

Meteors. ally taking place in different parts of the atmosphere, which will occasion winds varying in direction, violence, and continuance, according to the suddenness and the quantity of air destroyed or produced. Besides these, there are many other ingredients constantly mixing with the atmosphere, and many partial causes of condensation and rarefaction in particular places. To these, and probably to other causes hitherto unknown, are to be ascribed all those winds which blow in any place besides the general ones already explained; and which, as they depend on causes hitherto at least reckoned contingent, will probably for ever prevent uniformity and regularity in the winds. All these causes, however, may, and probably will, be discovered: the circumstances in which they will take place, and the effects they will produce, may be known; and whenever this is the case, the winds of any place may in some measure be reduced to calculation.

Chap. V. *Of Meteors.*

75 Meteors. THE principal luminous phenomena denominated meteors, have been fully considered under ATMOSPHERIC ELECTRICITY. Those meteors that burst in the air, and are followed by the falling of stones or other mineral substances, have been fully described and accounted for under METEOROLITE. We have here only to notice briefly the meteors called *falling stars*, and *ignes fatui*.

76 Falling star. The falling or shooting star is a very common phenomenon, and takes place more especially at those seasons and in those situations where the aurora borealis is most frequently observed. Indeed they are considered by most philosophers as modifications of the same phenomenon, and depending on the same cause. We have seen good reason to conclude that the aurora borealis is an electrical meteor; and if the falling star is so nearly allied to the aurora as is supposed, it must also be produced by electricity. Mr G. Morgan seems to have no doubt of the electrical nature of this meteor, and remarks that if what appears as an undulating flash in the aurora, could be concentrated or confined within smaller dimensions, it would probably assume the appearance of a falling star. He founds this opinion chiefly on the following experiment.

Into a tube 48 inches long, and $\frac{1}{4}$ inch diameter, Mr Morgan conveyed as much air, as, under the common pressure of the atmosphere, would fill two inches in length of the same tube. (The tube we presume was previously exhausted of air.) One extremity of the tube he connected with the ground by means of good conductors, and fastened to the other a metallic ball. Through the tube thus filled with rarefied air, he sent electric sparks of different magnitudes, by bringing the ball within the striking distance of different fixed conductors. When the sparks were small, a flash like that of the aurora borealis, seemed to fill the whole tube; but when the spark was what might be made to strike through 10 inches in the open air, it appeared to strike through the whole length of the tube, with all the brilliancy and straightness of a falling star. If, however, he extracted part of the air out of the tube, by the air-pump, he could never make the electric fluid assume any form excepting that of a flash; but by exchanging the tube for another with a thermometrical ball, and treating it in the same manner as the preceding, the flash never appeared, but the fluid in its passage assumed all the brilliancy of a falling star.

It is easy to trace the similarity of circumstances that take place in this experiment, and in the natural phenomenon of the falling star. Both take place in rarefied air; both are remarkable for the brightness of their light, and for the straightness of their direction. That falling stars are frequently, if not always, the concentration of an aurora borealis, may be inferred from their being the constant attendants of a very electrical state of the atmosphere; and from their frequent appearance near that portion of the heavens which is illumined by the northern lights at the time of their appearance.

Mr Morgan was riding towards Norwich late at night, when to the north-east of the town he beheld a fine conical stream of the aurora borealis. The whole body every now and then flashed, as if an additional quantity of electric fluid were thrown into it, and nearly at the same instant he perceived what is vulgarly called a falling star, darting from its summit. This appearance he observed twice successively.

The *ignis fatuus*, or *will-with-the-wisp*, that appears so often in boggy, marshy and damp situations, decoying the unwary traveller, and terrifying the superstitious vulgar, seems to be rather of a phosphoric than an electric nature, similar to the light which is emitted by stale fish, rotten wood, and other putrescent substances. Sir Isaac Newton defined it to be a vapour shining without heat. 77 Ignis fatuus.

A remarkable *ignis fatuus* was observed by Mr Derham, in some boggy ground, between two rocky hills. He was so fortunate as to be able to approach it within two or three yards. It moved with a brisk and desultory motion about a dead thistle, till a slight agitation of the air, occasioned, as he supposed, by his near approach to it, occasioned it to jump to another place; and as he approached, it kept flying before him. He was near enough to satisfy himself, that it could not be the shining of glow-worms or other insects—it was one uniform body of light.

M. Beccaria mentions two of these luminous appearances, which were frequently observed in the neighbourhood of Bologna, and which emitted a light equal to that of an ordinary faggot. Their motions were unequal, sometimes rising, and sometimes sinking towards the earth; sometimes totally disappearing, though in general they continued hovering about six feet from the ground. They differed in size and figure; and indeed, the form of each was fluctuating, sometimes floating like waves, and dropping sparks of fire. He was assured there was not a dark night in the whole year in which they did not appear; nor was their appearance at all affected by the weather, whether cold or hot, snow or rain. They have been known to change their colour from red to yellow; and generally grew fainter as any person approached, vanishing entirely when the observer came very near to them, and appearing again at some distance.

Dr Shaw also describes a singular *ignis fatuus*, which he saw in the Holy Land. It was sometimes globular, or in the form of the flame of a candle; and immediately afterwards spread itself so much, as to involve the whole company in a pale inoffensive light, and

Weather.

and then was observed to contract itself again, and suddenly disappear. In less than a minute, however, it would become visible as before, and run along from one place to another; or would expand itself over more than three acres of the adjacent mountains. The atmosphere at this time was thick and hazy.

All these luminous appearances are probably owing to the extrication of hydrogen gas so slightly impregnated with phosphorus as to continue emitting a faint light, without producing that brilliant flash which follows the sudden extrication into the air, of the common phosphorated hydrogen gas obtained in the usual chemical experiment of throwing phosphuret of lime into water.

Chap. VI. *Of the Application of Meteorology to Prognosticating the Weather.*

It has ever been a principal object among mankind, to foretel the changes of weather that are likely to follow particular appearances in the sky, among the heavenly bodies, &c.; and it has been often alleged, that in this respect the philosopher is far behind the husbandman and the shepherd. Were the former, however, to add to his scientific researches the observations to which the latter are indebted for their judgment of the weather, he would soon be far superior to them in this respect.

79 Kirwan's conclusions on the weather.

Dr Kirwan has lately endeavoured to discover probable rules for prognosticating the weather in different seasons, as far as regards this climate, from tables of observation alone; and from comparing a number of these observations made in England, from 1677 to 1789, he found,

1. That when there has been no storm before or after the vernal equinox, the ensuing summer is generally *dry*, at least five times in six.

2. That when a storm happens from an easterly point, either on the 19th, 20th, or 21st of May, the succeeding summer is generally *dry* four times in five.

3. That when a storm arises on the 26th, 27th, or 29th of May (and not before), in any point, the succeeding summer is generally *dry* four times in five.

4. If there be a storm at south-west or west-south-west on the 19th, 20th, 21st, or 22d of March, the succeeding summer is generally *wet* five times in six.

In this country winters and springs, if dry, are most commonly cold; if moist, warm: on the contrary, dry summers and autumns are usually *hot*, and moist summers cold. So that if we know the moistness or dryness of a season, we can judge pretty accurately of its temperature.

From a table of the weather kept by Dr Rutty, in Dublin, for 41 years, Dr Kirwan endeavoured to calculate the probabilities of particular seasons being followed by others. Though his rules relate chiefly to the climate of Ireland, yet as probably there is not much difference between that island and Britain, in the general appearance of the seaons, we shall mention his conclusions here.

In 41 years there were six wet springs, 22 dry, and 13 variable; 20 wet summers, 16 dry, and five variable; 11 wet autumns, 11 dry, and 19 variable. A season according to Dr Kirwan, is counted *wet*, when it contains two wet months. In general, the quantity of rain which falls in dry seasons is less than five inches; in wet seasons more. Variable seasons are those in which there falls between 30 and 36 pounds, a pound being equal to .157637 of an inch.

80 Probable succession of seasons.

The order in which the different seasons succeeded each other, was as in the following table.

	Has been followed by a		Times	Probability
A dry spring	dry	Summer	11	$\frac{11}{22}$
	wet		8	$\frac{8}{22}$
	variable		3	$\frac{3}{22}$
A wet spring	dry		0	0
	wet		5	$\frac{5}{6}$
	variable		1	$\frac{1}{6}$
A variable spring	dry		5	$\frac{5}{13}$
	wet		7	$\frac{7}{13}$
	variable		1	$\frac{1}{13}$
A dry summer	dry	Autumn	5	$\frac{5}{10}$

81 Rules for prognosticating the weather.

Hence Dr Kirwan deduced the probability of the kind of seasons which would follow others. This probability is expressed in the last column of the table, and is to be understood in this manner. The probability that

Weather.

that a dry summer will follow a dry spring is $\frac{11}{12}$; that a wet summer will follow a dry spring, $\frac{8}{22}$; that a variable summer will follow a dry spring. $\frac{3}{22}$, and so on.

This method of Dr Kirwan, if there is such a connexion between the different seasons that a particular kind of weather in one has a tendency to produce a particular kind of weather in the next, as it is reasonable to expect from theory, may in time, by multiplying observations, come to a great degree of accuracy, and may at last, perhaps, lead to that great desideratum, a rational theory of the weather. As we wish to throw as much light as possible on this important subject, we shall add to these a few maxims, the truth of which has either been confirmed by long observation, or which the knowledge we have already acquired of the causes of the weather has established on tolerably good grounds.

1. A moist autumn with a mild winter is generally followed by a cold and dry spring, which greatly retards vegetation. Such was the year 1741.

2. If the summer be remarkably rainy, it is probable that the ensuing winter will be severe; for the unusual evaporation will have carried off the heat of the earth. Wet summers are generally attended with an unusual quantity of seed on the white thorn and dog-rose bushes. Hence the unusual fruitfulness of these shrubs, is a sign of a severe winter.

3. The appearance of cranes and birds of passage early in autumn announces a very severe winter; for it is a sign it has already begun in the northern countries.

4. When it rains plentifully in May, it will rain but little in September, and *vice versa*.

5. When the wind is south-west during summer or autumn, and the temperature of the air unusually cold for the season, both to the feeling and the thermometer, with a low barometer, much rain is to be expected.

6. Violent temperatures, as storms or great rains, produce a sort of crisis in the atmosphere, which produces a constant temperature, good or bad, for some months.

7. A rainy winter predicts a steril year: a severe autumn announces a windy winter.

82 Signs of rain from birds.

To the above we shall add the following maxims, drawn from observation, and with these shall conclude this article.—Sea and fresh water-fowls, such as cormorants, sea-gulls, muir-hens, &c. flying from sea, or the fresh waters, to land, shew bad weather at hand: land fowls flying to waters, and these shaking, washing, and noisy, especially in the evening, denote the same; geese, ducks, cats, &c. picking, shaking, washing, and noisy; rooks and crows in flocks, and suddenly disappearing; pyes and jays in flocks, and very noisy; the raven or hooded-crow crying in the morning, with an interruption in their notes, or crows being very clamorous at even; the heron, bittern, and swallow flying low; birds forsaking their meat and flying to their nests; poultry going to roost, or pigeons to their dove-house; tame fowls grubbing in the dust, and clapping their wings; small birds seeming to duck and wash in the sand; the late and early crowing of the cock, and clapping his wings; the early singing of wood-larks; the early chirping of sparrows; the early note of the chaffinch near houses; the dull appearance of robin-redbreast near houses; peacocks and owls unusually clamorous.

83 Wind from birds.

Sea and fresh-water fowls gathering in flocks to the banks, and there sporting, especially in the morning; wild-geese flying high, and in flocks, and directing their course eastward; coots restless and clamorous; the hoopoe loud in his note; the king's-fisher taking to land; rooks darting or shooting in the air, or sporting on the banks of fresh waters; and lastly, the appearance of the malefigie at sea, is a certain forerunner of violent winds, and (early in the morning) denotes horrible tempests at hand.

84 Fair weather from birds.

Halcyons, sea-ducks, &c. leaving the land and flocking to the sea; kites, herons, bitterns, and swallows flying high and loud in their notes; lapwings restless and clamorous; sparrows after sunrise restless and noisy; ravens, hawks, and kestrils (in the morning), loud in their notes; robin-redbreast mounted high, and loud in his song; larks soaring high, and loud in their songs; owls hooting with an easy and clear note; bats appearing early in the morning.

85 Rain from beasts.

Asses braying more frequently than usual; hogs playing, scattering their food, or carrying straw in their mouths; oxen snuffing the air, looking to the south, while lying on their sides, or licking their hoofs; cattle gasping for air at noon; calves running violently and gamboling; deer, sheep, or goats, leaping, fighting, or pushing; cats washing their face and ears; dogs eagerly scraping up earth; foxes barking, or wolves howling; moles throwing up earth more than usual; rats and mice more restless than usual; a grumbling noise in the belly of hounds.

86 Rain from insects.

Worms crawling out of the earth in great abundance; spiders falling from their webs; flies dull and restless; ants hastening to their nests; bees hastening home, and keeping close in their hives; frogs and toads drawing nigh to houses; frogs croaking from ditches; toads crying on eminences; gnats stinging more than usual; but, if gnats play in the open air, or if hornets, wasps, and glow-worms appear plentifully in the evening, or if spiders webs are seen in the air, or on the grass, or trees, these do all denote fair and warm weather at hand.

87 Rain from the sun.

Sun rising dim or waterish; rising red with blackish beams mixed along with his rays; rising in a musty or muddy colour; rising red and turning blackish; setting under a thick cloud; setting with a red sky in the east.

N. B. Sudden rains never last long; but when the air grows thick by degrees, and the sun, moon, and stars shine dimmer and dimmer, then it is like to rain six hours usually.

88 Wind from the sun.

Sun rising pale and setting red, with an iris; rising large in surface; rising with a red sky in the north; setting of a bloody colour; setting pale, with one or more dark circles, or accompanied with red streaks; seeming concave or hollow; seeming divided, great storms; parhelia, or mock suns, never appear, but are followed by tempests.

89 Fair weather from the sun.

Sun rising clear, having set clear the night before; rising while the clouds about him are driving to the west; rising with an iris around him; and that iris wearing away equally on all sides, then expect fair and settled weather; rising clear and not hot; setting in red clouds, according to the old observation:

 The

The evening red and morning gray,
Is the sure sign of a fair day.

90 Rain from the moon. Moon pale in colour, rain; horns blunt at first rising, rain; horns blunt, at or within two or three days after the change, denotes rain from that quarter; an iris with a south wind, rain next day; wind south third night after change, rain next day; the wind south, and the moon not seen before the fourth night, rain most of that month; full moon in April, new and full moon in August, for most part bring rain; mock moons are the forerunners of great rains, land floods, and inundations.

91 Wind from the moon. Moon seeming greatly enlarged: appearing of a red colour; horns sharp and blackish; if included with a clear and ruddy iris; if the iris be double or seem to be broken in parts, tempests.

N. B. On the new moon, the wind for the most part changes.

When the moon, at four days old, has her horns sharp, she foretels a tempest at sea, unless she has a circle about her, and that too entire, because, by that she shows that it is not like to be bad weather, till it is full moon.

92 Fair weather from the moon. Moon seeming to exhibit bright spots: a clear iris with full moon; horns sharp fourth day, fair till full; horns blunt at first rising, or within two or three days after change, denotes rain for that quarter; but fair weather the other three quarters. Moon clear three days after change and before full, always denotes fair weather; after every change and full, rains for the most part, succeeded by fair settled weather; moon clear and bright, always fair weather.

93 Weather from the stars. Stars seeming large, dull, and pale of colour, rain; or when their twinkling is not perceptible, or if encompassed with an iris. In summer, when the wind is at east, and stars seem greater than usual, then expect sudden rain, stars appearing great in number, yet clear and bright, seeming to shoot or dart, denote fair weather in summer, and in winter frost.

94 Rain from the clouds. In cloudy weather, when the wind falls, rain follows; clouds growing bigger, or seeming like rocks or towers settling on tops of mountains, coming from the south, or often changing their course; many in number at north-west in the even; being black in colour from the east, rain at night; but out of the west, rain next day; being like fleece of wool, from the east, rain for two or three days; lying like ridges about mid-day in the south-west, shews great storms both of wind and rain to be nigh.

95 Wind from the clouds. Clouds flying to and fro; appearing suddenly from the south or west; appearing red, or accompanied with redness in the air, especially in the morning; being of a leadish colour in the north-west; single clouds denote wind from whence they come; but if at sunset, clouds appear with golden edges, or diminish in bulk, or small clouds sink low, or draw against the wind, or appear small, white, and scattered in the north-west (such as are vulgarly called mackerel) when the sun is high, these are signs of fair weather.

N. B. It is often observed, that though the mackerel sky denotes fair weather for that day, yet for the most part, rain follows in a day or two after.

96 Rain from a rainbow. After a long drought, the rainbow denotes sudden and heavy rains; if green be the predominant colour, it denotes rain, but if red, wind with rain; if the clouds grow darker, rain; if the bow seems broken, violent storms; if appearing at noon, much rain; if in the west great rain, with thunder.

N. B. It is observed, that if the last week in February, and the first fortnight of March, be mostly rainy, and attended with frequent appearances of the bow, a wet spring and summer may be expected.

97 Fair weather from the rainbow. The rainbow appearing after rains, denotes fair weather at hand, if the colours grow lighter, fair; if the bow suddenly disappears, fair; if the bow appear in the morning, it is the sign of small rains, followed by fair weather; and if appearing at night, fair weather; if appearing in the east in the evening, fair; if the bow appear double, it denotes fair weather at present but rain in a few days; if in autumn, it continues fair for two days after the appearance of the aurora borealis, expect fair weather for at least eight days more.

98 Rain from mists. If mists be attracted to the tops of hills then expect rain in a day or two; if, in dry weather, they be observed to ascend more than usual, then expect sudden rain; mists in the new moon foreshew rain in the old; mists also in the old moon denote rain to happen in the new; a misty white scare, in a clear sky in the south-east, is always a forerunner of rain.

99 Fair weather from mists. If mists dissipate quickly, or descend after rain, it is a sure sign of fair weather; a general mist before sun-rising near the full moon, denotes fair weather for about a fortnight running. If after sunset or before sunrise, a white mist arise from the waters and meads, it denotes warm and fair weather next day. A misty dew on the inside of glass windows shows fair weather for that day.

100 Rain from inanimate bodies. Wood swelling, or stones seeming to sweat; lute or viol strings breaking; printed canvas or pasted maps relaxing; salt becoming moist; rivers sinking, or floods suddenly abating; remarkable halo about the candle; great dryness of the earth; pools seeming troubled or muddy; yellow scum on the surface of stagnant waters; dandelion or pimpernel shutting up; trefoil swelling in stalk, while the leaves bow down.

N. B. A dry spring is always attended with a rainy winter.

101 Wind from inanimate bodies. Wind shifting to the opposite point; sea calm, with a murmuring noise; a murmuring noise from the woods and rocks when the air is calm; leaves and feathers seeming much agitated; tides high when the thermometer is high; trembling or flexuous burning of flames; coal burning white with a murmuring noise; thunder in the morning with a clear sky; thunder from the north.

N. B. Whensoever the wind begins to shift, it will not rest till it come to the opposite point; and if the wind be in the north, it will be cold; if in the north-east colder; if in the south; it brings rain; but if in the south-west more rain.

102 Signs of rain ceasing. The sudden closing of gaps in the earth; the remarkable rising of springs or rivers; if the rain begins an hour or two before sunrise it is like to be fair ere noon; but if an hour or two after sunrise, it for the most part happens to continue all day and then to cease; when it begins to rain from the south with a high wind for two or three hours, and that the wind falls, and it still continues raining, it is then like to continue for 12 hours or more, and then to cease.

N. B.

Weather.

N. B. These long rains seldom hold above 24 hours, or happen above once a-year.

103 [Signs] of wind ceasing.

A hasty shower after raging winds is a sure sign of the storm being near an end. If the water ruckles and frequent bubbles arise, or if the halcyon or king's-fisher attempts the sea while the storm lasts, or moles come out of their holes, or sparrows chirp merrily, these are all certain signs of the storm ceasing.

Both sea and fresh-water fishes by their frequent rising and fluttering on the surface of the water, foretel the storm nigh over, but especially dolphins spouting up water in a storm foretel a calm.

N. B. Let the wind be in what quarter it will, upon the new moon, it presently changes.

104 [S]igns of [ha]il.

Clouds white, inclining to yellow, and moving heavily though the wind be high, is a sure sign of hail; if the eastern sky before sunrise be pale, and refracted rays appear in thick clouds, then expect great storms of hail: white clouds in summer are a sign of hail, but in winter they denote snow, especially when we perceive the air to be a little warm; in spring or winter, when clouds appear of blueish white, and expand much, expect small hail or drizzling, which properly is no other than frozen mists.

105 [Si]gns of [th]under.

Meteors shooting in the summer's evening, or chops and clefts in the earth, when the weather is sultry, always foretel thunder is nigh; in summer or harvest, when the wind has been south two or three days, and the thermometer high, and clouds rise with great white tops like towers, as if one were upon the top of another, and joined with black on the nether side, expect rain and thunder suddenly; if two such clouds arise, one on either hand, it is then time to look for shelter, as the thunder is very nigh.

N. B. It is observed that it thunders most with a south wind, and least with an east.

106 [Si]gns of [co]ld and [fr]osty wea[th]er.

Sea-pyes, starlings, fieldfares, with other migratory birds appearing early denote a cold season to ensue; the early appearance of small birds in flocks, and of robin-redbreasts near houses; sun in harvest setting in a mist or broader than usual; moon bright, with sharp horns, after change; wind shifting to the east or north after change; sky full of twinkling stars; small clouds hovering low in the north; snow falling small, while clouds appear on heaps like rocks.

N. B. Frosts in autumn are always succeeded with rain.

107 [Si]gns of [th]aw.

Snow falling in large flakes while the wind is at south; cracks appearing in the ice; sun looking waterish; the moon's horns blunted; stars looking dull; wind turning to the south; wind extremely shifting. It is also observed, that, if October and November be frost and snow, January and February are like to be open and mild.

108 Signs of drought.

Fair weather for a week together, while the wind is all that time in the south, is for the most part followed by a great drought; if February be for most rainy, spring and summer quarters are like to be so too; but if it happen to be altogether fair, then expect a drought to follow; if lightning follow after 24 hours of dry and fair weather, drought will follow, but if within 24 hours, expect great rains.

109 Signs of a hard winter.

A moist and cold summer, and mild autumn, are sure signs of a hard and severe winter: store of hips and haws denote the same; the hazel-tree flowering is ever observed to foretel the same; acorns found without any insect is a sure prognostic of a hard winter.

110 Signs of pestilential seasons.

A dry and cold winter with a southerly wind; very rainy spring, sickness in summer; if summer be dry with the wind northerly, great sickness is like to follow; great heats in spring time without winds; roots having a luscious taste, while the wind has been long southerly without rain; and, lastly, great quantities of stinking atoms, insects or animals, as flies, frogs, snakes, locusts, &c.

111 Experiments with the leech.

Inclose the leech worm in an eight ounce phial glass, three-fourths filled with water, covered with a bit of linen; let the water be changed once a-week in summer, and once a fortnight in winter.

If the leech lies motionless at the bottom in a spiral form, fair weather; if crept to the top rain; if restless, wind; if very restless, and without the water, thunder; if in winter at bottom, frost; but if in the winter it pitches its dwelling on the mouth of the phial, snow. See HELMINTHOLOGY (F).

112 Signs of the weather from the barometer.

In calm weather, when the air is inclined to rain, the mercury is low; but when tending to fair, it will rise; in very hot weather when falling, it foreshews thunder; if rising in winter, frost; but if falling in frost, thaw; if rising in a continued frost, snow; if foul weather quickly on its falling, soon over; if fair weather quickly on its rising, soon over; also if rising high in foul weather, and so continuing for two or three days, before the foul weather is over, then expect a continuance of fair weather; but, if in fair weather the mercury fall low, and so continue for two or three days, then expect much rain, and probably high winds.

N. B. In an east wind, the mercury always rises and falls lowest before great winds *.

* *Nicholson's Journal*, Feb. 1804, p. 149.

It was intended to insert in this article a summary view of the opinions of Toaldo, Cotte, and Lamarck, respecting the influence of the moon in producing changes in our atmosphere; but peculiar circumstances render it necessary to postpone this view till we come to the article MOON. See articles, CLIMATE, DEW, HYGROMETRY, METEOROLOGY, in the SUPPLEMENT.

(F) In compliance with the writer of this paper, we have retained this passage on the leech; though, as we stated, when treating of the *Hirudo medicinalis*, in HELMINTHOLOGY, we are very sceptical respecting the *weather-judging* faculties of that worm.

INDEX.

INDEX.

Thau

Meteoromancy || Methodists.

METEOROMANCY, a species of divination by meteors, principally by lightning and thunder. This method of divination passed from the Tuscans to the Romans, with whom, as Seneca informs us, it was held in high esteem.

METESSIB, an officer of the eastern nations, who has the care and oversight of all the public weights and measures, and sees that things are made justly according to them.

METHEGLIN, a species of mead; one of the most pleasant and general drinks which the northern parts of Europe afford, and much used among the ancient inhabitants: (See MEAD). The word is Welsh, *meddyglin*, where it signifies the same.—There are divers ways of making it; one of the best whereof follows: Put as much new honey, naturally running from the comb, into spring water, as that when the honey is thoroughly dissolved an egg will not sink to the bottom, but just be suspended in it; boil this liquor for an hour or more, till such time as the egg swim above the liquor about the breadth of a groat; when very cool, next morning it may be barrelled up; adding to each 15 gallons an ounce of ginger, as much of mace and cloves, and half as much cinnamon, all grossly pounded; a spoonful of yeast may be also added at the bung hole to promote the fermentation. When it has done working, it may be closely stopped up; and after it has stood a month, it should be drawn off into bottles.

METHOD, the arrangement of our ideas in such a regular order, that their mutual connexion and dependence may be readily comprehended. See LOGIC, part iv.

METHODISTS, in ecclesiastical history, is a denomination applied to different sects, both Papists and Protestants.

I. The *Popish Methodists* were those polemical doctors, of whom the most eminent arose in France towards the middle of the 17th century, in opposition to the Huguenots or Protestants. Those Methodists, from their different manner of treating the controversy with their opponents, may be divided into two classes. The one may comprehend those doctors, whose method of disputing with the Protestants was disingenuous and unreasonable, and who followed the examples of those military chiefs, who shut up their troops in intrenchments and strong holds, in order to cover them from the attacks of the enemy. Of this number were the Jesuit Veron, who required the Protestants to prove the tenets of their church by plain passages of scripture, without being allowed the liberty of illustrating those passages, reasoning upon them, or drawing any conclusions from them; Nihusius, an apostate from the Protestant religion; the two Walenburgs, and others, who confined themselves to the business of answering objections and repelling attacks; and Cardinal Richelieu, who confined the whole controversy to the single article of the divine institution and authority of the church. The Methodists of the second class were of opinion, that the most expedient manner of reducing the Protestants to silence, was not to attack them by piecemeal, but to overwhelm them at once, by the weight of some general principle or presumption, some universal argument, which comprehended or might be applied to all the points contested between the two churches: thus imitating the conduct of those military leaders who, instead of spending their time and strength in sieges and skirmishes, endeavoured to put an end to the war by a general and decisive action. These polemics rested the defence of Popery upon prescription; the wicked lives of Protestant princes who had left the church of Rome; the crime of religious schism; the variety of opinions among Protestants with regard to doctrine and discipline;

pline; and the uniformity of the tenets and worship of the church of Rome. To this class belong Nicolle the Jansenist doctor, the famous Bossuet, &c.

II. The *Protestant Methodists* form a very considerable body in this country. The sect was founded in the year 1729 by one Mr Morgan and Mr John Wesley. In the month of November that year, the latter being then fellow of Lincoln college, began to spend some evenings in reading the Greek New Testament, along with Charles Wesley student, Mr Morgan commoner of Christ church, and Mr Kirkham of Merton college. Next year two or three of the pupils of Mr John Wesley, and one pupil of Mr Charles Wesley obtained leave to attend these meetings. Two years after they were joined by Mr Ingham of Queen's college, Mr Broughton of Exeter, and Mr James Hervey; and in 1735 they were joined by the celebrated Mr Whitefield, then in his 18th year.

At this time it is said that the whole kingdom of England was tending fast to infidelity. "It is come (says Bishop Butler), I know not how, to be taken for granted by many persons, that Christianity is not so much as a subject of inquiry, but that it is now at length discovered to be fictitious; and accordingly they treat it as if in the present age this were an agreement among all people of discernment, and nothing remained but to set it up as a principal subject of mirth and ridicule, as it were by way of reprisals, for its having so long interrupted the pleasures of the world." The Methodists are said, with great probability, to have been very instrumental in stemming this torrent. They obtained their name from the exact regularity of their lives; which gave occasion to a young gentleman of Christ church to say, "Here is a new set of *Methodists* sprung up;" alluding to a sect of ancient physicians which went by that name. This extreme regularity, however, soon brought a charge against them, perhaps not altogether without foundation, of being too scrupulous, and carrying their sanctity to too great a height. In particular it was urged, that they laid too much stress upon the rubrics and canons of the church, insisted too much on observing the rules of the university, and took the scriptures in too literal a sense; and to the name of *Methodists* two others were quickly added, viz. those of *Sacramentarians* and the *Godly Club*.

The principal person in this club while in its infancy appears to have been Mr Morgan, and next to him Mr John Wesley. They visited the sick, and instituted a fund for the relief of the poor; and the better to accomplish their benevolent designs, Mr Wesley abridged himself of all his superfluities, and even of some of the necessaries of life; and by proposing the scheme to some gentlemen, they quickly increased their funds to 80l. *per annum*. This, which one should have thought would have been attended with praise instead of censure, quickly drew upon them a kind of persecution; some of the seniors of the university began to interfere, and it was reported "that the college censors were going to blow up the Godly Club *." They found themselves, however, patronised and encouraged by some men eminent for their learning and virtue; so that the society still continued, though they had suffered a severe loss in 1730 in the death of Mr Morgan, who had indeed been the founder of it. In the month of October 1735, John and Charles Wesley, Mr Ingham, and Mr Delamotte son to a merchant in London, embarked for Georgia along with Mr Oglethorpe, afterwards General Oglethorpe. The design of this voyage was to preach the gospel to the Indians. By this time, however, it appears that Mr Wesley had embraced such notions as may without the least breach of charity be accounted fanatical. Thus in a letter to his brother Samuel, he conjures him to banish from his school "the classics with their poison," and to introduce instead of them such Christian authors as would work together with him in "building up his flock in the knowledge and love of God."

* See *Wesley's Life*, p. 105.

During the voyage such a profusion of worship was observed, as we cannot help thinking savoured more of a Pharisaical than Christian behaviour; an account of which, as a similar strictness would certainly be inculcated upon the disciples, and consequently must give a just idea of the principles of the early Methodists, we shall here transcribe from Mr Wesley's life. "From four in the morning till five, each of us used private prayer; from five to seven we read the Bible together, carefully comparing it (that we might not lean to our own understandings) with the writings of the earliest ages; at seven we breakfasted; at eight were the public prayers; from nine to twelve learned the languages and instructed the children; at twelve we met to give an account to one another what we had done since our last meeting, and what we designed to do before our next; at one we dined; the time from dinner to four we spent in reading to those of whom each of us had taken charge, or in speaking to them separately as need required; at four were the evening prayers, when either the second lesson was explained (as it always was in the morning), or the children were catechised and instructed before the congregation; from five to six we again used private prayer; from six to seven I read in our cabin to two or three of the passengers, of whom there were about 80 English on board, and each of my brethern to a few more in theirs; at seven I joined with the Germans in their public service, while Mr Ingham was reading between decks to as many as desired to hear; at eight we met again, to instruct and exhort one another; between nine and ten we went to bed, when neither the roaring of the sea nor the motion of the ship could take away the refreshing sleep which God gave us."

As they proceeded in their passage, this austerity instead of being diminished was increased. Mr Wesley discontinued the use of wine and flesh; confining himself to vegetables, chiefly rice and biscuit. He ate no supper; and his bed having been made wet by the sea, he lay upon the floor, and slept soundly till morning. In his Journal he says, "I believe I shall not find it needful to go to bed, *as it is called*, any more;" but whether this was really done or not, we cannot say.

The missionaries, after their arrival, were at first very favourably received, but in a short time lost the affections of the people entirely. This was owing to the behaviour of Mr Wesley himself, who appeared not only capricious but frequently despotic. He particularly gave offence by insisting upon the baptism of children by immersion; and his excessive austerity with regard to himself

 himself did not tend to give his hearers any favourable opinion either of the superior sanctity or wisdom of their teacher. At last, on account of a difference with Mr Causton the storekeeper and chief magistrate of Savannah which ended in a law-suit, he was obliged to return to England.

Thus the cause of Methodism seemed to be entirely lost in Georgia. But Mr Wesley was soon succeeded by a more popular and successful champion, viz. Mr George Whitefield; who having spent his time during the voyage in converting the soldiers with whom he sailed, arrived at Savannah in Georgia on the 7th of May 1738. Here he was received by Mr Delamotte, was joined by several of Mr Wesley's hearers, and became intimate with some other ministers. Mr Ingham had made some progress in converting a few runaway Creek Indians, who had a settlement about four miles from Savannah; but being obliged to return to England in a few months, this design was frustrated, and the Indians in a few years separated. During the short time that Mr Whitefield resided at Savannah, he became extremely popular; and indeed the instances of his success in the way of making converts are very surprising. However, he was obliged to return to England in the autumn of that year, that he might receive priests orders. On his return to America in October 1739, he landed at Philadelphia, and instantly began his spiritual labours as in other places; being attended with astonishing success not only there but wherever he went. Passing through the colonies of Virginia, Maryland, North and South Carolina, the number of converts continually increased; but on his arrival at Savannah, he found the colony almost deserted. He now resumed the scheme he had formerly projected of building an Orphan-house; and for this he made the first collection at Charlestown in South Carolina, amounting to about 70l. sterling. His zeal in the cause of religion, or of the colony, were not, however, sufficient to procure him the favour of those in power. On his return to Philadelphia, after a short stay at Savannah, the churches were denied him; but he was made ample amends by the success which attended his field preachings and private efforts. Religious societies were everywhere set up, and many were converted with symptoms of enthusiasm, different according to their various tempers and constitutions. During this excursion, he was so successful in his collection for the Orphan-house, that on his return to Savannah he brought along with him money and provisions to the value of 500l. sterling.

The success in Georgia was now greater than ever; but the many charities which it was necessary to supply, rendered it necessary in a short time for him to undertake another journey to Charlestown. Here his principles met with the greatest opposition. He had lost the favour of the commissary by his field-preaching, and was denied the sacrament. The opposition, however, was altogether fruitless; the number of converts increased wherever he went, and he now undertook a voyage to New England. In this place also the established clergy were his enemies; but the usual success attended his other endeavours, and procured 500l. more for the use of the Orphans in Georgia.

From the year 1741 to 1743 America was deprived of Mr Whitefield's preaching, he having spent that interval in England; but in 1744 he again set out for the western continent. The remarkable success which had hitherto attended his labours now stirred up many opponents; and these had met with the greater success, as none of the Methodist preachers whom he had left were possessed of such abilities either to gain the favour of those who heard them, or to defend their doctrines against objections. Mr Whitefield's sucess, however, was the same as before: he even found means to inspire the military class with such sentiments of devotion, that Colonel Pepperell could not undertake his expedition against Louisbourg without first consulting Mr Whitefield; and great numbers of New-Englanders went volunteers, confident of victory, in consequence of the discourses of their teacher.

From the continent of America Mr Whitefield took a voyage to the Bermudas islands; and here, as everywhere else, he met with the most surprising success. Here also collections were made for the Orphan-house in Savannah, which were transmitted to that place.

Supposing it to be better for his cause to visit different countries, than to take up a permanent residence in one, Mr Whitefield left Bermudas in a few months, and did not return to America till 1751, when the Orphan-house was found to be in a very flourishing situation. After a short stay, he set sail again for Britain. Here he remained two years, and then set out on another visit to America, landing at Charlestown on the 27th of May 1754. His presence constantly revived the spirits and cause of his party, and added to their numbers wherever he went. Next year he returned to England; but after labouring in the usual manner, and meeting with the usual success there till the year 1763, he set sail again for America, and arrived at Virginia in the latter end of August. He now visited all the colonies, and found that great progress had been made in converting the Indians. On his arrival at Georgia, matters were found in a very flourishing situation, and he received the thanks of the governor and principal people for the great benefit he had been to the colony; which shows, that the stories which had been so industriously propagated, concerning the avarice of him and other Methodist preachers, were, partly at least, unfounded. In 1765 he returned to England; and in 1769 made his seventh and last voyage to America, landing at Charlestown on the 30th of November the same year. He was still attended with the same success; and indeed it is impossible to read, without admiration, an account of the efforts made by himself and Mr Wesley, to propagate their tenets in the different parts of the world.

For a very considerable time Mr Whitefield was the only Methodist who paid any attention to America; and in that country he was more popular than even in Europe. Towards the end of his life, several Methodists having emigrated from Britain, formed distinct societies in New York and Philadelphia. These quickly increased in number; and, about the time that the war with Britain began, their numbers amounted to about 3000 in Virginia, Maryland, New York, and Pennsylvania. They would probably have increased much more, had it not been for the imprudence of some of their preachers, who introduced

troduced politics into their discourses, and thus rendered themselves obnoxious to the people among whom they lived. Among those who hurt the cause in this manner was Mr Wesley himself, who, by writing a piece entitled *A Calm Address to the American Colonies*, would in all probability have ruined it, had not a gentleman, with whom he was connected, destroyed or sent back to England the whole impression as soon as it arrived in America, so that its existence was scarce known in that continent. At the conclusion of the war, Dr Coke, who in 1776 had left a curacy in England in order to join Mr Wesley, paid a visit to his friends in America; though it had been imagined that a total separation had taken place between the American and European Methodists. This breach was, however, made up by a manœuvre of Mr Wesley; for no sooner had the Americans obtained their independence, than he, who had hitherto branded them with the name of *rebels*, sent a congratulatory letter on their freedom from the "State and the Hierarchy," and exhorting them to "stand fast in that liberty with which God had so strangely made them free." To show his zeal in their service still farther, he gave ordination, by laying on of hands, to several preachers who were to embark for America, and consecrated Dr Coke one of the bishops of the Methodist Episcopal church in that country. He extracted also from the liturgy of the English church one for the American Methodists, taking particular care to expunge every expression that had a particular respect to the regal authority.

Such proceedings in one who had formerly professed such extraordinary attachment to the English church, could not but require an apology; and this was accordingly made in a pastoral letter transmitted to the American societies, and addressed "to Dr Coke, Mr Astbury, and our brethren in North America." In this letter he makes the following defence of his conduct. "Lord King's account of the primitive church convinced me, many years ago, that bishops and presbyters are the same order, and consequently have the same right to ordain. For many years I have been importuned, from time to time, to exercise this right, by ordaining part of our travelling preachers. But I have still refused, not only for the sake of peace, but because I was determined, as little as possible, to violate the established order of the national church to which I belonged. But the case is widely different between England and North America. Here there are bishops who have a legal jurisdiction: in America there are none, neither any parish ministers: so that for some hundred miles together, there is none either to baptize, or to administer the Lord's supper. Here, therefore, my scruples are at an end; and I conceive myself at full liberty, as I violate no order, and invade no man's right, by appointing and sending labourers into the harvest. It has indeed been proposed to desire the English bishops to ordain part of our preachers for America; but to this I object. 1. I desired the bishop of London to ordain only one, but could not prevail. 2. If they consented, we know the slowness of their proceedings; but the matter admits of no delay. 3. If they would ordain them now, they would likewise expect to govern them; and how grievously would that entangle us. 4. As our American brethren are now totally disentangled, both from the state and the English hierarchy, we dare not entangle them again either with the one or the other. They are now at full liberty simply to follow the scripture and the primitive church; and we judge it best, that they should stand fast in that liberty wherewith God has so strangely made them free."

Dr Coke, on the consecration of Mr Astbury to the office of a bishop, made another apology. "The church of England (says he), of which the society of Methodists in general have till lately professed themselves a part, did for many years groan in America under grievances of the heaviest kind. Subjected to a hierarchy which weighs every thing in the scale of politics, its most important interests were repeatedly sacrificed to the supposed advantages of England. The churches were in general filled with the parasites and bottle-companions of the rich and great. The humble and most importunate entreaties of the oppressed flocks, yea the representations of a general assembly itself, were contemned and despised. Every thing sacred must bow down at the feet of a party; the holiness and happiness of mankind be sacrificed to their views; and the drunkard, the fornicator, and the extortioner, triumphed over bleeding Zion, because they were faithful abettors of the ruling powers. The memorable revolution has struck off these intolerable fetters, and broken the antichristian union which before subsisted between church and state. And had there been no other advantage arising from that glorious epoch, this itself, I believe, would have made ample compensation for all the calamities of the war; one happy consequence of which was the expulsion of most of those hirelings, who "ate the fat, and clothed themselves with the wool, but strengthened not the diseased," &c. The parochial churches in general being hereby vacant, our people were deprived of the sacraments through the greatest part of these states, and continue so still. What method can we take in so critical a juncture? God has given us sufficient resources in ourselves; and, after mature deliberation, we believe that we are called to draw them forth.

"But what right have you to ordain?" The same right as most of the churches in Christendom; our ordination, in its lowest view, being equal to any of the presbyterian, as originating with three presbyters of the church of England. "But what right have you to exercise the episcopal office?" To me the most manifest and clear. God has been pleased to raise up, by Mr Wesley, in America and Europe, a numerous society well known by the name of *Methodists*. The whole body have invariably esteemed this man as their chief pastor under Christ. He has constantly appointed all their religious officers from the highest to the lowest, by himself or his delegate. And we are fully persuaded there is no church office which he judges expedient for the welfare of the people entrusted to his charge, but, as essential to his station, he has power to ordain. "But, do not you break the succession?" The uninterrupted succession of bishops is a point that has long been given up by the most able Protestant defenders of episcopacy. Bishop Hoadley himself, in his celebrated controversy with Dr Calamy, allows it to be unnecessary. His words are, 'To the 13th question I answer, that I think not an uninterrupted line of succession

cession of regularly ordained bishops necessary.' He also grants the authenticity of the anecdote given us by St Jerome, which informs us, that the church of Alexandria had no regular succession from the time of St Mark the evangelist, the first bishop of that church, to the time of Dionysius, a space of 200 years; but the college of presbyters, on the death of a bishop, elected another in his stead. We are also informed, from the epistle of St Clement to the Corinthians, written soon after the death of St Paul, a writer whose works are next in precedence to the canon of scripture, and probably written by immediate inspiration, that the church of Corinth was then governed only by a college of presbyters. And from the epistle of Polycarp to the church of Philippi, written in 116, we also find that the Christian Philippians were then governed only by a college of presbyters. So that the primitive Christians were so far from esteeming the regular succession as essential to the constitution of a Christian church, that, in some instances, episcopacy itself was wholly omitted.

Such was the defence urged by Mr Wesley for this extraordinary assumption of episcopal powers: a conduct, however, of which he afterwards repented, as tending to make a final separation betwixt his followers and the church of England. Yet it does not appear that this had any bad effect on the minds of his American brethren; for Dr Coke, on his arrival on the western continent, found the societies numerous and flourishing. His first efforts were directed against the slave trade; and not only the abolition of that traffic, but the release of all those who were actually slaves at the time, seem to have been his favourite objects. By interfering in this matter, however, perhaps with too much zeal, he involved himself in danger. Some riots took place, and a lady offered the mob 50 guineas if they would give the Doctor 100 lashes. This piece of discipline would have been inflicted, had it not been for the interposition of a sturdy colonel; and the Doctor had not only the satisfaction of escaping the intended punishment, but of seeing his doctrine so far attended to, that some slaves were emancipated.

Mr Hampson, in his Memoirs of Mr Wesley, observes, that "the colonists, in the infancy of Methodism, conducted themselves with more propriety than the English. There was little or no persecution, nor any thing like a riot, except in one or two instances which have been mentioned as the consequence of the animadversions on slavery; and even these were productive of no mischief. Not a creature was materially injured; no bones were broken, nor any lives lost; which was not the case in this country. Here many thousands of innocent people were subjected to the grossest indignities, and several were eventually sacrificed to the fury of their persecutors.

"While we commend the Americans for their behaviour in opposition to the brutality of English mobs, it may be proper to inquire into the sources of this distinction. Something of this may have arisen from similarity of sentiment. The Americans, from the first beginnings of colonization, had been accustomed to the doctrines of the old puritans and nonconformists, which in many respects have a near affinity to the Methodistic tenets. The origin of Methodism in America was seldom, if ever, attended, either under the discourses of Mr Whitefield's or Mr Wesley's preachers, with those ridiculous effects with which it was accompanied in these kingdoms. Most of the preachers, who went over to the continent, having laboured for some years in Europe previous to their having crossed the water, had exhausted their wildfire; so that their discourses were more scriptural and rational than those of the primitive Methodists. Another reason may be found in the education of the Americans. As a people, they are better cultivated than the body of the English; they are chiefly composed of merchants and a respectable yeomanry: and there is but a small proportion of that class, so superabundant here, which we distinguish by the name of *mob*.

"The only exception we have heard, to their exemption from the extravagancies which in this country marked the infancy of Methodism, is a custom they have introduced in Maryland and Virginia. Frequently, at the conclusion of a sermon, the whole congregation began to pray and to praise God aloud. The uproar which this must create may easily be conceived. Some we are told, are great admirers of this species of enthusiasm, in which every man is his own minister, and one sings and another prays, with the most discordant devotion. But we will not dignify such indecency with such a name. Its proper appellation is *fanaticism*. We hope, that, for the future, religion will never appear in this country under so odious a form; and greatly is it to be lamented, that, among the friends of Christianity, any such absurdities should arise, to furnish infidels with occasions of triumph."

Our author informs us, that the occupation of the Methodist preachers in America was very laborious. In the course of the day they frequently rode 20 or 30 miles, preaching twice or thrice, and sometimes to considerable congregations. Notwithstanding this labour, however, few or none of them ever thought of returning to Britain. Several reasons may be assigned for the pleasure they took in this laborious exercise. "Their excursions (says Mr Hampson) through immense forests abounding in trees of all sorts and sizes, were often highly romantic. Innumerable rivers and falls of water; vistas opening to the view, in contrast with the uncultivated wild; deer now shooting across the road, and now scouring through the woods, while the eye was frequently relieved by the appearance of orchards and plantations, and the houses of gentlemen and farmers peeping through the trees; formed a scenery so various and picturesque, as to produce a variety of reflection, and present, we will not say to a philosophic eye, but to the mind of every reasonable creature, the most sublime and agreeable images.

"Their worship partook of the general simplicity. It was frequently conducted in the open air. The woods resounded to the voice of the preacher, or to the singing of his numerous congregations; while their horses, fastened to the trees, formed a singular addition to the solemnity. It was indeed a striking picture; and might naturally impress the mind with a retrospect of the antediluvian days, when the hills and valleys re-echoed the patriarchal devotions, and a Seth or an Enoch, in the shadow of a projecting rock, or beneath the foliage of of some venerable oak, delivered his primeval lectures, and was a "preacher of righteousness to the people."

The American hospitality is supposed by Mr Hampson to have been another reason for the assiduity of the Methodist teachers, as well as the consciousness of being well employed, and the satisfaction resulting from considerations of public utility. As many of the preachers were men of fervent piety, this reflection would have its full weight; and the instruction of the ignorant and the reformation of the profligate would be considered as the best recompense of their labours. Spreading themselves through the continent, they took in Nova Scotia, Georgia, with the principal places in both Carolinas, Virginia, Maryland, Delaware, Pennsylvania, New Jersey, and New York; numbering upwards of 43,000 members of their society, exclusive of about 80 itinerants, and a considerable number of local preachers, who took no circuits, but assisted occasionally in the neighbourhood of their respective residence.

The large and expensive buildings which the colonists have erected for public worship, almost exceed credibility; and several colleges are founded for the instruction of youth. How far the proposed plan of uniting genuine religion and extensive learning will be carried into execution, time only can discover. It must materially depend on the character of the presidents and tutors, and the provision that shall be made for their support. Men of real erudition will never be procured at low salaries; and it is in vain to attempt establishments of this sort without a liberal provision for the professors of every branch of science. Two of these places are called *Cokesbury* and *Wesley Colleges*. How they are endowed, or whether they propose to obtain authority to confer degrees, we are not informed. But perhaps they are rather schools than colleges; which indeed is a circumstance to be wished, as good grammar schools are of the utmost service to the progress of literature.

The great success which attended the Methodist preachers in America naturally determined Mr Wesley to try the West India islands. The Moravians had already attempted to establish their principles in some of these islands; and in 1786 some preachers were sent from the Methodists in England to the West Indies. In many of these they met with success. Societies were formed in Barbadoes, St Vincent's, Dominica, St Christopher's, Nevis, Antigua, St Eustatius, Tortola, and St Croix, amounting in all to near 5000 persons. At this time the whole number of Methodists in America and the West Indies amounted to about 48,302. These societies consisted both of whites and blacks: on the continent they were mostly whites, but in the islands negroes. "But it is to be observed (says Mr Hampson) that the subjection of the negroes, and the obedience in which they are trained, must inculcate a docility peculiarly favourable to the purposes of a mission." Some of the missionaries went also to St Vincent's, where they met with some success, and have established some schools, in which their children are carefully instructed in the principles of religion.

"In January 1789 (says our author), Dr Coke paid a visit to Jamaica, and gave them several sermons. As he made but a short stay, it could hardly be considered as a fair trial. Should a mission be established here, as well as in the other islands, which will probably be the case, it is hoped it will be the means of correcting one vice at least, and that is duelling; a savage relick of Gothic barbarity, by which all the islands have for many years been distinguished. Perhaps too it will give some check to the spirit of luxury and dissipation; and teach the planters, if it be found impracticable to emancipate their slaves, at least to treat them with humanity."

It has been debated among the leading men of the Methodistical profession, whether the cause might not be served by sending missionaries to the East Indies and to Africa; but these projects were dropped, as there was no invitation, nor any prospect of success if it had been adopted. A mission has been formed to the new settlement called *Kentucky*, on the confines of the Indian territories, near the Mississippi. The danger of the missionaries at the time they undertook this service was certainly very great; yet such was their zeal for the cause, that they voluntarily offered themselves: but we are not yet informed what success they have met with.

While Methodism was thus making rapid progress in America, its teachers were equally indefatigable in Britain. A most remarkable particular, however, occurs with regard to Mr Wesley himself; for though he had gone to Georgia, as has been already related, to convert the Indians to Christianity, yet on his return to England in 1738, he took it into his head that he, their teacher, was not yet converted: the reason was, that he had not the faith of assurance. This, however, was not long wanting. He arrived in England on the first day of February, and was blest with the assurance on the sixth of March following. This was immediately announced to the public; and the consequence, if we may believe him, was, that God then began to work by his ministry, which he had not done before. Being joined by one Kinchin, a fellow of Corpus, they travelled to Manchester, Holms Chapel, Newcastle in Staffordshire, and other places, where they preached, exhorted, and conversed on religious subjects, in public houses, stables, &c. sometimes meeting with success and sometimes not. During this peregrination Mr Wesley certainly displayed a great deal of superstition, which we must undoubtedly suppose to have been communicated to his hearers, and to have caused them act on many occasions in a very ridiculous manner. An instance follows:—"The next day (says he), March 11th, we dined at Birmingham, and, soon after we left it, were reproved for our negligence there (in letting those who attended us go without either exhortation or instruction) by a severe shower of hail!" About the latter end of March or beginning of April he and his companion began to pray *extempore*, leaving off entirely the forms of the church of England, to which he had formerly been so devoted. The doctrine of instantaneous conversion, which his imagination had suggested to him as a work performed on himself, was greedily received by some of his hearers; and all the converts to the new doctrine confirmed themselves, and contributed greatly to persuade others, by declarations of their *experiences*, as they called them: however,

ever, though a knowledge of the saving assurance had been given on March 6th, he does not date his conversion sooner than May 24th of the same year.

This new doctrine of an instantaneous, and in fact miraculous impulse, though greatly relished by the enthusiastical part of the society, was very much disliked by others, particularly Mr Charles Wesley his brother, who warned him of the mischief he was doing; though he himself was soon converted, and, what is very astonishing, two days before John Wesley himself. The particulars related of these miraculous conversions are truly disgraceful, and could not but bring into contempt the society which consisted of such enthusiasts. "Many (says Mr Hampson) are represented as falling suddenly to the ground, in horror and agony not to be conceived, and rising again with equal expressions of peace and consolation."—Their conversions were usually attended with these violent symptoms; and, for several years, few meetings occurred where Mr Wesley presided, without one or more instances of the same kind. It was not possible that such transactions should pass without notice. The confusion that too often prevailed, the emotions of the persons affected, and the exultations of the rest, which were severally animadverted upon, gave great and general offence. Many insisted, that it must either be occasioned by the heat of the rooms, and the agitation of the animal spirits under discourses of the most alarming nature; or that it was mere artifice and hypocrisy.

In the mean time, two of the sons of a Mrs Hutton in London, happening to become converts to the new doctrine, this lady was so much offended, that she wrote to Mr Samuel Wesley, informing him, that she was of opinion his brother John had lost his senses; and requesting, that the next time he came to his house, he, Mr Samuel, would either confine or convert him. All that could be done, however, to prevent the progress of the new doctrine was insufficient; and the first Methodist society was formed in London on the first of May 1738, when about 50 agreed to meet together once a-week, for free conversation, begun and ended with singing and prayer.

All this time, however, it seems that the conversion of Mr Wesley was far from being so complete as that of many of his hearers. He had preached and converted others, while he himself was absolutely unconverted. The knowledge of the true saving faith was only revealed to him on the 6th of March, and he did not experience its power till the 24th of May; and even after this, his doubts and fears were still so great, that on the 13th of June he undertook a voyage to Germany, where, in the company of Count Zinzendorff, his faith seems to have been thoroughly confirmed.

On Mr Wesley's return, September 16th, 1738, he applied himself with the greatest assiduity and success to the propagation of his doctrine. Multitudes of converts were made in various parts of the kingdom; and the reproaches poured upon him by his opponents, seemed to have rendered his zeal more fervent if possible than before. It is remarkable, however, that some of his old friends were now so much offended with his conduct or his principles, that they absolutely refused to keep company with him. His original plan seems to have been, to make an union of clergymen, and disseminate his principles by their means. But in this he succeeded so ill, that in a letter written in 1742, he wished for a clerical assistant, were he only in deacons orders: but adds, "I know of none such, who is willing to cast in his lot with us; and I scarce expect I shall, because I know how fast they are rivetted in the service of the devil and the world before they leave the university."—Finding at last that nothing could be done with them, he was obliged to have recourse to lay preachers; and easily selected those who appeared to have the greatest talents for prayer and exhortation in the private meetings appointed for that purpose. Thus he at once raised himself to be the head of a sect; as the lay preachers willingly yielded obedience to him who had the advantages of superior learning and abilities, and was besides in orders as a clergyman; and this obedience he did not fail on every occasion to exact.

If his doctrine had formerly given offence to the established clergy, the appointment of lay preachers was reckoned much worse; and their being appointed without any form of ordination whatever, which almost all of them were, subjected them to contempt and reproach, which their want of learning, and very often of natural abilities, did not contribute to remove. Thus finding the churches shut against him and his followers, he was obliged to preach in the fields, and made his first essay in this way on the second of April 1739, in the neighbourhood of Bristol; Mr Whitefield having set him an example the day before.

The success of those ignorant and itinerant preachers, with their absurd and uncharitable discourses and behaviour, so provoked their adversaries, that a persecution was soon commenced against them. Mr Wesley himself was calumniated in the harshest manner, being sometimes said to be a Jesuit, sometimes an illiterate enthusiast, as the people took it into their heads. Many pretended to answer him in writing, without being able to do so: the consequence was, that their deficiency of argument was supplied by invective, and the most scandalous performances made their appearance. Some of the English clergy so far forgot themselves as to instigate the mob against them, and the most cruel outrages were committed upon them in various places. For some time the persecuted party adhered to the doctrines of passive obedience and non-resistance, which their inhuman adversaries did not fail to take the advantage of.—The less they were opposed, the more insolent they became. The Methodists were frequently in danger of their lives. Men, women with child, and even children, were knocked down and abused with the same undistinguishing fury. Houses were stripped of their furniture, vast quantities of furniture carried off, featherbeds cut in pieces and strewed over the streets, several reputable people were forced into the army, &c. To the disgrace of magistracy also it was found, that when application was made to the justices of the peace, redress was commonly denied; nor was a stop put to these shameful proceedings without a royal mandate for the purpose.

From the year 1738 to 1747 Mr Wesley and his itinerants were employed in various parts of England. In

Methodists.

In 1747 he went over to Dublin, where a society had been formed by one Mr Williams a clergyman.—Here they proved so successful, notwithstanding the number of Papists, and the violence of their other opponents, that in 1750 they had erected meeting-houses in every part of the kingdom, and had formed 29 circuits, which employed 67 itinerants, besides a considerable number of local preachers. An invitation was given to Mr Wesley, in 1751, to visit Scotland, by an officer in quarters at Musselburgh. He accordingly took a journey thither the same year; but left the place, after preaching in it once or twice. In 1753 he returned to Scotland, and visited Glasgow. Societies were at length formed in that city, as well as at Edinburgh, Dundee, Aberdeen, Inverness, and a few other places: but his success was by no means equal to what it had been in other parts; for in 1790 the number of circuits in Scotland was no more than eight, which were supplied by 20 itinerants.

Mr Whitefield, the other great labourer in the vineyard, was equally indefatigable, and probably more successful than Mr Wesley. Before entering into orders, he had formed a society of religious persons at Gloucester: here he preached his first sermon on the Necessity and Benefit of Religious Society; here he became extremely popular, as well as at Bristol and London, while preparing to set sail for Georgia for the first time; and in all places to which he came, large collections were made for the poor. He maintained the same doctrine with Mr Wesley as to the new birth; which likewise gave offence to the clergy when delivered by him, as it had done with Mr Wesley. In the various intervals of his voyages to America, he employed himself with the very same assiduity in Britain and in Ireland, which we have already taken notice of in the western continent. His success was everywhere prodigious. In 1741 he was invited to Scotland, and preached his first sermon there at Dunfermline. From thence he went to Edinburgh, and preached in several of the established churches, but differed with Messrs Ralph and Ebenezer Erskine; so that he, as well as Mr Wesley, proved unsuccessful in forming a coalition with any other religious party. In the private way, however, his success was very considerable, at Edinburgh, Glasgow, Aberdeen, Dundee, and other places. In 1742 he paid a second visit to Scotland, and a third one in 1748. In 1751 he visited Ireland for the first time; and preached to great multitudes, without being molested, even in places where others had been mobbed. From thence he returned to Scotland the same year, and speaks in very favourable terms of the attention the people there paid to their Bibles. In 1752 and 1753 he again visited the same kingdom, and the last time distinguished himself by preaching against the playhouse in Glasgow. In 1756 he returned; and by his animated discourses at Edinburgh against Popery and arbitrary power, was owned to have contributed very much to the increase of courage and loyalty in this country. Next year he again visited the Scottish capital during the time that the General Assembly sat, and his sermons were attended by several of the members. At Glasgow he made a large collection for the poor of that city, and from thence took a voyage to Ireland. He was received with the usual affection by the lower classes of Protestants; but the Popish rabble, exasperated at his success, almost murdered him with stones. After passing through a great part of Ireland, visiting England and Wales, he paid another visit to Scotland, where four clergymen now lent him their pulpits. His last visit was in the summer of 1758, when his congregations were as large as ever; and it is to his endeavours principally that we are to ascribe the great number of Methodist societies now existing in Scotland.

With regard to the religious principles of the Methodists, we cannot enter into any particular detail; neither indeed are there any doctrines peculiar to all included under that name, except the single one of universal redemption. In March 1741, Mr Whitefield being returned to England, entirely separated from Mr Wesley and his friends, "because he did not hold the decrees."—Here was the first breach, which warm men persuaded Mr Whitefield to make, merely for a difference of opinion. Those indeed who believed universal redemption, had no desire at all to separate: but those who held particular redemption, would not hear of any accommodation, being determined to have no fellowship with men that "were in such dangerous errors." So there were now two sorts of Methodists so called; those for particular, and those for general redemption.

History of Methodism, &c.

Not many years passed, before William Cudworth and James Relly separated from Mr Whitefield.—These were properly Antinomians, absolute avowed enemies to the law of God, which they never preached or professed to preach, but termed all *legalists* who did. With them, preaching the law was an abomination. They had nothing to do with the law. They would preach Christ, as they called it; but without one word either of holiness or good works. Yet these were still denominated *Methodists*, although differing from Mr Whitefield both in judgment and practice, abundantly more than Mr Whitefield did from Mr Wesley.

In the mean time, Mr Venn and Mr Romaine began to be spoken of: and not long after Mr Madan and Mr Berridge, with a few other clergymen, who, although they had no connexion with each other, yet preaching salvation by faith, and endeavouring to live accordingly, to be Bible Christians, were soon included in the general name of *Methodists*. And so indeed were all others who preached salvation by faith, and appeared more serious than their neighbours. Some of these were quite regular in their manner of preaching: some were quite irregular, (though not by choice; but necessity was laid upon them, they must preach irregularly, or not at all): and others were between both; regular in most, though not in all particulars.

In 1762, George Bell and a few other persons began to speak great words. In the latter end of the year they foretold that the world would be at an end on the 28th of February. Mr Wesley, with whom they were then connected, withstood them both in public and private. This they would not endure: so, in January and February 1763, they separated from him, under the care of Mr Maxfield, one of Mr Wesley's preachers. But still Mr Maxfield and his adherents,

rents, even the wildest enthusiasts among them, go under the general name of *Methodists*, and so bring a scandal upon those with whom they have no connexion.

At present, those who remain with Mr Wesley are mostly Church of England men. They love her articles, her homilies, her liturgy, her discipline, and unwillingly vary from it in any instance. Mean time, all who preach among them declare, *we are all by nature children of wrath, but by grace we are saved through faith*: saved from both the guilt and from the power of sin. They endeavour to live according to what they preach, to be plain Bible Christians; and they meet together at convenient times, to encourage one another therein. They tenderly love many that are Calvinists, though they do not love their opinions. Yea, they love the Antinomians themselves; but it is with a love of compassion only, for they hate their doctrines with a perfect hatred; they abhor them as they do hell fire: being convinced nothing can so effectually destroy all faith, all holiness, and all good works.

We shall conclude this article with the words of Mr Hampson, which must certainly be accounted just, whatever objections may be made to some parts of the principles or behaviour of the Methodists. "If they possess not much knowledge, which, however, we do not know to be the case, it is at least certain, they are not deficient in zeal: and without any passionate desire to imitate their example, we may at least commend their endeavours for the general good. Every good man will contemplate with pleasure the operation of the spirit of reformation, whether foreign or domestic; and will rejoice in every attempt to propagate Christianity in the barbarous parts of the world. An attempt which, if in any tolerable degree successful, will do infinitely more for their civilization and happiness, than all the united energies of those boasted benefactors of mankind, the philosophic infidels."

The minutes of the conference of the Methodists held at Leeds in August, 1806, represent the numbers of that society to be as follows:

In Great Britain,	110,803
In Ireland,	23,773
Gibraltar,	40
Nova Scotia, New Brunswick, and Newfoundland,	1418
West Indies, whites 1775, coloured people 13,165,	14,940
United States, whites 95,628, coloured people 24,316,	119,945
Total,	270,919

METHODISTS (*Methodici*), in the history of medicine, a sect of ancient physicians, who reduced the whole art of healing to a few common principles or appearances. The Methodists were the followers of Thessalus; whence they were also called *Thessalici*. They were strenuously opposed by Galen in several of his writings; who scrupled not to assert, that the methodical heresy ruined every thing that was good in the art. According to Quincy, the *Methodists* (*Methodici*) are those physicians who adhere to the doctrine of Galen, and the schools; and who cure with bleeding, purges, &c. duly applied according to the symptoms, circumstances, &c. in opposition to empirics and chemists, who use violent medicines, and pretended secrets or nostrums.

METHUSELAH, the son of Enoch and father of Lamech, was born in the year of the world 687, begat Lamech in 874, and died in 1656, being the very year of the deluge, at the age of 969, which is the greatest age that has been attained to by any mortal man upon earth (Gen. v. 21, 22, &c.). According to the text of the Septuagint, Methuselah must have lived 14 years after the deluge; and according to other copies, he died six years before it: but it is generally agreed on, that these copies, as well as the Septuagint, are corrupted in this place.

METHYMNA, in *Ancient Geography*, a town the island of Lesbos. It was the second city of the island in greatness, population, and opulence. Its territory was fruitful, and the wines it produced excellent. It was the native place of Theophrastus, and of Arion the musician. When the whole island of Lesbos revolted from the power of the Athenians, Methymna alone remained firm to its ancient allies.

METOECI, a name given by the Athenians to such as had their fixed habitations in Attica, though foreigners by birth. The *metœci* were admitted by the council of Areopagus, and entered in the public register. They differed both from the πολιται and ξενοι; because the *politæ* or "citizens" were freemen of Athens, and the *xeni* or "strangers" had lodgings only for a short time; whereas the *metœci* though not freemen of Athens, constantly resided upon the spot whither they had removed.

METONYMY, in *Rhetoric*, is a trope in which one name is put for another, on account of the near relation there is between them. See ORATORY, N° 51.

METOPE, in *Architecture*, is the interval or square space between the triglyphs of the Doric frieze, which among the ancients used to be painted or adorned with carved work, representing the heads of oxen or utensils used in sacrifices.

METOPOSCOPY, the pretended art of knowing a person's dispositions and manners by viewing the traces and lines in the face. Ciro Spontoni, who has written expressly on metoposcopy, says, that seven lines are examined in the forehead, and that each line is considered as having its particular planet: the first is the line of Saturn, the second of Jupiter, the third of Mars, &c. Metoposcopy is only a branch of physiognomy, which founds its conjectures on all the parts of the body.

METRE, μετρον, in *Poetry*, a system of feet of a just length.

The different metres in poetry, are the different manners of ordering and combining the quantities, or the long and short syllables; thus hexameter, pentameter, iambic, sapphic verses, consist of different metres or measures. See HEXAMETER.

In English verses, the metres are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleases. The most usual are the heroic, generally consisting of five long and five short syllables, and verses of four feet, and of three feet, and a cæsura or single syllable.

The ancients, by variously combining and transposing their quantities, made a vast variety of different measures,

measures, by forming spondees, &c. of different feet. See POETRY.

METRETES, a Grecian measure, containing something more than nine English gallons. See MEASURE.

METRICAL VERSES, are those consisting of a determinate number of long and short syllables; as those of the Greek and Latin poets.—Capellus observes, that the genius of the Hebrew language is incompatible with metrical poetry.

METROCOMIA (from μήτηρ, *mother*, and κωμη, *town* or *village*), a term in the ancient church-history, signifying "a borough or village that had other villages under its jurisdiction."—What a metropolis was among cities, a *metrocomia* was among country towns. The ancient *metrocomiæ* had each its chorepiscopus or rural dean, and here was his see or residence. See METROPOLIS and CHORIEPISCOPUS.

METRONOMII, the name given by the Athenians to five officers in the city and ten in the *Piræus*, whose duty it was to inspect all sorts of measures except those of corn. The *Piræus* was the greatest mart in Attica.

METROPOLIS (from μητηρ, *mother*, and πολις, *city*), the capital of a country or province; or the principal city, and as it were mother of all the rest.

The term METROPOLIS is also applied to archiepiscopal churches, and sometimes to the principal or mother-church of a city. The Roman empire having been divided into 13 dioceses and 120 provinces, each diocese and each province had its metropolis or capital city, where the proconsul had his residence. To this civil division the ecclesiastical was afterwards adapted, and the bishop of the capital city had the direction of affairs, and the pre-eminence over all the bishops of the province. His residence in the metropolis gave him the title of *metropolitan*. This erection of metropolitans is referred to the end of the third century, and was confirmed by the council of Nice. A metropolitan has the privilege of ordaining his suffragans; and appeals from sentences passed by the suffragans are preferred to the metropolitan.

METROPOLIS, in *Ancient Geography*, a town of Acarnania, a little to the south of Stratos.—Another, of Lydia; situated between Colophon and Priene, near the Caÿster.—A third, of Phrygia; sacred to the mother of the gods, who was here worshipped.—A fourth Metropolis of Estiotis, a district in Thessaly, to the east of Gomphi, and the last town of that district. *Metropolitæ*, the people.

METULUM, in *Ancient Geography*, a considerable city of Liburnia, at the siege of which Octavius Cæsar was wounded. Said to be the metropolis, and situated on two eminences, intersected by a valley (Appian). Now generally thought to be *Metling* in Carniola. E. Long. 16. N. Lat. 46. 5.

METZ, an ancient, large, and strong town of France, and capital of the territory of Messin, with a citadel and a bishop's see, whose bishop used to hold the title of a prince of the empire. The cathedral church is one of the finest in Europe, and the square called *Coslin* and the house of the governor are worth seeing. The Jews live in a part of the town by themselves, where they have a synagogue. The sweetmeats they make here are in high esteem. It is seated at the confluence of the rivers Moselle and Seille. E. Long. 6. 16. N. Lat. 49. 7.

MEVANIA, in *Ancient Geography*, a town of the Cisapennine Umbria; seated at the confluence of the Tina and Clitumnus, on the Via Flaminia, famous for its herds of white cattle brought up there for sacrifice; the white colour said to be owing to the waters of the Clitumnus (Virgil). Mevania was the country of Propertius. *Mevenates* the people. Now said to be *Bevagna*, in the territory of the Pope.

MEURSIUS, JOHN, a learned and laborious writer, was born at Losdun, near the Hague, in 1579. He early discovered a fondness for polite literature and the sciences; and went to study law at Orleans with the son of Barneveldt, whom he accompanied in his travels. In 1610 he was made professor of history at Leyden, and afterwards Greek professor. In the following year, the magistrates of the United Provinces proved how high their opinion was of his abilities, by fixing on him to write the history of his country. Meursius married in the year 1612. His wife, Anna Catherina Bilberbeccia, descended from a very ancient and noble family in Angermond a city of Pomerania, possessed many amiable qualities, and rendered his domestic life remarkably happy, while he discharged the duties of his professorship with an assiduity equal to his abilities. At the same time the republic of letters did not lose the advantages to be derived from his labours; for during the fourteen years of his residence at Leyden, the works which he published were more numerous than those which had been presented to the world by the whole body of professors from the original foundation of the university in 1575.

Meursius's writings had now spread his reputation in every part of Europe; nor was the fame of his diligence and talents as a professor less known. In so high a rank, indeed, did he stand among his literary contemporaries, that Christian IV. king of Denmark conferred on him the place of historiographer royal, and invited him to undertake the professorship of history and politics in the academy of Sora, which was founded by King Frederick II. although the revival of its honours and dignities may be dated from this period, when it seemed to be again founded under the auspices of Christian IV. Meursius and his family left Leyden in the year 1635. On his arrival at Sora, he was received with the most friendly tokens of regard by his majesty and the Danish nobility, and more particularly by Chancellor Rosenkrantz, on whom he has bestowed very ample praises in one of his letters. Here he resided, equally beloved and admired, for above twelve years. His pupils were not very numerous, but his exertions never relaxed. Those hours likewise which were not devoted to the duties of his professorship, he employed in revising the works of the ancients and in philological disquisitions.

His health did not suffer by the intenseness of application, till in the year 1638 he had a violent attack of the stone, from which disorder he had suffered severely. In a letter to Vossius he thus describes his melancholy condition: "The state of my health during the whole of the last winter has been truly deplorable. My sufferings from the stone have been really dreadful. I have voided so many, that the repeated discharges brought on a wound which emitted

Meursius. ted blood for above four months. I was next attacked by a tertian fever, which increased constantly, and produced an universal lassitude of body, a dejection of spirits, and a total loss of appetite. But, thank heaven, I have now in some measure recovered my strength, and gotten the better of these complaints." He recovered from this attack; but in the following year the disorder returned with redoubled violence, and brought on a consumption, which terminated his existence on the 20th day of September 1639. He left behind him a son who was named after him, and one daughter.

So mild were the dispositions of Meursius, that in all his writings he constantly avoided literary disputes. He was sometimes unavoidably drawn into them; but constantly endeavoured to promote a reconciliation rather than widen any breach, by his replies to the attacks of his adversaries. In his friendships he was firm and affectionate. Of his domestic life, whatever is known has been gathered from his letters. The same easy tranquillity seems to have attended him in every situation. In his family he was particularly fortunate. In his son, to whom he gave his own name, he seemed to behold his own youth renewed. The same application, the same eagerness in the pursuit of knowledge, marked the conduct of this promising young man; who did not long survive his father, but died soon after he had recommended himself to the notice of the learned world by his publications. They were only three in number; but displayed so much solid learning that they have been assigned to the father, John Meursius, by l'Abbé Beughem and others. This mistake was occasioned as much by the similitude of their names, as by the nature of their works, and their manner of treating philological subjects.

His works may be divided into four classes, of which each might form a separate volume if they were ever to be republished. Meursius himself indeed, in one of his letters to Vossius, proposes such a division. From that epistle, and from another which the younger Meursius sent to G. I. Vossius, who strongly advised him to republish the whole of his father's writings, and from the collections of his posthumous works which have appeared from Struvius, Groschupsius, Moller, and some others, a catalogue of his works might be formed. Some assistance will also be derived from the indexes published in their respective works, by Hankins, Desselius, Wettenius, and Bartholinus. The plan which Meursius recommends for publishing his works, is to insert in the first volume all that he has written relative to Athens; in the second, his historical pieces; in the third his miscellaneous dissertations; and in the fourth, the various authors which he published, with his notes and corrections,.

Meursius || Mexico.

A scandalous and indecent work, which is entitled *Meursii elegantiæ Latini sermonis* ,and has *Aloisiæ Sigeæ Satyræ Sotadicæ* annexed to it, is very falsely attributed to Meursius; nor indeed are the *Satires* with more reason assigned to Aloisia Sigea, who was a Spanish lady eminent for her piety and virtue. The real author of these infamous productions was Westrenius, an advocate at Copenhagen, who probably assumed the name of Meursius, in order to shield himself from the disgrace which would naturally have attended the writer of such a performance.

MEW, SEA-MEW, or *Sea-mall.* } See LARUS, ORNITHOLOGY *Index.*
Winter MEW, or *Coddy-moddy.* }

MEWING, the falling off or change of hair, feathers, skin, horns, or other parts of animals, which happens in some annually, in others only at certain stages of their lives; but the generality of beasts mew in the spring. An old hart casts his horns sooner than a young one, which is commonly in the months of February and March: after which they begin to button in March or April: and as the sun grows strong, and the season of the year puts forth the fruits of the earth, so their heads grow, and are summed full by the middle of June. It is to be observed, that if a hart be gelt before he has a head, he will never have any; and if he be gelt after he has a head, he will never cast his horns; again, if he be gelt when he has a velvet head, it will always be so, without fraying or burnishing.

MEXICO,

History.

A PROVINCE of the Spanish empire in America, once a celebrated kingdom, the most powerful and civilized in the new world; lying between the 14th and 21st degrees of north latitude, and between 91 and 103 degrees west longitude; being near 2000 miles in length, and in some places 600 miles in breadth.

1 Toltecans the first inhabitants.

The Toltecans are the most ancient Mexican nation of which we know any thing. They were expelled, as we are told, from their own country (supposed by Clavigero to have been *Tollan*, to the northward of Mexico) in the year 472; and for some time led a wandering life. In whatever place they determined to reside for any considerable time, they erected houses and cultivated the ground. Thus their migrations were extremely slow, and it was not till 104 years after they set out that they reached a place about 50 miles to the eastward of the city of Mexico, where they settled for 20 years, giving to their new place of residence the name of *Tollantzinco*. From thence they proceeded about 40 miles farther to the west, where they built a city called, from the name of their country, *Tollan*, or *Tula*.

2 Their history.

After the final settlement of the Toltecans, the government was changed into a monarchy. Their first king began his reign in 667, and their monarchy lasted 384 years, during which time they reckon just eight princes. We are not, however, to imagine that each of their kings lived long enough to make up this space. It was a custom among them that the name of the king should be continued for 52 years, and no longer, from the time he ascended the throne. If he died within that period, the government was carried on in his name by a regency; if he survived, he was obliged to resign his authority. During the four centuries that the Toltecan monarchy continued, they had increased very considerably in number, and had built many cities; but when in the height of prosperity, almost the whole

History.

whole nation was destroyed by a famine occasioned by drought; and a pestilence, probably the consequence of the former. "According to Torquemada (says our author), at a certain festival-ball made by the *Toltecans*, the *sad-looking* devil appeared to them of a gigantic size, with immense arms, and in the midst of the entertainment he embraced and suffocated them; that then he appeared in the form of a child with a putrid head, and brought the plague; and, finally, at the persuasion of the same devil, they abandoned the country of Tula."

3 Succeeded by the Chichemecas.

They were succeeded by the Chichemecas, a much more barbarous people, who came from an unknown country called *Amaquemecan*, where they had for a long time resided; but of which no traces of remembrance can be found among any of the American nations known to Europeans; so that Clavigero supposes it must have been very far to the northward.

The motive which the Chichemecas had for leaving their own country is not known. They were eighteen months on their journey, and took possession of the desolate country of the Toltecans about an hundred years after the former had left it. They were much more uncivilized than the Toltecans; but, however, had a regular form of monarchical government, and in other respects were less disgusting in their manners than some of the neighbouring nations. The last king who reigned in Amaquemecan before the departure of the Chichemecas, had left his dominions between his two sons Auchcauhtli and Xolotl, and the latter conducted the new colony. Having proceeded from the ruins of Tula towards Chempoalla and Tepepolio, Xolotl sent his son to survey the county. The prince crossed the borders of the lakes and the mountains which surround the vale of Mexico; then ascending to the top of a very high one, he viewed the whole country, and took possession of it in the name of his father, by shooting four arrows to the four winds.

4 Xolotl their first king.

Xolotl being informed by his son of the nature of the country, chose for the capital of his kingdom Tenayuca, about six miles to the northward of the city of Mexico, and distributed his people in the neighbouring territory; but as most of them went to the northward, that part obtained the name of the country of the Chichemecas, in distinction from the rest. Here a review of the people was taken, and their number, according to Torquemada, was more than a million.

Xolotl finding himself peacefully settled in his new dominion, sent one of his officers to explore the sources of some of the rivers of the country. While performing this task he came to the habitations of some Toltecans, who it seems had still kept together, and were likely once more to become a nation. As these people were not inclined to war, and greatly esteemed for their knowledge and skill in the arts, the Chichemecas entered into a strict allianee with them, and Prince Nopaltzin, who had first surveyed the country, married a Toltecan princess. The consequence of this alliance was the introduction of the arts and knowledge of the Toltecans among the Chichemecas. Till now the latter had subsisted entirely by hunting, and such fruits and roots as the earth spontaneously produced. They were clad in the skins of wild beasts, and, like these beasts, they are said to have sucked the blood of the animals they caught; but after their connection with the Toltecans they began to sow corn, to learn the art of digging and working metals, to cut stones, manufacture cotton, and, in every respect, to make great improvements.

5 His people civilized by the Toltecans.

6 New inhabitants arrive and obtain settlements.

When Xolotl had reigned about eight years in his new territories, an embassy of six persons arrived from a distant country not far from *Amaquemecan*, expressing a desire of coming with their people to reside in the country of the Chichemecas. The king gave them a gracious reception, and assigned them a district; and, in a few years after, three other princes, with a great army of Acolhuans, who were likewise neighbours of Amaquemecan, made their appearance. The king was at that time at Tezcuco, to which place he had removed his court: and here he was accosted by the princes, who, in a submissive and flattering manner, requested him to allow them a place in his happy country, where the people enjoyed such an excellent government. Xolotl not only gave them a favourable reception, but offered them his two daughters in marriage, expressing his concern that he had no more, that none might have been excluded from the royal alliance. On the third prince, however, he bestowed a noble virgin of Chalco, in whom the Toltecan and Chichemecan blood were united. The nuptials were celebrated with extraordinary pomp; and the two nations, after the example of the sovereigns, continued to intermarry. As the Acolhuans were the more civilized nation of the two, the name of Chichemecas began to be appropriated to the more rude and barbarous part, who preferred hunting to agriculture, or chose a life of savage liberty in the mountains to the restraints of social laws. These barbarians associated with the Otomies, another savage nation who lived to the northward, occupying a tract of more than three hundred miles in extent; and by their descendants the Spaniards were harassed for many years after the conquest of Mexico.

7 Division of the dominions of Xolotl.

As soon as the nuptial rejoicings were over, Xolotl divided his territories into three parts, assigning one to each of the princes. Acolhuatzin, who had married his eldest daughter, had Azcopazalco, 18 miles to the westward of Tezcuco; Chiconquauhtli, who married the other, had a territory named Xaltocan; and Tzontecomatl, who married the lady of inferior rank, had one named Coatlichan. The country continued for some time to flourish, population increased greatly, and with it the civilization of the people; but as these advanced, the vices of luxury and ambition increased in proportion. Xolotl found himself obliged to treat his subjects with more severity than formerly, and even to put some of them to death.—This produced a conspiracy against him, which, however, he had the good fortune to escape; but while he meditated a severe revenge on the conspirators, he was seized with the distemper of which he died, in the fortieth year of his reign, and in a very advanced age.

8 Nopaltzin the second king.

Xolotl was succeeded by his son Nopaltzin, who at the time of his accession is supposed to have been about sixty years of age. In his time, the tranquillity of the kingdom, which had begun to suffer disturbance under his father, underwent much more violent shocks, and civil wars took place. Acolhuatzin, the only one of the three princes who remained alive, thinking the territory he possessed too narrow, made war upon the lord of a neighbouring province named Tapotzotlan,

History.

Tapotzotlan, and deprived him of his territory. Huetzin, son to the late Prince Tzontecomatl, lord of Coatlichan, fell in love with the grand-daughter of the queen, a celebrated beauty, but was rivalled by a neighbouring lord, who determined to support his pretensions by force of arms. Huetzin, however, got the better, defeated and killed his adversary, and then possessed himself of the lady and his estate. This was followed by a rebellion of the whole province of Tollantzinco, so that the king himself was obliged to take the field. As the rebels were very numerous, the royal army was at first defeated; but having at last received a strong reinforcement, the rebels were overcome, and their ringleaders severely punished. The king did not long survive the restoration of tranquillity to his dominions. He died in the thirty-second year of his reign, and ninety-second of his age, leaving the throne to his eldest son Tlotzin, who was an excellent prince, and reigned thirty-six years.

9 Quinatzin a luxurious prince.

Quinatzin, the son and successor of Tlotzin, proved a vain and luxurious prince. His accession to the throne was celebrated with much greater pomp than any of his predecessors. Xolotl had removed his court from Tenayuca to Tezcuco; but being disgusted with this last place, on account of the conspiracy formed against him there, he had returned to Tenayuca.—There the court continued to the reign of Quinatzin, who removed it back to Tezcuco.

10 Disturbances in various parts.

The reign of Quinatzin, though tranquil at first, was soon disturbed by dangerous revolts and rebellions. These first broke out in two states, named Maztillen and Totopec, situated among the northern mountains. The king, having collected a great army, marched without delay against the rebels, and challenged their leaders to come down and fight him in the plain.—This challenge being accepted, a furious engagement ensued, in which, though great numbers fell on both sides, no decisive advantage was gained by either party. Frequent engagements took place for the space of forty days, until at last the rebels perceiving that their own numbers were daily diminishing, without any possibility of being recruited like the royal army, made a final surrender to the king, who punished the ringleaders with great severity. Tranquillity, however, was not yet restored: the rebellion spread to such a degree, that the king was obliged not only to take the field in person, but to employ six other armies, under the command of faithful and experienced generals, to reduce the rebels. These proved so successful in their enterprises, that in a short time the rebellious cities were reduced to obedience, and the kingdom enjoyed the blessings of peace during the long reign of Quinatzin, who is said to have sat on the throne for no less than sixty years. He was succeeded by his son Techotlatla; but as the affairs of the Acolhuans now began to be connected with those of the Mexicans, it will be proper to give some account of that people.

11 Migrations of the Mexicans.

The Mexicans, called also the Aztecas, dwelt till the year 1160 in a country called *Aztlan*, situated to the north of the gulf of California, as appears by the route they pursued in their journey; but how far to the northward we are not certainly informed. Betancourt makes it no less than 2700 miles, and Boturini says it was a province of Asia. The cause of their migration is said to have been as follows:

Among the Aztecas was a person of great authority, named *Huiztilin*, to whose opinion every one paid the utmost deference. He had conceived a design to persuade his countrymen to change their residence; and to effect this he fell upon the following stratagem. Having heard, while meditating on his scheme, a little bird singing on the branches of a tree, the notes of which resembled the word *Tihui*, which in the Azteca language signified "let us go," he took that opportunity to work upon the superstition of the people. With this view, he took along with him a respectable person, and made him attend to the note of the bird. "What can it mean (says he), but that we must leave this country, and find ourselves another? Without doubt it is the warning of some secret divinity who watches over our welfare: let us obey, therefore, his voice, and not draw his anger upon us by a refusal." Tecpaltzin, for that was the name of his friend, readily agreed to the interpretation; and both of them being persons of great influence, their united persuasions soon gained over to their project the bulk of the nation, and they accordingly set out.

12 Separation of the tribes.

The Aztecas, when they left their original habitations, were divided into six tribes; but at Culiacan the Mexicans were left with their god * by five of them, viz. the Xochimilcas, Tepanecas, Chalcese, Tlahuicas, and Tlascalans. The cause of this separation is not known, but it was probably occasioned by some disagreement among themselves; for the remaining tribe was divided into two violent factions, which persecuted one another: neither did they afterwards construct any more edifices. However, they always travelled together, in order to enjoy the company of their imaginary god. At every place where they stopped an altar was erected to him; and at their departure they left behind them all their sick, and probably also some others to take care of them, or such as were not willing to endure the fatigue of farther journeys. They stopped in Tula nine years, and eleven more in the neighbouring parts. At last, in 1216, they arrived at Zumpanco, a considerable city in the vale of Mexico, where they were received in a very hospitable manner by the lord of that district. He not only assigned them proper habitations, but became very much attached to them; and even demanded from among them a wife for his son Ilhuicatl. This request was complied with; and from this marriage all the Mexican kings descended.

* *A wooden image.*

13 The Mexicans persecuted.

The Mexicans continued to migrate from one place to another along the lake of Tezcuco. Xolotl, who was then on the throne of the Acolhuans or Chichemecas, allowed them to settle in whatever places of his dominions they thought proper; but some of them finding themselves harassed by a neighbouring lord, were obliged in 1245, to retire to Chapoltepec, a mountain on the western borders of the lake, scarcely two miles distant from the site of Mexico. This took place in the reign of Nopaltzin, when disturbances began to take place in the Acolhuan dominions. The Mexicans, however, did not find themselves any more secure in their new place of residence than formerly: they were persecuted by the neighbouring lords, and obliged to take refuge in a number of small islands, named *Acocolco*, at the southern extremity of the lake of Mexico. Here for 52 years they lived in the most

miserable

History.

miserable manner, subsisting on fish, insects, roots, &c. and clothing themselves with the leaves of the amoxtli, which abounds in that lake.

14 and enslaved.

In this miserable plight the Mexicans continued till the year 1314, when they were reduced to a state of the most absolute slavery. This was done by the king of a petty state named Colhuacan, who, it is said, being unwilling to allow the Mexicans to maintain themselves in his territories without paying tribute, made war upon them, subdued and enslaved them. Others affirm that, pretending compassion for their miserable situation, he offered them a more commodious place of residence. The Mexicans readily accepted the offer; but had scarcely set out to take possession of their new place of residence when they were attacked by the Colhuans, made prisoners, and carried off for slaves.

15 Regain their liberty by cruelty.

After some years a war broke out betwixt the Colhuans and Xochimilcas, in which the latter gained such advantages, that they were obliged to employ their slaves to assist them. They accordingly ordered them to prepare for war, but without furnishing them with arms necessary for a military enterprise; so that the Mexicans were obliged to content themselves with long staves, having their points hardened in the fire; they also made knives of the stone iztli, and shields of reeds woven together. They agreed not to waste their time in making prisoners, but to content themselves with cutting off one ear of their enemies, and then leaving them without farther injury. They adhered punctually to this resolution; and rushing furiously upon the Xochimilcas, cut off an ear from as many as they could, killing those who struggled to such a degree that they could not effect their purpose. In short, so well did the Mexicans acquit themselves in this engagement, that the Xochimilcas fled, and took refuge among the mountains. After the battle, the Colhuan soldiers presented themselves before their general with the prisoners they had taken, by the number of which alone they judged of their valour. The Mexicans had taken only four, and these they kept concealed for the abominable purpose of sacrificing them. The Colhuans, therefore, seeing no trophies of their valour, began to reproach them with cowardice; but the Mexicans, producing their baskets of ears, desired them to judge from these how many prisoners they might have taken, had they not been unwilling to retard their victory by taking up time in binding them.

Notwithstanding the valour displayed by the Mexicans in this engagement, it doth not appear that their haughty masters were in the least inclined to afford them easier terms than before. Having erected an altar to their god, they demanded of their lord something precious to offer in sacrifice to him; but he in disdain sent them a dirty cloth, enclosing the filthy carcass of a vile bird. This was carried by Colhuan priests; and without any ceremony laid upon the altar. The Mexicans, with apparent unconcern, removed this filthy offering,

16 The first human sacrifice in Mexico.

and put in its place a knife made of iztli, and an odoriferous herb. On the day of consecration, the Colhuan prince attended with his nobility; not with a view to do honour to the festival, but to make a mockery of the Mexicans. Their derision, however, was soon changed into horror, when the Mexicans, after a solemn dance, brought forth the four Xochimilcan prisoners they had taken; and, after having made them dance a little, cut open their breasts with the knife which lay on the altar, and plucking out their hearts, offered them, while yet palpitating with life, to their diabolical idol. This had such an effect upon the spectators, that both king and subjects desired the Mexicans immediately to quit their territories and go where they pleased. This order was instantly obeyed: the whole nation took their route towards the north, until they came to a place named *Acatzitzintlan*, situated betwixt two lakes, and afterwards named *Mexicaltzinco;* but for some reason or other, being discontented with this situation, as indeed they seem very often to have been, they proceeded to *Iztacalco*, still nearer to the site of Mexico. Here they formed the image of a little mountain of paper, and danced round it a whole night, singing their victory over the Xochimilcas, and reuniting thanks to their god for having freed them from the yoke of the Colhuans. Clavigero is of opinion, that by this mountain they represented Colhuacan, as in their pictures it was always represented by a hunch-backed mountain; and this is the literal signification of the name.

17 The city of Mexico founded.

The city of Mexico was founded in the year 1325, in the most incommodious situation we can imagine, viz. on a small island named Tenochtitlan, in the middle of a great lake, without ground to cultivate for their subsistence, or even room sufficient to build their habitations. Their life was therefore as miserable here for some time as it had been when they were on the islands at the end of the lake, and they were reduced to the same shift to maintain themselves. To enlarge the boundaries of their island, they drove palisades into those parts of the water which were most shallow, terracing them with stones and turf, and uniting to their principal island several other smaller ones which lay in the neighbourhood. To procure to themselves afterwards stones, wood, &c. for constructing their habitations, as well as clothing and other necessaries, they instituted a commerce with the people who dwelt on the borders of the lake, supplying them with fish, waterfowl, and other more minute inhabitants of the lake and marshes, which they contrived to render eatable; and in return for all this they received the necessaries above mentioned. The greatest effort of their industry, however, was the construction of floating gardens, by means of bushes and the mud of the lake; and these they brought to such perfection that they produced maize, pepper, chia, French beans, and gourds.

18 The two factions separate.

For thirteen years that the Mexicans had to struggle with extreme difficulty, they remained at peace; but no sooner did they begin to prosper and live comfortably, than the inveterate enmity betwixt the two factions broke out in all its fury. This produced a separation; and one of the parties took up their residence on a small island at a little distance to the northward, which, from a heap of sand found there, they at first named *Xaltilolco*, but afterwards *Tlatelolco*, from a terrace constructed by themselves. This island was afterwards united to that of Tenochtitlan.

About this time the Mexicans divided their city into four parts, a division which still subsists; each quarter having now its tutelar saint, as it had formerly its tutelar god. In the midst of their city was the sanctuary of their great god *Mexitli*, whom they constantly preferred to all the rest. To him they daily performed acts

acts of adoration: but instead of making any progress in humanity, they seem to have daily improved in the most horrible barbarities, at least in their religion.

19 Monstrous barbarity of their religion.

The dreadful sacrifices made of their prisoners, could only be exceeded by that which we are now about to relate. Being now on a more respectable footing than formerly, they sent an embassy to the petty king of Colhuacan, requesting him to send them one of his daughters, that she might be consecrated the mother of their protecting god. The unsuspecting prince readily complied with their desire.—The unfortunate princess was conducted in great triumph to Mexico; but no sooner was she arrived, than she was sacrificed in a shocking manner; and, to add to the horror of the deed, the body was flayed, and one of the bravest young men of the nation dressed in her skin. Her father, ignorant of this dreadful transaction, was invited by the Mexicans to be present at the apotheosis of his daughter, and went to see the solemnity, and to worship the new divinity. He was led into the sanctuary, where the young man stood clothed in the bloody skin of his daughter; but the darkness of the place prevented him from seeing what was before him. They gave him a censer in his hand, and some copal to begin his worship; but having discovered by the flame of the copal the horrible spectacle, he ran out in a distracted manner, calling upon his people to revenge the injury; but this they were not able to do at that time nor ever after.

In the year 1352 the Mexican government was changed from an aristocracy to a monarchy. At first they were governed by 20 lords, of whom one had an authority superior to the rest. This naturally suggested the idea of monarchy; and to this change they were also induced by the contemptible state in which their nation still continued, thinking that the royal dignity would confer upon it a degree of splendour which otherwise it could not enjoy; and that by having one leader, they would be better able to oppose their enemies.

20 Acamapitzin the first king of Mexico.

Proceeding, therefore, to elect a king, the choice fell upon Acamapitzin, a man of great estimation among them, and descended from Opochtli, a noble Aztecan, and a princess of the royal family of Colhuacan. As he was yet a bachelor, they attempted to negociate a marriage, first with the daughter of the lord of Tacuba, and then of the king of Azcapozalco: but these proposals being rejected with disdain, they applied to Acolmiztli lord of Coatlichan, and a descendant of one of the three Acolhuan princes; who complied with their request, and the nuptials were celebrated with great rejoicings.

21 The Tlatelolcos also choose a king.

In the mean time, the Tlatelolcos, the natural rivals of the Mexicans, resolved not to be behind them in any thing which had the least appearance of augmenting the glory of their state. They likewise, therefore, chose a king; but not thinking proper to choose him from among themselves, they applied to the king of the Tepanecas, who readily sent them his son; and he was crowned first king of Tlatelolco in 1353. In this the Tlatelolcos seem to have had a design of humbling their rivals, as well as rendering themselves more respectable; and therefore it is probable that they had represented the Mexicans as wanting in that respect due to the Tepanecan monarch, as having elected a king without his leave, though at the same time they were tributaries to him. The consequence of this was, that he took a resolution to double their tribute.

22 Mexicans oppressed.

Hitherto they had paid only a certain number of fish and water-fowl; but now they were ordered to bring also several thousands of fir and willow plants to be set in the roads and gardens of Azcapozalco, and to transport to the court a great floating garden, which produced vegetables of every kind known in Anahnac. This being accomplished with great difficulty, the king commanded them next year to bring him another garden, with a duck and swan in it both sitting upon eggs; but so, that on their arrival at Azcapozalco the brood might be ready to hatch. This was also done; and the prince had the satisfaction of seeing the young birds come out of the eggs. The third year they were ordered to bring a live stag along with a garden. This was more difficult than any of the former tasks; because they were obliged, in order to hunt the stag, to go to the mountains of the continent, where they were in danger of falling into the hands of their enemies: however, this also was accomplished, and the desire of the king gratified.

In this manner the Mexicans were oppressed for no less than 50 years. They freed themselves, however, from all their difficulties by vigorous exertions, absurdly ascribing to the protection of that malevolent being whom they worshipped the glory of every deliverance. Acamapitzin governed this city, which at that time comprehended the whole of his dominions, for 37 years in peace. His queen being barren, he married another wife, but without abandoning the first; and these two, instead of being rivals to one another, lived together in the utmost harmony; the first wife taking upon herself the charge of educating *Huitzilihuitl*, the son of the second. He had, besides, several children by other women, and one named *Itzcoatl*, who afterwards proved one of the best and most renowned kings who sat on the throne of Mexico. He is said also to have conquered four considerable cities; but Clavigero thinks he must in this only have been an auxiliary, it being very improbable, that while he could scarce maintain his own territories, he should think of foreign conquests.

Acamapitzin died in 1389, greatly lamented by the Mexicans, and his death was followed by an interregnum of four months. As the deceased monarch had formerly resigned his authority into the hands of his nobles, it was necessary that a new election should take place; and when this was done, the choice fell upon Huitzilihuitl, the son of Acamapitzin.

23 Huitzilihuitl the second king.

As he was still unmarried, it was resolved, if possible, to procure him an honourable and advantageous match. With this view, a deputation of nobility was sent to the king of Azcapozalco, requesting, in very humble terms, an alliance with one of his daughters. The expressions made use of by these ambassadors are said by our author to have been particularly elegant in the Mexican language; but it is difficult to understand how a speech made among a people ignorant of the art of writing could be particularly recorded at the interval of some hundreds of years after. They are as follow: "We beseech you, with the most profound respect, to take compassion on our master and your servant Huitzilihuitl, confined among the thick rushes of the lake.—He is without a wife, and we without a queen.—Vouchsafe, Sir, to part with one of your jewels or most

most precious feathers. Give us one of your daughters, who may come to reign over us in a country which belongs to you."

24 Marries a daughter of the king of the Tepanecans.

This piece of oratory had such an effect upon the king, that he granted their request, and a Tepanecan princess was conducted in great triumph to Mexico, where the marriage was solemnized with the utmost joy. Though this princess brought him a son the first year of their marriage, the king, in order to strengthen himself by fresh alliances, married also the daughter of another prince, by whom he had Montezuma *Ilhuicamina*, the most celebrated of all the Mexican kings.

As the Mexicans advanced in wealth and power, so did their rivals the inhabitants of Tlatelolco.—Their first king died in 1399, leaving his subjects greatly improved in civilization, and the city much enlarged and beautified. The rivalship which subsisted between the two cities had indeed greatly contributed to the aggrandizement of both. The Mexicans had formed so many alliances by marriage with the neighbouring nations, had so much improved their agriculture and floating gardens on the lake, and had built so many more vessels to supply their extended commerce and fishing, that they were enabled to celebrate their secular year, answering to A. D. 1402, with greater magnificence than they had ever done since they left their original country of Atztlan.

25 Unfortunate reign of Techotlala's son.

All this time Techotlala, the son of Quinatzin, continued to reign in Acolhuacan, and for 30 years enjoyed uninterrupted tranquillity; but being now very far advanced in years, and finding his end approach, he called to him his son Ixtlilxochitl, and recommended to him to beware of the ambitious disposition of the king of Azcapozalco, as he was apprehensive that he might attempt something against the peace of the empire. His suspicions were verified; for on the death of Techotlala, which happened in 1406, the king of Azcapozalco, without making the usual submissions to the new king, to whom he was a feudatory, set out for his own territories, with a view to stir up the other feudatory princes to rebellion. Having called to him the kings of Mexico and Tlatelolco, he told them, that Techotlala, who had long tyrannized over that country, being dead, he designed to procure freedom to the princes, so that each might rule his own territory entirely independent of the king of Acolhuacan; but for this purpose he needed their assistance, and trusted to their well known spirit to take part with him in the enterprise. He informed them likewise, that in order to ensure success, he would find means to unite other princes in the confederacy.

The new king of Acolhuacan, in the mean time, was employed in settling the affairs of his kingdom, and endeavouring to gain the good will of his subjects. The combination against him was soon discovered: but though Ixtlilxochitl was desirous of heading his army in person, he was dissuaded from so doing by his courtiers; so that the conduct of the war was committed to his generals. To weaken the enemy, they ravaged the territories of six revolted states: but, notwithstanding this, and the superior discipline of the royal army, the war was carried on by the rebels with great obstinacy, their armies being constantly recruited by fresh troops in proportion to their losses. At last, after three years of a ruinous war, the king of Azcapozalco, finding that his resources would at last fail him, sued for peace; but with a design of accomplishing by treachery what he had not yet been able to do by force. His adversary, equally reduced with himself, consented to a peace, though he knew very well that the Tepanecan prince intended to observe it no longer than suited his purpose.

26 Chimalpopoca third king of Mexico.

In the year 1409 died Huitzilihuitl king of Mexico, who likewise left the right of electing a successor to the nobility. They made choice of his brother Chimalpopoca; and from thence it became an established law to choose one of the brothers of the deceased king, or, if he had no brothers, to elect one of his grandsons. While the new prince was endeavouring to secure himself on the throne, the treacherous Tezozomoc used all means in his power to strengthen the party he had formed against the king of Acolhuacan. In this he was attended with such success, that the unfortunate prince found himself reduced to the necessity of wandering among the neighbouring mountains, at the head of a small army, accompanied by the lords of Huexotla and Coatlichan, who remained always faithful to him. The Tepanecans distressed him to such a degree, by intercepting his provisions, that he was forced to beg them of his enemies.

27 Distress and death of the king of Acolhuacan.

One of his grandsons was sent to Otompan, a rebel state, to request them to supply their king with the provisions he stood in need of, and to exhort them to abandon the cause of the rebels, which they had espoused. No task could be more dangerous; yet such was the magnanimity of the young prince's disposition, that he readily set out on the journey; nor was he deterred by the information he got that there were in the place certain Tepanecans who had come on purpose to publish a proclamation from Tezozomoc. He went boldly to the most public place of the town, and in presence of those who published the proclamation made known his request. This heroism, however, did not meet with the success it deserved. His propositions were derided from the moment they were made; but the people did not offer any farther insult, until one of the meaner sort threw a stone at him, exciting others of the same stamp to put him to death. The Tepanecans, who had hitherto continued silent, perceiving their opportunity, joined in the general cry to kill the prince, and began also to throw stones. The prince attempted first to defend himself, and afterwards to escape by flight; but, both being equally impossible, he fell under a shower of stones. The Tepanecans, exulted in this act of treachery, and soon after cut off Ixtlilxochitl himself, after having treacherously persuaded him to a conference with two of their captains. This perfidious act was committed in sight of the royal army, who were too weak to revenge it; the royal corpse was saved with difficulty; and *Nezahualcojotl*, heir apparent to the crown, was obliged to shelter himself among the bushes from the fury of his enemies.

28 Acolhuacan conquered by Tezozomoc.

Tezozomoc having now in a great measure gained his point, proceeded to pour down his troops upon those cities and districts which had remained faithful to the late unfortunate monarch. The people made a most desperate defence, and killed vast numbers of their enemies; but at last being themselves reduced by the calamities of war, and in danger of total extermination, they were obliged to quit their habitations and

fly

History. fly to other countries. The tyrant, then, finding himself superior to all his adversaries, gave Tezcuco in fief to Chimalpopoca king of Mexico, Huexotla to Tlacacotl king of Tlatelolco; placing faithful governors in other places, and appointing Azcapozalco, the capital of his own territory, the royal residence and capital of Acolhuacan.

Prince Nezahualcojotl was present in disguise at this disposal of his dominions, along with several other persons of distinction who were enemies of the tyrant; and so much was he transported with passion, that it was with difficulty he could be restrained from killing Tezozomoc on the spot, though this would certainly have been done at the expence of his own life. All the rest of the Acolhuacan empire submitted; and Nezahualcojotl saw himself for the present deprived of all hopes of obtaining the crown.

29 His tyranny and death.

Tezozomoc had now attained the summit of his ambition: but instead of conciliating the minds of his new subjects, oppressed them with new taxes; and being conscious of the precarious situation in which he stood, and tormented with remorse on account of his crimes, fell into melancholy, and was constantly haunted with frightful dreams. He was now become so old, that his body no longer retained its natural heat. He was therefore obliged to be covered up with cotton in a great cradle, not being able to sit erect in a chair. In this miserable condition, however, he never forgot his tyranny or cruelty. From his cradle he issued oppressive laws relating to the Acolhuacans; and almost with his last breath renewed his commands with regard to Nezahualcojotl. At last he expired in the year 1422, leaving the crown to his son Tajatzin.

30 The throne usurped by Maxtlaton.

Tezozomoc was no sooner dead than Maxtlaton, without paying the least regard to his father's will, began to exercise the functions of a sovereign. Though it was the right of Tajatzin to invite to his father's funeral whom he pleased, Maxtlaton took that upon himself. Nezahualcojotl, though not invited, came among the rest; but though Teuctzintli, brother to Maxtlaton, insisted upon his being put to death, the latter opposed it, as it could not then be done privately, and he hoped to find another opportunity. No sooner were the funeral ceremonies over, however, than Maxtlaton behaved in such a manner to his brother Tajatzin, that the prince thought proper to retire to Chimilpopoca king of Mexico, to whom he had been particularly recommended by his father, in order to have his advice. This monarch, agreeable to the character of that age and people, advised him to invite his brother to an entertainment, and then murder him. Unluckily for them both, this discourse was overheard by a servant, who in expectation of a reward informed the tyrant of what he had heard: but instead of this, Maxtlaton, pretending to disbelieve his story, drove the informer from his presence with ignominy. Notwithstanding this pretence, the tyrant had not the least doubt of the truth of what was told him; and therefore determined to rid himself of his brother without delay. This he soon accomplished in the very same way that had been projected against himself. Tajatzin, along with the kings of Mexico, Tlatelolco, and some other feudatory princes, were invited by Maxtlaton to an entertainment. The king of Mexico prudently excused himself, but the unsuspecting Tajatzin fell into the snare. He came to the place of entertainment, and was instantly put to death. The company were greatly alarmed; but Maxtlaton, having explained to them his reasons for so doing, they not only excused him, but proclaimed him king; to which it is not to be doubted that their fears greatly contributed.

31 Tajatzin murdered.

32 Miserable fate of the king of Mexico.

Though the king of Mexico escaped a sudden death by his absence at this time, it was only to perish in a more slow and ignominious manner. The vengeance of Maxtlaton first appeared by sending him a woman's dress in return to the present he sent him as a feudatory; which being a reflection upon his courage, was the highest affront that could be offered him. This insult, however, was quickly followed by one of a much higher nature. Having heard that one of the Mexican prince's wives was an extraordinary beauty, he enjoined some Tepanecan ladies who were accustomed to visit that princess, to invite her to spend some days with them at Azcapozalco. This being complied with, the tyrant easily got an opportunity of ravishing her, and then sent her back to her husband. Chimilpopoca was so much affected by this misfortune, that he resolved to offer himself up a sacrifice to his god. Maxtlaton, however, was resolved that he should not have even this satisfaction. At the very time of the ceremony, therefore, he sent a body of troops; who entering Mexico without resistance, carried off the king alive, to the astonishment of the multitude; and who probably were so much confounded by this unexpected adventure, that they did not think of making any resistance.

Chimilpopoca being carried prisoner to Azcapozalco, was confined in a strong wooden cage, the common prison for criminals. Maxtlaton still was not satisfied: he wished to get into his hands Nezahualcojotl; and with this view sent a message to him, pretending that he was willing to come to an agreement with him respecting the kingdom of Acolhuacan. Though the prince was well assured of the tyrant's treacherous intentions, he went boldly to his palace, presented himself before him, and told him that he had heard of the imprisonment of the king of Mexico; he had heard also that he wished to take away his own life; he desired him to do so, and to gratify his malice. Maxtlaton was so struck with this speech, that he assured the prince he had not formed any design against his life, and that he neither had put to death the king of Mexico, nor would do so. He then gave orders for his being properly entertained, and even allowed him to pay a visit to the king of Mexico in prison. The unfortunate Chimilpopoca, after reciting his misfortunes, requested the prince not to return to court, where they would certainly fall upon some project for taking away his life; and having pathetically recommended to him the care of his subjects, made him a present of a gold pendant and some other jewels he wore; after which they took a last farewell.

33 He is visited in prison by Nezahualcojotl.

34 Itzcoatl raised to the throne of Mexico, who assists Nezahualcojotl.

In the mean time, the Mexicans raised to the throne Izcoatl, the son of Acamapitzin by a slave, and who was accounted the most prudent, just, and brave, of all the Mexican nation. His election was no less pleasing to Nezahualcojotl and his party, than it was offensive to Maxtlaton. An alliance was quickly concluded between

between the exiled prince and the king of Mexico; and this was soon followed by the commencement of hostilities on the part of the former. His first enterprize was against the city of Tezcuco, which he determined to take by assault, but was prevented by the submission of the inhabitants. He put to death, however, all the officers established by the tyrant; and all the Tepaneeans he found there. The very same day another large city named Acolman was furiously attacked by a detachment of his army; great numbers put to the sword, and among the rest the governor, who was brother to Maxtlaton; and the same day also Coatlichan was taken by the Chalcese.

The Mexican monarch, hearing of the successes of his ally, sent an embassy to congratulate him upon them. His ambassador was a son of king Huitzilihuitl, named *Montezuma*, who for his invincible courage and great qualities was surnamed the *man of great heart and the archer of heaven*. The journey was extremely dangerous; but Montezuma undertook it without any fear, accompanied by another nobleman. They got in safety to the place where the prince was; but had the misfortune to be taken prisoners, and were carried to Chalco; the lord of which city, named Toteotzin, was an inveterate enemy to the Mexicans. By him he was immediately put in close confinement, under the care of one Quateozin, who was inviolably attached to the Mexican interest. Orders were given to the latter to provide no sustenance for the prisoners but what was prescribed by his lord, until the mode of death which they were to suffer should be determined. Toteotzin then sent his prisoners to them, that they might be sacrificed there if they thought proper. These people, however, rejected the proposal with disdain; on which Toteotzin, thinking to regain the favour of Maxtlaton, informed him of the prisoners he had in his possession. But Maxtlaton called him a double-minded traitor, and commanded him instantly to set the prisoners at liberty. Before this answer arrived, however, Quateozin had instructed the prisoners how to make their escape, and directed them also not to return by land lest they should again be intercepted, but to embark at a certain place, and proceed by water to Mexico. They followed his advice exactly; and having got to the place to which they were directed, arrived safely at their city, to the great surprise and joy of the inhabitants.

35 Dangerous embassy undertaken by Montezuma.

Toteotzin, enraged at the loss of his prisoners, put Quateozin to a cruel death, destroying also all his family excepting one son and a daughter; of whom the latter fled to Mexico, where she was highly honoured on her father's account. Maxtlaton, too, notwithstanding his generosity to the prisoners (which Clavigero derives from mere opposition to Toteotzin), prepared to wage a formidable war with the Mexicans, who had agreed to unite their troops with those of the prince. The Mexican populace, terrified at engaging so powerful an enemy, demanded that their king should submit and beg for peace. So great was the tumult, that the king himself was obliged to consent; and it required the utmost exertions of Montezuma's eloquence to persuade the people to agree to a commencement of hostilities. This being done at last, the king next called together the chief nobility, and asked which of them would have the courage to carry an embassy to the king of the Tepanecans? This adventure appeared so hazardous, that all of them kept a deep silence, until Montezuma declared himself willing to undertake the arduous enterprise. He was ordered to propose peace to Maxtlaton, but to accept of no dishonourable conditions; to which he punctually adhered. Maxtlaton refused to give any immediate answer, but promised to give one next day, after he had consulted his nobility. Montezuma, dreading some treachery if he staid all night, promised to return next day; which he did, and was told that Maxtlaton had determined upon war. Montezuma then performed the ceremony of challenging him, by presenting him with certain defensive weapons, anointing his head, and fixing feathers upon it, as was customary to do with dead persons. Lastly, He protested, in the name of his master, that as Maxtlaton would not accept of the offered peace, he and all the Tepanecans would infallibly be ruined. Maxtlaton showed not the least sign of displeasure, but gave Montezuma arms in like manner to present to the king of Mexico; and directed him, for his personal security, to return in disguise through a small outlet from the palace. Montezuma followed his advice; but as soon as he found himself out of danger, began to insult the Tepanecan guards; and though they rushed violently upon him, he not only escaped from their attack, but killed one or two of them.

36 Maxtlaton declares war against Mexico.

On his return to Mexico, the populace were again thrown into the utmost consternation by the news that war was inevitable, as the chiefs of the two nations had challenged one another. They now requested the king to allow them to retire from their city, of which they supposed the ruin to be certain. The king encouraged them with the hopes of victory. "But if we are conquered (replied they), what will become of us? "If that happens (answered the king), we are that moment bound to deliver ourselves into your hands, to be made sacrifices at your pleasure." "Be it so (replied they), if we are conquered; but if we obtain the victory, we and our descendants are bound to be tributary to you; to cultivate your lands and those of your nobles; to build your houses; and to carry for you, when you go to war, your arms and baggage."

37 He is defeated and killed.

Matters being thus settled, intelligence was sent to Prince Nezahualcojotl to repair with his army to Mexico, which he did without delay; and the day after his arrival a furious engagement took place. The Tepanecan army was commanded by a general named *Mazatl;* Maxtlaton himself not judging it proper to quit his capital. The soldiers on both sides fought with the utmost bravery; but towards night the Mexicans, disheartened by seeing the army of their enemies continually increasing in number, began once more to lose their courage and talk of surrendering. The king, greatly concerned, asked Montezuma what should be done to dissipate the fears of the people? That brave prince replied, that they must fight till death; that if they died with their arms in their hands, it would be honourable; but to survive their defeat, would be eternal ignominy. Nothing could be more salutary than this advice at so critical a juncture: for the Mexicans were already begun to implore the mercy of their enemies, and to promise to sacrifice their chiefs, whose ambition had brought the whole nation into

History. into such a dilemma. On hearing this, the whole body of nobility, with the king and Montezuma, at their head, assaulted the enemy so furiously, that they repulsed them from a ditch of which they had taken possession; after which, Montezuma, happening to encounter Mazatl the Tepanecan general, struck him such a blow on the head that he fell down lifeless. Thus the Mexicans were inspired with fresh courage, and their enemies proportionally dispirited: however, they retired for that night to the city, in some hopes of being able to retrieve their fortune next day. Maxtlaton encouraged them by every method in his power; but fortune proved still more unfavourable than the day before. The Tepanecans were now entirely defeated, and the city of Azcapozalco taken. Maxtlaton, who seems not to have had the courage to fight, had not now the presence of mind to fly. He attempted indeed to hide himself; but being quickly discovered, he was beaten to death with sticks and stones. The city was plundered, the inhabitants butchered, and the houses destroyed by the victors.

38 he Tepa- ecans en- irely re- uced. This victory proved decisive in favour of the confederates. Every other place of strength in the country was quickly reduced, until the Tepanecans, finding themselves on the verge of destruction, sent an humble embassy to the king of Mexico, requesting to be taken under his protection, and to become tributaries to him. Itzcoatl received them graciously; but threatened them with total extirpation if they violated the fidelity they had sworn to him.

Itzcoatl, after this extraordinary success, took care to have the above-mentioned contract ratified between the nobility and common peole, by which the latter were bound to perpetual services. Those who had discouraged the soldiers in time of battle were banished for ever from the state of Mexico; while Montezuma and others who had distinguished themselves by their bravery, were rewarded with lands, as was usual with other conquerors.

39 ezahual- ojotl made ing of A- olhuacan. Itzcoatl, now finding himself firmly seated on the throne of Mexico, set about performing his engagements to the Acolhuacan prince, by seating him on the throne of his ancestors. Having again joined their armies, they marched against Huaxotla, a city which refused to submit, even though terms of pardon were offered them. Instead of this, they rashly ventured a battle, in which they were entirely defeated; and were then fain to send a deputation of their old men, pregnant women, &c. as was customary in cases of distress, to move the enemy to compassion. At last all obstacles being removed, Nezahualcojotl was seated on the threne of Acolhuacan, the auxiliary troops were dismissed, and Itzcoatl left at liberty to pursue his conquests, in which he was still assisted by the king of Acolhuacan. The first expedition was against Cojohuacan, and other two Tepanecan cities, who had not only refused submission themselves, but excited others to shake off the yoke al-

40 onquests the lexicans. so. The war against them proved bloody. Three battles were fought, in which Itzcoatl gained no other advantage than making the enemy retreat a little; but in the fourth, while the two armies were hotly engaged, Montezuma, with a body of chosen troops, which he had placed in ambuscade, attacked the rear-guard of the rebels with such vigour, that they were soon disordered, and obliged to fly to the city. The conquerors pursued them thither; and Montezuma perceiving that they intended to fortify themselves in the greater temple, frustrated their design by getting possession of it and burning the turret. By this disaster they were so much terrified, that they fled to the mountains south of Cojohuacan; but even there the royal army overtook and pursued them more than 30 miles, till they came to another mountain, where, quite exhausted with fatigue, and seeing no means of escape, they were obliged to surrender at discretion.

Having thus happily accomplished the conquest of Cojohuacan and the other rebellious cities, the two kings returned to Mexico. Itzcoatl gave great part of the Tepanecan country, with the title of king of *Tacuba*, to *Totoquihuatzin*, a grandson of Tezozomoc, but who does not appear to have been any way concerned in his projects against the Mexicans. An alliance was then formed among the three kings on the following terms: The king of Tacuba held his crown on condition of serving the king of Mexico with all his troops, at any time when required; for which he was to have a fifth part of the spoils taken from the enemy. 41 Alliance between the kings of Mexico, Acolhuacan, and Tepaneca. The king of Acolhuacan was likewise to assist the king of Mexico in war; and for this he was to have a third part of the plunder, after deducting the share of the king of Tabuca; and the remainder was to belong to the king of Mexico. The kings of Tacuba and Acolhuacan, were both declared honorary electors of the kings of Mexico; the real electors being four nobles: and the king of Mexico was likewise bound to assist in the wars of his allies whenever it was demanded.

After having thus settled matters among themselves, and rewarded their soldiers, Itzcoatl set out with Nezahualcojotl for Tezcuco, where the Acolhuacan king was crowned with all possible ceremony. Here the new king took every method which prudence could suggest to establish his authority on a permanent basis; but while he was thus employed, the Xochimilcas, fearing lest the Mexicans might conquer their country as they had done that of the Tepanecans, held a council on what was to be done to prevent such a disgrace. In this council it was determined to commence hostilities against that rising state, before it should become more formidable by new conquests. Itzcoatl was no sooner informed of this determination, than he sent Montezuma with a great army against them. 42 Other conquests. The Xochimilcas met him with one still more numerous; but being worse disciplined, they were quickly defeated, and their city taken in a very short time after. This conquest was followed by the reduction of Cuitlahuac, situated on a small island in the lake of Chalco. Their insular situation gave them confidence to atack the formidable power of the Mexicans. The king was so sensible of the difficulty of this enterprise, that he proposed to attack them with the whole force of the alliance: Montezuma, however, with only a small number of men of his own training, whom he furnished with proper vessels, reduced them in seven days.

43 Montezuma I. king of Mexico. Itzcoatl died in the year 1436, at a very advanced age, in the height of prosperity, and was succeeded by Montezuma I. the greatest monarch that ever sat on the Mexican throne. Before his coronation, in order to comply with the barbarous rites of his religion,

History.

gion, he made war upon the Chalcese, in order to procure the prisoners who were to be sacrificed at his coronation; and scarce was this ceremony over, when a new war commenced, which terminated in the destruction of that city. This quarrel happened between the Chalcese and the Tezcucans. Two of the royal princes of Tezcuco having gone a-hunting on the mountains which overlook the plains of Chalco, while employed in the chase, and separated from their retinue, with only three Mexican lords, fell in with a troop of Chalcese soldiers; who, to gratify the cruelty of their master, carried them all prisoners to Chalco. The cruel and inconsiderate tyrant who commanded there instantly put them all to death: after which he caused their bodies to be salted, dried, and placed in an hall of his palace, where they served as supporters to the pine torches burned there for lights every evening. The king of Tezcuco, overwhelmed with grief, and to the last degree exasperated at such an inhuman act, called for the assistance of the allied kings. The city was attacked at once by land and water. The inhabitants, knowing that they had no mercy to expect, fought like men in despair. Even the old tyrant who commanded them, though unable to walk, caused himself to be carried in a litter among the combatants; notwithstanding which they were totally defeated, and the most severe vengeance executed upon them.

44 Chalco taken.

Montezuma, on his return, found himself obliged to encounter an enemy more formidable on account of his vicinity, than more powerful ones at a distance. This was the king of Tlatelolco, who had formerly conspired against the life of Itzcoatl; and finding himself disappointed in this, had tried to reduce his power by entering into a confederacy with some of the neighbouring lords. At that time his designs proved abortive, but he resumed them in the time of Montezuma; the consequence of which was, that he was defeated and killed. One *Moquihuix* was chosen in his room; in whose election it is probable that Montezuma had a considerable share. This was followed by conquests of a much more important nature. The province of *Cuihixcas*, lying to the southward, was added to his dominions, comprehending a tract of country more than 150 miles in breadth; then, turning to the westward, he conquered another named *Tzompahuacan*. This success, however, was for a short time interrupted by a war with Atonaltzin, lord of a territory in the country of the Mixtacas. This prince, puffed up on account of the great wealth he possessed, took it into his head that he would allow no Mexican to travel through his country. Montezuma sent ambassadors to know the reason of such strange conduct; but Atonaltzin gave them no other answer than showing them some part of his wealth, making a present to the king, and desiring them from thence to observe how much the subjects of Atonaltzin loved him; and that he willingly accepted of war, which was to determine whether he should pay tribute to the Mexicans or the Mexicans to him. Montezuma having informed his allies of this insolent answer, sent a considerable army against Atonaltzin, but had the mortification to be informed of its defeat; in consequence of which the pride of Atonaltzin was increased to a great degree. Montezuma, greatly chagrined at this first check, determined to head his next army in person; but before he could call together another, Atonaltzin had drawn into a confederacy with him the Huexotzincas and Tlascalans, who were glad of the opportunity, as they supposed, of reducing the power of the Mexicans. Their numbers, however, availed but little; Montezuma in the very first engagement totally defeated the confederate army. The allies of Atonaltzin were particularly unfortunate; for such of them as were not killed in the field of battle, were destroyed by their own party out of revenge for the unfortunate event of the battle.

45 Tlatelolco reduced, and Moquihuix made king.

46 Atonaltzin defeated, and the Mexican dominions enlarged.

By this victory the Mexican monarch became master not only of the dominions of Atonaltzin, but of many other neighbouring princes, against whom he made war on account of their having put to death some Mexican merchants or couriers without any just cause. The conquest of *Cuetlachtlan* or *Cotasta*, however, which he attempted in 1457, proved a much more difficult task. This province lies on the coast of the Mexican gulf, and had been formerly inhabited by the Olmecans, whom the Tlascalans had driven out. The inhabitants were very numerous; but dreading the power of Montezuma, called in those of Tlascala, together with the Huexotzincas, to their assistance. Along with these the allies drew the Cholulans also into the confederacy; so that this seems to have been the most formidable combination that had yet been formed against the Mexican power. Montezuma collected an excellently equipped army; which, however, he did not on this occasion command in person. It contained a great number of persons of very high rank, among whom were three princes of royal blood, and *Moquihuix* king of Tlatelolco already mentioned. The combination of the three republics against Mexico was not known at court when the army set out; but Montezuma, being informed of it soon after, sent an order to his generals to return. This accorded so ill with the romantic notions of valour entertained by the Mexicans, that a consultation of the generals was held whether they should obey it or not. At last it was determined that the king's order should be obeyed; but no sooner was this agreed to than Moquihuix accused them all of cowardice, and threatened, with his own troops, unassisted, to go and conquer the enemy. His speech had such an effect upon them all, that they went to meet the confederates. The Cotastese fought with great valour, but were unable to resist the royal forces; and their allies were almost totally destroyed. Six thousand two hundred of them were taken prisoners, and soon after sacrificed to the Mexican god of war in the barbarous manner already described. The victory was said to have been owing principally to the valour and good conduct of Moquihuix, insomuch that to this day a song made in his praise on that occasion is known in Mexico. Montezuma was so well pleased with the victory, that he not only forgave the disobedience of his orders, but bestowed upon Moquihuix a princess, one of his own cousins, to wife.

47 Inundation and famine at Mexico.

During the reign of this great monarch a violent inundation happened in Mexico. The lake, swelled by the excessive rains which fell in the year 1446, poured its waters into the city with so much violence that many

History.

many houses were destroyed, and the streets inundated to such a degree that boats were everywhere made use of. The inundation was soon followed by a famine. This was occasioned by the stinting of the crop of maize in 1448; the ears while young and tender being destroyed by frost. In 1450 the crop was totally lost for want of water; and in 1451, besides the unfavourable seasons, there was a scarcity of seed. Hence, in 1452, the necessities of the people became so great, that they were obliged to sell themselves for slaves in order to procure subsistence. Montezuma permitted them to go to other countries for support; but being informed that many sold themselves for a few days provision, he ordered, by proclamation, that no woman should sell herself for less than 400 ears of wheat, nor any man for less than 500. He opened also the public granaries for the relief of the lower classes; but nothing was able to stop the progress of the famine.

48 Axayacatl succeeds Montezuma.

Montezuma was succeeded by Axayacatl, who like his predecessor instantly commenced a war, for no other reason than that he might have prisoners to sacrifice at his coronation. He pursued Montezuma's plan of conquest; in which, however, he was less successful, many of the provinces reduced by that monarch having revolted after his death, so that it was necessary to reconquer them. On his returning successful from one of these expeditions, he built a new temple, to which he gave the name of *Coatlon;* but the Tlatelolcos, whose ancient rivalship seems to have revived on the death of Montezuma, built another in opposition, which they called *Coaxolotl.* Thus the former hatred between the two nations was renewed, and a discord took place which ended in the ruin of the Tlatelolcos.

49 Death of the kings of Acolhuacan and Tacuba.

The Mexicans sustained an irreparable loss in 1469 and 1470 by the death of their allies the kings of Tacuba and Acolhuacan.

The king of Tacuba was succeeded by his son Chimalpopoca, and the Acolhuacan monarch by his son Nezahualpilli. A short time after the accession of the latter, the war broke out between the Tlatelolcos and Mexicans, which ended in the destruction of the former. King Moquihuix had been married by Montezuma to a sister of Axayacatl, now on the throne of Mexico; but it appears that this princess never was greatly the object of his affection. On the contrary, he took all methods of expressing his dislike, either out of enmity to herself, or envy of the superior greatness of her brother. Not content with this, he entered into an alliance with a great number of the neighbouring states, in order to reduce the Mexican greatness. His wife, however, being informed of this scheme, communicated the particulars to her brother; and soon after, being impatient of the ill usage she received, came to Mexico with her four sons to claim the protection of her brother. This uncommon accident exasperated the Mexicans and Tlatelolcos against each other to such a degree, that wherever they met, they fought, abused, and murdered each other. The king of Tlatelolco prepared for war with many horrid ceremonies, of which the drinking of human blood was one. A day was appointed for attacking Mexico. Xiloman, lord of Colcuacan, was to begin the attack, afterwards to pretend flight, in order to induce the Mexicans to follow him; after which the Tlatelolcos were to fall upon their rear.

50 Tlatelolcos subdued, and the king killed.

For some reason, however, with which we are not acquainted, the Tlatelolcos began the attack without waiting for Xiloman; the consequence of which was, that he retired in disgust, leaving them to finish their battle the best way they could. The engagement lasted till night, when the Tlatelolcos were obliged to retire. Axayacatl, during the night, disposed of his troops in all the roads which led to Tlatelolco, appointing them to meet in the market-place. The Tlatelolcos, finding themselves attacked on all sides, retired gradually before the Mexicans, until at last they were forced into the market-place, where they found themselves worse than ever on account of its narrowness, which did not allow them room to act. The king stood on the top of the great temple, encouraging his men to exert themselves against the enemy. His words, however, had now lost their usual influence. He not only was not obeyed, but was reproached with cowardice because he did not come down and fight among the rest. At last the Mexicans arrived at the temple, and ascended to the balcony where the king was. He made a desperate defence for a little; but by a violent push in the breast was thrown backwards upon the steps of the temple, and stunned or perhaps killed by the fall.

The Tlatelolcos being thus reduced, Axayacatl next set out on an expedition against the Matlazincas, a tribe in the vale of Toluca, who still refused to submit to the Mexican yoke. Having proved successful in this expedition, he undertook to subdue also the northern part of the valley, now called *Valle d' Ixtlahucan*, particularly *Xiquipilco*, a considerable city and state of the Otomies, whose chief was much renowned for strength and bravery. Axayacatl, who likewise valued himself on these qualites, encountered him in single combat. In this, however, he was overmatched, and received a violent wound in the thigh; after which he would have been taken prisoner, had not some young Mexicans made a desperate effort for his rescue. Notwithstanding this disaster, Axayacatl's army gained a complete victory, carrying off 11,060 prisoners among whom was the chief of the Otomies himself, and two of his officers who had attacked the king. These chiefs were put to death at an entertainment of the allied kings, the sight of their agonies not interrupting in the least the mirth of the feast; so much were they familiarized to the shedding of human blood.

51 Axayacatl wounded and in great danger.

He was succeeded by his elder brother Tizoc. He intended to have built a larger temple than any that had yet been seen in Mexico, though that originally built had been greatly enlarged by some of his predecessors. For this purpose he collected a great quantity of materials; but before he could bring his projects to bear, he was taken off by a conspiracy of his subjects. During the reign of Tizoc, the Acolhuacans made war upon the Huexotzincas, ruined their city, and conquered their territory. Nezahualpilli also, the Acolhuacan monarch, though he had already several wives, had not made any of them queen, having wished to confer that honour upon one of the royal family of Mexico. Tizoc readily gave him one of his grand-daughters, who had a sister of singular beauty named *Xocotzin*. The friendship betwixt these two ladies was such, that the one could

52 Is succeeded by Tizoc.

History. not think of being separated from the other; for which reason the new queen sought and obtained permission to take her sister along with her to Tezcuco. Xocotzin had not been long there before the king fell in love with her, and married her with the title of queen likewise. Soon after this second marriage, the first queen brought forth a son named *Cacamatzin*, who succeeded him in the throne, and was afterwards taken prisoner by the Spaniards.

53
Ahuitzotl dedicates a temple with a multitude of human victims.

Ahuitzotl, the brother of Tizoc, succeeded him in the kingdom of Mexico. His first object was to finish the great temple begun by his predecessor; and such was the number of workmen, that it was completed in four years. During the time that it was building, the king employed himself in making war with different nations, reserving all the prisoners he took for victims at the dedication of the temple. The number of prisoners sacrificed at this dedication is said by Torquemada to have been 72,324; by other historians 64,060. The miserable victims were ranged in two files, each a mile and a half in length, terminating at the temple. The same year another temple was built by a feudatory lord, in imitation of the great one built by the king; at the dedication of which a vast number of prisoners were also sacrificed. These temples were dedicated in 1486. In 1487 happened a violent earthquake; and Chimalpopoca king of Acolhuacan died, who was succeeded by Totoquihuatzin II.

Ahuitzotl died in 1502, of a disorder produced by a contusion in his head. At the time of his death, the Mexican empire was brought to its utmost extent. His successor, Montezuma *Xocojotzin* or Montezuma *Junior*, was a person of great bravery, besides which he was likewise a priest, and held in great estimation on account of his gravity and the dignity of his deportment. His election was unanimous; and the nobles congratulated themselves on the happiness the country was to enjoy under him, little thinking how short the duration of their happiness or of their empire was to be.

54
Montezuma.

The first care of the new monarch, as usual, was to procure victims for the barbarous sacrifices to be made at his coronation. The people of Atlixco, who had again shaken off the Mexican yoke, were the sufferers on this occasion, being once more reduced, though not without great loss on the part of the Mexicans, some of whose bravest officers perished in the war. The ceremony of coronation was performed with such pomp as had never been seen before in Mexico; but no sooner was this ceremony over than Montezuma began to discover a pride which nobody had suspected before. All his predecessors had been accustomed to confer offices upon persons of merit, and those who appeared the most able to discharge them, without any partiality as to birth or wealth. Montezuma, however, disapproved of the conduct of his predecessors, under pretence that the plebeians should be employed according to their rank; for that in all their actions the baseness of their birth and the meanness of their education appeared: and in consequence of this maxim he deprived all the commoners of the offices they held about the court, declaring them incapable of holding any for the future. All the royal servants now were people of rank. Besides these who lived in the palace, 600 feudatory lords and nobles came to pay court to him. They passed the whole day in the antichamber, where none of their servants were permitted to enter; conversing in a low voice, and waiting the orders of their sovereign.—The servants of these lords were so numerous that they occupied three small courts of the palace, and many waited in the streets.

55
Magnificence displayed in his palace.

In every respect Montezuma kept up, as far as was possible, an extravagant appearance of dignity. His kitchen utensils were of the finest earthen ware, and his tablecloths and napkins of the finest cotton; but none of these ever served the emperor more than once, being immediately made a present of to some nobleman. The vessels in which his chocolate and other drinks from cocoa were prepared, were all of gold, or some beautiful sea-shell, or naturally-formed vessels, curiously varnished. He had also gold plate, but it was used only on particular occasions in the temple. The number and variety of his dishes astonished the Spaniards. He took great delight in the cleanliness of his own person, and of every thing about him. He bathed regularly every day, and had baths in all his palaces. Every day he wore four dresses, never using again those which he had put off, but reserving them as largesses for the nobility, or those who had distinguished themselves in war. The expence of all this rendered him very disagreeable to a great number of his subjects; though others were pleased with the readiness he showed to relieve the necessities of individuals, and his generosity in rewarding his generals and ministers who deserved it. Among other actions worthy of imitation, he appointed the city of Colhuacan as an hospital for all invalids, who after having faithfully served the crown either in the civil or military line, required a provision on account of their age and infirmities. In this place they were maintained and attended at the expence of the king.

56
His unsuccessful war with Tlascala.

The reign of Montezuma, even before the arrival of the Spaniards, was far from being so glorious with regard to his successes in war as those of his predecessors had been. He reduced indeed one rebellious province, and conquered another which had never before been subjugated; but in his war with Tlascala he was by no means successful. This was but a small republic at no great distance from the capital, but the inhabitants were remarkable for their bravery and independent spirit. The neighbouring states, however, who had been reduced by the Mexicans, envious of their liberty and prosperity, exasperated the Mexicans against them, by representing that the Tlascalans were desirous of making themselves masters of the maritime provinces on the Mexican gulf, and that by their commerce with these provinces they were increasing their wealth and power, and gaining the hearts of the people with whom they were to traffic. In consequence of this representation, strong garrisons were placed on the frontiers of Tlascala, to obstruct the commerce of the inhabitants, and thus to deprive them of the means of obtaining some of the necessaries of life. The Tlascalans complained; but received no other answer than that the king of Mexico was lord of all the world, and that the Tlascalans must submit and pay tribute to him. The Tlascalans returned a spirited answer to this insolent speech, and began to fortify their frontier. They had already enclosed all the lands of the repu-

blic

blic with intrenchments; and to these they now added a wall of six miles in length on the west side, where an invasion was most to be apprehended; and so well did they defend themselves, that though they were frequently attacked by the neighbouring states in alliance with Mexico, or subject to it, not one of them was able to wrest a foot of ground from them. Thus a continual series of wars and engagements took place between the states of Mexico and this republic, which continued till the arrival of the Spaniards.

57 Apprehensions entertained by the Mexicans of the arrival of a new people.

During the remainder of Montezuma's reign the empire was disturbed by various rebellions, of which the accounts are not sufficiently interesting to merit a particular detail; but in the year 1508, Montezuma began to entertain apprehensions of that fatal event which at length overtook him. An expedition having been undertaken against a very distant region named Amatla, the army in marching over a lofty mountain were attacked by a furious north wind, accompanied with snow; which made great havock in the army, many of them perishing with cold, and others being killed by the trees rooted up by the wind. The remains of the army continued their march to Amatla, where they were almost all killed in battle. By this and other calamities, together with the appearance of a comet, the Mexicans were thrown into the utmost consternation. Montezuma was so terrified by these omens, that having in vain consulted his astrologers, he applied to the king of Acolhuacan, who was reported to be very skilful in divination. Nezahualpilli having conferred with him upon the subject, told Montezuma that the comet presaged some calamity which was about to befal their kingdoms by the arrival of a new people: but this being unsatisfactory to the emperor, the king of Acolhuacan challenged him to a game at foot-ball, staking the truth of his prediction on the issue of the game. Montezuma lost the game, but did not yet acquiesce in the truth of his prediction. He therefore applied to a celebrated astrologer, whom it seems he had not yet consulted; but he confirmed the interpretation of Nezahualpilli: for which the emperor caused his house to be pulled down, and himself buried in the ruins.

58 Conquest of Mexico undertaken by Cortes.

Mexico itself was first discovered, though imperfectly, by a Spaniard named *Nunez de Balboa;* but in 1518 the conquest of it was undertaken by a celebrated adventurer named *Ferdinando Cortes.* On the 10th of February 1519, he set sail from the Havannah in Cuba; and soon landed on the island of Cozumel, on the coast of Yucatan, discovered the preceding year. Here he joined one of his officers named *Pedro d'Alvaredo*, who had arrived some days before, and collected some booty and taken a few prisoners. But the general severely censured his conduct; and the prisoners were dismissed, after they had been informed by an Indian interpreter named *Melchior*, that such injuries were entirely disagreeable to the intentions and wishes of Cortes. Here he mustered his army, and found that it amounted to 508 soldiers, 16 horsemen, and 109 mechanics, pilots, and mariners. Having encouraged his men by a proper speech, and released, by means of some Indian ambassadors, a Spaniard named *Jerom de Aguilar*, who had been detained a prisoner for eight years, he proceeded to the river Tabasco, where he hoped to be received in a friendly manner, as one Grijalva had been a short time before; but, from some unknown cause, he was violently attacked by them: however, the superiority of the Spanish arms soon decided the victory, and the inhabitants were obliged to own the king of Castile as their sovereign.

The Spaniards then continued their course westward, to the harbour of St Juan de Ullua; where they were met by two Mexican canoes, which carried two ambassadors from the emperor of that country, and showed the greatest signs of peace and amity. Their language was unknown to Aguilar; but one of the female prisoners above mentioned understood it, and translated it into the Yucatan tongue; after which Aguilar interpreted the meaning in Spanish. This slave was afterwards named *Donna Marina*, and proved very useful in their conferences with the natives.

59 State of the empire at that time.

At this time the Mexican empire, according to Dr Robertson, was arrived at a pitch of grandeur to which no society had ever attained in so short a period. Though it had subsisted only for 130 years, its dominion extended from the north to the south sea, over territories stretching about 500 leagues from east to west, and more than 200 from north to south; comprehending provinces not inferior in fertility, population, and opulence, to any in the torrid zone.—Though by nature Montezuma possessed a good deal of courage and resolution; yet from the first moment that the Spaniards appeared on his coast, he discovered symptoms of timidity and embarrassment, and all his subjects were embarrassed as well as himself. The general dismay which took place on this occasion was partly owing to the strange figure the Spaniards made, and the prodigious power of their arms; but partly also to the following circumstance. An opinion prevailed almost universally among the Americans, that some dreadful calamity impended over their heads, from a race of formidable invaders who should come from regions towards the rising sun, to overrun and desolate their country.

By means of his two interpreters, Donna Marina and Aguilar, Cortes learned that the chiefs of the Mexican embassy were deputies from Pilpatoe and Teutile; the one governor of a province under the emperor, and the other the commander of all his forces in that province: the purport of their embassy was to inquire what his intentions were in visiting their coasts, and to offer him what assistance he might need in order to continue his voyage. Cortes, in his turn, also professed the greatest friendship; and informed the ambassadors, that he came to propose matters of the utmost consequence to the welfare of the prince and his kingdom; which he would more fully unfold in person to the governor and the general. Next morning, without waiting for any answer, he landed his troops, his horses, and his artillery; began to erect huts for his men, and to fortify his camp.

60 Cortes lands and fortifies his camp.

The next day the ambassadors had a formal audience; at which Cortes acquainted them, that he came from Don Carlos of Austria, king of Castile, the greatest monarch of the east, and was intrusted with propositions of such moment that he would impart them to none but the emperor himself, and therefore required to be conducted immediately to the capital. This demand produced the greatest uneasiness; and

History.

61 The Indians endeavour to dissuade him from going to the capital, but in vain.

and the ambassadors did all in their power to dissuade Cortes from his design, endeavouring to conciliate his good will by the presents sent him by Montezuma. These they introduced with great parade, and consisted of fine cotton cloth, of plumes of various colours, and of ornaments of gold and silver to a considerable value, the workmanship of which appeared to be as curious as the materials were rich. But these presents served only to excite the avidity of the Spaniards, and to increase their desire for becoming masters of a country which abounded with so many precious commodities. Cortes indeed could scarcely restrain himself so far as to hear the arguments made use of by the ambassadors to dissuade him from going to the capital; and, in a haughty, determined tone, insisted on his former demand of being admitted to a personal interview with their sovereign.

During this conversation, some painters in the retinue of the Mexican chiefs had been diligently employed in delineating, upon white cotton cloths, figures of the ships, horses, artillery, soldiers, and whatever else attracted their eyes as singular.

62 Montezuma made acquainted with his design.

While exerting their utmost efforts in representing all these wonderful things, messengers were immediately despatched to Montezuma with the pictures, and a full account of every thing that had passed since the arrival of the Spaniards, together with some European curiosities to Montezuma; which Cortes believed would be acceptable on account of their novelty. The Mexican monarchs had couriers posted at proper stations along the principal roads; and as these were trained to agility by a regular education, they conveyed intelligence with surprising rapidity. Though the city in which Montezuma resided was above 180 miles from St Juan de Ullua, Cortes's presents were carried thither, and an answer returned to his demands, in a few days. As the answer was unfavourable, Montezuma had endeavoured to mollify the Spanish general by the richness of his presents. These consisted of the manufactures of the country; cotton stuffs so fine, and of such delicate texture, as to resemble silk; pictures of animals, trees, and other natural objects, formed with feathers of different colours, disposed and mingled with such skill and elegance as to rival the works of the pencil in truth and beauty of imitation. But what chiefly attracted their attention, were two large plates of a circular form; one of massive gold representing the sun, the other of silver representing the moon. These were accompanied with bracelets, collars, rings, and other trinkets of gold; and that nothing might be wanting which could give the Spaniards a complete idea of what the country afforded, some boxes filled with pearls, precious stones, and grains of gold unwrought, as they had been found in the mines or rivers, were sent along with the rest. Cortes received all with an appearance of the most profound respect for Montezuma; but when the Mexicans, presuming upon this, informed him, that their master, though he desired him to accept of what he had sent as a token of his regard for the prince whom he represented, would not give his consent that foreign troops should approach nearer to his capital, or even allow them to continue longer in his dominions, Cortes declared in a manner more resolute and peremptory than formerly, that he must insist on his first demand; as he could not, without dishonour, return to his own sovereign until he was admitted into the presence of the prince whom he was appointed to visit in his name.

63 Sends an unfavourable answer, but accompanied with rich presents.

64 Cortes still insists on his demands.

The pusillanimity of the Indian monarch afforded time to the Spaniards to take measures which would have been out of their power had they been vigorously attacked on their first refusal to obey his orders. Cortes used every method of securing the affections of the soldiers; which indeed was very necessary, as many of them began to exclaim against the rashness of his attempt in leading them against the whole force of the Mexican empire. In a short time Teutile arrived with another present from Montezuma, and together with it delivered the ultimate orders of that monarch to depart instantly out of his dominions; and when Cortes, instead of complying with his demands, renewed his request of audience, the Mexican immediately left the camp with strong marks of surprise and resentment. Next morning, none of the natives appeared; all friendly correspondence seemed to be at an end, and hostilities were expected to commence every moment. A sudden consternation ensued among the Spaniards, and a party was formed against him by the adherents of Velasques; who took advantage of the occasion, and deputed one of their number, a principal officer, to remonstrate, as if in name of the whole army, against his rashness, and to urge the necessity of his returning to Cuba. Cortes received the message without any appearance of emotion; and as he well knew the temper and wishes of his soldiery, with much complacency he pretended to comply with the request now made him, and issued orders that the army should be in readiness next day to embark for Cuba. Upon hearing this, the troops, as Cortes had expected, were quite outrageous: they positively refused to comply with these orders, and threatened immediately to choose another general if Cortes continued to insist on their departure.

65 Montezuma peremptorily commands him to leave his dominions.

Our adventurer was highly pleased with the disposition which now appeared among his troops: nevertheless, dissembling his sentiments, he declared, that his orders for embarking had proceeded from a persuasion that it was agreeable to his fellow-soldiers, to whose opinion he had sacrificed his own; but now he acknowledged his error, and was ready to resume his original plan of operation. This speech was highly applauded; and Cortes, without allowing his men time to cool, set about carrying his designs into execution. In order to give a beginning to a colony, he assembled the principal persons in his army, and by their suffrages elected a council and magistrates, in whom the government was to be vested. The persons chosen were most firmly attached to Cortes; and the new settlement had the name of *Villa Rica de la Vera Cruz;* that is, the rich town of the true cross.

66 Villa Rica founded.

Before this court of his own making, Cortes did not hesitate at resigning all his authority, and was immediately re-elected chief-justice of the colony, and captain-general of his army, with an ample commission, in the king's name, to continue in force till the royal pleasure should be farther known. The soldiers eagerly ratified their choice by loud acclamations; and Cortes, now considering himself as no longer accountable to any subject, began to assume a much

67 The government of the new colony vested in Cortes.

much greater degree of dignity, and to exercise more extensive powers than he had done before.

Cortes having thus strengthened himself as well as he could, resolved to advance into the country; and to this he was encouraged by the behaviour of the cacique or petty prince of Zempoalla, a considerable town at no great distance. Here he was received in the most friendly manner imaginable, and had a respect paid towards him almost equivalent to adoration. The cacique informed him of many particulars relating to the character of Montezuma.—He told him that he was a tyrant, haughty, cruel, and suspicious; who treated his own subjects with arrogance, ruined the conquered provinces by his extortions, and often tore their sons and daughters from them by violence; the former to be offered as victims to his gods, the latter to be reserved as concubines for himself and favourites. Cortes, in reply, artfully insinuated, that one great object of the Spaniards in visiting a country so remote from their own was, to redress grievances, and to relieve the oppressed; and having encouraged him to hope for this interposition in due time, continued his march to Quiabislan, the territory of another cacique, and where, by the friendly aid of the Indians, a Spanish colony was soon formed.

68 Character of Montezuma given by the cacique.

During the residence of Cortes in these parts, he so far wrought on the minds of the caciques of Zempoalla and Quiabislan, that they ventured to insult the Mexican power, at the very name of which they had been formerly accustomed to tremble. Some of Montezuma's officers having appeared to levy the usual tribute, and to demand a certain number of human victims, as an expiation of their guilt in presuming to hold intercourse with those strangers whom the emperor had commanded to leave his dominions; instead of obeying his orders, they made them prisoners, treated them with great indignity, and, as their superstition was no less barbarous than Montezuma's, they threatened to sacrifice them to their gods.

Though Cortes had now taken such measures as in a manner ensured his success; yet as he had thrown off all dependence on the governor of Cuba, who was his lawful superior, and apprehended his interest at court, he thought proper, before he set out on his intended expedition, to take the most effectual measures against the impending danger. With this view, he persuaded the magistrates of his colony to address a letter to the king, containing a pompous account of their own services, of the country they had discovered, &c. and of the motives which had induced them to throw off their allegiance to the governor of Cuba, and to settle a colony dependent on the crown alone, in which the supreme power, civil as well as military, had been vested in Cortes; humbly requesting their sovereign to ratify what had been done by his royal authority.

Some soldiers and sailors, secretly disaffected to Cortes, formed a design of seizing one of the brigantines, and making their escape to Cuba, in order to give such intelligence to the governor as might enable him to intercept the vessel which was to carry the treasure and despatches to Spain. This conspiracy was conducted with profound secrecy; but at the moment when every thing was ready for execution, the secret was discovered by one of the associates. The latent spirit of disaffection which Cortes was now too well convinced had not been extinguished amonst his troops, gave him very great uneasiness. The only method which he could think of to prevent such conspiracies for the future was to destroy his fleet, and thus deprive his soldiers of every resource except that of conquest: and with this proposal he persuaded his men to comply. With universal consent therefore the ships were drawn ashore, and, after being stripped of their sails, rigging, iron work, and whatever else might be of use, they were broke in pieces.

69 Cortes burns his fleet.

Cortes having thus rendered it necessary for his troops to follow wherever he chose to lead, began his march to Zempoalla with 500 infantry, 15 horse, and six field pieces. The rest of his troops being less fit for active service, he left them as a garrison in Villa Rica, under the command of Escalante, an officer of merit, and warmly attached to his interest. The cacique of Zempoalla supplied him with provisions; and with 200 of those Indians called *Tamanes*, whose office, in a country where tame animals were unknown, was to carry burdens, and perform all manner of servile labour. He offered likewise a considerable body of troops; but Cortes was satisfied with 400; taking care, however, to choose persons of such note, that they might serve as hostages for the fidelity of their master.

Nothing memorable happened till the Spaniards arrived on the confines of the republic of Tlascala. The inhabitants of that province were warlike, fierce, and revengeful, and had made considerable progress in agriculture and some other arts. They were implacable enemies to Montezuma; and therefore Cortes hoped that it would be an easy matter for him to procure their friendship. With this view, four Zempoallans of high rank were sent ambassadors to Tlascala, dressed with all the badges of that office usual among the Indians. The senate were divided in their opinions with regard to the proposals of Cortes: but at last Magiscatzin, one of the oldest senators, and a person of great authority, mentioned the tradition of their ancestors, and the revelations of their priests; that a race of invincible men, of divine origin, who had power over the elements, should come from the east to subdue their country. He compared the resemblance which the strangers bore to the persons figured in the traditions of Mexico, their dominion over the elements of fire, air, and water; he reminded the senate of their prodigies, omens, and signals, which had lately terrified the Mexicans, and indicated some very important event; and then declared his opinion, that it would be rashness to oppose a force apparently assisted by heaven, and men who had already proved, to the sad experience of those who opposed them, that they were invincible. This orator was opposed by Xicotencal, who endeavoured to prove that the Spaniards were at best but powerful magicians: that they had rendered themselves obnoxious to the gods by pulling down their images and altars (which indeed Cortes had very imprudently done at Zempoalla); and of consequence, that they might easily be overcome, as the gods would not fail to resent such an outrage. He therefore voted for war, and advised the crushing of these invaders at one blow.

70 Sends ambassadors to the republic of Tlascala.

The advice of Xicotencal prevailed; and in consequence of it, the ambassadors were detained; which giving

History.

giving Cortes the alarm, he drew nearer the city of Tlascala. They suffered him with his army drawn up in good order, to pass a strong wall between two mountains, which might have been very advantageously defended against him. He had not advanced far beyond this pass, however, before a party of Tlascalans with plumes were discovered, which denoted that an army was in the field. These he drove before him by a detachment of six horse, obliged them to join another party, and then reinforcing the advanced detachment, charged the enemy with such vigour that they began to retire. Five thousand Tlascalans then rushed out of their hiding places, just as the infantry came up to assist their slender body of cavalry. The enemy attacked with the utmost fury: but were so much disconcerted by the first discharge of the fire-arms, that they retreated in confusion, furnishing the Spaniards with an opportunity of pursuing them with great slaughter. Cortes, however, supposing that this could not be their whole force, advanced with the utmost caution, in order of battle, to an eminence, from whence he had a view of the main body of the Tlascalan army commanded by Xicotencal, consisting of no fewer than 40,000 men. By these the small army of Cortes was entirely surrounded; which Xicotencal no sooner perceived, than he contracted the circle with incredible diligence, while the Spaniards were almost overwhelmed with showers of arrows, darts, and stones. It is impossible but in this case many of the Spaniards must have perished, had it not been for the insufficiency of the Indian weapons. This circumstance gave the Spaniards a prodigious advantage over them; and therefore the Tlascalans, notwithstanding their valour and superiority in number, could accomplish no more in the present instance, than to kill one horse and slightly wound nine soldiers.

71 The Tlascalans resolve on war.

The Tlascalans being taught by this, and some subsequent encounters, how much they were inferior to the Spaniards, began to conceive them to be really what Magiscatzin had said; a superior order of beings, against whom human power could not prevail. In this extremity they had recourse to their priests, requiring them to reveal the causes of such extraordinary events, and to declare what means they should take to repel such formidable invaders. The priests, after many sacrifices and incantations, delivered their respone, That these strangers were the offspring of the sun, procreated by his animating energy in the regions of the east: that, by day, while cherished with the influence of his parental beams, they were invincible; but by night, when his reviving heat was withdrawn, their vigour declined and faded like herbs in the field, and they dwindled down into mortal men. In consequence of this, the Tlascalans acted in contradiction to one of their most established maxims in war, and ventured to attack the enemy in the night time, hoping to destroy them when enfeebled and surprised. But the Spanish centinels having observed some extraordinary movements among the Tlascalans, gave the alarm. Immediately the troops were under arms, and sallying out, defeated their antagonists with great slaughter, without allowing them to approach the camp. By this disaster the Tlascalans were heartily disposed to peace; but they were at a loss to form an adequate idea of the enemies they had to deal with. They could not ascertain the nature of these surprising beings, or whether they were really of a benevolent or malignant disposition. There were circumstances in their behaviour which seemed to favour each opinion. On the one hand, as the Spaniards constantly dismissed the prisoners whom they took, not only without injury, but often with presents of European toys, and renewed their offers of peace after every victory; this lenity amazed people accustomed to the exterminating system of war known in America, and who sacrificed and devoured without mercy all the captives taken in battle; and disposed them to entertain sentiments favourable to their humanity. But, on the other hand, as Cortes had seized 50 of their countrymen who brought provisions to their camp, and cut off their heads; this bloody spectacle, added to the terror occasioned by the fire-arms and horses, filled them with dreadful ideas of their ferocity. Accordingly they addressed them in the following manner: "If (said they) you are divinities of a cruel and savage nature, we present to you five slaves, that you may drink their blood and eat their flesh. If you are mild deities, accept an offering of incense and variegated plumes. If you are men, here is meat, bread and fruit, to nourish you." After this address, the peace was soon concluded, to the great satisfaction of both parties. The Tlascalans yielded themselves as vassals to the crown of Castile, and engaged to assist Cortes in all his operations; while he took the republic under his protection, and promised to defend their persons and possessions from injury and violence.

72 But are defeated and sue for peace.

History.

73 Which is granted.

Cortes left no method untried to gain the favour and confidence of the Tlascalans; which, however, he had almost entirely lost, by his untimely zeal in destroying their idols as he had done those of Zempoalla. But he was deterred from this rash action by his chaplain Father Bartholomew de Olmedo; and left the Tlascalans in the undisturbed exercise of their superstition, requiring only that they should desist from their horrid practice of offering human victims. As soon as his troops were fit for service, he resolved to continue his march towards Mexico, notwithstanding the remonstrances of the Tlascalans, who looked upon his destruction as unavoidable if he put himself into the power of such a faithless prince as Montezuma. But the emperor, probably intimidated with the fame of his exploits, had resolved to admit his visit; and informed Cortes that he had given orders for his friendly reception at Cholula, the next place of any consequence on the road to Mexico. Cortes was received with much seeming cordiality; but 6000 Tlascalan troops who accompanied him were obliged to remain without the town, as the Cholulans refused to admit their ancient enemies within their precincts. Yet two of these, by disguising themselves, got into the city, and acquainted Cortes that they observed the women and children belonging to the principal citizens retiring every night in a great hurry, and that six children had been sacrificed in the great temple; a sign that some warlike enterprise was at hand. At the same time Donna Marina, the interpreter, received information from an Indian woman of distinction, whose confidence she had gained, that the destruction of the Spaniards was concerted; that a body of Mexican troops lay concealed near the town; that some of the streets were barricaded, in others deep pits or trenches were dug,

74 Cortes continues his march for Mexico.

75 Treachery of Montezuma and the Cholulans.

History.

dug, and slightly covered over, as traps into which the horse might fall; that stones and missile weapons were collected on the tops of the temples, with which to overwhelm the infantry; that the fatal hour was already at hand, and their ruin unavoidable. Cortes, alarmed at this news, secretly arrested three of the chief priests, from whom he extorted a confession that confirmed the intelligence he had already received. As not a moment was to be lost, he instantly resolved to prevent his enemies, and to inflict on them such dreadful vengeance as might strike Montezuma and his subjects with terror. On a signal given, the troops rushed out, and fell upon the multitude, destitute of leaders, and so much astonished, that the weapons dropped from their hands, and they stood motionless, and incapable of defence. While the Spaniards attacked them in front, the Tlascalans did the same in the rear; the streets were filled with slaughter; the temples, which afforded a retreat to the priests and some leading men, were set on fire, and they perished in the flames. At length the carnage ceased, after the slaughter of 6000 Cholulans, without the loss of a single Spaniard. Cortes then released the magistrates; and reproaching them bitterly for their intended treachery, declared, that as justice was now appeased, he forgave the offence; but required them to recal the inhabitants who had fled, and re-establish order in the town.

76 Severe punishment of the Cholulans.

77 Disaffection of Montezuma's subjects.

From Cholula, Cortes advanced directly towards Mexico; and throughout the whole of his journey was entertained with accounts of the oppressions and cruelty of Montezuma. This gave him the greatest hope of accomplishing his design; as he now perceived that the empire was entirely divided, and no sort of unanimity prevailed among them. No enemy appeared to check his progress. Montezuma was quite irresolute; and Cortes was almost at the gates of the capital before the emperor had determined whether to receive him as a friend or oppose him as an enemy. But as no sign of open hostility appeared, the Spaniards, without regarding the fluctuations of Montezuma's sentiments, continued their march to Mexico, with great circumspection and the strictest discipline, though without seeming to suspect the prince whom they were about to visit.

78 Meeting of Cortes and Montezuma.

When they drew near the city, about 1000 persons who appeared to be of distinction, came forth to meet them, adorned with plumes, and clad in mantles of fine cotton. Each of these, in his order, passed by Cortes, and saluted him according to the mode deemed most respectful and submissive in their country. They announced the approach of Montezuma himself, and soon after his harbingers came in sight. There appeared first 200 persons in an uniform dress, with large plumes of feathers, alike in fashion, marching two and two, in deep silence, barefooted, with their eyes fixed on the ground. These were followed by a company of higher rank, in their most showy apparel: in the midst of whom was Montezuma, in a chair or litter richly ornamented with gold and feathers of various colours. Four of his principal favourites carried him on their shoulders, others supported a canopy of curious workmanship over his head. Before him marched three officers with rods of gold in their hands, which they lifted up on high at certain intervals; and at that signal all the people bowed their heads, and hid their faces, as unworthy to look on so great a monarch. When he drew near, Cortes dismounting, advanced towards him with officious haste, and in a respectful posture. At the same time Montezuma alighted from his chair, and leaning on the arms of two of his near relations, approached with a slow and stately pace, his attendants covering the streets with cotton cloths, that he might not touch the ground. Cortes accosted him with profound reverence, after the European fashion. He returned the salutation, according to the mode of his country, by touching the earth with his hand, and then kissing it. This ceremony appeared such amazing condescension in a proud monarch, who scarcely deigned to consider the rest of mankind as of the same species with himself, that all his subjects firmly believed those persons, before whom he humbled himself in this manner, to be something more than human. Accordingly, as they marched through the crowd, the Spaniards frequently, and with much satisfaction, heard themselves denominated *teules*, or *divinities*. Nothing material passed in this first interview. Montezuma conducted Cortes to the quarters which he had prepared for his reception; and immediately took leave of him with a politeness not unworthy of a court more refined: "You are now (says he), with your brothers, in your own house; refresh yourselves after your fatigue, and be happy until I return." The place allotted to the Spaniards for their lodging was a house built by the father of Montezuma. It was surrounded by a stone wall, with towers at proper distances, which served for defence as well as for ornament; and its apartments and courts were so large as to accommodate both the Spaniards and their Indian allies. The first care of Cortes was to take precautions for his security, by planting the artillery so as to command the different avenues which led to it, by appointing a large division of his troops to be always on guard, and by posting centinels at proper stations, with injunctions to observe the same vigilant discipline as if they were within sight of an enemy's camp.

In the evening Montezuma returned to visit his guests with the same pomp as in their first interview; and brought presents of such value, not only to Cortes and to his officers, but even to the private men, as proved the liberality of the monarch to be suitable to the opulence of his kindom. A long conference ensued, in which Cortes learned what was the opinion of Montezuma with respect to the Spaniards. It was an established tradition, he told him, among the Mexicans, that their ancestors came originally from a remote region, and conquered the provinces now subject to his dominion; that after they were settled there, the great captain who conducted this colony returned to his own country, promising, that at some future period his descendants should visit them, assume the government, and reform their constitutions and laws: that, from what he had heard and seen of Cortes and his followers, he was convinced that they were the very persons whose appearance their prophecies taught them to expect; that accordingly he had received them, not as strangers, but as relations of the same blood and parentage, and desired that they might consider themselves as masters in his dominions; for both himself and his subjects should be ready to comply with their will, and even to prevent their wishes. Cortes made a reply

History.

ply in his usual style with respect to the dignity and power of his sovereign, and his intention in sending him into that country; artfully endeavouring so to frame his discourse, that it might coincide as much as possible with the idea which Montezuma had formed concerning the origin of the Spaniards. Next morning, Cortes and some of his principal attendants were admitted to a public audience of the emperor. The three subsequent days were employed in viewing the city; the appearance of which, so far superior in the order of its buildings and the number of its inhabitants to any place the Spaniards had beheld in America, and yet so little resembling the structure of an European city, filled them with surprise and admiration.

79 Description of the city of Mexico.

Mexico is situated in a large plain, environed by mountains of such height, that though within the torrid zone, the temperature of its climate is mild and healthful. All the moisture which descends from the high grounds is collected in several lakes, the two largest of which, of about 90 miles in circuit, communicate with each other. The waters of the one are fresh, those of the other brackish. On the banks of the latter, and on some small islands adjoining to them, the capital of Montezuma's empire was built. The access to the city was by artificial causeways or streets, formed of stones and earth, about 30 feet in breadth. As the waters of the lake, during the rainy season, overflowed the flat country, these causeways were of considerable length. That of Tacuba on the west a mile and a half; that of Tezcuco on the north-west three miles; that of Cuoyacan towards the south six miles. On the east there was no causeway, and the city could be approached only by canoes. In each of these causeways were openings at proper intervals, through which the waters flowed; and over these beams of timber were laid, which being covered with earth, the causeway or street had everywhere an uniform appearance. As the approaches to the city were singular, its construction was remarkable. Not only the temples of their gods, but the houses belonging to the monarch, and to persons of distinction, were of such dimensions, that in comparison with any other buildings which had been discovered in America, they might be termed *magnificent*. The habitations of the common people were mean, resembling the huts of other Indians. But they were all placed in a regular manner, on the banks of the canals which passed through the city, in some of its districts, or on the sides of the streets which intersected it in other quarters. In several places were large openings or squares, one of which, allotted for the great market, is said to have been so spacious that 40,000 or 50,000 persons carried on traffic there. In this city, the pride of the New World, and the noblest monument of the industry and art of man, while unacquainted with the use of iron, the Spaniards, who are most moderate in their computations, reckon that there were at least 60,000 inhabitants.

80 Uneasiness of the Spaniards.

But how much soever the novelty of those objects might amuse or astonish the Spaniards, they felt the utmost solicitude with respect to their own situation. From a concurrence of circumstances, no less unexpected than favourable to their progress, they had been allowed to penetrate into the heart of a powerful kingdom, and were now lodged in its capital, without having once met with open opposition from its monarch. The Tlascalans, however, had earnestly dissuaded them from placing such confidence in Montezuma as to enter a city of such a peculiar situation as Mexico, where that prince would have them at mercy, shut up as it were in a snare, from which it was impossible to escape. They assured them that the Mexican priests had, in the name of the gods, counselled their sovereign to admit the strangers into the capital, that he might cut them off there at one blow with perfect security. The Spaniards now perceived, too plainly, that the apprehensions of their allies were not destitute of foundation; that, by breaking the bridges placed at certain intervals on the causeways, or by destroying part of the causeways themselves, their retreat would be rendered impracticable, and they must remain cooped up in the centre of a hostile city, surrounded by multitudes sufficient to overwhelm them, and without a possibility of receiving aid from their allies.

81 Some hostilities between the Spaniards and Mexicans.

Before he set out from Cholula, Cortes had received advice from Villa Rica, that Qualpopoca, one of the Mexican generals on the frontiers, having assembled an army in order to attack some of the people whom the Spaniards had encouraged to throw off the Mexican yoke, Escalante had marched out with part of the garrison to support his allies; that an engagement had ensued, in which, though the Spaniards were victorious, Escalante, with seven of his men, had been mortally wounded, his horse killed, and one Spaniard had been surrounded by the enemy and taken alive; that the head of this unfortunate captive, after being carried in triumph to different cities, in order to convince the people that their invaders were not immortal, had been sent to Mexico. Cortes, though alarmed with this intelligence, as an indication of Montezuma's hostile intentions, had continued his march. But as soon as he entered Mexico he became sensible, that, from an excess of confidence in the superior valour and discipline of his troops, as well as from the disadvantage of having nothing to guide him in an unknown country but the defective intelligence which he received from people with whom his mode of communication was very imperfect, he had pushed forward into a situation, where it was difficult to continue, and from which it was dangerous to retire. Disgrace, and perhaps ruin, was the certain consequence of attempting the latter. The success of his enterprise depended upon supporting the high opinion which the people of New Spain had formed with respect to the irresistible power of his arms. Upon the first symptom of timidity on his part, their veneration would cease, and Montezuma, whom fear alone restrained at present, would let loose upon him the whole force of his empire. At the same time, he knew that the countenance of his own sovereign was to be obtained only by a series of victories; and that nothing but the merit of extraordinary success could screen his conduct from the censure of irregularity. From all these considerations, it was necessary to maintain his station, and to extricate himself out of the difficulties in which one bold step had involved him, by venturing upon another still bolder. The situation was trying, but his mind was equal to it; and after revolving the matter with deep attention, he fixed upon a plan no less extraordinary than daring. He determined to seize Montezuma in his palace, and carry him a prisoner to the

82 Cortes resolves to seize Montezuma in his palace.

History.

the Spanish quarters. From the superstitious veneration of the Mexicans for the person of their monarch, as well as their implicit submission to his will, he hoped, by having Montezuma in his power, to acquire the supreme direction of their affairs; or at least, with such a sacred pledge in his hands, he made no doubt of being secure from any effort of their violence.

This he immediately proposed to his officers. The timid startled at a measure so audacious, and raised objections. The more intelligent and resolute, conscious that it was the only resource in which there appeared any prospect of safety, warmly approved of it, and brought over their companions so cordially to the same opinion, that it was agreed instantly to make the attempt. At his usual hour of visiting Montezuma, Cortes went to the palace, accompanied by Alvarado, Sandoval, Lugo, Velasquez de Leon, and Davila, five of his principal officers, and as many trusty soldiers. Thirty chosen men followed, not in regular order, but sauntering at some distance, as if they had no object but curiosity; small parties were posted at proper intervals, in all the streets leading from the Spanish quarters to the court; and the remainder of his troops, with the Tlascalan allies, were under arms, ready to sally out on the first alarm. Cortes and his attendants were admitted without suspicion; the Mexicans retiring, as usual out of respect. He addressed the monarch in a tone very different from that which he had employed in former conferences; reproaching him bitterly as the author of the violent assault made upon the Spaniards by one of his officers, and demanding public reparation for the loss which he had sustained by the death of some of his companions, as well as for the insult offered to the great prince whose servants they were. Montezuma, confounded at this unexpected accusation, and changing colour either from the consciousness of guilt, or from feeling the indignity with which he was treated, asserted his own innocence with great earnestness; aud, as a proof of it, gave orders instantly to bring Qualpopoca and his accomplices prisoners to Mexico. Cortes replied, with seeming complaisance, that a declaration so respectable left no doubt remaining in his own mind; but that something more was requisite to satisfy his followers, who would never be convinced that Montezuma did not harbour hostile intentions against them, unless, as an evidence of his confidence and attachment, he removed from his own palace and took up his residence in the Spanish quarters, where he should be served and honoured as became a great monarch. The first mention of so strange a proposal bereaved Montezuma of speech, and almost of motion. At length he haughtily answered, "That persons of his rank were not accustomed voluntarily to give up themselves as prisoners; and were he mean enough to do so, his subjects would not permit such an affront to be offered to their sovereign." Cortes, unwilling to employ force, endeavoured alternately to soothe and intimidate him. The altercation became warm: and having continued above three hours, Velasquez de Leon, an impetuous and gallant young man, exclaimed with impatience, "Why waste more time in vain? Let us either seize him instantly, or stab him to the heart." The threatening voice and fierce gestures with which these words were uttered, struck Montezuma. The Spaniards, he was sensible, had now proceeded so far, as left him no hope that they would recede. His own danger was imminent, the necessity unavoidable. He saw both; and abandoning himself to his fate, complied with their request.

83
The emperor carried to the Spanish quarters.

His officers were called. He communicated to them his resolution. Though astonished and afflicted, they presumed not to question the will of their master, but carried him in silent pomp, all bathed in tears, to the Spanish quarters.

They at first pretended to treat Montezuma with great respect; but soon took care to let him know that he was entirely in their power. Cortes wished that the shedding the blood of a Spaniard should appear the most heinous crime that could be committed; and therefore not only took a most exemplary vengeance on those who had been concerned in the affair of Villa Rica, but even put the emperor himself in chains till the execution of the Mexican general was over. By these, and other insults, he at last gained entirely the ascendant over this unhappy monarch; and he took care to improve his opportunity to the utmost. He sent his emissaries into different parts of the kingdom, accompanied with Mexicans of distinction, who might serve both to guide and to protect them. They visited most of the provinces, viewed their soil and productions, surveyed with particular care the districts which yielded gold or silver, pitched upon several places as proper for future colonies, and endeavoured to prepare the minds of the people for submitting to the Spanish yoke: and while they were thus employed, Cortes, in the name and by the authority of Montezuma, degraded some of the principal officers in the empire, whose abilities or independent spirit excited his jealousy; and substituted in their place persons who he imagined would be more obsequious. One thing, however, was still wanting to complete his security. He wished to have such a command of the lake as might ensure a retreat, if, either from levity or disgust, the Mexicans should take arms against him, and break down the bridges or causeways, in order to enclose him in the city. In order to obtain this without giving disgust to the emperor or his court, Cortes artfully inflamed the curiosity of the Indians with accounts of the Spanish shipping, and those floating palaces that moved with such velocity on the water, without the assistance of oars; and when he found that the monarch himself was extremely desirous of seeing such a novelty, he gave him to understand, that nothing was wanting to his gratification besides a few necessaries from Vera Cruz, for that he had workmen in his army capable of building such vessels. The bait took with Montezuma; and he gave immediate orders that all his people should assist Cortes in whatever he should direct concerning the shipping. By this means, in a few days, two brigantines were got ready, full rigged and equipped; and Montezuma was invited on board, to make the first trial of their sailing, of which he could form no idea. Accordingly he embarked for this purpose, and gave orders for a great hunting upon the water, in order that all his people might be diverted with the novelty presented by the Spaniards. On the day appointed, the royal equipage was ready early in the morning; and the lake was covered with a multitude of boats and canoes loaded with people. The Mexicans had augmented the

84

85
By a pretence, he obtains leave to build two brigantines on the lake.

History.

the number of their rowers on board the royal barges, with an intention to disgrace the Spanish vessels, which they regarded as clumsy, unwieldy, and heavy. But they were soon undeceived; a fresh gale started up, the brigantines hoisted sail, to the utter astonishment of all the spectators, and soon left all the canoes behind; while the monarch exulted in the victory of the Spaniards, without once considering that now he had effectually rivetted his own chains.

86 Montezuma owns himself a vassal to the king of Spain.

Cortes having obtained this important point, resolved to put the condescension of the emperor to a trial still more severe. He urged Montezuma to acknowledge himself a vassal to the crown of Castile; to hold his crown of him as superior, and to subject his dominions to the payment of an annual tribute. With this requisition, humiliating as it was, Montezuma complied. He called together the chief men of his empire, and, in a solemn harangue, reminded them of the traditions and prophecies which led them to expect the arrival of a people sprung from the same stock with themselves, in order to take possession of the supreme power; he declared his belief that the Spaniards were this promised race; and that therefore he recognised the right of their monarch to govern the Mexican empire, would lay his crown at his feet, and obey him as a tributary. While uttering these words, Montezuma discovered how deeply he was affected in making such a sacrifice. Tears and groans frequently interrupted his discourse. The first mention of such a resolution struck the assembly dumb with astonishment. This was followed by a sullen murmur of sorrow mingled with indignation; which indicated some violent eruption of rage to be near at hand. This Cortes foresaw, and seasonably interposed to prevent it, by declaring that his master had no intention to deprive Montezuma of the royal dignity, or to make any innovation upon the constitution and laws of the Mexican empire. This assurance, added to their dread of the Spanish arms, and the authority of their monarch's example, extorted the consent of the assembly; and the act of submission and homage was executed with all the formalities which the Spaniards pleased to prescribe.

Montezuma, at the request of Cortes, accompanied this profession of fealty and homage with a magnificent present to his new sovereign; and, after his example, his subjects brought in very liberal contributions. The Spaniards then collected all the treasure which had been either voluntarily bestowed upon them at different times by Montezuma, or had been extorted from his people under various pretences; and having melted the gold and silver, the value of these amounted to 600,000 pesos. The soldiers were impatient to have it divided; and Cortes complied with their desire. A fifth of the whole was set apart as the tax due to the king. Another fifth was allowed to Cortes as commander. The sums advanced by the governor of Cuba, who had originally fitted out the expedition, were then deducted. The remainder was then divided among the army, including the garrison of Vera Cruz, in proportion to their different ranks; and after so many deductions, the share of a private man did not exceed 100 pesos. This sum fell so far below their sanguine expectations, that it required all the address, and no small exertions of the liberality of Cortes, to prevent an open mutiny. However, he at last restored tranquillity; but had no sooner escaped this danger, than he involved himself by his imprudent zeal for religion, in one much worse. Montezuma, though often importuned, had obstinately refused to change his religion, or abolish the superstitious rites which had been for such a long time practised throughout his dominions. This at last transported the Spaniards with such rage, that, in a sally of zeal, he led out his soldiers in order to throw down the idols in the great temple by force. But the priests taking arms in defence of their altars, and the people crowding with great ardour to support them, Cortes's prudence overruled his zeal, and induced him to desist from his rash attempt, after dislodging the idols from one of the shrines, and placing in their stead an image of the Virgin Mary.

87 The Spaniards divide their treasure.

88 Cortes attempts to destroy the Mexican idols.

89 Which produces a general disaffection.

From this moment the Mexicans began to meditate the expulsion or the destruction of the Spaniards. The priests and leading men held frequent meetings with Montezuma for this purpose. But as any violent attempt might have proved fatal to the captive monarch, it was thought proper first to try more gentle means. Having called Cortes into his presence, he observed, that now, as all the purposes of his embassy were fully accomplished, the gods had declared their will, and the people signified their desire, that he and his followers should instantly depart out of the empire. With this he required them to comply, or unavoidable destruction would fall suddenly on their heads. This unexpected requisition, as well as the manner in which it was delivered, alarmed Cortes. However, he supposed that more might be gained by a feigned compliance than by open resistance; and therefore replied with great composure, that he had already begun to prepare for his return; but as he had destroyed the vessels in which he arrived, some time was requisite for building other ships. This appeared reasonable; and a number of Mexicans were sent to Vera Cruz to cut down timber, and some Spanish carpenters were appointed to superintend the work.

90 The Spaniards are commanded to depart.

91 An armament sent from Cuba against Cortes.

Cortes flattered himself, that, during this interval, he might either find means to avert the threatened danger, or receive such reinforcements as would enable him to defend himself. Nine months had now elapsed since Portocarrero and Montejo had sailed with his despatches to Spain; and he daily expected a return, with a confirmation of his authority from the king, without which all that he had done served only to mark him out as an object of punishment. While he remained in great anxiety on this account, news were brought that some ships had appeared on the coast. These were imagined by Cortes to be a reinforcement sent him from Spain: but his joy was of short continuance, for a courier very soon arrived from Vera Cruz, with certain information that the armament was fitted out by Velasquez, the governor of Cuba; and instead of bringing succours, threatened them with immediate destruction.

Velasquez had been excited to this hostile measure chiefly through the indiscretion, or rather treachery, of the messengers of Cortes; who, contrary to his express injunctions, had landed on the island of Cuba, and given intelligence of all that had passed: and Velasquez, transported with rage at hearing of the proceedings of Cortes, had now sent against him this armament; consisting of 18 ships, which carried 80 horsemen,

History.

men, 800 infantry, of which 80 were musketeers, and 120 cross bowmen, commanded by a brave officer named *Pamphilo de Narvaez;* whose instructions were, to seize Cortes and his principal officers, to send them prisoners to him, and then to complete the discovery and conquest of the country in his name. This proved a most afflicting piece of news to Cortes.

92
Which is defeated by that general.

Having now no resource but in war, he left 150 men under the command of Pedro de Alvarado, an officer of great bravery, and much respected by the Mexicans, to guard the capital and the captive emperor; while he himself marched with the remainder, to meet his formidable opponent, who had taken possession of Zempoalla. Even after being reinforced by Sandoval his governor of Vera Cruz, the force of Cortes did not exceed 250 men. He hoped for success chiefly from the rapidity of his motions and the possibility of surprising his enemies; and as he chiefly dreaded their cavalry, he armed his soldiers with long spears, accustoming them to that deep and compact arrangement which the use of this formidable weapon enabled them to assume. As he advanced, however, he repeated his proposals of accommodation; but these being constantly rejected, and a price set upon his head, he at last attacked Narvaez in the night-time, entirely defeated and took him prisoner, obliging all his troops to own allegiance to himself.

Nothing could be more seasonable than this victory, by which Cortes found his army very considerably increased; for most of the soldiers of Narvaez chose rather to follow Cortes than to return to Cuba, whither the conqueror had offered to send them if they chose. His affairs at Mexico, in the mean time, were in the utmost danger of being totally ruined; and had this decisive victory been delayed but a few days longer, he must have come too late to save his companions. A short time after the defeat of Narvaez, a courier arrived from Mexico with the disagreeable intelligence that the Mexicans had taken arms; and having seized and destroyed the two brigantines which he had built in order to secure the command of the lake, had attacked the Spaniards in their quarters, killed some, and wounded many more, burnt their magazine of provisions, and, in short, carried on hostilities with such fury, that though Alvarado and his men defended themselves with undaunted resolution, they must either be cut off by famine, or sink under the multitude of their enemies. This revolt was excited by motives which rendered it still more alarming. On the departure of Cortes for Zempoalla, the Mexicans flattered themselves, that the long-expected opportunity of restoring their sovereign to liberty, and driving out the Spaniards, was arrived; and consultations were accordingly held for bringing about both these events. The Spaniards in Mexico, conscious of their own weakness, suspected and dreaded these machinations; but Alvarado, who had neither the prudence nor the address of Cortes, took the worst method imaginable to overcome them. Instead of attempting to soothe or cajole the Mexicans, he waited the return of one of their solemn festivals, when the principal persons in the empire were dancing, according to custom, in the court of the great temple; he seized all the avenues which led to it; and, allured partly by the rich ornaments which they wore in honour of their gods, and partly by the facility of cutting off at once the authors of that conspiracy which he dreaded, he fell upon them, unarmed and unsuspicious of danger, and massacred a great number; none escaping but such as made their way over the battlements of the temple. An action so cruel and treacherous filled not only the city, but the whole empire, with indignation and rage; and the Mexicans immediately proceeded in the manner above mentioned.

93
Dangerous situation of the Spaniards left in Mexico.

Cortes advanced with the utmost celerity to the relief of his distressed companions: but as he passed along, had the mortification to find that the Spaniards were generally held in abhorrence. The principal inhabitants had deserted the towns through which he passed; no person of note appeared to meet him with the usual respect; nor were provisions brought to his camp as usual. Notwithstanding these signs of aversion and horror, however, the Mexicans were so ignorant of the military art, that they again permitted him to enter the capital without opposition; though it was in their power to have easily prevented him, by breaking down the bridges and causeways which led to it.

94
Cortes allowed to return to Mexico;

Cortes was received by his companions with the utmost joy; and this extraordinary success so far intoxicated the general himself, that he not only neglected to visit Montezuma, but expressed himself very contemptuously concerning him. These expressions being reported among the Mexicans, they all at once flew to arms, and made such a violent and sudden attack, that all the valour and skill of Cortes were scarce sufficient to repel them. This produced great uneasiness among the soldiers of Narvaez, who had imagined there was nothing to do but to gather the spoils of a conquered country. Discontent and murmurings, however, were now of no avail; they were enclosed in a hostile city, and, without some extraordinary exertions, were inevitably undone. Cortes, therefore, made a desperate sally; but, after exerting his utmost efforts for a whole day, was obliged to retire with the loss of 12 killed, and upwards of 60 wounded. Another sally was attempted with the like bad success, and in it Cortes himself was wounded in the hand.

95
but is furiously attacked by the natives.

The Spanish general was now thoroughly convinced of his error; and therefore betook himself to the only resource which was left; namely, to try what effect the interposition of Montezuma would have to soothe or overawe his subjects. When the Mexicans approached the next morning to renew the assault, that unfortunate prince, at the mercy of the Spaniards, and reduced to the sad necessity of becoming the instrument of his own disgrace, and of the slavery of his people, advanced to the battlements in his royal robes, and with all the pomp in which he used to appear on solemn occasions. At the sight of their sovereign, whom they had been long accustomed to reverence almost as a god, the Mexicans instantly forebore their hostilities, and many prostrated themselves on the ground: but when he addressed them in favour of the Spaniards, and made use of all the arguments he could think of to mitigate their rage, they testified their resentment with loud murmurings; and at length broke

forth with such fury, that before the soldiers, appointed to guard Montezuma, had time to cover him with their shields, he was wounded with two arrows, and a blow on his temple with a stone struck him to the ground. On seeing him fall, the Mexicans instantly fled with the utmost precipitation: but the unhappy monarch, now convinced that he was become an object of contempt even to his own subjects, obstinately refused all nourishment; and thus in a short time ended his days.

97 A terrible engagement between the Spaniards and Mexicans.

On the death of Montezuma, Cortes having lost all hope of bringing the Mexicans to any terms of peace, prepared for retreat. But his antagonists, having taken possession of a high tower in the great temple, which overlooked the Spanish quarters, and placing there a garrison of their principal warriors, the Spaniards were so much exposed to their missile weapons, that none could stir without danger of being killed or wounded. From this post, therefore, it was necessary to dislodge them at any rate; and Juan de Escobar, with a large detachment of chosen soldiers, was ordered to make the attack. But Escobar, though a valiant officer, and though he exerted his utmost efforts, was thrice repulsed. Cortes, however, sensible that not only his reputation, but the safety of his army, depended on the success of this assault, caused a buckler to be tied to his arm, as he could not manage it with his wounded hand, and rushed with his drawn sword amongst the thickest of the combatants. Encouraged by the presence of their general, the Spaniards returned to the charge with such vigour, that they gradually forced their way up the steps, and drove the Mexicans to the platform at the top of the tower. There a dreadful carnage began; when two young Mexicans of high rank, observing Cortes, as he animated his soldiers, resolved to sacrifice their own lives in order to cut off the author of so many calamities which desolated their country. They approached him in a suppliant posture, as if they intended to lay down their arms; and seizing him in a moment, hurried him towards the battlements, over which they threw themselves headlong, in hopes of dragging him along with them. But Cortes, by his strength and agility, disengaged himself from their grasp; so that the two Mexicans perished alone.

As soon as the Spaniards became masters of the tower, they set fire to it, and without further molestation continued the preparations for their retreat. This became the more necessary, as their enemies, astonished at this last effort of their valour, had now entirely changed their system of hostility; and, instead of incessant attacks, endeavoured, by barricading the streets, and breaking down the causeways, to cut off the communication of the Spaniards with the continent, and thus to starve an enemy whom they could not subdue. The first point to be determined, was whether they should march out openly in the face of day, when they could discern every danger, or whether they should endeavour to retire secretly in the night. The latter was preferred, partly from hopes that the superstition of the Mexicans would prevent them from attacking them in the night, and partly from their own superstition in giving credit to the predictions of a private soldier, who pretended to astrology, and assured them of success if they retreated in this manner. Towards midnight, therefore, they began their march, in three divisions. Sandoval led the van; Pedro Alvarado and Velasquez de Leon had the conduct of the rear; and Cortes commanded in the centre, where he placed the prisoners, among whom were a son and two daughters of Montezuma, together with several Mexicans of distinction, the artillery, baggage, and a portable bridge of timber intended to be laid over the breaches in the causeway. They marched in profound silence along the causeway which led to Tacuba, because it was shorter than any of the rest, and, lying more remote from the road towards Tlascala and the sea coast, had been left most entire by the Mexicans.

History.

98 Cortes retreats with great loss.

They reached the first breach in the causeway without molestation, hoping that their retreat was undiscovered. But the Mexicans had not only watched all their motions, but made preparations for a most formidable attack. While the Spaniards were intent upon placing their bridges in the breach, and occupied in conducting their horses and artillery along it, they were suddenly alarmed with the sound of warlike instruments, and found themselves assaulted on all sides by an innumerable multitude of enemies. Unfortunately the wooden bridge was wedged so fast in the mud by the weight of the artillery, that it was impossible to remove it. Dismayed at this accident, the Spaniards advanced with precipitation to the second breach. The Mexicans hemmed them in on every side; and though they defended themselves with their usual courage, yet, crowded as they were in a narrow causeway, their discipline and military skill were of little avail; nor did the obscurity of the night allow them to derive much advantage from their fire-arms or the superiority of their other weapons. At last the Spaniards, overborne with the numbers of their enemies, began to give way, and in a moment the confusion was universal. Cortes, with about 100 foot soldiers, and a few horse, forced his way over the two remaining breaches in the causeway, the bodies of the dead serving to fill up the chasms, and reached the main land. Having formed them as soon as they arrived, he returned with such as were yet capable of service, to assist his friends in their retreat. He met with part of his soldiers who had forced their way through the enemy, but found many more overwhelmed by the multitude of their aggressors, or perishing in the lake; and heard the grievous lamentations of others whom the Mexicans were carrying off in triumph to be sacrificed to the god of war.

In this fatal retreat more than one half of Cortes's army perished, together with many officers of distinction. All the artillery, ammunition, and baggage, were lost; the greater part of the horses and above 2000 Tlascalans were killed, and only a very small part of their treasure saved. The first care of the Spanish general was to find some shelter for his wearied troops; for, as the Mexicans infested them on every side, and the people of Tacuba began to take arms, he could not continue in his present station. At last he discovered a temple seated on an eminence, in which he found not only the shelter he wanted, but some provisions; and though the enemy did not intermit their attacks throughout the day, they were without much difficulty prevented from making any impression. For six

six days after, they continued their march through a barren, ill cultivated, and thinly peopled country, where they were often obliged to feed on berries, roots, and the stalks of green maize; at the same time they were harassed without intermission by large parties of Mexicans, who attacked them on all sides. On the sixth day they reach Otumba, not far from the road between Mexico and Tlascala. Early next morning they began to advance towards it, flying parties of the enemy still hanging on their rear; and amidst the insults with which they accompanied their hostilities, Donna Marina remarked, that they often exclaimed with exultation, "Go on, robbers; go to the place where you shall quickly meet the vengeance due to your crimes." The meaning of this threat the Spaniards did not comprehend, until they reached the summit of an eminence before them. There a spacious valley opened to their view, covered with a vast army as far as the eye could reach. The Mexicans, while with one body of their troops they harassed the Spaniards in their retreat, had assembled their principal force on the other side of the lake; and marching along the road which led directly to Tlascala, posted it in the plain of Otumba, through

99 The battle of Otumba.

which they knew Cortes must pass. At the sight of this incredible multitude, which they could survey at once from the rising ground, the Spaniards were astonished, and even the boldest began to despair. But Cortes, without allowing their fears time to operate, after warning them briefly that no alternative remained but to conquer or die, led them instantly to the charge. The Mexicans waited their approach with unusual fortitude: yet such was the superiority of the Spanish discipline and arms, that the impression of this small body was irresistible; and whichever way its force was directed, it penetrated and dispersed the most numerous battalions. But while these gave way in one quarter, new combatants advanced from another; and the Spaniards, though successful in every attack, were ready to sink under these repeated efforts, without seeing any end to their toil, or any hope of victory. At that time Cortes observed the great standard of the empire, which was carried before the Mexican general, advancing; and fortunately recollecting to have heard, that on the fate of it depended the event of every battle, he assembled a few of his bravest officers, whose horses were still capable of service, and placing himself at their head, pushed towards the standard with such impetuosity that he bore down every thing before him. A chosen body of nobles, who guarded the standard, made some resistance, but were soon broken. Cortes, with a stroke of his lance, wounded the Mexican general, and threw him to the ground. One of his followers alighting, put an end to his life, and laid hold of the imperial standard. The moment that their leader fell, and the standard, towards which all directed their eyes, disappeared, an universal panic struck the Mexicans; and, as if the bond which held them together had been dissolved, every ensign was lowered, each

100 Mexicans defeated.

soldier threw away his weapons, and fled with precipitation to the mountains. The Spaniards, unable to pursue them far, returned to collect the spoils of the field; and these were so valuable as to be some compensation for the wealth which they had lost in Mexico; for in the enemy's army were most of their principal warriors dressed out in their richest ornaments, as if they had been marching to assured victory.

The day after this important action (being July 8. 1520), the Spaniards entered the Tlascalan territories, where they were received with the most cordial friendship. Cortes endeavoured to avail himself of this disposition as much as possible; for which purpose he distributed among them the rich spoils taken at Otumba with such a liberal hand, that he made himself sure of obtaining from the republic whatever he should desire. He drew a small supply of ammunition, and two or three field-pieces, from his stores at Vera Cruz. He despatched an officer of confidence with four ships of Narvaez's fleet to Hispaniola and Jamaica, to engage adventurers, and to purchase horses, gunpowder, and other military stores. And as he knew that it would be in vain to attempt the reduction of Mexico, unless he could secure the command of the lake, he gave orders to prepare, in the mountains of Tlascala, materials for building 12 brigantines, so that they might be carried thither in pieces, ready to be put together, and launched when he stood in need of their service. But, in the mean time, his soldiers, alarmed at the thoughts of being exposed to such calamities a second time, presented a remonstrance to their general; in which they represented the imprudence of attacking a powerful empire with his shattered forces, and formally required him to return back to Cuba. All the eloquence of Cortes could now only prevail with them to delay their departure for some time, when he promised to dismiss such as should desire it. However, this was only a pretence; for Cortes, in fact, had the conquest of Mexico as much at heart as ever. Without giving his soldiers an opportunity of caballing, therefore, he daily employed them against the people of the neighbouring provinces, who had cut off some detachments of Spaniards during his misfortunes at Mexico; and by which, as he was constantly attended with success, his men soon resumed their wonted sense of superiority.

101 Cortes receives an unexpected reinforcement.

But all the efforts of Cortes could have been of little avail, had he not unexpectedly obtained a reinforcement of Spanish soldiers. These belonged to an armament fitted out by Francisco de Garay, governor of Jamaica, who had long aimed at dividing with Cortes the glory and gain of annexing the empire of Mexico to the crown of Castile. They had, however, unadvisedly made their attempt on the northern provinces, where the country was poor and the inhabitants fierce and warlike; so that, after a succession of disasters, they were now obliged to venture into Vera Cruz, and cast themselves upon the mercy of their countrymen; and here they also were soon persuaded to throw off their allegiance to their master, and to enlist with Cortes. About the same time a ship arrived from Spain, freighted by some private adventurers, with military stores; and the cargo was eagerly purchased by Cortes, while the crew, following the example of the rest, joined him at Tlascala.

From these various quarters, the army of Cortes was augmented with 180 men and 20 horses; by which means he was enabled to dismiss such of the soldiers of Narvaez as were most troublesome and discontented; after the departure of whom he still mustered 550 infantry, of whom 80 were armed with muskets or cross-

History.

cross bows, 40 horsemen, and nine pieces of artillery. At the head of these, with 10,000 Tlascalans and other friendly Indians, he began his march towards Mexico, on the 28th of December, six months after his fatal retreat from that city.

102 He sets out again for Mexico.

As soon as Cortes entered the enemy's territories, he discovered various preparations to obstruct his progress. But his troops forced their way with little difficulty; and took possession of Tezcuco, the second city of the empire, situated on the banks of the lake, about 20 miles from Mexico. Here he determined to establish his head quarters, as the most proper station for launching his brigantines, as well as for making his approaches to the capital. In order to render his residence there more secure, he deposed the cacique or chief, who was at the head of that community, under pretence of some defect in his title, and substituted in his place a person whom a faction of the nobles pointed out as the right heir of that dignity. Attached to him by this benefit, the new cacique and his adherents served the Spaniards with inviolable fidelity.

As the construction of the brigantines advanced slowly under the unskilful hands of soldiers and Indians, whom Cortes was obliged to employ in assisting three or four carpenters who happened fortunately to be in his service, and as he had not yet received the reinforcement which he expected from Hispaniola, he was not in a condition to turn his arms directly against the capital. To have attacked a city so populous, so well prepared for defence, and in a situation of such peculiar strength, must have exposed his troops to inevitable destruction. Three months elapsed before the materials for constructing the brigantines were finished, and before he heard any thing with respect to the success of his negociation in Hispaniola. This, however, was not a season of inaction to Cortes. He attacked successively several of the towns situated around the lake; and though all the Mexican power was exerted to obstruct his operations, he either compelled them to submit to the Spanish crown, or reduced them to ruins. Other towns he endeavoured to conciliate by more gentle means; and though he could not hold any intercourse with the inhabitants but by the intervention of interpreters, yet, under all the disadvantages of that tedious and imperfect mode of communication, he had acquired such a thorough knowledge of the state of the country, as well as of the dispositions of the people, that he conducted his negociations and intrigues with astonishing dexterity and success. Most of the cities adjacent to Mexico were originally the capitals of small independent states; and some of them having been but lately annexed to the Mexican empire, still retained the remembrance of their ancient liberty, and bore with impatience the rigorous yoke of their new masters. Cortes having early observed symptoms of their disaffection, availed himself of this knowledge to gain their confidence and friendship. By offering with confidence to deliver them from the odious dominion of the Mexicans, and by liberal promises of more indulgent treatment if they would unite with him against their oppressors, he prevailed on the people of several considerable districts, not only to acknowledge the king of Castile as their sovereign, but to supply the Spanish camp with provisions, and to strengthen his army with auxiliary troops. Guatimozin, on the first appearance of defection among his subjects, exerted himself with vigour to prevent or to punish their revolt; but, in spite of his efforts, the spirit continued to spread. The Spaniards gradually acquired new allies; and with deep concern he beheld Cortes arming against his empire those very hands which ought to have been active in his defence, and ready to advance against the capital at the head of a numerous body of his own subjects.

103 Cortes makes great progress.

While, by these various methods, Cortes was gradually circumscribing the Mexican power within such narrow limits that his prospect of overturning it seemed neither to be uncertain nor remote, all his schemes were well nigh defeated by a conspiracy against his own person, and which was discovered only a short time before it was to have been executed. Though many were concerned, Cortes did not think proper to punish any more than the principal ringleader, whom he caused immediately to be hanged; and then, without allowing them leisure to ruminate on what had happened, and as the most effectual means of preventing the return of a mutinous spirit, he determined to call forth his troops immediately to action. Fortunately a proper occasion for this occurred, without his seeming to court it. He received intelligence, that the materials for building the brigantines were at length completely finished, and waited only for a body of Spaniards to conduct them to Tezcuco. The command of this convoy, consisting of 200 foot soldiers, 15 horsemen, and two field-pieces, he gave to Sandoval, who by the vigilance, activity, and courage, which he manifested on every occasion, was growing daily in his confidence, and in the estimation of his fellow-soldiers. The Tlascalans furnished 8000 *Tamenes*, an inferior order of men destined for servile tasks, to carry the materials on their shoulders, and appointed 15,000 warriors to accompany and defend them. Sandoval made the disposition for their progress with great propriety, placing the Tamenes in the centre, one body of warriors in the front, another in the rear, with considerable parties to cover the flanks. To each of these he joined some Spaniards, not only to assist them in danger, but to accustom them to regularity and subordination. Parties of Mexicans frequently appeared hovering around them on the high grounds: but perceiving no prospect of success in attacking an enemy continually on his guard, and prepared to receive them, they did not venture to molest him; and Sandoval had the glory of conducting safely to Tezcuco a convoy on which all the future operations of his countrymen depended.

104 Mexico besieged.

Cortes determined to attack the city from three different quarters; from Tezcuco on the east side of the lake, from Tacuba on the west, and from Cuayocan towards the south. Those towns were situated on the principal causeways which led to the capital, and intended for their defence. He appointed Sandoval to command in the first, Pedro de Alvarado in the second, and Christoval de Olid in the third; allotting to each a numerous body of Indian auxiliaries, together with an equal division of Spaniards, who, by the junction of the troops from Hispaniola, amounted now to 86 horsemen, and 818 foot foot soldiers; of whom 118 were armed with muskets or cross-bows. Their train of artillery consisted of three battering cannon, and 15 field-pieces.

pieces. He reserved for himself, as the station of greatest importance and danger, the conduct of the brigantines, each armed with one of his small cannon, and manned with 25 Spaniards.

As Alvarado and Olid proceeded towards the posts assigned them, they broke down the aqueducts which the ingenuity of the Mexicans had erected for conveying water into the capital, and, by the distress to which this reduced the inhabitants, gave a beginning to the calamities which they were destined to suffer. Alvarado and Olid found the towns, of which they were ordered to take possession, deserted by their inhabitants, who had fled for safety to the capital, where Guatimozin had collected the chief force of his empire, as there alone he could hope to make a successful stand against the formidable enemies who were approaching to assault him.

105 The Spaniards defeat the Mexicans, and become masters of the lake.

The first effort of the Mexicans was to destroy the fleet of brigantines, the fatal effects of whose operations they foresaw and dreaded. Though the brigantines, after all the labour and merit of Cortes in forming them, were of inconsiderable bulk, rudely constructed, and manned chiefly with landmen, hardly possessed of skill enough to conduct them, they must have been objects of terror to a people unacquainted with any navigation but that of their lake, and possessed of no vessel larger than a canoe. Necessity, however, urged Guatimozin to hazard the attack; and hoping to supply by numbers what he wanted in force, he assembled such a multitude of canoes as covered the face of the lake. They rowed on boldly to the charge, while the brigantines, retarded by a dead calm, could scarcely advance to meet them. But as the enemy drew near, a breeze suddenly sprung up; in a moment the sails were spread, and the brigantines with irresistible impetuosity broke their feeble opponents, overset many canoes, and dissipated the whole armament with such slaughter, as convinced the Mexicans, that the progress of the Europeans in knowledge and arts rendered their superiority greater on this new element than they had hitherto found it by land.

From that time Cortes remained master of the lake; and the brigantines not only preserved a communication between the Spaniards in their different stations, though at a considerable distance from each other; but were employed to cover the causeways on each side, and keep off the canoes, when they attempted to annoy the troops as they advanced towards the city. He formed the brigantines in three divisions, allotting one to each station, with orders to second the operations of the officer who commanded there. From all the three stations he pushed on the attack against the city with equal vigour; but in a manner so very different from that by which sieges are conducted in regular war, as might appear no less improper than singular to persons unacquainted with his situation. Each morning his troops assaulted the barricades which the enemy had erected on the causeways, forced their way over the trenches which they had dug, and through the canals where the bridges were broken down, and endeavoured to penetrate into the heart of the city, in hopes of obtaining some decisive advantage, which might force the enemy to surrender, and terminate the war at once; but when the obstinate valour of the Mexicans rendered the efforts of the day ineffectual, the Spaniards retired in the evening to their former quarters. Thus their toil and danger were, in some measure, continually renewed, the Mexicans repairing in the night what the Spaniards had destroyed through the day, and recovering the posts from which they had driven them. But necessity prescribed this slow and untoward mode of operation. The number of his troops was so small, that Cortes durst not, with a handful of men, attempt to make a lodgement in a city where he might be surrounded and annoyed by such a multitude of enemies. The remembrance of what he had already suffered by the ill-judged confidence with which he had ventured into such a dangerous situation, was still fresh in his mind. The Spaniards, exhausted with fatigue, were unable to guard the various posts which they daily gained; and though their camp was filled with Indian auxiliaries, they durst not devolve this charge upon them, because they were so little accustomed to discipline, that no confidence could be placed in their vigilance. Besides this, Cortes was extremely solicitous to preserve the city as much as possible from being destroyed, both as he destined it to be the capital of his conquests, and wished that it might remain as a monument of his glory. From all these considerations, he adhered obstinately, for a month after the siege was opened, to the system which he had adopted. The Mexicans, in their own defence, displayed valour which was hardly inferior to that with which the Spaniards attacked them. On land, on water, by night and by day, one furious conflict succeeded to another. Several Spaniards were killed, more wounded, and all were ready to sink under the toils of unintermitting service, which were rendered more intolerable by the injuries of the season, the periodical rains being now set in with their usual violence.

Astonished and disconcerted with the length and difficulties of the siege, Cortes determined to make one great effort to get possession of the city before he relinquished the plan which he had hitherto followed, and had recourse to any other mode of attack. With this view he sent instructions to Alvarado and Sandoval to advance with their divisions to a general assault, and took the command in person of that posted on the causeway of Cuyocan. Animated by his presence, and the expectation of some decisive event, the Spaniards pushed forward with irresistible impetuosity. They broke through one barricade after another, forced their way over the ditches and canals, and having entered the city, gained ground incessantly, in spite of the multitude and ferocity of their opponents. Cortes, though delighted with the rapidity of his progress, did not forget that he might still find it necessary to retreat; and in order to secure it, appointed Julian de Alderete, a captain of chief note in the troops which he had received from Hispaniola, to fill up the canals and gaps in the causeway as the main body advanced. That officer deeming it inglorious to be thus employed, while his companions were in the heat of action and the career of victory, neglected the important charge committed to him, and hurried on inconsiderately to mingle with the combatants. The Mexicans, whose military attention and skill were daily improving, no sooner observed this, than they carried an account of it to their monarch.

Guatimozin instantly discerned the consequences of the

History. the error which the Spaniards had committed, and, with admirable presence of mind, prepared to take advantage of it. He commanded the troops posted in the front to slacken their efforts, in order to allure the Spaniards to push forward, while he despatched a large body of chosen warriors through different streets, some by land, and others by water, towards the great breach in the causeway, which had been left open. On a signal which he gave, the priests in the great temple struck the great drum consecrated to the god of war. No sooner did the Mexicans hear its doleful solemn sound, calculated to inspire them with contempt of death and with enthusiastic ardour, than they rushed upon the enemy with frantic rage. The Spaniards, unable to resist men urged on no less by religious fury than hope of success, began to retire, at first leisurely, and with a good countenance; but as the enemy pressed on, and their own impatience to escape increased, the terror and confusion became so general, that when they arrived at the gap in the causeway, Spaniards and Tlascalans, horsemen and infantry, plunged in promiscuously, while the Mexicans rushed upon them fiercely from every side, their little canoes carrying them through shoals which the brigantines could not approach. In vain did Cortes attempt to stop and rally his flying troops; fear rendered them regardless of his entreaties or commands. Finding all his endeavours to renew the combat fruitless, his next care was to save some of those who had thrown themselves into the water; but while thus employed, with more attention to their situation than to his own, six Mexican captains suddenly laid hold of him, and were hurrying him off in triumph; and though two of his officers rescued him at the expence of their own lives, he received several dangerous wounds before he could break loose. Above 60 Spaniards perished in the rout; and what rendered the disaster more afflicting, 40 of these fell alive into the hands of an enemy never known to show mercy to a captive.

106 Cortes repulsed in an attack.

The approach of night, though it delivered the dejected Spaniards from the attacks of the enemy, ushered in, what was hardly less grievous, the noise of their barbarous triumph, and of the horrid festival with which they celebrated their victory. Every quarter of the city was illuminated; the great temple shone with such peculiar splendour, that the Spaniards could plainly see the people in motion, and the priests busy in hastening the preparations for the death of the prisoners. Through the gloom they fancied that they discerned their companions by the whiteness of their skins, as they were stripped naked and compelled to dance before the image of the god to whom they were to be offered. They heard the shrieks of those who were sacrificed, and thought they could distinguish each unhappy victim by the well known sound of his voice. Imagination added to what they really saw or heard, and augmented its horror. The most unfeeling melted into tears of compassion, and the stoutest heart trembled at the dreadful spectacle which they beheld.

Cortes, who, besides all that he felt in common with his soldiers, was oppressed with the additional load of anxious reflections natural to a general on such an unexpected calamity, could not like them relieve his mind by giving vent to its anguish. He was obliged to assume an air of tranquillity in order to revive the spirits and hopes of his followers. The juncture, indeed, required an extraordinary exertion of fortitude. The Mexicans, elated with their victory, sallied out next morning to attack him in his quarters. But they did not rely on the efforts of their own arms alone: they sent the heads of the Spaniards whom they had sacrificed to the leading men in the adjacent provinces, and assured them that the god of war, appeased by the blood of their invaders, which had been shed so plentifully on his altars, had declared with an audible voice, that in eight days time those hated enemies should be finally destroyed, and peace and prosperity re-established in the empire. History.

107 The Mexicans renew the attack with great fury.

A prediction, uttered with such confidence, and in terms so void of ambiguity, gained universal credit among a people prone to superstition. The zeal of the provinces which had already declared against the Spaniards augmented, and several which had hitherto remained inactive took arms with enthusiastic ardour to execute the decrees of the gods. The Indian auxiliaries who had joined Cortes, accustomed to venerate the same deities with the Mexicans, and to receive the responses of their priests with the same implicit faith, abandoned the Spaniards as a race of men devoted to certain destruction. Even the fidelity of the Tlascalans was shaken, and the Spanish troops were left almost alone in their stations. Cortes, finding that he attempted in vain to dispel the superstitious fears of his confederates by argument, took advantage, from the imprudence of those who had framed the prophecy in fixing its accomplishment so near at hand, to give them a striking demonstration of its falsity. He suspended all military operations during the period marked out by the oracle. Under cover of the brigantines, which kept the enemy at a distance, his troops lay in safety, and the fatal term expired without any disaster.

His allies, ashamed of their own credulity, returned to their station. Other tribes, judging that the gods, who had now deceived the Mexicans, had decreed finally to withdraw their protection from them, joined his standard; and such was the levity of a simple people, moved by every slight impression, that, in a short time after such a general defection of his confederates, Cortes saw himself, if we may believe his own account, at the head of 150,000 Indians. Even with such a numerous army, he found it necessary to adopt a new and more wary system of operation. Instead of renewing his attempts to become master of the city at once, by such bold but dangerous efforts of valour as he had already tried, he made his advances gradually, and with every possible precaution against exposing his men to any calamity similar to that which they still bewailed. As the Spaniards pushed forward, the Indians regularly repaired the causeways behind them. As soon as they got possession of any part of the town, the houses were instantly levelled with the ground. Day by day, the Mexicans, forced to retire as their enemies gained ground, were hemmed in within more narrow limits. Guatimozin, though unable to stop the career of the enemy, continued to defend his capital with obstinate resolution, and disputed every inch of ground. But the Spaniards, having not only varied their mode of attack, but, by order of Cortes, having changed the weapons with

108 Cortes adopts a more cautious method of proceeding.

History.

with which they fought, were again armed with the long Chinantlan spears, which they had employed with such success against Narvaez: and, by the firm array in which this enabled them to range themselves, they repelled, with little danger, the loose assault of the Mexicans; incredible numbers of whom fell in the conflicts, which they renewed every day. While war wasted without, famine began to consume them within the city. The Spanish brigantines, having the entire command of the lake, rendered it impossible to receive any supply of provisions by water. The vast number of his Indian auxiliaries enabled Cortes to shut up the avenues to the city by land. The stores which Guatimozin had laid up were exhausted by the multitudes which crowded into the capital to defend their sovereign and the temples of their gods. Not only the people, but persons of the highest rank, felt the utmost distresses of want. What they suffered brought on infectious and mortal distempers, the last calamity that visits besieged cities, and which filled up the measure of their woes.

109 Guatimozin refuses to submit on any terms.

But, under the pressure of so many and such various evils, the spirit of Guatimozin remained firm and unsubdued. He rejected with scorn every overture of peace from Cortes; and, disdaining the idea of submitting to the oppressors of his country, determined not to survive its ruin. The Spaniards continued their progress. At length all the three divisions penetrated into the great square in the centre of the city, and made a secure lodgment there. Three-fourths of the city were now reduced, and laid in ruins. The remaining quarter was so closely pressed, that it could not long withstand assailants who attacked it from their new station with superior advantage, and more assured expectation of success. The Mexican nobles, solicitous to save the life of a monarch whom they revered, prevailed on Guatimozin to retire from a place where resistance was now vain, that he might rouse the more distant provinces of the empire to arms, and maintain there a more successful struggle with the public enemy. In order to facilitate the execution of this measure, they endeavoured to amuse Cortes with overtures of submission, that, while his attention was employed in adjusting the articles of pacification, Guatimozin might escape unperceived. But they made this attempt upon a leader of greater sagacity and discernment than to be deceived by their arts. Cortes suspecting their intention, and aware of what moment it was to defeat it, appointed Sandoval, the officer on whose vigilance he could most perfectly rely, to take the command of the brigantines, with strict injunctions to watch every motion of the enemy. Sandoval, attentive to the charge, observing some large canoes crowded with people rowing along the lake with extraordinary rapidity, instantly gave the signal to chase. Gracia Holguin, who commanded the fleetest brigantine, soon overtook them, and was preparing to fire on the foremost canoe, which seemed to carry some person whom all the rest followed and obeyed. At once the rowers dropt their oars, and all on board, throwing down their arms, conjured him with cries and tears to forbear, as the emperor was there. Holguin eagerly seized his prize; and Guatimozin, with a dignified composure, gave himself up into his hands, requesting only that no insult might be offered to the empress or his children. When conducted to Cortes, he appeared neither with the sullen fierceness of a barbarian, nor with the dejection of a supplicant. "I have done," said he, addressing himself to the Spanish general, "what became a monarch. I have defended my people to the last extremity. Nothing now remains but to die. Take this dagger," laying his hand on one which Cortes wore, "plant it in my breast, and put an end to a life which can no longer be of use."

110 He is taken prisoner.

111 Mexico submits.

As soon as the fate of their sovereign was known, the resistance of the Mexicans ceased; and Cortes took possession of that small part of the capital which yet remained undestroyed. Thus terminated the siege of Mexico, the most memorable event in the conquest of America. It continued 75 days, hardly one of which passed without some extraordinary effort of one party in the attack, or of the other in the defence of a city, on the fate of which both knew that the fortune of the empire depended. As the struggle here was more obstinate, it was likewise more equal, than any between the inhabitants of the Old and New Worlds. The great abilities of Guatimozin, the number of his troops, the peculiar situation of his capital, so far counterbalanced the superiority of the Spaniards in arms and discipline, that they must have relinquished the enterprise, if they had trusted for success to themselves alone. But Mexico was overturned by the jealousy of neighbours who dreaded its power, and by the revolt of subjects impatient to shake off its yoke. By their effectual aid, Cortes was enabled to accomplish what, without such support, he would hardly have ventured to attempt. How much soever this account of the reduction of Mexico may detract, on the one hand, from the marvellous relations of some Spanish writers, by ascribing that to simple and obvious causes which they attribute to the romantic valour of their countrymen, it adds, on the other, to the merit and abilities of Cortes, who, under every disadvantage, acquired such an ascendant over unknown nations, as to render them instruments towards carrying his scheme into execution.

The exultation of the Spaniards, on accomplishing this arduous enterprise, was at first excessive. But this was quickly damped by the cruel disappointment of those sanguine hopes which had animated them amidst so many hardships and dangers. Instead of the inexhaustible weath which they expected from becoming masters of Montezuma's treasures, and the ornaments of so many temples, their rapaciousness could collect only an inconsiderable booty amidst ruins and desolation (A). Guatimozin, aware of his impending fate, had ordered what remained of the riches amassed by his ancestors to be thrown into the lake. The Indian auxiliaries, while the Spaniards were engaged in conflict

(A) The gold and silver, according to Cortes, amounted only to 120,000 pesos, (Relat. 280, A.) a sum far inferior to that which the Spaniards had formerly divided in Mexico.

History.

flict with the enemy, had carried off the most valuable part of the spoil. The sum to be divided among the conquerors was so small, that many of them disdained to accept of the pittance which fell to their share, and all murmured and exclaimed: some against Cortes and his confidants, whom they suspected of having secretly appropriated to their own use a large portion of the riches which should have been brought into the common stock; others against Guatimozin, whom they accused of obstinacy, in refusing to discover the place where he had hidden his treasure.

Arguments, entreaties, and promises, were employed in order to soothe them; but with so little effect, that Cortes, from solicitude to check this growing spirit of discontent, gave way to a deed which stained the glory of all his great actions. Without regarding the former dignity of Guatimozin, or feeling any reverence for those virtues which he had displayed, he subjected the unhappy monarch, together with his chief favourite, to torture, in order to force from them a discovery of the royal treasures, which it was supposed they had concealed. Guatimozin bore whatever the refined cruelty of his tormentors could inflict, with the invincible fortitude of an American warrior. His fellow-sufferer, overcome by the violence of the anguish, turned a dejected eye towards his master, which seemed to implore his permission to reveal all that he knew. But the high-spirited prince, darting on him a look of authority mingled with scorn, checked his weakness, by asking, "Am I now reposing on a bed of flowers?" Overawed by the reproach, he persevered in his dutiful silence, and expired. Cortes, ashamed of a scene so horrid, rescued the royal victim from the hands of his torturers, and prolonged a life reserved for new indignities and sufferings.

112 Guatimozin tortured.

113 The Spaniards become masters of the whole Mexican empire.

The fate of the capital, as both parties had foreseen, decided that of the empire. The provinces submitted one after another to the conquerors. Small detachments of Spaniards marching through them without interruption, penetrated, in different quarters, to the great Southern ocean, which, according to the ideas of Columbus, they imagined would open a short as well as easy passage to the East Indies, and secure to the crown of Castile all the envied wealth of those fertile regions; and the active mind of Cortes began already to form schemes for attempting this important discovery. In his after-schemes, however, he was disappointed; but Mexico hath ever since remained in the hands of the Spaniards.

Till Humboldt's work appeared, the internal situation of Mexico was very imperfectly known. This celebrated traveller, who spent a considerable time in visiting the most remarkable objects, and had access to the best sources of information, has furnished us with a very interesting account of the colony.

One of the most remarkable peculiarities of New Spain is the great elevation of the soil. Three fifths of the viceroyalty consist of table land, elevated from 6000 to 8000 feet above the sea. It presents a continuous and hardly broken plain between 18° and 40° of north latitude. The slight ridges that interrupt it seldom rise more than 600 or 800 feet above the valleys they separate. Some of the mountains, however, are of colossal magnitude. The tops of four only are covered with perpetual snow, the highest of which has an altitude of 17,700 feet. The table land gradually declines towards the north. The more elevated plains are arid, destitute of trees, and covered with a saline efflorescence. But the greater part of it is extremely fertile, and the whole exceedingly healthy. It enjoys a dry and light atmosphere, and a mild and temperate climate. The medium temperature of winter is from 55° to 57° of Fahrenheit's thermometer, and in the greatest heat of summer it never rises above 75°. On the coast, however, the air is moist, hot, and unwholesome, and the medium temperature of the whole year is about 78° or 79°. The settlers divide the cultivated part into three zones. 1. The *tierras calientes*, or warm grounds, which never rising 1000 feet above the sea, have a heat of about 80°, and yield abundantly sugar, indigo, cotton, plantains, or bananas. 2. The *tierras templadas*, or temperate grounds, which lying on the declivity of the great ridge, at an altitude from 4000 to 5000 feet, enjoy a mild vernal temperature of 68° or 70°, that seldom varies 10° through the whole year. 3. The *tierras frias*, or cold grounds, having an elevation of 8000 feet, and comprehending the high plains or table land, of which the temperature is generally under 63°, and never exceeds 75°.

Rivers, Lakes, &c.

The great chain of mountains called the *Andes* is continued through the isthmus of Panama and through all Mexico, until they are lost in the unknown mountains of the north. The most considerable of that chain is known in Mexico by the name of *Sierra Madre*.

Mexico, like Old Spain, suffers from the want of water and navigable rivers. The Rio Bravo del Norte, and the Rio Colorado are the most considerable, the former having a course of 512 leagues, and the latter of 250. Those rivers, however, are situated in the most uncultivated part of the country. In the southern part of Mexico there are only small rivers, the Alvarado, Guasacualco, Mortezuma, and Zacatula; but the Santiago which flows westward, and falls into the Pacific ocean in latitude $21\frac{1}{2}$°, is a large river.

There are likewise in this country several lakes of very considerable magnitude; but those of Nicaragua, Chapalla, and Pazquaro, which are of the greatest extent, did not belong to the ancient Mexican empire. The most remarkable were those in the vale of Mexico, upon which the capital of the empire was founded. Of these, the fresh water one, called the *lake of Chalco*, extended in length from east to west 12 miles, as far as the city of Xochimilco; from thence, taking a northerly direction, it incorporated itself by means of a canal with the lake of Tezeuco; but its breadth did not exceed six miles. The other, named the *lake of Tezcuco*, extended 15, or rather 17 miles from east to west, and something more from south to north; but its extent is now much less, by reason of the Spaniards having diverted the course of many of the streams which run into it. This lake is salt, which Clavigero supposes to arise from the nature of the soil which forms its bed.

Besides these, there are a number of smaller lakes, some of which are very delightful. There is a vast variety of mineral waters, of the nitrous, sulphureous, and aluminous kinds, some of them so hot that meat may be boiled in them. At Tetuhuacan is a kind of petrifying water, as well as in several other parts of

Vegetable Productions.

of the empire. One of them forms a kind of smooth white stones, not displeasing to the taste; the scrapings of which taken in broth are celebrated as a diaphoretic, probably without any good reason. The dose for a person not difficult to be sweated is one dram of the scrapings. Many of the rivers of Mexico afford surprising and beautiful cascades; particularly the river Guadalaxara, at a place called *Tempizque*, 15 miles to the southward of that city. Along a deep river called *Atoyaque* is a natural bridge, consisting of a vast mound of earth, along which carriages pass conveniently. Clavigero supposes it to have been the fragment of a mountain thrown down by an earthquake, and then penetrated by the river.

The agriculture of Mexico, with all other branches of industry, have been much improved within the last 30 or 40 years; and so far from the mines operating against it, the cultivation of the soil is generally carried on with the greatest spirit in the mining districts. The plantain or banana tree, which is cultivated over an extent of country containing a million and a half of inhabitants, yields so great a produce, that an *arpent* of ground covered with it will maintain 50 persons, though if sown with wheat it would not support two. The fruit is farinaceous, and contains much saccharine matter. The tree does not thrive where the medium temperature is below 75° F. The cassava root, which grows also in the warm region, at a height from 2000 to 2700 feet, affords a flour, called manioc, which has the inestimable advantage, that when dried and toasted it is secure from the depredations of worms and other insects. But maize is the chief food of the inhabitants. It is cultivated from the coast to the height of 9000 feet above the sea. On very fertile lands, and in good years, it yields 800 for 1; but the average return for the intratropical part of the country is not more than 150 for 1, and in New California 70 or 80. The crop is very uncertain, and as it is seldom equally good in every part of the country, the transport of maize comes to be the principal branch of internal commerce. A general failure is followed by scarcity, or even famine. Its price varies from $2\frac{1}{2}$ to 25 livres the fanega (equal to $1\frac{1}{2}$ English bushels). The annual produce of New Spain in maize is estimated at 17 millions of fanegas. The Mexican wheat is of excellent quality, and the medium return is from 22 to 25 for 1. Much wheat is exported to Cuba. Barley and rye thrive well; oats are very little cultivated. The potato is raised abundantly in the high and cold parts of the country. Rice is but little attended to, though well adapted for the marshy lands on the coast. The cerealia are not cultivated in the intratropical part of Mexico, at a lower elevation than about 2700 feet above the sea, and in very small quantity at a less height than 4000. Neither wheat nor rye come to maturity at a greater height than 12000 feet.

The sugar cane has been successfully introduced into some of the interior provinces of the continent. Sugar plantations are spreading rapidly in the plain of Mexico, and supply not only the home consumption, but afford an export of half a million of arobas (equal to about 25 lbs. avoirdupois each). The sugar cane is not cultivated by slaves.

The Spanish government has always discouraged the cultivation of the vine, the olive, the mulberry-tree, and the plants producing hemp and flax. When Humboldt was in the country, an order came from Madrid to grub up all the vines in the northern parts of the kingdom, where they had been cultivated with so much success as to give alarm to the merchants of Cadiz, by the diminished consumption of wine from the mother country. There is but one olive plantation in the country, which belongs to the archbishop of Mexico. Since 1764, when the royal monopoly was established, no tobacco can be planted, except in particular districts, and none can be sold except to the king's officers. Parties of soldiers are employed to go about the country in search of tobacco fields; and where they find one on forbidden ground, they impose a fine on the owner, and direct the plantation to be destroyed. This monopoly produces a revenue of more than 20 millions of livres annually.

From maize the Indians obtain several kinds of beer or cyder by fermentation. A spirituous liquor named *pulque* is also procured from this plant. But the intoxicating liquor most in use, and which is also called *pulque*, is made from the *agave Americana*. A vigorous plant will afford four gallons of sap per day during four or five months; and this when fermented three or four days forms *pulque*. It tastes like cyder, but has an offensive smell of meat in a state of putrefaction. The ardent spirit from it is strictly prohibited by law, lest it should interfere with the sale of Spanish brandy; but great quantities of it are made clandestinely.

Cotton, indigo, coffee, and cacao, are not cultivated to a great extent in New Spain. But the whole of the vanilla consumed in Europe comes from the provinces of Oaxaca and Vera Cruz, amounting to 900,000 pods, the value of which, at Vera Cruz, is about 30,000 or 40,000 piastres or dollars. The province of Oaxaca also furnishes 32,000 arobas of cochineal, valued at 2,400,000 dollars.

The whole annual produce of the agriculture of New Spain is valued by Humboldt at 29 millions of dollars; and as this amount is founded on accurate returns of the amount of the tithes, and was revised and corrected by well informed persons, it may be considered as a near approximation to the truth.

The wages of labour in New Spain are $2\frac{1}{2}$ reals de plata a-day on the coast, and 2 reals de plata, or $\frac{1}{4}$ dollar, on the table land. The average price of maize on the table land is estimated by Humboldt at 5 livres the fanega; and consequently a labourer on the table land, earns about $1\frac{3}{4}$ pecks of Indian corn a-day. Wheat is dearer in the city of Mexico than in Paris, chiefly in consequence of the cost of transportation.

The tree producing liquid amber, the liquid storax of the Mexicans, is of a large size, the leaves similar to those of the maple, indented, white in one part and dark in the other, disposed in threes; the fruit is thorny and round, but polygonous, with the surface and the angles yellow; the bark of the tree partly green and partly tawney. By incisions in the trunk they extract that valuable substance named *liquid amber*, and the oil of the same name, which is still more valuable. Liquid amber is likewise obtained from a decoction of the branches, but it is inferior to that obtained from the trunk.

The name *copalli* in Mexico is generic, and common

mon to all the resins; but especially signifies those made use of for incense. There are ten species of these trees yielding resins of this kind; the principal of which is that from which the COPAL is got, so well known in medicine and varnishes. A great quantity of this was made use of by the ancient Mexicans, and is still used for similar purposes by the Spaniards. The *tecopalli* or *tepecopalli* is a resin similar to the incense of Arabia; which distils from a tree of moderate size that grows in the mountains, having a fruit like an acorn, and containing the nut enveloped in a mucilage, within which there is a small kernel useful in medicine.

The *mitzquitl*, or mezquite, is a species of true acacia, and the gum distilled from it is said to be the true gum arabic. It is a thorny shrub, with branches irregularly disposed, the leaves small, thin, and pinnated; the flowers being like those of the birch-tree. Of the elastic gum, which is found in plenty in Mexico, the natives were in use to make foot-balls, which, though heavy, have a better spring than those filled with air. With this they varnish their hats, cloaks, boots, and great coats, in a manner similar to what is done in Europe with wax; and by which means they are rendered all water proof.

114 Mexican animals.

The quadrupeds found in Mexico at the arrival of the Spaniards, were lions, tygers, wild cats, bears, wolves, foxes, the common stags, white stags, bucks, wild goats, badgers, polecats, weasels, martins, squirrels, polatucas, rabbits, hares, otters, and rats. All these animals are supposed to be common to both continents. The white stag, whether it be the same species of the other or not, is undoubtedly common to both, and was known to the Greeks and Romans. The Mexicans call it the *king of the stags*. M. Buffon imagines the white colour of this creature to be the effect of captivity; but Clavigero says, that it is found wild, and of the same white colour, on the mountains of New Spain. In many other points, he also controverts the opinions of this celebrated naturalist, who will not allow the lion, tyger, or rabbit, to be natives of America.

Clavigero enumerates the quadrupeds common to New Spain with the rest of the continent of America. Among these he will not allow a place to the Peruvian sheep, the *huanaco*, and sloth; all of which are peculiar to South America. Hernandez indeed makes mention of the Peruvian sheep, and gives a drawing of it; but this was only on account of a few individuals brought thence from Peru, which the Mexicans called by that name, in the same manner as he describes several animals of the Philippine isles; not that they had ever been bred in Mexico, or found in any country of North America, unless it was some individual carried there, as they are carried as a curiosity from Europe. The animals which he allows to be common to both countries, are, the Mexican hog, the moufete, the opossum, the armadillo, the *techichi*, a small animal resembling a dog; which being perfectly dumb, gave occasion to a report that the Mexican dogs could not bark. The flesh of this animal was eaten by them, and was esteemed agreeable and nourishing food. After the conquest of Mexico, the Spaniards having neither large cattle nor sheep, provided their markets with this quadruped; by which means, the species soon came to be extinct, though it had been very numerous. The land-squirrel is very numerous in the kingdom of Michuacan, has great elegance of form, and is extremely graceful in its movements; but it cannot be tamed, and bites most furiously every person who approaches it.

Besides these, there are sea lions, ratoons, and that voracious animal named the *tapir*. Oviedo informs us, that he has seen it at one bite tear off two or three hand-breadths of skin from a hound, and at another a whole leg and thigh. The flesh is eatable, and its skin is valued on account of its being sufficiently strong to resist musket-balls. There are likewise great numbers of monkeys of many different kinds; some of which have heads resembling those of dogs. Some of them are strong and fierce, equalling a man in stature when they stand upright.

Among the animals peculiar to Mexico, is one named *coyoto*, which appears to have been inaccurately described by natural historians; some making it one species and some another. It is about the size of a mastiff, but more slender. The eyes are yellow and sparkling, ears small, pointed, and erect; the snout blackish, strong limbs, and the feet armed with large crooked nails. The tail is thick and hairy, the skin a mixture of black, brown, and white; and the voice is compounded of the howl of the wolf and the bark of the dog. It pursues the deer, and will sometimes even attack men. Its usual pace is a trot, but so quick that a horse at the gallop can scarcely overtake it. The *tlalcojotl* or *tlalcoyoto* is about the size of a middling dog, and the largest animal that lives under the earth. Its head has some resemblance to that of a cat; but in colour and length of hair it resembles the lion.—It has a long thick tail, and feeds upon poultry and small animals, which it catches in the night-time. The *tepeizuintli*, or mountain-dog, though it is but of the size of a small dog, is so bold that it attacks deer, and sometimes kills them. Its hair and tail are long, the body black, but the head, neck, and breast, white. M. Buffon reckons this animal the same with the glutton, but Clavigero denies it. Another animal, larger than the two foregoing, is called the *xoloitzcuintli*. Some of these are no less than four feet in length. It has a face like the dog, but tusks like the wolf, with erect ears, the neck gross, and the tail long.—It is entirely destitute of hair, excepting only the snout, where there are some thick crooked bristles. The whole body is covered with a smooth, soft ash-coloured skin, spotted partly with black and tawney. This species of animals, as well as the two former, are almost totally extinct. A Lyncean academician named *Giovanni Febri*, has endeavoured to prove that the xoloitzcuintli is the same with the wolf of Mexico; but this is denied by Clavigero.

A curious animal of the mole kind is called *tozan* or *tuza*. It is about the size of a European mole, but very different otherwise. The body is about seven or eight inches long, and well made; the snout like that of a mouse, the ears small and round, with the tail short. The mouth is armed with very strong teeth, and its paws are furnished with strong crooked nails, with which it digs its habitation in the earth. It is extremely destructive to the corn fields by the quantity of grain it steals, and to the highways by the number

Animals. ber of holes it makes in them; for when, on account of the dimness of its sight, it cannot find its first hole, it makes another, and so on. It digs the earth with its claws and two canine teeth, which it has in the upper jaw.

115 Mexican Birds. The birds are so numerous, and of such various appearances and qualities, that Mexico has been called the country of birds, as Africa is of quadrupeds. Hernandez describes above 200 peculiar to the country. He allows to the eagles and hawks of Mexico a superiority over those of Europe; and the falcons of this country were formerly esteemed so excellent, that, by the desire of Philip II. a hundred of them were sent every year over to Spain. The largest, the most beautiful, and the most valuable kind of eagles, is called by the Mexicans *itzquauhtli*, and will pursue not only the larger kinds of birds, but quadrupeds, and even men.

The ravens of Mexico, do not, like those of other countries, feed upon carrion, but subsist entirely by stealing corn. The carrion is devoured by the birds called in South America *gallinazzi*, in Mexico *zopilots* and *aure*. By Hernandez they are said to be a species of ravens; but, according to Clavigero, they are very different, not only in their size, but in the shape of their head, their flight, and their voice.

The aquatic birds are very numerous, and of great variety.—There are at least 20 species of ducks, a vast number of geese, with several kinds of herons, great numbers of swans, quails, water rails, divers, king's fishers, pelicans, &c. The multitude of ducks is sometimes so great, that they cover the fields, and appear at a distance like flocks of sheep. Some of the herons and egrets are perfectly white, some ash-coloured; others have the plumage of the body white, while the neck, with the tops and upper part of the wings, and part of the tail, are enlivened with a bright scarlet, or beautiful blue.

Numbers of the other classes of birds are valuable for their flesh, plumage, or song, while some are remarkable for their extraordinary instinct or other properties. Clavigero enumerates more than 70 species of those which afford an agreeable and wholesome food. Besides the common fowls which were brought from the Canaries to the Antilles, and from these to Mexico, there were, and still are, fowls peculiar to the country itself. These partly resemble the common fowl and partly the peacock, whence they had the name of *gallipavos* from the Spaniards. From Mexico they were imported into Europe, where they have multiplied very fast, especially in Italy, though the common fowls have multiplied much more in Mexico.

There are great numbers of birds valuable on account of their plumage, which was made use of by the Mexicans in their excellent mosaic works; an art which seems now to be totally lost. Peacocks have been carried from the old continent to Mexico; but, not being attended to, have propagated very slowly. The birds remarkable for their song are likewise very numerous; among which that called the *centxonitl*, by Europeans the *mocking-bird*, is the most remarkable, on account of its counterfeiting naturally the notes of all others it hears. There are great numbers of beautiful parrots; and there is a bird which counterfeits the human voice, but in a kind of burlesque tone, and will follow travellers a great way. The *tzacua* is remarkable for its instinct. Birds of this kind live in society, every tree being a village or city to them, having great numbers of nests in the neighbourhood of each other, all hanging from the boughs. One of them, whose office it is to be the head or guard of the village, resides in the middle of the tree; from which it flies about from one nest to another, visiting them all, and after singing a little, returns to its place, while the rest continue perfectly silent. If any bird of a different species approaches the tree, he flies to it, and with his bill and wings endeavours to drive it off; but if a man or any large animal comes near, he flies screaming to another tree; and if at that time any of his fellows happen to be returning to their nests, he meets them, and, changing his note, obliges them to retire again: as soon as he perceives the danger over, he returns to his wonted round of visiting the nests.

Mexico, like all other American countries, abounds with reptiles, many of them of an enormous size. 116 Reptiles. The crocodiles are not less to be dreaded than those of Africa or Asia, and there are likewise some of those monstrous serpents met with in the East Indies and in South America: though happily the species of those terrible creatures seems to be nearly extinct, as they are seldom to be found but in some solitary wood, or other remote place. There are great numbers of lizards, some of which the people suppose to be poisonous; but Clavigero thinks this opinion ill-founded. There are several kinds of poisonous serpents, of which the rattlesnake is one.

The aquatic animals are innumerable. Clavigero mentions a species of frogs so large that a single one 117 Aquatic animals. will weigh a pound, and which are excellent food.—Of fish proper for food, he says that he has counted upwards of 100 species, without taking in the turtle, crab, lobster, or any other crustaceous animal. The sharks are well known for their voracity. A whole sheep's skin, and even a large butcher's knife, has been found in the belly of one of them. They are accustomed to follow vessels, to devour any filth that is thrown overboard: and, according to Oviedo, they have been known to keep up with ships sailing before a fair wind for no less than 500 miles. The bottetto is a fish about eight inches in length, but excessively thick. While this fish lies alive upon the beach, it swells whenever it is touched to an enormous size, and boys often take pleasure in making it burst with a kick. The liver is so poisonous as to kill with strong convulsions in half an hour after it is eaten.

Of flying and other minute insects, the number is 118 Insects. prodigiously great. There are a variety of beetles: some of a green colour make a great noise in flying; on which account children are fond of them. There are great numbers of shining beetles, which make a delightful appearance at night, as well as the luminous flies which abound in the country. There are six kinds of bees and four kinds of wasps; of which last, one collects wax and honey of a very sweet taste; another is called the *wandering wasp* from its frequent change of abode; and in consequence of these changes, it is constantly employed in collecting materials for its habitations. The lake of Mexico abounds with a kind of

Animals.

of fly, the eggs of which are deposited upon the flags and rushes in such quantities as to form large masses. These are collected by the fishermen, and carried to market for sale. They are eaten by both Mexicans and Spaniards, and have much the same taste as the caviare of fish. There are abundance of gnats in the moist places and lakes; but the capital, though situated upon a lake, is entirely free from them. The butterflies are in vast numbers, and their wings glow with colours far superior to those of Europe; the figures of some of them are given by Hernandez. But notwithstanding its beauties and advantages, Mexico is subject to the dreadful devastations of locusts, which sometimes occasion the most destructive famines.

There are some of the worms of Mexico made use of by the inhabitants as food; others are poisonous. There are great numbers of scolopendræ and scorpions, some of the former growing to an immense size. Hernandez says, that he has seen some of them two feet long and two inches thick. The scorpions are very numerous; and in the hot parts of the country their poison is so strong as to kill children, and give terrible pain to adults. Their sting is most dangerous during those hours of the day in which the sun is hottest. There is a mischievous kind of tick, which in the hot countries abounds among the grass. From thence it easily gets among the clothes, and from them upon the skin. There it fixes with such force, from the particular figure of its feet, that it can scarcely be got off. At first it seems nothing but a small black speck, but in a short time enlarges to such a degree, from the blood which it sucks, that it equals the size of a bean, and then assumes a leaden colour. If it is not speedily removed, a wound is made similar to that which the nigera or chegoe makes.

Mines, Manufactures, &c.

Mexico produces silk-worms: and the manufacture of silk might be carried on to great advantage, were it not prohibited for some political reasons. Besides the common silk, there is another found in the woods, very white, soft, and strong. It grows on the trees in several maritime places, particularly in dry seasons. Unless by poor people, however, this silk is not turned to any use, partly from inattention to their interests, but "chiefly (says our author) from the obstructions which would be thrown in the way of any one who should attempt a trade of that kind. We know from Cortes's letters to Charles V. that silk used to be sold in the Mexican markets; and some pictures are still preserved, done by the ancient Mexicans upon a paper made of silk."

The mines of Mexico have greatly increased in productiveness within the last forty years. They are chiefly of silver; and the ore is remarkable for its poverty; but, to balance this disadvantage, it occurs in great abundance. The whole number of persons employed under ground does not exceed 30,000, and all these are free labourers, who have high wages; the *mita tanda*, or forced labour of the Indians, having been abolished more than forty years ago. The subjoined table gives the average annual coinages of Mexico during successive periods; and, as very little bullion is exported from Mexico, the amount of the coinage expresses very nearly the produce of the mines.

More than three-fourths of the silver obtained from America is extracted from the ore by means of quicksilver; and such is the abundance of the ore in Mexico, that the only limit to the quantity of silver obtained, is the want of mercury for amalgamation. The sale of mercury is a royal monopoly: The quantity consumed annually is 16,000 quintals.

The chief manufactures of New Spain are woollens, cottons, gold and silver-lace, hats, leather, soap, and earthen-ware; but the total value of the goods they produced, when Mr Humboldt was in the country, did not exceed seven or eight millions of dollars annually. Some manufactures of silk have since been introduced; and, in general, all the manufactures, the finer sorts especially, had increased considerably, in consequence of the interruption of foreign commerce by the war. Tobacco and gunpowder are royal manufactures and monopolies; and the former brings in to the crown a clear revenue of four millions of dollars annually. The Mexican tradesmen are remarkably skilful in works of plate and jewellery; and, like some of the eastern nations, they have a singular turn for imitation. Very good carriages are made in Mexico, though the best coaches come from England.

The commerce of New Spain has increased greatly since 1765, and especially since 1778. From the first of these periods to 1789, various new edicts were issued, all tending to break down the monopoly which a few opulent merchants of Cadiz and Mexico had previously enjoyed. The average exportation from Vera Cruz, before the year 1778, when the old system subsisted, was about 617,000 piastres annually; but from

Commerce, Revenue, &c. 1787 to 1790, under the new system, it amounted to 2,840,000 piastres annually. The commerce of Mexico with the mother country, is almost entirely carried on through Vera Cruz. In time of peace, Mr Humboldt estimates the annual value of the exports in that commerce at 22,000,000 piastres, and the imports at 15,000,000. Of the former, about 17,000,000 consists of gold and silver, in coin, bullion, and plate; the other articles are cochineal, sugar, flour, indigo, salted provisions, tanned hides, sarsaparilla, vanilla, jalap, &c. Of the imports, 9,000,000 consists of bale goods, including woollens, cottons, linen, and silk. The other articles are, paper, brandy, cacao, quicksilver, iron, steel, wine, and bees-wax. This estimate does not include the imports in the contraband trade, which, in time of peace, are supposed to be about a fourth of the whole. The temptations to engage in this trade are very great, as the value of commodities imported in Spanish vessels is increased 35 or 40 per cent. by the duties. Mexico also carries on a considerable trade with Cuba, Porto-Rico, Florida, and Manilla. The whole exports are estimated at 31,500,000 piastres, including specie, and the imports at 22,000,000. The demand for foreign merchandise in New Spain and Goatemala, amounts nearly to seven millions sterling.

The revenue of New Spain has augmented with the progress of industry. In 1712 the gross revenue amounted to 3,068,400 piastres; in 1765 to 6,141,981; in 1780 to 15,010,974; and in 1802 to 20,200,000. It is derived chiefly from the following sources. From the produce of the mines, consisting of duties, profits on coinage, and on the sale of mercury, about 5,500,000 piastres. From the manufacture of tobacco, 4,000,000 to 4,500,000. From the alcavala, or duty on every sale of goods, nearly 3,000,000. From the Indian capitation, 1,300,000. From the duty on *pulque*, 800,000. From the net produce of the duty on imports and exports, 500,000. From the sale of papal indulgences, 270,000. From the post, net produce 250,000. From the sale of powder, 150,000. From clerical benefices, 100,000. From the sale of cards, 120,000. Stamp duties, 80,000. From the farm of cock-fighting, 45,000. From the farm of snow, 30,000. The expence of collection is estimated by Humboldt, on an average, at 16 or 18 per cent. of the gross receipts. Of this revenue of 20,000,000 piastres, 10,500,000 are consumed by the internal expenses of the government; 3,500,000 are remitted to other colonies to supply deficiences in their revenues; and the remainder consisting of about 6,000,000, is the clear revenue derived by the mother country from the colony. The value of the specie circulating in Mexico is estimated at fifty-five or sixty millions of piastres, which is nearly ten piastres a head for the whole population. The national wealth of Mexico is supposed to be equal to two fifths of the whole Spanish continental colonies.

The military force of the colony in 1804 consisted of 9,919 regular troops, and 22,277 militia, one half of both being cavalry. The military spirit in the militia service is partly kept up by the vanity of some families, who aspire to the titles of colonels and brigadiers. And the distribution of these titles has become a source of revenue to those individuals who have influence with the ministry. Here, as in the United States, merchants in provincial towns are transformed into colonels and majors. The petty warfare continually carried on with the wandering Indians, in the *provincias externas*, and the maintenance of the *presidios* or military posts, require a considerable expence. The state of the eastern coast, and the nature of the country, facilitate its defence against any attempt by a maritime power.

Population. In the year 1776, the old provincial divisions were laid aside, and the country was divided anew into twelve intendancies, to which must be added three districts, very remote from the capital, which have preserved the simple denomination of provinces. The whole of New Spain, in 1803, contained 118,478 square leagues, and 5,837,100 inhabitants. The population of the twelve intendancies was as follows:

Mexico, - - -	1,511,000
Puebla, - - -	813,300
Vera Cruz, - - -	156,000
Oaxaca, - - -	534,800
Merida, - - -	465,800
Valladolid, - -	467,400
Guadalaxara, - -	630,500
Zacatecas, - -	153,300
Guanaxuato, - -	517,300
San Luis Potosi, -	230,000
Old California, - -	9,000
New California, - -	15,600
Add the population of the *Provincias Internas*,	423,000
	5,837,100

This population is distinguished into different classes:

Whites,—of whom 70,000 are European Spaniards,	1,100,000
Indians, - - -	2,500,000
Mestizoes, or mixed race,	2,231,000
Negroes, - - -	6,100
	5,837,100

Of all the circumstances in the state of Spanish America, this division of its inhabitants into casts, marked by nature with differences of colour, and distinguished in law or opinion by differences of rank or privilege, is the most adverse to its happiness and prosperity. The first class is divided within itself. Though the *Gachepines*, or European Spaniards, and the Creoles, or American Spaniards, have in law equal title to preferment, the former enjoy almost all places of trust or emolument. One cause of this partiality is, that the needy court of Madrid, which has been in the practice of raising money by the sale of colonial offices, fills up even the most inferior situations. A keen spirit of jealousy is thus kept up between the parties, and the government, by showing favour to the one, has made enemies of the other.

The Mestizoes, or descendants of Spaniards and Indians, form the class next in rank after the whites. In colour they hardly differ from the Creoles; but the scantiness of their beards, the smallness of their hands and feet, and a particular cast of their eyes, betray their Indian original. Some consider them as a superior race of men to the Creoles both in bodily constitution and mental endowments. In rank they follow the condition of their fathers. The Creoles and Mestizoes

Condition and Character of the Indians.

Mestizoes form by their union, their numbers, and their property, the principal force, and the most respectable part of the Spanish colonists. As they have the same interests to maintain, and the same grievances to redress, it is probable that in the event of any civil dissensions, they would act together, whether against Indians or Europeans.

The fate of the Indians living under the Spanish government, is a striking proof of the inefficacy of law to afford protection, where those who are the objects of its care have no controul over the persons charged with its execution. The Indians are fenced by the strictest provisions against the tyranny and injustice of their rulers, and yet no people have suffered more from rapacity and oppression. They are born free, and exempt from all sorts of personal service; they are admissible into all incorporated trades, in the same manner as Spaniards; and their caciques have the privileges of Spanish nobles. Those who live in separate villages are governed by alcaldes and regidors of their own nation, and no Spaniards or mixed races are permitted to settle among them, or encroach on their lands. To prevent their facility from being abused by the fraudulent and designing, they cannot dispose of their real property without the intervention of a magistrate, nor enter into contracts, nor conclude bargains for a greater sum than three dollars. They are exempt from the alcavala, and pay only a moderate tribute,—not exceeding two dollars for every person from 10 to 50 years of age. These anxious provisions for their protection have undoubtedly operated against their progress in civilization. Their living in separate communities deprives them of the means of instruction. The state of pupilage in which they are kept destroys the energy of their characters, and detains them in perpetual childhood. The multiplicity of laws in their favour, enables the priest or magistrate to interfere when he pleases in their concerns, and, on pretext of serving them, to become their worst oppressor. The produce of the common lands of their villages, which they are bound to cultivate, is withheld from the beneficial purposes to which it is applicable by law, and openly diverted to other uses in which they have no interest or concern. The privileges of their caciques are almost illusory.

Climate has little effect on the complexion of the Indians. Those who live on the Rio Negro are darker than those who inhabit the banks of the Lower Orinoko, though they enjoy a much cooler temperature. Their children, contrary to the testimony of some authors, have a copper colour at birth. The Indians are a long lived race, when their days are not shortened by intoxication. *Pulque*, a fermented liquor from the juice of the agave americana, which is their native liquor, is less prejudicial to their health than rum or brandy, the use of which they have learned from Europeans. They have little sensibility of body, and suffer less from wounds and injuries than other casts, and they are also less subject to personal deformities. A crooked spine is never seen among them, and very few of them are squint-eyed or lame. In the provinces afflicted with the goitre, the Indians are totally exempt, and even the Mestizoes rarely suffer from that malady. Of all the races in the old world they have the greatest resemblance to the Moguls, but they have a smaller facial angle, though greater than the negro. Their skull is thicker than that of the European, the frontal bone more depressed, the occiput less protuberant, and the brain smaller. The Mexican Indian is grave, melancholy, and silent, unless when under the influence of spirituous liquors. He affects an air of mystery in the most unimportant transactions, and no expression is to be seen in his countenance of the most violent passions that agitate him. He is obstinately attached to ancient customs, manners, and opinions. He seems to be destitute of imagination, and to have little feeling; but when properly educated, has a clear head, an acute and logical understanding. The Indians are generally excessively poor, but some of them under an appearance of wretchedness conceal considerable wealth. In every village there are eight or ten individuals who live in idleness at the expence of the others, on pretence of the nobility of their birth.

Ancient Inhabitants.

119 Of the Toltecas and Chichemecas.

The Toltecas, who first inhabited Mexico, were accounted much more polished than those who came after them, insomuch that in after ages it was customary to distinguish people of ingenuity and learning by the name of Toltecas. They always lived in society, collected into cities, under the government of kings, and had regular laws. They were more addicted to the arts of peace than of war; and it was to them that the succeeding nations owed themselves indebted for their knowledge of the culture of grain, cotton, pepper, &c. They understood the art of casting gold and silver, and melting them in whatever forms they pleased, acquiring also great reputation from their skill in cutting gems of all kinds; and they were besides well versed in the sciences of astronomy and chronology.

According to the ancient histories of these people, they observed, about a hundred years before the Christian era, how far the solar year exceeded the civil one; supplying the defect, as we do, by the addition of a day once in four years. In the year 660, while their monarchy continued in Tula, a celebrated astronomer named Huematzin, assembled with the king's consent all the wise men of the nation; and with their assistance painted a famous book named *Teoamoxtli*, or "divine book," in which were represented, in very plain figures, the origin of the Indians, their dispersion after the confusion of tongues at Babel, their journey in Asia, their first settlements in America, the founding of the kingdom of Tula, and their progress till that time: but these, and other accounts of their great knowledge and accuracy, savour too much of exaggeration, or perhaps invention, from both which it is impossible to clear the Spaniards when speaking of American affairs.

120 Their progress in agriculture.

The Chichemecas derived their knowledge of agriculture from the Toltecas, and of consequence the Mexicans also. Being destitute of ploughs or animals of sufficient strength to assist them in their labour, they made use of an instrument of hard copper, which they called *coatl* or *coa*, but differing in shape either from a spade or mattock. They used copper axes to cut trees, the figure of which was the same with ours; only that they put the axe into the eye of the handle, instead of putting the handle into the eye of the axe as we do. They had several other instruments of agriculture, but the forms of them are not mentioned by historians. They watered their fields by means of the rivers

Ancient Inhabitants.

rivers and small torrents which came from the mountains; raising dams to collect them, and forming canals to conduct them properly to the places which required moisture. They used enclosures of stone, as well as hedges for the fields, using for their hedges the aloe plant, which is well calculated for the purpose; and what reparations were necessary they gave in December. They dibbled their maize: a method of sowing more slow indeed than the ordinary one, but which certainly repays the trouble by a vastly larger crop, as well as by saving a very considerable quantity of seed. Close to the newly sown fields they commonly erected a small tower of wood, where a man kept watch, in order to drive away the birds that came to feed upon the grain; a custom still preserved among the Spaniards.

121 Magnificent gardens.

In the cultivation of their gardens, the Mexicans were extremely skilful and magnificent; planting in them not only kitchen herbs, but fruit trees, medicinal herbs, and flowers, with great taste and regularity. Some of the royal gardens excited the admiration of the Spaniards so much, that Cortes, in a letter to Charles V. informed him that the garden at Huaxtepec was the most extensive, the most beautiful, and most delightful, that had ever been beheld. It was for many years preserved by the Spaniards.——The plants most cultivated, next to maize, were cotton, cocoa, and aloe; which last served a great many useful purposes. See ALOE.

122 Tame animals.

Though they had not the advantage of the larger quadrupeds, as horses, oxen, or sheep, they bred up an immense number of quadrupeds unknown in Europe. Private persons brought up the small quadrupeds already mentioned, resembling little dogs; as well as turkeys, quails, geese, ducks, and other kinds of fowl. In the houses of the great men were bred fish, deer, rabbits, and a variety of birds; and in the royal palaces, almost all the species of quadrupeds and winged animals to be found in these kingdoms were kept, as well as a great number of aquatic animals and reptiles. According to Clavigero, Montezuma II. surpassed all the kings in the world in this kind of magnificence; and there never was a nation equal to the Mexicans in the care they took in taming animals.

123 Paintings.

Painting was an art in great request among the Mexicans, and one of very great use; as it was only by means of paintings that they recorded their histories. This art they derived, like others, from the Toltecas. Some of these paintings were mere images of their gods, kings, heroes, or terrestrial objects. Others were historical, containing an account of particular events; others mythological, of which a volume is preserved in the great library of the order of Bologna: others were codes of law, civil and religious; while some were chronological, astronomical, or astrological; in which were represented their calendar, the position of the stars, changes of the moon, eclipses, and prognostications and variations of the weather. Great numbers of these were burned by the superstitious Spaniards, who imagined that they contained some emblems of heathen worship. They had likewise geographical paintings, which served not only to show the extent and boundaries of their possessions, but likewise the situation of places, the direction of the coasts, and the course of the rivers. In his first letter to Charles V. Cortes says, that having made inquiries if there was any secure harbour for vessels on the Mexican coast, Montezuma presented him with a painting of the whole coast, from the port of Vera Cruz, at that time called *Chalchiuhuecan*, to the river Coatzacualco. Another author informs us also, that Cortes, in a long and difficult voyage which he made to the bay of Honduras, made use of a chart presented to him by the lords of Coatzacualco, in which all the places and rivers were marked from the coast of Coatzacualco to Huejacallan.

The cloth on which paintings were done was made of the thread of the aloe or a kind of palm; or they painted on sheep's skins or upon paper. This last was made of the leaves of a certain kind of aloe, steeped like hemp, and afterwards washed, stretched, and smoothed. They used also the bark of other trees, prepared with gum: but we are ignorant of the method they used in the manufacture. This paper is similar in thickness to the European pasteboard, but softer, smoother, and more easy for writing. In general it was made up in very long sheets, which they preserved in rolls, or folded like bed-skreens. The volume of Mexican paintings, preserved in the library of Bologna, is a thick skin, ill dressed, composed of different pieces painted all over, and folded up in that manner. The beautiful colours which they employed both in their paintings and in their dyes, were obtained from wood, leaves, and the flowers of different plants, as well as from various animal substances. Their white was made from a kind of stone which burns into a fine plaster; or from a mineral, which after being made into a paste worked like clay, and formed into small balls, turns white in the fire like Spanish white. Their *black* was got from another mineral, which has a disagreeable smell, or from the soot of a kind of pine collected in small earthen vessels. They obtain *blue* and *azure* colours from indigo; but their mode of obtaining these was very different from that used by the moderns. They put the branches of the plant into hot, or rather lukewarm, water; and after having stirred them about for a sufficient time with a stick or ladle, they passed the water, when impregnated with the dye, into certain pots or cups, in which they let it remain until the solid part of the dye was deposited; after which they poured off the water. This sediment was first dried in the sun, and afterwards put between two plates before a fire until it grew hard. They had another plant which likewise afforded a blue colour, but inferior to the indigo. *Red* was obtained from the seeds of the achiot or rocou, and *purple* from cochineal. Their *yellows* were ochre, and a colour extracted from the beautiful flower of a plant resembling artemisia. With nitre these flowers afforded a fine orange colour; and by means of alum they extracted other colours.

The Mexican painters were by no means arrived at much perfection in the knowledge of light and shade, or of design; nevertheless, in some of the ancient paintings, particularly in the portraits of their kings, the proportions were exactly observed. Besides paintings, however, the Mexicans are said to have employed hieroglyphics and characters; but this is absolutely denied by Clavigero; who tells us, that "they represented material things by their proper figures; but, in order to

124 They did not use hieroglyphics or characters.

Ancient Inhabitants.

to save labour, paper, and colours, they contented themselves with representing part of an object, which was sufficient to make it understood. But as we cannot understand the writings of others till we have learned to read them; in like manner those American authors, who say that the Mexicans made use of characters, required to have been first instructed in the Mexican manner of representing objects, in order to have been able to understand the paintings which served them in place of writing. When they would represent any person, they painted a man or human head, and over it a figure expressing the meaning of his name, as appears in the figures of the Mexican kings. To express a city or village, they painted in like manner a figure which signified the same thing with its name. To form their histories or annals, they painted on the margin of the cloth or paper the figures of the years in so many squares, and at the side of each square the event or events which happened that year: and if, on account of the number of years, the history of which they meant to relate, they could not all be contained in one canvas, they were continued on another. With respect to the order of representing the years and events, it was at the liberty of the historian to begin at whichever angle of the piece he pleased; but at the same time constantly observing, that if the painting began at the upper angle of the right-hand, he proceeded towards the left; but if it began, as it most commonly did, at the upper angle of the left hand, he proceeded straight downwards. If he painted the first year at the lower angle of the left, he continued towards the right; but if he began at the lower angle of the right, he painted straight upwards; so that on the upper part of his canvas he never painted from left to right, nor ever on the lower part from right to left; never advanced upwards from the left, nor downwards from the right. When this method of the Mexicans is understood, it is easy to discover at first sight which is the beginning and which the ending of any historical painting. Their paintings, however, ought not to be considered as a regular full history, but only as monuments and aids of tradition. We cannot express too strongly the care which parents and masters took to instruct their children and pupils in the history of the nation. They made them learn speeches and discourses which they could not express by the pencil; they put the events of their ancestors into verse, and taught them to sing them. This tradition dispelled the doubts and undid the ambiguity which paintings alone might have occasioned; and, by the assistance of those monuments, perpetuated the memory of their heroes and of virtuous examples, their mythology, rites, laws, and customs.

125 Careful to preserve their traditions.

126 Preserved the memory of events by knotted threads.

"Nor did that people only make use of tradition, paintings, and songs, to preserve the memory of events, but also of threads of different colours and differently knotted. This curious method of the representation of things, however much used in Peru, does not appear to have been employed in the province of Anahuac, if not in the most early ages; for no traces of such monuments are now to be found. Boturini says, that after the most diligent search, he with difficulty found one in a place in Tlascala, the threads of which were already wasted and consumed by time. If those who peopled South America ever passed the country of Anahuac, they possibly might have left there this art, which was afterwards abandoned for that of painting, introduced by the Toltecans or some other nations still more ancient."

127 Their knowledge in sculpture.

The Mexicans arrived at greater perfection in sculpture, casting of metals, and mosaic works, than in painting. Sculpture was likewise one of the arts exercised by the ancient Toltecans; but the Mexicans had sculptors among them when they left their native country of Atztlan. Several of the Toltecan statues, however, were preserved till the time of the conquest, particularly that of the idol Tlaloc, placed upon the mountain of the same name, and some gigantic statues in one of their temples. Stone and wood were the usual materials of their statues: the former was worked with a chissel made of flint; and, in spite of the unfitness of the instrument, such was the phlegmatic nature of the people, that they surmounted every difficulty arising from the tediousness of the work. In their statues they learned to express all the attitudes and postures of which the human body is capable. They observed the proportions exactly, and could, when necessary execute the most delicate strokes with the chissel. They not only made entire statues, but cut out in wood and in stone figures in basso relievo; of which kind are those of Montezuma II. and one of his sons, recorded with praises by Acosta. They also made statues of clay and wood, employing for these a chissel of copper. The number of their statues was in proportion to that of their idols; but so active were the Spanish priests in destroying these, that there is now scarce any vestige of them remaining. The foundation of the first church in Mexico was laid with idols; on which occasion many thousand statues of their gods were necessarily broke in pieces. In casting of metals, however, the Mexicans greatly excelled their works either of painting or sculpture. "The miracles they produced of this kind (says Clavigero), would not be credible, if, besides the testimony of those who saw them, a great number of curiosities of this kind had not been sent from Mexico to Europe. The works of gold and silver sent in presents from the conqueror Cortes to Charles V. filled the goldsmiths of Europe with astonishment; who, as several authors of that period attest, declared that they were altogether inimitable. The Mexican founders made both of gold and silver the most perfect images of natural bodies. They made a fish in this manner, which had its scales alternately one of silver and the other of gold; a parrot with a moveable head, tongue, and wings; and an ape with a moveable head and feet, having a spindle in its hand in the attitude of spinning. They set gems in gold and silver, and made most curious jewellery of great value. In short, these sorts of works were so admirably finished, that even the Spanish soldiers, all stung with the same wretched thirst for gold, valued the workmanship above the materials. This wonderful art, formerly practised by the Toltecas, the invention of which they ascribed to one of their gods, has been entirely lost by the debasement of the Indians, and the indolent neglect of the Spaniards. We are doubtful if there are any remains of those curious works; at least we apprehend that it would be more easy to find them in some of the cabinets of Europe than in all New Spain. Covetousness to profit by the materials must unquestionably have conquered all desire to preserve them as curiosities." The works of the Mexicans in gold and silver, executed

128 Excelled in the art of casting metals.

executed with the hammer, were much inferior to those of the Europeans.

But of all the works executed by the ancient Mexicans, those of mosaic were the most curious, as well as
129 Beautiful mosaic. most highly valued by themselves. These were made of the feathers of birds; and for procuring them they reared a great number of those birds of fine plumage, with which the country abounded, not only in the royal palaces, but also in private houses; and at certain seasons they carried off the feathers for these purposes, or to sell them at market. They valued particularly the feathers of the humming birds, on account of their smallness, fineness, and various colours; and in these, as well as other birds of fine plumage, nature supplied them not only with all the colours produceible by art, but likewise with many which art cannot imitate. Their mosaic works, as well as indeed all others of the Mexicans, required infinite patience. At the undertaking of every work of this kind several artists assembled; and having agreed upon a design, and fixed their measure and proportions, each artist charged himself with the execution of a certain part of the image, and exerted himself so diligently in it, that he frequently spent a whole day in adjusting a feather; first trying one and then another, viewing it sometimes one way, then another, until he found one which gave his part that ideal perfection proposed to be attained. When the part which each artist undertook was done, they assembled again to form the entire image from them. If any part happened to be in the least deranged, it was wrought again until it was perfectly finished. They laid hold of the feathers with small pincers, that they might not do them the least injury, and pasted them on the cloth with some glutinous matter; then they united all the parts upon a little table or a plate of copper, and flattened them softly until they left the surface of the image so equal and smooth, that it appeared to be the work of a pencil. These works were prodigiously admired by the Spaniards.

130 Their architecture. The Mexicans were skilled in architecture even before they left their native country; and many edifices still remain which were constructed by them during their frequent journeys from one place to another. At their first arrival on the lake, they had no other materials to build their houses with but reeds and mud, until the success of their commerce allowed them to purchase better materials. When the city came to its perfection, the houses of the principal people were constructed of stone and lime: they consisted of two floors, having halls, large court-yards, and chambers fitly disposed: the roofs were flat and terraced; the walls so well whitened, polished, and shining, that they appeared to the Spaniards when at a distance to have been constructed of silver. The floor was paved with plaster, perfectly level, plain, and smooth. Many of their houses were crowned with battlements and turrets; and their gardens had fish ponds, and the walks of them symmetrically laid out. The large houses had in general two entrances, the principal one to the street, the other to the canal: they had no wooden doors to their houses, but covered the entrance with small reeds, from whence they suspended a string of cocoa shells, or some other materials which would make a noise, so as to awake the attention of the family when any person lifted up the reeds to enter the house. —The houses of the poorer sort were constructed of reeds, unburnt bricks, stone, or mud; and the roofs made of a kind of a long hay which grows plentifully in the fields, particularly in the warm parts of the country. For this purpose they used also the leaves of the aloe placed in the manner of tiles, to which they bear some resemblance both in thickness and shape. One of the columns or supports of these houses was generally a tree in the vigour of its growth; by which means, besides the pleasure derived from its foliage and shade, they saved themselves some labour and expence. These houses had one or more apartments according to the circumstances of the family.

The ancient Mexicans understood the method of constructing arches or vaults, as appears from some remains of their buildings as well as from their paintings. They had likewise cornices and other ornaments of architecture. They had also square or cylindrical columns; but it is not known whether they had any capitals or not. They frequently adorned them with figures in *basso relievo;* but their great ambition was to have them all made out of one stone. The foundations of the large houses in the capital were laid upon beams of cedar driven into the ground, on account of its want of solidity; and the same method is still practised by the Spaniards. The roofs of these were made of cedar, fir, cypress, pine, &c. In the royal palaces the columns were of marble or even of alabaster, which the Spaniards mistook for jasper. In the reign of Ahuizotl a new kind of stone, named *tetzontli*, was discovered in the Mexican lake, which was ever afterwards made use of for building. It is hard, light, and porous like a sponge; by which means the lime adheres very firmly to it. It is valued likewise on account of its colour, which is a blood red. Some of the pavements were chequered with marble and other valuable stones.

The most remarkable pieces of Mexican architecture 131 Remarkable aqueducts.
were their aqueducts. There were two which conveyed the water to the capital from the distance of two miles. These were constructed of stone and cement, five feet high, and two paces broad, upon a road for that purpose upon the lake; by which the water was brought to the entrance of the city, from whence it was sent forth in smaller channels to supply the different fountains. The famous aqueduct of Chempoallan, which was done in the 16th century, is worthy of being ranked among the greatest in Europe. The conductor of this work was a Franciscan missionary named *Tembleque;* and it was executed with great skill by the Chempoallese. The water was brought from a great distance, and the country through which it must pass was mountainous and rocky; but every difficulty was overcome by the industry of the Mexicans. The aqueduct, including all the turnings and windings, exceeded 30 miles in length. The principal difficulty consisted in crossing three great precipices, over which they were obliged to construct three bridges, the first of 47, the second of 13, and the third of 67 arches. The largest arch was 100 feet high, and 61 broad; so that a large vessel could have passed under it. It must, however, be observed, that, in executing this undertaking, the Mexicans were undoubtedly assisted by European

European tools, and the directions of European workmen; so that we cannot with strict propriety call it one of their works.

132 Excellent jewellers. They were expert jewellers, and understood the art of cutting and polishing the stones, as well as of setting them. The gems most common in their country were the emeralds, amethysts, carnelians, turquoises, and some others. Emeralds were so common, that no lord or noble wanted them; and none of them died without having one fixed to his lip, that it might serve him, as they imagined, in the other world, instead of a heart. When Cortes returned the first time to Spain, he brought with him five emeralds, valued, by the jewellers there, at 100,000 ducats. The first was in the form of a rose; the second of a horn; the third of a little fish with eyes of gold; the fourth in the form of a bell, with a fine pearl for a clapper. The fifth was a small cup with a foot of gold, and four little golden chains which united in a pearl in the form of a button. For this alone the Genoese merchants offered 40,000 ducats, in order to sell it again to the grand signior. Besides these, he had two emerald vases valued at 300,000 ducats; but these last were lost by shipwreck in the unfortunate expedition of Charles V. against Algiers. There are no such gems wrought at present, nor is it even known where the emerald mines are situated; though it is said there are still some large pieces of this precious stone in some of the churches; but the priests take care to secure them with iron chains, lest they should be carried off.

133 Manufactures of different kinds. In other more common manufactures the Mexicans were by no means deficient. The earthen ware of Cholula was much praised by the Spaniards; and they had the art of ornamenting this kind of ware with various colours, though they did not understand the making of glass. Their carpenters wrought with instruments of copper; and there are still remains of their labours which display a tolerable skill. Almost every one was acquainted with the method of making cloth. Being destitute of wool, common silk, lint, or hemp, they were obliged to supply the deficiency by other materials. For wool they substituted cotton, for silk they used feathers, the wool of the hare or rabbit; and instead of lint and hemp, they used the fibrous part of the leaves of the aloe. From these last they obtained a thread as fine as from lint; and from some species they had a coarser sort resembling hemp. To obtain this thread they soaked the leaves in water, cleaned them, exposed them to the sun, and then beat them till they were fit to be spun. Sometimes they interwove with their cotton the finest down on the belly of the rabbits or hares, after having spun it into thread; and of these they made most beautiful cloths, which were particularly used for winter waistcoats for the lords. Their cotton manufactures were equal to any produced in Europe; they wove them with different figures and colours, representing different animals and flowers. Of feathers interwoven with cotton they made mantles and bed-curtains, carpets, gowns, &c. These were exceedingly beautiful; but this kind of manufacture is now lost, though there are still some of these garments in the possession of the principal lords, who wear them upon solemn occasions.

134 Their horrible religion. All these advances towards civilization, however, in the ancient Mexicans, were much more than counterbalanced by the horrible barbarities they committed in their religious ceremonies, and in which they exceeded every nation on earth. Human sacrifices were indeed in use among all the ancient heathens; but such prodigious massacres at the dedication of their temples are unheard of in history. Whether they used these barbarous sacrifices in their own country, or whether the practice began with that of the four Xochimilca prisoners, is not known; but as they only used their prisoners or slaves whom they bought in this way, it is impossible that, during the infancy of their state, the number of human victims could have been very great. Most of those unhappy creatures perished by having their breasts opened, and their hearts pulled out; some were drowned, others starved to death with hunger; and sometimes they were burnt. Prisoners of high rank were allowed to die by what Clavigero calls the *gladiatorian* sacrifice, which was performed in the following manner: Near to the greater temple of large cities, in an open space of ground sufficient to contain an immense number of people, was a round terrace eight feet high, upon which was placed a large round stone resembling a millstone in shape, but much larger, almost three feet high, well polished, and having figures cut upon it. On this stone, which was called *temalcatl*, the prisoner was placed, armed with a shield and short sword, and tied by one foot. Here he was encountered by a Mexican officer or soldier better armed than himself. If the prisoner was vanquished, he was carried, dead or alive, to the temple, where his heart was taken out and offered in the usual manner; but if he conquered six combatants, he gained his life and liberty. An instance, however, is given in which this custom was infringed; for the Huetzotzincas having taken the principal lord of Cholula, a man of singular bravery, he overcame seven combatants; notwithstanding which he was put to death; but on this account the Huetzotzincas were rendered for ever infamous among these nations. 135 Gladiatorian sacrifice.

136 Number of human victims annually sacrificed. Historians differ concerning the number of victims who perished annually in these sacrifices: Clavigero inclines to think it was 20,000, but others make it much more. Zumarraga, the first bishop of Mexico, says in a letter of the 12th of June 1531, addressed to the general chapter of his order, that in that capital alone there were above 20,000 victims annually sacrificed. Some authors, quoted by Gomara, say that 50,000 were annually sacrificed in the various parts of the empire. Acosta says, that there was a certain day of the year on which they sacrificed 5000 victims, and another on which 20,000 were sacrificed. According to others they sacrificed, on the mountain Tepeyacac only, 20,000 annually to one of their female deities. On the other hand, Bartholomew de las Casas reduces the number of human victims to 50 or at most to 100. "We are strongly of opinion (says Clavigero), that all these authors have erred in the number; Las Casas by diminution, and the rest by exaggerating the truth."

137 Their monstrous austerities. Besides the cruelties which they practised upon others, the Mexicans were accustomed to treat themselves with the most inhuman austerities, thinking that the diabolical rage of their deities would be appeased by human blood. "It makes one shudder (says Clavigero), to read the austerities which they practised upon themselves, either in atonement for

Ancient Inhabitants.

for their transgressions, or in preparation of their festivals. They mangled their flesh as if it had been insensible, and let their blood run in such profusion as if it had been a superfluous fluid in the body. The effusion of blood was frequent and daily with some of their priests. They pierced themselves with the sharpest spines of the aloe, and bored several parts of their bodies, particularly their ears, lips, tongue, and the fat of their arms and legs. Through the holes which they made with these spines they introduced pieces of cane, the first of which were small; but every time this penitential suffering was renewed, a thicker piece was made use of. The blood which flowed from them was carefully collected in the leaves of the plant *aczojatl*. They fixed the bloody spines in little balls of hay, which they exposed upon the battlements of the walls of the temple, to testify the penance which they did for the people. Those who exercised such severities upon themselves within the enclosure of the greater temple of Mexico, bathed in a pond that was formed there, and which, from being always tinged with blood, was called *ezapan*."

138 Their dress.

The dress of the Mexicans was very simple; that of the men consisted only of a large belt or girdle, the two ends of which hung down before and behind; the women wore a square mantle, about four feet long; the two ends were tied upon the breast or upon one shoulder. The Mexican gown was also a piece of square cloth, in which the women wrapped themselves from the waist down to the middle of the leg. They wore also a small under vest or waistcoat without sleeves, named *huepilli*.

The dress of the poorer sort was made of the thread of the mountain palm, or of coarse cotton: but those of better station wore the finest cotton, embellished with various colours, and figures of animals or flowers; or woven with feathers, or the fine hair of the rabbit, &c. The men wore two or three mantles, and the women three or four vests, and as many gowns, putting the longest undermost, so that a part of each of them might be seen. Their shoes were only soles of leather, or coarse cloth of the mountain palm tied with strings; but those of the great people were adorned with ribbands of gold and jewels. They all wore long hair, and thought themselves dishonoured by being shaved, or having their hair clipped, except the consecrated virgins in the temple. The women wore it loose; but the men tied it up in different forms, and adorned their heads with fine feathers, both when they danced and went to war. With this simplicity, however, they mixed no small quantity of extravagance. Besides feathers and jewels, with which they used to adorn their heads, they wore ear-rings, pendants at their upper lip, as well as many at their noses, necklaces, bracelets for the hands and arms, as well as certain rings like collars which they wore about their legs. The ear-rings of the poor were shells, pieces of crystal, amber, &c.; but the rich wore pearls, emeralds, amethysts, or other gems set in gold.

Instead of soap the Mexicans used a kind of fruit called *copalxocotl*; the pulp of which is white, viscous, and very bitter, makes water white, raises a froth, and will clean linen like soap. They used also a kind of root named *amolli*, which is not unlike the *saponaria* of the old continent. It is now more used for washing the body, especially the head than for clothes. Clavigero says, that there is a kind of this root which dyes the hair of a golden colour, and that he has been witness to this effect on the hair of an old man.

139 Mexicans cruelly treated by the Spaniards.

It is generally believed, that the first conquerors massacred the Indians out of wantonness, and that even the priests incited them to these acts of ferocity. Undoubtedly these inhuman soldiers frequently shed blood without even an apparent motive; and certainly their fanatic missionaries did not oppose these barbarities as they ought to have done. The cruelties exercised upon them, however, at length raised up a protector for them in the person of Bartholomew de las Casas.

140 Bartholomew de las Casas takes their part.

This man, so famous in the annals of the new world, had accompanied his father in the first voyage made by Columbus. The mildness and simplicity of the Indians affected him so strongly, that he made himself an ecclesiastic, in order to devote his labours to their conversion. But this soon became the least of his attention. As he was more a *man* than a *priest*, he felt more for the cruelties exercised against them than for their superstitions. He was continually hurrying from one hemisphere to the other, in order to comfort the people for whom he had conceived an attachment, or to soften their tyrants. This conduct, which made him be idolized by the one and dreaded by the other, had not the success he expected. The hope of striking awe, by a character revered among the Spaniards, determined him to accept the bishoprick of Chiapa in Mexico. When he was convinced that this dignity was an insufficient barrier against that avarice and cruelty which he endeavoured to check, he abdicated it. It was then that this courageous, firm, disinterested man, accused his country before the tribunal of the whole universe. In his account of the tyranny of the Spaniards in America, he accuses them of having destroyed 15,000,000 of Indians. They ventured to find fault with the acrimony of his style; but no one convicted him of exaggeration. His writings, which indicate the amiable turn of his disposition, and the sublimity of his sentiments, have stamped a disgrace upon his barbarous countrymen, which time hath not, and never will, efface.

141 Their condition rendered somewhat easier.

The court of Madrid, awakened by the representations of the virtuous Las Casas, and by the indignation of the whole world, became sensible at last, that the tyranny it permitted was repugnant to religion, to humanity, and to policy; and resolved to break the chains of the Mexicans. Their liberty was now only constrained by the sole condition, that they should not quit the territory where they were settled. This precaution owed its origin to the fear that was entertained of their going to join the wandering savages to the north and south of the empire.

The city of Mexico is situated in a valley of the same name, which is of an oval form, about 67 leagues in circumference, and bounded by mountains. The lakes, five in number, occupy about one tenth of the surface of the valley. The city is now about a mile distant from the west side of the lake Tezcuco, which surrounded it in the time of Cortes. The soil on which it stands is about 7200 feet above the sea, a height exceeding

Cities.

ceeding that of the pass of St Gothard. Mexico is one of the finest cities ever built by Europeans in either hemisphere. The ground is very level, the streets broad and regular, the style of the architecture is generally pure, and some of the buildings truly beautiful. The streets have foot pavements, and are kept clean and well lighted by an excellent police. Among the objects worthy of notice are the cathedral, the treasury, the convent of St Francis, the hospital, the school of mines with its fine collections in physics, mechanics, and mineralogy, the botanic garden, the university, and academy of fine arts, the equestrian statue of Charles IV. of great beauty and colossal size, weighing 450 quintals, and made by a native artist. The most considerable monuments of ancient Mexican art remaining are two pyramids on the north-east side of the lake Tezcuco, the larger of which has at present a base of 682 feet in length, with an elevation of 180. The faces of these pyramids correspond with considerable exactness to the cardinal points of the compass. The population of the city in 1803 was about 137,000, of which 2500 were Europeans, 65,000 white Creoles, 33,000 Indians, 26,500 Mestizoes, and 10,000 Mulattoes. The convents contain about 1200 men, and 2100 women. The clergy of the city exceed 2000, exclusive of lay brothers and novices. The whole intendancy of Mexico contains 5927 square leagues. The only considerable towns in it beside the capital, are Queretaro containing 35,000 inhabitants, and the port of Acapulco, on the South sea, containing 9000.

The most considerable cities in the other parts of New Spain are, La Puebla, containing 67,000 inhabitants; Guanaxuato, which contains, including the rich mines in its neighbourhood, 70,000 inhabitants; Zacatecas, also situated in a rich mining district, contains 33,000; Oaxaca, 24,000; Vera Cruz, the principal port in the colony, but unhealthy in its situation, has only a population of 16,000.

The population of New Spain is in a state of rapid increase, as appears from the registers of births and burials, which are kept in many places with great accuracy. The proportion of births to deaths throughout the kingdom, is as 170 to 100. In some part of the table land the proportion is as high as 253 to 100; but at Panuco on the coast of the North sea, it was as low as 123 to 100.

A very great inequality of fortune prevails in Mexico. The count of Valenciana enjoys an income of about 100,000l. sterling per annum, of which three fourths are derived from his mine. The marquis of Fagoaga drew 83,000l. sterling, from a single mine in six months. The count of Regla built two first-rate men of war, at his own expence, and made a present of them to his sovereign. Close to this wealth is to be seen the most wretched poverty. In the city of Mexico alone, there are from 20,000 to 30,000 Sarugates and Guachinangoes, who can be compared only to the Lazaroni of Naples. Quiet, sober, and indolent, they give occasion to no alarm, though they are half naked, and pass the night in the street, under the canopy of heaven. This inequality of condition exists equally among the clergy. The archbishop of Mexico has a revenue of 130,000 dollars; there are four bishops whose revenues are from 80,000 to 110,000 each, while many of the parish clergy have not above 100 dollars a year. The whole Mexican clergy including lay brothers and sisters, does not exceed 13,000 or 14,000. The revenues arise chiefly from tithes, the church lands being inconsiderable.

Volcanoes and Insurrection.

There are five burning volcanoes in New Spain, Orizaba, Popocatepetl, Tustla, Jorullo, and Colima. The second of these is 17,700 feet in height, which is 2000 feet higher than Mount Blanc. It is situated at the south-east extremity of the valley of Mexico, and is visible from the capital. The Pic d' Orizaba has nearly the same elevation. The mountain Jorullo, which rises 1690 feet above the surrounding plains, was thrown up by a volcanic eruption in 1759. Several of these mountains, and some others that seem to be extinguished volcanies, ascend beyond the inferior limit of perpetual snow, which has here an elevation of 8360 feet. The snow is carried to Mexico and other cities, where it is sold, and pays duty as an article of luxury. Vera Cruz is supplied from the volcano of Orizaba, at the distance of 28 leagues, over which space the snow is carried on the backs of mules.

The extraordinary events in Old Spain, which produced revolutions in some of the other American colonies, also led to an insurrection in Mexico. An extensive conspiracy was formed, at the head of which were some ecclesiastics and military officers; but the secret was betrayed, and the conspirators were prematurely driven to take up arms in September 1810. They were under the command of Hidalgo a priest; and having been joined by some parties of cavalry and infantry, they got possession of Guanaxuato, a large town. Great numbers declared for them in all parts of the country. After defeating some divisions of military, Hidalgo advanced to the neighbourhood of the capital; but discouraged by the means of defence which the new viceroy had collected, and hearing of the defeat of some of his adherents in other quarters, he retired. He was followed by a considerable military force, routed in several engagements, great part of his troops, who consisted chiefly of Indians without firelocks, were dispersed, and himself taken and shot in July 1811. His partizans, however, under Morelos continued the war, and gained occasional successes. Zitaquaro, a city containing 10,000 inhabitants, in which they had established themselves, was taken by the royalists, and utterly rased in the beginning of 1812. In the same year the insurgents were joined by Toledo, who had been a member of the cortes for Spanish America, and brought with him a few troops from the United States; but he was soon compelled to seek safety in flight. In 1814 the insurgents called a congress, which issued a democratic constitution in October. In 1815 Morelos when marching to the coast to join Toledo and General Humbert, who had brought a supply of arms, was surprised, taken prisoner, and shortly after executed. His death broke the strength of the insurgents, though guerilla parties still traversed the country. In 1816 a new attempt was made by Colonel Mina, who had distinguished himself in the wars in the peninsula. He landed at Matagorda, and appears to have made some progress at first; but was finally surrounded and taken by the royal troops in November 1817. The new viceroy Apodaca, by following a

Insurrection. a lenient and conciliatory system, has restored some degree of order and quiet to the colony; but bands of guerillas still maintain themselves in different parts, and interrupt the communications between the capital and the sea coast. See article MEXICO, SUPPLEMENT.

New Mexico. MEXICO, NEW, so called because it was discovered later than Old Mexico, a country of North America, lying on the eastern side of the northern Andes, or Stony mountains, and extending from the 31st to the 38th degree of latitude. Its length from north to south is 175 leagues, and its breadth from east to west from 30 to 50. Its surface covers 5700 square leagues, and it contained in 1803 40,200 inhabitants according to Humboldt. It is fertile, but is believed to be destitute of metallic wealth. It is watered through its whole extent by the Rio del Norte, the banks of which are picturesque, and are adorned with beautiful poplars, and other trees peculiar to the temperate zone.

Though under the same latitude with Syria and central Persia, this country has a remarkably cold climate. Near Santa Fe, and a little further north, the Rio del Norte is sometimes covered for a succession of several years with ice thick enough to admit the passage of horses and carriages. The mountains which bound the valley of the Rio del Norte, lose their snow towards the beginning of the month of June.

The Rio del Norte has a periodical swell like the Mississippi. Its waters, which are always muddy, begin to rise in April, are at their height in May, and fall towards the end of June. The inhabitants can only ford the river on horses of an extraordinary size, during the drought of summer. Humboldt informs us that in 1752, the whole bed of this river, for more than 30 leagues above and 20 leagues below Passo del Norte, became dry of a sudden, the water having precipitated itself into a newly formed chasm, and only made its re-appearance near the Presidio de San Eleazario; at length, after the lapse of several weeks, the water resumed its ancient course, no doubt because the chasm and the subterraneous conductors had been filled up. In the northern part of New Mexico, rivers take their rise which run into the Mississippi.

The colonists of this province, known for their great energy of character, live in a state of perpetual warfare with the neighbouring Indians. It is on account of this insecurity of the country life, that we find the towns more populous than we should expect in so desert a country. Some commercial intercourse exists however, between the whites and the Indians, and it is carried on in a singular manner. The savages plant upon the road from Chihuahua to Santa Fe, small crosses, to which they suspend a leathern pocket, with a piece of stag's flesh; and below a buffalo's hide is stretched. The Indian indicates by these signs that he wishes to exchange hides for provisions with the men who adore the cross. The soldiers of the Presidios, who understand these signs, take away the buffalo hide and leave some salted flesh at the foot of the cross. This system of commerce indicates at once an extraordinary mixture of good faith and distrust.

The Indians to the west of the Rio del Norte are in a much less barbarous state than the wandering tribes on the east. Father Garces who visited the country of the Moqui in 1773, was surprised to find an Indian town with two great squares, houses of several stories, and streets well laid out and parallel to one another. Here, and in other points on the west coast, every thing appears to announce traces of the cultivation of the ancient Mexicans.

The province of New Mexico contains 3 towns, 26 villages, 3 parishes, 19 missions, and no solitary farm. Santa Fe the capital, has a population of 3600; Albuquerque 6000, and Taos 8900.

New Mexico, Mezeray. MEZERAY, FRANCIS EUDES DE, an eminent French historian, the son of Isaac Eudes a surgeon, was born at Rye, in Lower Normandy, in 1610; and took the surname of *Mezeray*, from a hamlet near Rye. Having performed his studies at Caen, he discovered a strong inclination to poetry; but going to Paris, he, by the advice of one of his friends, applied himself to the study of politics and history, and procured the place of commissary at war, which he held for two campaigns. He then shut himself up in the college of St Barbe, in the midst of books and manuscripts; and, in 1643, published the first volume of the History of France, in folio; and some years after, the other two volumes. Mezeray in that work surpassed all who had written the history of France before him, and was rewarded by the king with a pension of 4000 livres. In 1668, he published an Abridgement of his History of France, in three volumes 4to, which was well received by the public; but as he inserted in that work the origin of most of the taxes, with very free reflections, M. Colbert complained of it, when Mezeray promised to correct what he had done in a second edition; but those corrections being only palliations, the minister caused half of his pension to be suppressed. Mezeray complained of this in very severe terms; when he obtained no other answer than the suppression of the other half. Vexed at this treatment, he resolved to write on subjects that could not expose him to such disappointments; and composed his treatise on the origin of the French, which did him much honour. He was elected perpetual secretary to the French academy; and died in 1683. He is said to have been a man extremely negligent in his person, and so careless in his dress, that he might have passed for a begger rather than for what he was. He was actually seized one morning by the *archers des pauvres*, or parish officers; which mistake was so far from provoking him, that he was highly diverted with it, and told them, that "he was not able to walk on foot, but that as soon as a new wheel was put to his chariot, he would attend them wherever they thought proper." He used to study and write by candle light, even at noon-day in summer; and, as if there had been no sun in the world, always

always waited upon his company to the door with a candle in his hand. With regard to religion, he affected Pyrrhonism; which however was not, it seems, so much in his heart as in his mouth. This appeared from his last sickness; for having sent for those friends who had been the most usual witnesses of his licentious talk about religion, he made a sort of recantation, which he concluded with desiring them "to forget what he might formerly have said upon the subject of religion, and to remember, that Mezeray dying was a better believer than Mezeray in health." Besides his history, he also wrote, 1. A continuation of the history of the Turks. 2. A French translation of John de Salisbury's Latin treatise on the vanities of the court. 3. There are attributed to him several satires against the government; and in particular, those that bear the name of *Sandricourt*.

MEZIERS, a strong town of France, in the department of Ardennes, with a citadel. It was besieged with a powerful army by Charles V. who was obliged to raise the siege in 1521. It is seated on the river Maese, partly upon a hill, and partly in a valley, in E. Long. 4. 48. N. Lat. 49. 46.

MEZIRIAC, CLAUDE GASPAR BACKET SIEUR DE, one of the most ingenious men of the 17th century, was born at Bresse, of an ancient and noble family. He was a good poet in French, Italian, and Latin; an excellent grammarian, a great Greek scholar, and an admirable critic. He was well versed in the controversies, both in philosophy and religion; and was deeply skilled in algebra and geometry, of the former of which he gave proof by publishing the six books of Diophantus, enriched with a very able commentary and notes. In his youth he spent a considerable time at Paris and at Rome; at which last place he wrote a small collection of Italian poems, in competition with Vaugelas, who was there at the same time; among which there are imitations of the most beautiful similes contained in the first eight books of the Æneid. He also translated Ovid's Epistles; a great part of which he illustrated with very curious commentaries of his own. Whilst he was at Paris, they talked of making him preceptor of Louis XIII. upon which he left the court in great haste, and afterwards declared that he had never felt so much pain upon any occasion of his life; for he seemed to have already upon his shoulders the important weight of the whole kingdom. He undertook the translation of all Plutarch's works, with notes; which he had brought nearly to a conclusion, when he died at Bourg, in Bresse, anno 1638, at 45 years of age. He left behind him several finished works, that were not printed.

MEZUZOTH, in the Jewish customs, certain pieces of parchment, which the Jews fix to the door-posts of their houses, taking that literally which Moses commands them, saying, "Thou shalt never forget the laws of thy God, but thou shalt write them upon the posts of thy house, and on thy gates." This expression means nothing else, but that thou shalt always remember them, whether thou comest into thy house or goest out. But the Hebrew doctors imagined, that the lawgiver meant something more than this. They pretended that, to avoid making themselves ridiculous, by writing the commandments of God without their doors, or rather to avoid exposing themselves to the profanation of the wicked, they ought at least to write them on a parchment, and to enclose it in something. Therefore they wrote these words upon a square piece of parchment prepared on purpose, with a particular ink, and in a square kind of character. Deut. vi. 4, 5, 6, 7, 8, 9. "Hear, O Israel, the Lord our God is one Lord," &c.—Then they left a little space, and afterwards went on, Deut. xi. 13. "And it shall come to pass if thou shalt hearken diligently to my commandments," &c. as far as, "Thou shalt write them upon the door-posts of thy house," &c. After this they rolled up the parchment, and put it into a case of reeds or other matter; they wrote on the end of the case the word *Shaddai*, which is one of the names of God; and they put it at the doors of their houses, chambers, and all places most frequented; they fixed it to the knockers of the door, on the right side; and as often as they entered in or went out they touched it in this place, with the end of their finger, which they afterwards kissed out of devotion. The Hebrew word *mezuza* properly signifies the door-posts of a house; but it is also given to this roll of parchment now mentioned.

MEZZOTINTO, a particular manner of representing figures on copper, so as to form prints in imitation of painting in Indian ink. See ENGRAVING.

The invention of this art has been usually attributed to Prince Rupert. But Baron Heinikin, a very judicious and accurate writer upon the subject of engraving, asserts, with great appearance of truth, that it was a lieutenant-colonel de Siegan, an officer in the service of the landgrave of Hesse, who first engraved in this manner: and that the print which he produced was a portrait of the princess Amelia Elizabeth of Hesse, engraved in the year 1643. Prince Rupert learned the secret from this gentleman, and brought it into England when he came over the second time with Charles II. Prince Rupert's print of An Executioner holding a Sword in one Hand and a Head in the other, a half length, from Spagnoletto, is dated 1658. This art has never been cultivated with success in any country but England.

The prince laid his grounds on the plate with a channelled roller: but one Sherwin, about the same time, laid his grounds with a half-round file, which was pressed down with a heavy piece of lead. Both these grounding tools have been laid aside for many years; and a hand tool, resembling a shoe-maker's cutting board knife, with a fine crenelling on the edge, was introduced by one Edial, a smith by trade, who afterwards became a mezzotinto painter.

It is very different from the common way of engraving. To perform it, they rake, hatch, or punch, the surface of the plate all over with a knife, or instrument made for the purpose, first one way, then the other, across, &c. till the surface of the plate be thus entirely furrowed with lines or furrows, close and as it were contiguous to each other; so that, if an impression was then taken from it, it would be one uniform blot or smut. This done, the design is drawn or marked on the same face; after which, they proceed with burnishers, scrapers, &c. to expunge and take out the dents or furrows, in all parts where the lights of the piece are to be; and that more or less as the lights are to be stronger or fainter; leaving those parts

Mezzotinto.

parts black which are to represent the shadows or deepenings of the draught.

As it is much easier to scrape or burnish away parts of a dark ground corresponding with the outline of any design sketched upon it, than to form shades upon a light ground by an infinite number of hatches, strokes, and points, which must all terminate with exactness on the outline, as well as differ in their force and manner; the method of scraping, as it is called, in mezzotinto, consequently becomes much more easy and expeditious than any other method of engraving. The instruments used in this kind of engraving are cradles, scrapers and burnishers.

In this engraving, the plate must be prepared and polished in the same manner as for other engraving; and afterwards divided equally by lines parallel to each other, and traced out with very soft chalk.—The distance of these lines should be about one-third of the length of the face of the cradle which is to be used, and these lines should be marked with capital letters, or strokes of the chalk. The cradle is then to be placed exactly betwixt the two first lines, and passed forwards in the same direction; being kept as steady as possible, and pressed upon with a moderate force. The same operation must be repeated with respect to all other lines; till the instrument has thus passed over the whole surface of the plate.—Other lines must be then drawn from the extremities of the other two sides, in the same manner; which, intersecting the first at right angles, will with them form squares; and the same operation must be repeated with the cradle as in the case of the first. New lines must then be drawn diagonally, and the cradle passed betwixt them as before; and when the first diagonal operation is performed, the lines must be crossed at right angles as the former, and the cradles passed betwixt them in the same manner.—The plate having undergone the action of the cradle, according to the disposition of the first order of lines, a second set must be formed, having the same distances from each other as the first. But they must be so placed as to divide those already made into spaces one-third less than their whole extent; i. e. every one after the first on each side will take in one-third of that before it, e. g. beginning at A, of which the first third must be left out; a third of B will consequently be taken in, and so of the rest. These lines of the second order must be marked with small letters, or lesser strokes, to distinguish them from the first: and the same treatment of the plate must be pursued with respect to them as was practised for the others. When this second operation is finished, a third order of lines must be made, the first of which, e. g. in A, must omit two-thirds of it, and consequently take in two-thirds of B, &c. By these means, the original spaces will be exactly divided into equal thirds; and the cradle must be again employed betwixt these lines as before.—When the whole of this operation is finished, it is called *one turn;* but in order to produce a very dark and uniform ground, the plate must undergo the repetition of all these several operations for above twenty times; beginning to pass the cradle again betwixt the first lines, and proceeding in the same manner through all the rest. When the plate is prepared with a proper ground, the sketch must be chalked on it, by rubbing the paper on the backside with chalk. It is also proper to overtrace it afterwards with black lead or Indian ink. The scraping is then performed, by paring or cutting away the grain of the ground in various degrees; so that none of it is left in the original state except in the touches of the strongest shade. The general manner of proceeding is the same as drawing with white upon black paper. The masses of light are first begun with; and those parts which go off into light in their upper part, but are brown below: the reflections are then entered upon; after which the plate is blackened with a printer's blacking ball made of felt, in order to discover the effect: and then the work is proceeded with; observing always to begin every part in the places where the strongest lights are to be.

The art of scraping mezzotintos has been applied to the printing with a variety of colours, in order to produce the resemblance of paintings. The inventor of the method of doing this was J. C. Le Blon, a native of Frankfort, and pupil of Carlo Marata, between the years 1720 and 1730. It was established by the inventor on this principle, that there are three primitive colours, of which all the rest may be composed by mixing them in various proportions; that any two of these colours being mixed together, preserve their original power, and only produce a third colour such as their compound must necessarily give; but if transparent colours be mixed, and three primitive kinds compounded together, they destroy each other, and produce black, or a tendency to it, in proportion to the equality or inequality of the mixture; and that if, therefore, these three colours be laid, either separately or upon each other, by three plates, engraved correspondently on these principles to the colouring of the design, the whole variety of teints necessary may be produced. The requisites, therefore, to the execution of any design in this method of printing are as follows: 1. To settle a plan of the colouring to be imitated; showing where the presence of each of the three simple colours is necessary, either in its pure state or combined with some other, to produce the effect required; and to reduce this plan to a painted sketch of each, in which not only the proper outlines, but the degree of strength should be expressed. 2. To engrave three plates according to this plan, which may print each of the colours exactly in the places where, and proportion in which, they are wanted. 3. To find three transparent substances proper for printing with these three primitive colours. The manner in which M. le Blon prepared the plates was as follows: The three plates of copper were first well fitted with respect to size and figure to each other, and grounded in the same manner as those designed for mezzotinto prints: and the exact place and boundary of each of the three primitive colours, conformably to the design, were sketched out on three papers, answering in dimensions to the plate. These sketches were then chalked on the plates; and all the parts of each plate that were not to convey the colour to which it was appropriated to the print, were entirely scraped away, as in forming the light of mezzotinto prints. The parts that were to convey the colours were then worked upon; and where the most light or diluted teints of the colour were to be, the grain in the ground was proportionably taken off; but where the full

Mezzotinto || Micah.

full colour was required, it was left entire. In this regard was had, not only to the effects of the colour in its simple state, but to its combined operation, either in producing orange-colour, green, or purple, by its admixture with one alone; and likewise to its forming brown, gray, and shades of different degrees, by its co-operation with both the others. But though the greatest part of the engraving was performed in the mezzotinto manner, yet the graver was employed occasionally for strengthening the shades, and for correcting the outline where it required great accuracy and steadiness. It was found necessary sometimes to have two separate plates for printing the same colour, in order to produce a stronger effect: but the second plate, which was used to print upon the first, was intended only to glaze and soften the colours in particular parts that might require it. With respect to the black and brown teints, which could not be so conveniently produced in a due degree by the mixture of the colours, umber and black were likewise used.

With respect to the order in which the plates are to be applied, it may be proper to observe, that the colour which is least apparent in the picture should be laid on first; that which is betwixt the most and least apparent next; and that which predominates last; except where there may be occasion for two plates for the same colour, as was before mentioned; or where there is any required for adding browns and shades.

M. le Blon applied this art to portraits, and showed, by the specimens he produced, the possibility of its being brought, by farther improvements, to afford imitations of painting which might have some value. It is nevertheless much better adapted to the simpler subjects, where there are fewer intermixtures of colours; and where the accuracy of the reflections, and demi-teints, are not so essentially necessary to the truth of the design, from the greater latitude of form, and disposition of the colour, as in plants, anatomical figures, and some subjects of architecture. But perhaps plates engraved or rather finished with the tool, particularly with respect to the outline, would be better accommodated in some of these cases than those prepared only by scraping.

M. Cochin remarks at the end of an account he has given of M. le Blon's manner, that though this ingenious artist confined his method principally to the use of three colours; yet, should this invention be again taken up and cultivated, there would be more probability of success in using a greater variety; and that several different kinds might be printed by one plate, provided they were laid on in their respectively proper places by printing-balls, which should be used for that colour only. His hint might however be very greatly improved, by the further assistance of pencils, accommodated to the plates, for laying on the colours in the proper parts.—For the method of taking off mezzotinto prints on glass, see *Back-painting*.

MIASMA, among physicians, a particular kind of effluvia, by which certain fevers, particularly intermittents, are produced.

MICA, *Muscovy glass*, or *Glimmer*, a species of mineral substance. See Mineralogy *Index*.

MICAH, or *The Book of Micah*, a canonical book of the Old Testament, written by the prophet Micah, who is the sixth of the twelve lesser prophets. He is cited by Jeremiah, and prophesied in the days of Jotham, Ahaz, and Hezekiah. He censures the reigning vices of Jerusalem and Samaria, and denounces the judgments of God against both kingdoms. He likewise foretels the confusion of the enemies of the Jews, the coming of the Messiah, and the glorious success of his church.

Micah, Michael.

MICHAEL, or Michel, (i. e. *who is like to God?*) The scripture account of Michael is, that he was an archangel, who presided over the Jewish nation, as other angels did over the Gentile world, as is evident of the kingdoms of Persia and Greece, (Dan. x. 13.): that he had an army of angels under his command (Rev. xii. 7.); that he fought with the Dragon, or Satan and his angels; and that, contending with the Devil, he disputed about the body of Moses, (Jude 9.). As to the combat between Michael and the Dragon, some authors understand it literally, and think it means the expulsion of certain rebellious angels, with their head or leader, from the presence of God. Others take it in a figurative sense; and refer it, either to the contest that happened at Rome between St Peter and Simon Magus, in which the apostle prevailed over the magician, or to those violent persecutions under which the church laboured for three hundred years, and which happily ceased when the powers of the world became Christian. Among the commentators who maintain the former opinion is Grotius; and among those who take it in a figurative sense are Hammond and Mede.

The contest about the body of Moses is likewise taken both literally and figuratively. Those who understand it literally are of opinion, that Michael by the order of God hid the body of Moses after his death; and that the Devil endeavoured to discover it, as a fit means to entice the people to idolatry, by a superstitious worship of his relics. But this dispute is figuratively understood to be a controversy about rebuilding the temple, and restoring the service of God among the Jews at Jerusalem; the Jewish church being fitly enough styled the body of Moses. It is thought by some, that this story of the contest between Michael and the Devil was taken by St Jude out of an apocryphal book called *The Assumption of Moses*.

The Romish church celebrates three appearances of Michael, of which no mention is made in scripture, and which have happened, they say, a long time after the age of the apostles. The first appearance of this archangel was at Colossæ in Phrygia, but at what time is uncertain. The second is that of Mount Garganus, in the kingdom of Naples, about the end of the fifth century. The third is his appearance to Aubert bishop of Avranches, upon a rock called the *Tomb*, where at this day is the abbey of St Michael. This was about the year 706. The first of these festivals is observed on the 6th of September, the second on the 6th of May, and the last on the 16th of October. It has been supposed, that it was Michael the archangel who conducted the Israelites in their journey through the wilderness, (see Exod. xxxii. 20, 23, and xxxiii. 2.); that it was he who appeared to Moses in the burning bush; who appeared to Joshua in the fields of Jericho, and to Gideon and Manoah the father of Samson;

and,

Michael.

and, in a word, to him have been imputed the greatest part of the most remarkable appearances either in the Old or New Testament.

Michael Angelo. See Angelo.

Mount Michael, formerly one of the most celebrated state prisons of France, lies about 20 miles from Granville. It is a rock situated in the middle of the bay of Avranches; and is only accessible at low water. Nature has completely fortified one side, by its craggy and almost perpendicular descent, which renders it impracticable to mount it by any address or courage, however consummate. The other parts are surrounded by walls fenced with semilunar towers after the Gothic manner; but sufficiently strong, together with the advantage of its situation, to render it impregnable to any attack. At the foot of the mountain begins a street or town, which winds round its base to a considerable height. Above are chambers where state prisoners are kept, and where there are other buildings intended for residence. On the summit is erected the abbey itself, occupying a prodigious space of ground, and of a strength and solidity equal to its enormous size; since it has for many centuries withstood all the injuries of the weather, to which it is so much exposed. In an apartment, called the *Sale de Chavalerie*, the knights of St Michael used to meet in solemn convocation on important occasions. They were the defenders and guardians of this mountain and abbey, as those of the Temple, and of St John of Jerusalem, were of the holy sepulchre. The hall in which they met is very spacious, but rude and barbarous. At one end is a painting of the archangel, the patron of their order; and in this hall Louis XI. first instituted and invested with the insignia of knighthood the chevaliers of the cross of St Michael. There is a miserable dark apartment, or rather dungeon, in which many eminent persons were formerly confined. In the middle of it is a cage, composed of prodigious bars of wood; and the wicket which gives entrance into it is 10 or 12 inches in thickness. The inside of it comprises about 12 or 14 feet square, and it is nearly 20 in height. Towards the latter end of the 17th century, a newswriter in Holland, who had presumed to print some very severe and sarcastic reflections on Madame de Maintenon, was confined in this place. Some months after his publication, he was induced, by a person sent expressly for that purpose, to make a tour into French Flanders. The moment he had quitted the Dutch territories, he was put under arrest; and immediately, by his majesty's express command, conducted to Mount Michael, where he was shut up in this cage. Here he lived upwards of 23 years; and here he at length expired. During the long nights of winter, no candle or fire was allowed him. He was not permitted to have any book. He saw no human face, except the gaoler, who came once every day to present him, through a hole in the wicket, with his little portion of bread and wine. No instrument was given him with which he could destroy himself: but he found means at length to draw out a nail from the wood, with which he engraved, or cut on the bars of his cage, certain fleurs de lis and armorial bearings, which formed his only employment and recreation. They are very curiously performed considering the rudeness of his instrument.

The subterraneous chambers in this mountain are said to be so numerous, that the gaolers themselves do not know them. There are certain dungeons called *aubliettes*, into which they were accustomed anciently to let down malefactors guilty of very heinous crimes: they provided them with a loaf of bread and a bottle of wine, and then they were totally forgotten, and left to perish by hunger in the dark vaults of the rock. This punishment, however, has not been inflicted by any king in the last or present century.

Here also is a remarkable chamber, in one corner of which is a kind of window: between this and the wall of the building is a very deep space, of near 100 feet perpendicular, at the bottom of which is another window opening to the sea. It is called the *Hole of Montgomeri*; and the history of it is as follows: In the year 1559, Henry II. king of France was unfortunately killed at a tournament by the count de Montgomeri *. He was a Huguenot; and having escaped the massacre of Paris, made head against the royal forces in Normandy, supported by Queen Elizabeth with arms and money. Being driven from his fortresses in these parts, he retired to a rock called the *Tombelaine*: This is another similar to Mount Michael; only three quarters of a league from it, and of nearly equal dimensions. At that time there was a castle upon it, which has since been demolished, and of which scarce any vestiges now remain. From this fortress, accessible only at low-water, he continually made excursions, and annoyed the enemy, who never dared to attack him. He coined money, laid all the adjacent country under contribution, and rendered himself universally dreaded. Desirous, however, to surprise Mount Michael, he found means to engage one of the monks resident in the abbey; who promised to give him the signal for his enterprise by displaying a handkerchief. The monk having made the signal, betrayed him, and armed all his associates, who waited Montgomeri's arrival. The chieftan came, attended by 50 chosen soldiers, all desperate, and capable of any attempt. They crossed the sand; and having placed their sealing-ladders, mounted one by one. As they came to the top, they were despatched, each in turn, without noise. Montgomeri, who followed last, discovered the perfidy, and escaped with only two of his men, with whom he regained the Tombelaine. They preserve with great care the ladders and grappling irons used on this occasion. The count was at last besieged and taken prisoner, by the mareschal de Matignon, in 1574, at Domfront, in Normandy; and Catharine de Medicis, who hated him for having been, though innocently, the cause of her husband's death, caused him to be immediately executed.

* See *France*, N° 140.

The church of Mount Michael is a great curiosity. It stands on nine pillars of most enormous dimensions, built on the solid rock. Each of them appears to be about 25 feet in circumference: besides these, there are two others much inferior in size, on which the centre of the church rests, and over which is the tower. The following is the legendary account of the origin of this church: In the reign of Childibert II. there was a bishop of Avranches named *St Aubert*. To this holy man the archangel Michael was pleased to appear one night, and ordered him to go to this rock to build a church. St Aubert treated this as a dream; upon which the angel appeared a second time; and being still disobeyed,

disobeyed, he returned a third time, when, by way of imprinting his command upon the saint's memory, he made a hole in his skull by touching it with his thumb. The skull is still preserved in the treasury of the church. It is enclosed in a little shrine of gold, and a crystal, which opens over the orifice, admits the gratification of curiosity by the minutest examination of it. The hole is of a size and shape proportionable to the thumb said to have produced it; but it is impossible to determine whether it has been really made by a knife or any other way. It is not to be supposed that the saint would forget such a sensible mark of the angel's displeasure; he therefore immediately repaired to the rock, and constructed a small church, as he had been commanded. Here, however, true history supplies the place of fable; and informs us, that it was in 966 when Richard the second duke of Normandy began to build the abbey. It was completed about the year 1070, under William the Conqueror, though many other additions were made by succeeding abbots.

In the treasury of the church are innumerable other relics: among which some few have a real and intrinsic value. There is a fine head of Charles VI. of France, cut in a crystal, and the representation of a cockle-shell in gold, weighing many pounds, given by Richard II. duke of Normandy, when he founded the abbey. There is an arm said to belong to *St Richard* king of England; but who this saint was it must be very difficult to determine. Such is the history of the prison, abbey, and church of Mount Michael previous to the revolution; they have probably undergone some changes since that period.

St MICHAEL'S, a borough town of Cornwall, between St Columb and Truro, 247 miles from London. Though one of the oldest boroughs in the county by prescription, and of great note in the Saxon times, it is a mean hamlet in the parishes of Newland and St Enidore; yet it is governed by a portreeve, chosen yearly by a jury of the chief inhabitants, out of the six chief tenants, called deputy lords of the manor, because they hold lands in the borough. Here is no market, but two fairs. A court-leet is held here twice a-year. This place was formerly called Modishole, and afterwards Michael. Its list of members begins in the 6th of Edward VI.

St Michael's Mount, in the county of Cornwall, in the corner of Mount's Bay, is a very high rock, only divided by the tide from the main land, so that it is land and island twice a-day. The town here was burnt by the French in the reign of King Henry VIII. At the bottom of this mount, in digging for tin, there have been found spear heads, battle axes, and swords, of brass, all wrapt up in linen. The county is contracted here into a sort of isthmus, so that it is scarcely four miles between the Channel and the Severn sea.—Large trees have been driven in by the sea between this mount and Penzance.

MICHAELIS, John David, a celebrated biblical critic, and author of many esteemed works, was the eldest son of Dr Christian Benedict Michaelis, professor in the university of Halle in Lower Saxony, and was born at that place, Feb. 27. 1717. His father devoted him at an early age to an academical life; and with that view he received the first part of his education in a celebrated Prussian seminary, called the *Orphan house*, at Glanche, in the neighbourhood of his native place. He commenced his academical career at Halle in 1733, and took his master's degree in the faculty of philosophy in 1739. In 1741 he made an excursion to this country, where his superior knowledge of the oriental languages, which was considerably increased by his indefatigable researches in the Bodleian library at Oxford, introduced him to the acquaintance, and gained him the esteem, of our first literary characters; with several of whom, and particularly Bishop Lowth, he was in correspondence for many years. On his return to Halle, after an absence of fifteen months, he began to read lectures on the historical books of the Old Testament, which he continued after his removal to Gottingen in 1745. In 1746 he was appointed professor extraordinary, and soon after professor of philosophy, in that university. The next year he obtained a place of secretary to the Royal Society there, of which he was director in 1761, and was soon afterwards made aulic counsellor by the court of Hanover. In 1764 his distinguished talents, but chiefly a publication relative to a journey to Arabia, which was undertaken by several literary men, at the expence of the king of Denmark, in consequence of his application by means of Count Bernsdorf, procured him the honour of being chosen a correspondent, and afterwards foreign member of the Academy of Inscriptions at Paris, of whom the institution admitted only eight; and in the same year he became a member of the society of Haerlem. In 1775, Count Hopkin, who eighteen years before had prohibited the use of his writings at Upsal, when he was chancellor of that university, prevailed on the king of Sweden to confer on him the order of the Polar Star, as a national compensation. In 1786 he was raised to the distinguished rank of privy counsellor of justice by the court of Hanover; and in 1788 received his last literary honour, by being unanimously elected a fellow of the Royal Society of London.—His great critical knowledge of the Hebrew language, which he displayed in a new translation of the Bible, and in other works, raised him to a degree of eminence almost unknown before in Germany; and his indefatigable labours were only equalled by his desire of communicating the knowledge he acquired to the numerous students of all countries who frequented his admirable lectures, which he continued to deliver on various parts of the sacred writings in half-yearly courses, and on the Hebrew, Arabic, and Syriac languages, to the last year of his life. He was professor in the university of Gottingen 45 years, and, during that long period, he filled the chair with dignity, credit, and usefulness. He died October 22. 1791, aged 74. He is said to have left behind him several valuable MSS. Of the works that were published during his life-time, and which are very numerous, a catalogue, in the order of their publication, is given in the *Gentleman's Magazine* for March 1792.

MICHAELMAS, or *Feast of St Michael and all Angels*, a festival of the Christian church, observed on the 29th of September. See Michael.

MICKLE, William Julius, the celebrated translator of the Lusiad, was the son of the reverend Alexander Mickle a Scotish clergyman, who had formerly been a dissenting minister in London, an assistant to the reverend Dr Watts, and one of the translators of Bayle's Dictionary.

Mickle.

Dictionary. This gentleman having resided a few years in London, was presented to the church of Langholm in Scotland, where he married; and our author was one of the younger sons. He was born about the year 1735, and was educated by his father. In his early years his passion for poetry frequently discovered itself; though till the age of 13 he did not show any particular attachment to books. At that time having accidentally met with Spenser's Faery Queen, he became enamoured of his manner of writing, and instantly began to imitate him. After the death of his father, he came to Edinburgh to reside with his uncle who was a brewer there, and who admitted him into a share of his business; not being qualified to succeed in this line, he went to London about the time of the conclusion of the war which began in 1755, with a view to procure a commission in the marine service. Here he was disappointed; but introduced himself to the first Lord Lyttelton, to whom he sent one of his poems. From his Lordship, however, he received no other favour than being admitted to several interviews, and encouraged to persevere in his poetical plans.

So closely did our author cultivate the study of the muses, that before he was 18 years of age he had written two tragedies and half an epic poem; but all these were committed to the flames. The first of his poems which appeared in print was published in one of the Edinburgh magazines, and entitled, "On passing through the Parliament Close of Edinburgh at Midnight." This was afterwards inserted in A Collection of Original Poems by a Scotch gentleman, vol. ii. p. 137.

From the time of Mr Mickle's arrival in London till the year 1765, it is not known how he employed his time, though it is probable that he was employed in some branch of the printing business; and in 1765 he engaged himself as corrector to the Clarendon press. This year he published the Poem which first brought him into notice, entitled, "Pollio, an Elegiac Ode, written in the Wood near R—— (Roslin) Castle," 4to. This was an elegy written on the death of his brother, which, previous to its publication, had been shown to Lord Lyttelton, and received some corrections from him. The latter, in an epistle to the author, spoke of it as equal to any thing of the kind in our language. In 1767 he published a poem called "The Concubine, in two cantos, after the manner of Spencer," 4to; and in 1769 he published, "A Letter to Mr Harwood, wherein some of his evasive glosses, false translations, and blundering criticisms, in support of the Arian Heresy, contained in his literal translation of the New Testament, are pointed out and confuted," 8vo: and next year he published "Mary Queen of Scots, an Elegy;" "Hengist and Mary, a ballad;" and "Knowledge, an Ode;" in Pearch's Collection of Poems. In 1770 he published "Voltaire in the Shades, or Dialogues on the Deistical Controversy," 8vo. The Elegy on Mary had been submitted to the judgment of Lord Lyttelton, who declined to criticise it, not for its deficiency in poetical merit, but from thinking differently from the author concerning that unfortunate princess.

About this time Mr Mickle was a frequent writer in the Whitehall Evening Post; but a more important work now engaged his attention. When no more than 17 years of age he had read Castara's translation of the Lusiad of Camoens into French, and then projected the design of giving an English translation of it. From this, however, he was prevented by various avocations till the year 1771, when he published the first book as a specimen: and having prepared himself by acquiring some knowledge of the Portuguese language, he determined to apply himself entirely to this work. With this view he quitted his residence at Oxford, and went to a farm house at Forest-hill, where he pursued his design with unremitting assiduity till the year 1775, when the work was entirely finished.

During the time that Mr Mickle was engaged in this work, he subsisted entirely by his employment as corrector of the press; and on his quitting that employment he had only the subscriptions he received for his translation to support him. Notwithstanding these difficulties, he adhered steadily to the plan he laid down, and completed it in about five years.

When his work was finished, Mr Mickle applied to a person of great rank, with whom his family had been connected, for permission to dedicate it to him. Permission was granted, and his patron honoured him with a very polite letter; but after receiving a copy, for which an extraordinary price was paid for the binding, he did not think proper to take any notice of the author. At last a gentleman of high rank in the political world, a firm friend to the author, and who afterwards took him under his protection, waited on the patron, and heard him declare that he had not read the work, but that it had been represented not to have the merit it was at first said to possess. The applause with which the work was received, however, soon banished from the author's mind those disagreeable sensations which had been occasioned by the contemptuous neglect of his patron, as well as some severe criticisms which had been circulated concerning it. A second edition was prepared in 1778, with a plate prefixed to it, executed by the celebrated artist Mortimer; on whom Mr Mickle wrote an epitaph in 1779. This year also he published a pamphlet, entitled, "A Candid Examination of the Reasons for depriving the East India Company of its Charter, contained in The History and Management of the East India Company from its Commencement to the Present Time; together with some Strictures on the Self-Contradictions and Historical Errors of Dr Adam Smith, in his Reasons for the Abolition of the said Company," 4to. About this time some of his friends thought of recommending him to the king as deserving of a pension; but this scheme was never put in execution. Dr Lowth, bishop of London, would have put him into orders, and provided for him in the church; but this was not agreeable to our author's disposition. While he was meditating a publication of all his poems, in which he would most probably have found his account, he was appointed secretary to Commodore Johnstone, who had lately obtained the command of the Romney man of war. In November 1779 he arrived at Lisbon, and was named by his patron joint agent for the prizes which were taken. In this capital and its neighbourhood he resided more than six months, being every where received with every mark of politeness and attention;

Mickle || Micrometer.

tention; and during this period he composed his poem called "Almada Hill," which in 1781 was published in quarto. He collected also many particulars concerning the manners of the Portuguese, which he intended also to have published. During his stay at Lisbon the Royal Academy was opened; and Mr Mickle, who was present at the ceremony of its commencement, had the honour to be admitted a member under the presidency of Don John of Braganza, duke of Lafoens. His presence being thought necessary in England to attend to the proceedings of the courts of law respecting the condemnation of some of the prizes, he did not accompany the Commodore in his last expedition, nor did he go any more to sea. In 1782 he published "The Prophecy of Queen Emma, an ancient Ballad lately discovered, written by Johannes Turgottus, prior of Durham, in the reign of William Rufus; to which is added by the Editor, an Account of the Discovery, and Hints towards a Vindication of the Authenticity, of the Poems of Ossian and Rowley," 8vo.

In June this year Mr Mickle married Miss Tomkins, daughter of the person with whom he resided at Forest-hill, while engaged in translating the Lusiad. Having received some fortune with this lady, as well as made some money himself when in the service of Commodore Johnstone, he now enjoyed a comfortable independence. He afterwards fixed his residence at Wheatley in Oxfordshire, and devoted his time to the revision of his poetical works, which he proposed to publish by subscription. During the last seven years of his life he was employed in writing for the European Magazine. The Fragments of Leo, and some of the most approved reviews of books, in that periodical work, were of his production. He died after a short illness, on the 25th of October 1788, at Wheatley, leaving one son behind him. His poetry possesses much beauty, variety, harmony of numbers, and vigour of imagination: his life was without reproach; his foibles were few and inoffensive; his virtues many; and his genius very considerable.

MICROCOSM, a Greek term signifying the *little world;* used by some for *man*, as being supposed an epitome of the universe or great world.

MICROGRAPHY, the description of objects viewed with the assistance of a microscope. See *Microscopic objects*.

MICROMETER, an astronomical instrument, by which small angles, or the apparent magnitudes of objects viewed through telescopes or microscopes are measured with great exactness.

Micrometer first invented by Gascoigne.

1. The first TELESCOPIC micrometers were only mechanical contrivances for measuring the image of an object in the focus of the object-glass. Before these contrivances were thought of, astronomers were accustomed to measure the field of view in each of their telescopes, by observing how much of the moon they could see through it, the semidiameter being reckoned at 15 or 16 minutes; and other distances were estimated by the eye, comparing them with the field of view. Mr Gascoigne, an English gentleman, however, fell upon a much more accurate method before the year 1641, and had a Treatise on Optics prepared for the press; but he was killed during the civil wars in the service of Charles I. and his manuscript was never found. His instrument, however, fell into the hands of Mr R. Townly *, who says, that by the help of it he could mark above 40,000 divisions in a foot.

* Phil. Trans. No 25.

2. Mr Gascoigne's instrument being shown to Dr Hooke, he gave a drawing and description of it, and proposed several improvements†. Mr Gascoigne divided the image of an object in the focus of the object-glass, by the approach of two pieces of metal ground to a very fine edge, in the place of which Dr Hooke would substitute two fine hairs stretched parallel to one another.

† See *Phil. Trans. Abr.* vol. i. p. 217. *Hooke's Posthumous Works*, p. 497, 498; and *Phil. Trans.* vol. xlviii. p. 190.

Huygens's micrometer.

3. Mr Huygens measured the apparent diameters of the planets, by first determining the quantity of the field of view in his telescope; which, he says, is best done by observing the time that a star takes up in passing over it, and then preparing two or three long and slender brass plates, of various breadths, the sides of which are very straight, and converging to a small angle. In using these pieces of brass, he made them slide in two slits, made in the sides of the tube, opposite to the place of the image, and observed in what place it just covered the diameter of any planet, or any small distance that he wanted to measure ‡. It was observed, however, by Sir Isaac Newton, that the diameters of planets, measured in this manner, will be larger than they should be, as all lucid objects appear to be when they are viewed upon dark ones.

‡ *Systema Saturnium*, p. 82.

Marquis of Malvasia's micrometer.

4. In the Ephemerides of the Marquis of Malvasia, published in 1662, it appears that he had a method of measuring small distances between fixed stars and the diameters of the planets, and also of taking accurate draughts of the spots of the moon by a net of silver wire, fixed in the focus of the eye-glass. He likewise contrived to make one of two stars pass along the threads of this net, by turning it, or the telescope, as much as was necessary for that purpose; and he counted, by a pendulum-clock, beating seconds, the time that elapsed in its passage from one wire to another, which gave him the number of minutes and seconds of a degree contained between the intervals of the wires of his net, with respect to the focal length of his telescope.

Auzout's micrometer.

5. In 1666, Messrs Auzout and Picard published a description of a micrometer, which was nearly the same with that of the Marquis of Malvasia, excepting the method of dividing it, which they performed with more exactness by a screw. In some cases they used threads of silk, as being finer than silver wires. Dechales also recommends a micrometer consisting of fine wires, or silken threads, the distances of which were exactly known, disposed in the form of a net, as peculiarly convenient for taking a map of the moon.

De la Hire's micrometer.

6. M. de la Hire says, that there is no method more simple or commodious for observing the digits of an eclipse than a net in the focus of the telescope. These, he says, were generally made of silken threads; and that for this particular purpose six concentric circles had also been made use of, drawn upon oiled paper; but he advises to draw the circles on very thin pieces of glass with the point of a diamond. He also gives several particular directions to assist persons in the use of them.

Common micrometer.

7. *Construction of Different Micrometers.* The first we shall describe is the common micrometer. Let ABCD be a section of the telescope at the principal focus of the object-glass

Micrometer. Plate CCCXXXV. Fig. 1. object-glass, or where the wires are situated, which are placed in a short tube containing the eye-glass, and may be turned into any position by turning that tube; $m n$ is a fine wire extended over its centre; vw, xy, are two parallel wires well defined, and perpendicular to mn; vw is fixed, and xy moves parallel to it by means of a screw, which carries two indexes over a graduated plate, to show the number of revolutions and parts of a revolution which it makes. Now to measure any angle, we must first ascertain the number of revolutions and parts of a revolution corresponding to some known angle, which may be thus done: 1st, Bring the inner edges of the wires exactly to coincide, and set each index to 0; turn the screw, and separate the wires to any distance; and observe the time a star m is in passing along the wire $m n$ from one vertical wire to the other: for that time, turned into minutes and seconds of a degree, will be the angle answering to the number of revolutions, or the angle corresponding to the distance. Thus, if d=cos. of the star's declination, we have $15' \, dm$, the angle corresponding to this distance; and hence, by proportion, we find the angle answering to any other. 2*dly*, Set up an object of a known diameter, or two objects at a given distance, and turn the screw till the vertical wires become tangents to the object, or till their opening just takes in the distance of the two objects upon the wire mn; then from the diameter, or distance of the two objects from each other, and their distance from the glass, calculate the angle, and observe the number of revolutions and parts corresponding. 3*dly*, Take the diameter of the sun on any day, by making the wires tangents to the opposite limbs, and find, from the nautical almanac, his diameter on that day. Here it will be best to take the upper and lower limbs of the sun when on the meridian, as he has then no motion perpendicular to the horizon. If the edges do not coincide when the indexes stand at 0, we must allow for the error. Instead of making a proportion, it is better to have a table calculated to show the angle corresponding to every revolution and parts of a revolution. But the observer must remember, that when the micrometer is fixed to telescopes of different focal lengths, a new table must be made. The whole system of wires is turned about in its own plane, by turning the eye-tube round with the hand, and by that means the wire $m n$ can be thrown into any position, and consequently angles in any position may be measured. Dr Bradley added a small motion by a rack and pinion to set the wires more accurately in any position.

8. But the micrometer, as now contrived, is of use, not only to find the angular distance of bodies in the field of view at the same time, but also of those which, when the telescope is fixed, pass through the field of view successively; by which means we can find the difference of their right ascensions and declinations.

Fig. 2. Let A a, B b, C c, be three parallel and equidistant wires, the middle one bisecting the field of view; HOR a fixed wire perpendicular to them passing through the centre of the field; and F f, G g, two wires parallel to it, each moveable by a micrometer screw, as before, so that they can be brought up to HOR, or a little beyond. Then to find the angular distance of two objects, bring them very near to B b, and in a line parallel to it, by turning about the wires, and bring one upon HOR, and by the micrometer screw make F f or G g pass through the other; then turn the screw till that wire coincides with HOR, and the arc which the index has passed over shows their angular distance. If the objects be further remote than you can carry the distance of one of the wires F f, G g from HOR, then bring one object to F f and the other to G g; and turn each micrometer screw till they meet, and the sum of the arcs passed over by each index gives their angular distance. If the objects be two stars, and one of them be made to run along HOR, or either of the moveable wires as occasion may require, the motion of the other will be parallel to these wires, and their difference of declinations may be observed with great exactness; but in taking any other distances, the motion of the stars being oblique to them, it is not quite so easy to get them parallel to B b; because if one star be brought near, and the eye be applied to the other to adjust the wires to it, the former star will have gotten a little away from the wire. Dr Bradley, in his account of the use of this micrometer, published by Dr Maskelyne in the Philosophical Transactions for 1772, thinks the best way is to move the eye backwards and forwards as quick as possible; but it seems to be best to fix the eye at some point between, by which means it takes in both at once sufficiently well defined to compare them with B b. In finding the difference of declination, if both bodies do not come into the field of view at the same time, make one run along the wire HOR, as before, and fix the telescope and wait till the other comes in, and then adjust one of the moveable wires to it, and bring it up to HOR, and the index gives the difference of their declinations. The difference of time between the passage of the star at either of the cross moveable wires, and the transit of the other star over the cross fixed wire (which represents a meridian), turned into degrees and minutes, will give the difference of right ascension. The star has been here supposed to be bisected by the wire; but if the wire be a tangent to it, allowance must be made for the breadth of the wire, provided the adjustment be made for the coincidence of the wires. In observing the diameters of the sun, moon, or planets, it may perhaps be most convenient to make use of the outer edges of the wires, because they appear most distinct when quite within the limb: but if there should be any sensible inflection of the rays of light in passing by the wires, it will be best avoided by using the inner edge of one wire and the outward edge of the other; for by that means the inflection at both limbs will be the same way, and therefore there will be no alteration of the relative position of the rays passing by each wire. And it will be convenient in the micrometer to note at what division the index stands when the moveable wire coincides with HOR; for then you need not bring the wire when a star is upon it up to HOR, only reckon from the division at which the index then stands to the above division.

The divided object-glass micrometer hinted at by Mr Savery.

9. With a micrometer thus adapted to a telescope, Mr S. Savery of Exeter proposed a new way of measuring the difference between the greatest and least apparent diameters of the sun, although the whole of the sun was not visible in the field of view at once. The method we shall briefly describe. Place two object-glasses instead

Micrometer. instead of one, so as to form two images whose limbs shall be at a small distance from each other; or instead of two perfect lenses, he proposed to cut a single lens into four parts of equal breadths by parallel lines, and to place the two segments with their straight sides against each other, or the two middle frustums with their opposite edges together; in either case, the two parts which before had a common centre and axis, have now their centres and axes separated, and consequently two images will be formed as before by two perfect lenses. Another method in reflectors was to cut the large concave reflector through the centre, and by a contrivance to turn up the outer edges whilst the straight ones remained fixed; by which means the axis of the two parts became inclined, and formed two images. Two images being formed in this manner, he proposed to measure the distance between the limbs when the diameters of the sun were the greatest and least, the difference of which would be the difference of the diameters required. Thus far we are indebted to Mr Savery for the idea of forming two images; and the admirable uses to which it was afterwards applied we shall next proceed to describe.

Improved by Mr John Dollond. 10. The divided object-glass micrometer, as now made, was contrived by the late Mr John Dollond, and by him adapted to the object-end of a reflecting telescope, and has been since by the present Mr P. Dollond his son applied with equal advantage to the end of an achromatic telescope. The principle is this: The object-glass is divided into two segments in a line drawn through the centre: each segment is fixed in a separate frame of brass, which is moveable, so that the centres of the two segments may be brought together by a handle for that purpose, and thereby form one image of an object; but when separated they will form two images, lying in a line passing through the centre of each segment; and consequently the motion of each image will be parallel to that line, which can be thrown into any position by the contrivance of another handle to turn the glass about in its own plane. The brass-work carries a vernier to measure the distance of the centres of the two segments. Now let E and H be the centres of the two segments, F their principal focus, and PQ two distant objects in FE, FH, produced, or the opposite limbs of the same object PBQD; then the images of P and Q, formed by each segment, or the images of the opposite limbs of the object PBQD, coincide at F: hence two images $m\,z\,$F, $n\,x\,$F of that object are formed, whose limbs are in contact; therefore the angular distance of the points P and Q is the same as the angle which the distance EH subtends at F, which, as the angles supposed to be measured are very small, will vary as EH extremely nearly; and consequently if the angle corresponding to one interval of the centres of the segments be known, the angle corresponding to any other will be found by proportion. Now to find the interval for some one angle, take the horizontal diameter of the sun on any day, by separating the images till the contrary limbs coincide, and read off by the vernier the interval of their centres, and look into the nautical almanac for the diameter of the sun on that day, and you have the corresponding angle. Or if greater exactness be required than from taking the angle in proportion to the distances of their centres, we may proceed thus:—Draw FG perpendicular to EH, which therefore bisects it; then one half EH, or EG, is the tangent of half the angle EFH; hence, half the distance of their centres is to the tangent of half the angle corresponding to that distance as half any other distance of the centres is to the tangent of half the corresponding angle (A).

Fig. 3.

11. From this the method of measuring small angles is manifest; for we consider P, Q either as two objects whose images are brought together by separating the two segments, or as the opposite limbs of one object PBQA, whose images formed by the two segments E, H, touch at F; in the former case, EH gives the angular distance of the two objects; and in the latter, it gives the angle under which the diameter of the object appears. In order to find the angular distance of two objects, therefore, separate the segments till the two images which approach each other coincide; and to find the diameter of an object, separate the segments till the contrary limbs of the images touch each other, and read off the distance of the centres of the segment from the vernier (B), and find the angle as directed in the last article. Hence appears one great superiority in this above the wire micrometer; as, with the one any diameter of an object may be measured with the same ease and accuracy; whereas with the other we cannot with accuracy measure any diameter, except that which is at right angles to the direction of motion.

12. But, besides these two uses to which the instrument

(A) If the object is not distant let f be the principal focus; then Ff : FG :: FG : FK (FG being produced to meet a line joining the apparent places of the two objects P, Q,), ∴ dividendo, fG : FG :: GK : FK, and alternando, fG : GK :: FG : FK :: (by similar triangles) EH : PQ, hence $\frac{\text{EH}}{f\text{G}}=\frac{\text{PQ}}{\text{GK}}$, therefore the angle subtended by EH at $f=$ the angle subtended by PQ at G; and consequently, as fG is constant, the angle measured at G is, in this case, also proportional to EH. The instrument is not adapted to measure the angular distance of bodies, one of which is near and the other at a distance, because their images would not be formed together.

(B) To determine if there be any error in the adjustment of the micrometer scale, measure the diameter of any small well-defined object, as Jupiter's equatoreal diameter, or the longest axis of Saturn's ring, both ways, that is, with 0 on the vernier to the right and left of 0 on the scale, and half the difference is the error required. This error must be added to or subtracted from all observations, according as the diameter measured with 0 on the vernier, when advanced on the scale, is less or greater than the diameter measured the other way. And it is also evident, that half the sum of the diameters thus measured gives the true diameter of the object.

Micrometer. ment seems so well adapted, Dr Maskelyne * has shown, how it may be applied to find the difference of right ascensions and declinations. For this purpose, two wires at right angles to each other, bisecting the field of view, must be placed in the principal focus of the eye-glass, and moveable about in their own plane.—Let HCR *c* be the field of view, HR and C *c* the two wires; turn the wires till the westernmost star, (which is the best, having further to move) run along ROH; then separate the two segments, and turn about the micrometer till the two images of the same star lie in the wire C *c*; and then, partly by separating the segments, and partly by raising or depressing the telescope, bring the two innermost images of the two stars to appear and run along ROH, as *a*, *b*, and the vernier will give the difference of their declinations; because, as the two images of one of the stars coincided with C *c*, the image of each star was brought perpendicularly upon HR, or to HR in their proper meridian. And, for the same reason, the difference of their times of passing the wire CO *c* will give their difference of right ascensions. These operations will be facilitated, if the telescope be mounted on a polar axis. If two other wires KL, MN, parallel to C *c*, be placed near H and R, the observation may be made on two stars whose difference of meridians is nearly equal to HR the diameter of the field of view, by bringing the two images of one of the stars to coincide with one of these wires. If two stars be observed whose difference of declinations is well settled, the scale of the micrometer will be known.

* *Phil. Trans.* 1771.

Fig. 4.

13. It has hitherto been supposed, that the images of the two stars can be both brought into the field of view at once upon the wire HOR: but if they cannot, set the micrometer to the difference of their declinations as nearly as you can, and make the image which comes first run along the wire HOR, by elevating or depressing the telescope; and when the other star comes in, if it do not also run along HOR, alter the micrometer till it does, and half the sum of the numbers shown by the micrometer at the two separate observations of the two stars on the wire HOR will be the difference of their declinations. That this should be true, it is manifestly necessary that the two segments should recede equally in opposite directions; and this is effected by Mr Dollond in his new improvement of the object-glass micrometer.

14. The difference of right ascensions and declinations of Venus or Mercury in the sun's disk and the sun's limb may be thus found. Turn the wires so that the north limb *n* of the sun's image AB, or the north limb of the image V of the planet, may run along the wire RH, which therefore will then be parallel to the equator, and consequently C *c* a secondary to it; then separate the segments, and turn about the micrometer till the two images V *v* of the planet pass C *c* at the same time, and then by separating the segments, bring the north limb of the northernmost image V of the planet to touch HR, at the time the northernmost limb *n* of the southernmost image AB of the sun touches it, and the micrometer shows the difference of declinations of the northernmost limbs of the planet and sun, for the reason formerly given (Art. 11.) we having brought the northernmost limbs of the two innermost images V and AB to HR, these two being manifestly interior to *v* and the northernmost limb N of the image PQ. In the same manner we take the difference of declinations of their southernmost limbs; and half the difference of the two measures (taking immediately one after another) is equal to the difference of the declinations of their centres, without any regard to the sun's or planet's diameters, or error of adjustment of the micrometer; for as it affects both equally, the difference is the same as if there were no error: and the difference of the times of the transits of the eastern or western limbs of the sun and planet over C *c* gives the difference of their right ascensions.

Fig. 5.

15. Instead of the difference of right ascensions, the distance of the planet from the sun's limb, in lines parallel to the equator, may be more accurately observed thus: Separate the segments, and turn about the wires and micrometer, so as to make both images V, *v*, run along HR, or so that the two intersections I, T of the sun's image may pass C *c* at the same time. Then bring the planet's and sun's limbs into contact, as at V, and do the same for the other limb of the sun, and half the difference gives the distance of the centre of the planet from the middle of the chord on the sun's disk parallel to the equator, or the difference of the right ascensions of their centres, allowing for the motion of the planet in the interval of the observations, without any regard to the error of adjustment, for the same reason as before. For if you take any point in the chord of a circle, half the difference of the two segments is manifestly the distance of the point from the middle of the chord; and as the planet runs along HR, the chord is parallel to the equator.

Fig. 6.

In like manner, the distances of their limbs may be measured in lines perpendicular to the equator, by bringing the micrometer into the position already described, (Art. 13.), and instead of bringing V to HR, separate the segments till the northernmost limbs coincide as at V; and in the same manner make their southernmost images to coincide, and half the difference of the two measures, allowing for the planet's motion, gives the difference of the declinations of their centres.

Fig. 7.

Hence the true place of a planet in the sun's disc may at any time of its transit be found; and consequently the nearest approach to the centre and the time of ecliptic conjunction may be deduced, although the middle should not be observed.

16. But however valuable the object-glass micrometer undoubtedly is, difficulties sometimes have been found in its use, owing to the alteration of the focus of the eye, which will cause it to give different measures of the same angle at different times. For instance, in measuring the sun's diameter, the axis of the pencil coming through the two segments from the contrary limbs of the sun, as PF, QF, fig. 3. crossing one another in the focus F under an angle equal to the sun's semidiameter, the union of the limbs cannot appear perfect, unless the eye be disposed to see objects distinctly at the place where the images were formed; for if the eye be disposed to see objects nearer to or further off than that place, in the latter case the limbs will

Disadvantage of the object-glass micrometer.

Micrometer.

will appear separated, and in the former they will appear to lap over (c). This imperfection led Dr Maskelyne to inquire, whether some method might not be found of producing two distinct images of the sun, or any other object, by bringing the axis of each pencil to coincide, or very nearly so, before the formation of the images, by which means the limbs when brought together would not be liable to appear separated from any alteration of the eye; and this he found would be effected by the refraction of two prisms, placed either without or within the telescope; and on this principle, placing the prisms within, he constructed a new micrometer, and had one executed by Mr Dollond, which upon trial answered as he expected. The construction is as follows.

Dr Maskelyne's prismatic micrometer. Fig. 8, 9.

17. Let AB be the object-glass; *a b* the image, suppose of the sun, which would have been formed in the principal focus Q; but let the prisms PR, SR be placed to intercept the rays, and let EF, WG, be two rays proceeding from the eastern and western limbs of the sun, converging, after refraction at the lens, to *a* and *b*; and suppose the refraction of the prisms to be such, that in fig. 8. the ray EFR, after refraction at R by the prism PR, may proceed in the direction RQ; and as all the rays which were proceeding to *a* suffer the same refraction at the prism, they will all be refracted to Q; and therefore, instead of an image *a b*, which would have been formed by the lens alone, an image Q *c* is formed by those rays which fall on the prism PR; and for the same reason, the rays falling on the prism SR will form an image Q *d*: and in fig. 9. the image of the point *b* is brought to Q, by the prism PR, and consequently an image Q *d* is formed by those rays which fall on PR: and for the same reason, an image Q *c* is formed by the rays falling on SR. Now in both cases, as the rays EFR, WGR, coming from the two opposite limbs of the sun, and forming the point of contact of the two limbs, proceed in the same direction RQ, they must thus accompany each other through the eye-glass and also through the eye, whatever refractive power it has, and therefore to every eye the images must appear to touch. Now the angle *a* R *b* is twice the refraction of the prism, and the angle *a* C *b* is the diameter of the sun; and as these angles are very small, and have the same subtense *a b*, we have the angle *a* R *b* : angle *a* C *b* :: CQ : RQ.—Now as CQ is constant, and also the angle *a* R *b* being twice the refraction of the prism, the angle *a* C *a* varies as RQ. Hence the extent of the scale for measuring angles becomes the focal length of the object-glass, and the angle measured is in proportion to the distance of the prisms from the principal focus of the object-glass; and the micrometer can measure all angles (very small ones excepted, for the reason given in Art. 19.) which do not exceed the sum of the refractions of the prisms; for the angle *a* C *b*, the diameter of the object to be measured, is always *less* than the angle *a* R *b*, the sum of the refractions of the prisms, except when the prisms touch the object-glass, and then they become *equal*. The scale can never be out of adjustment, as the point o, where the measurement begins, answers to the focus of the object-glass, which is a fixed point for all distant objects, and we have only to find the value of the scale answering to some known angle; for instance, bring the two limbs of the sun's images into contact, and measure the distance of the prisms from the focus, and look in the nautical almanac for the sun's diameter, and you get the value of the scale.

Fig. 8.

18. In fig. 8. the limb Q of the image Q *c*, is illuminated by the rays falling on the object-glass between A and F, and of the image Q *d* by those falling between B and G; but in fig. 9. the same limbs are illuminated by the rays falling between B and F, A and G respectively, and therefore will be more illuminated than in the other case; but the difference is not considerable in achromatic telescopes, on account of the great aperture of the object-glass compared with the distance FG.

It might be convenient to have two sets of prisms, one for measuring angles not exceeding 36′, and therefore fit for measuring the diameters of the sun and moon, and the lucid parts and distances of the cusps in their eclipses; and another for measuring angles not much greater than 1′, for the conveniency of measuring the diameters of the planets. For as Q *c* : QR :: sum of the refractions of the prisms : angle *a* C *b*, the apparent diameter of the object, it is evident that if you diminish the third term, you must increase the second in the same ratio, in order to measure the same angle; and thus by diminishing the refractive angle of the prisms, you throw them further from Q, and consequently avoid the inconvenience of bringing them near to Q, for the reason in the next paragraph; and at the same time you will increase the illumination in a small degree. The prisms must be achromatic, each composed of two prisms of flint and crown glass, placed with their refracting angles in contrary directions, otherwise the images will be coloured.

19. In the construction here described, the angle measured becomes evanescent when the prisms come to the principal focus of the object-glass, and therefore o on the scale then begins: but if the prisms be placed in the principal focus they can have no effect, because the pencil of rays at the junction of the prisms would then vanish, and therefore it is not practicable to bring the two images together to get o on the scale. Dr Maskelyne, therefore, thought of placing another pair of prisms within, to refract the rays *before* they came to the other prisms, by which means the two images would be formed into one before they came to the principal focus, and therefore o on the scale could be determined. But to avoid the error arising from the

(c) For if the eye can see distinctly an image at F, the pencils of rays, of which PF, QF are the two axes, diverging from F, are each brought to a focus on the retina at the same point; and therefore the two limbs appear to coincide: but if we increase the refractive power of the eye, then each pencil is brought to a focus, and they cross each other before the rays come to the retina, consequently the two limbs on the retina will lap over; and if we diminish the refractive power of the eye, then each pencil being brought to a focus beyond the retina, and not crossing till after they have passed it, the two limbs on the retina must be separated.

Micrometer.

the multiplication of mediums, he, instead of adding another pair of prisms, divided the object-glass through its centre, and sliding the segments a little it separated the images, and then by the prisms he could form one image very distinctly, and consequently could determine 0 on the scale; for by separating the two segments you form two images, and you will separate the two pencils so that you may move up the two prisms, and the two pencils will fall on each respectively, and the two images may be formed into one. In the instrument which Dr Maskelyne had made, 0 on the scale was chosen to be about $\frac{2}{7}$ of the focal length of the object-glass, and each prism refracted 27′. By this means all angles are measured down to 0.

20. In the Philosophical Transactions for 1779, Mr Ramsden has described two new micrometers, which he contrived with a view of remedying the defects of the object-glass micrometer.

Ramsden's reflecting micrometer.

21. 1. One of these is a *catoptric* micrometer, which, beside the advantage it derives from the principle of reflection, of not being disturbed by the heterogeneity of light, avoids every defect of other micrometers, and can have no aberration, nor any defect arising from the imperfection of materials or of execution; as the extreme simplicity of its construction requires no additional mirrors or glasses to those required for the telescope; and the separation of the images being effected by the inclination of the two specula, and not depending on the focus of any lens or mirror, any alteration in the eye of an observer cannot affect the angle measured. It has peculiar to itself the advantages of an adjustment, to make the images coincide in a direction perpendicular to that of their motion; and also of measuring the diameter of a planet on both sides of the zero, which will appear no inconsiderable advantage to observers who know how much easier it is to ascertain the contact of the external edges of two images than their perfect coincidence.

Fig. 10.

22. A represents the small speculum divided into two equal parts; one of which is fixed on the end of the arm B; the other end of the arm is fixed on a steel axis X, which crosses the end of the telescope C. The other half of the mirror A is fixed on the arm D, which arm at the other end terminates in a socket *y*, that turns on the axis X; both arms are prevented from bending by the braces *a a*. G represents a double screw, having one part *e* cut into double the number of threads in an inch to that of the part *g*: the part *e* having 100 threads in one inch, and the part *g* 50 only. The screw *e* works in a nut F in the side of the telescope, while the part *g* turns in a nut H, which is attached to the arm B; the ends of the arms B and D, to which the mirrors are fixed, are separated from each other by the point of the double screw pressing against the stud *h*, fixed to the arm D, and turning in the nut H on the arm B The two arms B and D are pressed against the direction of the double screw *e g* by a spiral spring within the part *n*, by which means all shake or play in the nut H, on which the measure depends, is entirely prevented.

From the difference of the threads on the screw at *e* and *g*, it is evident, that the progressive motion of the screw through the nut will be half the distance of the separation of the two halves of the mirror; and consequently the half mirrors will be moved equally in contrary directions from the axis of the telescope C.

23. The wheel V fixed on the end of the double screw had its circumference divided into 100 equal parts, and numbered at every fifth division with 5, 10, &c. to 100, and the index I shows the motion of the screw with the wheel round its axis, while the number of revolutions of the screw is shown by the divisions on the same index. The steel screw at R may be turned by the key S, and serves to incline the small mirror at right angles to the direction of its motion. By turning the finger head T, the eye-tube P is brought nearer or farther from the small mirror, to adjust the telescope to distinct vision; and the telescope itself hath a motion round its axis for the conveniency of measuring the diameter of a planet in any direction. The inclination of the diameter measured with the horizon is shown in degrees and minutes by a level and vernier on a graduated circle, at the breech of the telescope.

Fig. 11.

A correction to be applied to the angle.

24. Besides the table for reducing the revolutions and parts of the screw to minutes, seconds, &c. it will require a table for correcting a small error which arises from the excentric motion of the half mirrors. By this motion their centre of curvature will approach a little towards the large mirror: the equation for this purpose in small angles is insensible; but when angles to be measured exceed ten minutes, it should not be neglected. Or, the angle measured may be corrected by diminishing it in the proportion the versed sine of the angle measured, supposing the eccentricity radius, bears to the focal length of the small mirror.

25. Mr Ramsden preferred Cassegrain's construction of the reflecting telescope to either the Gregorian or Newtonian; because in the former, the errors of one speculum are corrected by those of the other. From a property of the reflecting telescope, not generally known, that the apertures of the two specula are to each other very nearly in the proportion of their focal lengths, it follows, that their aberrations will be in the same proportion; and these aberrations will be in the same direction, if the two specula are concave; or in contrary directions if one speculum is concave and the other convex. In the Gregorian telescope, both specula being concave, the aberration at the second image will be the sum of the aberrations of the two mirrors; but in the Cassegrainian telescope, one mirror being concave and the other convex, the aberration at the second image will be the difference between the two aberrations. By assuming such proportions for the *foci* of the specula as are generally used in the reflecting telescope, which is about as 1 to 4, the aberration in the Cassegrainian construction will be to that in the Gregorian as 3 to 5.

Mr Ramsden's eye-glass micrometer.

26. The other is a *dioptric* micrometer, or one suited to the principle of refraction. This micrometer is applied to the erect eye-tube of a refracting telescope, and is placed in the conjugate focus of the first eye-glass: in which position, the image being considerably magnified before it comes to the micrometer, any imperfection in its glass will be magnified only by the remaining eye-glasses, which in any telescope seldom exceeds five or six times. By this position also the size of the micrometer glass will not be the $\frac{1}{100}$ part of the area which would be required if it was placed in the object-glass; and, notwithstanding this great disproportion

Micrometer.

proportion of size, which is of great moment to the practical optician, the same extent of scale is preserved, and the images are uniformly bright in every part of the field of the telescope.

Plate CCCXXXVI.

27. Fig. 12. represents the glasses of a refracting telescope; xy, the principal pencil of rays from the object-glass O; tt and uu, the axis of two oblique pencils; a, the first eye-glass; m, its conjugate focus, or the place of the micrometer; b the second eye-glass; c the third; and d the fourth, or that which is nearest the eye. Let p be the diameter of the object-glass, e the diameter of a pencil at m, and f the diameter of the pencil at the eye; it is evident, that the axis of the pencils from every part of the image will cross each other at the point m; and e, the width of the micrometer-glass, is to p the diameter of the object-glass, as ma is to go, which is the proportion of the magnifying power at the point m; and the error caused by an imperfection in the micrometer-glass placed at m will be to the error, had the micrometer been at O, as m is to p.

Fig. 13.

28. Fig. 13. represents the micrometer; A, a convex or concave lens bisected by a plane across its centre; one of these semi-lenses is fixed in a frame B, and the other in the frame E; which two frames slide on a plate H, and are pressed against it by thin plates $a\,a$: the frames B and E are moved in contrary directions by turning the button D: L is a scale of equal parts on the frame B; it is numbered from each end towards the middle with 10, 20, &c. There are two verniers on the frame E, one at M and the other at N, for the convenience of measuring the diameter of a planet, &c. on both sides the zero. The first division on both these verniers coincides at the same time with the two zeros on the scale, L; and, if the frame is moved towards the right, the relative motion of the two frames is shown on the scale L by the vernier M; but if the frame B be moved towards the left, the relative motion is shown by the vernier N.—This micrometer has a motion round the axis of vision, for the convenience of measuring the diameter of a planet, &c. in any direction, by turning an endless screw F; and the inclination of the diameter measured with the horizon is shown on the circle g by a vernier on the plate V. The telescope may be adjusted to distinct vision by a screw, which moves the whole eye-tube with the micrometer nearer to or farther from the object-glass, as telescopes are generally made; or the same effect may be produced without moving the micrometer, by sliding the part of the eye tube m on the part n, by help of a screw or pinion.

Disadvantages of the common micrometer.

29. Notwithstanding these improvements on micrometers, they are still liable to many sources of error. The imperfections of the wire micrometer, (which was still the most correct instrument for measuring small angles) when employed to determine the distance of close double stars, have been ably pointed out by Dr Herschel.

* *Phil. Trans.* 1782.

30. When two stars are taken between the parallel wires the diameters must be included. Dr Herschel* has in vain attempted to find lines sufficiently thin to extend them across the centres of the stars so that their thickness might be neglected. The threads of the silk-worm, with such lenses as he uses, are so much magnified that their diameter is more than that of many of the stars. Besides, if they were much smaller, the deflection of light would make the attempt to measure the distance of the centres this way fruitless; for he has always found the light of the stars to play upon those lines and separate their apparent diameters into two parts. Now since the spurious diameters of the stars thus included, are continually changing with the state of the air, and the length of time we look at them, we are, in some respect, left at an uncertainty; and our measures taken at different times, and with different degrees of attention, will vary on that account. Nor can we come at the true distance of the centres of any two stars, unless we know the semidiameters of the stars themselves; for different stars have different apparent diameters, which, with a power of 227, may differ from each other as far as two seconds (D).

31. The next imperfection arises from a deflection of light upon the wires when they approach very near to each other; for if this be owing to a power of repulsion lodged at the surface, it is easy to see that such powers must interfere with each other, and give the measures larger in proportion than they would have been if the repulsive power of one wire had not been opposed by a contrary power of the other wire.

32. Another disadvantage of these micrometers is an uncertainty of the real zero. The least alteration in the situation and quantity of light will affect the zero; and a change in the position of the wires will sometimes produce a difference. To remove this difficulty Dr Herschel always found his zero while the apparatus preserved the situation which it had when his observations were made; but this introduces an additional observation.

33. The next imperfection, is that every micrometer hitherto used requires either a screw, or a divided bar and pinion, to measure the distance of the wires or the two images. Those acquainted with works of this kind are sensible how difficult it is to have screws perfectly equal in every thread or revolution of each thread; or pinions and bars that shall be so evenly divided as to be depended upon in every leaf and tooth to the two or three thousandth part of an inch: and yet, on account of the small scale of those micrometers, these quantities are of the greatest consequence; an error of a single thousandth part inducing in most instruments a mistake of several seconds.

34. The greatest imperfection of all is, that the wires require to be illuminated; and when Dr Herschel had double stars to measure, one of which was very obscure, he was obliged to be content with less light than is necessary to make the wires distinct; and several stars on this account could not be measured at all, though not too close for the micrometer.

Dr Herschel, therefore, was led to direct his attention to the improvement of these instruments; and the result of his endeavours has been a very ingenious *lamp-micrometer*, which is not only free from the imperfections above specified, but also possesses the advantages of a large scale.

Dr Herschel's lamp micrometer.

35. It is represented in fig. 14. where ABGCFE is a stand nine feet high, upon which a semicircular board $q\,h\,o\,g\,p$ is moveable upwards or downwards, and is held in its situation by a peg p put into any one of the holes of

(D) These imperfections are remedied in the instrument described in p. 801.

Micrometer. Fig. 1. of the upright piece AB. This board is a segment of a circle of fourteen inches radius, and is about three inches broader than a semicircle, to give room for the handles r D, e P, to work. The use of this board is to carry an arm L, thirty inches long, which is made to move upon a pivot at the centre of the circle, by means of a string, which passes in a groove upon the edge of the semicircle $p\ g\ o\ h\ q$; the string is fastened to a hook at o (not expressed in the figure, being at the back of the arm L), and passing along the groove from $o\ h$ to q is turned over a pulley at q, and goes down to a small barrel c, within the plane of the circular board, where a double-jointed handle e P commands its motion. By this contrivance, we see, the arm L may be lifted up to any altitude from the horizontal position to the perpendicular, or be suffered to descend by its own weight below the horizontal to the reverse perpendicular situation. The weight of the handle P is sufficient to keep the arm in any given position; but if the motion should be too easy, a friction spring applied to the barrel will moderate it at pleasure.

36. In front of the arm L a small slider, about three inches long, is moveable in a rabbet from the end L towards the centre backwards and forwards. A string is fastened to the left side of the little slider, and goes towards L, where it passes round a pulley at m, and returns under the arm from m, n, towards the centre, where it is led in a groove on the edge of the arm, which is of a circular form, upwards to a barrel (raised above the plane of the circular board) at r, to which the handle r D is fastened. A second string is fastened to the slider, at the right side, and goes towards the centre, where it passes over a pulley n; and the weight w, which is suspended by the end of this string, returns the slider towards the centre, when a contrary turn of the handle permits it to act.

37. By a and b are represented two small lamps, two inches high, $1\frac{1}{2}$ in breadth by $1\frac{1}{4}$ in depth. The sides, back, and top, are made so as to permit no light to be seen, and the front consists of a thin brass sliding door. The flame in the lamp a is placed three-tenths of an inch from the left side, three-tenths from the front, and half an inch from the bottom. In the lamp b it is placed at the same height and distance, measuring from the right side. The wick of the flame consists only of a single very thin lamp cotton-thread; for the smallest flame being sufficient, it is easier to keep it burning in so confined a place. In the top of each lamp must be a little slit lengthways, and a small opening in one side near the upper part, to permit the air to circulate to feed the flame. To prevent every reflection of light, the side opening of the lamp a should be to the right, and that of the lamp b to the left. In the sliding door of each lamp is made a small hole with the point of a very fine needle just opposite the place where the wicks are burning, so that when the sliders are shut down, and every thing dark, nothing shall be seen but two fine lucid points of the size of two stars of the third or fourth magnitude. The lamp a is placed so that its lucid point may be in the centre of the circular board where it is fixed. The lamp b is hung to the little slider which moves in the rabbet of the arm, so that its lucid point, in an horizontal position of the arm, may be on a level with the lucid point in the centre. The moveable lamp is suspended upon a piece of brass fastened to the slider by a pin exactly behind the flame, upon which it moves as a pivot. The lamp is balanced at the bottom by a leaden weight, so as to remain upright, when the arm is either lifted above or depressed below the horizontal position. The double-jointed handles r D, e P, consist of deal rods, 10 feet long, and the lowest of them may have divisions, marked upon it near the end P, expressing exactly the distance from the central lucid point in feet, inches, and tenths.

38. Hence we see, that a person at a distance of 10 feet may govern the two lucid points, so as to bring them into any required position south or north preceding or following from 0 to 90° by using the handle P, and also to any distance from six-tenths of an inch to five or six and twenty inches by means of the handle D. If any reflection or appearance of light should be left from the top or sides of the lamps, a temporary screen, consisting of a long piece of pasteboard, or a wire frame covered with black cloth, of the length of the whole arm, and of any required breadth, with a slit of half an inch broad in the middle, may be affixed to the arm by four bent wires projecting an inch or two before the lamps, situated so that the moveable lucid point may pass along the opening left for that purpose.

Fig. 15. Fig. 15. represents part of the arm L, half the real size; S the slider; m the pulley, over which the cord $x\ t\ y\ z$ is returned towards the centre; v the other cord going to the pulley n of fig. 14.; R the brass piece moveable upon the pin c, to keep the lamp upright. At R is a wire rivetted to the brass piece, upon which is held the lamp by a nut and screw. Fig. 16. 17. represent the lamps a, l, with the sliding doors open, to show the situation of the wick. W is the leaden weight with a hole d in it, through which the wire R of fig. 15. is to be passed when the lamp is to be fastened to the slider S. Fig. 18. represents the lamp a with the sliding door shut; l the lucid point; and $i\ k$ the openings at the top, and s at the sides, for the admission of air. Fig. 16. 17. Fig. 18.

39. The motions of this micrometer are capable of great improvement by the application of wheels and pinions, and other mechanical resources; but as the principal object is only to be able to adjust the two lucid points to the required position and distance, and to keep them there for a few minutes, while the observer measures their distance, it will be unnecessary to say more upon the subject.

40. It is well known that we can with one eye look into a telescope, and see an object much magnified, while the other eye may see a scale upon which the magnified picture is thrown. In this manner Dr Herschel generally determined the power of his telescopes; and any one who has been accustomed to make such observations will seldom mistake so much as one in fifty in determining the power of an instrument, and that degree of exactness is fully sufficient for the purpose.

Method of applying the lamp micrometer.

41. When Dr Herschel uses this instrument he puts it at ten feet distance from the left eye, in a line perpendicular to the tube of his Newtonian telescope, and raises the moveable board to such a height that the lucid point of the central lamp may be upon a level with the eye. The handles, lifted up, are passed through two loops fastened to the tube, just by the observer, so as to be ready for his use. The end of tube is cut away, so

Micrometer.

so as to leave the left eye entirely free to see the whole micrometer.

42. The telescope being directed to a double star, it is viewed with the right eye, and at the same time with the left it is seen projected upon the micrometer; then, by the handle P, the arm is raised or depressed so as to bring the two lucid points to a similar situation with the two stars; and, by the handle D, the moveable lucid point is brought to the same distance of the two stars, so that the two lucid points may be exactly covered by the stars.

43. With a rule, divided into inches and fortieth parts, the distance of the lucid points is thus determined with the greatest accuracy; and the measure thus obtained is the tangent of the magnified angle under which the stars are seen to a radius of ten feet; therefore, the angle being found and divided by the power of the telescope, the real angular distance of the centres of a double star is ascertained. On September 25. 1781, Dr Herschel measured α Herculis with this instrument. Having caused the two lucid points to coincide with the stars, he found the radius or distance of the central lamp from the eye 10 feet 4.15 inches; the tangent or distance of the two lucid points 50.6 fortieth parts of an inch; this gives the magnified angle 35′, and dividing by the power 460, we obtain 4″ 34‴ for the distance of the centres of the two stars. The scale of the micrometer at this convenient distance, with the power of 460, is above a quarter of an inch to a second; and by putting on a power of 932, we obtain a scale of more than half an inch to a second, without increasing the distance of the micrometer; whereas the most perfect micrometers, with the same instrument, had a scale of less than the two thousandth part of an inch to a second.

Mr Brewster's micrometer.

44. Mr Brewster has lately directed his attention to the improvement of micrometers, and has invented one in particular which appears to be highly deserving of notice in this place. In this instrument a pair of *fixed* wires is made to subtend different angles by varying the magnifying power of the telescope, by sliding one tube within another; whereas in all other micrometers with wires this effect is produced by mechanical contrivances. Mr Brewster's method of shutting and opening the wires optically is therefore free from all those sources of error to which other micrometers are subject, and renders it particularly useful to the practical astronomer; while the mode of changing the magnifying power by the motion of a second object-glass affords a length of scale equal to the local distance of the principal object-glass. The same principle is peculiarly applicable to the Gregorian telescope; for the magnifying power of this instrument can be changed by merely increasing or diminishing the distance of the eye-piece from the large speculum.

45. In the common micrometer, which can manifestly, as well as Mr Cavallo's and Mr Brewster's, be used in the mensuration of distances, the focal length of the telescope to which it is attached remains always the same; so that a correction computed from an optical theorem must be applied to every angle that is measured: but in Mr Brewster's telescope and micrometer, the focal length varies in the same proportion as the distance of the object; and consequently no correction of the angles can be necessary. To obviate the necessity of having a stand for the instrument, which would prevent its usefulness at sea, Mr Brewster divides the second or moveable object-glass into two, as in the divided object-glass micrometer. By this contrivance two images are formed, and these images are separated or made to form different angles at the eye, by bringing the moveable object-glass nearer to the fixed one. In determining the angle, therefore, we have only to bring the two images of the object into contact; and such contact the eye is capable of ascertaining even during the agitation of a carriage, as the two images retain the same relative position whatever be their absolute motion.

This ingenious instrument, being formed with sliding tubes, is very portable and convenient; and will be found extremely useful to medical gentlemen, and others who may wish to ascertain distances without a more cumbersome apparatus. *Haüy's Nat. Phil. by Gregory*, vol. ii. p. 427.

46. Mr Brewster, we understand, still continues to direct his attention to the subject of micrometers, keeping in view the improvement of these instruments, not only in greater accuracy of construction, but also in their more extensive application to various practical purposes. An account of those uses and improvements is to form the subject of an appropriate publication; and, if we are rightly informed, the author deems them of sufficient importance to secure to himself, by patent, the exclusive right to the advantages which he thinks will arise from using them.

Cavallo's mother-of-pearl micrometer.

47. A very simple micrometer for measuring small angles with the telescope has been invented by Mr Cavallo*. It consists of a thin and narrow slip of mother-of-pearl finely divided, and situated in the focus of the eye-glass of a telescope, just where the image of the object is formed. It is immaterial whether the telescope be a refractor or a reflector, provided the eye-glass be a convex lens.

* *Philos. Trans.* 1771, p. 283.

The simplest way of fixing it is to stick it upon the diaphragm, which generally stands within the tube, in the focus of the eye-glass. When thus fixed, the divisions of the micrometrical scale will appear very distinct, unless the diaphragm is not exactly in the focus; in which case, the scale must be placed accurately in the focus of the eye-glass, either by moving the diaphragm, or by interposing any thin substance, such as paper or card between it and the scale. This construction is fully sufficient, when the telescope is always to be used by the same person; but when different persons are to use it, then the diaphragm which supports the micrometer must be constructed so as to be easily moved backwards or forwards, though that motion need not be greater than about $\frac{1}{8}$ or $\frac{1}{10}$ of an inch.

Fig. 19.

The scale of the micrometer is represented in fig. 19. which is about four times greater than one which Mr Cavallo has adapted to a three-feet achromatic telescope that magnifies about 84 times. It is something less than the 24th part of an inch broad; its thickness is equal to that of common writing paper; and the length of it is determined by the breadth of the field of view. The divisions are 200ths of an inch, and the lines which form them reach from one edge of the scale to about the middle of it, excepting every fifth and tenth division, which are longer. Two divisions of the scale in the telescope already mentioned are very nearly equal to one minute; and as a quarter of one of those divisions may be easily distinguished by the eye, an angle of one-eighth part of a minute, or of $7''\frac{1}{2}$, may be measured with it.

In

Micrometer.

In looking through a telescope furnished with such a micrometer, the field of view appears divided by the micrometer scale, the breadth of which occupies about $\frac{1}{7}$th of the aperture; and as the scale is semitransparent, that part of the object which is behind it may be discerned sufficiently well to ascertain the division, with which its borders coincide. Fig. 20. shows the appearance of the field of the telescope with the micrometer, when directed to the title page of the Philosophical Transactions, in which it appears that the thickness of the letter C is equal to three-fourths of a division, the diameter of the O is equal to three divisions, and so on.

Fig. 20.

48. After having adapted this micrometer to the telescope, we must then ascertain the value of the divisions. It is hardly necessary to mention in this place, that though those divisions measure the chords of the angles, and not the angles or arches themselves, and the chords are not as the arches, yet in small angles the chords, arches, sines, and tangents, follow the same proportion so very nearly, that the difference may be safely neglected: so that if one division of this micrometer is equal to one minute, we may conclude that two divisions are equal to two minutes, three divisions to three minutes, and so on. In order to ascertain the value of the divisions of this micrometer, the following simple and accurate method may be adopted,

Mark upon a wall the length of six inches, by making two dots or lines six inches asunder, or by fixing a six-inch ruler upon a stand; then place the telescope before it so that the ruler or six-inch length may be at right angles with the direction of the telescope, and just 57 feet $3\frac{1}{2}$ inches distant from the object-glass of the telescope: this done, look through the telescope at the ruler or other extension of six inches, and observe how many divisions of the micrometer are equal to it, and that same number of divisions is equal to half a degree, or 30′, as it may be shewn by plane trigonometry.

49. When this value has been once ascertained, any other angle measured by any other number of divisions is determined by simple proportion. Thus, if the diameter of the sun seen through the same telescope, be equal to 12 divisions, say as $11\frac{1}{2}$ divisions are to 30 minutes, so are 12 divisions to $\left(\frac{12' \times 30'}{11.5}\right)$ 31′.3, which is the required diameter of the sun.

Notwithstanding the facility of this calculation, a scale may be made answering to the divisions of a micrometer, which will show the angle corresponding to any number of divisions by mere inspection. Thus, for the above-mentioned small telescope, the scale is represented in fig. 21. AB is a line drawn at pleasure; it is then divided into 23 equal parts, and those divisions which represent the divisions of the micrometer that are equal to one degree, are marked on one side of it. The line is then divided again into 60 equal parts, which are marked on the other side of it; and these divisions represent the minutes which correspond to the divisions of the micrometer: thus the figure shows, that six divisions of the micrometer are equal to $15\frac{1}{2}$ minutes, $11\frac{1}{4}$ divisions are nearly equal to 29 minutes, &c. What has been said of minutes may be said of seconds also, when the scale is to be applied to a large telescope.

Fig. 21.

50. We shall therefore add some practical rules to render this micrometer useful to persons unacquainted with trigonometry and the use of logarithms.

Problem I. The angle, not exceeding one degree, which is subtended by an extension of one foot perpendicular to the axis of the telescope being given, to find its distance from the object-glass of the telescope.

Rule 1. If the angle be expressed in minutes, say, as the given angle is to 60, so is 687.55 to a fourth proportional, which gives the answer in inches.—2. If the angle be expressed in seconds, say, as the given angle is to 3600, so is 687.55 to a fourth proportional, which expresses the answer in inches.

Example. At what distance is a globe of one foot diameter when it subtends an angle of two seconds?

$$2'' : 3600'' :: 687.55 : \frac{3600 \times 687.55}{2} = 1237590$$

inches, or $103132\frac{1}{2}$ feet, which is the answer required.

Problem II. The angle, not exceeding one degree, which is subtended by any known extension, being given, to find its distance from the object-glass of the telescope.

Rule. Proceed as if the extension were of one foot by Problem I. and call the answer B; then, if the extension in question be expressed in inches, say, as 12 inches are to that extension, so is B to a fourth proportional, which is the answer in inches; but if the extension in question be expressed in feet, then you need only multiply it by B, and the product is the answer in inches.

Example. At what distance is a man six feet high, when he appears to subtend an angle of 30″.

By Problem I. if the man were one foot high, the distance would be 82506 inches; but as he is six feet high, therefore multiply 82506 by 6, and the product gives the required distance, which is 495036 inches, or 41253 feet.

For greater conveniency, especially in travelling, or in such circumstances in which one has not the opportunity of making even the easy calculations required in those problems, the following two tables have been computed; the first of which shows the distance answering to any angle from one minute to one degree, which is subtended by a man, the height of which has been called an extension of six feet; because, at a mean, such is the height of a man when dressed with a hat and shoes on.

Thus, if it is required to measure the extension of a street, let a foot ruler be placed at the end of the street; measure the angle it subtends, which suppose to be 36′, and in the table you will have the required distance opposite 36′, which is $95\frac{1}{2}$ feet. Thus also a man who appears to be 49′ high, is at the distance of 421 feet.

51. The following is the account of a micrometer invented by Mr Brewster, of the circumstances which led to the invention, and of its advantages. We shall give it in his own words *.

Mr Brewster's circular mother-of-pearl micrometer.

"In the winter of 1805 (he observes), when I was employed in delineating the surface of the moon, I wished to measure the diameter of the lunar spots by applying Mr Cavallo's micrometer to a thirty-inch achromatic telescope made by Berge. But as the eye-piece was moved by a rack and pinion, and consequently could not turn round its axis, the micrometer must have remained stationary, and could only measure angles in one direction. This difficulty, indeed, might have been surmounted by a mechanical contrivance for turning the diaphragm about its centre, or more simply by giving a motion of rotation to the tube which contains the third and fourth eye-glasses. Such a change in the eye-piece, however, was both inconvenient and difficult to be made. Mr Cavallo's micrometer, therefore, has this great disadvantage, that it cannot be used in reflecting telescopes, or in any achromatic telescope where the adjustment of the eye-piece is effected by rackwork, unless the structure of these instruments is altered for the purpose. Another disadvantage of this micrometer arises from the slip of mother-of-pearl passing through the centre of the field. The picture in the focus of the eye-glass is broken into two parts, and the view is rendered still more unpleasant by the inequality of the segments into which the field is divided. In addition to these disadvantages, the different divisions of the micrometer are at unequal distances from the eye-glass which views them, and therefore can neither appear equally distinct nor subtend equal angles at the eye.

* *Phil. Mag.* vol. xxix. p. 48.

"Finding that Mr Cavallo's instrument laboured under these imperfections, I thought of a circular mother-of-pearl micrometer which is free from them all, and has likewise the advantage of a kind of diagonal scale, increasing in accuracy with the angle to be measured. This micrometer, which I got executed by Miller and Adie, optical instrument-makers in Edinburgh, and which I have often used, both in determining small angles in the heavens and such as are subtended by terrestrial objects, is represented in fig. 27. which exhibits its appearances in the focus of the fourth eye-glass. The black ring, which forms part of the figure, is the diaphragm, and the remaining part is a ring of mother-of-pearl, having its interior circumference divided into 360 equal parts. The mother-of-pearl ring, which appears connected with the diaphragm, is completely separate from it, and is fixed at the end of a brass tube which is made to move between the third eye-glass and the diaphragm, so that the divided circumference may be placed exactly in the focus of the glass next the eye. When the micrometer is thus fitted into the telescope, the angle subtended by the whole field of view, or by the diameter of the innermost circle of the micrometer, must be determined either by measuring a base or by the passage of an equatoreal star, and the angles subtended by any number of divisions or degrees will be found by a table constructed in the following manner.

Plate CCCXXXVI. Fig. 27.

52. "Let $AmpnB$, fig. 28. be the interior circumference of the micrometer scale, and let $m\,n$ be the object to be measured. Bisect the arch $m\,n$ in p, and draw $C\,m$, $C\,p$, $C\,n$. The line $C\,p$ will be at right angles to $m\,n$, and therefore $m\,n$ will be twice the sine of half the arch $m\,n$. Consequently, AB : $m\,n$ = rad. sine of $\frac{1}{2}\,m\,p\,n$;

Fig. 28.

Micrometer.

$\frac{1}{2} mpn$; therefore $mn \times R = \sin.\ \frac{1}{2} mpn \times AB$, and $mpn = \frac{\sin.\ \frac{1}{2} mpn \times AB}{R} = \frac{\sin.\ \frac{1}{2} mpn}{R} \times AB$; a formula by which the angle subtended by the chord of any number of degrees may be easily found. The first part of the formula, viz. $\frac{\sin\ \frac{1}{2} mpn}{R}$ is constant, while AB varies with the size of the micrometer and with the magnifying power which is applied. We have therefore computed the following table, containing the value of the constant part of the formula for every degree or division of the scale.

Deg.	Constant Part of the Formula	Deg.	Constant Part.	Deg.	Constant Part	Deg.	Constant Part.
1	.0087	46	.3907	91	.7133	136	.9272

43	.3665	88	.6947	133	.9171	178	.9998
44	.3746	89	.7009	134	.9205	179	1.0000
45	.3827	90	.7071	135	.9239	180	1.0000

53. "In order to find the angle subtended by any number of degrees, we have only to multiply the constant part of the formula corresponding to that number in the table by AB, or the angle subtended by the whole field. Thus if AB is 30 minutes, as it happens to be in the micrometer which I have constructed, the angle subtended by 1 degree of the scale will be $30' \times .009 = 16\frac{2}{5}$ seconds, and the angle subtended by 40 degrees will be $30' \times .342 = 10'\ 15.6''$; and by making the calculation it will be found that as the angle to be measured increases, the accuracy of the scale also increases; for when the arch is only 1 or 2 degrees, a variation of 1 degree produces a variation of about 16 seconds in the angle; whereas when the arch is between 170 and 180, the variation of a degree does not produce a change much more than one second in the angle. This is a most important advantage in the circular scale, as in Cavallo's micrometer a limit is necessarily put to the size of the divisions.

"It is obvious, from an inspection of fig. 27. that there is no occasion for turning the circular micrometer round its axis, because the divided circumference lies in every possible direction. In fig. 2. for example, if the object has the direction *a b* it will be measured by the arch *a o b*, and if it lies in the line *c d* it will be measured by the arch *c r d*.

"In the circular micrometer which I have been in the habit of using, AB, or the diameter of the field of view, is exactly half an inch, the diameter of the brass tube in which it is fixed is one inch, the length of the tube half an inch, and the degrees of the divided circumference $\frac{1}{230}$ of an inch.

Application of the micrometer to microscopes.

54. II. The micrometer has not only been applied to telescopes, and employed for astronomical purposes; but there have also been various contrivances for adapting it to MICROSCOPICAL observations. Mr Leeuwenhoeck's method of estimating the size of small objects was by comparing them with grains of sand, of which 100 in a line took up an inch. These grains he laid upon the same plate with his objects, and viewed them at the same time. Dr Jurin's method was similar to this; for he found the diameter of a piece of fine silver wire, by wrapping it as close as he could about a pin, and observing how many rings made an inch; and he used this wire in the same manner as Leeuwenhoeck employed his sand. Dr Hooke looked upon the magnified object with one eye, while at the same time he viewed other objects placed at the same distance with the other eye. In this manner he was able, by the help of a ruler, divided into inches and small parts, and laid on the pedestal of the microscope, to cast as it were the magnified appearance of the object upon the ruler, and thus exactly to measure the diameter which it appeared to have through the glass; which being compared with the diameter as it appeared to the naked eye, showed the degree in which it was magnified.

55. Mr Martin * recommended such a micrometer for a microscope as had been applied to telescopes: for he advises to draw a number of parallel lines on a piece of glass, with the fine point of a diamond, at the distance of one-fortieth of an inch from one another, and to place it in the focus of the eye-glass. By this method, Dr Smith contrived to take the exact draught of objects viewed by a double microscope; for he advises

* *Martin's Optics*, p. 277.

Micrometer.

to get a lattice, made with small silver wires or squares drawn upon a plain glass by the strokes of a diamond, and to put it into the place of the image, formed by the object-glass: then by transferring the parts of the object, seen in the squares of the glass or lattice upon similar corresponding squares drawn on paper, the picture may be exactly taken. Mr Martin also introduced into compound microscopes another micrometer, consisting of a screw.

† *Microscopical Essays*, p. 59.

56. The mode of actual admeasurement (Mr Adams observes †) is without doubt the most simple that can be used; as by it we comprehend, in a manner, at one glance, the different effects of combined glasses; and as it saves the trouble, and avoids the obscurity of the usual modes of calculation: but many persons find it exceedingly difficult to adopt this method, because they have not been accustomed to observe with both eyes at once. To obviate this inconvenience, the late Mr Adams contrived an instrument called the *Needle-Micrometer*, which was first described in his *Micrographia Illustrata;* and of which, as now constructed, we have the following description by his son Mr George Adams in the ingenious Essays above quoted.

This micrometer consists of a screw, which has 50 threads to an inch; this screw carries an index, which points to the divisions on a circular plate, which is fixed at right angles to the axis of the screw. The revolutions of the screw are counted on a scale, which is an inch divided into 50 parts; the index to these divisions is a flower-de-luce marked upon the slider, which carries the needle point across the field of the microscope. Every revolution of the micrometer screw measures $\frac{1}{50}$th part of an inch, which is again subdivided by means of the divisions on the circular plate, as this is divided into 20 equal parts, over which the index passes at every revolution of the screw; by which means we obtain with ease the measure of 1000th part of an inch: for 50, the number of threads on the screw in one inch, being multiplied by 20, the divisions on the circular plate are equal to 1000; so that each division on the circular plate shows that the needle has either advanced or receded 1000th part of an inch.

Fig. 25.

57. To place this micrometer on the body of the microscope, open the circular part FKH, fig. 25. by taking out the screw G, throw back the semicircle FK, which moves upon a joint at K; then turn the sliding tube of the body of the microscope, so that the small holes which are in both tubes may exactly coincide, and let the needle g of the micrometer have a free passage through them; after this, screw it fast upon the body by the screw G. The needle will now traverse the field of the microscope, and measure the length and breadth of the image of any object that is applied to it. But further assistance must be had, in order to measure the object itself, which is a subject of real importance; for though we have ascertained the power of the microscope, and know that it is so many thousand times, yet this will be of little assistance towards ascertaining an accurate idea of its real size; for our ideas of bulk being formed by the comparison of one object with another, we can only judge of that of any particular body, by comparing it with another whose size is known: the same thing is necessary, in order to form an estimate by the microscope; therefore, to ascertain the real measure of the object, we must make the point of the needle pass over the image of a known part of an inch placed on the stage, and write down the revolutions made by the screw, while the needle passed over the image of this known measure; by which means we ascertain the number of revolutions on the screw, which are adequate to a real and known measure on the stage. As it requires an attentive eye to watch the motion of the needle point as it passes over the image of a known part of an inch on the stage, we ought not to trust to one single measurement of the image, but ought to repeat it at least six times; then add the six measures thus obtained together, and divide their sum by six, or the number of trials; the quotient will be the mean of all the trials. This result is to be placed in a column of a table next to that which contains the number of the magnifiers.

Fig. 22, 23, 24.

58. By the assistance of the sectoral scale, we obtain with ease a small part of an inch. This scale is shown at fig. 22, 23, 24, in which the two lines $c\,a$, $c\,b$, with the side $a\,b$, form an isosceles triangle; each of the sides is two inches long, and the base still only of one-tenth of an inch. The longer sides may be of any given length, and the base still only one-tenth of an inch. The longer lines may be considered as the line of lines upon a sector opened to one-tenth of an inch. Hence whatever number of equal parts $c\,a$, $c\,b$ are divided into, their transverse measure will be such a part of one-tenth as is expressed by their division. Thus if it be divided into ten equal parts, this will divide the inch into 100 equal parts; the first division next c will be equal to 100th part of an inch, because it is the tenth part of one-tenth of an inch. If these lines are divided into twenty equal parts, the inch will be by that means divided into 200 equal parts. Lastly, if $a\,b$, $c\,a$, are made three inches long, and divided into 100 equal parts, we obtain with ease the 1000th part. The scale is represented as solid at fig. 23. but as perforated at fig. 22. and 24. so that the light passes through the aperture, when the sectoral part is placed on the stage.

59. To use this scale, first fix the micrometer, fig. 25. to the body of the microscope; then fit the sectoral scale, fig. 24. in the stage, and adjust the microscope to its proper focus or distance from the scale, which is to be moved till the base appears in the middle of the field of view; then bring the needle point g, fig. 25. (by turning the screw L) to touch one of the lines $c\,a$, exactly at the point answering to 20 on the sectoral scale. The index a of the micrometer is to be set to the first division, and that on the dial plate to 20, which is both the beginning and end of its divisions; we are then prepared to find the magnifying power of every magnifier in the compound microscope which we are using.

60. *Example.* Every thing being prepared agreeable to the foregoing directions, suppose you are desirous of ascertaining the magnifying power of the lens marked N° 4. turn the micrometer screw until the point of the needle has passed over the magnified image of the tenth part of one inch; then the division, where the two indices remain, will show how many revolutions, and parts of a revolution, the screw has made, while the needle point traversed the magnified image of the one-tenth of an inch; suppose the result to be 26 revolutions

Micrometer.

volutions of the screw, and 14 parts of another revolution, this is equal to 26 multiplied by 20, added to 14; that is, 534,000 parts of an inch. The 26 divisions found on the straight scale of the micrometer, while the point of the needle passed over the magnified image of one-tenth part of an inch, were multiplied by 20, because the circular plate CD, fig. 25. is pivided into 20 equal parts; this produced 520; then adding the 14 parts of the next revolution, we obtain the 534,000 parts of an inch, or five-tenths and 3400 parts of another tenth, which is the measure of the magnified image of one-tenth of an inch, at the aperture of the eye-glasses or at their foci. Now if we suppose the focus of the two eye-glasses to be one inch, the double thereof is two inches; or if we reckon in the 1000th part of an inch, we have 2000 parts for the distance of the eye from the needle point of the micrometer. Again, if we take the distance of the image from the object at the stage at 6 inches, or 6000, and add thereto 2000, double the distance of the focus of the eye-glass, we shall have 8000 parts of an inch for the distance of the eye from the object; and as the glasses double the image, we must double the number 534 found upon the micrometer, which then makes 1068; then, by the following analogy, we shall obtain the number of times the microscope magnifies the diameter of the object; say, as 240, the distance of the eye from the image of the object, is to 800, the distance of the eye from the object; so is 1068, double the measure found on the micrometer, to 3563, or the number of times the microscope magnifies the diameter of the object. By working in this manner, the magnifying power of each lens used with the compound microscope may be easily found, though the result will be different in different compound microscopes, varying according to the combination of the lenses, their distance from the object and one another, &c.

Fig. 25.

61. Having discovered the magnifying power of the microscope, with the different object-lenses that are used therewith, our next subject is to find out the real size of the objects themselves, and their different parts: this is easily effected, by finding how many revolutions of the micrometer screw answer to a known measure on the sectoral scale or other object placed on the stage; from the number thus found, a table should be constructed, expressing the value of the different revolutions of the micrometer with that object lens, by which the primary number was obtained. Similar tables must be constructed for each object lens. By a set of tables of this kind, the observer may readily find the measure of any object he is examining; for he has only to make the needle point traverse over this object, and observe the number of revolutions the screw has made in its passage, and then look into his table for the real measure which corresponds to this number of revolutions, which is the measure required.

Description of Mr Coventry's micrometers for microscopes.

62. Mr Coventry of Southwark has favoured us with the description of a micrometer of his own invention; the scale of which, for minuteness, surpasses every instrument of the kind of which we have any knowledge, and of which, indeed, we could scarcely have formed a conception, had he not indulged us with several of these instruments, graduated as underneath.

The micrometer is composed of glass, ivory, silver, &c. on which are drawn parallel lines from the 10th to the 10,000th part of an inch. But an instrument thus divided, he observes, is more for curiosity than use: but one of those which Mr Coventry has sent us is divided into squares, so small that sixteen millions of them are contained on the surface of one square inch, each square appearing under the microscope true and distinct; and though so small, it is a fact, that animalcula are found which may be contained in one of these squares.

The use of micrometers, when applied to microscopes, is to measure the natural size of the object, and how much that object is magnified. To ascertain the real size of an object in the single microscope, nothing more is required than to lay it on the micrometer, and adjust it to the focus of the magnifier, noticing how many divisions of the micrometer it covers. Suppose the parallel lines of the micrometer to be the 1000th of an inch, and the object covers two divisions; its real size is 500ths of an inch; if five, 200ths, and so on.

But to find how much the object is magnified, is not mathematically determined so easily by the single as by the compound microscope: but the following simple method (says Mr Coventry) I have generally adopted, and think it tolerably accurate. Adjust a micrometer under the microscope *o*, say the 100th of an inch of divisions, with a small object on it; if square, the better: notice how many divisions one side of the object covers, suppose 10: then cut a piece of white paper something larger than the magnified appearance of the object: then fix one eye on the object through the microscope, and the other at the same time on the paper, lowering it down till the object and the paper appear level and distinct: then cut the paper till it appear exactly the size of the magnified object; the paper being then measured, suppose an inch square: Now, as the object under the magnifier, which appeared to be one inch square, was in reality only ten hundredths, or the tenth of an inch, the experiment proves that it is magnified ten times in length, one hundred times in superfices, and one thousand times in cube, which is the magnifying power of the glass; and, in the same manner, a table may be made of the power of all the other glasses.

In using the compound microscope, the real size of the object is found by the same method as in the single: but to demonstrate the magnifying power of each glass to greater certainty, adopt the following method.—Lay a two-feet rule on the stage, and a micrometer level with its surface (an inch suppose, divided into 100 parts): with one eye see how many of those parts are contained in the field of the microscope, suppose 50); and with the other, at the same time, look for the circle of light in the field of the microscope, which with a little practice will soon appear distinct; mark how much of the rule is intersected by the circle of light, which will be half the diameter of the field. Suppose eight inches; consequently the whole diameter will be sixteen. Now, as the real size of the field, by the micrometers, appeared to be only 50 hundredths, or half an inch, and as half an inch is only one 32d part

Micrometer.

part of 16 inches, it shows the magnifying power of the glass to be 32 times in length, 1024 superfices, and 32,768 cube (E).

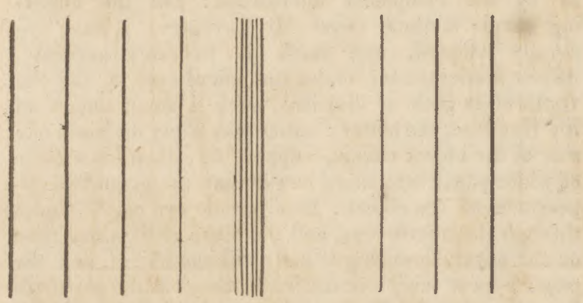
63. Another way of finding the magnifying power of compound microscopes, is by using two micrometers of the same divisions; one adjusted under the magnifier, the other fixed in the body of the microscope in the focus of the eye-glass. Notice how many divisions of the micrometer in the body are seen in one division of the micrometer under the magnifier, which again must be multiplied by the power of the eye-glass. Example: Ten divisions of the micrometer in the body are contained in one division under the magnifier; so far the power is increased ten times: now, if the eye-glass be one inch focus, such glass will of itself magnify about seven times in length, which, with the ten times magnified before, will be seven times ten, or 70 times in length, 4900 superfices, and 343,000 cube.

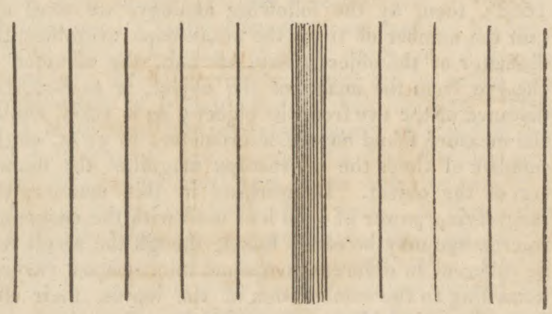
"If (says Mr Coventry) these micrometers are employed in the solar microscope, they divide the object into squares on the screen in such a manner as to render it extremely easy to make a drawing of it. And (says he) I apprehend they may be employed to great advantage with such a microscope as Mr Adam's lucernal; because this instrument may be used either by day or night, or in any place, and gives the actual magnifying power without calculation."

Micrometer, Micropus.

The case with which we have been favoured by Mr Coventry contains six micrometers, two on ivory and four on glass. One of those on ivory is an inch divided into one hundred parts, every fifth line longer than the intermediate ones, and every tenth longer still, for the greater ease in counting the divisions under the microscope, and is generally used in measuring the magnifying power of microscopes. The other ivory one is divided into squares of the 50th and 100th of an inch, and is commonly employed in measuring opaque objects.

Those made of glass are for transparent objects, which, when laid on them, show their natural size.—That marked on the brass 100, are squares divided to the 100th of an inch: that marked 5000 are parallel lines forming nine divisions, each division the 1000th of an inch; the middle division is again divided into 5, making divisions to the 5000th of an inch. That marked 10,000 is divided in the same manner, with the middle division divided into 10, making the 10,000th of an inch. Example:





The glass micrometer without any mark is also divided, the outside lines into 100th, the next into 1000th, and the inside lines into the 4000th of an inch: these are again crossed with an equal number of lines in the same manner, making squares of the 100th, 1000th, and 4000th of an inch, thus demonstrating each other's size. The middle square of the 1000th of an inch (see fig. 26.) is divided into sixteen squares; now as 1000 squares in the length of an inch, multiplied by 1000, gives one million in an inch surface; by the same rule, one of those squares divided into 16 must be the sixteen millionth parth of an inch surface. See fig. 26. which is a diminished view of the apparent surface exhibited under the magnifier N° 1. of Wilson's microscope. In viewing the smallest lines, Mr Coventry uses N° 2. or 3.; and they are all better seen, he says, by candle than by day-light.

MICROPUS, Bastard Cudweed; a genus of plants belonging to the syngenesia class, and in the natural method ranking under the 49th order, *Compositæ*. See Botany *Index*.

(E) It will be necessary, for great accuracy, as well as for comparative observations, that the two-feet rule should always be placed at a certain distance from the eye; eight inches would, in general, be a proper distance.
