Encyclopædia Britannica.

Material, Materialists.

MATERIAL, denotes something composed of *matter*. In which sense the word stands opposed to *immaterial*. See MATTER and METAPHYSICS.

MATERIALISTS, a sect in the ancient church, composed of persons who, being prepossessed with that maxim in the ancient philosophy, *Ex nihilo nihil fit*, "Out of nothing nothing can arise," had recourse to an internal matter, on which they supposed God wrought in the creation; instead of admitting God alone as the sole cause of the existence of all things. Tertullian vigorously opposes the doctrine of the materialists in his treatise against Hermogenes, who was one of their number.

Materialists.

MATERIALISTS is also a name given to those who maintain that the soul of man is material; or that the principle of perception and thought is not a substance distinct from the body, but the result of corporeal organization: See METAPHYSICS. There are others, called by this name, who have maintained that there is nothing but matter in the universe; and that the Deity himself is material. See SPINOZA.

MATHEMATICS.

Definition of mathematics.

MATHEMATICS is divided into two kinds, *pure* and *mixed*. In *pure mathematics* magnitude is considered in the abstract; and as they are founded on the simplest notions of quantity, the conclusions to which they lead have the same evidence and certainty as the elementary principles from which these conclusions are deduced. This branch of mathematics comprehends, 1. *Arithmetic*, which treats of the properties of numbers. 2. *Geometry*, which treats of extension as endowed with three dimensions, length, breadth, and thickness, without considering the physical qualities inseparable from bodies in their natural state. 3. *Algebra*, sometimes called universal arithmetic, which compares together all kinds of quantities, whatever be their value. 4. The *direct and inverse method of Fluxions*, (called on the continent, the *differential* and *integral calculi*), which consider magnitudes as divided into two kinds, constant and variable, the variable magnitudes being generated by motion; and which determines the value of quantities from the velocities of the motions with which they are generated. *Mixed Mathematics* is the application of pure mathematics to certain established physical principles, and comprehends all the physico-mathematical sciences, namely, 1. *Mechanics*; 2. *Hydrodynamics*; 3. *Optics*; 4. *Astronomy*; 5. *Acoustics*; 6. *Electricity*; and, 7. *Magnetism*. The history of these various branches of science having been given at full length, we shall at present direct the attention of the reader to the origin and progress of pure mathematics.

2. In attempting to discover the origin of arithmetic and geometry, it would be a fruitless task to conduct the reader into those ages of fable which preceded the records of authentic history. Our means of information upon this subject are extremely limited and imperfect; and it would but ill accord with the dignity of a science whose principles and conclusions are alike irresistible, to found its history upon conjecture and fable. But notwithstanding this obscurity in which the early history of the sciences is enveloped, one thing appears certain, that arithmetic and geometry, and some of the physical sciences, had made considerable progress in Egypt, when the mysteries and the theology of that favoured kingdom were transplanted into Greece. It is highly probable that much natural and moral knowledge was taught in the Eleusinian and Dionysian mysteries, which the Greeks borrowed from the Egyptians, and that several of the Grecian philosophers were induced by this circumstance to travel into Egypt, in search of those higher degrees of knowledge, which an acquaintance with the Egyptian mysteries had taught them to anticipate. We accordingly find Thales and Pythagoras successively under the tuition of the Egyptian priests, and returning into Greece loaded with the intellectual treasures of Egypt. By the establishment of the Ionian school at Miletus, Thales instructed his countrymen in the knowledge which he had received, and gave birth to that spirit of investigation and discovery with which his followers were inspired. He taught them the method of ascertaining the height of the pyramids of Memphis by the length of their shadows; and there is reason to believe that he was the first

The sciences originated in Egypt.

A. C. 640. A. C. 590.

Discoveries of Thales.

first who employed the circumference of a circle for the mensuration of angles. That he was the author of greater discoveries, which have been either lost or ascribed to others, there can be little doubt; but these are the only facts in the history of Thales which time has spared.

Discoveries of Pythagoras.

3. The science of arithmetic was one of the chief branches of the Pythagorean discipline. Pythagoras attached several mysterious virtues to certain combinations of numbers. He swore by *four*, which he regarded as the chief of numbers. In the number *three* he supposed many wonderful properties to exist; and he regarded a knowledge of arithmetic as the chief good. But of all Pythagoras's discoveries in arithmetic, none have reached our times but his multiplication table. In geometry, however, the philosopher of Samos seems to have been more successful. The discovery of the celebrated proposition which forms the 47th of the first book of Euclid's Elements, that in every right-angled triangle the square of the side subtending the right angle is equal to the sum of the squares of the other two sides, has immortalized his name; and whether we consider the inherent beauty of the proposition, or the extent of its application in the mathematical sciences, we cannot fail to class it among the most important truths in geometry. From this proposition its author concluded that the diagonal of a square is incommensurate to its side; and this gave occasion to the discovery of several general properties of other incommensurate lines and numbers.

4. In the time which elapsed between the birth of Pythagoras and the destruction of the Alexandrian school, the mathematical sciences were cultivated with great ardour and success. Many of the elementary propositions of geometry were discovered during this period; but history does not enable us to refer each discovery to its proper author. The method of letting fall a perpendicular upon a right line from a given point (Euclid, B. I. prop. xi.);—of dividing an angle into two equal parts, (Euclid, B. I. prop. ix.); and of making an angle equal to a given angle, (Euclid, B. I. prop. xxiii.) were invented by Oenopidus of Chios. About the same time Zenodorus, some of whose writings have been preserved by Theon in his commentary on Ptolemy, demonstrated, in opposition to the opinion then entertained, that isoperimetrical figures have equal areas. Coeval with this discovery was the theory of regular bodies, for which we are indebted to the Pythagorean school.

Discoveries of Oenopidus and Zenodorus.

The celebrated problem of the duplication of the cube proposed and investigated.

5. About this time the celebrated problem of the duplication of the cube began to occupy the attention of the Greek geometers. In this problem it was required to construct a cube whose solid content should be double that of a given cube; and the assistance of no other instrument but the rule and compasses was to be employed. The origin of this problem has been ascribed by tradition to a demand of one of the Grecian deities. The Athenians having offered some affront to Apollo, were afflicted with a dreadful pestilence; and upon consulting the oracle at Delos, received for answer, *Double the altar of Apollo.* The altar alluded to happened to be cubical; and the problem, supposed to be of divine origin, was investigated with ardour by the Greek geometers, though it afterwards baffled all their acuteness. The solution of this difficulty was attempted by Hippocrates of Chios. He discovered, that if

A. C. 450.

two mean proportionals could be found between the side of the given cube, and the double of that side, the first of these proportionals would be the side of the cube sought. In order to effect this, Plato invented an instrument composed of two rules, one of which moved in grooves cut in two arms at right angles to the other, so as always to continue parallel with it; but as this method was mechanical, and likewise supposed the description of a curve of the third order, it did not satisfy the ancient geometers. The doctrine of conic sections, which was at this time introduced into geometry by Plato, and which was so widely extended as to receive the name of the *higher geometry*, was successfully employed in the problem of doubling the cube. Menechmus found that the two mean proportionals mentioned by Hippocrates, might be considered as the ordinates of two conic sections, which being constructed according to the conditions of the problem, would intersect one another in two points proper for the solution of the problem. The question having assumed this form, gave rise to the theory of geometrical loci, of which so many important applications have been made. In doubling the cube, therefore, we have only to employ the instruments which have been invented for describing the conic sections by one continued motion. It was afterwards found, that instead of employing two conic sections, the problem could be solved by the intersection of the circle of the parabola. Succeeding geometers employed other curves for this purpose, such as the conchoid of Nicomedes and the cissoid of Diocles, &c. An ingenious method of finding the two mean proportionals, without the aid of the conic sections, was afterwards given by Pappus in his mathematical collections.

Conic sections discovered by Plato. A. C. 390.

A. C. 280. A. C. 460. A. D. 400.

6. Another celebrated problem, to trisect an angle, was agitated in the school of Plato. It was found that this problem depended upon principles analogous to those of the duplication of the cube, and that it could be constructed either by the intersection of two conic sections, or by the intersection of a circle with a parabola. Without the aid of the conic sections, it was reduced to this simple proposition:—To draw a line to a semicircle from a given point, which line shall cut its circumference, and the prolongation of the diameter that forms its base, so that the part of the line comprehended between the two points of intersection shall be equal to the radius. From this proposition several easy constructions may be derived. Dinostratus of the Platonic school, and the cotemporary of Menechmus, invented a curve by which the preceding problem might be solved. It had the advantage also of giving the multiplication of an angle, and the quadrature of the circle, from which it derived the name of quadratrix.

The trisection of an angle.

7. While Hippocrates of Chios was paving the way for the method of doubling the cube, which was afterwards given by Pappus, he distinguished himself by the quadrature of the lunulæ of the circle; and had from this circumstance the honour of being the first who found a curvilineal area equal to a space bounded by right lines. He was likewise the author of Elements of Geometry, a work, which, though highly approved of by his cotemporaries, has shared the same fate with some of the most valuable productions of antiquity.

Hippocrates's lunula. A. C. 450.

8. After the conic sections had been introduced into geometry by Plato, they received many important additions from Eudoxus, Menechmus, and Aristeus. The latter

A. C. 380. latter of these philosophers wrote *five* books on conic sections, which, unfortunately for science, have not A. C. 300. reached our times.

Elements of Euclid. 9. About this time appeared Euclid's Elements of Geometry, a work which has been employed for 2000 years in teaching the principles of mathematics, and which is still reckoned the most complete work upon the subject. Peter Ramus has ascribed to Theon both the propositions and the demonstrations in Euclid. It has been the opinion of others that the propositions belong to Euclid, and the demonstrations to Theon, while others have given to Euclid the honour of both. It seems most probable, however, that Euclid merely collected and arranged the geometrical knowledge of the ancients, and that he supplied many new propositions in order to form that chain of reasoning which runs through his elements. This great work of the Greek geometer consists of fifteen books: the eleven first books contain the elements of pure geometry, and the rest contain the general theory of ratios, and the leading properties of commensurate and incommensurate numbers.

Discoveries of Archimedes. A. C. 250. 10. Archimedes, the greatest geometer among the ancients, flourished about half a century after Euclid. He was the first who found the ratio between the diameter of a circle and its circumference; and, by a method of approximation, he determined this ratio to be as 7 to 22. This result was obtained by taking an arithmetical mean between the perimeters of the inscribed and circumscribed polygon, and is sufficiently accurate for every practical purpose. Many attempts have since been made to assign the precise ratio of the circumference of a circle to its diameter; but in the present state of geometry this problem does not seem to admit of a solution. The limits of this article will not permit us to enlarge upon the discoveries of the philosopher of Syracuse. We can only state, that he discovered the superficies of a sphere to be equal to the convex surface of the circumscribed cylinder, or to the area of four of its great circles, and that the solidity of the sphere is to that of the cylinder as 3 to 2. He discovered that the solidity of the paraboloid is one half that of the circumscribed cylinder, and that the area of the parabola is two thirds that of the circumscribed rectangle; and he was the first who pointed out the method of drawing tangents and forming spirals. These discoveries are contained in his works on the dimension of the circle, on the sphere and cylinder, on conoids and spheroids, and on spiral lines. Archimedes was so fond of his discovery of the proportion between the solidity of the sphere and that of the cylinder, that he ordered to be placed upon his tomb a sphere inscribed in a cylinder, and likewise the numbers which express the ratio of these solids.

Discoveries of Apollonius. A. C. 200. 11. While geometry was thus advancing with such rapid steps, Apollonius Pergæus, so called from being born at Perga in Pamphylia, followed in the steps of Archimedes, and widely extended the boundaries of the science. In addition to several mathematical works, which are now lost, Apollonius wrote a treatise on the theory of the conic sections, which contains all their properties with relation to their axes, their diameters, and their tangents. He demonstrated the celebrated theorem, that the parallelogram described about the two conjugate diameters of an ellipse or hyperbola is equal to the rectangle described round the two axes, and that the sum or difference of the squares of the two conjugate diameters are equal to the sum or difference of the squares of the two axes. In his fifth book he determines the greatest and the least lines that can be drawn to the circumferences of the conic sections from a given point, whether this point is situated in or out of the axis. This work, which contains everywhere the deepest marks of an inventive genius, procured for its author the appellation of the *Great Geometer*.

12. There is some reason to believe, that the Egyptians were a little acquainted with plane trigonometry; and there can be no doubt that it was known to the Greeks. Spherical trigonometry, which is a more difficult part of geometry, does not seem to have made any progress till the time of Menelaus, an excellent geometrician and astronomer. In his work on spherical triangles, he gives the method of constructing them, and of resolving most of the cases which were necessary in the ancient astronomy. An introduction to spherical trigonometry had already been given to the world by Theodosius in his Treatise on Spherics, where he examines the relative properties of different circles formed by cutting a sphere in all directions. Menelaus writes on spherical triangles. A. D. 55. Theodosius's spherics. A. C. 60.

13. Though the Greeks had made great progress in the science of geometry, they do not seem to have hitherto considered quantity in its general or abstract state. In the writings of Plato we can discover something like traces of geometrical analysis; and in the seventh proposition of Archimedes's work on the sphere and the cylinder, these traces are more distinctly marked. He reasons about unknown magnitudes as if they were known, and he finally arrives at an analogy, which, when put into the language of algebra, gives an equation of the third degree, which leads to the solution of the problem. Progress of analysis.

14. It was reserved, however, for Diophantus to lay the foundation of the modern analysis, by his invention of the analysis of indeterminate problems; for the method which he employed in the resolution of these problems has a striking analogy to the present mode of resolving equations of the 1st and 2d degrees. He was likewise the author of thirteen books on arithmetic, several of which are now lost. The works of Diophantus were honoured with a commentary by the beautiful and learned Hypatia, the daughter of Theon. The same A. D. 410. fanaticism which led to the murder of this accomplished female was probably the cause that her works have not descended to posterity. The analysis of indeterminate problems invented by Diophantus. A. D. 350.

15. Near the end of the fourth century of the Christian era, Pappus of Alexandria published his mathematical collections, a work which, besides many new propositions of his own, contains the most valuable productions of ancient geometry. Out of the eight books A. D. 400. of which this work consisted, two have been lost; the rest are occupied with questions in geometry, astronomy, and mechanics. Mathematical collections of Pappus.

16. Diocles, whom we have already had occasion to mention as the inventor of the cissoid, discovered the solution of a problem proposed by Archimedes, viz. to cut a sphere by a plane in a given ratio. The solution of Diocles has been conveyed to us by Eutocius, who wrote commentaries on some of the works of Archimedes and Apollonius, A. D. 520. About the time of Discoveries of Diocles.

and Serenus. of Diocles flourished Serenus, who wrote two books on the cylinder and cone, which have been published at the end of Halley's edition of Apollonius.

Labours of Proclus. A. D. 500. 17. Geometry was likewise indebted to Proclus, the head of the Platonic school at Athens, not only from his patronage of men of science, but his commentary on the first book of Euclid. Mathematics were also cultivat- by Marinus, the author of the Introduction to Euclid's Data;—by Isidorus of Miletus, who was a disciple of Proclus, and by Hero the younger, whose work, entitled Geodesia, contains the method of determining the area of a triangle from its three sides.

Destruction of the Alexandrian library. 18. While the mathematical sciences were thus flourishing in Greece, and were so successfully cultivated by the philosophers of the Alexandrian school, their very existence was threatened by one of those great revolutions with which the world has been convulsed. The dreadful ravages which were committed by the successors of Mahomet in Egypt, Persia, and Syria, the destruction of the Alexandrian library by the caliph Omar, and the dispersion of a number of those illustrious men who had flocked to Alexandria as the cultivators of science, gave a deadly blow to the progress of geometry. Revival of science. When the fanaticism of the Mahometan religion, however, had subsided, and the termination of war had turned the minds of the Arabs to the pursuits of peace, the arts and sciences engaged their affection, and they began to kindle those very intellectual lights which they had so assiduously endeavoured to extinguish. The works of the Greek geometers were studied with care; and the arts and sciences reviving under the auspices of the Arabs, were communicated in a more advanced condition to the other nations of the world.

19. The system of arithmetical notation at present adopted in every civilized country, had its origin among A. D. 960. the Arabs. Their system of arithmetic was made known to Europe by the famous Gerbert, afterwards Pope Sylvester II. who travelled into Spain when it was under the dominion of that nation.

20. The invention of algebra has been ascribed to the Arabs by Cardan and Wallis, from the circumstance of their using the words *square*, *cube*, *quadrato-quadratum*, &c. instead of the 2d, 3d, 4th, &c. powers as employed by Diophantus. But whatever truth there may be in this supposition, it appears that they were able to resolve cubic, and even biquadratic equations, as there is in the Leyden library, an Arabic MS. entitled "The Algebra of Cubic Equations, or the Solution of Solid Problems."

Progress of the Arabs in geometry. 21. The various works of the Greek geometers were translated by the Arabs, and it is through the medium of an Arabic version, that the fifth and sixth books of Apollonius have descended to our times. Mahomet Ben Musa, the author of a work on Plane and Spherical Figures, and Geber Ben Aphla, who wrote a commentary on Plato, gave a new form to the plane and spherical trigonometry of the ancients. By reducing the theory of triangles to a few propositions, and by substituting, instead of the chords of double arcs, the sines of the arcs themselves, they simplified this important branch of geometry, and contributed greatly to the abridgement of astronomical calculation. A treatise on the art of surveying was likewise written by Mahomet of Bagdad.

22. After the destruction of the Alexandrian school founded by Lagus, one of the successors of Alexander, the dispersed Greeks continued for a while to cultivate their favourite sciences, and exhibited some marks of that genius which had inspired their forefathers. The *magic squares* were invented by Moschopulos, a discovery more remarkable for its ingenuity than for its practical use. Moschopulos's discovery of the magic squares. The same subject was afterwards treated by Cornelius Agrippa in his work on occult philosophy; by Bachet de Meziriac, a learned algebraist, about the beginning of the 17th century, and in later times by Frenicle de Bessi, M. Poignard of Brussels, De la Hire, and Sauveur.

23. The science of pure mathematics advanced with a doubtful pace during the 13th, 14th, and 15th centuries. Algebra introduced into Italy by Leonard of Pisa 1202, 1228. The algebra of the Arabians was introduced into Italy by Leonard of Pisa, who, in the course of his commercial speculations in the east, had considerable intercourse with the Arabs. A work on the Plani sphere, and ten books on arithmetic, were written by Jordanus Nemorarius. The Elements of Euclid were A.D. 1230. translated by Campanus of Novara. A.D. 1250. A work on algebra, entitled *Summa de Arithmetica, Geometria, Proportione et Proportionalitate*, was published by Lucas Paccioli; and about the same time appeared Regiomontanus's treatise on trigonometry, which contains the method of resolving spherical triangles in general, when A.D. 1494. the three angles or three sides are known.

24. During the 16th century, algebra and geometry advanced with rapidity, and received many new discoveries from the Italian philosophers. The formula for A.D. 1505. the solution of equations of the third degree was dis- A.D. 1535. covered by Scipio Ferri professor of mathematics at Bologna, and perhaps by Nicholas Tartalea of Brescia; and equations of the fourth order were resolved by Lewis Ferrari, the disciple of Hieronymus Cardan of Bononia. This last mathematician published nine books of arithmetic in 1539; and in 1545, he added a tenth, containing the doctrine of cubic equations which he had received in secrecy from Tartalea, but which he had so improved as to render them in some measure his own. The common rule for solving cubic equations still goes by the name of Cardan's Rule.

Discoveries of Bombelli. A.D. 1579. 25. The irreducible case in cubic equations was successfully illustrated by Raphael Bombelli of Bologna. He has shown in his algebra, what was then considered as a paradox, that the parts of the formula which represents each root in the irreducible case, form, when taken together, a real result; but the paradox vanished when it was seen from the demonstration of Bombelli that the imaginary quantities contained in the two numbers of the formula necessarily destroyed each other by their opposite signs. Labours of Maurolycus. Born 1494. Died 1579. About this time Maurolycus, a Sicilian mathematician, discovered the method of summing up several serieses of numbers, such as the series 1, 2, 3, 4, &c.; 1, 4, 9, 16, &c. and the series of triangular numbers, 1, 3, 6, 10, 15, 21, &c.

Discoveries of Vieta. Born 1540. Died 1603. 26. The science of analysis is under great obligations to Francis Vieta, a native of France. He introduced the present mode of notation, called *literal*, by employing the letters of the alphabet to represent indefinite given quantities; and we are also indebted to him for the method of transforming one equation into another, whose roots are greater or less than those of the original equation by a given quantity; for the method of multiplying or dividing their roots by any given number,

ber, of depriving equations of the second term, and of freeing them from fractional coefficients. The method which he has given for resolving equations of the third and fourth degree is also new and ingenious, and his mode of obtaining an approximate solution of equations of every order is entitled to still higher praise. We are also indebted to Vieta for the theory of angular sections, the object of which is to find the general expressions of the chords or sines for a series of arcs that are multiples of each other.

Logarithms invented by Baron Napier. Born 1550. Died 1617.

27. While analysis was making such progress on the continent, Baron Napier of Merchiston in Scotland was bringing to perfection his illustrious discovery of the *logarithms*, a set of artificial numbers, by which the most tedious operations in multiplication and division may be performed merely by addition and subtraction. This discovery was published at Edinburgh in 1614 in his work entitled *Logarithmorum Canonis Descriptio, seu Arithmetica Supputationum Mirabilis Abbreviatio.* It is well known that there is such a correspondence between every arithmetical and geometrical progression, viz. $\left\{\begin{matrix}0, & 1, & 2, & 3, & 4, & 5, & 6,\\ 1, & 2, & 4, & 8, & 16, & 32, & 64,\end{matrix}\right\}$ that any terms of the geometrical progression may be multiplied or divided by merely adding or subtracting the corresponding terms of the arithmetical progression; thus the product of four and eight may be found by taking the sum of the corresponding terms in the arithmetical progression, viz. 2 and 3, for their sum 5 points out 32 as the product of 4 and 8. The numbers 0, 1, 2, 3, &c. are therefore the logarithms of 1, 2, 4, 8, &c. The choice of the two progressions being altogether arbitrary, Baron Napier took the arithmetical progression which we have given above, and made the term 0 correspond with the unit of the geometrical progression, which he regulated in such a manner that when its terms are represented by the abscissæ of an equilateral hyperbola in which the first absciss and the first ordinate are each equal to 1, the logarithms are represented by the hyperbolic spaces. In consequence, however, of the inconvenience of this geometrical progression, Baron Napier, after consulting upon the subject with Henry Briggs of Gresham College, substituted the decuple progression, 1, 10, 100, 1000, of which 0, 1, 2, 3, 4, &c. are the logarithms. Nothing now remained but to construct tables of logarithms, by finding the logarithms of the intermediate numbers between the terms of the decuple progression. Napier, however, died before he was able to calculate these tables; but his loss was in some measure supplied by Mr Briggs, who applied himself with zeal to this arduous task, and published in 1618 a table of the logarithms of all numbers from 1 to 1000. In 1624 he published another table containing the logarithms from 1000 to 20,000, and from 90,000 to 100,000. The defects in Briggs's tables were filled up by his friends Gellibrand and Hadrian Vlacq, who also published new tables containing the logarithms of sines, tangents, &c. for 90 degrees.

Tables of logarithms computed by Mr Briggs.

A.D. 1618.

Discoveries of Harriot. Born 1560. Died 1621.

28. During the time when Napier and Briggs were doing honour to their country by completing the system of logarithms, algebra was making great progress in the hands of our countryman Harriot. His *Artis analyticæ Praxis*, which appeared in 1620, contains, along with the discoveries of its author, a complete view of the state of algebra. He simplified the notation by substituting small letters instead of the capitals introduced by Vieta; and he was the first who showed that every equation beyond the first degree may be considered as produced by the multiplication of as many simple equations as there are units in the exponent of the highest power of the unknown quantity. From this he deduced the relation which exists between the roots of an equation, and the coefficients of the terms of which it consists.

Fernel first gives the measure of the earth.

29. About the same time, a foreign author named Fernel, physician to King Henry II. of France, had the merit of being the first who gave the measure of the earth. By reckoning the number of turns made by a coach-wheel from Amiens to Paris, till the altitude of the pole star was increased one degree, he estimated the length of a degree of the meridian to be 56,746 toises, which is wonderfully near the truth. He also wrote a work on mathematics, entitled *De Proportionibus.*—About this time it was shown by Peter Metius, a German mathematician, that if the diameter of a circle be 113, its circumference will be 355. This result, so very near the truth, and expressed in so few figures, has preserved the name of its author.

Metius finds more correct numbers for the diameter and circumference of a circle.

Discoveries of Descartes in algebra. born 1596. Died 1650.

30. The next author, whose labours claim our attention, is the illustrious Descartes. We do not allude to those wild and ingenious speculations by which this philosopher endeavoured to explain the celestial phenomena; but to these great discoveries with which he enriched the kindred sciences of algebra and geometry. He introduced the present method of marking the powers of any quantity by numerical exponents. He first explained the use of negative roots in equations, and showed that they are as real and useful as positive roots, the only difference between them being founded on the different manner in which the corresponding quantities are considered. He pointed out the method of finding the number of positive and negative roots in any equation where the roots are real; and developed the method of indeterminates which Vieta had obscurely hinted at.

He extends the application of algebra to geometry.

31. Though Regiomontanus, Tartalea, and Bombelli, had resolved several geometrical problems by means of algebra, yet the general method of applying geometry to algebra was first given by Vieta. It is to Descartes, however, that we are indebted for the beautiful and extensive use which he made of his discovery. His method of representing the nature of curve lines by equations, and of arranging them in different orders according to the equations which distinguished them, opened a vast field of inquiry to subsequent mathematicians; and his methods of constructing curves of double curvature, and of drawing tangents to curve lines, have contributed much to the progress of geometry. The inverse method of tangents, which it was reserved for the fluxionary calculus to bring to perfection, originated at this time in a problem which Florimundus de Beaune proposed to Descartes. It was required to construct a curve in which the ratio of the ordinate and subtangent should be the same as that of a given line to the portion of the ordinate included between the curve and a line inclined at a given angle. The curve was constructed by Descartes, and several of its properties detected, but he was unable to accomplish the complete solution of the problem. These discoveries of Descartes were studied and improved by his successors, among whom

A. D. 1647.

A. D. 1658.

whom we may number the celebrated Hudde, who published in Schooten's commentary on the geometry of Descartes, an excellent method of determining if an equation of any order contains several equal roots, and of discovering the roots which it contains.

Discoveries of Pascal. Born 1623. Died 1662.

32. The celebrated Pascal, who was equally distinguished by his literary and his scientific acquirements, extended the boundaries of analysis by the invention of his arithmetical triangle. By means of arbitrary numbers placed at the vertex of the triangle, he forms all the figurate numbers in succession, and determines the ratio between the numbers of any two cases, and the various sums resulting from the addition of all the numbers of one rank taken in any possible direction. This ingenious invention gave rise to the calculation of probabilities in the theory of games of chance, and formed the foundation of an excellent treatise of Huygens, entitled *De Ratiociniis in Ludo Aleæ*, published in 1657.

Discoveries of Fermat. Born 1590. Died 1663.

33. Several curious properties of numbers were at the same time discovered by Fermat at Toulouse. In the theory of prime numbers, particularly, which had first been considered by Eratosthenes, Fermat made great discoveries; and in the doctrine of indeterminate problems, he seems to have been deeply versed, having republished the arithmetic of Diophantus, and enriched it with many valuable notes of his own. He invented the method of discovering the *maxima* and *minima* of variable quantities, which serves to determine the tangents of geometrical curves, and paved the way for the invention of the fluxionary calculus.

Cavaleri's method of indivisibles. 1635.

34. Another step towards the discovery of fluxions was at this time made by Cavaleri in his geometry of indivisibles. In this work, which was published in 1635, its author supposes every plane surface to consist of an infinite number of planes; and he lays it down as an axiom, that these infinite sums of lines and surfaces have the same ratio when compared with the unit in each case as the superficies and solids to be measured. This ingenious method was employed by Cavaleri in the quadrature of the conic sections, and in the curvature of solids generated by their revolution; and in order to prove the accuracy of his theory, he deduced the same results from different principles.

The same subject discussed by Roberval. 1634.

35. Problems of a similar kind had been solved by Fermat and Descartes, and now occupied the attention of Roberval. The latter of these mathematicians began his investigation of this subject about a year before the publication of Cavaleri's work, and the methods which both of them employed were so far the same as to be founded on the principles of indivisibles. In the mode, however, which Roberval adopted, planes and solids were considered as composed of an infinite number of rectangles, whose altitudes and the thickness of their sections were infinitely small.—By means of this method, Roberval determined the area of the cycloid, the centre of gravity of this area, and the solids formed by its revolution on its axis and base. He also invented a general method for tangents, similar in metaphysical principles to that of fluxions, and applicable both to mechanical and geometrical curves. By means of this, he determined the tangents of the cycloid; but there were some curves which resisted its application. Considering every curve to be generated by the motion of a point, Roberval regarded this point as acted upon at every instant with two velocities ascertained from the nature of the curve. He constructed a parallelogram having its sides in the same ratio as the two velocities; and he assumes as a principle, that the direction of the tangent must fall on the diagonal, the position of which being ascertained, gives the position of the tangent.

Labours of Torricelli. 1644.

36. In 1644, solutions of the cycloidal problems formerly resolved by Roberval were published by Torricelli as invented by himself. The demonstrations of Roberval had been transmitted to Galileo the preceptor of Torricelli, and had also been published in 1637 in Mersennus's Universal Harmony. The Italian philosopher was consequently accused of plagiarism by Roberval, and the charge so deeply affected his mind as to bring him prematurely to the grave. It is obvious, however, from the demonstrations of Torricelli, that he had never seen those of Roberval, and that he was far from meriting that cruel accusation which deprived science of one of its brightest ornaments.

Farther discoveries of Pascal. 1658.

37. The cycloid having attracted the notice of geometers from the number and singularity of its properties, the celebrated Pascal proposed to them a variety of new problems relative to this curve, and offered prizes for their solution. These problems required the area of any cycloidal segment, the centre of gravity of that segment, the solids, and the centres of gravity of the solids, which are generated either by a whole revolution, a half or a quarter of a revolution of this segment round an abscissa or an ordinate. The resolution of these problems was attempted by Huygens, Sluze, Sir Christopher Wren, Fermat, and Roberval. Sluze discovered an ingenious method of finding the area of the curve. Huygens squared the segment comprised between the vertex, and as far as a fourth of the diameter of the generating circle; and Sir Christopher Wren ascertained the length of the cycloidal arc included between the vertex and the ordinate, the centre of gravity of this arc, and the surfaces of the solids generated during its revolution. These attempts were not considered by their authors as solutions of Pascal's problems, and therefore they did not lay claim to his prize. Our countryman Wallis, however, and Lallouere a Jesuit, gave in a solution of all the problems, and thought themselves entitled to the proffered reward. In the methods employed by these mathematicians, Pascal detected several sources of error; and it was reserved for that great genius to furnish a complete solution of his own problems. Extending his investigations to curtate and prolate cycloids, he proved that the length of these curves depends on the rectification of the ellipse, and assigned in each case the axis of the ellipse. From this method he deduced this curious theorem, that if two cycloids, the one curtate and the other prolate, be such, that the base of the one is equal to the circumference of the circle by which the other is generated, the length of these two cycloids will be equal.

Labours of Wallis. 1655.

38. While these discoveries were making on the continent, the friends of science in Britain were actively employed in promoting its advancement. In 1655, Wallis published his *Arithmetica Infinitorum*, a work of great genius. He attempted to determine by the summation of infinite series, the quadrature of curves, and the curvature of solids, subjects which were afterwards 1682.
investigated in a different manner by Ishmael Bullialdus. By Wallis's method, curves were squared when their ordinates are expressed by one term, and when their

their ordinates were complex quantities raised to entire and positive powers, these ordinates were resolved into series, of which each term is a monomial. Wallis attempted to extend his theory to curves whose ordinates were complex and radical, by attempting to interpolate the series of the former kind with a new series; but he was unsuccessful.

Discoveries of Newton.

39. It was left to Newton to remove this difficulty. He solved the problem in a more direct and simple manner by the aid of his new formula for expanding into an infinite series any power of a binomial, whether its exponent was positive or negative, an integer or a fraction. Algebra is also indebted to this illustrious mathematician for a simple and extensive method of resolving an equation into commensurable factors; for a method of summing up the powers of the roots of an equation, of extracting the roots of quantities partly commensurable, and partly incommensurable, and of finding by approximation the roots of literal and numerical equations of all orders.

Lord Brouncker discovers continued fractions. Born 1620. Died 1684.

40. About this time, William Lord Brouncker, in attempting to demonstrate an expression of Wallis on the magnitude of the circle, discovered the theory of continued fractions. When an irreducible fraction is expressed by numbers too great and complicated to be easily employed by the analyst, the method of Lord Brouncker enables us to substitute an expression much more simple and nearly equivalent. This theory, which enables us to find a very accurate relation between the diameter and circumference of the circle, was employed by Huygens * in the calculation of his planetary automaton, for representing the motions of the solar system, and was enlarged and improved by other celebrated geometers. Lord Brouncker had likewise the merit of discovering an infinite series to represent the area of the hyperbola. The same discovery was made by Nicholas Mercator, who published it in his *Logarithmotechnia* in 1668.

* *Opera Posthuma*, tom. ii. *sub finem.*

Labours of James Gregory.

41. The subject of infinite series received considerable addition from Mr James Gregory. He was the first who gave the tangent and secant in terms of the arc, and, inversely, the arc in terms of the tangent and secant. He constructed series for finding directly the logarithm of the tangent and secant from the value of the arc, and the logarithm of the arc from that of the tangent and secant; and he applied this theory of infinite series to the rectification of the ellipsis and hyperbola.

Labours of Dr Barrow.

42. The differential triangle invented by the learned Dr Barrow, for drawing tangents to curves, may be regarded as another contribution towards the invention of fluxions. This triangle has for its sides the element of the curve and those of the absciss and ordinate, and those sides are treated as quantities infinitely small.

Theory of evolutes discovered by Huygens, 1673.

43. The doctrine of evolutes had been slightly touched upon by Apollonius. It remained, however, for the illustrious Huygens to bring it to perfection. His theory of evolutes is contained in his *Horologium Oscillatorium*, published in 1673, and may be regarded as one of the finest discoveries in geometry. When any curve is given, Huygens has pointed out the method of constructing a second curve, by drawing a series of perpendiculars to the first, which are tangents to the second; and of finding the first curve from the second. From this principle he deduces several theorems on the rectification of curves; and that remarkable property of the cycloid, in which an equal and similar cycloid is produced by evolution.

History of the discovery of fluxions.

44. In contemplating the progress of analysis from the beginning of the 17th century, to the invention of fluxions, we cannot fail to perceive the principles of that calculus gradually unfolding themselves to view. The human mind seemed to advance with rapidity towards that great discovery; and it is by no means unlikely that it would soon have arrived at the doctrine of fluxions, even if the superior genius of Newton had not accelerated its progress. In Cavalerius's *Geometria Indivisibilium*, we perceive the germ of the infinitesimal calculus; and the method of Roberval for finding the tangents of curves, bears a striking analogy to the metaphysics of the fluxionary calculus. It was the glory of Newton, however, to invent and illustrate the method of fluxions; and the obscure hints which he received from preceding mathematicians, do not in the least detract from the merit of our illustrious countryman.

General remarks on the dispute between Newton and Leibnitz.

45. On the claims of Leibnitz as a second inventor of fluxions, and the illiberal violence with which they have been urged by foreign mathematicians, we would wish to speak with delicacy and moderation. Who that can appreciate the discoveries of that celebrated mathematician, or is acquainted with that penetrating genius which threw light on every department of human knowledge, would willingly stain his memory with an ungracious imputation? The accusation of plagiarism is one of those charges which it is difficult either to substantiate or repel, and when directed against a great man, ought never, without the clearest evidence, to be wantonly preferred or willingly received. If charitable sentiments are ever to be entertained towards others,—to what class of beings should they be more cheerfully extended than to those who have been the ornaments of human nature? If society has agreed to regard as sacred the failings and excentricities of genius,—when ought that reverence to be more strongly excited than when we are passing judgment on its mightiest efforts? Inquiries into the motives and actions of the learned ought never to be wantonly indulged. When the honour of our country, or the character of an individual, requires such an investigation, a regard to truth, and a contempt of national prejudice, should guide the inquiry.—We should proceed with delicacy and forbearance.—We should tread lightly even on the ashes of genius. It is not uncommon to witness the indulgence of malicious pleasure, in detracting from the merits of a distinguished character. The assailant raises himself for a while to the level of his enemy, and acquires glory by his fall. But let him remember that the laurels thus won cannot flourish long. The same public opinion which conferred them will tear them from his brow, and consign the accuser to that infamy from which the brightest abilities will be insufficient to raise him. The consequences of such conduct have been seen in the fall of Torricelli. It was the charges of plagiarism, preferred by Roberval, that hurried this young and accomplished philosopher to an early grave.

46. We have been led into these observations by studying the dispute between the followers of Newton and Leibnitz. The claims of the British, as well as those of the

the foreign mathematicians, have undoubtedly been too high; and victory rather than truth seems to have been the object of contest. Even the name of Newton has not escaped from serious imputations. The immensity of the stake for which the different parties contended, may perhaps justify the commencement of the dispute; and the brilliancy of the talents that were called into action, may leave us no cause to regret its continuance: But nothing can reconcile us to those personal animosities in which the good sense and temper of philosophy are lost, and that violence of literary warfare where science can gain nothing in the combat.—In giving an account, therefore, of that interesting dispute, we shall merely give a brief view of the facts that relate to the discovery of the higher calculus, and make a few observations on the conclusions to which they lead.

Newton publishes a tract containing the principles of fluxions.

47. In the year 1669, a paper of Sir Isaac Newton's, entitled *De analysi per equationes numero terminorum infinitas*, was communicated by Dr Barrow to Mr Collins, one of the secretaries of the Royal Society. In this paper the author points out a new method of squaring curves, both when the expression of the ordinate is a rational quantity, and when it contains complex radicals, by evolving the expression of the ordinate into an infinite number of simple terms by means of the binomial theorem. In a letter from Newton to Collins, dated December 10. 1672, there is contained a method of drawing tangents to curve lines, without being obstructed by radicals; and in both these works, an account of which was circulated on the continent by the secretaries of the Royal Society, the principles of the fluxional calculus are plainly exhibited; and it is the opinion of all the disputants, that those works at least prove, that Newton must have been acquainted with the method of fluxions when he composed them.

48. Leibnitz came to London in 1673, and though there is no direct evidence that he saw Newton's paper *De Analysi per Equationes*, &c. yet it is certain that he had seen Sir Isaac's letter to Collins of 1672; and it is highly improbable that such a man as Leibnitz should have been ignorant of a paper of Newton's which had been four years in the possession of the public, and which contained discussions at that time interesting to every mathematician.

Correspondence between Leibnitz and Oldenburg.

49. A letter from Newton to Oldenburg, one of the secretaries of the Royal Society, dated October 24. 1676, was communicated to Leibnitz. This letter contains several theorems without the demonstrations, which are founded on the method of fluxions, and merely states that they result from the solution of a general problem. The enunciation of this problem he expresses in a cypher, the meaning of which was, An equation containing any number of flowing quantities being given, to find the fluxions, and inversely. In reply to this communication, Leibnitz transmitted a letter to Oldenburg, dated June 21. 1677, where he explains the nature of the differential calculus, and affirms, that he had long employed it for drawing tangents to curve lines.

Leibnitz publishes an account of the differential calculus.

50. The correspondence between Leibnitz and Oldenburg having been broken off by the death of the latter, Leibnitz published in the *Acta Erudit. Lips.* for October 1684, the principles of the new analysis, under the title of *Nova Methodus pro maximis et minimis, itemque tangentibus, quæ nec fractas, nec irrationales quantitates moratur, et singulare pro illis calculus.* This paper contains the method of differencing simple, fractional, and radical quantities, and the application of the calculus to the solution of some physical and geometrical problems. In 1685, he likewise published two small pamphlets on the quadrature of curves, containing the principles of the *Calculus Summatorius*, or the *Inverse Method of Fluxions;* and in 1686 there appeared another tract by the same author, *On the Recondite Geometry, and the Analysis of Indivisibles and Infinites*, containing the fundamental rule of the integral calculus.

Newton publishes his Principia.

51. Towards the close of the year 1686, Sir Isaac Newton gave to the world his illustrious work entitled *Philosophiæ Naturalis Principia Mathematica.* Some of the most difficult problems in this work are founded on the fluxional calculus; and it is allowed by Bossut, one of the defenders of Leibnitz, "that mathematicians did Newton the justice to acknowledge, that at the period when his *Principia* was published, he was master of the method of fluxions to a high degree, at least with respect to that part which concerns the quadrature of curves." The claim of Leibnitz, as a separate inventor of the differential calculus, is evidently allowed by Newton himself, when he observes, that Leibnitz had communicated to him a method similar to his own for drawing tangents, &c. and differing from it only in the enunciation and notation.

Leibnitz proposes the problem of the isochronous curve; which is solved by Huygens in 1687.

52. About this time, it became fashionable among geometers to perplex each other by the proposal of new and difficult problems, a practice which powerfully contributed to the progress of mathematics. The dispute in which Leibnitz was engaged with the Cartesians respecting the measure of active forces, which the former supposed to be as the simple velocity, while the latter asserted, that they were as the square of the velocity, led him to propose the problem of the isochronous curve, or "to find the curve which a heavy body must describe equally, in order to approach or recede from a horizontal plane in equal times." This curve was found by Huygens to be the second cubic parabola; but he gave only its properties and construction without the demonstrations. The same solution, along with the demonstration, was given by Leibnitz in 1689, who, at the same time, proposed to geometers to find the *paracentric isochronal curve*, or the curve in which a body would equally approach or recede from a given point in equal times.

James Bernouilli also finds the isochronous curve.

53. It was at this time that the two brothers, James and John Bernouilli, began to display those talents from which the physical and mathematical sciences received such immense improvements. James was born in 1654, and died in 1705; and John, who was his pupil, was born in 1667, and lived to the advanced age of 68 years. In 1690, James Bernouilli gave the same solution of the isochronous curve that had been given by Huygens and Leibnitz; and proposed the celebrated problem of the catenary curve, which had formerly perplexed the ingenuity of Galileo. In two memoirs, published in 1691, he determined, by means of the inverse method of fluxions, the tangents of the parabolic spiral, the logarithmic spiral, and the loxedromic curve, and likewise the quadratures of their areas.

1691. Solution of the problem of the catenarian curve, and other analogous problems.

54. The problem of the catenary curve having occupied the attention of geometers, was resolved by Huygens, Leibnitz,

Leibnitz, and John Bernouilli. In these solutions, however, the gravity of the catenary curve was supposed to be uniform; but James Bernouilli extended the solution to cases where the weight of the curve varies from one point to another, according to a given law. From this problem he was also conducted to the determination of the curvature of a bended bow, and that of an elastic bar fixed at one extremity, and loaded at the other with a given weight. In the hopes of contributing to the progress of navigation, the same mathematician considered the form of a sail swoln with the wind. When the wind, after striking the sail, is not prevented from escaping, the curvature of the sail is that of the common catenarian curve; but when the sail is supposed perfectly flexible, and filled with a fluid pressing downwards on itself, as water presses on the sides of a vessel, the curve which it forms is one of those denominated *lintcariæ*, which is expressed by the same equation as the common elastic curve, where the extensions are reckoned proportional to the forces applied at each point. —The same problem was solved in the *Journal des Sçavans* for 1692, by John Bernouilli; but there is satisfactory evidence that it was chiefly borrowed from his brother James.

Labours of James Bernouilli. 1692.

55. The attention of James Bernouilli was now directed to the theory of curves produced by the revolution of one curve upon another. He considers one curve rolling upon a given curve, equal to the first, and immoveable. He determines the evolute and the caustic of the epicycloid, described by a point of the moving circle, and he deduces from it other two curves, denominated the *antievolute* and *pericaustic*. He found also that the logarithmic spiral was its own evolute, caustic, antievolute, and pericaustic; and that an analogous property belonged to the cycloid.

1692. Problem of Viviani solved.

56. About this time Viviani, an Italian geometer, distinguished as the restorer of Aristeus's conic sections, required the solution of the following problem, that there existed a temple of a hemispherical form, pierced with four equal windows, with such skill that the remainder of the hemisphere might be perfectly squared. With the aid of the new analysis, Leibnitz and James Bernouilli immediately found a solution, while that of Viviani was founded on the ancient geometry. He proved that the problem might be solved, by placing, parallel to the base of the hemisphere, two right cylinders, the axes of which should pass through the centres of two radii, forming a diameter of the circle of the base, and piercing the dome each way.

Tschirnhausen on caustic curves.

57. Prior to some of these discussions, the curves called *caustic*, and sometimes *Tschirnhausenian*, were discovered by Tschirnhausen. These curves are formed by the crossing of the rays of light, when reflected from a curved surface, or refracted through a lens so as not to meet in a single point. With the assistance of the common geometry, Tschirnhausen discovered that they are equal to straight lines when they are formed by geometrical curves, and found out several other curious properties. By the aid of the higher calculus, James Bernouilli extended these researches, and added greatly to the theory of caustics produced by refraction.

James Bernouilli attends to the same subject, 1693.

and solves the problem of the paracentric isochronal curve,

58. The problem of the paracentric isochronal curve, proposed by Leibnitz in 1689, was solved by James Bernouilli, who took for ordinates parallel straight lines, and for abscissas the chords of an infinite number of concentric circles described about the given point. In this way he obtained a separate equation, constructed at first by the rectification of the elastic curve, and afterwards by the rectification of an algebraic curve. The same problem was solved by John Bernouilli and Leibnitz. 1689.

The exponential calculus invented by Leibnitz and John Bernouilli.

59. In 1694, a branch of the new analysis, called the *exponential calculus*, was invented separately by John Bernouilli and Leibnitz. It consists in differencing and integrating exponential quantities or powers with variable exponents. To Leibnitz, the priority in point of invention certainly belongs; but John Bernouilli was the first who published the rules and uses of the calculus.

The Marquis l'Hospital publishes his analysis of infinites.

60. The marquis l'Hospital, who, in 1695, had solved the problem about the curve of equilibration in draw-bridges, and shewn it to be an epicycloid, published in the following year his *Analysis of Infinites for the understanding of curve lines.* In this celebrated work, the differential calculus, or the direct method of fluxions, was fully explained and illustrated; and as the knowledge of the higher geometry had been hitherto confined to a few, it was now destined to enlighten the different nations of Europe.

Newton finds the solid of least resistance.

61. The methods which were employed by Descartes, Fermat, &c. for finding the maxima and minima of quantities, yielded in point of simplicity and generality to that which was derived from the doctrine of fluxions. Another class of problems, however, of the same kind, but more complicated, from their requiring the inverse method of fluxions, began now to exercise the ingenuity of mathematicians. A problem of this class for finding the solid of least resistance, was solved by Newton in the 34th proposition of the 2d book of his *Principia*. After having determined the truncated right cone, which being moved in a fluid by the smallest base (which is unknown,) experiences the least resistance, he gave without any demonstration the ratio from which might be derived the differential equation of the curve that generates by a revolution of its axis the solid of least resistance. A general solution, however, was still wanting, till the attention of geometers was directed to the subject by John Bernouilli, who proposed, in 1697, the celebrated problem of the *Brachystochronon*, or the curve along the concave side of which if a heavy body descend, it will pass in the least time possible from one point to another, the two points not being in the same vertical line. This problem was resolved by Leibnitz, Newton, the marquis de l'Hospital, and James Bernouilli, who demonstrated that the curve of quickest descent is a cycloid reversed. This result will appear at first surprising, when we consider a line to be the shortest distance between two points; but the surprise will cease when we reflect, that in a concave curve lying between the two given points the moving body descends at first in a more vertical direction, and therefore acquires a greater velocity than when it rolls down an inclined plane. This addition to its velocity, consequently, at the commencement of its path may balance the increase of space through which it has to move.

Dispute between James and John Bernouilli on isoperimetrical figures.

62. At the close of this discussion, commenced that celebrated dispute about isoperimetrical problems, between James and John Bernouilli, in which the qualities of the head were more conspicuous than those of the heart.

heart. These illustrious characters, connected by the strongest ties of affinity, were, at the commencement of their distinguished career, united by the warmest affection. John was initiated by his elder brother into the mathematical sciences; and a generous emulation, softened by friendship in the one, and gratitude in the other, continued for some years to direct their studies, and accelerate their progress. There are few men, however, who can support at the same time the character of a rival and a friend. The success of the one party is apt to awaken the envy of the other, and success itself is often the parent of presumption. A foundation is thus laid for future dissension; and it is a melancholy fact in the history of learning, that the most ardent friendships have been sacrificed on the altar of literary ambition. Such was the case between the two
1695. Bernouillis. As soon as John was settled as professor of mathematics at Groningen, all friendly intercourse between the two brothers was at an end. Regarding John as the aggressor, and provoked at the ingratitude which he exhibited, his brother James challenged him
Problems proposed by James to John Bernouilli. by name to solve the following problems: 1. "To find, among all the isoperimetrical curves between given limits, such a curve, that, constructing a second curve, the ordinates of which shall be the functions of the ordinates or arcs of the former, the area of the second curve shall be a maximum or a minimum.—2. "To find among all the cycloids which a heavy body may describe in its descent from a point to a line, the position of which is given, that cycloid which is described in the least possible time."—A prize of 50 florins was promised to John Bernouilli, if, within three months, he engaged to solve these problems, and publish within a year legitimate solutions of them.

63. In a short time John Bernouilli produced his solution and demanded the prize. He succeeded in constructing the problem of swiftest descent; but his solution of the other problem was radically defective. This failure mortified that vanity with which he gloried in his apparent success. He acknowledged the mistake in his solution, and, with the same imperious tone, transmitted a new result, and redemanded the prize. This new solution, which was still defective, drew down the wit and ridicule of James Bernouilli, which his brother attempted to repel by a torrent of coarse invective.

1700. 64. Leibnitz, Newton, and the marquis l'Hospital, being appointed arbiters in this dispute, James Bernouilli published, in 1700, the formulæ of the isoperimetrical problem, without any demonstration; and John transmitted his solution to the French academy in February 1701, on condition that it should not be opened till his brother's demonstrations were published. In consequence of this, James Bernouilli published his solution in May 1701, in the *Acta Eruditorum*, under the following title, *Analysis magni Problematis Isoperimetrici*, and gained great honour from the skill which it displayed. For five years John Bernouilli was silent upon the subject; but his brother dying in 1705, he published his solution in the Memoirs of the Academy for 1706. About 13 years afterwards, John Bernouilli having perceived the source of his error, confessed his mistake, and published a new solution, not very different from that of his brother, in the Memoirs of the Academy for 1718.

65. In the problem relative to the cycloid of swiftest descent, John Bernouilli obtained a result similar to that of his brother, by a very ingenious method, which extended the bounds of the new analysis. In his investigations he employed the synchronous curve, or that which cuts a series of similar curves placed in similar positions, so that the arcs of the latter included between a given point and the synchronous curve, shall be described by a heavy body in equal times. He demonstrated, that of all the cycloids thus intersected, that which is cut perpendicularly is described in less time than any other terminating equally at the synchronous curve. But being unable to give a general solution of the problem, he applied to Leibnitz, who easily resolved it, and at that time invented the method of differencing *de curva in curvam*. John Bernouilli's solution of the second problem. 1704.

66. About a month after the death of the marquis de l'Hospital, John Bernouilli declared himself the author of a rule given by the marquis in his Analysis of Infinites, for finding the value of a fraction, whose numerator and denominator should vanish at the same instant, when the variable quantity that enters into it has a certain given value. The defence made by the marquis's friends only induced John Bernouilli to make greater demands, till he claimed as his own the most important parts of the Analysis of Infinites: But it does not appear, from an examination of the subject, that there is any foundation for his claims.

67. Towards the close of 1704, Sir Isaac Newton published, at the end of his Optics, his *Enumeratio linearum tertiæ ordinis*, and his treatise *De Quadratura Curvarum*. The first of these papers displays great ability; but is founded only on the common algebra, and the doctrine of series which Newton had brought to such perfection. His treatise, *De Quadratura Curvarum*, contains the resolution of fluxional formulæ, with one variable quantity which leads to the quadrature of curves. By means of certain series he obtains the resolution of several complicated formulæ, by referring them to such as are more simple; and these series being interrupted in particular cases, give the fluents in finite terms. From this several interesting propositions are deduced, among which is the method of resolving rational fractions. In 1711 Newton published his *Method of Fluxions*. The object of this work is to determine, by simple algebra, the linear coefficients of an equation that satisfies as many conditions as there are coefficients, and to construct a curve of the parabolic kind passing through any number of given points. Hence arises a simple method of finding the approximate quadrature of curves, in which a certain number of ordinates are determinable. It has been the opinion of some able mathematicians, that this treatise contains the first principles of the integral calculus with finite differences, afterwards invented by Dr Taylor. A posthumous work of Newton's, entitled *The Method of Fluxions, and of Infinite Series*, was published by Dr Pemberton about nine years after the death of its author; but it does not contain any new investigations which accelerated the progress of the new analysis. Labours of Newton. 1704. 1711. 1736.

68. The mathematical sciences were at this time indebted to the labours of Manfredi, Parent, and Saurin. The former of these geometers published a very able work, *De Constructione Equationum differentialium primi gradus*. To Parent we are indebted for the problem Labours of Manfredi, Parent, and Saurin, 1707.

by

by which we obtain the ratio between the velocity of the power and the weight, for finding the *maximum* effect of machines; but his reputation was much injured by the obscurity of his writings. Saurin was celebrated for his theoretical and practical knowledge of watchmaking, and was the first who elucidated the theory of tangents to the multiple points of curves.

Account of the dispute between Newton and Leibnitz.

69. While the science of analysis was thus advancing with rapidity, the dispute between Newton and Leibnitz began to be agitated among the mathematicians of Europe. These illustrious rivals seemed to have been hitherto contented with sharing the honour of having invented the fluxional calculus. But as soon as the priority of invention was attributed to Newton, the friends of Leibnitz came forward with eagerness to support the claims of their master.

Facio de Duillier commences the dispute in favour of Newton.

70. In a small work on the curve of swiftest descent, and the solid of least resistance, published in 1699, Nicholas Facio de Duillier, an eminent Genoese, attributed to Newton the first invention of Fluxions, and hinted, that Leibnitz, as the second inventor, had borrowed from the English philosopher. Exasperated at this improper insinuation, Leibnitz came forward in his own defence, and appeals to the admission of Newton in his *Principia*, that neither had borrowed from the other. He expressed his conviction, that Facio de Duillier was not authorised by Sir Isaac, to prefer such a charge, and threw himself upon the testimony and candour of the English geometer.

Leibnitz defends himself.

Dr Keill makes the samecharge against Leibnitz. 1708.

71. The discussion rested in this situation for several years, till our celebrated countryman, Dr Keill, instigated by an attack upon Newton in the Leipsic Journal, repeated the same charge against Leibnitz. The German philosopher made the same reply as he did to his former opponent, and treated Dr Keill as a young man incapable of judging upon the subject. In 1711, Dr Keill addressed a letter to Sir Hans Sloane, secretary to the Royal Society, and accused Leibnitz of having adopted the differential notation, in order to have it believed that he did not borrow his calculus from the writings of Newton.

1711.

Leibnitz appeals to the Royal Society.

72. Leibnitz was with reason irritated at this accusation, and called upon the Royal Society to interfere in his behalf. A committee of that learned body was accordingly appointed to investigate the subject, and their report was published in 1712, under the title of *Commercium Epistolicum de Analysi promota*. In this report the committee maintain that Leibnitz was not the first inventor, and absolve Dr Keill from all blame in giving the priority of invention to Newton. They were cautious, however, in stating their opinion upon that part of the charge in which Leibnitz was accused of plagiarism.

1712.

Who appoint a committee to examine and report.

John Bernouilli replies to their report given in the *Commercium Epistolicum*.

73. In answer to the arguments advanced in the *Commercium Epistolicum*, John Bernouilli, the particular friend of Leibnitz, published a letter, in which he has the assurance to state, that the method of fluxions did not precede the differential calculus, but that it might have taken its rise from it. The reason which he assigns for this strange assertion is, that the differential calculus was published before Newton had introduced an uniform algorithm into the method of fluxions. But it may as well be maintained that Newton did not discover the theory of universal gravitation, because the attractive force of mountains and of smaller portions of matter was not ascertained till the time of Maskelyne and Cavendish. The principles of fluxions are allowed to have been discovered before those of the differential calculus, and yet the former originated from the latter, because the fluxional notation was not given at the same time!

Remarks on the controversy.

74. Notwithstanding the ridiculous assertion of John Bernouilli, it has been admitted by all the foreign mathematicians that Newton was the first inventor of the method of fluxions. The point at issue therefore is merely this:—did Leibnitz see any of the writings of Newton that contained the principles of fluxions before he published in 1684 his *Nova Methodus pro maximis et minimis*? The friends of Leibnitz have adduced some presumptive proofs that he had never seen the treatise of Newton *de Analysi*, nor the letter to Collins, in both of which the principles of the new calculus were to be found; and in order to strengthen their argument, they have not scrupled to assert, that the writings already mentioned contained but a vague and obscure indication of the method of fluxions, and that Leibnitz might have perused them without having discovered it. This subsidiary argument, however, rests upon the opinion of individuals; and the only way of repelling it is to give the opinion of an impartial judge. M. Montucla, the celebrated historian of the mathematics, who being a Frenchman, cannot be suspected of partiality to the English, has admitted that Newton in his treatise *de Analysi* "has disclosed in a very concise and obscure manner his principles of fluxions," and "that the suspicion of Leibnitz having seen this work is not destitute of probability, for Leibnitz admitted, that in his interview with Collins he had seen a part of the epistolary correspondence between Newton and that gentleman." It is evident therefore that Leibnitz had opportunities of being acquainted with the doctrine of fluxions, before he had thought of the differential calculus; and as he was in London, where Newton's treatise was published, and in company with the very men to whom the new analysis had been communicated, it is very likely that he then acquired some knowledge of the subject. In favour of Leibnitz, however, it is but justice to say, that the transition from the method of tangents by Dr Barrow to the differential calculus is so simple, that Leibnitz might very easily have perceived it; and that the notation of his analysis, the numerous applications which he made of it, and the perfection to which he carried the integral calculus, are considerable proofs that he was innocent of the charge which the English have attempted to fix upon his memory.

Works on the doctrine of chance. 1708.

75. In 1708, Remond de Montmort published a curious work, entitled the Analysis of Games of Chance, in which the common algebra was applied to the computation of probabilities, and the estimation of chances. Though this work did not contain any great discovery, yet it gave extent to the theory of series, and admirably illustrated the doctrine of combinations. The same subject was afterwards discussed by M. de Moivre, a French protestant residing in England, in a small treatise entitled *Mensura Sortis*, in which are given the elements of the theory of recurrent series, and some very ingenious applications of it. Another edition was published in English in 1738, under the title of the *Doctrine of Chances*.

1711.

Leibnitz proposes to the English the problem of orthogonal trajectories.

76. A short time before his death, Leibnitz proposed to the English geometers the celebrated problem of orthogonal trajectories, which was to find the curve that cuts a series of given curves at a constant angle, or at an angle varying according to a given law. This problem was put into the hands of Sir Isaac Newton when he returned to dinner greatly fatigued, and he brought it to an equation before he went to rest. Leibnitz being recently dead, John Bernouilli assumed his place, and maintained, that nothing was easier than to bring the problem to an equation, and that the solution of the problem was not complete till the differential equation of the trajectory was resolved. Nicholas Bernouilli, the son of John, resolved the particular case in which the intersected curves are hyperbolas with the same centre and the same vertex. James Hermann and Nicholas Bernouilli, the nephew of John, treated the subject by more general methods, which applied to the cases in which the intersected curves were geometrical. The most complete solution, however, was given by Dr
1717. Taylor in the Philosophical Transactions for 1717, though it was not sufficiently general, and could not apply to some cases capable of resolution. This defect was supplied by John Bernouilli, who in the Leipsic
1718. Transactions for 1718, published a very simple solution, embracing all the geometrical curves, and a great number of the mechanical ones.

Integration of rational fractions. 1719.

77. During these discussions, several difficult problems on the integration of rational fractions were proposed by Dr Taylor, and solved by John Bernouilli. This subject, however, had been first discussed by Roger Cotes, professor of mathematics at Cambridge, who died in 1710. In his posthumous work entitled *Harmonia Mensurarum*, published in 1716, he gave general and convenient formulæ for the integration of rational fractions; and we are indebted to this young geometer for his method of estimating errors in mixed mathematics, for his remarks on the differential method of Newton, and for his celebrated theorem for resolving certain equations.

Labours of Roger Cotes, born 1676.

Dr Taylor invents the integral calculus of finite differences.

78. In 1715, Dr Taylor published his learned work entitled *Methodus incrementorum directa et inversa.* In this work the doctor gives the name of increments or decrements of variable quantities to the differences, whether finite or infinitely small, of two consecutive terms in a series formed after a given law. When the differences are infinitely small, their calculus belongs to fluxions; but when they are finite, the method of finding their relation to the quantities by which they are produced forms a new calculus, called the integral calculus of finite differences. In consequence of this work, Dr Taylor was attacked anonymously by John Bernouilli, who lavished upon the English geometer all that dull abuse, and angry ridicule, which he had formerly heaped upon his brother.

Problem of reciprocal trajectories. 1716.

79. The problem of reciprocal trajectories was at this time proposed by the Bernouillis. This problem required the curves which, being constructed in two opposite directions in one axis, given in position, and then moving parallel to one another with unequal velocities, should perpetually intersect each other at a given angle. It was long discussed between John Bernouilli and an anonymous writer, who proved to be Dr Pemberton. It was by an elegant solution of this problem that the celebrated Euler began to be distinguished among mathematicians. He was the pupil of John Bernouilli, and continued through the whole of his life, the friend and rival of his son Daniel. The great object of his labours was to extend the boundaries of analysis; and before he had reached his 21st year, he published a new and general method of resolving differential equations of the second order, subjected to certain conditions.

Resolved by Euler, born 1707, died 1783. 1728.

Labours of Count Fagnani.

80. The common algebra had been applied by Leibnitz and John Bernouilli to determine arcs of the parabola, the difference of which is an algebraic quantity, imagining that such problems in the case of the ellipse and hyperbola resisted the application of the new analysis. The Count de Fagnani, however, applied the integral calculus to the arcs of the ellipsis and hyperbola, and had the honour of explaining this new branch of geometry.

Problem of Count Riccati.

81. In the various problems depending on the analysis of infinites, the great difficulty is to resolve the differential equation to which the problems are reduced. Count James Riccati having been puzzled with a differential 1725.
equation of the first order, with two variable quantities, proposed it to mathematicians in the Leipsic Acts for 1725. This question baffled the skill of the most celebrated analysts, who were merely able to point out a number of cases in which the indeterminate can be separated, and the equation resolved by the quadrature of curves.

Problem of Offenburg.

82. Another problem suggested by that of Viviani was proposed in 1718 by Ernest Von Offenburg. It was required to pierce a hemispherical vault with any number of elliptical windows, so that their circumferences should be expressed by algebraic quantities; or in other words, to determine on the surface of a sphere, curves algebraically rectifiable. In a paper on the rectification of spherical epicycloids, Herman * imagined that these curves were algebraically rectifiable, and therefore satisfied the question of Offenburg; but John Bernouilli (Mem. Acad. Par. 1732) demonstrated, that as the rectification of these curves depended on the quadrature of the hyperbola, they were only rectifiable in certain cases, and gave the general method of determining the curves that are algebraically rectifiable on the surface of a sphere.

* *Petersburgh Transactions*, 1726.

Resolved by John Bernouilli.

Labours of Clairaut.

83. The same subject was also discussed by Nicole and Clairaut, (Mem. Acad. 1734). The latter of these mathematicians had already acquired fame by his *Recherches sur les Courbes à double Courbure*, published in 1730, before he was 21 years of age; but his reputation was extended by a method of finding curves whose property consists in a certain relation between these branches expressed by a given equation. In this research, Clairaut pointed out a species of paradox in the integral calculus, which led to the celebrated theory of particular integrals which was afterwards fully illustrated by Euler and other geometers.

Problem of isochronous curves.

84. The celebrated problem of isochronous curves began at this time to be reagitated among mathematicians. The object of this problem is to find such a curve that a heavy body descending along its concavity shall always reach the lowest point in the same time, from whatever point of the curve it begins to descend. Huygens had already shewn that the cycloid was the isochronous curve *in vacuo*. Newton had demonstrated the same curve to be isochronous when the descending body experiences from the air a resistance proportional to its velocity;

Memoirs of Petersburgh, 1729, and Mem. Par. 1730.

locity; and Euler* and John Bernouilli†, had separately found the isochronous curve when the resistance was as the square of the velocity. These three cases, and even a fourth in which the resistance was as the square of the velocity added to the product of the velocity by a constant coefficient, were all resolved by Fontaine, by means of an ingenious and original method; and it is very remarkable that the isochronous curve is the same in the third and fourth cases.—The method of Fontaine was illustrated by Euler, who solved a fifth case, including all the other four, when the resistance is composed of three terms, the square of the velocity, the product of the velocity by a given coefficient, and a constant quantity. He found also an expression of the time which the body employs to descend through any arc of the curve.

Solved by Fontaine.

Algebra of sines and cosines.

85. The application of analytical formulæ to the physico-mathematical sciences was much facilitated by the algebra of sines and cosines with which Frederick Christian Mayer, and Euler, enriched geometry. By the combination of arcs, sines, and cosines, formulæ are obtained which frequently yield to the method of resolution, and enable us to solve a number of problems which the ordinary use of arcs, sines, and cosines, would render tedious and complicated.

Improvement in the resolution of differential equations.

86. About this time a great discovery in the theory of differential equations of the first order was made separately by Euler, Fontaine, and Clairaut. Hitherto geometers had no direct method of ascertaining if any differential equation were resolvable in the state in which it was presented, or if it required some preparation prior to its resolution. For every differential equation a particular method was employed, and their resolution was often effected by a kind of tentative process, which displayed the ingenuity of its author, without being applicable to other equations. The conditions under which differential equations of the first order are resolvable were discovered by the three mathematicians whom we have mentioned. Euler made the discovery in 1736, but did not publish it till 1740. Fontaine and Clairaut lighted upon it in 1739. Euler afterwards extended the discovery to equations of higher orders.

Discovery of the integral calculus with partial differences.

87. The first traces of the integral calculus with partial differences appeared in a paper of Euler's in the Petersburgh Transactions for 1734; but d'Alembert, in his work *Sur les Vents*, has given clearer notions of it, and was the first who employed it in solution of the problem of vibrating cords proposed by Dr Taylor, and investigated by Euler and Daniel Bernouilli. The object of this calculus is to find a function of several variable quantities, when we have the relation of the coefficients which affect the differentials of the variable quantities of which this function is composed. Euler exhibited it in various points of view, and shewed its application to a number of physical problems; and he afterwards, in his paper entitled *Investigatio Functionum ex data Differentialium conditione* ‡, completely explained the nature, and gave the algorithm of the calculus.

‡ *Petersburgh Transactions*, 1762.

The principles of fluxions attacked by Dr Berkeley, 1734.

88. While the analysis of infinites was making such rapid progress on the continent, it was attacked in England by the celebrated Dr Berkeley, bishop of Cloyne, in a work called the *Analyst, or a discourse addressed to an Infidel Mathematician, wherein it is examined whether the object, principles, and inferences of the modern analysis, are more distinctly conceived than Religious Mysteries and Points of Faith.* In this work the doctor admits the truth of the conclusions, but maintains that the principles of fluxions are not founded upon reasoning strictly logical and conclusive. This attack called forth Robins and Maclaurin. The former proved that the principles of fluxions were consistent with the strictest reasoning, while Maclaurin, in his *Treatise of Fluxions*, gave a synthetical demonstration of the principles of the calculus after the manner of the ancient geometricians, and establishes it with such clearness and satisfaction that no intelligent man could refuse his assent. The differential calculus had been attacked at an earlier period by *Nieuwentiet* and *Rolle*, but the weapons wielded by these adversaries were contemptible when compared with the ingenuity of Dr Berkeley.

Works of Thomas Simpson.

89. Notwithstanding this attack upon the principles of the new analysis, the science of geometry made rapid advances in England in the hands of Thomas Simpson, Landen, and Waring. In 1740, Mr Simpson published his *Treatise on Fluxions*, which, besides many original researches, contains a convenient method of resolving differential equations by approximation, and various means of hastening the convergency of slowly converging series. We are indebted to the same geometer for several general theorems for summing different series, whether they are susceptible of an absolute or an approximate summation. His *Mathematical Dissertations*, published in 1743, his *Essays on several Subjects in Mathematics*, published in 1740, and his *Select Exercises for Young Proficients in the Mathematics*, published in 1752, contain ingenious and original researches which contributed to the progress of geometry.

1740.

1743.

The residual analysis invented by Landen. Died in 1777.

90. In his *Mathematical Lucubrations*, published in 1755, Mr Landen has given several ingenious theorems for the summation of series; and the Philosophical Transactions for 1775 contain his curious discovery of the rectification of a hyperbolic arc, by means of two arcs of an ellipsis, which was afterwards more simply demonstrated by Legendre. His invention of a new calculus, called the *residual analysis*, and in some respects subsidiary to the method of fluxions, has immortalized his name. It was announced and explained in a small pamphlet published in 1715, entitled a *Discourse concerning the Residual Analysis*.

Labours of Waring. *Ph. Trans.* 1784, and 1791, p. 146.

91. The progress of geometry in England was accelerated by the labours of Mr Edward Waring, professor of mathematics at Cambridge. His two works entitled *Meditationes Analyticæ*, published in 1769, and *Meditationes Algebraicæ*, and his papers in the Philosophical Transactions on the summation of forces, are filled with original and profound researches into various branches of the common algebra, and the higher analysis.

Discoveries of Lagrange.

92. It was from the genius of Lagrange, however, that the higher calculus has received the most brilliant improvements. This great man was born in Piedmont. He afterwards removed to Berlin, and hence to Paris, where he still resides. In addition to many improvements upon the integral analysis, he has enriched geometry with a new calculus called the *method of variations*. The object of this calculus is, when there is given an expression or function of two or more variable quantities whose relation is expressed by a certain law, to find what this function becomes when that law suffers any variation infinitely;

His method of variations.

ly small, occasioned by the variation of one or more of the terms which express it. This calculus is as much superior to the integral calculus, as the integral calculus is above the common algebra. It is the only means by which we can resolve an immense number of problems *de maximis et minimis*, and is necessary for the solution of the most interesting problems in mechanics.

His theory of analytical functions. His theory of analytical functions is one of the most brilliant specimens of human genius. In the Memoirs of Berlin for 1772 he had touched upon this interesting subject, but the theory was completely developed in 1797 in his work entitled *Theorie des fonctions analytiques, contenant les principes du calcul differentiel, degagées de toute consideration d'infiniments petits, ou evanouissements, ou des limites, ou des fluxions; et reduit à l'analyse algebrique des quantites finies*. In a great number of memoirs which are to be found in the Memoirs of the Academy of Paris, in those of the Academy of Berlin, and in those of the French Academy, Lagrange has thrown light on every branch both of the common algebra and the new analysis.

Labours of La Place. 93. The new geometry has likewise been much indebted to the celebrated Laplace. His various papers in the *Memoires des Sçavans Etrangers* *, and the Memoirs of the French Academy, have added greatly to the higher calculi, while his application of analysis to the celestial phenomena, as exhibited in the *Mechanique Celeste*, and his various discoveries in physical astronomy, entitle him to a high rank among the promoters of science.

* Tom. 6. 7.

Works of Cousin, Lacroix, Bossut, and Legendre. 94. Among the celebrated French mathematicians of the last and present century, we cannot omit the names of Cousin, Lacroix, and Bossut; all of whom have written large works on the differential and integral calculi, and illustrated the new analysis by their discoveries. The *Elemens de Geometrie* by Legendre is one of the best and most original works upon elementary geometry, and his papers in the Memoirs of the Academy contain several improvements upon the new analysis.

Agnesi's analytical institutions. 1784. 95. In Italy the mathematical sciences were destined to be improved and explained by a celebrated female. Donna Maria Gaetana Agnesi (see AGNESI, Supplement) was professor of mathematics in the university of Bologna, and published a learned work entitled *Analytical Institutions*, containing the common analysis, and the differential and integral calculi. It has been translated into English by Professor Colson, and was published at the expence of Baron Maseres. A few years ago several curious properties of the circle have been discovered by Mascheroni, another Italian mathematician, who has published them in his interesting work entitled *sur le Geometrie du Compas*.

Mascheroni on the circle.

English mathematicians. 96. In England the mathematical sciences have been successfully cultivated by Emerson, Baron Maseres, Dr M. Young, Dr Hutton, Professor Vince, and Professor Robertson of Oxford. The *Doctrine of Fluxions* by Emerson, and his *Method of Increments*, are good introductions to the higher geometry.

Emerson.

Baron Maseres. The *Scriptores Logarithmici* of Baron Maseres; his *Tracts on the Resolution of Equations*; his *Principles of Life Annuities*, and his other mathematical papers, do the highest honour to his talents as a mathematician; while his zeal for the promotion of the mathematical sciences, and his generous attention to those who cultivate them, entitle him to the noble appellation of the friend and patron of genius.

Dr M. Young. Dr Matthew Young, bishop of Clonfert, has given a synthetical demonstration of Newton's rule for the quadrature of simple curves; and has written on the extraction of cubic and other roots.

Dr Hutton and Dr Vince. Dr Hutton and Dr Vince have each published several elementary treatises on mathematics, and have invented ingenious methods for the summation of series.

Mr Robertson. Mr Robertson of Oxford is the author of an excellent treatise on conic sections.

Scottish mathematicians. 97. The ancient geometry was assiduously cultivated in Scotland by Dr Robert Simpson and Dr Matthew Stewart.

Dr Simpson. Dr Simpson's edition of Euclid and his treatise on conic sections have been much admired.

Dr M. Stewart. The *Tracts Physical and Mathematical* of Dr Matthew Stewart, and his *Propositiones Geometricæ more veterum demonstratæ* contain fine specimens of mathematical genius. In the present day the names of Professor Playfair and Professor Leslie of the university of Edinburgh, Mr Wallace and Mr Ivory now of the Royal Military College at Great Marlow, are well known to mathematicians.

Mr Playfair. Mr Playfair's Elements of Geometry, and his papers on *the Arithmetic of Impossible Quantities* and on *Porisms*, are proofs of his great talents as a mathematician and a philosopher.

Mr Leslie. Mr Leslie, well known for his great discoveries on heat, has found a very simple principle, capable of extensive application, by which the complicated expressions in the solution of indeterminate problems may be easily resolved.

Mr Wallace. Mr Wallace's papers on *Geometrical Porisms* in the 4th vol. of the Edinburgh Transactions, display much genius;

Mr Ivory. and Mr Ivory's Treatises in the last vol. of Baron Maseres's *Scriptores Logarithmici*, and his paper on *A New Series for the Rectification of the Ellipsis*, Edin. Trans. vol. 4th. entitle him to a high rank among modern mathematicians.

Mathematical, Matlock.

MATHEMATICAL, any thing belonging to the science of mathematics.

Mathematical Instruments, such instruments as are usually employed by mathematicians, as compasses, scales, quadrants, &c.

Machine for dividing Mathematical Instruments. See RAMSDEN's *Machine*.

MATLOCK, a town or village of Derbyshire, near Wicksworth, situated on the very edge of the Derwent; noted for its bath, the water of which is milk-warm; and remarkable for the huge rocks in its environs, particularly those called the *Torr*, which is 140 yards high. It is an extensive straggling village, built in a very romantic style, on the steep side of a mountain, and containing, in 1801, above 2000 inhabitants. Near the bath are several small houses, whose situation is is on the little natural horizontal parts of the mountain, a few yards above the road, and in some places the roofs of some almost touch the floors of others. There are excellent accommodations for company who resort to the bath; and the poorer inhabitants are supported by the sale of petrifactions, crystals, &c. and notwithstanding the rockiness of the soil, the cliffs produce an immense number of trees, whose foliage adds greatly to the beauty of the place.

MATRASS, Cucurbit, or Bolthead, among chemists. See Chemistry, Explanation of Plates.

MATRICARIA, Feverfew; a genus of plants, belonging to the syngenesia class; and in the natural method ranking under the 49th order, *Compositæ*. See Botany *Index*.

MATRICE, or Matrix, See Matrix.

Matrice, or matrix, in *Dyeing*, is applied to the five simple colours, whence all the rest are derived or composed. These are, the black, white, blue, red, and yellow or root colour.

Matrice, or matrices, used by the letter-founders, are those little pieces of copper or brass, at one end whereof are engraven, dentwise, or *en creux*, the several characters used in the composing of books. Each character, virgula, and even each point in a discourse, has its several matrix; and of consequence its several puncheon to strike it. Matrices are cut or graved by engravers in metal.

When types are to be cast, the matrice is fastened to the end of the mould, so disposed, as that when the metal is poured on it, it may fall into the creux or cavity of the matrice, and take the figure and impression thereof. See *Letter Foundery*.

Matrices, used in coining, are pieces of steel in form of dies, whereon are engraven the several figures, arms, characters, legends, &c. wherewith the species are to be stamped. The engraving is performed with several puncheons, which being formed in relievo, or prominent, when struck on the metal, make an indented impression, which the French call *en creux*.

MATRICULA, a register kept of the admission of officers and persons entered into any body or society whereof a list is made. Hence those who are admitted into our universities are said to be matriculated. Among ecclesiastical authors, we find mention made of two kinds of matricule; the one containing a list of the ecclesiastics, called *matricula clericorum*: the other of the poor subsisted at the expence of the church, called *matricula pauperum*.

Matricula was also applied to a kind of almshouse, where the poor were provided for. It had certain revenues appropriated to it, and was usually built near the church, whence the name was also frequently given to the church itself.

MATRIMONY. See Marriage.

MATRIX, in *Anatomy*, the womb, or that part of the female of any kind, wherein the fœtus is conceived and nourished till the time of its delivery. See Anatomy, N° 108.

Matrix is also applied to places proper for the generation of vegetables, minerals, and metals. Thus the earth is the matrix wherein seeds sprout; and marcasites are by many considered as the matrices of metals.

The matrix of ores is the earthy and stony substances in which these metallic matters are enveloped: these are various, as lime and heavy spar, quartz, fluors, &c.

MATRON, an elderly married woman.

Jury of Matrons. When a widow feigns herself with child in order to exclude the next heir, and a supposititious birth is suspected to be intended, then, upon the writ *de ventre inspiciendo*, a jury of women is to be impannelled to try the question whether the woman is with child or not. So, if a woman is convicted of a capital offence, and, being condemned to suffer death, pleads in stay of execution, that she is pregnant, a jury of matrons is impannelled to inquire into the truth of the allegation; and, if they find it true, the convict is respited till after her delivery.

MATRONA, in *Ancient Geography*, a river separating Gallia Celtica from the Belgica (Cæsar). Now the Marne; which, rising in Champagne near Langres, runs north-west, and then west, and passing by Meaux falls into the Seine at Charenton, two leagues to the east of Paris.

MATRONALIA, a Roman festival instituted by Romulus, and celebrated on the kalends of March, in honour of Mars. It was kept by matrons in particular, and bachelors were entirely excluded from any share in the solemnity. The men during this feast sent presents to the women, for which a return was made by them at the Saturnalia: And the women gave the same indulgence to their servants now which the men gave to theirs at the feast of Saturn, serving them at table, and treating them as superiors.

MATROSSES, are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and spunging the great guns. They carry firelocks, and march along with the store waggons, both as a guard, and to give their assistance in case a waggon should break down.

MATSYS, Quintin, painter of history and portraits, was born at Antwerp in 1460, and for several years followed the trade of a blacksmith or farrier, at least till he was in his 20th year. Authors vary in their accounts of the cause of his quitting his first occupation, and attaching himself to the art of painting. Some affirm, that the first unfolding of his genius was occasioned by the sight of a print which accidentally was shown to him by a friend who came to pay him a visit while he was in a declining state of health from the labour of his former employment, and that by his copying the print with some degree of success, he was animated with a desire to learn the art of painting. Others say, he fell in love with a young woman of great beauty, the daughter of a painter, and they allege that love alone wrought the miracle, as he could have no prospect of obtaining her except by a distinguished merit in the profession of painting: for which reason he applied himself with incessant labour to study and practise the art, till he became so eminent as to be entitled to demand her in marriage, and he succeeded. Whatever truth may be in either of these accounts, it is certain that he appeared to have an uncommon genius; his manner was singular, not resembling the manner of any other master; and his pictures were strongly coloured and carefully finished, but yet they are somewhat dry and hard. By many compe-

Matsys ‖ Matthew.

tent judges it was believed, when they observed the strength of expression in some of his compositions, that if he had studied in Italy to acquire some knowledge of the antiques and the great masters of the Roman school, he would have proved one of the most eminent painters of the Low Countries. But he only imitated ordinary life; and seemed more inclined, or at least more qualified, to imitate the defects than the beauties of nature. Some historical compositions of this master deserve commendation; particularly a Descent from the Cross, which is in the cathedral at Antwerp; and it is justly admired for the spirit, skill, and delicacy of the whole. But the most remarkable and best known picture of Matsys, is that of the Two Misers in the gallery at Windsor. He died in 1529.

MATT, in a ship, is a name given to rope-yarn, junk, &c. beat flat and interwoven; used in order to preserve the yards from galling or rubbing, in hoisting or lowering them.

MATTER, in common language, is a word of the same import with *body*, and denotes that which is tangible, visible, and extended; but among philosophers it signifies that substance of which all bodies are composed; and in this sense it is synonymous with the word ELEMENT.

It is only by the senses that we have any communication with the external world; but the immediate objects of sense, philosophers have in general agreed to term *qualities*, which they conceive as inhering in something which is called their *subject* or *substratum.* It is this substratum of sensible qualities which, in the language of philosophy, is denominated *matter;* so that *matter* is *not* that which we immediately see or handle, but the *concealed subject* or *support* of visible and tangible qualities. What the moderns term *qualities*, was by Aristotle and his followers called *form;* but so far as the two doctrines are intelligible, there appears to be no essential difference between them. From the moderns we learn, that body consists of *matter* and *qualities;* and the Peripatetics taught the same thing, when they said that body is composed of *matter* and *form.*

How philosophers were led to analyze body into matter and form, or, to use modern language, into matter and qualities; what kind of existence they attribute to each; and whether *matter* must be conceived as self-existent or created—are questions which shall be considered afterwards (See METAPHYSICS). It is sufficient here to have defined the term.

MATTHEW, or *Gospel of St MATTHEW*, a canonical book of the New Testament.

St MATTHEW wrote his gospel in Judea, at the request of those he had converted; and it is thought he began in the year 41, eight years after Christ's resurrection. It was written, according to the testimony of all the ancients, in the Hebrew or Syriac language; but the Greek version, which now passes for the original, is as old as the apostolical times.

St MATTHEW the Evangelist's Day, a festival of the Christian church, observed on September 21st.

St MATTHEW, the son of Alpheus, was also called *Levi.* He was of a Jewish original, as both his names discover, and probably Galilean. Before his call to the apostolate, he was a publican or toll-gatherer to the Romans; an office of bad repute among the Jews, on account of the covetousness and exaction of those who managed it; St Matthew's office particularly consisting in gathering the customs of all merchandise that came by the sea of Galilee, and the tribute that passengers were to pay who went by water. And here it was that Matthew sat at the receipt of customs, when our Saviour called him to be a disciple. It is probable, that, living at Capernaum, the place of Christ's usual residence, he might have some knowledge of him before he was called. Matthew immediately expressed his satisfaction in being called to this high dignity, by entertaining our Saviour and his disciples at a great dinner at his own house, whither he invited all his friends, especially those of his own profession, hoping, probably, that they might be influenced by the company and conversation of Christ. St Matthew continued with the rest of the apostles till after our Lord's ascension. For the first eight years afterwards, he preached in Judea. Then he betook himself to propagating the gospel among the Gentiles, and chose Ethiopia as the scene of his apostolical ministry; where it is said he suffered martyrdom, but by what kind of death is altogether uncertain. It is pretended, but without any foundation, that Hyrtaeus, king of Ethiopia, desiring to marry Iphigenia, the daughter of his brother and predecessor Æglippus, and the apostle having represented to him that he could not lawfully do it, the enraged prince ordered his head immediately to be cut off. Baronius tells us, the body of St Matthew was transported from Ethiopia to Bithynia, and from thence was carried to Salernum in the kingdom of Naples in the year 954, where it was found in 1080, and where Duke Robert built a church bearing his name.

Matthew, Matthias.

St MATTHEW, a town of Spain, in the kingdom of Arragon, seated in a pleasant plain, and in a very fertile country watered with many springs. W. Long. 0. 15. N. Lat. 40. 22.

MATTHEW of Paris. See PARIS.

MATTHEW of Westminster, a Benedictine monk and accomplished scholar, who wrote a history from the beginning of the world to the end of the reign of Edward I. under the title of *Flores Historiarum;* which was afterwards continued by other hands. He died in 1380.

St MATTHIAS, an apostle, was chosen instead of Judas. He preached in Judea and part of Ethiopia, and suffered martyrdom. See the *Acts of the Apostles*, chap. i. There was a gospel published under Matthias's name, but rejected as spurious; as likewise some traditions, which met with the same fate.

St MATTHIAS's Day, a festival of the Christian church, observed on the 24th of February. St Matthias was an apostle of Jesus Christ, but not of the number of the twelve chosen by Christ himself. He obtained this high honour upon a vacancy made in the college of the apostles by the treason and death of Judas Iscariot. The choice fell on Matthias by lot; his competitor being Joseph called *Barsabas*, and surnamed *Justus.* Matthias was qualified for the apostleship, by having been a constant attendant upon our Saviour all the time of his ministry. He was, probably, one of the 70 disciples. After our Lord's resurrection, he preached the gospel first in Judea.

Afterwards

Matthias || Maty. Afterwards it is probable he travelled eastward, his residence being principally near the irruption of the river Apsarus and the haven Hyssus. The barbarous people treated him with great rudeness and inhumanity; and, after many labours and sufferings in converting great numbers to Christianity, he obtained the crown of martyrdom; but by what kind of death, is uncertain.—They pretend to show the relics of St Matthias at Rome; and the famous abbey of St Matthias near Treves boasts of the same advantage; but doubtless both without any foundation. There was a gospel ascribed to St Matthias; but it was universally rejected as spurious.

MATTIACÆ Aquæ, or Mattiaci Fontes, in *Ancient Geography*, now Wisbaden, opposite to Mentz, in Weteravia. E. Long. 8. N. Lat. 50. 6.

MATTIACUM, or Mattium, in *Ancient Geography*, a town of the Mattiaci, a branch of the Catti in Germany. Now Marpurg in Hesse. E. Long. 8. 40. N. Lat. 50. 40.

MATTINS, the first canonical hour, or the first part of the daily service in the Romish church.

MATTHIOLUS, Peter Andrew, an eminent physician in the 16th century, born at Sienna, was well skilled in the Greek and Latin tongues. He wrote learned commentaries on Dioscorides, and other works which are esteemed; and died in 1577.

MATURANTS, in *Pharmacy*, medicines which promote the suppuration of tumors.

MATY, Matthew, M. D. an eminent physician and polite writer, was born in Holland in the year 1718. He was the son of a clergyman, and was originally intended for the church; but in consequence of some mortifications his father met with from the synod, on account of the peculiar sentiments he entertained about the doctrine of the Trinity, turned his thoughts to physic. He took his degree of M. D. at Leyden; and in 1740 came to settle in England, his father having determined to quit Holland for ever. In order to make himself known, he began in 1749 to publish in French an account of the productions of the English press, printed at the Hague under the name of the *Journal Britannique*. This journal, which continues to hold its rank amongst the best of those which have appeared since the time of Bayle, answered the chief end he intended by it, and introduced him to the acquaintance of some of the most respectable literary characters of the country he had made his own. It was to their active and uninterrupted friendship he owed the places he afterwards possessed. In 1758 he was chosen fellow, and in 1765, on the resignation of Dr Birch, who died a few months after, and had made him his executor, secretary to the Royal Society. He had been appointed one of the under librarians of the British museum at its first institution in 1753, and became principal librarian at the death of Dr Knight in 1772. Useful in all these situations, he promised to be eminently so in the last, when he was seized with a languishing disorder, which in 1776 put an end to a life which had been uniformly devoted to the pursuit of science and the offices of humanity. He was an early and active advocate for inoculation; and when there was a doubt entertained that one might have the smallpox this way a second time, tried it upon himself unknown to his family. He was a member of the medical club (with the Drs Parsons, Templeman, Fothergill, Watson and others), which met every fortnight in St Paul's Churchyard. He was twice married, viz. the first time to Mrs Elizabeth Boisragon; and the second to Mrs Mary Deners. He left a son and three daughters. He had nearly finished the Memoirs of the earl of Chesterfield; which were completed by his son-in-law Mr Justamond, and prefixed to that nobleman's Miscellaneous Works, 1777, 2 vols 4to.

Maty. Maubeuge.

Maty, *Paul Henry*, M. A. F. R. S. son of the former, was born in 1745, and was educated at Westminster and Trinity college, Cambridge, and had their travelling fellowship for three years. He was afterwards chaplain to Lord Stormont at Paris, and soon after vacated his next fellowship by marrying one of the three daughters of Joseph Clerk, Esq. and sister of Captain Charles Clerk (who succeeded to the command on the death of Captain Cook). On his father's death in 1776, he was appointed to the office of one of the under librarians of the British Museum, and was afterwards preferred to a superior department, having the care of the antiquities, for which he was eminently qualified. In 1776 he also succeeded his father in the office of secretary to the Royal Society. On the disputes respecting the reinstatement of Dr Hutton in the department of secretary for foreign correspondence in 1784, Mr Maty took a warm and distinguised part, and resigned the office of secretary; after which he undertook to assist gentlemen or ladies in perfecting their knowledge of the Greek, Latin, French, and Italian classics. Mr Maty was a thinking conscientious man; and having conceived some doubts about the articles he had subscribed in early life, he never could be prevailed upon to place himself in the way of ecclesiastical preferment, though his connexions were amongst those who could have served him essentially in this point; and soon after his father's death he withdrew himself from ministering in the established church, his reasons for which he published in the 47th volume of the Gent. Magazine, p. 466. His whole life was thenceforwards taken up in literary pursuits. He received 100l. from the duke of Marlborough, with a copy of that beautiful work, the *Gemmæ Marlburienses*, of which only 100 copies were worked off for presents; and of which Mr Maty wrote the French account, as Mr Bryant did the Latin. In January 1782 he set on foot a Review of publications, principally foreign, which he carried on, with great credit to himself and satisfaction to the public, for near five years, when he was obliged to discontinue it from ill health. He had long laboured under an asthmatic complaint, which at times made great ravages in his constitution, and at last put a period to his life in Jan. 1787, at the age of 42; leaving behind him one son.—Mr Maty was eminently acquainted with ancient and modern literature, and particularly conversant in critical researches. The purity and probity of his nature were unquestionable; and his humanity was as exquisite as it would have been extensive, had it been seconded by his fortune.

MAUBEUGE, a fortified town of the Netherlands, in Hainault, which formerly contained an abbey of canonesses, who were noble both by the father and mother's side. In 1678 this place was ceded to France, in whose possession it still remains. In September 1793, 1793, the Austrians formed the blockade of this place, but were driven from their position in the following month. It is seated on the river Sambre, in E. Long. 4. 2. N. Lat. 50. 16.

MAUCAUCO, MACACO, or *Maki*, a genus of quadrupeds belonging to the order *Primates*. See MAMMALIA *Index*.

MAVIS, a species of turdus. See ORNITHOLOGY *Index*.

MAUNCH, in *Heraldry*, the figure of an ancient coat sleeve, borne in many gentlemen's escutcheons.

MAUNDY THURSDAY, is the Thursday in passion week; which was called *Maunday*, or *Mandate Thursday*, from the command which our Saviour gave his apostles to commemorate him in the Lord's supper, which he this day instituted; or from the new commandment which he gave them to love one another, after he had washed their feet as a token of his love to them.

MAUPERTUIS, PETER LOUIS MORCEAU DE, a celebrated French academician, was born at St Malo in 1698; and was there privately educated till he arrived at his 16th year, when he was placed under the celebrated professor of philosophy M. le Blond, in the college of La Marche, at Paris. He soon discovered a passion for mathematical studies, and particularly for geometry. He likewise practised instrumental music in his early years with great success, but fixed on no profession till he was 20, when he entered into the army. He first served in the Grey musqueteers; but in the year 1720, his father purchased for him a company of cavalry in the regiment of La Rocheguyon. He remained but five years in the army, during which time he pursued his mathematical studies with great vigour; and it was soon remarked by M. Freret and other academicians, that nothing but geometry could satisfy his active soul and unbounded thirst for knowledge. In the year 1723, he was received into the Royal Academy of Sciences, and read his first performance, which was a memoir upon the construction and form of musical instruments, November 15. 1724. During the first years of his admission, he did not wholly confine his attention to mathematics; he dipt into natural philosophy, and discovered great knowledge and dexterity in observations and experiments upon animals. If the custom of travelling into remote climates, like the sages of antiquity, in order to be initiated into the learned mysteries of those times had still subsisted, no one would have conformed to it with greater eagerness than M. de Maupertuis. His first gratification of this passion was to visit the country which had given birth to Newton: and during his residence at London he became as zealous an admirer and follower of that philosopher as any one of his own countrymen. His next excursion was to Basil in Switzerland, where he formed a friendship with the famous John Bernouilli and his family, which continued to his death. At his return to Paris, he applied himself to his favourite studies with greater zeal than ever:—And how well he fulfilled the duties of an academician, may be gathered by running over the memoirs of the academy from the year 1724 to 1736; where it appears that he was neither idle nor occupied by objects of small importance. The most sublime questions in geometry and the relative sciences received from his hands that elegance, clearness, and precision, so remarkable in all his writings. In the year 1736, he was sent by the king of France to the polar circle to measure a degree, in order to ascertain the figure of the earth, accompanied by Messrs Clairault, Camus, Le Monnier, l'Abbe Outhier, and Celsius the celebrated professor of astronomy at Upsal. This distinction rendered him so famous, that at his return he was admitted a member of almost every academy in Europe.

In the year 1740 Maupertuis had an invitation from the king of Prussia to go to Berlin; which was too flattering to be refused. His rank among men of letters had not wholly effaced his love for his first profession, namely that of arms. He followed his Prussian majesty into the field, and was a witness of the dispositions and operations that preceded the battle of Molwitz; but was deprived of the glory of being present, when victory declared in favour of his royal patron, by a singular kind of adventure. His horse, during the heat of the action, running away with him, he fell into the hands of the enemy; and was at first but roughly treated by the Austrian soldiers, to whom he could not make himself known for want of language; but being carried prisoner to Vienna, he received such honours from their Imperial Majesties as were never effaced from his memory. From Vienna he returned to Berlin; but as the reform of the academy which the king of Prussia then meditated was not yet mature, he went again to Paris, where his affairs called him, and was chosen in 1742 director of the Academy of Sciences. In 1753 he was received into the French academy; which was the first instance of the same person being a member of both the academies at Paris at the same time. M. de Maupertuis again assumed the soldier at the siege of Fribourg, and was pitched upon by Marshal Cogny and the Count d'Argenson to carry the news to the French king of the surrender of that citadel.

He returned to Berlin in the year 1744, when a marriage was negotiated and brought about by the good offices of the queen-mother, between our author and Mademoiselle de Borek, a lady of great beauty and merit, and nearly related to M. de Borck, at that time minister of state. This determined him to settle at Berlin, as he was extremely attached to his new spouse, and regarded this alliance as the most fortunate circumstance of his life.

In the year 1746, M. de Maupertuis was declared by his Prussian majesty president of the Royal Academy of Sciences at Berlin, and soon after by the same prince was honoured with the order of Merit: However, all these accumulated honours and advantages, so far from lessening his ardour for the sciences, seemed to furnish new allurements to labour and application. Not a day passed but he produced some new project or essay for the advancement of knowledge. Nor did he confine himself to mathematical studies only: metaphysics, chemistry, botany, polite literature, all shared his attention, and contributed to his fame. At the same time, he had, it seems, a strange inquietude of spirit, with a morose temper, which rendered him miserable amidst honours and pleasures.—Such a temperament did not promise a very pacific life, and he was engaged in several quarrels. He had a

Maupertuis. a quarrel with Koenig the professor of philosophy at Franeker, and another more terrible with Voltaire. Maupertuis had inserted into the volume of Memoirs of the Academy of Berlin for 1746, a discourse upon the laws of motion; which Koenig was not content with attacking, but attributed to Leibnitz. Maupertuis, stung with the imputation of plagiarism, engaged the academy of Berlin to call upon him for his proof; which Koenig failing to produce, he was struck out of the academy, of which he was a member. Several pamphlets were the consequence of this; and Voltaire, for some reason or other, engaged against Maupertuis. We say, for some reason or other; because Maupertuis and Voltaire were apparently upon the most amicable terms; and the latter respected the former as his master in the mathematics. Voltaire, however, exerted all his wit and satire against him; and on the whole was so much transported beyond what was thought right, that he found it expedient in 1753 to quit the court of Prussia.

Our philosopher's constitution had long been considerably impaired by the great fatigues of various kinds in which his active mind had involved him; though from the amazing hardships he had undergone in his northern expedition, most of his future bodily sufferings may be traced. The intense sharpness of the air could only be supported by means of strong liquors, which served to increase his disorder, and bring on a spitting of blood, which began at least 12 years before he died. Yet still his mind seemed to enjoy the greatest vigour; for the best of his writings were produced, and most sublime ideas developed, during the time of his confinement by sickness, when he was unable to occupy his presidial chair at the academy. He took several journeys to St Malo, during the last years of his life, for the recovery of his health: And though he always received benefit by breathing his native air, yet still, upon his return to Berlin, his disorder likewise returned with greater violence.—His last journey into France was undertaken in the year 1757; when he was obliged, soon after his arrival there, to quit his favourite retreat at St Malo, on account of the danger, and confusion which that town was thrown into by the arrival of the English in its neighbourhood. From thence he went to Bourdeaux, hoping there to meet with a neutral ship to carry him to Hamburgh, in his way back to Berlin; but being disappointed in that hope, he went to Thoulouse, where he remained seven months. He had then thoughts of going to Italy, in hopes a milder climate would restore him to health: but finding himself grow worse, he rather inclined towards Germany, and went to Neufchatel, where for three months he enjoyed the conversation of Lord Marischal, with whom he had formerly been much connected. At length he arrived at Basil, October 16. 1758, where he was received by his friend Bernouilli and his family with the utmost tenderness and affection. He at first found himself much better here than he had been at Neufchatel: but this amendment was of short duration; for as the winter approached, his disorder returned, accompanied by new and more alarming symptoms. He languished here many months during which he was attended by M. de la Condamine; and died in 1759.

He wrote in French, 1. The figure of the earth determined. 2. The measure of a degree of the meridian. 3. A discourse on the parallax of the moon. 4. A discourse on the figure of the stars. 5. The elements of geography. 6. Nautical astronomy. 7. Elements of astronomy. 8. A physical dissertation on a white inhabitant of Africa. 9. An essay on cosmography. 10. Reflections on the origin of languages. 11. An essay on moral philosophy. 12. A letter on the progress of the sciences. 13. An essay on the formation of bodies. 14. An eulogium on M. de Montesquieu. 15. Letters, and other works.

Maupertuis || Maurice.

MAUR, St, was a celebrated disciple of St Benedict. If we can believe a life of St Maur ascribed to Faustus his companion, he was sent by Benedict on a mission to France. But this life is considered as apocryphal. In rejecting it, however, as well as the circumstances of the mission, we must beware of denying the mission itself. It is certain that it was believed in France as early as the 9th century; and notwithstanding the silence of Bede, Gregory of Tours, and others, there are several documents which prove this, or at least render it extremely probable. A celebrated society of Benedictines, took the name of *St Maur* in the beginning of the last century, and received the sanction of Pope Gregory XV. in 1621. This society was early distinguished by the virtue and the knowledge of its members, and it still supports the character. There are, perhaps, fewer eminent men in it than formerly; but this may be ascribed to the levity of the age, and partly to the little encouragement for the researches of learned men. The chief persons of ingenuity which this society has produced are, the Fathers Menard, d'Acheri, Mabillon, Ruinart, Germain, Lami, Montfaucon, Martin, Vaissette, le Nourri, Martianay, Martenne, Massuet, &c. &c. See *L'Histoire Litteraire de la Congregation de St Maur*, published at Paris under the title of *Brussels*, in 4to, 1770, by Dom. Tassin.

MAURICEAU, Francis, a French surgeon, who applied himself with great success and reputation to the theory and practice of his art for several years at Paris. Afterwards he confined himself to the disorders of pregnant and lying-in-women, and was at the head of all the operators in this way. His *Observations sur la grossesse* and *sur l'accouchement des femmes, sur leurs maladies, et celles des enfans nouveaux*, 1694, in 4to, is reckoned an excellent work, and has been translated into several languages, German, Flemish, Italian, English: and the author himself translated it into Latin. It is illustrated with cuts. He translated another piece or two, by way of supplement, on the same subject; and died at Paris in 1709.

MAURICE, St, commander of the Theban legion, was a Christian, together with the officers and soldiers of that legion, amounting to 6600 men.—This legion received its name from the city Thebes in Egypt, where it was raised. It was sent by Dioclesian to check the Bagaudæ, who had excited some disturbances in Gaul. Maurice having carried his troops over the Alps, the emperor Maximinian commanded him to employ his utmost exertions to extirpate Christianity. This proposal was received with horror both by the commander and by the soldiers. The emperor, enraged at their opposition, commanded the legion to be decimated; and when they still

Maurice. declared that they would sooner die than do any thing prejudicial to the Christian faith, every tenth man of those who remained was put to death. Their perseverance excited the emperor to still greater cruelty; for when he saw that nothing could make them relinquish their religion, he commanded his troops to surround them, and cut them to pieces. Maurice, the commander of these Christian heroes, and Exuperus and Candidus, officers of the legion, who had chiefly instigated the soldiers to this noble resistance, signalized themselves by their patience and their attachment to the doctrines of the Christian religion. They were massacred, it is believed, at Agaune, in Chablais, the 22d of September 286.—Notwithstanding many proofs which support this transaction, Dubordier, Hottinger, Moyle, Burnet, and Mosheim, are disposed to deny the fact. It is defended, on the other hand, by Hicks an English writer, and by Dom Joseph de Lisle a Benedictine monk *de la congregration de Saint Vannes*, in a work of his, entitled *Defence de la Verité du Martyre de la Legion Thebenne*, 1737. In defence of the same fact, the reader may consult *Historia de S. Mauritie*, by P. Rossignole a Jesuit, and the *Acta Sanctorum* for the month of September. The martyrdom of this legion, written by St Eucherius bishop of Lyons, was transmitted to posterity in a very imperfect manner by Surius. P. Chifflet a Jesuit, discovered, and gave to the public, an exact copy of this work. Don Ruinart maintains, that it has every mark of authenticity. St Maurice is the patron of a celebrated order in the king of Sardinia's dominions, created by Emanuel Philibert duke of Savoy, to reward military merit, and approved by Gregory XIII. in 1572. The commander of the Theban legion must not be confounded with another *St Maurice*, mentioned by Theodoret, who suffered martyrdom at Apamea in Syria.

Maurice, (*Mauritius Tiberius*), was born at Arabissus in Cappadocia, A. D. 539. He was descended from an ancient and honourable Roman family.—After he had filled several offices in the court of Tiberius Constantine, he obtained the command of his armies against the Persians. His gallantry was so conspicuous that the emperor gave him his daughter Constantina in marriage, and invested him with the purple the 13th August 582. The Persians still continued to make inroads on the Roman territories, and Maurice sent Philippicus, his brother-in-law, against them. This general conducted the war with various success. At first he gained several splendid victories, but he did not continue to have a decided superiority. As there was a great use for soldiers in these unfortunate times, the emperor issued a mandate in 592, forbidding any soldier to become a monk till he had accomplished the term of his military service. Maurice acquired much glory in restoring Chosroes II. king of Persia, to the throne, after he had been deposed by his subjects. The empire was in his reign harassed by the frequent inroads of the Arabian tribes. He purchased peace from them, by granting them a pension nearly equal to 100,000 crowns; but these barbarians took frequent opportunities to renew the war. In different engagements the Romans destroyed 50,000, and took 17,000 prisoners. These were restored, on condition that the king of the Abari should return all the Roman captives in his dominions. Maurice. Regardless of his promise, he demanded a ransom of 10,000 crowns. Maurice, full of indignation, refused the sum: and the barbarian, equally enraged, put the captives to the sword. While the emperor, to revenge this cruelty, was making preparations against the Abari, Phocas, who from the rank of centurion had attained the highest military preferment, assumed the purple, and was declared emperor. He pursued Maurice to Chalceden, took him prisoner, and condemned him to die. The five sons of this unfortunate prince were massacred before his eyes, and Maurice, humbling himself under the hand of God, was heard to exclaim, *Thou art just, O Lord, and thy judgments are without partiality*. He was beheaded on the 26th November 602, in the 63d year of his age and 20th of his reign. Many writers have estimated the character of this prince by his misfortunes instead of his actions. They believed him guilty without evidence, and condemned him without reason. It cannot be denied, however, that he allowed Italy to be harassed; but he was a father to the rest of the empire. He restored the military discipline, humbled the pride of his enemies, supported the Christian religion by his laws, and piety by his example. He loved the sciences, and was the patron of learned men.

Maurice, elector of Saxony, son of Henry le Pieux, was born A. D. 1521. He was early remarkable for his courage, and during his whole life he was engaged in warlike pursuits. He served under the emperor Charles V. in the campaign of 1544 against France; and in the year following against the league of Smalkalde; with which, although a Protestant, he would have no manner of connexion. The emperor, as a reward for his services, in the year 1547, made him elector of Saxony, having deprived his cousin John Frederick of that electorate. Ambition had led him to second the views of Charles, in the hope of being elector, and ambition again detached him from that prince. In 1551 he entered into a league against the emperor, together with the elector of Brandenburgh, the Count Palatine, the duke of Wirtemburg, and many other princes. This league, encouraged by the young and enterprising Henry II. of France, was more dangerous than that of Smalkalde. The pretext for the association was the deliverance of the landgrave of Hesse, whom the emperor kept prisoner. Maurice and the confederates marched, in 1552, to the defiles of Tyrol, and put to flight the Imperial troops who guarded them. The emperor and his brother Ferdinand narrowly escaped, and fled from the conquerors in great disorder. Charles having retired into Passau, where he had collected an army, brought the princes of the league to terms of accommodation. By the famous peace of Passau, which was finally ratified the 12th of August 1552, the emperor granted an amnesty without exception to all those who had carried arms against him from the year 1546. The Protestants not only obtained the free exercise of their religion, but they were admitted into the imperial chamber, from which they had been excluded since the victory of Mulberg.—Maurice soon after united himself with the emperor against the margrave of Brandenburg, who laid waste the German provinces. He engaged him in 1553, gained

Maurice. ed the battle of Sivershausen, and died of the wounds he had received in the engagement two days after. He was one of the greatest protectors of the Lutherans in Germany, and a prince equally brave and politic. After he had profited by the spoils of John Frederick, the chief of the Protestants, he became himself the leader of the party, and by these means maintained the balance of power against the emperor in Germany.

Maurice de Nassau, Prince of Orange, succeeded to the government of the Low Countries after the death of his father William, who was killed in 1584 by the fanatic Gerard. The young prince was then only eighteen years of age, but his courage and abilities were above his years. He was appointed captain general of the United Provinces, and he reared that edifice of liberty of which his father had laid the foundation. Breda submitted to him in 1590; Zutphen, Deventer, Hulst, Nimeguen, in 1591. He gained several important advantages in 1592, and in the year following he made himself master of Gertrudenburg. When he had performed these splendid services, he returned to the Low Countries by the way of Zealand. His fleet was attacked by a dreadful tempest, in which he lost forty vessels, and he himself had very nearly perished. His death would have been considered by the Hollanders as a much greater calamity than the loss of their vessels. They watched over his safety with exceeding care. In 1594, one of his guards was accused of an intention to take away his life; and it was generally believed that he was bribed to this service by the enemies of the republic. He fell a sacrifice at Bruges, either to his own fanaticism or to the jealous anxiety of the friends of Maurice. The prince of Orange, increasing in reputation, defeated the troops of the archduke Albert in 1597, and drove the Spaniards entirely out of Holland. In 1600 he was obliged to raise the siege of Dunkirk; but he took ample vengeance on Albert, whom he again defeated in a pitched battle near Nieuport. Before the action, this great general sent back the ships which had brought his troops into Flanders: *My brethren* (said he to his army), *we must conquer the enemy or drink up the waters of the sea. Determine for yourselves; I have determined I shall either conquer by your bravery, or I shall never survive the disgrace of being conquered by men in every respect our inferiors.* This speech elevated the soldiers to the highest pitch of enthusiasm, and the victory was complete. Rhinberg, Grave, and Ecluse, cities in Flanders, submitted to the conqueror the following year. Maurice, however, not only laboured for the commonwealth, but also for himself. He coveted the sovereignty of Holland, and was opposed in the prosecution of his design by the pensioner Barneveldt. The zeal and activity of this wise republican cost him his life. He was an Arminian; and at this time Maurice defended Gomar against Arminius.—Taking advantage of the general odium under which the Arminians lay, he found means to get Barneveldt condemned in 1619. His death, wholly owing to the cruel ambition of the Prince of Orange, made a deep impression on the minds of the Hollanders. The truce with Spain being expired, Spinola laid siege to Breda in 1624, and in six months, by the proper direction of his great talents, though with great slaughter of his troops, he took the place. The prince of Orange, unsuccessful in every attempt to raise the siege, died of vexation in 1625, aged 55 years, with the reputation of the greatest warrior of his time.—"The life of this stadtholder (says the abbe Raynal) was almost an uninterrupted series of battles, of sieges, and of victories. Of moderate abilities in every thing else, he shone conspicuous in his military capacity. His camp was the school of Europe; and those who received their military education in his armies augmented, perhaps, the glory of their master.—Like Montecuculi, he discovered inimitable skill in his marches and encampments; like Vauban, he possessed the talent of fortifying places, and of rendering them impregnable; like Eugene, the address of finding subsistence for great armies in countries barren by nature, or ravaged by war; like Vendome, the happy talent of calling forth, in the moment they became necessary, greater exertions from his soldiers than could reasonably be expected; like Condé, that infallible quickness of eye which decides the fortune of battles; like Charles XII. the art of rendering his troops almost invincible to cold, hunger, and fatigue; like Turenne, the secret of making war with the least possible expence of human blood." The Chevalier Folard maintains, that Maurice was the greatest commander of infantry since the time of the Romans. He studied the military art of the ancients, and applied their rules with great exactness in the various occurrences of war. He not only took advantage of the inventions of others, but he enriched the science of war with several improvements. Telescopes were first used by him for a military purpose; and, besides a kind of gallery in conducting a siege, and the plan of blockading a strong place, which were of his invention, he greatly improved the whole art by his method of pushing an attack with great vigour, and of defending, for the greatest length of time, and in the best manner, a place besieged. In short, the many useful things which he practised or invented, placed him in the highest rank among men of a military character. On one occasion, a lady of quality asked him, *Who was the first general of the age? Spinola* (replied he) *is the second.* It was his constant practice, during sleep, to have two guards placed by his bedside, not only to defend him in case of danger, but to awake him if there should be the least occasion. The war betwixt Spain and Holland was never carried on with greater keenness and animosity than during his administration.—The Grand Signior, hearing of the vast torrents of blood shed in this contest, thought that a great empire must depend on the decision. The object of so many battles was pointed out to him on a map, and he said coldly, *If it were my business, I would send my pioneers, and order them to cast this little corner of earth into the sea.* Maurice, like many great men, was impatient under contradiction, and too much devoted to women. He was succeeded by Frederick Henry his brother.

Mauritania. MAURITANIA, an ancient kingdom of Africa, bounded on the west by the Atlantic ocean, on the south by Getulia or Libya Interior, and on the north by the Mediterranean; comprehending the greater part of the kingdoms of Fez and Morocco.—Its ancient limits are not exactly mentioned by any historian; neither

Mauritania.

neither can they now be ascertained by any modern observations, these kingdoms being but little known to Europeans.

This country was originally inhabited by a people called *Mauri*, concerning the etymology of which name authors are not agreed. It is probable, however, that this country, or at least great part of it, was first called *Phut*, since it appears from Pliny, Ptolemy, and St Jerome, that a river and territory not far from Mount Atlas went by that name. From the Jerusalem Targum it likewise appears, that part of the Mauri may be deemed the offspring of Lud the son of Misraim, since his descendants, mentioned Genesis x. are there called מדרטאי, *Mauri*, or *Mauritani*. It is certain, that this region, as well as the others to the eastward of it, had many colonies planted in it by the Phœnicians. Procopius tells us, that in his time two pillars of white stone were to be seen there, with the following inscription in the Phœnician language and character upon them: "We are the *Canaanites*, that fled from *Joshua* the son of Nun, that notorious robber." *Ibnu Rachic*, or *Ibnu Raquig*, an African writer cited by Leo, together with Evagrius and Nicephorus Callistus, assert the same thing.

The Mauritanians, according to Ptolemy, were divided into several cantons or tribes. The *Metagonitæ* were seated near the straits of Hercules, now those of Gibraltar. The *Saccosii*, or *Cocosii*, occupied the coast of the Iberian sea. Under these two petty nations the *Masices*, *Verues*, and *Verbicæ* or *Vervicæ*, were settled. The *Salisæ* or *Salinsæ*, were situated lower, towards the ocean; and, still more to the south, the *Volubiliani*. The *Maurensii* and *Herpiditani* possessed the eastern part of this country, which was terminated by the *Mulucha*. The *Angaucani*, or *Jangacaucani*, *Nectiberes*, *Zagrensii*, *Baniubæ*, and *Vacuntæ*, extended themselves from the southern foot of Ptolemy's Atlas Minor to his Atlas Major. Pliny mentions the *Baniuræ*, whom Father Hardouin takes to be Ptolemy's Baniubæ; and Mela the Atlantes, whom he represents as possessed of the western part of this district.

The earliest prince of Mauritania mentioned in history is Neptune; and next to him were Atlas and Antæus his two sons, both famous in the Grecian fables on account of their wars with Hercules. Antæus, in his contention with that hero, seems to have behaved with great bravery and resolution. Having received large reinforcements of Libyan troops, he cut off great numbers of Hercules's men. But that celebrated commander, having at last intercepted a strong body of Libyans sent to the relief of Antæus, gave him a total overthrow, wherein both he and the best part of his forces were put to the sword. This decisive action put Hercules in possession of Libya and Mauritania, and consequently of the riches of all these kingdoms. Hence came the fable, that Hercules, finding Antæus, a giant of an enormous size with whom he was engaged in single combat, to receive fresh strength as often as he touched his mother earth when thrown upon her, at last lifted him up in the air and squeezed him to death. Hence likewise may be deduced the fable intimating that Hercules took the globe from Atlas upon his own shoulders, overcame the dragon that guarded the orchards of the Hesperides, and made himself master of all the golden fruit there. Bochart thinks that the fable alluded chiefly to naval engagements, wherein Hercules, for the most part, was victorious; though Antæus from time to time received succours by sea. But at last Hercules, coming up with one of his squadrons which had a strong reinforcement on board, made himself master of it, and thus rendered Antæus incapable for the future of making head against him. The same author likewise insinuates, that the notion of Antæus's gigantic stature prevailing for so many centuries amongst the Tingitanians, pointed out the size of the vessels of which his fleets and squadrons were composed. As for the golden apples so frequently mentioned by the old mythologists, they were the treasures that fell into Hercules's hands upon the defeat of Antæus; the Greeks giving the oriental word מאל *riches*, the signification affixed to their own term *μηλα*, *apples*.

With regard to the age in which Atlas and Antæus lived, the most probable supposition seems to be that of Sir Isaac Newton. According to that illustrious author, Ammon the father of Sesac was the first king of Libya, or that vast tract extending from the borders of Egypt to the Atlantic ocean; the conquest of which country was effected by Sesac in his father's lifetime. Neptune afterwards excited the Libyans to a rebellion against Sesac, and slew him; and then invaded Egypt under the command of Atlas or Antæus, the son of Neptune, Sesac's brother and admiral. Not long after, Hercules, the general of Thebais and Ethiopia for the gods or great men of Egypt, reduced a second time the whole continent of Libya, having overthrown and slain Antæus near a town in Thebais, from that event called *Antæa* or *Antæopolis*: this, we say, is the notion advanced by Sir Isaac Newton, who endeavours to prove, that the first reduction of Libya, by Sesac, happened a little above a thousand years before the birth of Christ, as the last, by Hercules, did some few years after. Now, though we do not pretend to adopt every particular circumstance of Sir Isaac Newton's system, yet we cannot forbear observing, that it appears undeniably plain from Scripture, that neither the western extremity of Libya, nor even the other parts of that region, could possibly have been so well peopled before the time of David or Solomon, as to have sent a numerous army to invade Egypt. For Egypt and Phœnicia, from whence the greatest part of the ancestors of the Libyans came, and which were much nearer the place from whence the first dispersion of mankind was made, could not themselves have been greatly overstocked with inhabitants any considerable time before the reign of Saul. And that such an invasion happened in the reign of Neptune, or at least of his son Antæus, has been most fully evinced by this most excellent chronologer.

From the defeat of Antæus, nothing remarkable occurs in the history of Mauritania till the times of the Romans, who at last brought the whole kingdom under their jurisdiction; for which see the article ROME. 1. With regard to the customs, &c. of this people, it would seem, from what Hyginus insinuates, that they fought only with clubs, till one Belus, the son of Neptune, as that author calls him, taught

them

them the use of the sword. Sir Isaac Newton makes this Belus to have been the same person with Sesostris king of Egypt, who overran a great part of the then known world. 2. All persons of distinction in Mauritania went richly attired, wearing much gold and silver in their clothes. They took great pains in cleansing their teeth, and curled their hair in a curious and elegant manner. They combed their beards, which were very long, and always had their nails pared extremely close. When they walked out in any numbers, they never touched one another, for fear of disconcerting the curls into which their hair had been formed. 3. The Mauritanian infantry, in time of action, used shields made of elephants skins, being clad in those of lions, leopards, and bears, which they kept on both night and day. 4. The cavalry of this nation was armed with broad short lances, and carried targets or bucklers, made likewise of the skins of wild beasts. They used no saddles. Their horses were small and swift, had wooden collars about their necks, and were so much under the command of their riders, that they would follow them like dogs. The habit of these horsemen was not much different from that of the foot above mentioned, they constantly wearing a large tunic of the skins of wild beasts. The Phutæi, of whom the Mauritanians were a branch, were eminent for their shields, and the excellent use they made of them, as we learn from Homer, Xenophon, Herodotus, and Scripture. Nay, Herodotus seems to intimate, that the shield and helmet came from them to the Greeks. 5. Notwithstanding the fertility of their soil, the poorer sort of the Mauritanians never took care to manure the ground, being strangers to the art of husbandry; but roved about the country in a wild savage manner, like the ancient Scythians or Arabes Scenitæ. They had tents, or *mapalia*, so extremely small, that they could scarce breathe in them. Their food was corn, herbage, &c. which they frequently did eat green, without any manner of preparation, being destitute of wine, oil, and all the elegancies as well as many necessaries of life. Their habit was the same both in summer and winter, consisting chiefly of an old tattered, though thick garment, and over it a coarse rough tunic; which answered probably to that of their neighbours the Numidians. Most of them lay every night upon the bare ground; though some of them strewed their garments thereon, not unlike the present African Kabyles and Arabs, who, according to Dr Shaw, use their hykes for a bed and covering in the night. 6. If the most approved reading of Horace may be admitted, the Mauritanians shot poisoned arrows; which clearly intimates, that they had some skill in the art of preparing poisons, and were excellent dartmen. This last observation is countenanced by Herodian and Ælian, who entirely come into it, affirming them to have been in such continual danger of being devoured by wild beasts, that they durst not stir out of their tents or mapalia without their darts. Such perpetual exercise must render them exceedingly skilful in hurling that weapon. 7. The Mauritanians sacrificed human victims to their deities, as the Phœnicians, Carthaginians, &c. did.

The country people were extremely rude and barbarous; but those inhabiting cities must undoubtedly have had at least some smattering in the literature of the several nations they deduced their origin from. That the Mauritanians had some knowledge in naval affairs, seems probable, not only from the intercourse they had with the Phœnicians and Carthaginians, as well as the situation of their country; but likewise from Orpheus, or Onomacritus, who asserts them to have made a settlement at the entrance into Colchis, to which place they came by sea. Magic, sorcery, divination, &c. they appear to have applied themselves to in very early times. Cicero and Pliny say, that Atlas was the inventor of astrology, and the doctrine of the sphere, i. e. he first introduced them into Mauritania. This, according to Diodorus Siculus, gave rise to the fable of Atlas bearing the heavens upon his shoulders. The same author relates that Atlas instructed Hercules in the doctrine of the sphere and astrology, or rather astronomy, who afterwards brought those sciences into Greece.

MAURITIA, the GINKGO, or *Maidenhair Tree*; a genus of plants belonging to the natural order of palmæ. See BOTANY *Index*.

MAURITIUS, or MAURICE, an island of Africa, about 400 miles east of Madagascar, lying in the latitude of 20 and 21 degrees south. It is about 150 miles in circumference. In the beginning of the 16th century it was discovered by the Portuguese, who knowing that Pliny and other ancient writers had mentioned the island of Cerne in these seas, took it for granted that this must be it; and accordingly we find it styled *Cerne* or *Sirne*, in their maps: but, notwithstanding this, they did not think fit to settle it; and indeed their force was so small, in comparison of the vast dominions they grasped, that it was very excusable. However, according to their laudable custom, they put some hogs, goats, and other cattle, upon it, that in case any of their ships either going to the Indies or returning to Portugal should be obliged to touch there, they might meet with refreshments. The Dutch, in the second voyage they made to the East Indies under their admiral James Cornelius Vanneck, came together with five ships on the 15th of September 1568; anchored in a commodious port, to which they gave the name of *Warwick Haven*; and gave a very good account of the place in their journals. Captain Samuel Castleton, in the Pearl, an English East India ship, arrived there on the 27th of March 1612; and taking it to be an island undiscovered before, bestowed upon it the name of *England's Forest*, though others of his crew called it *Pearl Island*; and in the account of their voyage, written by John Tatton the master of the ship, celebrated it as a place very convenient for shipping, either outward or homeward bound, to refresh at. This they sometimes accordingly did, and brought some cargoes of ebony, and rich wood from thence, but without fixing any settlement.

At length, in 1638, the Dutch seated themselves here: and it is highly remarkable, that at the very time they were employed in making their first settlement, the French sent a vessel to take possession of it, who found the Dutch beforehand with them, and refused the assistance of an English Indiaman, wooding and watering in another part of the island, who very frankly offered it, to drive the Dutch from their half settled posts. They continued for some time in quiet

Mauritius. possession of the places they fortified in this island, to which they gave the name of *Mauritius*, in honour of Prince Maurice their stadtholder. But having engaged the French, who were settled on Madagascar, to steal 50 of the natives, and sell them for slaves, for the improvement of the Dutch settlements here, this proved the ruin of both colonies; for the negroes surprised and massacred the French in Madagascar; and the slaves in Mauritius fled into the centre of the island; from whence they so much and so incessantly molested those who had been formerly their masters, that they chose to quit a country where they could no longer remain in any tolerable degree of safety. The East India Company, however, from motives of conveniency, and a very imperfect notion of its value, disapproved this measure, and therefore ordered it to be resettled; which was accordingly done, and three forts erected at the principal havens. Things now went on somewhat better than they did before; but they were still very much disturbed by the revolted negroes in the heart of the isle, whom they could never subdue. One principal use that the company made of this place, was to send thither state prisoners, who, as they were not men of the best morals, quickly corrupted the rest of the inhabitants, and rendered them such a race of outrageous smugglers, the situation of the place concurring with their bad disposition, that, after various ineffectual attempts made to reform them, orders were at length given to abandon Mauritius a second time, which after some delays, were put in execution in the year 1710.

Two years after this, the French took possession of it, and named it the *isle de France*. This name has obtained among themselves, but the Europeans in general continue to call it Mauritius. It lies in S. Lat. 20. 15. E. Long. 6. 15. The inconveniences arising from the want of a port at the island of Bourbon, induced the French to take possession of Mauritius, it having two very good harbours, to fortify which no expence has been spared. That on the north-west is called *Port Louis*, that on the south-east side of the island is called *Port Bourbon*. The trade-wind from the south-east in these latitudes blows all the year round, excepting for a few days at the summer solstice, when it is interrupted by hard gales and hurricanes from the north. The ease with which this wind enables ships to enter the port of Bourbon, caused the French, when they first took possession of this spot, to esteem it the best port in the island; but experience pointing out to them, that the same wind often rendered the passage out of the harbour so difficult, that a ship was sometimes obliged to wait a considerable time before the weather admitted of her putting to sea, this harbour is in a great measure abandoned, and the principal town and seat of government is now fixed at Port Louis, which is nearly in the middle of the north side of the island, and its entrance is through a channel formed by two shoals, which advance abont two miles into the sea. When a ship arrives opposite to this channel, the south-east wind hinders her from entering the port under sail, and she must either warp in with cables or be towed in with boats. The necessity of this operation, joined to the extreme narrowness of the channel, which does not admit of two ships abreast of each other entering at the same time, is one of the best defences the harbour has against an attack by sea; for, from these obstacles, an enemy would find it a matter of the greatest difficulty to force the port; and in addition to this natural strength, they have built two forts and as many batteries, which are mounted with heavy cannon, and entirely command the approach to the harbour, should ships presume to force an entry under sail. This port is capable of containing 100 sail of ships, and is well provided with every requisite for repairing and even building of ships. This port has proved of the greatest advantage to France in the several wars which have been carried on between Great Britain and her; and has proved of great utility to the French East India Company's commerce; for here their ships and crews were sure to meet with all necessary refreshment after a long voyage. The port of Bourbon is also fortified; and an army landed here would find it an extremely difficult task to pass the mountains to the different parts of the island. There are several places between the north-east extremity and Port Louis where boats may land, but all these are defended by batteries; and the country behind them is a continued thicket: The rest of the coast is inaccessible. In the north-eastern quarter is a plain extending about 10 miles from east to west, and in some places five miles inland from the northern coast. All the rest of the island is full of high and steep mountains, lying so near to one another, and the intervals between them so narrow, that, instead of valleys, they rather resemble the beds of torrents; and these are choked with huge fragments of rocks which have fallen from the steep sides of the impending mountains. On the summits of the mountains ice is frequently to be found, and they are covered with forests of ebony and other large trees. The ground they shade produces herbage, shrubs, and plants of various sorts, from the common grass to the strongest thorn, and that in such profusion, that they form a thicket so closely interwoven, that no progress can be made but by means of a hatchet. Notwithstanding these difficulties, plantations have been formed on these mountains, and very considerable progress has been made in the plains; but the productions, although mostly of the same kind, are not only in less quantity, but of an inferior quality to those produced at Bourbon island.

In a course of years, however, the settlement cost so much, and was considered in every light worth so little, that it had been more than once under deliberation, whether, after the example of the Dutch, they should not leave it again to its old negro inhabitants; which sooner or later in all likelihood would have been its fate, if, in 1735, the famous M. de la Bourdonnais had not been sent thither with the title of *governor-general of the French islands*.

He found this isle in the worst state possible, thinly inhabited by a set of lazy people, who equally hated industry and peace, and who were continually flattering this man to his face, and belying him wherever and as far as they durst. He gave himself no trouble about this, having once found the means to make himself obeyed; he saw the vast importance of the island; he conceived that it might be settled to great advantage; and, without so much as expecting the thanks of those for whom he laboured, he began to execute this great design. His first step was to bring over black

Mauritius. black boys from Madagascar, whom he carefully trained up in good principles, and in continual exercise; by which he rendered them so good soldiers, that he very quickly obliged the Marones, or wild negroes, either to submit or to quit the island: he taught the planters to cultivate their lands to advantage; he, by an aqueduct, brought fresh water to the sea side; and whereas they had not so much as a boat at his coming thither, he made a very fine dock, where he not only built sloops and large vessels, but even a ship of the burden of 500 tons. However incredible it may seem, yet it is certainly fact, that in the space of five years he converted this country into a paradise, that had been a mere wilderness for 5000; and this in spite of the inhabitants, and of the company, who being originally prejudiced by them, behaved ill to him at his return. He soon made the cardinal de Fleury, however, sensible of the true state of things; and compelled the company to acknowledge, though they did not reward, his services. He afterwards returned into the Indies, and perfected the work he had begun, and to him it is owing that the isle of France was rendered one of the finest and most important spots upon the globe. Here no coffee is raised; but by the indefatigable industry of M. de Bourdonnais, sugar, indigo, pepper, and cotton (which are not at Bourbon), came to be cultivated with success. Since the departure of that most excellent governor, the plantations have been neglected, and are fallen off; but if a proper spirit of activity was raised among the inhabitants, they might soon be made to resume their flourishing appearance. Mines of iron have been discovered in the mountains near the great plain, in the north-east part of the island; and these mountains affording in great abundance the necessary fuel, forges have been erected: but the iron produced is of a very inferior quality, it being brittle, and only fit for making cannon-balls and bomb-shells. Black cattle, sheep, and goats, are preserved with difficulty; the first generally die before they have been a year in the island, and this occasions frequent importations of them from Madagascar and other parts. Common domestic poultry breed in great plenty; and, with fish and turtle, furnish a great part of the food of the European inhabitants.

The approach to the island is extremely dangerous, it being surrounded with ledges of rocks, and many of them covered by the sea. The shore abounds with coral and shells. This island is said to contain 60 rivers: some are considerable streams, and most of them have their sources from lakes, of which there are several in the middle part of the island. The rivers afford plenty of various kinds of fish, particularly eels. These are of an enormous size, some having been found that were six feet long, and six inches in circumference, and so extremely voracious, that it is dangerous to bathe in those parts of the river where they lie, as they will seize a man without fear, and have strength sufficient to keep him under water till he is drowned. Here is a great variety of birds, and bats as large as a young kitten: the inhabitants esteem them a delicate morsel. The air is both hot and moist, but not unwholesome. The place abounds with insects, which are very troublesome; but there are no serpents. It has been discovered, that off Port Louis the south-east wind generally blows with least strength about sunrise; and it also happens, on four or five days, at intervals, in the course of a month, that early in the morning the wind ceases in the northern part of the island for an hour or two, when a breeze rises, although but faintly, from the north-west; during which, a ship stationed at the entrance of the channel to avail herself of this breeze, may enter the harbour and attack the forts.

Mauritius || Maxentius.

This island, during the period of the French revolution, did not entirely escape from the storm which then agitated the parent country. In the year 1799, a conspiracy was formed, and broke out, for the purpose of resisting the government which had been established under the authority of the republic. It was, however, soon suppressed by the activity of the civil authorities, supported by the majority of the inhabitants.

The population of this island in 1799 amounted to 65,000, viz. 55,000 slaves, and 10,000 whites and mulattoes. The following is a state of the produce of this island in 1800: viz. coffee, 6000 bales, of 100 lbs. French; indigo, 300,000 lbs. from 2s. to 8s. per lb.; cotton, 2000 bales, of 250 lbs.; raw sugar, 20,000,000 lbs.; cloves, 20,000 lbs. The island of Mauritius, as well as the other French islands in the Indian ocean, were taken by the British in 1811; and their possession was confirmed to Britain by the treaty of Paris in 1814.

MAURUA, one of the Society islands in the South sea. It is a small island, entirely surrounded with a ridge of rocks, and without any harbour for shipping. It is inhabited; and its productions are the same with those of the neighbouring islands. A high round hill rises in the middle of it, which may be seen at the distance of 10 or 12 leagues. W. Long. 152. 32. S. Lat. 16. 25.

MAUSOLEUM, a magnificent tomb or sepulchral monument. The word is derived from Mausolus king of Caria, to whom Artemisia his widow erected a most stately monument, esteemed one of the wonders of the world, and called it, from his own name, *Mausoleum.*

St MAWES, a town of Cornwall, in England, seated on the east side of Falmouth haven, in W. Long. 4. 56. N. Lat. 50. 6. Though but a hamlet of the parish of St Just, two miles off, without a minister, or either church, chapel, or meeting-house, it has sent members to parliament ever since 1562, who are returned by its mayor or portreve. It consists but of one street, under a hill, and fronting the sea, and its inhabitants subsist purely by fishing. K. Henry VIII. built a castle here, opposite to Pendennis, for the better security of Falmouth haven. It has a governor, a deputy, and two gunners, with a platform of guns. Here is a fair the Friday after St Luke's day.

MAXENTIUS, Marcus Aurelius Valerius, a son of the emperor Maximianus Hercules, was, by the voluntary abdication of Dioclesian, and of his father, raised to the empire A. D. 306. He afterwards incited his father to reassume his imperial authority; and in a perfidious manner destroyed Severus, who had delivered himself into his hands, and relied upon his honour for the safety of his life. His victories and successes were impeded by Galerius Maximianus, who opposed him with a powerful force. The defeat and

and voluntary death of Galerius soon restored peace to Italy; and Maxentius passed into Africa, where he rendered himself odious by his cruelty and oppression. He soon after returned to Rome, and was informed that Constantine was come to dethrone him. He gave his adversary battle near Rome, and, after he had lost the victory, he fled back to the city. The bridge over which he crossed the Tiber was in a decayed situation, and he fell into the river, and was drowned, A. D. 312. The cowardice and luxuries of Maxentius were as conspicuous as his cruelties. He oppressed his subjects with heavy taxes, to gratify the cravings of his pleasures, or the avarice of his favourites. He was debauched in his manners, and neither virtue nor innocence were safe whenever he was inclined to voluptuous pursuits. His body was deformed and unwieldy. To visit a pleasure ground, or to exercise himself under a marble portico, or walk on a shady terrace, was to him a Herculean labour, which required the greatest exertions of strength and resolution.

MAXILLA, the JAW. See ANATOMY, N° 20—26.

MAXIM, an established proposition or principle: in which sense it denotes much the same with axiom.

MAXIMILIAN I. emperor of Germany, signalized himself against the French while he was king of the Romans, and after he was emperor entered into the army of Henry VIII. of England as a volunteer against that nation: he was a protector of learned men, and abolished an iniquitous tribunal, styled *Judicium occultum Westphaliæ;* he composed some poems, and the memoirs of his own life. He died in 1519, aged 60.

MAXIMUM, in *Mathematics*, denotes the greatest quantity attainable in any given case.

If a quantity conceived to be generated by motion increases or decreases till it arrives at a certain magnitude or position, and then, on the contrary, grows greater or lesser, and it be required to determine the said magnitude or position, the question is called a *problem de maximis et minimis*.

MAXIMUS, a celebrated Cynic philosopher, and magician, of Ephesus. He instructed the emperor Julian in magic; and, according to the opinion of some historians, it was in the conversation and company of Maximus that the apostasy of Julian originated. The emperor not only visited the philosopher, but he even submitted his writings to his inspection and censure. Maximus refused to live in the court of Julian; and the emperor, not dissatisfied with the refusal, appointed him high pontiff in the province of Lydia, an office which he discharged with the greatest moderation and justice. When Julian went into the east, the philosopher promised him success, and even said that his conquests would be more numerous and extensive than those of the son of Philip. He persuaded his imperial pupil, that, according to the doctrine of metempsychosis, his body was animated by the soul which once animated the hero whose greatness and victories he was going to eclipse. After the death of Julian, Maximus was almost sacrificed to the fury of the soldiers; but the interposition of his friends saved his life, and he retired to Constantinople. He was soon after accused of magical practices, before the emperor Valens, and beheaded at Ephesus, A. D. 366. He wrote some philosophical and rhetorical treatises, some of which were dedicated to Julian. They are all now lost.

MAXIMUS *of Tyre*, a Platonic philosopher, went to Rome in 146, and acquired such reputation there, that the emperor Marcus Aurelius became his scholar, and gave him frequent proofs of his esteem. This philosopher is thought to have lived till the reign of the emperor Commodus. There are still extant 41 of his dissertations; a good edition of which was printed by Daniel Heinsius, in 1624, in Greek and Latin, with notes.

MAXIMUS MARIUS. See *MARIUS*.

MAY, the fifth month in the year, reckoning from our first, or January; and the third, counting the year to begin with March, as the Romans anciently did. It was called Maius by Romulus, in respect to the senators and nobles of his city, who were named *majores;* as the following month was called *Junius*, in honour of the youth of Rome, *in honorem juniorum*, who served him in the war; though some will have it to have been thus called from *Maia*, the mother of Mercury, to whom they offered sacrifice on the first day of it; and Papius derives it from *Madius, eo quod tunc terra madeat*. In this month the sun enters Gemini, and the plants of the earth in general begin to flower. —The month of May has ever been esteemed favourable to love; and yet the ancients, as well as many of the moderns, look on it as an unhappy month for marriage. The original reason may perhaps be referred to the feast of the Lemures, which was held in it. Ovid alludes to this in the fifth of his Fasti, when he says,

> *Nec viduæ tædis eadem, nec virginis apta*
> *Tempora; quæ nupsit, non diuturna fuit;*
> *Hac quoque de causa, si te proverbia tangunt,*
> *Mense malum* Maio *nubere vulgus ait.*

MAY-dew. See DEW.

MAY-duke, a species of cherry. See PRUNUS, BOTANY *Index*.

MAY, *Isle of*, a small island at the mouth of the frith of Forth, in Scotland, about a mile and a half in circumference, and seven miles from the coast of Fife, almost opposite to the rock called the *Bass*. It formerly belonged to the priory of Pittenweem: and was dedicated to St Adrian, supposed to have been martyred in this place by the Danes; and hither, in times of Popish superstition, barren women used to come and worship at his shrine, in hopes of being cured of their sterility. Here is a tower and lighthouse built by Mr Cunningham of Barns, to whom King Charles I. granted the island in fee, with power to exact twopence per ton from every ship that passes, for the maintenance of a lighthouse. In the middle of it there is a fresh-water spring, and a small lake.—The soil produces pasturage for 100 sheep and 20 black cattle. On the west side the steep rocks render it inaccessible; but to the east there are four landing places and good riding. It was here that the French squadron, having the chevalier de St George on board, anchored in the year 1708, when the vigilance of Sir George Byng obliged him to relinquish his design, and bear away for Dunkirk. The shores all round the island abound with fish, and the cliffs with water fowl.

MAY, *Thomas*, an eminent English poet and historian in the 17th century, was born of an ancient but decayed family in Sussex, educated at Cambridge, and afterwards removed to London. While he resided at court, he wrote the five plays now extant under his name. In 1622, he published a translation of Virgil's Georgics, with annotations; and in 1635 a poem on King Edward III. and a translation of Lucan's Pharsalia; which poem he continued down to the death of Julius Cæsar, both in Latin and English verse. Upon the breaking out of the civil wars he adhered to the parliament; and in 1647, he published, "The history of the parliament of England, which began November the third, MDCXL. With a short and accessary view of some precedent years." In 1649, he published, *Historiæ Parliamenti Angliæ Breviarium*, in three parts; which he afterwards translated into English. He wrote the History of Henry II. in English verse. He died in 1642. He went well to rest over night, after a cheerful bottle as usual, and died in his sleep before morning: upon which his death was imputed to his tying his nightcap too close under his fat cheeks and chin, which caused his suffocation; but the facetious Andrew Marvel has written a poem of 100 lines, to make him a martyr of Bacchus, and die by the force of good wine. He was interred near Camden in Westminster Abbey; which caused Dr Fuller to say, that "if he were a biassed and partial writer, yet he lieth buried near a good and true historian indeed." Soon after the Restoration, his body, with those of several others, was dug up, and buried in a pit in St Margaret's churchyard; and his monument, which was erected by the appointment of parliament, was taken down and thrown aside.

MAYER, TOBIAS, one of the greatest astronomers and mechanics the 18th century produced, was born at Maspach, in the duchy of Wirtemberg, 1723. He taught himself mathematics, and at the age of fourteen designed machines and instruments with the greatest dexterity and justness. These pursuits did not hinder him from cultivating the belles lettres. He acquired the Latin tongue, and wrote it with elegance. In 1750, the university of Gottingen chose him for their mathematical professor; and every year of his short life was thenceforward marked with some considerable discoveries in geometry and astronomy. He published several works in this way, which are all reckoned excellent; and some are inserted in the second volume of the "Memoirs of the university of Gottingen." His labours seem to have exhausted him; for he died worn out in 1762.

MAYERNE, SIR THEODORE DE, baron of Aulbone, was the son of Lewis de Mayerne, the celebrated author of the General History of Spain, and of the *Monarchie aristo-democratique*, dedicated to the states-general. He was born in 1573, and had for his godfather Theodore Beza. He studied physic at Montpelier, and was made physician in ordinary to Henry IV. who promised to do great things for him, provided he would change his religion. James I. of England invited him over, and made him first physician to himself and his queen, in which office he served the whole royal family to the time of his death in 1655. His works were printed at London in 1700, and make a large folio, divided into two books; the first containing his *Consilia, Epistolæ, et Observationes*; the second his *Pharmacopœia variæque medicamentorum formulæ*.

MAYHEM. See MAIM.

MAYNE, JASPER, an eminent English poet and divine in the 17th century, who was bred at Oxford, and entered into holy orders. While his majesty resided at Oxford, he was one of the divines appointed to preach before him. He published in 1647 a piece entitled ΟΧΛΟΜΑΧΙΑ, or *The people's war examined according to the principles of reason and scripture, by Jasper Mayne.* In 1648 he was deprived of his studentship at Christ church, and two livings he had; but was restored with the king, who made him his chaplain and archdeacon of Chichester; all which he held till he died. Dr Mayne was held in very high esteem both for his natural parts and his acquired accomplishments. He was an orthodox preacher, and a man of severe virtue and exemplary behaviour; yet of a ready and facetious wit, and a very singular turn of humour. From some stories that are related of him, he seems to have borne some degree of resemblance in his manner to the celebrated Dr Swift; but if he did not possess those very brilliant parts that distinguished the Dean, he probably was less subject to that capricious and those unaccountable whimsies which at times so greatly eclipsed the abilities of the latter. Yet there is one anecdote related of him, which, although it reflects no great honour on his memory, as it seems to carry some degree of cruelty with it, yet it is a strong mark of his resemblance to the Dean, and a proof that his propensity for drollery and joke did not quit him even in his latest moments. The story is this: The Doctor had an old servant, who had lived with him some years, to whom he had bequeathed an old trunk, in which he told him he would find *something that would make him drink after his death.* The servant, full of expectation that his master, under this familiar expression, had left him somewhat that would be a reward for the assiduity of his past services, as soon as decency would permit, flew to the trunk; when, behold, to his great disappointment, the boasted legacy proved to be a red herring. The doctor, however, bequeathed many legacies by will to pious uses; particularly 50 pounds towards the rebuilding of St Paul's cathedral, and 200 pounds to be distributed to the poor of the parishes of Cassington and Pyrton, near Wattington, of both which places he had been vicar. In his younger years he had an attachment to poetry; and wrote two plays, the latter of which may be seen in the tenth volume of Dodsley's Collection, viz. 1. Amorous war, a tragi-comedy. 2. The city-match, a comedy. He published a poem upon the naval victory by the duke of York over the Dutch, printed in 1665. He also translated into English from the Greek, part of Lucian's Dialogues.

MAYNOOTH, or MANOOTH, a post town in the county of Kildare, in Ireland, 12 miles from Dublin. At this place there is a catholic college, established by the

the Irish parliament in 1795. Young men destined for the catholic church had formerly gone to the continent for their education. This had now become nearly impossible, in consequence of the war with France and Spain; and for this reason, as well as to prevent those foreign attachments which grow out of a foreign education, it was thought prudent to provide the means of domestic instruction for the catholics. They had only petitioned for leave to establish a seminary; but the parliament also granted 8000l. per annum for its support, which was afterwards enlarged to 13,000l.; but has since been diminished. There were in 1808, eight professorships and three lectureships; and there was accommodation for 200 students, to whom the establishment afforded commons and instruction.

MAYNWARING, Arthur, an eminent political writer in the beginning of the 18th century, staid several years at Oxford, and then went to Cheshire, where he lived some time with his uncle Mr Francis Cholmondeley, a very honest gentleman, but extremely averse to the government of King William III. to whom he refused the oaths. Here he prosecuted his studies in polite literature with great vigour; and coming up to London, applied to the study of the law. He was hitherto very zealous in anti-revolutional principles, and wrote several pieces in favour of King James II.; but upon being introduced to the duke of Somerset and the earls of Dorset and Burlington, began to entertain very different notions in politics. His father left him an estate of near 800l. a-year, but so encumbered, that the interest money amounted to almost as much as the revenue. Upon the conclusion of the peace he went to Paris, where he became acquainted with Mr Boileau. After his return he was made one of the commissioners of the customs, in which post he distinguished himself by his skill and industry. He was a member of the Kit-cat club, and was looked upon as one of the chief supports of it by his pleasantry and wit. In the beginning of Queen Anne's reign, the lord treasurer Godolphin engaged Mr Donne to quit the office of auditor of the imprests, and made Maynwaring a present of a patent for that office worth about 2000l. a-year in a time of business. He had a considerable share in the Medley, and was author of several other pieces. The Examiner, his antagonist in politics, allowed that he wrote with tolerable spirit, and in a masterly style. Sir Richard Steele dedicated the first volume of the Tatler to him.

MAYO, one of the Cape de Verd islands, lying in the Atlantic ocean, near 300 miles from Cape Verd in Africa, about 17 miles in circumference. The soil in general is very barren, and water scarce: however, they have some corn, yams, potatoes, and plantains, with plenty of beeves, goats, and asses. What trees there are, grow on the sides of the hills, and they have some figs and water melons. The sea round about the island abounds with fish. The chief commodity is salt, with which many English ships are loaded in the summer time. The principal town is Pinosa, inhabited by negroes, who speak the Portuguese language, and are stout, lusty, and fleshy. They are not above 200 in number, and many of them go quite naked. W. Long. 23. 5. N. Lat. 15. 10.

Mayo, a county of Ireland, in the province of Con-

naught, having Sligo and the sea on the north; Roscommon on the south, Leitrim and Roscommon on the east, and the Atlantic ocean on the west. It contains 724,640 Irish plantation acres, 68 parishes, and 140,000 inhabitants. It gives title of earl to the family of Bourke. This county takes its name from an ancient city, built in 664; the ruins of the cathedral, and some traces of the stone walls which encompassed the city, yet remain on the plains of Mayo. It was a university, founded for the education of such of the Saxon youths as were converted to the Christian faith: it was situated a little to the south of Lough Conn; and is to this day frequently called *Mayo of the Saxons*, being celebrated for giving education to Alfred the Great, king of England. As this town has gone to decay, Balinroke is reckoned the chief town. The county by the sea is mountainous; but inland has good pastures, lakes, and rivers. It is about 62 miles long, and 52 broad. Castlebar is the assizes town.—Mayo was formerly a bishop's see, which is now united to Tuam.

MAYOR, the chief magistrate of a city or town, chosen annually out of the aldermen. The word, anciently wrote *meyr*, comes from the British *miret*, i. e. *custodire*, or from the old English *maier*, viz. *potestas*, and not from the Latin *major*. King Richard I. in 1189, changed the bailiff of London into a mayor, and from that example King John made the bailiff of King's Lynn a mayor anno 1204: Though the famous city of Norwich obtained not this title for its chief magistrates till the seventh year of King Henry V. anno 1419; since which there are few towns of note but have had a mayor appointed for government.

Mayors of corporations are justices of peace *pro tempore*, and are mentioned in several statutes; but no person shall bear any office of magistracy concerning the government of any town, corporation, &c. who hath not received the sacrament according to the church of England within one year before his election, and who shall not take the oaths of supremacy, &c.

If any person intrudes into the office of mayor, a *quo warranto* lies against him, upon which he shall not only be ousted, but fined. And no mayor, or person holding an annual office in a corporation for one year, is to be elected into the same office for the next; in this case, persons obstructing the choice of a successor are subject to 100l. penalty. Where the mayor of a corporation is not chosen on the day appointed by charter, the next officer in place shall the day after hold a court and elect one; and if there be a default or omission that way, the electors may be compelled to choose a mayor, by a writ of mandamus out of the king's bench. Mayors, or other magistrates of a corporation, who shall voluntarily absent themselves on the day of election, are liable to be imprisoned, and disqualified from holding any office in the corporation.

Mayor's Courts. To the lord mayor and city of London belong several courts of judicature. The highest and most ancient is that called the *hustings*, destined to secure the laws, rights, franchises, and customs of the city. The second is a court of *request*, or of *conscience;* of which before. The third is the court of the lord mayor and aldermen, where also the sheriffs sit;

sit; to which may be added two courts of sheriffs, and the court of the city orphans, whereof the lord mayor and aldermen have the custody. Also the court of common council, which is a court or assembly, wherein are made all by-laws which bind the citizens of London. It consists, like the parliament, of two houses: an upper, consisting of the lord mayor and aldermen; and a lower, of a number of common council men, chosen by the several wards as representatives of the body of the citizens. In the court of common council are made laws for the advancement of trade, and committees yearly appointed, &c. But acts made by them are to have the assent of the lord mayor and aldermen by stat. 11. Geo. I. Also the chamberlain's court, where every thing relating to the rents and revenues of the city, as also the affairs of servants, &c. are transacted. Lastly, to the lord mayor belong the courts of coroner and of eschcator; another court for the conservation of the river Thames; another of gaol delivery, held usually eight times a year, at the Old Bailey, for the trial of criminals, whereof the lord mayor is himself the chief judge. There are other courts called *wardmotes* or meetings of the wards; and courts of halymote or assemblies of the several guilds and fraternities.

MAZA, among the Athenians, was a sort of cake made of flour boiled with water and oil, and set as the common fare, before such as were entertained at the public expence in the common hall or *Prytaneum*.

MAZAGAN, a strong place of Africa in the kingdom of Morocco, and on the frontiers of the province of Duguela. It was fortified by the Portuguese, and besieged by the king of Morocco with 200,000 men in 1562, but to no purpose. It is situated near the sea. W. Long. 8. 15. N. Lat. 33. 12.

MAZARA, an ancient town of Sicily, and capital of a considerable valley of the same name, which is very fertile, and watered with several rivers. The town is a bishop's see, and has a good harbour; is seated on the sea coast, in E. Long. 12. 30. N. Lat. 37. 53.

MAZARINE, Julius a famous cardinal and prime minister of France, was born at Piscina in the province of Abruzzo, in Naples, in 1602. After having finished his studies in Italy and Spain, he entered into the service of Cardinal Sachetts, and became well skilled in politics, and in the interests of the princes at war in Italy; by which means he was enabled to bring affairs to an accommodation, and the peace of Queiras was shortly concluded. Cardinal Richlieu being taken with his conduct, did from thenceforward highly esteem him; as did also Cardinal Antonio, and Louis XIII. who procured him a cardinal's hat in 1641. Richlieu made him one of the executors of his will; and during the minority of Louis XIV. he had the charge of affairs. At last he became the envy of the nobility, which occasioned a civil war; whereupon Mazarine was forced to retire, a price was set on his head, and his library sold. Notwithstanding, he afterwards returned to the court in more glory than ever; concluded a peace with Spain, and a marriage treaty betwixt the king and the infanta. This treaty of peace passes for the masterpiece of Cardinal de Mazarine's politics, and procured him the French king's most intimate confidence: but at last his continual application to business threw him into a disease, of which he died at Vincennes in 1661.—Cardinal Mazarine was of a mild and affable temper. One of his greatest talents was his knowing mankind, and his being able to adapt himself, and to assume a character conformable to the circumstances of affairs. He possessed at one and the same time the bishopric of Metz, and the abbeys of St Arnauld, St Clement, and St Vincent, in the same city; that of St Dennis, Clugny, and Victor, of Marseilles; of St Michel at Soissons, and a great number of others. He founded Mazarine college at Paris; which is also called the *college of the four nations*. There has been published a collection of his letters, the most copious edition of which is that of 1745, in 2 vols. duodecimo.

MAZZUOLI. See Parmigiano.

MEAD, a wholesome, agreeable liquor, prepared with honey and water.

One of the best methods of preparing mead is as follows: Into twelve gallons of water put the whites of six eggs; mixing these well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour; and when boiled, add cinnamon, ginger, cloves, mace, and rosemary. As soon as it is cold, put a spoonful of yest to it, and tun it up, keeping the vessel filled as it works; when it has done working, stop it up close; and, when fine, bottle it off for use.

The author of the Dictionary of Chemistry directs to choose the whitest, purest, and best tasted honey, and to put it into a kettle with more than its weight of water: a part of this liquor must be evaporated by boiling, and the liquor scummed, till its consistence is such, that a fresh egg shall be supported on its surface without sinking more than half its thickness into the liquor; then the liquor is to be strained and poured through a funnel into a barrel; this barrel, which ought to be nearly full, must be exposed to a heat as equable as possible, from 20 to 27 or 28 degrees of Mr Reaumur's thermometer, taking care that the bunghole be slightly covered, but not closed. The phenomena of the spirituous fermentation will appear in this liquor, and will subsist during two or three months, according to the degree of heat; after which they will diminish and cease. During this fermentation, the barrel must be filled up occasionally with more of the same kind of liquor of honey, some of which ought to be kept apart, on purpose to replace the liquor which flows out of the barrel in froth. When the fermentation ceases, and the liquor has become very vinous, the barrel is then to be put into a cellar, and well closed; a year afterwards the mead will be fit to be put into bottles. Mead is a liquor of very ancient use in Britain. See Feast.

Mead, *Dr Richard*, a celebrated English physician, was born at Stepney near London, where his father, the Reverend Mr Matthew Mead, had been one of the two ministers of that parish; but in 1662 was ejected for nonconformity, but continued to preach at Stepney till his death. As Mr Mead had a handsome fortune, he bestowed a liberal education upon 13 children, of whom Richard was the eleventh; and for that purpose kept a private tutor in his house,

who

Mead. who taught him the Latin tongue. At 16 years of age Richard was sent to Utrecht, where he studied three years under the famous Grævius; and then choosing the profession of physic, he went to Leyden, where he attended the lectures of the famous Pitcairn on the theory and practice of medicine, and Herman's botanical courses. Having also spent three years in these studies, he went with his brother and two other gentlemen to visit Italy, and at Padua took his degree of doctor of philosophy and physic in 1695. Afterwards he spent some time at Naples and at Rome; and returning home the next year, settled at Stepney, where he married, and practised physic with a success that laid the foundation of his future greatness.

In 1703, Dr Mead having communicated to the Royal Society an analysis of Dr Bonomo's discoveries relating to the cutaneous worms that generate the itch, which they inserted in the Philosophical Transactions; this, with his account of poisons, procured him a place in the Royal Society, of which Sir Isaac Newton was then president. The same year he was elected physician of St Thomas's hospital, and was also employed by the surgeons to read anatomical lectures in their hall, which obliged him to remove into the city. In 1707 his Paduan diploma for doctor of physic was confirmed by the university of Oxford; and being patronized by Dr Radcliffe, on the death of that famous physician he succeeded him in his house at Bloomsbury-square, and in the greatest part of his business. In 1727 he was made physician to King George II. whom he had also served in that capacity while he was prince of Wales; and he had afterwards the pleasure of seeing his two sons-in-law, Dr Nichols and Dr Wilmot, his coadjutors in that eminent station.

Dr Mead was not more to be admired for the qualities of the head than he was to be loved for those of his heart. Though he was himself a hearty whig, yet, uninfluenced by party principles, he was a friend to all men of merit, by whatever denomination they might happen to be distinguished. Thus he was intimate with Garth, with Arbuthnot, and with Freind; and long kept up a constant correspondence with the great Boerhaave, who had been his fellow student at Leyden: they communicated to each other their observations and projects, and never loved each other the less for being of different sentiments. In the mean time, intent as Dr Mead was on the duties of his profession, he had a greatness of mind that extended itself to all kinds of literature, which he spared neither pains nor money to promote. He caused the beautiful and splendid edition of Thuanus's history to be published in 1713, in seven volumes folio: and by his interposition and assiduity, Mr Sutton's invention of drawing foul air from ships and other close places was carried into execution, and all the ships in his majesty's navy provided with this useful machine. Nothing pleased him more than to call hidden talents into light; to give encouragement to the greatest projects, and to see them executed under his own eye. During almost half a century he was at the head of his business, which brought him one year about seven thousand pounds, and for several years between five and six thousand; yet clergymen, and in general all men of learning, were welcome to his advice. His library consisted of 10,000 volumes, of which his Latin, Greek, and oriental manuscripts, made no inconsiderable part. He had a gallery for his pictures and antiquities, which cost him great sums. His reputation, not only as a physician, but as a scholar, was so universally established, that he corresponded with all the principal literati in Europe: even the king of Naples sent to desire a complete collection of his works; and in return made him a present of the two first volumes of Signior Bajardi, which may be considered as an introduction to the collection of the antiquities of Herculaneum. At the same time that prince invited him to his palace, that he might have an opportunity of showing him those valuable monuments of antiquity; and nothing but his great age prevented his undertaking a journey so suited to his taste. No foreigner of learning ever came to London without being introduced to Dr Mead; and on these occasions his table was always open, and the magnificence of princes was united with the pleasures of philosophers. It was principally to him that the several counties of England and our colonies abroad applied for the choice of their physicians, and he was likewise consulted by foreign physicians from Russia, Prussia, Denmark, &c. He wrote, besides the above works, 1. A Treatise on the Scurvy. 2. *De variolis et morbillis dissertatio.* 3. *Medica sacra: sive de Morbis insignioribus, qui in Bibliis memorantur, Commentarius.* 4. *Monita et Præcepta medica.* 5. A Discourse concerning pestilential contagion, and the methods to be used to prevent it. The works he wrote and published in Latin were translated into English, under the Doctor's inspection, by Thomas Stack, M. D. and F. R. S. This great physician, naturalist, and antiquarian, died on the 16th of February 1754.

Mead ‖ Meal.

MEADOW, in its general signification, means pasture or grass lands, annually mown for hay: but it is more particularly applied to lands that are so low as to be too moist for cattle to graze upon them in winter without spoiling the sward. For the management and watering of meadows, see AGRICULTURE, p. 435.

MEAL, the flour of grain. The meal or flour of Britain is the finest and whitest in the world. The French is usually browner, and the German browner than that. Our flour keeps well with us; but in carrying abroad it often contracts damp, and becomes bad. All flour is subject to breed worms; these are white in the white flour, and brown in that which is brown; they are therefore not always distinguishable to the eye; but when the flour feels damp, and smells rank and musty, it may be conjectured that they are there in great abundance.

The colour and the weight are the two things which denote the value of meal or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions these two characters as the marks of good flour; and tells us, that Italy in his time produced the finest in the world. This country indeed was famous before his time for this produce; and the Greeks have celebrated it; and Sophocles in particular says, that no flour is so white or so good as that of Italy. The corn of this country has, however, lost much of its reputation since that time;

Meal.

time; and the reason of this seems to be, that the whole country being full of sulphur, alum, vitriol, marcasites, and bitumens, the air may have in time affected them so far as to make them diffuse themselves through the earth, and render it less fit for vegetation; and the taking fire of some of these inflammable minerals, as has sometimes happened, is alone sufficient to alter the nature of all the land about the places where they are.

The flour of Britain, though it pleases by its whiteness, yet wants some of the other qualities valuable in flour; the bread that is made of it is brittle and does not hold together, but after keeping a few days becomes hard and dry as if made of chalk, and is full of cracks in all parts; and this must be a great disadvantage in it when intended for the service of an army, or the like occasions, where there is no baking every day, but the bread of one making must necessarily be kept a long time.

The flour of Picardy is very like that of Britain; and after it has been kept some time, is found improper for making into paste or dough. The French are forced either to use it immediately on the grinding, or else to mix it with an equal quantity of the flour of Brittany, which is coarser, but more unctuous and fatty; but neither of these kinds of flour keep well.

The flour of almost any country will do for the home consumption of the place, as it may be always fresh ground; but the great care to be used in selecting it, is in order to the sending it abroad, or furnishing ships for their own use. The saline humidity of the sea air rusts metals, and fouls every thing on board, if great care be not taken in the preserving them. This also makes the flour damp and mouldy, and is often the occasion of its breeding insects, and being wholly spoiled.

The flour of some places is constantly found to keep better at sea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of those places. Thus the French find that the flour of Poitou, Normandy, and Guienne, all bear the sea carriage extremely well; and they make a considerable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preserve it in the ships; the keeping it dry is the grand consideration in regard to this; the barrels in which it is put up ought to be made of dry and well seasoned oak, and not to be larger than to hold two hundred weight at the most. If the wood of the barrels have any sap remaining in it, it will moisten and spoil the flour; and no wood is so proper as oak for this purpose, or for making the bins and other vessels for keeping flour in at home, since when once well dried and seasoned it will not contract humidity afterwards. The beech wood, of which some make their bins for flour, is never thoroughly dry, but always retains some sap. The fir will give the flour a taste of turpentine; and the ash is always subject to be eaten by worms. The oak is preferable, because of its being free from these faults; and when the several kinds of wood have been examined in a proper manner, there may be others found as fit, or possibly more so, than this for the purpose. The great test is their having more or less sap. See FLOUR and WOOD.

Mean || Measure.

MEAN, in general, denotes the middle between two extremes: thus we say the mean distance, mean proportion, &c.

MEAN, Arithmetical, is half the sum of the two extremes, as 4 is the arithmetical mean between 2 and 6; for $\frac{2+6}{2}=4$.

MEAN, Geometrical, is the square root of the rectangle, or product of the two extremes: thus,

$$\sqrt{1\times 9}={}^{2}\sqrt{9}=3.$$

To find two mean proportionals between two extremes: multiply each extreme by the square of the other, then extract the cube root out of each product, and the two roots will be the mean proportionals required.

Required two proportionals between 2 and 16,

$\overline{2\times 2}\times 16=64$, and ${}^{3}\sqrt{64}=4$. Again, ${}^{3}\sqrt{2\times 16^{2}}={}^{3}\sqrt{512}=8$. 4 and 8 therefore are the two proportionals sought.

MEARNSSHIRE, a county of Scotland. See KINCARDINESHIRE.

MEASLES, a cutaneous disease attended with a fever, in which there is an appearance of eruptions that do not tend to a suppuration. See MEDICINE *Index*.

MEASURE *of an angle*, is an arch described from the vertex in any place between its legs. Hence angles are distinguished by the ratio of the arches, described from the vertex between the legs to the peripheries. Angles then are distinguished by those arches; and the arches are distinguished by their ratio to the periphery. Thus an angle is said to be so many degrees as there are in the said arch.

MEASURE of a solid, is a cube whose side is an inch, a foot, or a yard, or any other determinate length. In geometry it is a cubic perch, divided into cubic feet, digits, &c.

MEASURE of velocity, in *Mechanics*, is the space passed over by a moving body in a given time. To measure a velocity, therefore, the space must be divided into as many equal parts as the time is conceived to be divided into; the quantity of space answering to such a part of time is the measure of the velocity.

MEASURE, in *Geometry*, denotes any quantity assumed as one, or unity, to which the ratio of the other homogeneous or similar quantities is expressed.

MEASURE, in a legal and commercial sense, denotes a certain quantity or proportion of any thing bought, sold, valued, or the like.

It is necessary, for the convenience of commerce, that an uniformity should be observed in weights and measures, and regulated by proper standards. A foot-rule may be used as a standard for measures of length, a bushel for measures of capacity, and a pound for weights. There should be only one authentic standard of each kind, formed of the most durable materials, and kept with all possible care. A sufficient number of copies, exactly corresponding to the principal standard, may be distributed for adjusting the weights and measures that are made for common use. There are several standards of this kind both in England

Measure. England and Scotland. See the article *Weights and Measures*.

If any one of the standards above mentioned be justly preserved, it will serve as a foundation for the others, by which they may be corrected if inaccurate, or restored if entirely lost. For instance, if we have a standard foot, we can easily obtain an inch, and can make a box which shall contain a cubical inch, and may serve as a standard for measures of capacity. If it be known that a pint contains 100 cubical inches, we may make a vessel five inches square, and four inches deep, which will contain a pint. If the standard be required in any other form, we may fill this vessel with water, and regulate another to contain an equal quantity. Standards for weights may be obtained from the same foundation; for if we know how many inches of water it takes to weigh a pound, we have only to measure that quantity, and the weight which balances it may be assumed as the standard of a pound.

Again, If the standard of a pound be given, the measure of an inch may be obtained from it; for we may weigh a cubical inch of water, and pour it into a regular vessel; and having noticed how far it is filled, we may make another vessel of like capacity in the form of a cube. The side of this vessel may be assumed as the standard for an inch; and standards for a foot, a pint, or a bushel, may be obtained from it. Water is the most proper substance for regulating standards; for all other bodies differ in weight from others of the same kind; whereas it is found by experience that spring and river water, rain, and melted snow, and all other kinds, have the same weight; and this uniformly holds in all countries when the water is pure, alike warm, and free from salt and minerals.

Thus, any one standard is sufficient for restoring all the rest. It may further be desired to hit on some expedient, if possible, for restoring the standards, in case that all of them should ever fall into disorder, or should be forgotten, through the length of time, and the vicissitudes of human affairs. This seems difficult, as no words can convey a precise idea of a foot-rule, or a pound weight. Measures, assumed from the dimensions of the human body, as a foot, a hand-breadth, or a pace, must nearly be the same in all ages, unless the size of the human race undergo some change; and therefore, if we know how many square feet a Roman acre contained, we may form some judgment of the nature of the law which restricted the property of a Roman citizen to seven acres; and this is sufficient to render history intelligible; but it is too inaccurate to regulate measures for commercial purposes. The same may be said of standards, deduced from the measure of a barley-corn, or the weight of a grain of wheat. If the distance of two mountains be accurately measured and recorded, the nature of the measure used will be preserved in a more permanent manner than by any standard; for if ever that measure fall into disuse, and another be substituted in its place, the distance may be measured again, and the proportion of the standards may be ascertained by comparing the new and ancient distances.

But the most accurate and unchangeable manner of establishing standards is, by comparing them with the length of pendulums. The longer a pendulum is, it vibrates the slower; and it must have one precise length in order to vibrate in a second. The slightest difference in length will occasion a difference in the time; which will become abundantly sensible after a number of vibrations, and will be easily observed if the pendulum be applied to regulate the motion of a clock. The length of a pendulum which vibrates seconds in London is about $39\frac{1}{8}$ inches, is constantly the same at the same place, but it varies a little with the latitude of the place, being shorter as the latitude is less. Therefore, though all standards of weights and measures were lost, the length of a second pendulum might be found by repeated trials: and if the pendulum be properly divided, the just measure of an inch will be obtained; and from this all other standards may be restored. See *Whitehurst on Invariable Measures*.

Measures are various, according to the various kinds and dimensions of the things measured.—Hence arise lineal or longitudinal measures, for lines or lengths; square measures, for areas or superfices; and solid or cubic measures, for bodies and their capacities; all which again are very different in different countries and in different ages, and even many of them for different commodities. Whence arise other divisions of ancient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c.

I. *Long Measures, or Measures of Application.*

1.] The *English* and *Scotch* Standards.

The English lineal standard is the yard, containing 3 English feet; equal to 3 Paris feet 1 inch and $\frac{3}{10}$ of an inch, or $\frac{7}{9}$ of a Paris ell. The use of this measure was established by Henry I. of England, and the standard taken from the length of his own arm. It is divided into 36 inches, and each inch is supposed equal to 3 barleycorns. When used for measuring cloth, it is divided into four quarters, and each quarter subdivided into 4 nails. The English ell is equal to a yard and a quarter, or 45 inches, and is used in measuring linens imported from Germany and the Low Countries.

The Scots *elwand* was established by King David I. and divided into 37 inches. The standard is kept in the council chamber of Edinburgh, and being compared with the English yard, is found to measure $37\frac{1}{5}$ inches; and therefore the Scots inch and foot are larger than the English, in the proportion of 180 to 185; but this difference being so inconsiderable, is seldom attended to in practice. The Scots ell, though forbidden by law, is still used for measuring some coarse commodities, and is the foundation of the land measure of Scotland.

Itinerary measure is the same both in England and Scotland. The length of the chain is four poles, or 22 yards; 80 chains make a mile. The old Scots computed miles were generally about a mile and a half each.

The reel for yarn is $2\frac{1}{2}$ yards, or 10 quarters, in circuit; 120 threads make a cut, 12 cuts make a hasp or hank, and 4 hanks make a spindle.

2.] The *French* standard was formerly the aune or ell, containing 3 Paris feet 7 inches 8 lines, or 1 yard $\frac{2}{7}$ English; the Paris foot royal exceeding the English by $\frac{68}{1000}$ parts, as in one of the following tables. This ell

Measure.

ell is divided two ways; viz. into halves, thirds, sixths, and twelfths; and into quarters, half-quarters, and sixteenths.

The French, however, have also formed an entirely new system of weights and measures, according to the following table.

Proportions of the measures of each species to its principal measure or unity.	First part of the name which indicates the proportion to the principal measure or unity.	Length.	Capacity.	Weight.	Agrarian.	For firewood.
10,000 1,000 100 10 0 0.1 0.01 0.001	Myria Kilo Hecto Deca —— Deci Centi Milli	Metre.	Litre.	Gramme.	Are.	Stere.
Proportion of the principal measures between themselves and the length of the meridian.		10,000,000th part of the distance from the pole to the equator.	A decimetre cube.	Weight of a centimetre cube of distilled water.	100 square metres.	One cubic metre.
Value of the principal measures in the ancient French measures.		3 feet 11 lines and $\frac{1}{2}$ nearly	1 pint and $\frac{1}{20}$ or 1 litron and $\frac{1}{4}$ nearly.	18 grains and 841,000 parts.	Two square perches dex eaux et forêt.	1 demi-voie, or $\frac{1}{4}$ of a cord des eaux et forêt.
Value in English measures.		Inches 39.383.	61.083 inches, which is more than the wine, and less than the beer quart.	22,966 grains.	11.968 square yards.	

The English avoirdupois pound weighs troy grains 7004; whence the avoirdupois ounce, whereof 16 make a pound, is found equal to 437.75 troy grains.—And it follows that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636. that the troy ounce is to the avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 438. And, lastly, That the avoirdupois pound and ounce is to the Paris two marc weight and ounce, as 63 to 68 nearly; for as 63 to 68, so is 7004 to 7559.873. See WEIGHT. The Paris foot, expressed in decimals, is equal to 1.0654 of the English foot, or contains 12.785 English inches. See FOOT.

3.] The standard in *Holland*, *Flanders*, *Sweden*, a good part of *Germany*, many of what were formerly called the *Hans-towns*, as *Dantzick* and *Hamburgh*, and at *Geneva*, *Frankfort*, &c. is likewise the ell: but the ell in all these places differs from the Paris ell. In Holland it contains one Paris foot eleven lines, or four-sevenths of the Paris ell. The Flanders ell contains two feet one inch five lines and half a line; or seven-twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders.

4.] The *Italian* measure is the branchio, brace, or fathom. This obtains in the states of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At Venice, it contains one Paris foot eleven inches three lines, or eight-fifteenths of the Paris ell. At Bologna, Modena, and Mantua, the brace is the same as at Venice. At Lucca it contains one Paris foot nine inches ten lines, or half a Paris ell. At Florence, it contains one foot nine inches four lines, or forty-nine hundredths of a Paris ell. At Milan, the brace for measuring of silks is one Paris foot seven inches four lines, or four-ninths of a Paris ell: that for woollen cloths is the same with the ell of Holland. Lastly, at Bergama, the brace is one foot seven inches six lines, or five-ninths of a Paris ell. The usual measure at Naples, however, is the canna, containing six feet ten inches and two lines, or one Paris ell and fifteen-seventeenths.

5.] The *Spanish* measure is the vara or yard, in some places called the bara; containing seventeen twenty-fourths of the Paris ell. But the measure in Castile and Valencia is the pan, span, or palm; which is used, together with the canna, at Genoa. In Arragon, the vara is equal to a Paris ell and a half, or five feet five inches six lines.

6.] The *Portuguese* measure is the cavedos, containing two feet eleven lines, or four-sevenths of a Paris ell; and the vara, an hundred and six whereof make an hundred Paris ells.

7.] The *Piedmontese* measure is the ras, containing one

one Paris foot nine inches ten lines, or half a Paris ell. In Sicily, their measure is the canna, the same with that of Naples.

8.] The *Muscovy* measures are the cubit, equal to one Paris foot four inches two lines; and the arcin, two whereof are equal to three cubits.

9.] The *Turkish* and *Levant* measures are the picq, containing two feet two inches and two lines, or three-fifths of the Paris ell. The Chinese measure, the cobre; ten whereof are equal to three Paris ells. In Persia, and some parts of the Indies, the gueze, whereof there are two kinds; the royal gueze, called also the *gueze monkelser*, containing two Paris feet ten inches eleven lines, or four-fifths of the Paris ell; and the shorter gueze, called simply *gueze*, only two-thirds of the former. At Goa and Ormuz, the measure is the vara, the same with that of the Portuguese, having been introduced by them. In Pegu, and some other parts of the Indies, the cando or candi, equal to the ell of Venice. At Goa, and other parts, they use a larger cando, equal to seventeen Dutch ells; exceeding that of Babel and Balsora by $\frac{7}{8}$ per cent. and the vara by $6\frac{1}{2}$. In Siam, they use the ken, short of three Paris feet by one inch. The ken contains two soks, the sok two keubs, the keub twelve nious or inches, the niou to be equal to eight grains of rice, i. e. to about nine lines. At Camboia, they use the haster; in Japan, the tatam; and the span on some of the coasts of Guinea.

An Italian mile	$\frac{1}{1}\frac{1}{2}$	ditto
A Spanish league	$3\frac{2}{5}$	ditto
A Russian verst	¾	ditto

II. Square, Superficial, or *Land Measure.*

1. *English* square measures are raised from the yard of 36 inches multiplied into itself, and thus producing 1296 square inches in the square yard; the divisions of this are square feet and inches; and the multiples, poles, roods, and acres. Because the length of a pole is 5½ yards, the square of the same contains 30¼ square yards. A square mile contains 640 square acres. In measuring fens and woodlands, 18 feet are generally allowed to the pole, and 21 feet in forest lands.

A hide of land, frequently mentioned in the earlier part of the English history, contained about 100 arable acres; and 5 hides were esteemed a knight's fee. At the time of the Norman conquest, there were 243,600 hides in England.

2. *Scotch* square or land measure is regulated by the Scotch ell: 36 square ells = 1 fall, 40 falls = 1 rood, 4 roods = 1 acre.—The proportion between the Scotch and English acre, supposing the feet in both measures alike, is as 1369 to 1089, or nearly as 5 to 4. If the difference of the feet be regarded, the proportion is as 10,000 to 7869. The length of the chain for measuring land in Scotland is 23 ells, or 74 feet.—A husband-land contains 6 acres of sock and scythe land, that is, of land that may be tilled with a plough or mown with a scythe; 13 acres of arable land make one ox-gang, and four ox-gangs make a pound-land of old extent.

3. *French* square measures are regulated by 12 square lines in the inch square; 12 inches in the foot, 22 feet in the perch, and 100 perches in the arpent or acre.

Tables of Square Measure.

1. English.

Inches						
144	Feet					
1296	9	Yards				
3600	25	$2\frac{7}{9}$	Paces

Sextans	4800	48	0	16	132.43
Uncia	2400	24	0	8	66.21

Note, Actus major was 14,400 square feet, equal to a semis; clima, 3600 square feet, equal to sescuncia; and actus minimus equal to a sextans.

III. *Cubical Measures*, or Measures of Capacity, for Liquids.

1. The *English* measures were originally raised from troy weight: it being enacted by several statutes, that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine measure, the divisions and multiples whereof were to form the other measures; at the same time it was also ordered, that there should be but one liquid measure in the kingdom: yet custom has prevailed; and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter standard are raised two several measures, the one for ale, the other for beer. The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches; and on this supposition the other measures raised therefrom will contain as in the table underneath: yet, by actual experiment, made in 1688, before the lord mayor and the commissioners of excise, this gallon was found to contain only 224 cubic inches: it was, however, agreed to continue the common supposed contents of 231 cubic inches: so that all computations stand on their own footing. Hence, as 12 is to 231, so is $14\frac{12}{20}$ to $281\frac{1}{4}$ the cubic inches in the ale gallon: but in effect the ale quart contains $70\frac{1}{2}$ cubic inches, on which principle the ale and beer gallon will be 282 cubic inches. The several divisions and multiples of these measures, and their proportions, are exhibited in the tables underneath.

The barrel for ale in London is 32 gallons, and the barrel for beer 36 gallons. In all other places of England, the barrel, both for ale and beer, is 34 gallons.

2. *Scotch* liquid measure is founded on the pint. The Scotch pint was formerly regulated by a standard jug of cast metal, the custody of which was committed to the borough of Stirling. This jug was supposed to contain 105 cubic inches; and though, after several careful trials, it has been found to contain only about $103\frac{1}{2}$ inches; yet, in compliance with established custom, founded on that opinion, the pint *stoups* are still regulated to contain 105 inches, and the customary ale measures are about $\frac{1}{16}$ above that standard. It was enacted by James I. of Scotland, that the pint should contain 41 ounces trone weight of the clear water of Tay, and by James VI. that it should contain 55 Scots troy ounces of the clear water of Leith. This affords another method of regulating the pint, and also ascertains the ancient standard of the trone weight. As the water of Tay and Leith is alike, the trone weight must have been to the Scots troy weight as 55 to 41; and therefore the pound trone must have contained about $21\frac{1}{2}$ ounces Scots troy.

4 gills	=	1 mutchkin.
2 mutchkins	=	1 chopin.
2 chopins	=	1 pint.
2 pints	=	1 quart.
4 quarts	=	1 gallon.

The Scotch quart contains 210 inches; and is, therefore, about $\frac{1}{10}$ less than the English wine gallon, and about $\frac{1}{4}$ less than the ale gallon.

3. As to the liquid measures of foreign nations, it is to be observed, that their several vessels for wine, vinegar, &c. have also various denominations according to their different sizes and the places wherein they are used. The woeders of Germany, for holding Rhenish and Moselle wines, are different in their gauges; some containing 14 aumes of Amsterdam measure, and others more or less. The aume is reckoned at Amsterdam for 8 steckans, or 20 verges, or for $\frac{1}{6}$ of a tun of 2 pipes, or 4 barrels, of French or Bourdeaux, which $\frac{1}{6}$ at this latter place is called *tierçon*, because

Measure. because 3 of them make a pipe or 2 barrels, and 6 the said tun. The steckan is 16 mingles, or 32 pints; and the verge is, in respect of the said Rhenish and Moselle, and some other sorts of wine, 6 mingles; but, in measuring brandy it consists of $6\frac{1}{6}$ mingles. The aume is divided into 4 anckers, and the ancker into 2 steckans, or 32 mingles. The ancker is taken sometimes for $\frac{1}{24}$ of a tun, or 4 barrels; on which footing the Bourdeaux barrel ought to contain at Amsterdam (when the cask is made according to the just gauge) $12\frac{1}{2}$ steckans, or 200 mingles, wine and lees; or 12 steckans, or 192 mingles, racked wine; so that the Bourdeaux tun of wine contains 50 steckans, or 800 mingles, wine and lees; and 48 steckans, or 768 mingles, of pure wine. The barrels or poinçons of Nantes and other places on the river Loire, contain only 12 steckans, Amsterdam measure. The wine tun of Rochelle, Cogniac, Charente, and the isle of Rhé, differs very little from the tun of Bourdeaux, and consequently from the barrels and pipes. A tun of wine of Chalosse, Bayonne, and the neighbouring places, is reckoned 60 steckans, and the barrel 15, Amsterdam measure.

The muid of Paris contains 150 quarts or 300 pints, wine and lees; or 280 pints clear wine; of which muids 3 make a tun, and the fractions are,

The muid	containing	36 setiers
The setier		4 quarts
The quart		2 pints
The pint		2 chopins
The chopin		2 demi-setiers
The demi-setier		2 poissons

The muid is also composed of pipes or poinçons, quarteaux, queves, and demiqueves; those poinçons of Paris and Orleans contain about 15 steckans Amsterdam measure, and ought to weigh with the cask 666lb. a little more or less. In Provence they reckon by milleroles, and the millerole of Toulon contains 66 Paris pints, or 100 pints of Amsterdam, nearly, and the Paris pint is nearly equal to the English wine quart (A).

The butts or pipes from Cadiz, Malaga, Alicant, Benecarlo, Saloe, and Mataro, and from the Canaries, from Lisbon, Oporto, and Fayal, are very different in their gauges, though in affreightments they are all reckoned two to the tun.

Vinegar is measured in the same manner as wine; but the measures for brandies are different: these spirits from France, Spain, Portugal, &c. are generally shipped in large casks called *pipes*, *butts* and *pieces*, according to the places from whence they are imported, &c. In France, brandy is shipped in casks called *pieces* at Bourdeaux, and *pipes* at Rochelle, Cogniac, the isle of Rhé, and other neighbouring places, which contain some more and some less, even from 60 to 90 Amsterdam verges or veertels, according to the capacity of the vessels, and the places they come from, which, being reduced into barrels, will stand as follows, viz.

At Rochelle, Cogniac, the isle of Rhé, and the country of Aunis,	27 Veertels	per barrel.
At Nantes, and several places of Bretagne and Anjou	29 Veertels	
At Bourdeaux, and different parts of Guienne	32 Verges	
At Amsterdam, and other cities of Holland	30 Veertels	
At Hamburgh and Lubeck	30 Verges	
At Embden	27 Verges	

In Provence and Languedoc, brandy is sold by the quintal, the casks included; and at Bruges in Flanders, the verges are called *sesters* of 16 stops each, and the spirits is sold at so much per stop.

Olive oil is also shipped in casks of various sizes, according to the custom of the places where it is embarked, and the conveniency of stowage. In England it is sold by the tun of 236 gallons; and at Amsterdam by the tun of 717 mingles, or 1434 pints. In Provence it is sold by milleroles of 66 Paris pints; from Spain and Portugal it is brought in pipes or butts, of different gauges; at the first place it is sold by roves, where 40 go to the butt; and at the latter place by almoudas, whereof 26 make a pipe. Train oil is sold in England by the tun, at Amsterdam by the barrel.

IV. *Measures*

Measure.

IV. *Measure of Capacity for things Dry.*

1.] *English* dry or corn measure. The standard for measuring corn, salt, coals, and other dry goods, in England, is the Winchester gallon, which contains $272\frac{1}{4}$ cubic inches. The bushel contains 8 gallons, or 2178 inches. A cylindrical vessel, $18\frac{1}{2}$ inches diameter, and 8 inches deep, is appointed to be used as a bushel in levying the malt tax. A vessel of these dimensions is rather less than the Winchester bushel of 8 gallons, for it contains only 2150 inches; though probably there was no difference intended. The denominations of dry measure commonly used, are given in the first of the subjoined tables. Four quarters corn make a chaldron, 5 quarters make a wey or load, and 10 quarters make a ton. In measuring sea coal, 5 pecks make a bushel, 9 bushels make a quarter or vatt, 4 quarters make a chaldron, and 21 chaldrons make a score.

40 feet hewn timber make a load.
50 feet unhewn timber make a load.
32 gallons make a herring barrel.
42 gallons make a salmon barrel.
1 cwt. gunpowder makes a barrel.
256 lbs. soap make a barrel.
10 dozen candles make a barrel.
12 barrels make a last.

2.] *Scotch* dry measure. There was formerly only one measure of capacity in Scotland; and some commodities were heaped, others *straiked*, or measured exactly to the capacity of the standard. The method of heaping was afterwards forbidden as unequal, and a larger measure appointed for such commodities as that custom had been extended to.

The wheat firlot, used also for rye, pease, beans, salt, and grass seeds, contains 21 pints 1 mutchkin, measured by the Stirling jug. The barley firlot, used also for oats, fruit, and potatoes, contains 31 pints. A different method of regulating the firlot was appointed from the dimensions of a cylindrical vessel. The diameter for both measures was fixed at $19\frac{1}{6}$ inches, the depth $7\frac{1}{7}$ inches for the wheat firlot, and $10\frac{1}{2}$ for the barley firlot. A standard construeted by these measures is rather less than when regulated by the pint; and as it is difficult to make vessels exactly cylindrical, the regulation by the pint has prevailed, and the other method gone into disuse.

If the Stirling jug contains $103\frac{1}{5}$ inches, the wheat firlot will contain 2109 inches; which is more than 2 per cent. larger than the legal malt bushel of England, and about 1 per cent. larger than the Winchester bushel: and the barley firlot will contain 3208 inches. The barley boll is nearly equal to six legal malt bushels.

In Stirlingshire, 17 pecks are reckoned to the boll: in Inverness-shire, 18 pecks: in Ayrshire the boll is the same as the English quarter. And the firlots, in many places, are larger than the Linlithgow standard.

3.] *French dry*, are, the litron, bushel, minot, mine, septier, muid, and tun. The litron is divided into two demilitrons, and four quarter litrons, and contains 36 cubic inches of Paris. By ordonnance, the litron is to be three inches and a half high, and three inches 10 lines broad. The litron for salt is larger, and is divided into two halves, four quarters, eight demi-quarters, and 16 mesurettes. The French bushel is different in different jurisdictions. At Paris it is divided into demibushels; each demibushel into two quarts; the quart into two half quarts; and the half quart into two litrons: so that the bushel contains 16 litrons. By ordonnance the Paris bushel is to be eight inches two lines and a half high, and ten inches broad, or in diameter within-side. The minot consists of three bushels, the mine of two minots or six bushels, the septier of two mines or 12 bushels, and the muid of 12 septiers or 144 bushels. The bushel of oats is estimated double that of any other grain: so that there go 24 bushels to make the septier, and 288 to make the muid. It is divided into four picotins, the picotin containing two quarts, or four litrons. The bushel for salt is divided into two half bushels, four quarters, eight half quarters, and 16 litrons: four bushels make a minot, 16 a septier, and 192 a muid. The bushel for wood is divided into halves, quarters, and half quarters. Eight bushels make the minot, 16 a mine; 20 mines or 320 bushels, the muid. For plaster, 12 bushels make a sack, and 36 sacks a muid. For lime, three bushels make a minot, and 48 minots a muid. The minot is by ordonnance to be 11 inches 9 lines high, and 14 inches 8 lines in diameter. The minot is composed of three bushels, or 16 litrons: four minots make a septier, and 48 a muid. The French mine is no real vessel, but an estimation of several others. At Paris the mine contains six bushels, and 24 make the muid; at Rouen the mine is four bushels; and at Dieppe 18 mines make a Paris muid. The septier differs in different places: at Paris it contains two mines, or eight bushels, and 12 septiers the muid. At Rouen the septier contains two mines or 12 bushels. Twelve septiers make a muid at Rouen as well as at Paris; but 12 of the latter are equal to 14 of the former. At Toulon the septier contains a mine and a half; three of which mines make the septier of Paris. The muid or muy of Paris consists of 12 septiers; and is divided into mines, minots, bushels, &c. That for oats is double that for other grain, i. e. contains twice the number of bushels. At Orleans the muid is divided into mines, but those mines only contain two Paris septiers and a half. In some places they use the tun in lieu of the muid; particularly at Nantes, where it contains 10 septiers of 16 bushels each, and weighs between 2200 and 2250 pounds. Three of these tuns make 28 Paris septiers. At Rochelle, &c. the tun contains 42 bushels, and weighs two per cent. less than that of Nantes. At Brest it contains 20 bushels, is equal to 10 Paris septiers, and weighs about 2240 pounds. See TUN.

4.] *Dutch, Swedish, Polish, Prussian*, and *Muscovite*. In these places, they estimate their dry things on the foot of the *last, lest, leth*, or *lecht*; so called according to the various pronunciations of the people who use it. In Holland, the last is equal to 19 Paris septiers, or 38 Bourdeaux bushels, and weighs about 4560 pounds; the last they divide into 27 mudes, and the mude into four scheples. In Poland, the last is 40 Bourdeaux bushels, and weighs about 4800 Paris pounds. In Prussia, the last is 133 Paris septiers. In Sweden and Muscovy they measure by the great and little last; the first containing 12 barrels, and the second half as many. See LAST.

LAST. In Muscovy, they likewise use the chefford, which is different in various places: that of Archangel is equal to three Rouen bushels.

5.] *Italian.* At Venice, Leghorn, and Lucca, they estimate their dry things on the foot of the staro or staio; the staro of Leghorn weighs 54 pounds: 112 staros and seven-eighths are equal to the Amsterdam last. At Lucca, 119 staros make the last of Amsterdam. The Venetian staro weighs 128 Paris pounds: the staro is divided into four quarters. Thirty-five staros and one-fifth, or 140 quarters and four-fifths, make the last of Amsterdam. At Naples and other parts, they use the tomolo or tomalo, equal to one-third of the Paris septier. Thirty-six tomoli and a half make the carro, and a carro and a half, or 54 tomoli, make the last of Amsterdam. At Palermo, 16 tomoli make the salma, and four mondili the tomolo. Ten salmas and three-sevenths, or 171 tomoli and three-sevenths, make the last of Amsterdam.

6.] *Flemish.* At Antwerp, &c. they measure by the viertel; 32 and one-half whereof make 19 Paris septiers. At Hamburgh, the schepel; 90 whereof make 19 Paris septiers.

7.] *Spanish* and *Portuguese.* At Cadiz, Bilboa, and St Sebastian, they use the fanega; 23 whereof make the Nantes or Rochelle tun, or 9 Paris septiers and a half: though the Bilboa fanega is somewhat larger, insomuch that 21 fanegas make a Nantes tun. At Seville, &c. they use the anagoras, containing a little more than the Paris mine; 36 anagoras make 19 Paris septiers. At Bayonne, &c. the concha; 30 whereof are equal to nine Paris septiers and a half. At Lisbon, the alquiver, a very small measure, 240 whereof make 19 Paris septiers, 60 the Lisbon muid.

MEASURE of Wood for Firing, is usually the cord four feet high, and as many broad, and eight long; this is divided into two half cords, called *ways*, and by the French *membrures*, from the pieces stuck upright to bound them; or *voyes*, as being supposed half a waggon load.

MEASURE for Horses, is the hand, which by statute contains four inches.

MEASURE, among *Botanists.* In describing the parts of plants, Tournefort introduced a geometrical scale, which many of his followers have retained. They measured every part of the plant; and the essence of the description consisted in an accurate mensuration of the whole.

As the parts of plants, however, are liable to variation in no circumstance so much as that of dimension, Linnæus very rarely admits any other mensuration than that arising from the respective length and breadth of the parts compared together. In cases that require actual mensuration, the same author recommends, in lieu of Tournefort's artificial scale, the following natural scale of the human body, which he thinks is much more convenient, and equally accurate.

The scale in question consists of 11 degrees, which are as follow: 1. A hair'sbreadth, or the diameter of a hair, (*capillus*). 2. A line, (*linea*), the breadth of the crescent or white appearance at the root of the finger (not. thumb, measured from the skin towards the body of the nail; a line is equal to 12 hairbreadths, and is the 12th part of a Parisian inch. 3. A nail (*unguis*), the length of a finger nail; equal to six lines, or half a Parisian inch. 4. A thumb (*pollex*), the length of the first or outermost joint of the thumb; equal to a Parisian inch. 5. A palm (*palmus*), the breadth of the palm exclusive of the thumb; equal to three Parisian inches. 6. A span (*spithama*), the distance between the extremity of the thumb and that of the first finger when extended; equal to seven Parisian inches. 7. A great span (*dodrans*), the distance between the extremity of the thumb and that of the little finger, when extended; equal to nine inches. 8. A foot (*pes*), measuring from the elbow to the basis of the thumb; equal to 12 Parisian inches. 9. A cubit (*cubitus*), from the elbow to the extremity of the middle finger; equal to 17 inches. 10. An arm length (*brachium*), from the armpit to the extremity of the middle finger; equal to 24 Parisian inches, or two feet. 11. A fathom (*orgya*), the measure of the human stature; the distance between the extremities of the two middle fingers, when the arms are extended; equal, where greatest, to six feet.

MEASURE is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable.

The different measures or metres in poetry, are the different

Measure. different manners of ordering and combining the quantities, or the long and short syllables. Thus, hexameter, pentameter, iambic, sapphic verses, &c. consist of different measures.

In English verses, the measures are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleases. The most usual are the heroic, generally consisting of five long and five short syllables; and verses of four feet; and of three feet and a cæsura, or single syllable.

The ancients, by variously combining and transposing their quantities, made a vast variety of different measures. Of words, or rather feet of two syllables, they formed a spondee, consisting of two long syllables; a pyrrhic, of two short syllables; a trochee, of a long and a short syllable; and an iambic, of a short and a long syllable.

Of their feet of three syllables they formed a molossus, consisting of three long syllables; a tribrach, of three short syllables; a dactyl, of one long and two short syllables; and an anapæst, of two short and one long syllable. The Greek poets contrived 124 different combinations or measures, under as many different names, from feet of two syllables to those of six.

Measure, in *Music*, the interval or space of time which the person who beats time takes between the rising and falling of his hand or foot, in order to conduct the movement, sometimes quicker, and sometimes slower, according to the kind of music, or the subject that is sung or played.

The measure is that which regulates the time we are to dwell on each note. See Time.

The ordinary or common measure is one second, or 60th part of a minute, which is nearly the space between the beats of the pulse or heart; the systole, or contraction of the heart, answering to the elevation of the hand; and its diastole, or dilatation, to the letting it fall. The measure usually takes up the space that a pendulum of two feet and a half long employs in making a swing or vibration. The measure is regulated according to the different quality or value of the notes in the piece; by which the time that each note is to take up is expressed. The semibreve, for instance, holds one rise and one fall; and this is called the *measure* or *whole measure*, sometimes the *measure note*, or *time note*; the minim, one rise, or one fall; and the crotchet, half a rise, or half a fall, there being four crotchets in a full measure.

Measure Binary, or *Double*, is that wherein the rise and fall of the hand are equal.

Measure Ternary, or *Triple*, is that wherein the fall is double to the rise; or where two minims are played during a fall, and but one in the rise. To this purpose, the number 3 is placed at the beginning of the lines, when the measure is intended to be triple; and a C, when the measure is to be common or double. This rising and falling of the hands was called by the Greeks αρσις and θεσις. St Augustine calls it *plausus*, and the Spaniards *compas*. See Arsis and Thesis.

Powder Measures in Artillery, are made of copper, and contain from an ounce to 12 pounds: these are very convenient in a siege, when guns or mortars are loaded with loose powder, especially in ricochet firing, &c.

Measure || Meat.

MEASURING, or Mensuration, is the using a certain known measure, and determining thereby the precise extent, quantity, or capacity of any thing.

Measuring, in general, includes the practical part of geometry. From the various subjects on which it is employed, it acquires various names, and constitutes various arts. See Geometry, Levelling, Mensuration, Trigonometry, &c.

MEAT. See Food, Diet, Drink, &c.

Amongst the Jews, several kinds of animals were forbidden to be used as food. The flesh with the blood, and the blood without the flesh, were prohibited; the fat also of sacrificed animals was not to be eaten. Roast meat, boiled meat, and ragouts, were in use among the Hebrews, but we meet with no kind of seasoning except salt, bitter herbs, and honey.—They never mingled milk in any ragout or hash, and never ate at the same meal both meat and milk, butter, or cheese. The daily provision for Solomon's table was 30 measures of fine wheat flour, 60 of common flour, 10 fat oxen, 20 pasture oxen, 100 sheep, besides venison and wildfowl. See Luxury.

The principal and most necessary food among the ancient Greeks, was bread, which they called αρτος, and produced in a wicker basket called κανεον. Their loaves were sometimes baked under the ashes, and sometimes in an oven. They also used a sort of bread called *maza*. Barley meal was used amongst the Greeks, which they called αλφιτον. They had a frequent dish called θριον, which was a composition of rice, cheese, eggs, and honey, wrapped in fig leaves. The μυττωτον was made of cheese, garlic, and eggs, beaten and mixed together. Their bread, and other substitutes for bread, were baked in the form of hollow plates, into which they poured a sauce. Garlic, onions, and figs, seem to have been a very common food amongst the poorer Athenians. The Greeks, especially in the heroical times, ate flesh roasted; boiled meat seldom was used. Fish seems not to have been used for food in the early ages of Greece. The young people only, amongst the Lacedæmonians, ate animal food; the men and the old men were supported by a black soup called μεγα ζωμος, which to people of other nations was always a disagreeable mess. Grasshoppers and the extremities or tender shoots of trees were frequently eaten by the poor among the Greeks. Eels dressed with beet root were esteemed a delicate dish, and they were fond of the jowl and belly of saltfish. Neither were they without their sweet-meats; the dessert consisted frequently of fruits, almonds, nuts, figs, peaches, &c. In every kind of food we find salt to have been used.

The diet of the first Romans consisted wholly of milk, herbs, and roots, which they cultivated and dressed with their own hands; they also had a kind of gruel, or coarse gross pap, composed of meal and boiling water; this served for bread: And when they began to use bread, they had none for a great while but of unmixed rye. Barley-meal was eaten by them, which they called *polenta*. When they began to eat animal food, it was esteemed a piece of luxury, and an indulgence not to be justified but by some particu-

 lar

Meat, Meath.

lar occasion. After animal food had grown into common use, the meat which they most frequently produced upon their tables was pork.

*Method of Preserving Flesh-*MEAT *without spices, and with very little salt.* Jones, in his *Miscellanea Curiosa*, gives us the following description of the Moorish *Elcholle*, which is made of beef, mutton, or camel's flesh, but chiefly beef, which is cut in long slices, and laid for 24 hours in a pickle. They then remove it out of those jars or tubs into others with water; and when it has lain a night, they take it out, and put it on ropes in the sun and air to dry. When it is thoroughly dried and hard, they cut it into pieces of two or three inches long, and throw it into a pan or caldron, which is ready with boiling oil and suet sufficient to hold it, where it boils till it be very clear and red when cut. After this they take it out, and set it to drain; and when all is thus done it stands to cool, and jars are prepared to put it up in, pouring upon it the liquor in which it was fried; and as soon as it is thoroughly cold, they stop it up close. It will keep two years; will be hard, and the hardest they look upon to be the best done. This they dish up cold, sometimes fried with eggs and garlic, sometimes stewed, and lemon squeezed on it. It is very good any way, either hot or cold.

MEATH, commonly so called, or otherwise *East* Meath, to distinguish it from the county called *West* Meath: A county of Ireland, in the province of Leinster, bounded by the counties of Cavan and Louth on the north, the Irish channel on the east, Kildare and Dublin on the south, and West Meath and Longford on the west. It is a fine champaign country, abounding with corn, and well inhabited. It returns two members to parliament; and gives title of earl to the family of Brabazan. It contains 326,480 Irish plantation acres, 139 parishes, and 112,000 inhabitants. The chief town is Trim. This district being the most ancient settlement of the Belgians in Ireland, the inhabitants were esteemed the eldest and most honourable tribe: from which seniority their chieftains were elected monarchs of all the Belgæ; a dignity that was continued in the Hy-n-Faillian without intermission, until the arrival of the Caledonian colonies, under the name of Tuath de Danan, when Conor-Mor, chieftain of these people, obtained, or rather usurped, the monarchal throne, obliged Eochy Failloch, with several of his people, to cross the Shannon, and establish themselves in the present county of Roscommon, where Crothar founded the palace of Atha or Croghan, a circumstance which brought on a long and bloody war between the Belgian and Caledonian races, which was not finally terminated until the close of the 4th century, when the Belgian line was restored in the person of O'Nial the Great, and continued until Briam Boromh usurped the monarchical dignity, by deposing Malachy O'Malachlin, about the year 1001. Tuathal Tetethomar, by a decree of the Tarah assembly, separated certain large tracts of land from each of the four provinces, where the borders joined together; whence, under the notion of adopting this spot for demesne lands to support the royal household, he formed the county or kingdom of Meath, which afterwards became the peculiar inheritance of the monarchs of Ireland. In each of the portions thus separated from the four provinces, Tuathal caused palaces to be erected, which might adorn them, and commemorate the name in which they had been added to the royal domain. In the tract taken out of Munster, he built the palace called Flachtaga, where the sacred fire, so called, was kindled, and where all the priests and druids annually met on the last day of October; on the evening of which day it was enacted, that no other fire should be used throughout the kingdom, in order that all the fires might be derived from this, which being lighted up as a fire of sacrifice, their superstition led them to believe would render all the rest propitious and holy; and for this privilege every family was to pay threepence, by way of acknowledgment to the king of Munster. The second royal palace was erected in the proportion taken out of Connaught, and was built for the assembly called the convocation of Visneach, at which all the inhabitants were summoned to appear on the 1st day of May, to offer sacrifice to *Beal*, or *Bel*, the god of fire, in whose honour two large fires being kindled, the natives used to drive their cattle between them, which was supposed to be a preservative for them against accidents and distempers, and this was called *Beal-Tinne*, or *Bel-Tine*, or the festival of the god of fire. The king of Connaught at this meeting claimed a horse and arms from every lord of a manor or chieftain, as an acknowledgment for the lands taken from that province, to add to the territory of Meath. The third was that which Tailtean erected in the part taken from Ulster, where the fair of that name was held, which was remarkable for this particular circumstance, that the inhabitants brought their children thither, males and females, and contracted them in marriage, where the parents having agreed upon articles, the young people were joined accordingly; every couple contracted at this meeting paid the king of Ulster an ounce of silver by way of acknowledgment. The royal mansion of Tarah, formerly destroyed by fire, being rebuilt by Tuathal, on the lands originally belonging to the king of Leinster, was reckoned as the fourth of these palaces; but as a fabric of that name had stood there before, we do not find that any acknowledgment was made for it to the king of Leinster.

Meath, with *Clonmacnois*, is a bishop's see, valued in the king's books at 373l. 7s. 0½d. sterling, by an extent returned anno 28th Elizabeth; but, by a former extent taken anno 30th Henry VIII. the valuation amounts to 373l. 12s. which being the largest and most profitable for the king, is the measure of the first fruits at this day. This see is reputed to be worth annually 3400l. There were formerly many episcopal sees in Meath, as Clonard, Duleck, Kells, Trim, Ardbraccan, Donshaghlin, Slaine, and Foure, besides others of less note; all these, except Dulcek and Kells, were consolidated, and their common see was fixed at Clonard, before the year 1152; at which time the divisions of the bishoprics in Ireland were made by John Paparo, cardinal priest, entitled Cardinal of St Lawrence in Damaso, then legate from Pope Eugene III. to the Irish. This division was made in a synod held on the 6th of March in the abbey of Mellifont, or, as some say, at Kells: and the two sees of Duleck and Kells afterwards submitted to the same fate. The constitution of this diocese is singular, having

Meath || Mecænas.

ing no dean nor chapter, cathedral, or œconomy.—Under the bishop, the archdeacon is the head officer, to whom, and to the clergy in general, the *conge d'elire* issued while bishops were elective. The affairs of the diocese are transacted by a synod, in the nature of a chapter, who have a common seal, which is annually lodged in the hands of one of the body, by the appointment and vote of the majority. The diocese is divided into twelve rural deaneries.

Of Clonmacnois, now annexed to Meath: There is no valuation of this see in the king's books; but it is supposed to be included in the extent of the see of Meath, taken anno 30th Henry VIII. The chapter of this see consisted anciently of dean, chanter, chancellor, treasurer, archdeacon, and twelve prebendaries, but most of their possessions have fallen into lay hands. At present the deanery is the only part of the chapter which subsists, to which the prebend of Cloghran is annexed, and he hath a seal of office, which appears to have been the ancient episcopal seal of this see. This see was founded by St Kiaran, or Ciaran, the younger, in 548 or 549; and Dermod, the son of Ceronill, king of Ireland, granted the site on which the church was built.

West Meath. See Westmeith.

MEATUS auditorius. See Anatomy, N° 144.

MEAUX, an ancient town of France, in the department of the Seine and Marne, with a bishop's see, seated in a place abounding in corn and cattle, on the river Marne, which divides it into two parts; and its trade consists in corn, wool, and cheese. It sustained a siege of three months against the English in 1421. E. Long. 2. 58. N. Lat. 48. 58.

MECÆNAS, or Mecoenas, C. Cilnius, a celebrated Roman knight, descended from the kings of Etruria. He has rendered himself immortal by his liberal patronage of learned men and of letters; and to his prudence and advice Augustus acknowledged himself indebted for the security he enjoyed. His fondness for pleasure removed him from the reach of ambition; and he preferred dying, as he was born, a Roman knight, to all the honours and dignities which either the friendship of Augustus or his own popularity could heap upon him. To the interference of Mecænas, Virgil owed the retribution of his lands; and Horace was proud to boast that his learned friend had obtained his forgiveness from the emperor, for joining the cause of Brutus at the battle of Philippi. Mecænas was himself fond of literature: and, according to the most received opinion, he wrote a history of animals, a journal of the life of Augustus, a treatise on the different natures and kinds of precious stones, besides the two tragedies of Octavia and Prometheus, and other things, all now lost. He died eight years before Christ; and on his deathbed he particularly recommended his poetical friend Horace to the care and confidence of Augustus. Seneca, who has liberally commended the genius and abilities of Mecænas, has not withheld his censure from his dissipation, indolence, and effeminate luxury. From the patronage and encouragement which the princes of heroic and lyric poetry among the Latins received from the favourite of Augustus, all patrons of literature have ever since been called *Mecænates*. Virgil dedicated to him his Georgics, and Horace his Odes.

Mecca.

MECCA, an ancient and very famous town of Asia, in Arabia Felix; seated on a barren spot, in a valley surrounded with little hills, about a day's journey from the Red sea. It is a place of no strength, having neither walls nor gates; and the buildings are very mean. That which supports it is the resort of a great many thousand pilgrims annually, for the shops are scarcely open all the year besides. The inhabitants are poor, very thin, lean, and swarthy. The hills about the town are very numerous; and consist of a blackish rock, some of them half a mile in circumference. On the top of one of them is a cave, where they pretend Mahomet usually retired to perform his devotions, and hither they affirm the greatest part of the Alcoran was brought him by the angel Gabriel. The town has plenty of water, and yet little garden-stuff; but there are several sorts of good fruits to be had, such as grapes, melons, water melons, and cucumbers. There are also plenty of sheep brought thither to be sold to the pilgrims. It stands in a very hot climate; and the inhabitants usually sleep on the tops of their houses for the sake of coolness. In order to protect themselves from the heat through the day, they carefully shut the windows, and water the streets to refresh the air. There have been instances of persons suffocated in the middle of the town by the burning wind called *Simoom*.

As a great number of the people of distinction in the province of Hedsjas stay in the city, it is better built than any other in Arabia. Amongst the beautiful edifices it contains, the most remarkable is the famous *Kaba* or *Caaba*, "The house of God," which was held in great veneration by the Arabs even before Mahomet's time,

No Christian dares go to Mecca; not that the approach to it is prohibited by any express law, or that the sensible part of the Mahometans have any thi g to object to it; but on account of the prejudices of the people, who regarding this ground as sacred, th nk Christians unworthy of setting their foot on it; it would be profaned in the opinion of the superstious, if it was trod upon by infidels. The people even believe, that Christians are prevented from approaching by some supernatural power; and they tell the story of an infidel, who having got so far as the hills that surround Mecca, all the dogs of the city came out and fell upon him; and who, being struck with this miracle, and the august appearance of the Kaba, immediately became a mussulman. It is therefore to be presumed that all the Europeans who describe Mecca as eye-witnesses, have been renegadoes escaped from Turkey. A recent example confirms this supposition. On the promise of being allowed to preserve his religion, a French surgeon was prevailed on to accompany the Emir Hadsji to Mecca, in quality of physician; but at the very first station, he was forced to submit to circumcision, and then he was permitted to continue his journey.

Although the Mahometans do not allow Europeans to go to Mecca, they do not refuse to give them descriptions of the Kaba, and information with regard to that building; and there are persons who gain their bread by making designs and little pictures of the Kaba, and selling them to pilgrims. See Caaba.

The Mahometans have so high an opinion of the sanctity

Mecca.

sanctity of Mecca, that they extend it to the places in the neighbourhood. The territory of that city is held sacred to certain distances, which are indicated by particular marks. Every caravan finds in its road a similar mark, which gives notice to the pilgrims when they are to put on the modest garb in which they must appear in those sacred regions. Every mussulman is obliged to go once in his life at least to Mecca, to perform his devotions there. If that law was rigourously enforced, the concourse of pilgrims would be prodigious, and the city would never be able to contain the multitudes from all the countries where the Mahometan religion prevails. We must therefore, suppose, that devotees alone perform this duty, and that the others can easily dispense with it. Those whose circumstances do not permit a long absence, have the liberty of going to Mecca by a substitute.—A hired pilgrim, however, cannot go for more than one person at a time; and he must, to prevent frauds, bring an attestation in proper form, from an imam of Mecca, that he has performed the requisite devotions on behalf of such a person, either alive or dead; for, after the decease of a person who has not obeyed the law during his life, he is still obliged to perform the journey by proxy.

The caravans, which are not numerous, when we consider the immense multitude of the faithful, are composed of many people who do not make the journey for purposes of devotion. These are merchants, who think they can transport their merchandises with more safety, and dispose of them more easily; and contractors of every kind, who furnish the pilgrims and the soldiers who escort the caravans, with necessaries. Thus it happens, that many people have gone often to Mecca, solely from views of interest. The most considerable of those caravans is that of Syria, commanded by the pacha of Damascus. It joins at some distance the second from Egypt, which is conducted by a bey, who takes the title of Emir Hadsji. One comes from Yemen, and another, less numerous, from the country of Lachsa. Some scattered pilgrims arrive by the Red sea from the Indies, and from the Arabian establishments on the coasts of Africa. The Persians come in that which departs from Bagdad; the place of conductor to this last is bestowed by the pacha, and is very lucrative, for he receives the ransoms of the heretical Persians.

It is of consequence to a pilgrim to arrive early at the holy places. Without having been present from the beginning at all the ceremonies, and without having performed every particular act of devotion, a man cannot acquire the title of Hadsji: this is an honour very much coveted by the Turks, for it confers real advantages, and makes those who attain it to be much respected. Its infrequency, however, in the Mahometan dominions, shows how much the observation of the law commanding pilgrimages is neglected. A similar custom prevails among the Oriental Christians, who are exceedingly emulous of the title of Hadsji, or Mokdasi, which is given to pilgrims of their communion. In order to acquire this title, it is not sufficient that the person has made the journey to Jerusalem; he must also have kept the passover in that city, and have assisted at all the ceremonies of the holy weeks.

After all the essential ceremonies are over, the pilgrims next morning move to a place where they say Abraham went to offer up his son Isaac, which is about two or three miles from Mecca: here they pitch their tents, and then throw seven small stones against a little square stone building. This, as they affirm, is performed in defiance of the devil. Every one then purchases a sheep, which is brought for that purpose, eating some of it themselves, and giving the rest to the poor people who attend upon that occasion. Indeed these are miserable objects, and such starved creatures, that they seem ready to devour each other. After all, one would imagine that this was a very sanctified place; and yet a renegado who went in pilgrimage thither, affirms there is as much debauchery practised here as in any part of the Turkish dominions. It is 25 miles from Jodda, the sea port town of Mecca, and 220 south-east of Medina. E. Long. 40. 55. N. Lat. 21. 45.

Mecca, Mechanical.

MECHANICAL, an epithet applied to whatever relates to mechanics: Thus we say, mechanical powers, causes, &c. See the articles Power, Cause, &c.

The mechanical philosophy is the same with what is otherwise called *corpuscular philosophy*, which explains the phenomena of nature, and the operations of corporeal things, on the principles of mechanics; viz. the motion, gravity, arrangement, disposition, greatness or smallness, of the parts which compose natural bodies. See Corpuscular.

This manner of reasoning is much used in medicine; and, according to Dr Quincy, is the result of a thorough acquaintance with the structure of animal bodies: for considering an animal body as a composition out of the same matter from which all other bodies are formed, and to have all those properties which concern a physician's regard, only by virtue of its peculiar construction; it naturally leads a person to consider the several parts, according to their figures, contexture, and use, either as wheels, pulleys, wedges, levers, screws, cords, canals, strainers, &c. For which purpose, continues he, it is frequently found helpful to design in diagrams, whatsoever of that kind is under consideration, as is customary in geometrical demonstrations.

For the application of this doctrine to the human body, see the article Medicine.

Mechanical, in mathematics, denotes a construction of some problem, by the assistance of instruments, as the duplicature of the cube and quadrature of the circle, in contradistinction to that which is done in an accurate and geometrical manner.

Mechanical Curve, is a curve, according to Descartes, which cannot be defined by any algebraic equation; and so stands contradistinguished from algebraic or geometrical curves.

Leibnitz and others call these mechanical curves *transcendental*, and dissent from Descartes, in excluding them out of geometry. Leibnitz found a new kind of transcendental equations, where these curves are defined: but they do not continue constantly the same in all points of the curve, as algebraic ones do. See the article Transcendental.

Mechanical Solution of a problem is either when the thing is done by repeated trials, or when lines used in

Mechanical. in the solution are not truly geometrical, or by organical construction.

Mechanical Powers, are certain simple machines, which are used for raising greater weights; or overcoming greater resistances, than could be effected by the natural strength without them. See MECHANICS.

MECHANICS.

Definition. 1. MECHANICS is the science which enquires into the laws of the equilibrium and motion of solid bodies; into the forces by which bodies, whether animate or inanimate, may be made to act upon one another; and into the means by which these may be increased so as to overcome such as are most powerful.—The term *mechanics* was originally applied to the doctrine of equilibrium. It has by some late writers been extended to the motion and equilibrium of all bodies, whether solid, fluid, or aëriform; and has been employed to comprehend the sciences of hydrodynamics and pneumatics.

HISTORY.

Progress of practical mechanics among the ancients. 2. As the science of mechanics is intimately connected with the arts of life, and particularly with those which exist even in the rudest ages of society, the construction of machines must have arrived at considerable perfection before the theory of equilibrium, or the simplest properties of the mechanical powers, had engaged the attention of philosophers. We accordingly find that the lever, the pulley, the crane, the capstan, and other simple machines, were employed by the ancient architects in elevating the materials of their buildings, long before the dawn of mechanical science; and the military engines of the Greeks and Romans, such as the catapultæ and balistæ, exhibit an extensive acquaintance with the construction of compound machinery. In the splendid remains of Egyptian architecture, which in every age have excited the admiration of the world, we perceive the most surprising marks of mechanical genius. The elevation of immense masses of stone to the tops of their stupendous fabrics, must have required an accumulation of mechanical power which is not in the possession of modern architects.

Aristotle the first who attended to the theory of mechanics. A. C. 320. 3. The earliest traces of any thing like the theory of mechanics are to be found in the writings of Aristotle. In some of his works we discover a few erroneous and obscure opinions, respecting the doctrine of motion, and the nature of equilibrium; and in his 28th mechanical question he has given some vague observations on the force of impulse, tending to point out the difference between impulse and pressure. He maintained that there cannot be two circular motions opposite to one another; that heavy bodies descended to the centre of the universe, and that the velocities of their descent were proportional to their weights.

Archimedes lays the foundation of theoretical mechanics. A. C. 250. 4. The notions of Aristotle, however, were so confused and erroneous, that the honour of laying the foundation of theoretical mechanics is exclusively due to the celebrated Archimedes, who, in addition to his inventions in geometry, discovered the general principles of hydrostatics. In his two books, *De Equiponderantibus*, he has demonstrated that when a balance with unequal arms, is in equilibrio, by means of two weights in its opposite scales, these weights must be reciprocally proportional to the arms of the balance. From this general principle, all the other properties of the lever, and of machines referable to the lever, might have been deduced as corollaries; but Archimedes did not follow the discovery through all its consequences. In demonstrating the leading property of the lever, he lays it down as an axiom, that if the two arms of the balance are equal, the two weights must also be equal when an equilibrium takes place; and then shows that if one of the arms be increased, and the equilibrium still continue, the weight appended to that arm must be proportionally diminished. This important discovery conducted the Syracusan philosopher to another equally useful in mechanics. Reflecting on the construction of his balance, which moved upon a fulcrum, he perceived that the two weights exerted the same pressure on the fulcrum as if they had both rested upon it. He then considered the sum of these two weights as combined with a third, and the sum of these three as combined with a fourth; and saw that in every such combination the fulcrum must support their united weight, and therefore that there is in every combination of bodies, and in every single body which may be conceived as made up of a number of lesser bodies, *a centre of pressure or gravity*. This discovery Archimedes applied to particular cases, and pointed out the method of finding the centre of gravity of plane surfaces, whether bounded by a parallelogram, a triangle, a trapezium, or a parabola. The theory of the inclined plane, the pulley, the axis in peritrochio, the screw, and the wedge, which was first published in the eighth book of Pappus's mathematical collections, is generally attributed to Archimedes. It appears also from Plutarch and other ancient authors, that a greater number of machines which have not reached our times was invented by this philosopher. The military engines which he employed in the siege of Syracuse against those of the Roman engineer Appius, are said to have displayed the greatest mechanical genius, and to have retarded the capture of his native city.

5. Among the various inventions which we have received from antiquity, that of water mills is entitled to the highest place, whether we consider the ingenuity which they display, or the useful purposes to which they are subservient. In the infancy of the Roman republic the corn was ground by hand-mills, consisting of two millstones, one of which was moveable, and the other at rest. The upper millstone was made to revolve either by the hand applied directly to a winch, or by means of a rope winding round a capstan. The precise time when the impulse or the weight of water was substituted in the place of animal labour, is not exactly known. From an epigram in the *Anthologia Græca*, there is reason to believe that water-mills were invented during the reign of Augustus; but it is strange that in the Invention of water-mills and wind-mills.

History.

the description given of them by Vitruvius, who lived under that emperor, they are not mentioned as of recent origin. The invention of wind-mills is of a later date. According to some authors, they were first used in France in the sixth century; while others maintain that they were brought to Europe in the time of the crusades, and that they had long been employed in the east, where the scarcity of water precluded the application of that agent to machinery.

Stevinus discovers the parallelogram of forces. Died in 1635.

6. The science of mechanics seems to have been stationary till the end of the 16th century. In 1577 a treatise on mechanics was published by Guidus Ubaldus, but it contained merely the discoveries of Archimedes. Simon Stevinus, however, a Dutch mathematician, contributed greatly to the progress of the science. He discovered the parallelogram of forces; and has demonstrated in his Statics, published in 1586, that if a body is urged by two forces in the direction of the sides of a parallelogram and proportional to these sides, the combined action of these two forces is equivalent to a third force acting in the direction of the diagonal of the parallelogram, and having its intensity proportional to that diagonal. This important discovery, which has been of such service in the different departments of physics, should have conferred upon its author a greater degree of celebrity than he has actually enjoyed. His name has scarcely been enrolled in the temple of fame, but justice may yet be done to the memory of such an ingenious man. He had likewise the merit of illustrating other parts of statics; and he appears to have been the first who, without the aid of the properties of the lever, discovered the laws of equilibrium in bodies placed on an inclined plane. His works were reprinted in the Dutch language in 1605. They were translated into Latin in 1608, and into French in 1634; and in these editions of his works his Statics were enlarged by an appendix, in which he treats of the rope machine, and on pulleys acting obliquely.

Lucas Valerius writes on the centre of gravity of solids. 1661.

7. The doctrine of the centre of gravity, which had been applied by Archimedes only to plane surfaces, was now extended by Lucas Valerius to solid bodies. In his work entitled *De Centro Gravitatis Solidorum Liber*, published at Bologna in 1661, he has discussed this subject with such ability, as to receive from Galileo the honourable appellation of the *Novus nostræ ætatis Archimedes*.

Discoveries of Galileo. Born 1564. Died 1642.

8. In the hands of Galileo the science of mechanics assumed a new form. In 1572 he wrote a small treatise on statics, which he reduced to this principle, that it requires an equal power to raise two different bodies to altitudes in the inverse ratio of their weights, or that the same power is requisite to raise 10 pounds to the height of 100 feet, and 20 pounds to the height of 50 feet. This fertile principle was not pursued by Galileo to its different consequences. It was left to Descartes to apply it to the determination of the equilibrium of machines, which he did in his explanation of machines and engines, without acknowledging his obligations to the Tuscan philosopher. In addition to this new principle, Galileo enriched mechanics with his theory of local motion. This great discovery has immortalized its author; and whether we consider its intrinsic value, or the change which it produced on the physical sciences, we are led to regard it as nearly of equal importance with the theory of universal gravitation, to which it paved the way. The first hints of this new theory were given in his Systema Cosmicum, *Dialogus* II. The subject was afterwards fully discussed in another, entitled *Discursus et Demonstrationes Mathematicæ circa duas novas Scientias pertinentes ad Mechanicam et Motum Localem*, and published in 1638. This work is divided into four dialogues; the first of which treats of the resistance of solid bodies before they are broken: The second points out the cause of the cohesion of solids. In the third he discusses his theory of local motions, comprehending those which are equable, and those which are uniformly accelerated. In the fourth he treats of violent motion, or the motion of projectiles; and in an appendix to the work he demonstrates several propositions relative to the centre of gravity of solid bodies. In the first of these dialogues he has founded his reasoning on principles which are far from being correct, but he has been more successful in the other three. In the third dialogue, which contains his celebrated theory, he discusses the doctrine of equable motions in six theorems, containing the different relations between the velocity of the moving body, the space which it describes, and the time employed in its description. In the second part of the dialogue, which treats of accelerated motion, he considers all bodies as heavy, and composed of a number of parts which are also heavy. Hence he concludes that the total weight of the body is proportional to the number of the material particles of which it is composed, and then reasons in the following manner. As the weight of a body is a power always the same in quantity, and as it constantly acts without interruption, the body must be continually receiving from it equal impulses in equal and successive instants of time. When the body is prevented from falling by being placed on a table, its weight is incessantly impelling it downwards, but these impulses are incessantly destroyed by the resistance of the table which prevents it from yielding to them. But where the body falls freely, the impulses which it perpetually receives are perpetually accumulating, and remain in the body unchanged in every respect excepting the diminution which they experience from the resistance of air. It therefore follows, that a body falling freely is uniformly accelerated, or receives equal increments of velocity in equal times. Having established this as a definition, he then demonstrates, that the time in which any space is described by a motion uniformly accelerated from rest, is equal to the time in which the same space would be described by an uniform equable motion with half the final velocity of the accelerated motion; and that in every motion uniformly accelerated from rest, the spaces described are in the duplicate ratio of the times of description. After having proved these theorems, he applies the doctrine with great success to the ascent and descent of bodies on inclined planes.

History. 1638.

Labours of Torricelli. 1644.

9. The theory of Galileo was embraced by his pupil Torricelli, who illustrated and extended it in his excellent work entitled *De motu gravium naturaliter accelerato*, published in 1664. In his treatise *De motu projectorum*, published in the Florentine edition of his works, in 1664, he has added several new and important propositions to those which were given by his master on the motion of projectiles.

Invention of the steam engine.

10. It was about this time that steam began to be employed

History.

employed as the first mover of machinery. This great discovery has been ascribed by the English to the marquis of Worcester, and to Papin by the French; but it is almost certain, that about 34 years before the date of the marquis's invention, and about 61 years before the construction of Papin's digester, steam was employed as the impelling power of a stamping engine by one Brancas an Italian, who published an account of his invention in 1629. It is extremely probable, however, that the marquis of Worcester had never seen the work of Brancas, and that the fire-engine which he mentions in his Century of Inventions was the result of his own ingenuity. The advantages of steam as an impelling power being thus known, the ingenious Captain Savary invented an engine which raised water by the expansion and condensation of steam. Several engines of this construction were actually erected in England and France, but they were incapable of raising water from depths which exceeded 35 feet. The steam-engine received great improvements from our countrymen Newcomen, Brighton, and Blakey; but it was brought to it present state of perfection by Mr Watt of Birmingham, one of the most accomplished engineers of the present age. Hitherto it had been employed merely as a hydraulic machine for draining mines or raising water, but in consequence of Mr Watt's improvements it has long been used as the impelling power of almost every species of machinery. It is a curious circumstance, that the steam-engine was not only invented, but has received all its improvements, in our own country.

Discoveries of Huygens. 1673.

11. The success of Galileo in investigating the doctrine of rectilineal motion, induced the illustrious Huygens to turn his attention to curvilineal motion. In his celebrated work *De Horologio Oscillatorio*, published in 1673, he has shown that the velocity of a heavy body descending along any curve, is the same at every instant in the direction of the tangent, as it would have been if it had fallen through a height equal to the corresponding vertical absciss; and from the application of this principle to the reversed cycloid with its axis vertical, he discovered the isochronism of the cycloid, or that a heavy body, from whatever part of the cycloid it begins to fall, always arrives at the lower point of the curve in the same space of time. By these discussions, Huygens was gradually led to his beautiful theory of central forces in the circle. This theory may be applied to the motion of a body in any curve, by considering all curves as composed of an infinite number of small arcs of circles of different radii, which Huygens had already done in his theory of evolutes. The theorems of Huygens concerning the centrifugal force and circular motions, were published without demonstrations.
1700. They were first demonstrated by Dr Keill at the end of his Introduction to Natural Philosophy. The demonstrations of Huygens, however, which were more prolix than those of the English philosopher, were afterwards given in his posthumous works.

The laws of collision discovered by Wallis, Huygens, and Wren. 1661.

12. About this time the true laws of collision or percussion were separately discovered by Wallis, Huygens, and Sir Christopher Wren in 1661, without having the least communication with each other. They were transmitted to the Royal Society of London in 1688, and appeared in the 43d and 46th numbers of their Transactions. The rules given by Wallis and Wren are published in N° 43, pp. 864 and 867, and those of Huygens in N° 46, p. 927. The foundation of all their solutions is, that in the mutual collision of bodies, the absolute quantity of motion of the centre of gravity is the same after impact as before it, and that when the bodies are elastic, the respective velocity is the same after as before the shock.—We are indebted likewise to Sir Christopher Wren for an ingenious method of demonstrating the laws of impulsion by experiment. He suspended the impinging bodies by threads of equal length, so that they might touch each other when at rest. When the two bodies were separated from one another, and then allowed to approach by their own gravity, they impinged against each other when they arrived at the positions which they had when at rest, and their velocities were proportional to the chords of the arches through which they had fallen. Their velocities after impact were also measured by the chords of the arches through which the stroke had forced them to ascend, and the results of the experiments coincided exactly with the deductions of theory. The laws of percussion were afterwards more fully investigated by Huygens, in his posthumous work *De Motu Corporum ex Percussione*, and by Wallis in his *Mechanica*, published in 1670.

Mechanical problems proposed by Mersennus. 1635.

13. The attention of philosophers was at this time directed to the two mechanical problems proposed by Mersennus in 1635. The first of these problems was to determine the centre of oscillation in a compound pendulum, and the second to find the centre of percussion of a single body, or a system of bodies turning round a fixed axis. The centre of oscillation is that point in a compound pendulum, or a system of bodies moving round a centre, in which, if a small body were placed and made to move round the same centre, it would perform its oscillations in the same time as the system of bodies. The centre of percussion, which is situated in the same point of the system as the centre of oscillation, is that point of a body revolving or vibrating about an axis, which being struck by an immoveable obstacle, the whole of its motion is destroyed.

Huygens solves the problem of the centre of oscillation.

These two problems were at first discussed by Descartes and Roberval, but the methods which they employed were far from being correct. The first solution of the problem on the centre of oscillation was given by Huygens. He assumed as a principle, that if several weights attached to a pendulum descended by the force of gravity, and if at any instant the bodies were detached from one another, and each ascended with the velocity it had acquired by its fall, they would rise to such a height that the centre of gravity of the system in that state would descend to the same height as that from which the centre of gravity of the pendulum had descended. The solution founded on this principle, which was not derived from the fundamental laws of mechanics, did not at first meet with the approbation of philosophers; but it was afterwards demonstrated in the clearest manner, and now forms the principle of the conservation of active forces.—The problem of the centre of percussion was not attended with such difficulties. Several incomplete solutions of it were given by different geometers; but it was at last resolved in an accurate and general manner by James Bernouilli by the principle of the lever.

Works of Borelli. 1666

14. In 1666, a treatise *De Vi Percussionis*, was published

History.

1686.

lished by J. Alphonso Borelli, and in 1686, another work, *De Motionibus Naturalibus à Gravitate Pendentibus*; but he added nothing to the science of mechanics. His ingenious work, *De Motu Animalium*, however, is entitled to great praise, for the beautiful application which it contains of the laws of statics to explain the various motions of living agents.

Labours of Varignon.

15. The application of statics to the equilibrium of machines, was first made by Varignon in his Project of a new System of Mechanics, published in 1687. The subject was afterwards completely discussed in his *Nouvelle Mecanique*, a posthumous work published in 1725. In this work are given the first notions of the celebrated principle of virtual velocities, from a letter of John Bernouilli's to Varignon in 1717. The virtual velocity of a body is the infinitely small space, through which the body excited to move has a tendency to describe in one instant of time. This principle has been successfully applied by Varignon to the equilibrium of all the simple machines. The resistance of solids, which was first treated by Galileo, was discussed more correctly by Leibnitz in the *Acta Eruditorum* for 1687. In the Memoirs of the Academy for 1702, Varignon has taken up the subject, and rendered the theory much more universal.

Parent on the maximum effect of machines.

16. An important step in the construction of machinery was about this time made by Parent. He remarked in general that if the parts of a machine are so arranged, that the velocity of the impelling power becomes greater or less according as the weight put in motion becomes greater or less, there is a certain proportion between the velocity of the impelling power, and that of the weight to be moved, which renders the effect of the machine a *maximum* or a *minimum* *. He then applies this principle to undershot wheels, and shows that a maximum effect will be produced when the velocity of the stream is equal to *thrice* the velocity of the wheel. In obtaining this conclusion, Parent supposed that the force of the current upon the wheel is in the duplicate ratio of the relative velocity, which is true only when a single floatboard is impelled by the water. But when more floatboards than one are acted upon at the same time, it is obvious that the momentum of the water is directly as the relative velocity; and by making this substitution in Parent's demonstration, it will be found that a maximum effect is produced when the velocity of the current is double that of the wheel. This result was first obtained by the Chevalier Borda, and has been amply confirmed by the experiments of Smeaton. (See HYDRODYNAMICS, § 279, 280, 281.) The principle of Parent was also applied by him to the construction of windmills. It had been generally supposed that the most efficacious angle of weather was 45°; but it was demonstrated by the French philosopher that a maximum effect is produced when the sails are inclined $54\frac{3}{7}$ degrees to the axis of rotation, or, when the angle of weather is $35\frac{1}{7}$ degrees. This conclusion, however, is subject to modifications which will be pointed out in a subsequent part of this article.

* *Mem. de l'Acad.* 1704.

De la Hire writes on the teeth of wheels.

17. The *Traite de Mecanique* of De la Hire, published separately in 1695, and in the 9th volume of the Memoirs of the French Academy from 1666 to 1699, contains the general properties of the mechanical powers, and the description of several ingenious and useful machines. But it is chiefly remarkable for the *Traite des Epicycloides*, which is added to the edition published in the Memoirs of the Academy. In his interesting treatise, De la Hire considers the genesis and properties of exterior and interior epicycloids, and demonstrates, that when one wheel is employed to drive another, the one will move sometimes with greater and sometimes with less force, and the other will move sometimes with greater and sometimes with less velocity, unless the teeth of one or both of the wheels be parts of a curve generated like an epicycloid. The same truth is applicable to the formation of the teeth of rackwork, the arms of levers, the wipers of stampers, and the lifting cogs of forge hammers; and as the epicycloidal teeth when properly formed roll upon one another without much friction, the motion of the machine will be uniform and pleasant, its communicating parts will be prevented from wearing, and there will be no unnecessary waste of the impelling power. Although De la Hire was the first who published this important discovery, yet the honour of it is certainly due to Olaus Roemer, the celebrated Danish astronomer, who discovered the successive propagation of light. It is expressly stated by Leibnitz *, in his letters to John Bernouilli, that Roemer communicated to him the discovery 20 years before the publication of De la Hire's work; but still we have no ground for believing that De la Hire was guilty of plagiarism. Roemer's researches were not published; and from the complete discussion which the subject has received from the French philosopher, it is not unlikely that he had the merit of being the second inventor. Even Camus †, who about 40 years afterwards gave a complete and accurate theory of the teeth of wheels, was unacquainted with the pretensions of Roemer, and ascribes the discovery to De la Hire.

Discoveries of Newton.

18. The publication of Newton's Principia contributed greatly to the progress of mechanics. His discoveries concerning the curvilineal motion of bodies, combined with the theory of universal gravitation, enabled philosophers to apply the science of mechanics to the phenomena of the heavens, to ascertain the law of the force by which the planets are held in their orbits, and to compute the various irregularities in the solar system, which arise from the mutual action of the bodies which compose it. The *Mecanique Celeste* of La Place will be a standing monument of the extension which mechanics has received from the theory of gravity. The important mechanical principle of the conservation of the motion of the centre of gravity is also due to Newton. He has demonstrated in his Principia, that the state of the centre of gravity of several bodies, whether in a state of rest or motion, is not affected by the reciprocal action of these bodies, whatever it may be, so that the centre of gravity of the bodies which act upon one another, either by the intervention of levers, or by the laws of attraction, will either remain at rest, or move uniformly in a right line.

Principle of the conservation of active forces first discovered by Huygens.

19. We have already seen that the principle of the conservation of active forces was discovered by Huygens when he solved the problem of the centre of oscillation. The principle alluded to consists in this, that in all the actions of bodies upon each other, whether that action consists in the percussion of elastic bodies, or is communicated from one body to another by threads or inflexible rods, the sums of the masses multiplied by the squares of the absolute velocities remain always the same. This

History.

This important law is easily deducible from two simpler laws admitted in mechanics. 1. That in the collision of elastic bodies, their respective velocities remain the same after impact as they were before it; and, 2. That the quantity of action, or the product of the masses of the impinging bodies, multiplied by the velocity of their centre of gravity, is the same after as before impact. The principle of the conservation of active forces, was regarded by its inventor only as a simple mechanical theorem. John Bernouilli, however, considered it as a general law of nature, and applied it to the solution of several problems which could not be resolved by direct methods; but his son Daniel deduced from it the laws of the motion of fluids from vessels, a subject which had been formerly treated in a very vague manner. He afterwards rendered the principle more general *, and showed how it could be applied to the motion of bodies influenced by their mutual attractions, or solicited towards fixed centres by forces proportional to any function of the distance.

Rendered general by Daniel Bernouilli.

* Mem. de l'Acad. Berlin, 1748.

Daniel Bernouilli and other philosophers demonstrate the parallelogram of forces.

20. After the parallelogram of forces had been introduced into statics by Stevinus, it was generally admitted upon the same demonstration which was given for the composition of motion. The first complete demonstration was given by Daniel Bernouilli in the Commentaries of Petersburgh for 1726, independent of the consideration of compound motion. This demonstration, which was both long and abstruse, was greatly simplified by D'Alembert in the Memoirs of the Academy for 1769. Fonseneix and Riccati have given a very ingenious one in the Memoirs of the Academy of Turin for 1761. This was also improved by D'Alembert, who gave another in the same Memoirs, and a third in his *Traité de Dynamique*, published in 1743. Dr Robison † has combined the demonstrations of Bernouilli and D'Alembert with one by Frisi, and produced one that is more expeditious and simple. La Place has likewise given a demonstration of the parallelogram of forces in his *Mecanique Celeste*.

† Sup. Encycl. § Dynamics.

Dispute about the measure of active forces.

21. About the beginning of the 18th century, the celebrated dispute about the measure of active forces was keenly agitated among philosophers. The first spark of this war, which for 40 years England maintained single-handed against all the genius of the continent, was excited by Leibnitz. In the Leipsic acts for 1686, he asserted that Descartes was mistaken in making the force of bodies proportional to their simple velocity, and maintained that it followed the ratio of the square of the velocity. He shewed, that a body, with a velocity of two feet, acquires the power of raising itself to a height four times as great as that to which a body could rise with a velocity of only one foot; and hence he concludes, that the force of that body is as the square of its velocity. The abbé de Cotilon, a zealous Cartesian, allowed the premises of Leibnitz, but denied his conclusion. The body, said he, which moves with a velocity of two feet, will certainly rise to quadruple the height of another body that has only the velocity of one foot; but it will take *twice the time* to rise to that height, and a quadruple effect, in a double time, is not a quadruple force, but only a double one. The theory of Leibnitz was supported by John Bernouilli, Herman, Gravesende, Muschenbroeck, Poleni, Wolff, and Bulfinger; and the opinion of Descartes by Maclaurin, Stirling, Clarke, Desaguliers, and other English philosophers. The question was at last involved in metaphysical reasoning; and if the dispute did terminate in favour of either party, the English philosophers were certainly victorious. It appears, in the clearest manner, that the force of a moving body, indicated by the space which it describes, is as the simple velocity, if we consider the space as described in a determinate time; but it is as the square of the velocity, if we do not consider the time in which the space is described. The question, therefore, comes to be this: In estimating the forces of bodies in motion, ought we to take time into consideration? If, with the followers of Leibnitz, we reject this element, then we may maintain that the force of a child is equal to that of a man carrying a load, because the child is also capable of carying the same load, though in small parts and in a greater length of time.

D'Alembert's principle of dynamics.

22. In 1743, D'Alembert published his *Traité de Dynamique*, founded upon a new principle in mechanics. This principle was first employed by James Bernouilli in his solution of the problem of the centre of oscillation; but D'Alembert had the honour of generalising it, and giving it all that simplicity and fertility of which it was susceptible. He showed, that in whatever manner the bodies of one system act upon another, their motions may always be decomposed into two others at every instant, those of the one being destroyed the instant following, and those of the other retained, and that the motions retained are necessarily known from the conditions of equilibrium between those which are destroyed. This principle is evidently a consequence of the laws of motion and equilibrium, and has the advantage of reducing all the problems of dynamics to pure geometry and the principles of statics. By means of it D'Alembert has resolved a number of beautiful problems which had escaped his predecessors, and particularly that of the precession of the equinoxes, which had occupied the attention of Newton. In his *Traité de Dynamique*, D'Alembert has likewise reduced the whole of mechanics to three principles, the force of inertia, compound motion, and equilibrium; and has illustrated his views on this subject by that profound and luminous reasoning which characterises all his writings.

Euler, Daniel Bernouilli, and d'Arcy, discover the conservation of the momentum of rotatory motion.

23. Another general principle in dynamics was about this time discovered separately by Euler, Daniel Bernouilli, and the chevalier D'Arcy, and received the name of *conservation of the momentum of rotatory motion*. According to the two first philosophers, the principle may be thus defined: In the motion of several bodies round a fixed centre, the sum of the products of the mass of each body multiplied by the velocity of its motion round the centre, and by its distance from that centre, is always independent of the mutual action which the bodies may exert upon each other, and always preserves itself the same, provided the bodies are not influenced by any external cause. This principle was given by Daniel Bernouilli in the Memoirs of the Academy of Berlin for 1746; and the same year by Euler in the first volume of his works. They were both led to the discovery, while investigating the motion of several bodies in a tube of a given form, and which can only turn round a fixed point. The principle discovered by the chevalier D'Arcy was given in a memoir dated 1746, and published in the Memoirs of the

1746.

History.

the Academy for 1747. He shewed, that the sum of the products of the mass of each body by the area which its radius vector describes round a fixed point, is always proportional to the times. The identity of this principle, which is a generalisation of Newton's theorem about the areas described by the planetary bodies, with that of Euler and Bernouilli, will be easily perceived, if we consider that the element of the circular arc, divided by the element of the time, expresses the velocity of circulation, and that the element of the circular arc, multiplied by the distance from the centre, gives the element of the area described round that centre; so that the principle of Euler is only a differential expression of the principle of D'Arcy, which he afterwards expressed in this form, that the sum of the products of the masses of each body by their velocities, and by the perpendiculars drawn from the centre to their lines of direction, is a constant quantity.

The principle of least action proposed by Maupertuis.

24. The principle of least action, which was first proposed by Maupertuis in 1744, consists in this, that when several bodies, acting upon one another, experience any change in their motion, this change is always such, that the quantity of action (or the product of the mass by the space and the velocity) employed by nature to produce it, is the least possible. From this principle Maupertuis deduced the laws of the reflection and refraction of light, and those of the collision of bodies*. He afterwards extended its application to the laws of motion, and made the principle so general as to comprehend the laws of equilibrium, the uniform motion of the centre of gravity in the percussion of bodies, and the conservation of active forces. This celebrated principle was attacked by Koenig, professor of mathematics at the Hague, in the Leipsic acts for 1751, who not only attempted to shew its falsity, but asserted that Leibnitz had first described it in 1707 in a letter to Herman. The paper of Koenig gave rise to a long and violent dispute about the accuracy of the principle, and the authenticity of the letter of Leibnitz. The academy of Berlin interfered in behalf of their president, and gave importance to a controversy which was too personal to merit the attention which it received.

* *Mem. Acad. Paris* 1744, and *Mem. Acad. Berlin* 1746.

Euler and Lagrange generalise the principle of Maupertuis.

25. In his *Traité des Isoperimetries*, printed at Lausanne in 1744, Euler extended the principle of least action, and shewed, "that in the trajectories described by means of central forces, the integral of the velocity, multiplied by the element of the curve, is either a *maximum* or a *minimum*." This remarkable property, which Euler recognised only in the case of insulated bodies, was generalised by Lagrange into this new principle, "that the sum of the products of the masses by the integrals of the velocities, multiplied by the elements of the spaces described, is always a maximum or a minimum." In the Memoirs of Turin, Lagrange has employed this principle to resolve several difficult problems in dynamics; and he has shewn†, that when it is combined with the conservation of active forces, and developed according to the rules of his method of variations, it furnishes directly all the equations necessary for the solution of each problem, and gives rise to a simple and general method of treating the various problems concerning the motion of bodies.

† *Mecanique Analytique*, p. 189, 1788.

Labours of Segner, 1765.

26. An important discovery in rotatory motion, was at this time made by Professor Segner. In a paper, entitled *Specimen Theoriæ Turbinum*, he demonstrated, that if a body of any form or magnitude, after it has received rotatory motions in all directions, be left entirely to itself, it will always have three principal axes of rotation; or, in other words, all the rotatory motions with which it is affected, may be reduced to three, which are performed round three axes, perpendicular to each, passing through the centre of gravity of the revolving body, and preserving the same position in absolute space, while the centre of gravity is either at rest or moving uniformly in a straight line.

Coulomb inquires into the force of torsion,

27. The force of torsion began at this time to be investigated by Coulomb, who published two ingenious papers on the subject, in the Memoirs of the French Academy. He has successfully employed this principle in several physical researches, but particularly in determining the law of magnetic action, and in finding the laws of the resistance of fluids when the motions are extremely slow*. It was by means of an elegant experiment on the principle of torsion that Mr Cavendish determined the mutual attraction of two masses of lead, and thence deduced the mean density of the earth.—We are also indebted to Coulomb for a complete set of experiments on the nature and effects of friction. By employing large bodies and ponderous weights, and conducting his experiments on a large scale, he has corrected errors which necessarily arose from the limited experiments of preceding writers; he has brought to light many new and interesting facts, and confirmed others which had hitherto been partially established. The most curious result of these experiments is the effect of time in increasing the friction between two surfaces. In some cases the friction reaches its maximum after the rubbing surfaces have remained in contact for one minute; and in other cases five or six days were necessary before this effect was produced. The increase of friction, which is generated by prolonging the time of contact, is so great, that a body, weighing 1650 pounds, was moved with a force of 64 pounds when first laid upon the corresponding surface. After remaining in contact for the space of three seconds, 100 pounds were necessary to put it in motion; and when the time was prolonged to six days, it could scarcely be moved with a power of 622 pounds†.

* *Memoirs de l Institut. Nat.* tom. iii. p. 246.

and into the subject of friction.

† *Memoires Presentees* tom. ix.

Works on mechanics.

28. One of the most important treatises on the science of motion is the Mechanics of the celebrated Euler, published in 1736. It contains the whole theory of rectilineal and curvilineal motion in an insulated body, affected by any accelerating forces, either in vacuo or in a resisting medium. He uniformly uses the analytical method, and has employed the principle of the *vis inertiæ*, and that of compound motion, for putting his problems into equations. By the *vis inertiæ*, motion is at every moment of time rectilineal and uniform; and by the principle of compound motion, a body, exposed to the action of any number of forces, tending to alter the quantity and the direction of its motion, will move in such a direction as to reach the very point at which it would have arrived, had it obeyed successively each of the forces which act upon it.—In the *Mecanique Analytique* of Lagrange, published in 1788, all the mechanical problems are reduced to general formulæ, which, being developed, furnish us with the equations that are necessary for the solution of each problem; and the different principles which

Euler's mechanics.

Lagrange's Mecanique Analytique.

Theory. which have been discovered for facilitating the solutions of mechanical questions, are brought under one point of view, and their connection and dependence clearly pointed out. The *Architecture Hydraulique*, by M. Prony, published in 1790, and the *Mecanique Philosophique*, of the same author, published in 1799, contain all the late improvements in mechanics, and a complete view both of the theory and application of that science. The first of these works is intended chiefly for the use of the engineer, though an extensive acquaintance with the higher geometry is necessary for perusing it with advantage. His *Mecanique Philosophique* is a profound work, in which, without the aid of a single diagram, he gives all the formulæ, and the various theorems and problems which belong to the sciences of mechanics and hydrodynamics. Every alternate page contains a methodical table of the results obtained in the preceding page, the description of the symbols, and the theorems, problems, and formulæ which may have been obtained. The *Traité de Mecanique Elementaire*, by M. Franceur, published in 1802 in one volume octavo, is an excellent abridgement of the works of Prony, and is intended as an introduction to the *Mecanique Philosophique* of that author, to the *Mecanique Analytique* of Lagrange, and to the *Mecanique Celeste* of Laplace.—None of these works have been translated into English; but their place is well supplied by a *Treatise on Mechanics Theoretical, Practical*, and *Descriptive*, by Olinthus Gregory, A M. published in 1806, and containing a complete view of the latest improvements, both in the theory and practice of mechanics.

Prony's Architecture Hydraulique and Mecanique Philosophique.

PART I. THEORY OF MECHANICS.

Objects of theoretical mechanics.

29. THE theory of mechanics properly comprehends, 1. Dynamics. 2. The motion of projectiles. 3. The theory of simple machines, or the mechanical powers. 4. The theory of compound machines, and their maximum effects. 5. The doctrine of the centre of gravity. 6. The centre of oscillation, gyration, &c. 7. The collision of bodies. 8. The theory of rotation. 9. The theory of torsion. 10. The strength of materials; and, 11. The equilibrium of arches, domes.—The subjects of DYNAMICS, PROJECTILES, ROTATION, and STRENGTH of MATERIALS, having been already ably treated by Dr Robison, under their respective heads, we shall now direct the attention of the reader to the other branches of theoretical mechanics.

CHAP. I. *On Simple Machines*, or the *Mechanical Powers.*

Division of machines into simple and compound.

30. THE simple machines have been generally reckoned six in number. 1. The lever; 2. The wheel and axle, or *axis in peritrochio*; 3. The pulley; 4. The inclined plane; 5. The wedge; and, 6. The screw: to which some writers on mechanics have added the *balance*, and others the *rope-machine*. It is evident, however, that all these machines may be reduced to three, the *lever*, the *inclined plane*, and the *rope-machine*. The *pulley*, and the *wheel* and *axle*, are obviously composed of an assemblage of levers; the *balance* is a lever with equal arms; the *wedge* is composed of two inclined planes, with their bases in contact; and the *screw* is either a wedge or an inclined plane, wrapped round a cylinder.—Under the head of simple machines, therefore, we cannot, in strict propriety, include any of the mechanical powers, excepting the lever, the inclined plane, and the rope-machine.

DEFINITIONS.

Definitions.

31. DEF. 1. When two forces act against each other by the intervention of a machine, the one force is called the *power*, and the other the *weight*. The *weight* is the resistance to be overcome, or the effect to be produced. The *power* is the force, whether animate or inanimate, which is employed to overcome that resistance, or to produce the required effect.

32. DEF. 2. The power and weight are said to balance each other, or to be in equilibrio, when the effort of the one to produce motion in one direction, is equal to the effort of the other to produce motion in the opposite direction;—or when the weight opposes that degree of resistance which is precisely required to destroy the action of the power.

SECT. I. *On the Lever.*

Levers divided into three kinds.

33. DEFINITIONS.. A *lever* is an inflexible bar or rod moving freely round a point, called its *fulcrum* or *centre of motion.*

Levers have been generally divided into *three* kinds. In levers of the first kind the fulcrum is situated between the power and the weight, as in steelyards, scissars, pincers, &c. Levers of the second kind have the weight between the power and the fulcrum, as in cutting knives fastened at the point of the blade, and in the oars of a boat where the water is regarded as the fulcrum. In levers of the third kind, the power is between the weight and the fulcrum, as in tongs, sheers for sheep, &c. The bones of animals are generally considered as levers of the third kind, for the muscles, by the contraction of which the power or moving force is generated, are fixed much nearer to the joints or centres of motion than the centre of gravity of the weight to be raised. On this subject, see Paley's Natural Theology, chap. 7. & 8. and *Borelli de Motu Animalium*.

AXIOMS.

Axioms.

34. AXIOM 1. *Equal weights acting at the extremities of equal arms of a straight lever, and having the lines of the direction in which they act at equal angles to these arms, will exert the same effort to turn the lever round its fulcrum.* This axiom has been generally restricted to the particular case when the weights act perpendicularly to the arms of the lever; but no reason can be assigned for such limitation. The truth in the axiom is as self-evident when the angles formed by the arms of the lever and the direction of the forces are 80°, as when they are 90°, for in each case the two weights exert

Theory.

exert their influence upon the lever in precisely the same circumstances.

35. Axiom 2. *If two equal weights are placed at the extremities of a lever supported by two fulcra; and if these fulcra are at equal distances from the weights, or the extremities of the lever; the pressure upon the fulcra will be equal to the sum of the weights, and the pressure upon each fulcrum will be equal to one of the weights.* The lever being supposed devoid of weight, it is obvious, that as each fulcrum is similarly situated with respect to both the weights, the pressure upon each must be equal; and as the fulcra support both the equal weights, the pressure upon each must be equal to one of the weights.

Proposition I.

36. If two weights or forces acting at equal angles upon a straight lever, devoid of weight, are in equilibrio, they are reciprocally proportional to their distances from the fulcrum.

37. Case 1. When the weights act on contrary sides of the fulcrum.

Plate CCCXVI. fig. 1. Let AB be a lever devoid of weight, and let it be supported on the two fulcra, fF, situated in such a manner that $Af = f\mathrm{F} = \mathrm{FB}$. Then if two equal weights C, D of one pound each are suspended at the extremities A, B, so as to act in the directions AC, BD, making the angles CAB, DBA equal, these weights will be in equilibrio, for since $Af = \mathrm{FB}$ (Axiom 1.) the effort of the weight D to turn the lever round the fulcrum F, will be equal to the effort of the weight C to turn it round the fulcrum f. Now (Axiom 2.) the pressure upon the fulcrum f is equal to one pound, therefore if that fulcrum be removed, and a weight E of one pound be made to act upward at the point F, the weights C and D will continue in equilibrio. Then it is obvious that since $\mathrm{FB} = \mathrm{F}f$, the weight E of one pound acting upwards at the point f, so that the angle $\mathrm{D}f\mathrm{F} = \mathrm{DBA}$, will have the same effect as an equal weight acting downwards at B. By removing the weight E, therefore, and suspending its equal C at the extremity B, the equilibrium will still be preserved. But the weights D, C, suspended at B, are equal to two pounds, and the weight C is only one pound; and as FA is double of FB, it follows that a weight of two pounds, placed at the end of one arm of a lever, will be in equilibrio with a weight of one pound placed at twice the distance of the former from the fulcrum. But $2 : 1 = 2\,\mathrm{FB}$ or $\mathrm{AF} : \mathrm{FB}$, that is, when the distances are as 2 to 1, an equilibrium takes place if the weights are reciprocally proportional to these distances.

38. Case 2. When weights act on the same side of the fulcrum.

Fig. 2. Let AB be a lever in equilibrio upon the fulcrum F, and let FA be equal to FB, consequently (Case 1.) we must have $\mathrm{C} = \mathrm{D} = 1$ pound. Now as the fulcrum F supports a weight equal to $\mathrm{C} + \mathrm{D} = 2$ pounds, the equilibrium will continue if a weight E of two pounds is made to act upwards at the point F, for in this case it supplies the place of the fulcrum. It is obvious also that a fulcrum placed at A or B will supply the place of the weights at these parts without affecting the equilibrium. Let, therefore, the weight D be removed, and let the extremity B rest upon a fulcrum; then since the lever is in equilibrio, we have a weight $\mathrm{E} = \mathrm{C} + \mathrm{D} = 2$ pounds acting at F, and balancing a weight C of one pound acting at A. But $2 : 1 = \mathrm{AB} : \mathrm{FB}$, consequently when there is an equilibrium between two weights C, D acting at the distances 2 and 1 from the fulcrum, and on the same side of the fulcrum, the weights are reciprocally proportional to these distances.

39. Again, let AB be the same lever supported by the fulcra f, F, and let $\mathrm{A}f = \mathrm{FB}$ and $f\mathrm{F} = 2\mathrm{FB}$. Then if two weights C, D of one pound each be suspended at the extremities A, B, they will be in equilibrio as before. But since the fulcrum f supports a pressure of one pound (Axiom 2.), the equilibrium will still continue when that fulcrum is removed and a weight of one pound made to act in a contrary direction f P at the point f, so that the angle $\mathrm{P}f\mathrm{F}$ may be equal to DBA. Now, (Axiom 1.) a weight E of one pound acting upward at f will be in equilibrio with a weight E′ of one pound acting downwards at f'; $\mathrm{F}f$ being equal to $\mathrm{F}f'$, and therefore by removing E from the point f and substituting E at the point f', an equilibrium will still obtain. But since $\mathrm{F}f' = 2\mathrm{FB}$ a weight of one pound suspended from f will have the same influence in turning the lever round F as a weight of two pounds suspended at B (Case 2.). Let us remove, therefore, the weight E′ from f', and substitute a weight $\mathrm{G} = 2\mathrm{E}'$, so as to act at B. Then since the equilibrium is not destroyed, we have a weight C of one pound acting at the distance FA, and the weights $\mathrm{D} + \mathrm{G} = 3$ pounds acting at the distance FB. But $\mathrm{FA} = 3\mathrm{FB}$ and $\mathrm{D} + \mathrm{G} = 3\mathrm{C}$, consequently $\mathrm{C} : \mathrm{D} + \mathrm{G} = \mathrm{FB} : \mathrm{FA}$: That is, when the distances from the fulcrum are as 3 to 1, and when an equilibrium exists, the weights are reciprocally proportional to these distances. Fig. 3.

40. By making FA in fig. 2. equal to 2FB it may be shewn, as in Case 2. that the weights are reciprocally proportional to their distances from the fulcrum, when they act on the same side of the fulcrum, and when the distances are as 3 to 1. Fig. 2.

41. In the same way the demonstration may be extended to any commensurable proportion of the arms, by making EA to FB in that proportion, and keeping fA always equal to FB. Hence we may conclude in general, that when two weights acting at equal angles upon a straight lever devoid of weight, are in equilibrio, they are reciprocally proportional to their distances from the centre of motion. Q. E. D. Fig. 3.

42. Cor. 1. If two weights acting at equal angles upon the arms of a straight lever devoid of weight are reciprocally proportional to their distances from the fulcrum, they will be in equilibrio. Corollari

For if an equilibrium does not take place, the proportion of the weights must be altered to procure an equilibrium, and then, contrary to the proposition, the weights would balance each other when they are not reciprocally proportional to their distances from the fulcrum.

43. Cor 2. If a weight W be supported by a horizontal lever resting on the fulcra A, B, the pressure upon A is to the pressure upon B in the inverse ratio of their distances from the point where the weight is suspended, that is, as BF to FA. Fig. 4.

For if we suppose B to be the fulcrum, and if removing the

Theory.

the fulcrum A, we support the extremity A of the lever by a weight E equivalent to the weight sustained by the fulcrum A, and acting upwards over the pulley P, then the weight E or that sustained by A : W=BF : BA (Prop. 1.); and if we conceive A to be the fulcrum, and support the extremity B by a weight F equal to that which was supported by the fulcrum B, we shall have the weight F or the weight sustained by B : W=FB : FA. Hence *ex æquo* the weight sustained by A is to the weight sustained by B as BF is to FA.

Fig. 5.

44. Cor. 3. We may now call the two weights P and W, the power and the weight, as in fig. 5, and since P : W=FB : FA, we have (Geometry, Sect. iv. Theor. 8.) $P\times FA=W\times FB$, when an equilibrium takes place,

consequently $P=\dfrac{W\times FB}{FA}$; $W=\dfrac{P\times FA}{FB}$

$$FA=\frac{W\times FB}{P}$$

$$FB=\frac{P\times FA}{W}.$$

45. Cor. 4. We have already seen (Axiom 2.) that when the power and the weight are on contrary sides of the fulcrum, the pressure upon the fulcrum is equal to $P+W$ or the sum of the weights; but it is obvious that when they act on the same side of the fulcrum, the pressure which it supports will be $P-W$, or the difference of their weights.

46. Cor. 5. If a weight P be shifted along the arm of a lever AD, the weight W, which it is capable of balancing at A, will be proportional to FA.

When the weights are in equilibrio (Cor. 3.) W : P=FA : FB, or by alternation W : FA=P : FB, and if w be another value of W and fa another value of FA, we shall also have w : P=fa : FB or w : fa= P : FB, consequently (Euclid, Book v. Prop. xi. and xvi.) W : w=FA : fa, that is, W varies as FA.

Fig. 6.

Cor. 6. It is obvious that the truths in the preceding proposition and corollaries, also hold when the lever has the form represented in fig. 6. only the straight lines AF, FB are in that case the length of the arm.

Description of the steelyard or statera.

47. Cor. 7. Since by the last corollary FA : fa= W : w, it follows that in the *Roman statera* or *steelyard*, which is merely a lever with a long and short arm, having a weight moveable upon the long one, the distances at which the constant weight must be hung are as the weights suspended from the shorter arm. The steelyard is represented in fig. 7. where AB is the lever with unequal arms AF, FB, and F the centre of motion. The body W, whose weight is to be found, is suspended at the extremity B of the lever, and the constant weight P is moved along the divided arm FB till an equilibrium takes place. As soon as this happens, the number placed at the point of suspension D, indicates the weight of the body. If the lever is devoid of weight, it is obvious that the scale EB will be a scale of equal parts of which EB is the unit, and that the weight of the body W will be always equal to the constant weight P multiplied by the number of divisions between P and F. Thus if the equilibrium takes place when P is pulled out to the 12 division, we shall have W=12 P, and if P=1 pound, W=12 pounds. But when the gravity

Fig. 7.

of the lever is considered, which must be done in the real steelyard, its arms are generally of unequal weight, and therefore the divisions of the scale must be ascertained by experiment. In order to do this, remove the weight P, and find the point C, at which a weight P′ equal to P being suspended, will keep the unequal arms in equilibrio, C will then be the point at which the equal divisions must commence. For when W and P are placed upon the steelyard and are in equilibrio, W balances P along with a weight which, placed at D, would support P placed at C: Therefore $W\times BF=P\times DF+P\times CF$; but $P\times DF+P\times CF=P\times DC$, consequently $W\times BF=P\times DC$, and (Geometry, Sect. iv. Theor. 8.) W : DC=P : BF. By taking different values of the variable quantities W and DC as w and dc, we shall have w : dc=P : BF, consequently (Euclid, B. V. Prop. xi. and xvi.) W : w=DC : dc, that is, the weight of W varies as DC, and therefore the divisions must commence at C. If the arm BF had been heavier than FA, which, however, can scarcely happen in practice, the point C would have been on the other side of F. In constructing steelyards, it might be advisable to make the unequal arms balance each other by placing a weight M at the extremity of the lighter arm, in which case the scale will begin at F. In the Danish and Swedish steelyard the body to be weighed and the constant weight are fixed at the extremities of the steelyard, but the point of suspension or centre of motion F moves along the lever till the equilibrium takes place. The point F then indicates the weight of the body required. —There are some steelyards in which the constant weight is fixed to the shorter arm, while the body to be weighed moves upon the longer arm. The method of dividing this and the preceding steelyard may be seen in De la Hire's *Traité de Mecanique*, Prop. 36, 37, 38.

Danish and Swedish steelyard.

Prop. II.

48. To find the condition of equilibrium on a straight lever when its gravity is taken into the account.

Fig. 8.

49. Let us suppose the lever to be of uniform thickness and density, as AB, fig. 7. and let it be suspended by the points c, d to another lever $a\,b$, considered as without weight, so that $a\,c=c\,f=f\,d=d\,b$. Then if f be the centre of motion or point of suspension, the cylinder A B will be in equilibrio; for the weight AB may be regarded as composed of a number of pairs of equal weights, equally distant from the centre of motion. For the same reason, if we conceive the cylinder to be cut through at F the equilibrium will continue, c, d being now the points at which the weights AF, FB act, and their distances $c\,f$, $d\,f$ from the centre of motion being equal. Consequently the arms AF, FB have the same energy in turning the lever round f as if weights equal to AF, FB were suspended at the distance of their middle points c, d from the fulcrum.

Fig. 5.

Let P therefore, in fig. 5. be the power, W the weight, m the weight of the arm AF, and n the weight of FB. Then when there is an equilibrium we shall have (Prop. I. Cor. 3.) $P\times AF+m\times\frac{1}{2}AF=W\times FB+n\times\frac{1}{2}FB$; and since the weight m, acting at half the distance AF is the same as half the weight m acting at the

Theory. the whole distance AF, we may substitute $\frac{1}{2}m \times AF$ instead of $m \times \frac{1}{2}AF$, and the equation becomes $\overline{P+\frac{1}{2}m} \times AF = \overline{W+\frac{1}{2}n} \times FB$. Hence

$$P = \frac{\overline{W+\frac{1}{2}n} \times FB}{AF} - \frac{1}{2}m$$

$$W = \frac{\overline{P+\frac{1}{2}n} \times AF}{FB} - \frac{1}{2}n$$

$$m = \frac{\overline{W=\frac{1}{2}n} \times 2FB}{AF} - 2P$$

$$n = \frac{\overline{P+\frac{1}{2}n} \times 2FB}{FB} - 2W$$

$$AF = \frac{\overline{W+\frac{1}{2}n} \times FB}{P+\frac{1}{2}m}$$

$$FB = \frac{\overline{P+\frac{1}{2}m} \times AF}{W+\frac{1}{2}m}.$$

50. Cor. If the arms of the lever are not of uniform density and thickness, instead of the distance of their middle points, we must take the distance of their centre of gravity from the fulcrum.

Prop. III.

51. If two forces acting in any direction, and in the same plane, upon a lever of any form, are in equilibrio, they will be reciprocally proportional to the perpendiculars let fall from the fulcrum upon the directions in which they act.

Plate CCCXVII. Fig. 1. & 2. 52. Let AFB be a lever of any form, F its fulcrum, A, B the points to which the forces, or the power P and weight W, are applied, and AE, BK the directions in which these forces act. Make AE to PK as P is to W, and they will therefore represent the forces applied at A and B. Draw AC perpendicular to AF and EC parallel to it, and complete the parallelogram ADEC. In the same way form the parallelogram BGKH. Produce EA and KB towards m and n if necessary, and let fall F m, F n perpendicular to AE, BK produced. Then P shall be to W as Fn is to Fm. By the resolution of forces (Dynamics, § 140.) the force AE is equivalent to forces represented by AD and AC, and acting in these directions. But as AD acts in the direction of the arm AF, it can have no influence in turning the lever round F, and therefore AC represents the portion of the force AD which contributes to produce an angular motion round F. In the same way it may be shewn that BG is the part of the force BK which tends to move the lever round F. Now suppose AF produced to B, FB being made equal to FB and B′G′=BG. Then by Prop. I. AC : B′G′ =FB′ : FA; but by Axiom 1. the effort of BG to turn the lever round F is equal to the effort of the equal force B′G′ to turn the lever round F; therefore AC : BG=FB : FA and AC×FA=BG×FB. Now the triangles ACE, AE m are similar, because the angles at F and M are both right, and on account of the parallels DF, AC, MAC=ADF; therefore AC : AE=F m : FA, and AC×FA=AE×F m. For the same reason in the similar triangles BGK, BF n we have BG : BK=F n : FB, and BK×Fn=BG×FB. Hence AE×Fm=BK×Fn, and AE : BK or P : W =F n : Fm. Q. E. D. Theory.

53. Cor. 1. The forces P and W are reciprocally Corollaries. proportional to the sines of the angles which their di- Fig. 1 & 2. rections make with the arms of the lever, for F m is evidently the sine of the angle FA m, and F n the sine of the angle FB n, FA, FB being made the radii;—therefore P : W=Sin. FB n : Sin. FA m, or P : W $=\frac{1}{\text{Sin. FA}\,m} : \frac{1}{\text{Sin. FB}\,n}$. Since FA : F m=Rad. : Sin. FAm, we have F$m=\frac{\text{FA}\times\text{Sin. FA}m}{\text{Rad.}}$; and since FB : F$n$=Rad. : Sin. FB$n$, we have F$m=\frac{\text{FB}\times\text{Sin. FB}n}{\text{Rad.}}$, but in the case of an equilibrium P : W=Fn : Fm, consequently P : W$=\frac{\text{FB}\times\text{Sin. FB}\,n}{\text{Rad.}} : \frac{\text{FA}\times\text{Sin. FA}\,m}{\text{Rad.}}$; and since magnitudes have the same ratio as their equimultiples, P : W=EB×Sin. EB n : FA×Sin. FAm.

54. Cor. 2. The energies of the forces P, W to turn the lever round the fulcrum F is the same at whatever point in the directions mE, nK they are applied, for the perpendiculars to which these energies are proportional remain the same.—The truth of this corollary has been assumed as an axiom by some writers on mechanics, who have very readily deduced from it the preceding proposition. But it is very obvious that the truth assumed as self-evident is nearly equivalent to the truth which it is employed to prove. Those who have adopted this mode of demonstration illustrate their axiom by the case of a solid body that is either pushed in one direction with a straight rod, or drawn by a cord; in both of which cases it is manifest that the effect of the force employed is the same, at whatever part of the rod or string it is applied: But these cases are completely different from that of a body moving round a fixed centre.

55. Cor. 3. If AE and BK the directions in which the forces P, W are exerted be produced till they meet at L; and if from the fulcrum E thel ine FS be drawn parallel to the direction AL of one force till it meets BL, the direction of the other; then LS, SF will represent the two forces. For as the sides of any triangle are as the sines of the opposite angles LS : SF=sin. LFS : sin. FLS; but on account of the parallels FS, AL the angle LFS=FLA, and FL being radius F m is the sine of FLA or LFS, and F n the sine of FLS, therefore by substitution LS : SF=F m : Fn, that is as the force W : P.

56. Cor. 4. If several forces act upon a lever, and keep it in equilibrio, the sum of the products of the forces and the perpendiculars from the fulcrum to the direction of the different forces on one side is equal to the sum of the products on the other. For since the energy of each force to turn the lever is equal to the product of the force and the perpendicular from the fulcrum on the line of its direction; and since in the case of an equilibrium, the energy of all the forces on one side of the fulcrum must be equal to the energy of all the forces on the other side, the products proportional to their energies must also be equal.

57. Cor. 5. If two forces act in a parallel direction upon an angular lever whose fulcrum is its angular point,

Theory. point, these forces will be in equilibrio when a line drawn from the fulcrum upon the line which joins the two points where the forces are applied, and parallel to the direction of the forces, cuts it in such a manner that the two parts are reciprocally proportional to the forces applied.

Fig. 3. Let AFB be the angular lever, whose fulcrum is F, and let the forces P, W be applied at A and B in the parallel directions P m, W n; then if the line FD, parallel to Pm or Wn, cut AB in such a manner that DB : DA=P : W, the forces will be in equilibrio. Draw Fm perpendicular to Pm, and produce it to n; then since Am, Bn are parallel, mn will also be perpendicular to Bn, and by the proposition (Art. 51.) Fn : Fm=P : W. Now, if through F, there be drawn $m'n'$ parallel to AB, the triangles Fmm', Fnn' will be similar, and we shall have Fn : Fm=Fn' : Fm', but on account of the parallels AB, $m'n'$; Fn' : Fm' =DB : DA, therefore DB : DA=P : W.

Fig. 4. 58. Cor. 6. Let CB be a body moveable round its centre of gravity F, and let two forces P, W act upon it at the points A, B in the plane AFB, in the directions AP, BW; then since this body may be regarded as a lever whose fulcrum is F, the forces will be in equilibrio when P : W=Fn : Fm the perpendiculars on the directions in which the forces act.

Fig. 5. 59. Cor. 7. If AB be an inflexible rod moveable round F as a fulcrum, and acted upon by two forces P, W in the directions Am, An, these forces will be in equilibrio when they are to one another as the perpendiculars Fn, Fm.—For by cor. 2. the forces may be considered as applied at m and n, and mFn may be regarded as the lever; but by the proposition (Art. 51.) P : W=Fn : Fm; Fm, Fn being perpendiculars upon Am, An.

Fig. 6. 60. Cor. 8. Let DE be a heavy wheel, and FG an obstacle over which it is to be moved, by a force P, acting in the direction AH. Join AF, and draw Fm, Fn perpendicular to CA and AH. The weight of the wheel is evidently the weight to be raised, and may be represented by W acting at the point A in the vertical direction AC. We may now consider AF as a lever whose fulcrum is F, and by cor. 7. there will be an equilibrium when P : W=Fn : Fm. Since Fm represents the mechanical energy of the power P to turn the wheel round F, it is obvious that when FG is equal to the radius of the wheel, the weight P, however great, has no power to move it over the obstacle; for when FG=AC, Fm=o, and Fm×P=o.

Fig. 7. 61. Cor. 9. If a man be placed in a pair of scales hung at the extremities of a lever, and is in equilibrio with a weight in the opposite scale, then if he presses against any point in the lever, except that point from which the scale is suspended, the equilibrium will be destroyed. Let CB be the lever in equilibrio, F its fulcrum, and let the scales be suspended from A and B, AP being the scale in which the man is placed. Then if he presses with his hand or with a rod against D, a point nearer the centre than A, the scale will take the position AP′, and the same effect will be produced as if AD were a solid mass acting upon the lever in the direction of gravity. Consequently if P′p be drawn perpendicular from the point P′ to FC, Fp will be the lever with which the man in the scale tends to turn the lever round the fulcrum; and as Fp is greater than FA, the man will preponderate. In the same way it may be shown, that if the man in the scale AP presses upwards against a point C, more remote from the fulcrum than A, he will diminish his relative weight, and the scale W will preponderate, for in this case the scale assumes the position AP″, and Fp' becomes the lever by which it acts. Theory.

62. Cor. 10. If a weight W be supported by an inclined lever resting on the fulcra A, B, the pressure upon A is to that upon B inversely, as Af is to fb, the sections of a horizontal line by the vertical direction of the weight W. Fig. 8.

Remove the fulcrum A, and support the extremity A by a weight P, equal to the pressure upon A; then B being the centre of motion, and mn being drawn through F perpendicular to the direction of the forces Am, Ef, and consequently parallel to Ab, we have (Art. 51.) P : W=Fn : Fm=fb : fA, that is, the pressure upon A is to the pressure upon B inversely as Af is to fb.

Scholium.

63. Various attempts have been made by different writers on mechanics to give a complete and satisfactory demonstration of the fundamental property of the lever. The first of these attempts was made by Archimedes, who assumes as an axiom, that if two equal bodies be placed upon a lever, they will have the same influence in giving it a rotatory motion as if they were both placed in the middle part between them. This truth, however, is far from being self-evident, and on this account Mr Vince * has completed the demonstration by making this axiom a preliminary proposition. The demonstration of Galileo † is both simple and elegant, and does not seem to have attracted much notice, though in principle it is exactly the same as that of Archimedes completed by Mr Vince. Galileo suspends a solid cylinder or prism from a lever by several threads. When the lever is hung by its centre, the whole is in equilibrio. He then supposes the cylinder to be cut into two unequal parts, which from their mode of suspension still retain their position, and then imagines each part of the cylinder to be suspended by its centre from the lever. Here then we have two unequal weights hanging at unequal distances from the centre of suspension, and it follows from the construction, that these weights are in the reciprocal ratio of their distances from that centre. Mr Vince, on the other hand, employs a cylinder balanced on a fulcrum. He supposes this cylinder divided into unequal parts, and thus concludes, from his preliminary proposition, that these unequal parts have the same effect in turning the lever as if the weight of these parts was placed in their centres; which is done by Galileo by suspending them from their centres. From this the fundamental property of the lever is easily deduced.—The next demonstration was given by Huygens, who assumes as an axiom, that if any weight placed upon a lever is removed to a greater distance from the fulcrum, its effort to turn the lever will be increased. This axiom he might have demonstrated thus, and his demonstration would have been completely satisfactory, though it applies only to cases where the arms of the lever are commensurable. Let AB be a lever with equal weights C, D, supported on the fulcra f, F, so that Af= Plate CCCXVI. Fig. 1.

* *Phil. Trans.* 1794, p. 33.

† *Discursus et Demonstrationes Mathemat.* Dial. ii. p. 98.

Theory. $Af=FB$; then, as was shown in Prop. I. the weights will be in equilibrio, and each fulcrum will support a weight equal to C or D. By removing the fulcrum f, the weight C must descend, as the equilibrium is destroyed by a weight equal to C acting at f; therefore the weight C, at the distance AF, has a greater effect in turning the lever than an equal weight D placed at a less distance FB.—In Sir Isaac Newton's demonstration, it is supposed that if a given weight act in any direction, and if several radii be drawn from the fulcrum to the line of direction, the effort of that weight to turn the lever will be the same to whatever of these radii it is applied. It appears, however, from Art. 54. that this principle is far from being self-evident, and therefore the demonstration which is founded upon it cannot be admitted as satisfactory. The demonstration given by Maclaurin * is simple and convincing, and has been highly approved of by Dr T. Young and other writers on mechanics, though it extends only to any commensurable proportion of the arms. He supposes the lever AB with equal arms to be in equilibrio upon the fulcrum F, by means of the equal forces P, W, in which case the fulcrum F will evidently be pressed down with a weight equal to $2\,P=P+W$. He then substitutes, instead of the weight P, a fixed obstacle O, which will not destroy the equilibrium, and *considers the fulcrum as still loaded with a weight equal to* $P+W$. The pressure on F being therefore equal to 2 P or $P+W$, a weight E equal to 2 P, and acting upwards, is substituted in the room of that pressure, so that the equilibrium will still continue. Here then we have a lever AB of the second kind, influenced by two forces E and W acting at different distances from the fulcrum A; and since $E=2\,P=2\,W$, and $AB=2\,AF$, we have $E:W=AB:AF$, which expresses the fundamental property of the lever. Without objecting to the circumstance that this demonstration applies only to the lever of the second kind, we may be allowed to observe, that it involves an axiom which cannot be called self-evident. It is certainly manifest that when P and W are in equilibrio, the pressure upon the fulcrum is $=2\,P=P+W$; but it by no means follows that this pressure remains the same when the fixed obstacle O is substituted in the room of P. On the contrary, the axiom assumed is a result of the proposition which it is employed to prove, or rather it is the proposition itself. For if, when the extremity A bears against the obstacle O, the pressure upon F is equal to 2 W, the force W obviously produces a pressure $=2W$ at half the distance AB, which is the property to be demonstrated. —The demonstrations given by Mr Landen and Dr Hamilton, the former in his Memoirs, and the latter in his Essays †, though in a great measure satisfactory, are long and tedious. In the demonstration of Dr Hamilton, he employs the following proposition: that when a body is at rest, and acted upon by three forces, they will be to one another as the three sides of a triangle parallel to the direction in which the forces act. When the three forces act on one point of a body, the proposition is true, but it is not applicable to the case of a lever where the forces are applied to three different points, and at all events the demonstration does not hold when any two of the forces act in parallel directions. The demonstration which we have given in Prop. I. is new, and different from any that have been noticed. The truths on which it is founded are perfectly axiomatic; and the only objection to which it seems liable is, that the demonstration extends only to a commensurate proportion of the arms of the lever.—An analytical demonstration of the fundamental property of the lever was given by Foncenex in the Miscellan. Jour. tom. ii. p. 321. which was afterwards improved by D'Alembert in the Mem. de l'Acad. 1769. p. 283.

* *Account of Newton's Discoveries.*

Plate CCCXVII. Fig. 9.

† See also *Phil. Trans.* vol. xciii. p. 113.

Prop. IV.

Plate CCCXVIII. Fig. 1.

64. When several levers AB, $a\,b$, $\alpha\,\beta$, whose fulcra are F, f, φ, are so combined as to act perpendicularly upon each other, or at equal angles; and if the directions in which the power and weight are applied, be also perpendicular to the arms, or at the same angles with them as those at which the levers act upon each other, there is an equilibrium when $P:W=\overline{BF\times bf\times\beta\varphi}:\overline{AF\times af\times\alpha\varphi}$.

Let M be the force which is exerted by the first lever AB upon the second $a\,b$, and N the force which is exerted by the second lever $a\,b$ upon the third $\alpha\,\beta$, then by Prop. I.

$$P:M=BF:AF$$
$$M:N=bf:af$$
$$N:W=\beta\varphi:\alpha\varphi.$$

Consequently by composition

$$P:W=\overline{BF\times bf\times\beta\varphi}:\overline{AF\times af\times\alpha\varphi}.$$

Prop. V.

65. To explain the new property of the lever discovered by M. Æpinus, and extended by Van Swinden.

Let AFB be any lever whose fulcrum is F, and to whose extremities A, B are applied the forces P, W in the directions AY, BO. Join AB, and produce it on both sides towards E and I. Produce also the lines YA, VB till they meet in H, and from H, through the fulcrum F, draw HFf, dividing AB into two parts Af, Bf. Let UM be a line given in position, and let α, β represent the angles which the direction of the forces YA, VB make with that line. Let YA and VB likewise represent the intensity of the forces P, W, and let VA be resolved into AE and YF; and the force VB into BI and VI.—Then the lever cannot be in equilibrium till Fig. 2.

I. $\overline{EA\times fA}+\overline{IB\times fB}$ is a maximum.

II. Or putting φ for the angles formed by the lines AB, UT, which the lever, when in equilibrio, makes with the line UM given in position, there cannot be an equilibrium till

$$\overline{\text{Tang.}\,\varphi\times P\times Af\times\text{Cos.}\,\alpha}+\overline{\text{Tang.}\,\varphi\times W\times Bf\times\text{Cos.}\,\beta}=\overline{W\times Bf\times\text{Sin}\,\beta}-\overline{P\times Af\times\text{Sin.}\,\alpha}.$$

III. And

III. And putting a, b for the arms AF, BF, and m, n for the angles EAB, EBA, there cannot be an equilibrium unless

$$\text{Tang. } \varphi = \frac{\text{W}.\,b\,(\text{Sin. }\beta \times \text{Cos. } n - \text{Sin. } n \times \text{Cos. }\beta) - \text{P}.\,a\,(\text{Sin. }\alpha \times \text{Cos. } m - \text{Sin. } m \times \text{Cos. }\alpha.)}{\text{P}.\,a\,(\text{Cos. }\alpha \times \text{Cos. } m + \text{Sin. }\alpha \times \text{Sin. } m) + \text{W}.\,b\,(\text{Cos. }\beta \times \text{Cos. } n + \text{Sin. }\beta \times \text{Sin. } n.)}.$$

As the demonstrations of these different cases are far from being elementary, we shall only refer the reader to the memoir upon this subject given by Æpinus in the *Nov. Comment. Petropol.* tom. viii. p. 271.

Scholium.

66. This property of the lever was only considered by Æpinus in the case of a rectilineal lever with equal arms; but was extended by J. H. Van Swinden. When the lever is rectilineal and with equal arms, we have AF=FB=Af=Bf, and also $m=n=0$, so that, if the last formula is suited to these conditions, we shall have the formula of Æpinus.

Prop. VI.

67. **If a power and weight acting upon the arms of any lever be in equilibrio, and if the whole be put in motion, the velocity of the power is to the velocity of the weight as the weight is to the power.**

Fig. 3. Let AFB be any lever whose fulcrum is F, and let the power P and weight W be applied to its extremities A, B, so as to be in equilibrio. Draw F m, F n perpendicular to AD, BE the direction of the forces P, W. Then suppose an uniform angular motion to be given to the lever, so as to make it describe the small angle AFA′, the position of the lever will now be A′FB′, and the directions of the forces, P, W will be A′D′, B′E, parallel to AD, BE respectively, since the angle AEF is exceedingly small. Join AA′, BB′, and from A′ and B′ draw A′x, B′z perpendicular to AD and BE. Now it is obvious, that though the point A has moved through the space AA′ in the same time that the point B has described the space BB′, yet A x is the space described by A in the direction AD, and B z the space described by B in the direction BE. For if we suppose a plane passing through A at right angles to AD, and another through P parallel to the former plane, it is manifest that A x measures the approach of the point A to the plane passing through P; and for the same reason B z measures the approach of the point B to a plane passing through W at right angles to WB. Therefore A x, B z represent the spaces uniformly and simultaneously described by the points A, B, and may therefore be taken to denote the velocities of these points (Dynamics, § 14.); consequently the velocity of A : the velocity of B=A x : B z. Now, in the triangles A x A′, F m A, the exterior angle x AF=A m F+m F, A (Euclid, B. I. Prop. 32.) and A′AF=A m F, because AFA′ is so exceedingly small that A′A is sensibly perpendicular to AF; consequently x AA′=AE m: and as the angles at x and m are right, the triangles A x A′, A m F are similar (Geometry, Theor. XX. Sect. IV.).

Therefore, A x : AA′=F m : FA, and in the similar triangles AFA′, BFB′ AA′ : BB′=FA : FB, and in the similar triangles BB′z, BF n, BB′ : Bz=FB : F n, therefore by composition we have A x : B z=Fm : Fn. But by Proposition II. P : W=Fn : Fm, consequently Ax : Bz=W : P, that is, the velocity of the power is to the velocity of the weight as the weight is to the power. Q. E. D.

68. Cor. Since Ax : Bz=W : P we have Ax×P =Bz×W, that is, the momenta of the power and weight are equal.

Sect. II. *On the Inclined Plane.*

69. Definition. An *inclined plane* is a plane surface AB, supported at any angle ABC formed with the horizontal plane BC. The *inclination of the plane* is the angle which one line in the plane AB forms with another in the horizontal plane BC, both these lines being at right angles to the common intersection of the two planes.—The line BA is called the *length of the plane*, AC its *height*, and BC the *length of its base*. Plate CCCXVIII fig. 4.

70. In order to understand how the inclined plane acts as a mechanical power, let us suppose it necessary to elevate the weight D from C to A. If this weight is lifted by the arms of a man to the point A, he must support the whole of the load; but when it is rolled up the inclined plane, a considerable part of its weight is supported upon the plane, and therefore a much smaller force is capable of raising it to A.

Prop. I.

71. **When any weight W is kept in equilibrio upon an inclined plane by a power P, the power is to the weight as the sine of the plane's inclination is to the sine of the angle which the direction of the power makes with a line at right angles to the plane.**

Let MN be the inclined plane, NO a horizontal line, and MNO the inclination of the plane, and let the weight W be sustained upon MN by means of the power P acting in the direction AE. From the point A, the centre of gravity of the weight, draw AB perpendicular to the horizontal plane ND, and AF perpendicular to MN; produce EA till it meets the plane in C, and from the point F where the body touches the plane draw Fm at right angles to AC, and Fn at right angles to AB. Then, since the whole body may be considered as collected in the centre of gravity A, AB will be the direction in which it tends to fall, or the direction of the weight, and EA is the direction of the power; but AF is a lever whose fulcrum is F, and since it is acted upon by two forces which are in equilibrio, we shall have (Art. 59.) P : W=F n : F m, that is, as the perpendiculars drawn from the fulcrum to the direction in which the forces act. Now FA being radius, F n is the sine of the angle FAB, and F m is the sine of the angle FAC; but FAB is equal to MNO the angle of the plane's inclination, on account of the right angles at F and B and the vertical angles at D; and FAC is the angle which the direction of the power makes with a line perpendicular to the plane; therefore P : W as Fig. 5.

Theory. as the sine of the plane's inclination, is to the sine of the angle formed by the direction of the power with a line at the right angles to the plane.

72. Cor. 1. When the power acts parallel to the plane in the direction AE′, P is to W as EA to E n, that is, as radius is to the sine of the plane's inclination, or on account of the similar triangles F A n, MNO, as the length of the plane is to its height. In this case the power acts to the greatest advantage.

73. Cor. 2. When the power acts in a vertical line A ϵ, F m becomes equal to or coincides with F n, and we have P : W=F n : F n, that is, the power in this case sustains the whole weight.

74. Cor. 3. When the power acts parallel to the base of the plane in the direction A e, P : W=F n : Ff =Fn : A n.

75. Cor. 4. When the power acts in the direction AF e' perpendicular to the plane, it has no power to resist the gravity of the weight; for the perpendicular from the fulcrum F, to which its energy is proportional, vanishes.

76. Cor. 5. Since the body W acts upon the plane in a direction AF perpendicular to the plane's surface, (for its force downwards may be resolved into two, one parallel to the plane, and the other perpendicular to it), and since the reaction of the plane must also be perpendicular to its surface (Dynamics, § 149.), that is, in the direction FA, then, when the direction of the power is A e parallel to the horizon, the power, the weight, and the pressure upon the plane, will be respectively as the height, the base, and the length of the plane. The weight W is acted upon by three forces; by its own gravity in the direction A n, by the reaction of the plane in the direction AF, and by the power P in the direction AF. Therefore, since these forces are in equilibrio, and since Af is parallel to nF, and Ff to An, the three sides AF, Af, Ff, will represent the three forces (Dynamics, § 144.). But the triangle AFf is similar to AnF, that is, to MNO, for it was already shewn that the angle n AF is equal to MNO, therefore, since in the triangle AFf, AF represents the pressure on the plane, Af the weight of the body, and Ff the energy of the power, these magnitudes will also be represented in the similar triangle MNO by the sides MN, MO, NO.

Fig. 6. 77. Cor. 6. If a power P and weight W are in equilibrio upon two inclined planes, AB, AC; P : W= AB : AC. Let p be the power, which acting on the weight W in a direction parallel to the plane would keep it in equilibrio, then we have p : W=AD : AC; but since the string is equally stretched at every point, the same power p will also sustain the power P, consequently P : p=AB : AD, and by composition P : W =AB : AC.

Prop. II.

78. If a spherical body is supported upon two inclined planes, the pressures upon these planes will be inversely as the sines of their inclination, while the absolute weight of the body is represented by the sine of the angle formed by the two planes.

Fig. 7. Let AC, BC be the two inclined planes, and F the spherical body which they support. The whole of its matter being supposed to be collected in its centre of gravity F, its tendency downwards will be in the vertical line FO. The reaction of the planes upon F is evidently in the direction MF, NF perpendicular to the surface of these planes, and therefore we may consider the body F as influenced by three forces acting in the directions FC, FM, FN; but these forces are represented by the sides of the triangle ABC perpendicular to their directions, (Dynamics, § 144.), consequently the absolute weight of the body F, the pressure upon the plane AC, and the pressure upon the plane BC, are respectively as AB, AC, and BC, that is, as the sines of the angles ACD, ABC, BAC, for in every triangle the sides are as the sines of the opposite angles, or to express it in symbols, W being the absolute weight of the body, w the pressure on AC, and w' the pressure on BC,

$$W : w : w' = AB : AC : BC, \text{ or}$$
$$W : w : w' = \sin. ACB : \sin. ABC : \sin. BCA.$$

But on account of the parallels AB, DF, the angle ABC=BCF, and BAC=ACD, therefore the pressures upon the planes are inversely as the sines of their inclination, the absolute weight of the body being represented by the sine of the angle formed by the surfaces of the two planes.

Corollaries. 79. Cor. 1. Since the two sides of a triangle are greater than the third, the sum of the relative weights supported by the two planes is greater than the absolute weight of the body.

80. Cor. 2. If the inclination of each plane is 60°, then ACB must also be 60°, and the triangle ABC equilateral, consequently the pressure upon each plane is equal to the absolute weight of the body.

81. Cor. 3. When the inclination of each plane increases, the pressure which each sustains is also increased; and when their inclination diminishes till it almost vanishes, the pressure upon each plane is one half of the absolute weight of the body F.

Prop. III.

82. If a body is raised with an uniform motion along an inclined plane, the velocity of the power is to the velocity of the weight as the weight is to the power.

Fig. 8. Let the weight W be drawn uniformly up the inclined plane AB, from B to D, by a power whose direction is parallel to DH. Upon DB describe the circle BFEDN, cutting BC in E, and having produced HD to F, join FP, FB, FE, and draw DC perpendicular to BD. Now the angles BFD, BED are right (Geometry, Sect. II. Theor. 17.), and therefore, though the power moves through a space equal to BD, yet its velocity in the direction DH is measured by the space FD uniformly described; and for the same reason, though the weight W describes the space BD, yet its velocity in the direction in which it acts, that is, in a vertical direction, is evidently measured by the space DE uniformly described. Then because the triangle DBE is equal to DFE, (Geometry, Sect. II. Theor. 15.) and DBE=DCH, (Geometry, Sect. IV. Theor. 23.) and FDE=DHC, (Geometry, Sect. I. Theor. 21.)

Theory.

21.) the triangles DFE, DHC are similar, and (GEOMETRY, Sect. IV. Theor. 20.) DF : DE=DH : HC. But DH : HC=sin. DCH . sin. HDC, that is, (art. 71.) DF : DE, or the velocity of the power to the velocity of the weight, as W : P. Q. E. D.

SCHOLIUM.

83. The inclined plane, when combined with other machinery, is often of great use in the elevation of weights. It has been the opinion of some writers, that the huge masses of stone which are found at great altitudes in the splendid remains of Egyptian architecture, were raised upon inclined planes of earth, with the aid of other mechanical powers. This supposition, however, is not probable, as the immense blocks of granite which compose the pyramids of Egypt could not possibly have been raised into their present situation by any combination of the mechanical powers with which we are acquainted.—The inclined plane has been very advantageously employed in the duke of Bridgewater's canal. After this canal has extended 40 miles on the same level, it is joined to a subterraneous navigation about 12 miles long by means of an inclined plane, and this subterraneous portion is again connected by an inclined plane with another subterraneous portion about 106 feet above it. This inclined plane is a stratum of stone which slopes one foot in four, and is about 453 feet long. The boats are conveyed from one portion of the canal to another by means of a windlass, so that a loaded boat descending along the plane turns the axis of the windlass, and raises an empty boat.—A pair of stairs, and a road that is not level, may be regarded as inclined planes; and hence it is a matter of great importance, in carrying a road to the top of a hill, to choose such a line that the declivity may be the least possible. The additional length, which, in order to effect this purpose, must sometimes be given to the line of road, is a trifling inconvenience, when compared with the advantages of a gentle declivity.

SECT. III. *On the Rope Machine.*

84. DEFINITION. When a body suspended by two more ropes, is sustained by powers which act by the assistance of these ropes, this assemblage of ropes is called a *rope machine.*

PROP. I.

85. If a weight is an equilibrium with two powers acting on a rope machine, these powers are inversely as the sines of the angles which the ropes form with the direction of the weight.

Fig. 9.

Let the weight W be suspended by the point B, where the ropes AB, BC are joined, and let the powers P, p acting at the other extremities of the ropes which pass over the pulleys A, C, keep this weight in equilibrio, we shall have P : p=sin. CBD : sin. ABD. Produce WB to F, and let BD represent the force exerted by W; then by drawing DE parallel to AB, the sides of the triangle BDE will represent the three forces by which the point B is solicited (DYNAMICS, § 144.), for AB, CB are the directions of the forces P and p. We have therefore P : p=DE : BE; but DE : BE=sin. DBE : sin. BDE, and on account of the parallels DE, AB, the angle BDE=ABD, consequently P : p=sin. DBE : sin. BDE.

Theory.

86. COR. 1. When the line joining the pulleys is horizontal, as AC, then P : p=FC : FA, for FC and FA are evidently the sines of the angles DBE, BDE.

87. COR. 2. Any of the powers is to the weight, as the sine of the angle which the other makes with the direction of the weight, is to the sine of the angles which the powers make with one another. For since DB represents the weight, and BE the power P, we have BE : BD=sin. BDE : sin. BED; but on account of the parallels DE, AB, the angle DEB=ABC, the angle made by the direction of the powers, consequently BE : BD, that is, p : W=sin. ABF : sin. ABC. In the same way it may be shown that P : W=sin. CBF : sin. ABC. Hence we have P+p : W=$\overline{\text{sin. CBF+sin. ABF}}$: sin. ABC, that is the sum of the powers is to the weight, as the sum of the sines of the angles which the powers make with the direction of the weight is to the sine of the angle which the powers make with one another.

88. COR. 3. The two powers P, p, are also directly proportional to the cosecants of the angles formed by the direction of the powers with the direction of the weight. For since P : p=sin. DBE : sin. BDE, and by the principles of trigonometry, sin. DBE : sin. DBE =cosec. BDE : cosec. DBE, we have P : p=cosec. ABF : cosec. CBF. It is also obvious that P : p as the secants of the angles which these powers form with the horizon, since the angles which they make with the horizon are the complements of the angles which they form with the direction of the weight, and the cosecant of any angle is just the secant of its complement, therefore P : p=sec. BAF : sec. BCF.

CHAP. II. *On Compound Machines.*

89. DEFINITION. Compound machines are those which are composed of two or more simple machines, either of the same or of different kinds. The number of compound machines is unlimited, but those which properly belong to this chapter, are, 1. The wheel and axle; 2. The pulley; 3. The wedge; 4. The screw; and, 5. The balance.

SECT. I. *On the Wheel and Axle.*

90. The *wheel and axle*, or the axis in peritrochio, Fig. 10. is represented in fig. 9. and consists of a wheel AB, and cylinder CD, having the same axis, and moving upon pivots E, F, placed at the extremity of the cylinder. The power P is most commonly applied to the circumference of the wheel, and acts in the direction of the tangent, while the weight W is elevated by a rope which coils round the cylinder CD in a plane perpendicular to its axis.—In this machine a winch or handle EH is sometimes substituted instead of the wheel, and sometimes the power is applied to the levers S, S fixed in the periphery of the wheel; but in all these forms the principle of the machine remains unaltered.—That the wheel and axle is an assemblage of levers will be obvious, by considering that the very same effect would be produced if a number of levers were to radiate

Theory. diate from the centre C, and if a rope carrying the power P were to pass over their extremities, and extricate itself from the descending levers when they come into a horizontal position.

91. Axiom. The effect of the power to turn the cylinder round its axis, is the same at whatever point in the axle it is fixed.

Prop. I.

92. In the wheel and axle the power and weight will be in equilibrium, when they are to one another reciprocally as the radii of the circles to which they are applied, or when the power is to the weight as the radius of the axle is to the radius of the wheel.

Fig. 11. Let AD be a section of the wheel, and BE a section of the axle or cylinder, and let the power P and weight W act in the directions AP, WP, tangents to the circumferences of the axle and wheel in the points A, B, by means of ropes winding round these circumferences. As the effect is the same according to the *axiom*, let the power and weight act in the same plane as they appear to do in the figure, then it is obvious that the effort of the power P and weight W will be the same as if they were suspended at the points A, B; consequently the machine may be regarded as a lever AFB, whose centre of motion is F. But since the directions of the power and weight make equal angles with the arms of the lever, we have (Art. 36.) $P : W = FB : FA$, that is, the power is to the weight as the radius of the axle is to the radius of the wheel.

Corollaries. 93. Cor. 1. If the power and weight act obliquely to the arms of the lever in the directions $A\,p$, $B\,w$, draw $F\,m$ $F n$ perpendicular to $A\,p$ and $B\,w$, and as in the case of the lever (Art. 51.) there will be an equilibrium when $P : W = F\,n : F\,m$. Hence the tangential direction is the most advantageous one in which the power can be applied, for FA is always greater than $F\,m$, and the least advantageous direction in which the weight can be applied, for it then opposes the greatest resistance to the power.

94. Cor. 2. If the plane of the wheel is inclined to the axle at any angle x, there will be an equilibrium when $P : W =$ semidiameter of the axle : sin. x.

95. Cor. 3. When the thickness of the rope is of a sensible magnitude, there will be an equilibrium when the power is to the weight as the sum of the radius of the axle, and half the thickness of its rope, is to the sum of the radius of the wheel and half the thickness of its rope; that is, if T be the thickness of the rope of the wheel, and t the thickness of the rope of the axle, there will be an equilibrium when $P : W = \overline{FB + \frac{1}{2}t} : \overline{FA + \frac{1}{2}T}$.

96. Cor. 4. If a number of wheels and axles are so combined that the periphery of the first axle may act on the periphery of the second wheel, either by means of a string or by teeth fixed in the peripheries of each, and the periphery of the second axle on the periphery of the third wheel, there will be an equilibrium when the power is to the weight as the product of the radii of all the axles is to the product of the radii of all the wheels. This corollary may be demonstrated by the some reasoning which is used in Art. 63. for the combination of Levers.

97. Cor. 5. In a combination of wheels, where the motion is communicated by means of teeth, the axle is called the *pinion*. Since the teeth therefore must be nearly of the same size, both in the wheel and pinion, the number of teeth in each will be as their circumferences, or as their radii; and consequently in the combination mentioned in the preceding corollary, the power will be to the weight, in the case of an equilibrium, as to the product of the number of teeth in all the pinions is to the product of the number of teeth in all the wheels.

Prop. II.

98. In the wheel and axle the velocity of the weight is to the velocity of the power as the power is to the weight.

If the power is made to rise through a space equal to the circumference of the wheel, the weight will evidently describe a space equal to the circumference of the axle. Hence, calling V the velocity of the power, v that of the weight, C the circumference of the wheel, and c that of the axle, we have $V : v = C : c$. But by the proposition $P : W = c : C$ therefore $P : W = v : V$.

Scholium.

99. The construction of the main-spring box of the fusee of a watch round which the chain is coiled, is a beautiful illustration of the principle of the wheel and axle. The spring-box may be considered as the wheel, and the fusee the axle or pinion to which the chain communicates the motion of the box. The power resides in the spring wound round an axis in the centre of the box, and the weight is applied to the lower circumference of the fusee. As the force of the spring is greatest when it is newly wound up, and gradually decreases as it unwinds itself, it is necessary that the fusee should have different radii, so that the chain may act upon the smallest part of the fusee when its force is greatest, and upon the largest part of the fusee when its force is least, for the equable motion of the watch requires that the inequality in the action of the spring should be counteracted so as to produce an uniform effect. In order to accomplish this, the general outline of the surface of the fusee must be an Apollonian hyperbola, in which the ordinates are inversely as their respective abscissæ. For further information on this subject, see *Recherches des Mathemat. par M. Parent*, tom. ii. p. 678.: *Traitè d'Horlogerie, par M. Berthoud*, tom. i. chap. 26.; and *Traitè de Mecanique, par M. de la Hire*, prop. 72. On the fusee of a watch.

Sect. II. *On the Pulley.*

100. Definition.—The pulley is a machine composed of a wheel with a groove in its circumference, and a rope which passes round this groove. The wheel moves on an axis whose extremities are supported on a kind of frame called the block, to which is generally suspended the weight to be raised. A system of pulleys is called a *muffle*, which is either fixed or moveable according as the block which contains the pulley is fixed or moveable. On the pulley.

Prop.

Theory.

Prop. I.

101. In a single pulley, or system of pulleys where the different portions of the rope are parallel to each other, and where one extremity of it is fixed, there is an equilibrium when the power is to the weight as unity is to the number of the portions of the rope which support the weight.

Fig. 12. 102. Case 1. In the single fixed pulley AA let the power P and weight W be equal, and act against each other by means of the rope PBAW, passing over the pulley AA; then it is obvious that whatever force is exerted by P in the direction PBA, the same force must be exerted in the opposite direction WBA, consequently these equal and opposite forces must be in equilibrio; and as the weight is supported only by one rope, the proposition is demonstrated, for P : W = 1 : 1.

Fig. 13. 103. Case 2. In the single moveable pulley, where the rope, fastened at H, goes beneath the moveable pulley D and over the fixed pulley C, the weight to be raised is suspended from the centre of the pulley D by the block *p*, and the power is applied at P in the direction PE. Now it is evident that the portions CF*p*, HGD of the rope sustain the weight W, and as they are equally stretched in every point, each must sustain one half of W; but (Case 1.) in the single pulley C the rope CEP sustains a weight equal to what the rope CF*p* sustains; that is, it sustains one-half of W. Consequently $P=\frac{1}{2}W$, or $W=2P$, when there is an equilibrium; and since the weight W is supported by *two* strings, we have P : W = 1 : 2.

Fig. 14. 15. 104. Case 3. When the same rope passes round a number of pulleys, the ropes which support the weight W are evidently equally stretched in every part, and therefore each of them sustains the same weight. Consequently if there be *ten* ropes supporting the weight, each sustains $\frac{1}{10}$th part of the weight, and therefore $P=\frac{1}{10}W$, or $W=10P$, which gives us P : W = 1 : 10. —The pulley in fig. 15. is the patent pulley invented by Mr White, in which the lateral friction and shaking motion is considerably removed.

Prop. II.

105. In a system of *n* moveable pulleys suspended by separate and parallel ropes, there is an equilibrium when $P : W = 1 : 2^n$; that is, if there are 4 pulleys $n=4$, and $P : W = 1 : 2\times2\times2\times2$, or P : W = 1 : 16.

Fig. 17. This system is represented in fig. 17. where the rope which carries the power P passes over the fixed pulley M, and beneath the moveable pulley A, to the hook E where it is fixed. Another rope fixed at A passes over B and is fixed at F, and so on with the rest. Then by Art. 103.

P : the weight at A = 1 : 2
The weight at A : the weight at B = 1 : 2
The weight at B : the weight at C = 1 : 2
The weight at C : the weight at D or W = 1 : 2; and therefore by composition
$P : W = 1 : 2\times2\times2\times2$ or P : W = 1 : 16. Q. E. D.

Prop. III.

106. In a system of moveable pulleys whose number is *n*, suspended by separate and parallel ropes, whose extremities are fixed to the weight W, there is an equilibrium when $P : W : 1 : 2^n - 1$.

In this systemof pulleys, the rope which sustains the Fig. 18. power P passes over the pulley C, and is fixed to the weight at D. Another rope attached to the pulley C passes over the pulley B and is fixed to the weight at E, and a third rope fastened to B passes over A and is fixed at F. Then it is manifest that the rope CD sustains a weight equal to P; and since the pulley C is pulled downward with a weight equal to 2P, the rope BC must support a weight equal to 2P, and the rope B the same weight; consequently the rope AB sustains 4P. The whole weight therefore is $P+2P+4P$; and hence $P : W = P : P+2P+4P$, or $P : W = 1 : 1+2+4$ &c. to *n* terms, so that $P : W = 1 : 2^n - 1$.

Prop. IV.

107. In the system of pulleys represented in Fig. 19. fig. 19. and called a Spanish barton, in which two pulleys are supported by one rope, there is an equilibrium when P : W = 1 : 4.

In this combination of pulleys, the rope AB which supports the power P passes over the moveable pulley A, and beneath C towards H, where it is fixed. Another rope, attached to the pulley A, passes over the fixed pulley B, and is fastened at E to the pulley C, which supports the weight W. Then, since the rope AP supports 1 pound, the rope AC also supports 1 pound, and therefore the pulley A, or the rope BA, is pulled down with a force of 2 pounds. But the rope BDE is equally stretched with BA, consequently the pulley C, to which DE is attached, is pulled upwards with a force of 2 pounds. Now the rope AC supporting 1 pound, the rope GH must likewise support 1 pound, consequently, since DE sustains 2 pounds, AC 1 pound, and HG 1 pound, they will together sustain W=4 pounds, and therefore P : W = 1 : 4.

Prop. V.

108. In the system of pulleys represented in fig. Fig. 20. 20. called a Spanish barton, where two pulleys are supported by one rope, there is an equilibrium when P : W = 1 : 5.

In this system the rope PB passes over B round C, and is fixed at E. Another rope attached to B passes round AF and is fixed at I to the pulley CD, which carries the weight W. Now the rope BP being stretched with a force of 1 pound, the ropes BGC, CDE are also stretched with a force of 1 pound each, and the pulley CD is pulled upwards with a force of 2 pounds. But since the three ropes BP, ED, and GC, are each stretched with a force of 1 pound, the pulley B and the rope BA, upon which they all act in one direction, must be pulled down with a force of 3 pounds. Now the rope FI is equally stretched with BA, consequently it will draw the pulley CD upwards with a force of 3 pounds, Theory. pounds, and since it is drawn upwards by the ropes CG, DF, with a force of two pounds, the whole force will sustain $W=5$ pounds; but this force of 5 pounds is by the hypothesis in equilibrio with P or 1 pound, consequently $P : W = 1 : 5$.

Prop. VI.

Plate CCCXIX. fig. 1. 109. **When the ropes are not parallel, and when two powers are in equilibrio with a weight by means of a pulley, and have their directions at equal angles to the direction of the weight, each of these powers is to the weight as the radius of the pulley is to the chord of that portion of the pulley's circumference with which the rope is in contact.**

Let the weight W suspended from C be sustained in equilibrio by two powers, P, p, which act by a rope PCFEp passing over the pulley CHEF, and touching the arch CFE of its circumference. Then since the angles PWD, pWD are equal, and the powers P, p in equilibrio, P must be equal to p; and making WA $=$WB, and drawing AI parallel to PW, and BI parallel to pW; WB, BI, WI will respectively represent the forces P, p, W or $P : p : W = WB : BI : WI$, Dynamics, Art. 144. Now the triangles WBI, BDE having their respectives sides at right angles to each other, are similar; consequently $WB : BI : WI = CD : DE : EC$, that is, $P : p : W = CD : DE : EC$; but CD, DE are equal to radius, and EC is obviously the chord of the arch CFE, therefore P : W or p : W as radius is to the chord of the arch with which the rope is in contact.

110. Cor. 1. Any of the powers is also to the weight as radius is to twice the cosine of the angle which either rope makes with the direction of the weight. For since CG is the cosine of DCG, and since CE is double of CG, CE is equal to 2 cosine DCG $=2$ Cos. PWD; but $P : W = CD : CE$, hence we have by substituting the preceding value of CE, $P : W = CD$ or radius : 2 Cos. PWD.

Scholium.

111. By means of this proposition and corollary, the proportion between the powers and the weight in the various systems of pulleys, represented in fig. 12, 13, 14, 15, 16, 17, 18, 19, 20. when the ropes are not parallel, may be easily found.

Prop. VII.

112. **In a system of moveable pulleys, where each has a separate rope, and where the ropes are not parallel, there is an equilibrium when the power is to the weight as radius is to the cosines of half the angles made by the rope of each pulley, multiplied into that power of 2 whose exponent is the number of pulleys.**

Fig. 2. Let the power P sustain the weight W by means of the pulleys A, B, C; let P, p, π be the different powers which support the pulleys, A, B, C, and let MAP, NBA, RCB be the angles formed by the ropes. Then, by the last proposition,

$$P : p = \text{rad.} : 2 \cos. MAP$$
$$p : \pi = \text{rad.} : 2 \cos. NBA$$
$$\pi : W = \text{rad.} : 2 \cos. RCB, \text{ consequently}$$ Theory.
$$P : W = \text{rad.} : \overline{2 \cos. MAP \times 2 \cos. NBA \times 2 \cos. RCB},$$

or, which is the same thing,

$$P : W = \text{rad.} : \overline{2 \times 2 \times 2} \times \cos. MAP \times \cos. NBA \times \cos. RCB.$$

Prop. VIII.

113. **In a single pulley, or in a combination of pulleys, the velocity of the power is to the velocity of the weight as the weight is to the power.**

114. Case 1. In the single fixed pulley, it is obvious, that if the weight W is raised uniformly one inch, the power D will also describe one inch, consequently velocity of P : velocity of $W = W : P$. Fig. 12.

115. Case 2. In the single moveable pulley, when the weight W is raised one inch, the ropes become one inch shorter; and since the rope has always the same weight, the power must describe two inches, therefore velocity P : velocity $W = W : P$. Fig. 13.

116. Case 3. In the combination of pulleys, in figs. 14, 15, 16, when the weight rises one inch, each of the four strings becomes an inch shorter, so that P must describe four inches, as the length of the rope is invariable; consequently velocity P : velocity $W = W : P$. Figs. 14, 16.

117. Case 4. In the system exhibited in fig. 17. it is evident, that when the weight W rises one inch, the rope DC is lengthened two inches, the rope CB four inches, the rope BA eight inches, and the rope AFP, to which the power is suspended, 16 inches; so that since the power of this pulley is as 16 to 1, we have velocity P : velocity $W = W : P$. Fig. 17.

118. Case 5. In the combination of pulleys, represented in fig. 18. when the weight W rises one inch, all the three ropes CD, BE, AF are each shortened one inch. But while CD shortens one inch, CP becomes *one inch longer*; while BE shortens one inch, BC becomes one inch longer, and CP *two inches* longer (art. 110.); and while AF shortens one inch, AB becomes one inch longer, BC two inches longer, and CP *four inches* longer; therefore CP is lengthened altogether seven inches, and as the power of the pulley is as 7 to 1, we have, as before, velocity P : velocity $W = W : P$. Fig. 18.

119. Case 6. In the system of pulleys called the Spanish barton, fig. 19. when the weight W rises one inch, the three ropes AC, DE, HG are each shortened one inch. By the shortening HG, CA one inch each, the rope AP is lengthened *two inches;* and by the shortening of DE one inch, BA is lengthened one inch, and AP *two inches* (art. 115.); consequently since AP is lengthened in all four inches, and since the power of the pulleys is four, we have velocity P : velocity $W = W : P$. Fig. 19.

120. Case 7. In the other Spanish barton, in fig. 20. when the weight is elevated one inch, the three ropes DE, IF, CG are each one inch shorter. While ED, and CG shorten one inch each, BP is lengthened *two inches,* Fig. 20.

Theory.

inches, and while IF becomes one inch shorter, AB becomes one inch longer; but when AB is lengthened one inch, BP becomes one inch longer, and ED, CG one inch shorter each, and by this shortening of ED, CG, the rope B is lengthened two inches, therefore, since the rope BP is lengthened altogether five inches, and since the pulleys have a power of five, we have, as formerly, velocity P : velocity W=W : P.

Sect. III. *On the Wedge.*

121. Definition. A wedge is a machine composed of two inclined planes with their bases in contact; or, more properly, it is a triangular prism, generated by the motion of a triangle, parallel to itself, along a straight line passing through the vertex of one of its angles. The wedge is called *isosceles*, *rectangular*, or *scalene*, according as the triangle ABC by which the wedge is generated, is an isosceles, a rectangular or a scalene triangle. The part AB is called the head or back of the wedge, DC its altitude, and AC, BC its faces.—The wedge is generally employed for cleaving wood, or for quarrying stones; but all cutting instruments, such as knives, swords, chisels, teeth, &c. properly belong to this mechanical power, when they act in a direction at right angles to the cutting surface; for when they act obliquely, in which case their power is increased, their operation resembles more the action of a saw.

Plate CCXIX. fig. 3.

Prop. I.

122. If each of the faces of an isosceles wedge, which are perfectly smooth, meet with an equal resistance from forces acting at equal angles of inclination to their faces, and if a power act perpendicularly upon the back, these forces will be in equilibrio, when the power upon the back is to the sum of the resistances upon the sides, as the sine of half the angle of the wedge, multiplied by the sine of the angle at which the resisting forces act upon its faces, is to the square of radius.

Fig. 3.

Let ABC be the wedge, AC, BC its acting faces, and MD, ND the directions in which the resisting forces act upon these faces, forming with them the equal angles DMA, DNB. Draw CD, DF, DE at right angles to three sides of the wedge, and join F, E meeting CD in G. On account of the equal triangles CAD, CDB (Euclid, Book i. Prop. 26.) AD=DB; and in the equal triangles ADM, BDN, MD=ND. In the same way DF=DE and AF=BE, therefore CF=CE. But in the triangles CFG, CEG there are two sides FC, CG equal to EC,CG, and the angle FCG=ECG, consequently FG=GE, and FGC, ABC are both right angles, therefore FE is parallel to AB.—Now the force MD is resolvable into DF, FM, of which FM has no effect upon the wedge. But, as the effective force FD is not in direct opposition to the perpendicular force exerted on the back of the wedge, we may resolve it into the two forces FG, GD, of which GD acts in direct opposition to the power, while FG acts in a direction parallel to the back of the wedge. In the same way it may be shewn that EG, GD are the only effective forces which result from the force ND. But the forces FG, EG being equal and opposite, destroy each other; consequently 2GD is the force which opposes that which is excited upon the back of the wedge, and the wedge will be kept at rest if the force upon the back is equal to 2GD, that is, when the force upon the back is to the sum of the resistances upon the faces as 2GD is to MD+ND, or as 2GD : 2DM, or as GD is to DM. Now

DG : DF=sin. DFG : radius, or as (Euclid, vi. 8.) sin. DCF : radius, and
DF : MD=sin. DMF : radius; therefore by composition,
DG : MD=sin. DCF × sin. DMF : rad. × rad. or $\overline{\text{rad.}}|^2$. But, DG : MD as the force upon the back is to the sum of the resistances, therefore the force upon the back is to the sum of the resistances, as sin. DCF × sin. DMF is to the square of the radius.

Corollaries.

123. Cor. 1. If the direction of the resisting forces is perpendicular to the faces of the wedge, DMF becomes a right angle, and therefore its sine is equal to radius. Consequently we have, in this case, the force upon the back to the sum of the resistances, as sin. DCF × rad. is to $\overline{\text{radius}}|^2$, that is, as sin DCF is to radius, or as AD half the back of the wedge is to AC the length of the wedge.

124. Cor. 2. In the particular case in the proposition, it is obvious that the forces MF, NE are not opposed by any other forces, and therefore the force upon the back will not sustain the resisting forces; but in the case in cor. 2. the forces MF, NE vanish, and therefore the other forces will sustain each other.

125. Cor. 3. If the resisting forces act in a direction perpendicular to AB, the angle DMF becomes equal to ACD, and therefore the force upon the back is to the sum of the resistances as sin. $\overline{\text{ACD}}|^2$ is to $\overline{\text{radius}}|^2$, that is, as the square of AD half the back of the wedge is to the square of AC the length of the wedge.

126. Cor. 4. When the direction of the resistances is parallel to the back of the wedge, the angle of inclination DMC becomes the complement of the semi-angle of the wedge, and therefore the force upon the back is to the sum of the resistances as the sin. ACD × cos. ACD is to the square of the radius, that is, as DA × DC is to $\overline{\text{AC}}^2$. But in the similar triangles DAF, DAC, we have DF : DA=DC : AC, and DF × AC=DA × DC, consequently the force upon the back of the wedge is to the sum of the resistances as DF × AC is to $\overline{\text{AC}}^2$, that is, as DF : AC.

Prop. II.

127. If, on account of the friction of the wedge, or any other cause, the resistances are wholly effective, that is, if the resisting surfaces adhere to the places to which they are applied without sliding, there will be an equilibrium, when the force upon the back is to the sum of the resistances, as the sine of the acute angle which the direction of the resisting forces makes with the back of the wedge is to radius. Fig. 3.

Join MN, which will cut DC perpendicularly at the point

Theory. point H. Then, since the forces MD, ND are resolvable into MH, HD and into NH, HD, and since MH, HN destroy each other, the force upon the back is sustained by 2 HD. Consequently, the force upon the back is to the sum of the resistances as 2 HD is to 2 MD, or as HD is to MD. But the angle ADM, which the direction of the forces makes with the back of the wedge, is equal to DMN, and HD is the sine of that angle, MD being radius, therefore the force upon the back is to the sum of the resistances as sin. ADM : radius. Q. E. D.

Corollaries. 128. Cor. 1. Since the angle AMD=MDC+MCD, the angle MDC is the difference between MCD the semiangle of the wedge, and AMD the angle which the direction of the resisting forces makes with the face of the wedge, and since HD is the cosine of that angle, MD being radius, we have the force upon the back to the sum of the resistances, as the cosine of the difference between the semiangle of the wedge and the angle which the direction of the resisting forces makes with the face of the wedge, is to radius.

Prop. III.

129. When there is an equilibrium between three forces acting perpendicularly upon the sides of a wedge of any form, the forces are to one another as the sides of the wedge.

This is obvious from Dynamics, § 144. Cor. 2. where it is shewn that when three forces are in equilibrio, they are proportional to the sides of a triangle, which are respectively perpendicular to their directions.

Prop. IV.

130. When the power acting upon the back of a wedge is in equilibrio with the resistances opposed to it, the velocity of the power is to the velocity of the resistance as the resistance is to the power.

Fig. 3. Produce DM to K, and draw CK perpendicular to DK. Then, by Art. 122. the power is to the resistance as MD : DH. Let the wedge be moved uniformly from D to C, and DK is the space uniformly described by the resisting force in the direction in which it acts; therefore, the velocity of the power is to the velocity of the resistance as DC : DK; that is, on account of the equiangular triangles DHM, DKC, as MD : DH; that is, as the resistance is to the power.

Sect. IV. *On the Screw.*

131. Definition. A screw is a cylinder with an inclined plane wrapped round it, in such a manner, that the surface of the plane is oblique to the axis of the cylinder, and forms the same angle with it in every part of the cylindrical surface. When the inclined plane winds round the exterior surface of a solid cylinder, it is called a male screw; but when it is fixed on the interior circumference of a cylindrical tube, it is called a female screw. In the female screw, the spiral grooves formed by the inclined plane on the surface of the cylindrical tube, must be equal in breadth to the inclined plane in the male screw, in order that the one may move freely in the other. By attending to the mode in which the spiral threads are formed by the circumvolution of the inclined plane, it will appear, that if one complete revolution of the inclined plane is developed, its altitude will be to its base as the distance between the threads is to the circumference of the screw. Thus, let $a\,b\,c$ (fig. 4.) be the inclined plane, whose base is $a\,c$ and altitude $b\,c$, and let it be wrapped round the cylinder MN (fig. 5.) of such a size that the points a, c may coincide. The surface $a\,b$ of the plane (fig. 4.) will evidently form the spiral thread $a\,d\,e\,b$ (fig. 5.), and ab the distance between the threads will be equal to $b\,c$ (fig. 4.) the altitude of the plane, and the circumference of the screw MN will be equal to $a\,c$ the base of the plane. If any body, therefore, is made to rise along the plane $a\,d\,e\,b$ in fig. 5. or along the spiral thread of the screw, by a force acting in a direction parallel to $a\,d\,c\,b$, there will be the same proportion between the power and the resistance as if the body ascended the plane $a\,b\,c$ (fig. 4.). Fig. 4

132. A male screw with triangular threads is represented by AB (fig. 6.), and its corresponding female screw by AB (fig. 7.). A male screw with quadrangular threads is exhibited in fig. 8. and the female screw in which it works in fig. 9. The friction is considerably less in quadrangular than in triangular threads, though, when the screw is made of wood, the triangular threads should be preferred. When the screws are metallic and large, the threads should be quadrangular; but the triangular form is preferable in small screws. When the screw is employed in practice, the power is always applied to the extremity of a lever fixed in its head. This is shewn in fig. 10. where AB is the lever acting upon the screw BC, which works in a female screw in the block F, and exerts its force in bending the spring CD. Fig. 6, 7. Fig. 8, 9. Fig. 10.

Prop. I.

133. If the screw is employed to overcome any resistance, there will be an equilibrium when the power is to the resistance as the distance between two adjacent threads is to the circumference described by the power.

Let FAK be a section of the screw represented in fig. 8. perpendicular to its axis; CD a portion of the inclined plane which forms the spiral thread, and P the power, which, when applied at C in the plane ACF, will be in equilibrium with a weight upon the inclined plane CD. Then, in the inclined plane, when the direction of the power is parallel to the base, we have (Art. 72.) P : W, as the altitude of the plane is to the base, or (Art. 131.) as the distance between two threads is to the whole circumference FKCF. If we suppose another power P′ to act at the end of the lever AB, and describe the arch HBG, and that this power produces the same effect at B as the power P did at C, then (Art. 36.), we have P′ : P=CA : BA, that is, as FKCF is to the circumference HBG; but it was shewn before, that P : W=as the distance between two contiguous threads is to FKCF; therefore, by composition, P′ : W as the distance between two threads is to HBG or the circumference of a circle whose radius is AB. Q. E. D. Fig. 11.

134. Cor. 1. It is evident from the proposition that the

Theory.

the power does not in the least depend upon the size of the cylinder FCK, but that it increases with the distance of that point from the centre A, to which the power is applied, and also with the shortness of the distance between the threads. Therefore, if P, p be the powers applied to two different screws, D, d the distances of these powers from the axis, and T, t the distances between the threads; their energy in overcoming a given resistance will be directly as their distances from the axis, and inversely as the distances of their threads, that is, $P:p=\frac{D}{T}:\frac{d}{t}$, or P varies as $\frac{D}{T}$.

Prop. II.

135. In the endless screw, there will be an equilibrium when the power is to the weight, as the distance of the threads multiplied by the radius of the axle, is to the distance of the power from the axis of the screw multiplied by the radius of the wheel.

Fig. 12.

The endless screw, which is represented in fig. 12. consists of a screw EF, so combined with the wheel and axle ABC, that the threads of the screw may work in teeth fixed in the periphery of the wheel, and thus communicate the power exerted at the handles or winches P, p. Let W′ represent the power produced by the screw at the circumference of the wheel; then, by the last proposition, P : W′ as the distance between the threads is to the distance of P from the axis of the screw; but (Art. 92.) in the wheel and axle W′ : W as the radius of the axle is to the radius of the wheel; therefore, by composition, P : W as the distances of the threads multiplied by the radius of the axle C, is to the distance of the power P from the axis multiplied by the radius of the wheel AB.

Prop. III.

136. When there is an equilibrium in the screw, the velocity of the weight is to the velocity of the power, as the power is to the weight.

Fig. 11.

It is obvious from fig. 11. that while the power describes the circumference of the circle HBG uniformly, the weight uniformly rises through a space equal to the distance between two adjacent threads; therefore, the velocity of the power is to the velocity of the weight as the distance between the threads is to the arch described by the power, that is, (by Art. 133.), as the weight is to the power.

Prop. IV.

137. To explain the construction and advantages of Mr Hunter's double screw *.

See *Phil. Trans.* vol. lxxi. p. 58.

Fig. 13.

Let the screw CD work in the plate of metal BA, and have n threads in an inch: the cylinder CD, of which this screw is formed, is a hollow tube, which is also formed into a screw, having $\overline{n+1}$ threads in an inch, and into this female screw is introduced a male screw DE, having, of course, $\overline{n+1}$ threads in an inch. The screw DE is prevented from moving round with CD by the frame ABGF and the cross bar $a\ b$, but is permitted to ascend and descend without a motion of rotation. Then, by a revolution of the screw CD, the other screw DE will rise through a space equal to $\frac{1}{\overline{n+1}\times n}$, and if the circumference described by the lever CK be m inches, we shall have $P:W=\frac{1}{\overline{n+1}\times n}:m$; or $P:W=1:mn\times\overline{n+1}$.

138. This reasoning will be more perspicuous by supposing n, or the number of threads in CD, to be 12, and $n+1$, or the number of threads in DE, will consequently be 13. Let us suppose that the handlo CK is turned round 12 times, the screw CD will evidently ascend through the space of an inch, and if the screw DE is permitted to have a motion of rotation along with CD, it will also advance an inch. Let the screw DE be now moved backwards by 12 revolutions, it will evidently describe a space of $\frac{12}{13}$ of an inch, and the consequence of both these motions will be that the point E is advanced $\frac{1}{13}$ of an inch. But, since DE is prevented from moving round with CD, the same effect will be produced as if it had moved 12 times round with CD, and had been turned 12 times backwards; that is, it will in both cases have advanced $\frac{1}{13}$ of an inch. Since, therefore, it has advanced $\frac{1}{13}$ of an inch in 12 turns, it will describe only $\frac{1}{12}$ of $\frac{1}{13}$, or $\frac{1}{156}$ of an inch uniformly at one turn; but if the length of the lever CK is 8 inches, its extremity K will describe, in the same time, a space equal to $16\times3.1416=50.2656$ inches, the circumference of the circle described by K; therefore the velocity of the weight is to the velocity of the power, as $\frac{1}{156}$ of an inch is to 50.2656 inches, or as 1 is to 7841.4336, that is, (Art. 136.) P : W $=1:7841.4336$. Hence the force of this double screw is much greater than that of the common screw, for a common one with a lever 8 inches long must have 156 threads in an inch to give the same power, which would render it too weak to overcome any considerable resistance.

139. Mr Hunter proposes * to connect with his double screws, a wheel and a lantern, which are put in motion by a winch or handle. The power of this compound machine is so great, that a man, by exerting a force of 32 pounds at the winch, will produce an effect of 172100 pounds; and if we suppose $\frac{2}{3}$ of this effect to be destroyed by friction, there will remain an effect of 57600 pounds.—In some screws it would be advantageous, instead of perforating the male screw CD, to have two cylindrical screws of different kinds at different parts of the same axis.

* *Phil. Trans.* vol. lxxi. p. 65.

Scholium.

140. The screw is of extensive use as a mechanical power, when a very great pressure is required, and is very successfully employed in the printing press. In the press which is used for coining money, the power of the screw is advantageously combined with an impulsive force, which is conveyed to the screw by the intervention of a lever. The screw is also employed for raising water, in which form it is called the screw of Archimedes (Hydrodynamics, § 328); and it has been lately employed in the flour mills in America for pushing the flour which comes from the millstones, to the end of a long trough, from which it is conveyed to other parts of

Theory. of the machinery, in order to undergo the remaining processes. In this case, the spiral threads are very large in proportion to the cylinder on which they are fixed.

141. As the lever attached to the extremity of the screw moves through a very great space when compared with the velocity of its other extremity, or of any body which it puts in motion; the screw is of immense use in subdividing any space into a great number of minute parts. Hence it is employed in the engines for dividing mathematical instruments, and in those which have been recently used in the art of engraving. It is likewise of great use in the common wire micrometer, and in the divided object-glass micrometer, instruments to which the science of astronomy has been under great obligations. See Micrometer.

Sect. V. *On the Balance.*

Plate CCCXX. Fig. 1. 142. Definition. The balance, in a mathematical sense, is a lever of equal arms, for determining the weights of bodies.—The physical balance is represented in fig. 1. where FA, FB are the equal arms of the balance, F its centre of motion situated a little above the centre of gravity of the arms, FD the handle which always retains a vertical position, P, W the scales suspended from the points A, B, and CF the tongue or index of the balance, which is exactly perpendicular to the beam AB, and is continued below the centre of motion, so that the momentum of the part below F is equal and opposite to the momentum of that part which is above it. Since the handle FD, suspended by the hook H, must hang in a vertical line, the tongue CF will also be vertical when its position coincides with that of FD, and consequently the beam AB, which is perpendicular to CF, must be horizontal. When this happens, the weights in the scale are evidently equal. Theory.

Prop. I.

143. To determine the conditions of equilibrium in a physical balance.

Let AOB be the beam, whose weight is S, and let P, Q be equal weights expressed by the letter p, and placed in the scales, whose weights are L and l. Let O be the centre of motion, and g the centre of gravity of the whole beam, when unloaded; we shall have in the case of an equilibrium, Fig. 2.

I. $\overline{p+L}\times AC=\overline{p+l}\times BC+\overline{S\times Cc}$; for since S is the weight of the beam and g its centre of gravity, its mechanical energy in acting against the weights $p+L$ is $=S\times Cc$, the distance of its centre of gravity from the vertical line passing through the centre of motion O.

II. But since $AC=BC$; $p\times\overline{AC}-p\times BC=0$. Then, after transposition, take this from the equation in N° I. and we shall have,

III. $l\times BC-L\times AC+S\times Cc$; or $L-l=\frac{S\times Cc}{AC}$.

Let us now suppose that a small weight w is placed in the scale L, the line AB which joins the points of suspension will be no longer horizontal, but will assume an inclined position. Let $BA\lambda=\varphi$ be the angle which the beam makes with the direction of gravity. Then by resolving the weight of the beam which acts in the direction O z, the parts $\frac{OG}{Og}$ and $\frac{Gg}{Og}$ will be in equilibrio, and we shall have,

$$\text{IV. } \overline{p+L}\times AO\times\text{Sin.}\,\lambda AO+S\times OG\times\text{Sin.}\,\varphi=\overline{p+l+w}\times BO\times\text{Sin. }ABO+S\times Cc\times\text{Cos.}\,\varphi.$$

But since the sines and cosines of any angles, are the same as the sines and cosines of their supplement, we have,

$$\text{V. } \overline{p+L}\times\overline{AC\times\text{Cos.}\varphi-Oc\times\text{Sin.}\varphi}+S\times OG\times\text{Sin.}\varphi=\overline{p+l+w}\times\overline{AC\times\text{Cos.}\varphi+OC\times\text{Sin.}\varphi}+S\times Cc\times\text{Cos.}\varphi.$$

Hence by N° III. we have,

$$\text{VI. Tang.}\,\varphi=\frac{w\times AC}{\overline{2p+L+l+w}\times OC+S\times OG}$$

But the force v, with which the balance attempts to recover its horizontal situation, is the excess of momenta with which one arm is moved, above the momenta with which the other arm is moved, therefore

$$v=\overline{2p+L+l}\times OC\times\text{Sin.}\varphi+S\times OG\times\text{Sin.}\varphi.$$

144. A more extended illustration of these conditions of equilibrium will be found in an excellent paper by Euler, published in the *Comment. Petropol.* tom. x. p. 1. and in another memoir upon the same subject by Kuhne in the *Versuche der naturforchende gesellchhaft* in Dantzig, tom. i. p. 1.—See also Hennert's *Cursus Matheseos applicatæ*, tom. i. § 123. From the preceding formulæ, the following practical corollaries may be deduced.

145. Cor. 1. The arms of the balance must be exactly equal in length, which is known by changing the weights in the scales; for if the equilibrium continues, the arms must be equal.

146. Cor. 2. The sensibility of the balance increases with the length of the arms.

147. Cor. 3. If the centre of motion coincides with the point C and the centre of gravity, the balance will be in equilibrio in any position, and the smallest weight added to one of the scales will bring the beam into a horizontal position. The centre of motion, therefore, should not coincide with the centre of gravity.

148. Cor. 4. If the centre of motion is in the line which joins the points of suspension, the accuracy of the balance will be increased. The excess of the weights may be easily determined by the inclination of the beam, pointed out by the tongue or index upon a circular arch fixed to the handle, or more accurately by means of two divided arches fixed near the points of suspension, on a stand independent of the balance. When the value of one of these divisions is determined experimentally, the rest are easily found, being proportional to the tangents of the inclination of the beam.

heory.

149. COR. 5. The sensibility of the balance will increase, the nearer that the centre of gravity approaches to the centre of motion.

150. COR. 6. If the centre of gravity is above the centre of motion, the balance is useless.

SCHOLIUM.

151. A balance with all the properties mentioned in the preceding corollaries, has been invented by M. Kuhne, and described in the work already quoted (Art. 144.). It is so contrived that the points of suspension may be placed either above the centre of motion or below it, or in the line of its axis: the beam is furnished with an index, which points out the proportion of the weights upon a divided scale, and the friction of the axis is diminished by the application of friction wheels.

hne's ance.

152. In order to get rid of the difficulties which attend the construction of the tongue, the handle, and the arms of the balance, M. Magellan invented a very accurate and moveable one, in which there is no handle, and where one of the arms acts as a tongue. The body to be weighed and the counterpoise are placed in the same scale, so that it is of little consequence whether the arms of the balance are equal or not. In this balance the centre of motion can be moved to the smallest distance from the centre of gravity. See *Journal de Physique*, Jan. 1781. tom. xvii. p. 43.

gellan's ance.

153. The balance invented by Ludlam, and described in the Philosophical Transactions for 1765, N° 55. depends upon Æpinus's property of the lever, which we have explained in Art 65. The angular lever AFB, in which AF=FB, is moveable round f, which is equidistant from A and B. The weight P is suspended by a thread from A, and the body W, which is to be weighed, is suspended by a thread from B. Hence it is obvious, that with different bodies the lever AFB will have different degrees of inclination, and the index or tongue LFf, which is perpendicular to AB, will form different angles ZFL, bFf with the line of direction ZFb. Now, by Art. 57. and by substituting for bB, bA the sines of the angles FbB, FbA, to which they are proportional, and also by taking instead of FbB the difference of the angles fFB, fFb, and instead of AFb, the sum of these angles, we shall have

dlam's lance. Plate CXVIII. fig. 3.

$$\text{Tang}, fFb=\frac{P-W}{P+W}\times\text{Tang.}\frac{AFB}{2},$$

whence, by transposition, and by GEOMETRY, Theor. VIII. Sect. IV.

$$\overline{P+W}:\overline{P-W}=\text{Tang.}\frac{AFB}{2}:\text{Tang.}\,fFb.$$

Hence, when the angle formed by the arms of the balance, and the angle of aberration fFb or ZFL, are known, the weights may be found, and *vice versa*.

CHAP. IV. *On the centre of Inertia, or Gravity.*

154. DEFINITION.—The centre of inertia, or the centre of gravity, of any body or system of bodies, is that point upon which the body or system of bodies, when influenced only by the force of gravity, will be in equilibrio in every position. The centre of inertia of plane surfaces bounded by right lines, and also of some solids may be easily determined by the common geometry. The application of the method of fluxions, however, to this branch of mechanics is so simple and beautiful, that we shall also avail ourselves of its assistance. The centre of gravity has been called, by some writers, the centre of position, and by others, the centre of mean distances.

Theory.

PROP. I.

155. To find the centre of inertia of any number of bodies, whatever be their position.

Let ABCD be any number of bodies influenced by the force of gravity. Suppose the bodies A, B connected by the inflexible line AB considered as devoid of weight, then find a point F, so that the weight of A : the weight of B=BF : FA. The bodies A, B will therefore be in equilibrio about the point F in every position (Art. 36.), and the pressure upon F will be equal to A+B. Join FC, and find the point f, so that A+B : C=Cf : fF; the bodies A, B, C, will consequently be in equilibrio upon the point f, which will sustain a pressure equal to A+B+C. Join Df, and take the point φ, so that A+B+C : D=φD : φf; the bodies A, B, C, D will therefore be in equilibrio about the point φ, which will be their common centre of inertia, and which supports a weight equal to A+B +C+D. In the same manner we may find the centre of inertia of any system of bodies, by merely connecting the last fulcrum with the next body by an inflexible right line, and finding a new fulcrum from the magnitude of the opposite weights which it is to sustain. Fig. 4.

156. COR. 1. If the weights of the bodies A, B, C, D be increased or diminished in a given ratio, the centre of inertia of the system will not be changed, for the positions of the points F, f, φ are determined by the relative and not by the absolute weights of the bodies.

157. COR. 2. A motion of rotation cannot be communicated to a body by means of a force acting upon its centre of inertia; for the resistances which the inertia of each particle opposes to the communication of motion act in parallel directions, and as they are proportional to the weights of the particles, they will be in equilibrio about the centre of gravity.

PROP. II.

158. To find the centre of inertia of any number of bodies placed in a straight line.

Let A, B, C, D, E be any number of bodies whose common centre of gravity is φ. In the straight line AE take any point X. Then since all the bodies are in equilibrio about their common centre of gravity φ, we have by the property of the lever (Art. 36.) $\overline{A\times A\varphi}+\overline{B\times B\varphi}=C\times C\varphi+\overline{D+D\varphi}+\overline{E\times E\varphi}$; but since $X\varphi-XA=A\varphi$, and $X\varphi-XB=B\varphi$, and so on with the rest, we have by substitution $A\times\overline{X\varphi-XA}+B\times\overline{X\varphi-XB}=C\times\overline{X\varphi-XC}+D\times\overline{X\varphi-XD}+E\times\overline{X\varphi-XE}$. Hence, by multiplying and transposing, we obtain $\overline{A\times X\varphi}+\overline{B\times X\varphi}+\overline{C\times X\varphi}+\overline{D\times X\varphi}+E\times X\varphi=\overline{A\times XA}+\overline{B\times XB}+\overline{C\times XC}+\overline{D\times XD}+E\times XE$, then dividing by A+B+C+D+E, we have Fig. 5.

Xφ

$$X\varphi = \frac{\overline{A\times XA}+\overline{B\times XB}+\overline{C\times XC}+\overline{D\times XD}+\overline{E\times XE}}{A+B+C+D+E}.$$

Now $A\times XA$, $B\times XB$, &c. are evidently the momenta of the bodies A, B, &c. and the divisor $A+B+C+D+E$ is the sum of the weights of all the bodies; therefore the distance of the point X from the centre of gravity φ is equal to the sum of the momenta of all the weights divided by the sum of the weights.

159. Cor. 1. If the point X had been taken between A and E, at x for example, then the quantity $A\times XA$ would have been reckoned negative, as lying on a different side of the point X.

160. Cor. 2. From this proposition we may deduce a general rule for finding the centre of gravity in any body or system of bodies. Let any point be assumed at the extremity of the system, then the product of the momenta of all the bodies, (or the product arising from the continual multiplication of each body by its distance from the point), divided by the sum of the weights of all the bodies, will be a quotient which expresses the distance of the centre of gravity from the point assumed.

Prop. III.

161. If, in a system of bodies, a perpendicular be let fall from each upon a given plane, the sum of the products of each body multiplied by its perpendicular distance from the plane, is equal to the sum of all the bodies multiplied by the perpendicular distance of their common centre of inertia from the given plane.

Fig. 6. Let A, B, C be the bodies which compose the system, and MN the given plane; by Art. 155. find F the centre of inertia of A and B, and G the centre of gravity of the three bodies; and from A, F, B, G, C draw Aa, Ff, Bb, Gg, Cc perpendicular to the plane MN. Through F draw xFy, meeting Aa produced in x, and Bb in y, then in the similar triangles AxF, ByF, we have $Ax : By = AF : BF$, that is, (Art. 155.) as $B : A$, hence $A\times Ax = B\times By$, that is, $A\times\overline{xa-Aa} = B\times\overline{Bb-yb}$, or on account of the equality of the lines xa, Ff, Bb; $A\times\overline{Ff-Aa} = B\times\overline{Bb-Ff}$, therefore, by multiplying and transposing, we have $\overline{A+B}\times Ff = \overline{A\times Aa}+\overline{B\times Bb}$. In the very same way, by drawing wGz parallel to the plane, it may be shewn that $\overline{A+B+C}\times Gg = A\times Aa + B\times Bb + C\times Cc$. Q. E. D.

162. Cor. By dividing by $A+B+C$ we have

$$G = \frac{\overline{A\times Aa}+\overline{B\times Bb}+\overline{C\times Cc}}{A+B+C}.$$

Prop. IV.

163. To find the centre of inertia of a straight line, composed of material particles.

If we consider the straight line as composed of a number of material particles of the same size and density, it is evident that its centre of inertia will be a point in the line equidistant from its extremities. For if we regard the line as a lever supported upon its middle point as a fulerum, it will evidently be in equilibrio, in every position, as the number of particles or weights on each side of the fulcrum is equal.

Prop. V.

164. To find the centre of inertia of a parallelogram.

Let ABCD be a parallelogram of uniform density, bisect AB in F, and having drawn Ff parallel to AC or BD, bisect it in φ; the point φ will be the centre of inertia of the parallelogram. The parallelogram may be regarded as composed of lines AB, ab parallel to one another, and consisting of material particles of the same size and density. Now, by Art. 155. the centre of inertia of AB is F, and the centre of inertia of ab is c; and in the same way it may be shewn that the centre of inertia, of every line of which the surface is composed, lies in the line Ff. But Ff may be considered as composed of a number of material particles of uniform density, each being equal in weight to the particles in the line AB, therefore by Art. 165. its centre of inertia will be in φ, its middle point. Fig. 7.

Prop. VI.

165. To find the centre of inertia of a triangle.

Let ABC be a triangle of uniform density, and let AB, BC be bisected in the points E, D. Join CE, AD, and the point of intersection F shall be the centre of inertia of the triangle ABC. The triangle may be considered as composed of a number of parallel lines of material particles BC, bc, $\beta\kappa$; but in the similar triangles ADC, Aec; $AD : DC = Ae : ec$, and in the triangles ADC, ADB, Aeb; $BD : DA = be : eA$; hence by composition $BD : DC = be : ec$; but BD and DC are equal; therefore, $be = ec$; and the line bc, supposed to consist of material particles, will be in equilibrio about e. In the same way it may be shewn that every other line $\beta\kappa$ will be in equilibrio about a point situated in the line AD; consequently the centre of gravity is in that line. For the same reason it follows, that the centre of gravity is in the line CE, that is, it will be in F, the point of intersection of these two lines. In order to determine the relation between FA and FD, join ED; then, since $BE = EA$, and $BD = DC$, $BE : EA = BD : DC$, and consequently, (Geometry, Sect. IV. Theor. 18.) ED is parallel to AC, and the triangles BED, BAC similar. We have, therefore, $CA : CB = DE : DB$, and by alternation $CA : DE = CB : DB$, that is, $CA : DE = 2 : 1$. In the similar triangles CFA, DFE, $AF : AC = DF : DE$, and by alternation $AF : DF = AC : DE$, that is, $AF : DF = 2 : 1$, or $AF = \frac{2}{3}AD$. Fig. 2.

166. Cor. 1. By Geometry, Theor. 16. Sect. IV. we have

$$AB^2 + AC^2 = 2BD^2 + 2AB^2 (= \tfrac{1}{2}BC^2 + \tfrac{9}{2}\overline{AF^2}$$
$$AB^2 + BC^2 = 2CC^2 + 2BG^2 = \tfrac{1}{2}\overline{AC^2} + \tfrac{9}{2}\overline{CF^2}$$
$$AC^2 + BC^2 = 2AE^2 + 2EC^2 = \tfrac{1}{2}AB^2 + \tfrac{9}{2}\overline{BF^2}.$$

By

Theory.

By adding these three equations, and removing the fractions, we have $AB^2+BC^2+AC^2=3\,AF^2+3\,CF^2+3BF^2$, or in any plane triangle, the sum of the squares of the three sides is equal to thrice the sum of the squares of the distances of the centre of gravity from each of the angular points.

167. Cor. 2. By resolving the three quadratic equations in the preceding corollary, we obtain $AF=\frac{1}{3}\sqrt{2AB^2+2AC^2-BC^2}$; $CF=\frac{1}{3}\sqrt{2BA^2+2BC^2-AC^2}$; and $BF=\frac{1}{3}\sqrt{2BC^2+2AC^2-AB^2}$, formulæ which express the distances of the centre of gravity from each of the angular points.

Prop. VII.

168. To find the centre of inertia of a trapezium or any rectilineal figure.

Fig. 9. Let ABCDE be the trapezium, and let it be divided into the triangles ABC, ACE, ECD by the lines AC, EC. By the last proposition find m, n, o, the centres of gravity of the triangles, and take the point F in the line $m\,n$, so that $F\,n : F\,m$ = triangle ABC : triangle ACE, then F will be the centre of gravity of these triangles. Join $F\,o$, and find a point f, so that $f\,o : F\,f$ = triangle ABC + triangle ACE : triangle CED, then all the triangles will be in equilibrio about f, that is, f is the centre of gravity of the rectilineal figure ABCDE. The same method may be employed in finding the centre of gravity of a trapezium, whatever be the number of its sides.

Prop. VIII.

169. To find the centre of inertia of a pyramid with a polygonal base.

Fig. 10. Let the pyramid be triangular, as ABCD, fig. 10. Bisect BD in F, and join CF and FA. Make $Ff=\frac{1}{3}$ of FC, and $F\,\varphi=\frac{1}{3}$ of FA, and draw $f\varphi$. It is evident, from Art 159. that f is the centre of gravity of the triangular base BCD, and that the line AF, which joins the vertex and the point f, will pass through the centre of gravity of all the triangular laminæ or sections of the pyramid parallel to its base ABC; for, by taking any section $b\;c\;d$, and joining $c\;m$, it may be easily shewn, that $b\;m=m\;d$, and $m\;n=\frac{1}{3}m\;c$, so that n is the centre of gravity of the section $b\;c\;d$. It follows, therefore, that $A\,f$ will pass through the centre of gravity of the pyramid. In the same way it may be shewn, by considering ABD as the base, and D the vertex, and making $F\varphi=\frac{1}{3}FA$, that the centre of gravity lies in the line φ C. But, as the lines $A\,f$, φ C lie in the plane of the triangle AFC, they must intersect each other; and therefore the point of intersection H will be the centre of inertia of the triangular pyramid. Now, since $Ff=\frac{1}{3}FC$, and $F\,\varphi=\frac{1}{3}FA$, we have $F\varphi : FA=Ff : FC$, therefore (Geometry, Theor. 8. Sect. IV.) φf is parallel to AC. The triangle φfH will consequently be similar to AHC, and $H\,\varphi : HC=Hf : HA=f\varphi : AC=1:3$; therefore $H\,\varphi=\frac{1}{3}HC=\frac{1}{4}\varphi\,C$, and $fH=\frac{1}{3}AH=\frac{1}{4}Af$.

170. When the pyramid has a polygonal base, it may be conceived to be formed of a number of triangular pyramids, whose centres of inertia will be in one plane parallel to the base. Their common centre of gravity will therefore be in the same plane, and in the line drawn from the vertex to the centre of gravity of all the triangles which compose the base; the distance of the centre of gravity, therefore, from the vertex, will be equal to three-fourths of the altitude of the pyramid.

171. Cor. 1. Hence it is obvious, that the centre of gravity of a right cone is a point in its axis, whose distance from the vertex is equal to three-fourths of the length of the axis; for as this may be demonstrated of a pyramid whose base is a polygon, with an infinite number of sides, it must hold also of a right cone which may be considered as a pyramid of this description.

172. Cor. 2. By proceeding as in Art. 160. it will be found, that in a triangular pyramid, the distance of any of the vertices from its centre of inertia, is equal to one-fourth of the square root of the difference of thrice the sum of the squares of the three edges which meet at that vertex, and the sum of the squares of the other three edges;—and likewise, that ths sum of the squares of the distances of the centre of inertia from the vertices of any triangular pyramid, is eqnal to one-fourth of the sum of the squares of the six edges of the pyramids. A demonstration of these theorems may be seen in Gregory's Mechanics, vol. i. p. 59, 60.

173. In order to shew the application of the doctrine of fluxions to the determination of the centre of inertia of curve lines, areas, solids, and the surfaces of solids, let ABC be any curve line whose axis is BR. Fig. 11.
Then, since the axis bisects all the ordinates DG, AC, each of the ordinates, considered as composed of material particles, will be in equilibrio about the points of bisection E, R; and therefore the centre of inertia of the body will lie in the axis. But, if we consider the body as composed of a number of small weights $D\,d\,g\,G$, we shall find its centre of inertia by multiplying each weight by its distance from any line $m\;n$ parallel to the ordinates, and dividing the sum of all these products by the sum of all the particles, Art. 158. Thus, let x denote the distance EB, then its fluxion $\dot{x}$ will be the breadth of the element or small weight $D\,d\,g\,G$, and $\dot{x}\times DG$ will represent the weight, and the fluent of this quantity will be the sum of all the weights. Again, if we multiply the weight $\dot{x}\times DG$ by $x=EB$ its distance from the point B, we shall have the momentum of that weight $=x\times\dot{x}\times DG$, and the fluent of this quantity will express the sum of the momenta of all the weights into which the body is divided. But, by Art. 158. the distance of the centre of gravity from a given point B is equal to the sum of all the momenta divided by the sum of all the weights or bodies, that is, if F be the centre of gravity of the body ABC, we have $FB=\frac{\text{fluent of } x\times\dot{x}\,DG}{\text{fluent of } \dot{x}\times DG}$, or calling y the ordinate DE, we have $DG=2y$, and $FB=\frac{\text{fluent of } x\,2y\dot{x}}{\text{fluent of } 2y\dot{x}}$, or $FB=\frac{\text{fluent of } xy\dot{x}}{\text{fluent } y\dot{x}}$, in the case of areas.

174. In the case of solids generated by rotation, the element or small weight $F\,\dot{x}\times DG$ will be a circular section,

Theory.

section, whose diameter is $2\,DE=2\,y$, and since the area of a circle is equal to its circumference multiplied by its diameter, we have (making $\pi=3.1416$) $2\pi y^2 \dot{x}$, $=$the circular section whose diameter is DG; and since $x \times 2\pi y^2 \dot{x}$, or $2\pi x y^2 \dot{x}$, will represent the momentum of the weight, we shall have $FB=\frac{\text{fluent of } 2\pi x y^2 \dot{x}}{\text{fluent of } 2\pi y^2 \dot{x}}$, and dividing by $2\pi y$, we have $FB=\frac{\text{fluent of } y x \dot{x}}{\text{fluent of } y \dot{x}}$.

175. In finding the centre of inertia of the surfaces of solids, the elements or small weights are the circumferences of circles, whose radii are the ordinates of the curve by whose revolution the solid is generated. Now, the surface of the solid may be conceived to be generated by the circumference of a circle increasing gradually from B towards A and C; making z therefore equal to BD, its fluxion $\dot{z}$ multiplied into the periphery of the circle whose diameter is DG, that is, $2\pi y \dot{z}$, will express the elementary surface or small weight whose diameter is DG. Then, since $x \times 2\pi y \dot{z}$, or $2\pi x y \dot{z}$, will be the momentum of the elementary weight, we shall have $FB=\frac{\text{fluent of } 2\pi x y \dot{z}}{\text{fluent of } 2\pi y \dot{z}}$, and dividing by 2π we obtain $FB=\frac{\text{fluent of } x y \dot{z}}{\text{fluent of } y \dot{z}}$,

176. If the body, whose centre of inertia is to be found, be a curve line, as GBD, then it is manifest that the small weights will be expressed by the fluxion of

Fig. 11. GBD, that is, by $2\dot{z}$, since $GBD=2\,BD=2z$; consequently their momenta will be $2x\dot{z}$, and we shall have $FB=\frac{\text{fluent } 2x\dot{z}}{\text{fluent } 2\dot{z}}=\frac{\text{fluent } x\dot{z}}{\text{fluent } \dot{z}}=\frac{\text{fluent } x\dot{z}}{z}$,

Prop. IX.

177. To find the centre of inertia of a circular segment.

Fig. 12. Let $AE=x$, $FC=y$, and AD the radius of the circle $=$ R, consequently $ME=2\,R-EA$. Then, since by the property of the circle (Geometry, Theor. 28. Sect. IV.) $ME \times EA=BE^2$, we have, by substitution, $BE^2=2R \times EA-EA \times EA$, or $y^2=2Rx-x^2$; hence $y=\sqrt{2Rx-x^2}$. Now, by Art. 174. we have the distance of the centre of gravity from A, that is, $AG=\frac{\text{fluent } x y \dot{z}}{\text{fluent } y \dot{x}}$; but the fluent of $y\dot{x}$ or the sum of all the weights, is equal to the area of half the segment ABEC; therefore $AG=\frac{\text{fluent } x y \dot{x}}{\frac{1}{2}ABEC}$. Then, by substituting instead of y, in this equation, the value of it deduced from the property of the circle, we have $AG=\frac{\text{fluent of } x \dot{x}\sqrt{2Rx-x^2}}{ABEC}$; or, in order to find GD the distance of the centre of gravity from the centre, we must substitute instead of x (without the vinculum) its value $R-x$, and we have $GD=\text{fluent } \frac{(R-x)\dot{x}\sqrt{(2Rx-x^2)}}{\frac{1}{2}ABEC}$. Now, in order to find the fluxion of the numerator of the preceding fraction, assume $z=2Rx-x^2$, and $z^{\frac{1}{2}}=\sqrt{2Rx-x^2}$, and by taking the fluxion, we have $\dot{z}=2R\dot{x}-2x\dot{x}=\overline{2R-2x}\times\dot{x}$; but this quantity is double of the first term of the numerator, therefore $\frac{\dot{z}}{2}=\overline{R-x}\times\dot{x}$. By substituting these values in the fractional formula, we obtain $GD=$fluent $\frac{z^{\frac{1}{2}}}{2}\times\frac{1}{2}\dot{z}=\frac{z^{\frac{3}{2}}}{3}=\frac{\sqrt{2Rx-xx}|^{3}}{3}$; but since $y=\overline{2Rx-xx}|^{\frac{1}{2}}$ we have, by raising both sides to the third power, $y^3=\overline{2Rx-xx}|^{\frac{3}{2}}$; therefore $GD=\frac{\frac{1}{3}y^3}{\frac{1}{2}ABEC}=\frac{\frac{1}{24}\times 8y^3}{\frac{1}{2}ABEC}=\frac{\frac{1}{12}(2y)^3}{ABEC}$, that is, the distance of the centre of gravity of a circular segment from the centre of the circle, is equal to the twelfth part of the cube of twice the ordinate, (or the chord of the segment) divided by the area of the segment.

178. Cor. When the segment becomes a semicircle we have $2y=2r$; and therefore $=GD=\frac{\frac{1}{12}(2r)^3}{ABEC}=\frac{(2r)^3}{12\,ABEC}=\frac{8\times r^3}{12\,ABEC}=\frac{r^3}{1\frac{1}{2}ABEC}$, that is, the distance of the centre of gravity of a semicircle from the centre of the semicircle, is equal to the cube of the radius, divided by one and a half times the area of the segment.

Prop. X.

179. To find the centre of inertia of the sector of a circle.

Let ABDC be the sector of the circle. By Art. 157. find m the centre of inertia of the triangle BCD, and by the last proposition find G the centre of inertia of the segment; then take a point n so situated between G and m, that $ABEC : BCB=m\,n : G\,n$, then the point n will be the centre of gravity of the sector.— By proceeding in this way, it will be found that D n, or the distance of the centre of gravity of the sector from the centre of the circle, is a fourth proportional to the semiarc, to the semichord, and to two-thirds of the radius.

Prop. XI.

180. To find the centre of inertia of a plane surface bounded by a parabola whose equation is $y=a\,x^n$.

Since $y=a\,x^n$, multiply both terms by $x\dot{x}$, and $\dot{x}$ separately, and we have $yx\dot{x}=ax^{n+1}\dot{x}$, and $y\dot{x}=ax^n\dot{x}$. But, by Art. 174. we have $FB=\frac{\text{fluent of } x y \dot{x}}{\text{fluent } y \dot{x}}$, therefore, by substituting the preceding values of $xy\dot{x}$ and $y\dot{x}$ in the formula, we obtain $FB=\frac{\text{fluent of } a\,x^{n+1}\dot{x}}{\text{fluent of } a\,x^n\,\dot{x}}$, and

Theory. and by taking the fluents it becomes

$$FB=\frac{\dfrac{a x^{n+2}}{n+2}}{\dfrac{a x^{n+1}}{n+1}}=\frac{n+1}{n+2}\times x.$$

If n, therefore, be equal to $\frac{1}{2}$, then $y=a x^{\frac{1}{2}}$, and, squaring both sides, $y^2=a^2 x$, which is the equation of the common or Apollonian parabola. Hence, $FB=\frac{3}{5}x$, that is, the distance of the centre of gravity from the vertex is $\frac{3}{5}$ths of the axis.

When n is equal to 1, then $y=ax$, and the parabola degenerates into a triangle, in which case $FB=\frac{2}{3}x$, as in Art. 165.

Prop. XII.

181. To find the centre of inertia of a solid, generated by the revolution of the preceding curve round its axis.

Since $y=a x^n$, square both sides, and we have $y^2=a^2x^{2n}$; then multiply both sides by $x\dot{x}$, and $\dot{x}$ separately, we obtain $y^2x\dot{x}=a^2x^{2n+1}\dot{x}$, and $y^2\dot{x}=a^2x^{2n}\dot{x}$. But, by Art. 174. we have $FB=\frac{\text{fluent of } y^2x\dot{x}}{\text{fluent of } y^2\dot{x}}$; therefore, by substituting the preceding values of $y^2x\dot{x}$, and $y^2\dot{x}$ in that formula, we obtain $FB=\frac{\text{fluent of } a^2x^{2n+1}\dot{x}}{\text{fluent of } a^2x^{2n}\dot{x}}$, and by taking the fluents we shall have

$$FB=\frac{\dfrac{a^2x^{2n+2}}{2n+2}}{\dfrac{a^2x^{2n+1}}{2n+1}}=\frac{2n+1}{2n+2}\times x.$$

When $n=\frac{1}{2}$, the solid becomes a common paraboloid, and we obtain $FB=\frac{2}{3}x$.

When $n=1$, the solid becomes a cone, and $FB=\frac{3}{4}x$, as in Art. 171.

Prop. XIII.

182. To find the centre of gravity of a spherical surface or zone, comprehended between two parallel planes, or of the spherical surface of any spherical segment.

Fig. 12. Let BMNC be a section of the spherical surface comprehended between the planes BC, MN, and let $EP=x$, $EC=y$, $DC=R$, and $z=$ the arc CN. Suppose the abscissa EP to increase by the small quantity Eo, draw $o\,r$ parallel to EC, Cs parallel to Eo, and Cr perpendicular to DC; then it is evident, that in the similar triangles CDE, Csr, EC : DC=Cs : Cr, that is, $y : R=$ Cs : Cr; but Cr is the fluxion of the arc NC, and Cs the fluxion of the abscissa PE; therefore $y : R=\dot{x} : \dot{z}$, and $\dot{z}y=R\dot{x}$, and $\dot{z}=\frac{R\dot{x}}{y}$. Now, by Art. 175. $FB=\frac{\text{fluent of } xy\dot{z}}{\text{fluent of } xy\dot{z}}$, therefore, by substituting the preceding value of $\dot{z}$ in this formula, we obtain $FB=\frac{\text{fluent of } Rx\dot{x}}{\text{fluent of } R\dot{x}}$, for Theory.

$$\frac{\dfrac{Rx\dot{x}\dot{z}}{y}}{\dfrac{R\dot{x}\dot{z}}{y}}=\frac{Ryx\dot{x}\dot{z}}{Ry\dot{x}\dot{z}}\text{ (and dividing by } y\dot{z})=\frac{Rx\dot{x}}{R\dot{x}}.$$

By taking the fluents we obtain $FB=\frac{1}{2}\frac{Rx^2}{Rx}=\frac{1}{2}x$, a fluent which requires no correction, as the other quantities vanish at the same time with x.

183. When DP is equal to DC, the solid becomes a spherical segment, and EA becomes the altitude of the segment, so that universally the centre of gravity of the spherical surface of a spherical segment is in the middle of the line which is the altitude of the segment, or in the middle of the line which joins the centres of the two circles that bound the spherical segment.

184. When the spherical segment is a hemispheroid, the centre of gravity of its hemispherical surface is obviously at the distance of one-half the radius from its centre.

Prop. XIV.

185. To find the centre of gravity of a circular arc.

Let BAC be the circular arc, it is required to find its centre of inertia, or the distance of the centre of inertia of the half arc AC from the diameter HG; for it is evident, that the line which joins the centres of gravity of each of the semiarcs AB, AC must be parallel to HG, and therefore the distance of their common centre of gravity, which must be in that line, from the line HG, will be equal to the distance of the centre of gravity of the semiarc from the same line. Make $PC=DE=x$; $EC=y$; $DC=DA=R$, and $AC=z$, then it may be shewn, as in the last proposition, that $y : R=\dot{x} : \dot{z}$; hence $\dot{z}y=R\dot{x}$. But, by Art. 176. Fig. 13.

we have $FB=\frac{\text{fluent of } y\dot{z}}{z}$, y being in this case equal to x in the formula in Art. 176. and substituting the preceding value of $y\dot{z}$, it becomes $FB=\frac{\text{fluent of } R\dot{x}}{z}$, and, taking the fluent, we have $FB=\frac{Rx}{z}$, which requires no correction, as the fluent of $y\dot{z}$ vanishes at the same time with x. Calling d, therefore, the distance of the centre of inertia of the arc BAC from the centre D, we have $d=\frac{Rx}{z}$, and $dz=Rx$; hence $z : x=R : d$, or $2Z : 2x=R : d$, that is, the distance of the centre of inertia of a circular arc from the centre of the circle is a fourth proportional to the arc, the chord of the arc, and radius.

186. When the arc BAC becomes a semicircle, PC or x is equal to DG or radius, so that we have $2z : 2R=R : d$, or $4Z : 4R=R : d$; but $4z$ is equal to the whole circumference of the circle, and $4R$ is

Theory.

is equal to twice the diameter; therefore, 3.141593 : 2 $=$R : d; hence $d=\frac{2\text{R}}{3.141593}=.63662$ R.

187. When y is equal to 2R, or when the arc ABC becomes equal to the whole circumference of the circle, x vanishes, and is $=0$, and therefore $\frac{\text{R}x}{z}=0$, which shews, that the centre of inertia coincides with the centre of the circle.

Scholium I.

188. From the specimens which the preceding propositions contain of the application of the formulæ in Articles 173, 174, 175, 176, the reader will find no difficulty in determining the centre of inertia of other surfaces and solids, when he is acquainted with the equation of the curves by which the surfaces are bounded, and by whose revolution the solids are generated.

A knowledge of the nature of these curves, however, is not absolutely necessary for the determination of the centres of inertia of surfaces and solids. A method of finding the centre of gravity, without employing the equation of the bounding curves, was discovered by our countryman, Mr Thomas Simson*. It was afterwards more fully illustrated by Mr Chapman, in his work on the Construction of Ships; by M. Leveque, in his translation of Don George Juan's Treatise on the Construction and Management of Vessels; and by M. Prony, in his *Architecture Hydraulique*, tom. i. p. 93. to which we must refer such readers as wish to prosecute the subject.

* *Mathematical Dissertations*, p. 109.

Scholium II.

Position of the centre of inertia in bodies of various forms.

189. As it is frequently of great use to know the position of the centre of inertia in bodies of all forms, we shall collect all the leading results which might have been obtained, by the method given in the preceding propositions.

1. The centre of inertia of a straight line is in its middle point.

2. The centre of inertia of a parallelogram is in the intersection of its diagonals.

3. The centre of inertia of a triangle is distant from its vertex two-thirds of a line drawn from the vertex to the middle of the opposite side.

4. The centre of inertia of a circle, and of a regular polygon, coincides with the centres of these figures.

5. The centre of inertia of a parallelopiped is in the intersection of the diagonals joining its opposite angles.

6. The centre of inertia of a pyramid is distant from its vertex three-fourths of the axis.

7. The centre of inertia of a right cone is in a point in its axis whose distance from the vertex is three-fourths of the axis.

8. In the segment of a circle, the centre of inertia is distant from the centre of the circle a twelfth part of the cube of the chord of the segment divided by the area of the segment, or $d=\frac{\frac{1}{2}\text{C}^3}{\text{A}}$, where $d=$ the distance of the centre of inertia from the centre of the circle, C $=$ the chord of the segment, and A its axis.

9. In the sector of a circle, the centre of inertia is distant from the centre of the circle, by a quantity which is a fourth proportional to the semiarc, the semichord, and two-thirds of the radius.

10. In a spherical surface or zone, comprehended between two planes, the centre of inertia is in the middle of the line which joins the centres of the two circular planes by which it is bounded. When one of the circular planes vanishes, the spherical zone becomes the spherical surface of a spherical segment; therefore,

11. In a spherical surface of a spherical segment, the centre of inertia is in the middle of its altitude or versed sine; consequently,

12. The centre of inertia of the surface of a complete sphere coincides with the centre of the sphere.

13. In a spherical segment, the centre of inertia is distant from the vertex by a quantity equal to $\frac{4a-3x}{6a-4x}\times x$, where a is the diameter of the sphere, and x the altitude or versed sine of the segment. Hence,

14. The centre of inertia of a hemisphere is distant from its vertex by a quantity equal to five-eighths of the radius, or it is three-eighths of the radius distant from the hemisphere; and,

15. The centre of inertia of a complete sphere coincides with the centre of the sphere.

16. In a circular arc the centre of inertia is distant from its centre by a quantity equal to $\frac{\text{R}x}{z}$, where R is the radius, x the semichord, and z the semiarc. Hence,

17. In a semicircular arc the centre of inertia is distant from its centre .63662 R, and,

18. The centre of inertia of the circumference of a circle coincides with the centre of a circle.

19. In a circular sector the centre of inertia is distant from the centre of the circle $\frac{2c\text{R}}{3a}$, where R is the radius, a the arc, and c its chord.

20. In a spherical sector, composed of a cone and a spherical segment, the centre of inertia is distant from the vertex of the segment by a quantity equal to $\frac{2\text{R}+3x}{8}$, where R is radius, and x the altitude or versed sine of the segment.

21. In an ellipsis the centre of inertia coincides with the centre of the figure.

22. The centre of inertia of an oblate and prolate spheroid, solids generated by the revolution of an ellipse round its lesser and its greater axis respectively, coincides with the centres of the figures.

23. In the segment of an oblate spheroid the centre of inertia is distant from its vertex by a quantity equal to $\frac{4m-3x}{6m-4x}\times x$, where m is the lesser axis, or axis of rotation, and x the altitude of the segment. Hence,

24. In a hemispheroid the centre of inertia is distant from its vertex five-eighths of the radius.

25. The centre of inertia of the segment of a prolate spheroid

Theory.

Theory.

spheroid is distant from its vertex by a quantity equal to $\frac{4n-3x}{6m-4x} \times x$, where n is the greater axis, or axis of rotation.

26. In the common or Apollonian parabola, the distance of the centre of inertia from its vertex is three-fifths of the axis.

27. In the cubical parabola the distance of the centre of inertia from its vertex is four-sevenths of the axis, in the biquadratic parabola five-ninths of the axis, and in the sursolid parabola six-elevenths of the axis.

28. In the common semiparabola, the distance of its centre of gravity from the centre of gravity of the whole parabola, in the direction of the ordinate passing through that centre, is $\frac{1}{8}$ of the greatest ordinate.

29. In the common paraboloid, the distance of the centre of inertia from its axis, is equal to $\frac{2}{3}$ of the axis.

30. In the common hyperboloid, the distance of the centre of inertia from the vertex is equal $\frac{4a+3x}{6a+4x} \times x$, where a is the transverse axis of the generating hyperbola, and x the altitude of the solid.

31. In the frustum of a paraboloid, the distance of the centre of inertia from the centre of the smallest circular end is $\frac{2R^2+r^2}{R^2+r^2} \times \frac{h}{4}$, where h is the distance between the centres of the circles which contain the paraboloidal frustum, R the radius of the greater circle, and r the radius of the lesser circle.

32. In a conic frustum or truncated cone, the distance of the centre of inertia from the centre of the smallest circular end is $\frac{3R^2+2Rr+r^2}{R^2+Rr+r^2} \times \frac{h}{4}$ which represents the distance between the centres of the circles which contain the frustum, and R, r the radii of the circles.

33. The same formula is applicable to any regular pyramid, R and r representing the sides of the two polygons by which it is contained.

Prop. XIV.

190. If a quantity of motion be communicated to a system of bodies, the centre of gravity of the system will move in the same direction, and with the same velocity, as if all the bodies were collected in that centre, and received the same quantity of motion in the same direction.

Fig. 14. Let A, B, C be the bodies which compose the system, and let F be the centre of gravity of the bodies B, C, and f the centre of gravity of the whole system, as determined by Art. 155. Then if the body A receives such a momentum as to make it move to a in a second, join F a, and take a point φ so that F φ : φ a= F f : f a, φ will now be the centre of gravity of the system, $f\varphi$ the path of that centre will be parallel to A a, and $f\varphi$ will be to A a as B is to A+B+C. Let the same quantity of motion be now communicated to B, so as to make it describe the space B b, in a second; and having drawn φ G parallel to B b, take a point G, so that φ G : B b=B : A+B+C, and G will be the centre of gravity of the bodies after B has moved to b. In the same way it may be found, that H will be the common centre of gravity of the bodies after the same quantity of motion has been communicated to C in the direction C c. Now if the quantity of motion which was communicated to A, B, C separately had been communicated to them at the same instant, they would have been found at the end of a second in the points a, b, c, and their centre of gravity would have been the point H. Let us now suppose the three bodies collected in their common centre of gravity f, the body at F will be equal to A+B+C, and if the same quantity of motion which made A move to a in a second be communicated to the body at f and in the same direction, it will be found somewhere in the line $f\varphi$ at the end of a second. But as the quantity of motion is equal to the product of the velocity of the body multiplied by its quantity of matter, the velocities are inversely as the quantities of matter, and consequently the velocity of the body at f is to A's velocity as A is to A+B+C, that is, as $f\varphi$ is to A a; therefore A a and $f\varphi$ are described by A and by the body at f in equal times, and the body at f will be found at φ at the end of a second. In the same way it may be shewn, that the body at f will be found at G if it receives the same momentum that was given to B, and in the same direction, and that it will be found at H after it has received the momentum that was communicated to C, consequently if it received all these momenta at the same instant, it would have described f H in a second. Q. E. D.

191. Cor. 1. If the bodies of a system move uniformly in right lines, their common centre of gravity will either be at rest, or move uniformly in a right line. For if the momenta communicated to the bodies A, B, C were communicated to a body at f=A+B+C, it will either remain at rest or move uniformly in a straight line. See *Newton's Principia*, I. Sect. III. Cor. 1.

192. Cor. 2. The centre of gravity of any system is not affected by the mutual action of the bodies which compose it. For let B and C be two bodies whose common centre of gravity is F; and let the points β, $\varkappa$, be taken, so that B β : C $\varkappa$=C : B, the spaces B β, C $\varkappa$ will represent the mutual action of the bodies B, C, that is, B β will represent the action of C upon B, or the motion which is the result of that action, and C $\varkappa$ the action of B upon C, or the motion which results from it. Then, since F is the common centre of gravity of B and C, we have (Art. 155.) B : C=FC : FB, but B : C=C $\varkappa$: B β, therefore FC : FB=C $\varkappa$: B β; but C $\varkappa$ is a magnitude taken from FC, and B β is a magnitude taken from FB, consequently (Playfair's Euclid, Book V. Prop. 19.) the remainder $\varkappa$ F : β F =FC : FB, that is, $\varkappa$ F : β F=B : C, that is, (Art. 155.) the point F continues to be the centre of gravity notwithstanding the action of the bodies B, C. If the system is composed of several bodies, the same thing may be proved of every two of the bodies, and consequently of the whole system. See *D'Alembert's Dynamique*, Art. 76. and *Newton's Principia*, I. Sect. III. Cor. 4. Fig. 14.

Prop. XV.

193. If a body is placed upon a horizontal plane, or suspended by two threads, it cannot be in equilibrio

Theory.

equilibrio unless a perpendicular drawn from the centre of gravity to the horizontal plane, or to a horizontal line passing through the two threads, fall within the base of the body, or upon that part of the horizontal line which lies between the threads.

Fig. 15. 194. Let ABCD be a body placed in the horizontal plane CD, G its centre of gravity, and GE a perpendicular drawn to the horizontal line DE. Then the whole matter of the body ABCD may be conceived as united in its centre of gravity G, and as its tendency downwards is in the vertical line GE, it can descend only by turning round the point C as a centre. Here then we have a body G placed at the end of a lever GC whose fulcrum is C, and its power to turn round C is represented by the quantity of matter in G multiplied by the perpendicular CE, let fall from the fulcrum upon its line of direction; and as there is no force to counterbalance this, the body G, and consequently the body ABCD, will fall by turning round C. When the vertical line GE coincides with GC, EC vanishes, and the weight of the body concentrated at G has no power to turn the lever round C, but is supported upon the fulcrum C. When the vertical line GE, (by some writers called the *line of direction*), falls within the base CD, it is obvious that the weight at G has no influence in producing a motion round C or D, but is employed in pressing the body upon the horizontal plane ED.

Fig. 16. 195. 2. Let the body ACBD be suspended at the points f, φ by the threads hf, $h'\varphi$, and let G be the centre of gravity of the body. Join Gφ, Gf, draw $f\varphi$ parallel to the horizon, and through G draw $n\ o$ parallel to $f\varphi$. Continue hf, $h'\varphi$ to o and n, and draw Gi perpendicular to $f\varphi$, the body AB cannot be in equilibrio unless the point i falls upon the horizontal line $f\varphi$ which passes through the threads. It is obvious that the centre of gravity can never change its distance from the fixed points of suspension f, φ; if therefore the body is not in equilibrio, its centre of gravity must descend either towards m or n; let it descend towards m till it rests at the point γ, then $\gamma f = f$G; but $\gamma\varphi$ is greater than Gφ (Euclid, Book I. Prop. 7.) which is absurd, therefore the point G cannot descend, that is, the body is in equilibrio. It may be shewn in the same way, that it will be in equilibrio when G is any where between n and o, that is, when the perpendicular let fall from G cuts the horizontal line $f\varphi$ that lies between the threads. If the body be suspended by the two threads HE, hf, so that the perpendicular Gi falls without the line fF, the body is not in equilibrio, for the centre of gravity G acting at the end of the lever GF tends to turn round F with a power eqal to G$\times$Gm, it will therefore descend, and as its distance from f cannot change, the point f will rise, and the thread fh will be relaxed. When G arrives at m the perpendicular Gm vanishes, and G has no power to turn round F. The body AB therefore cannot be in equilibrio till the perpendicular Gi falls within fF, which it does as soon as it arrives at m.

196. Cor. 1. If a body is placed upon an inclined plane, supposed without friction, it will slide down the plane when the line of direction falls within its base, and will roll down when this line falls without the base. This is the reason why a sphere or cylinder rolls down an inclined plane; for as they touch the plane only in one point or line, the line of direction must always fall without the base. Theory.

197. Cor. 2. The higher the centre of gravity of a body is, the more easily will it be overturned. For if ABCD be the body whose centre of gravity is F, and if any force be employed to move it round C as a fulcrum, the power with which it will resist this force is inversely as FC; then, if the centre of gravity is raised to f, fC will be greater than FC, and the power with which it resists being overturned is diminished, that is, the body is the more easily overturned the higher that its centre of gravity is placed. Fig. 17.

198. Cor. 3. If a body be suspended by one thread, it will not be at rest unless its centre of gravity is in the direction of the thread produced, for when the two threads hf', $h'\varphi$ approach so near each other as to coincide with the single thread HE, the point i must in the case of an equilibrium fall upon F, and the lines Gi, GF must coincide with mF; but HF and mF are both perpendicular to the horizontal line $f\varphi$, therefore the centre of gravity G is in the direction of the the thread HF.

199. Cor. 4. If the bodies A, B, C, fig. 18. be suspended by any point F from the hook H, they will not be in equilibrio unless their common centre of gravity G is in the vertical line FG passing through the point of suspension; and in fig. 19. the bodies A, B connected by the bent rod AFB will not be in equilibrio unless their common centre of gravity G is in a vertical line passing through F, the point in which the system rests upon the plane CD. Fig. 18. Fig. 19.

Scholium.

200. We have seen in the preceding proposition and corollaries, the position which must be given to the centre of gravity in order to procure an equilibrium. It is evident, however, that though the bodies are necessarily at rest, yet they have different degrees of stability, depending on the position of the centre of gravity with regard to the centre of motion. Hence bodies are said to have a stable equilibrium when their centre of gravity cannot move without ascending, or when the path described by their centre of gravity has its concavity upwards;—a tottering equilibrium when the centre of gravity cannot move without descending, or when the path which it describes has its concavity downwards,—and a neutral equilibrium when the body will rest in any position. Thus in fig. 20. if the vessels A, B have their handles so placed that in the one the handle A is fixed above the centre of gravity g, and in the other the handle B is fixed below the centre of gravity g, then the equilibrium of A will be stable, and that of B tottering; for if A is held by the handle it will require a considerable force to make its centre of gravity describe the path $m\ n$, whereas the smallest force will destroy the equilibrium of B. The vessel A, too, has a constant tendency to recover its equilibrium, and always recovers it as soon as the disturbing force is removed, but the vessel B has no tendency to do this even when its equilibrium is affected in the smallest degree. For the same reason the elliptical body A, when resting on the extremity of its conjugate axis, has a stable equilibrium, but when resting on its transverse axis as at B, its equilibrium

Different kinds of equilibrium.

Fig. 20. Fig. 21.

heory. um is tottering. The equilibrium of a circle or sphere is always neutral, for when it is disturbed, the body has neither a tendency to fall nor to resume its former situation.—A flat body A supported by a sphere B will have its equilibrium stable when its centre of gravity is nearer the point of contact than the centre of the sphere is, and the equilibrium of C will be tottering when its centre of gravity is farther distant from the surface of the sphere D than the centre of the sphere is.

. 22.

Prop. XVI.

1. To find the centre of inertia mechanically.

chanical thod of ling the tre of vity.

201. If the body whose centre of inertia is to be found can be suspended by a thread, then when the body is in equilibrio, the centre of gravity will be somewhere in the line, prolonged if necessary, that is formed by the thread upon the surface of the body. Let a body be again suspended from another part of its surface, so that the direction of the thread may be nearly at right angles to its former direction, then as the centre of gravity must also be in the new direction of the thread prolonged, it will be in the point where these two lines intersect each other.

202. 2. If the body is of such a kind that it cannot be conveniently suspended, balance it upon two sharp points, and its centre of motion will be somewhere in the line which joins these points. Balance it a second time upon the sharp points, so that the line which joins the points may be nearly at right angles to the former line. The intersection of these two lines will be the centre of inertia of the body.

203. 3. If the body is so flexible that it can neither be suspended by a thread nor balance upon points, then let a thin board be balanced upon the points as before, and let the body be so placed upon this board when balanced, that the equilibrium may still continue; then, having found the centre of gravity of the board when loaded with the body, the centre of gravity of the body will be a point on its surface exactly opposite to that centre.

204. The preceding method, however, only gives us the centre of gravity when the body has no sensible thickness, for when it is of three dimensions, the centre of gravity must be somewhere between the two opposite surfaces.

205. *Definition.*—The centro-baryc method is the method of determining the areas of surfaces, and the contents of solids, by considering them as generated by motion, and by employing the laws of the centre of gravity.

Prop. XVII.

entro-ryc me-od of uldinus.

206. If any straight or curve line, or any plane surface bounded by straight or curve lines, revolve round an axis situated in the same plane with the lines or surfaces, the surface or solid thus generated will be respectively equal to a surface or solid whose base is equal to the given line or surface, and whose height is equal to the arc described by the centre of gravity of the generating line or surface.

g. 23. Let ABCD be the plane surface by whose revolution round the axis MPN is generated the solid a D, contained by the parallelograms ABCD, $a\,b\,c\,d$, and by the areas a AC c, b BD d, and a AB b, c CD d; let G be the centre of gravity of ABCD, then the solid a D shall be equal to a solid whose base is ABCD, and whose altitude is a line equal to G g, the space described by its centre of gravity G. It is evident from Art. 161. that the sum of the products of all the particles of the surface ABCD, multiplied by their respective distances from any given point P, is equal to the sum of all the particles multiplied by the distance of their common centre of gravity G from the same point P. Now every particle of the surface ABCD, during its revolution round the point P, will obviously describe the arch of a circle proportional to the distance of that particle from the point P, which is the centre of all the arches; therefore the sum of the product of all the particles multiplied by the arch described by each of them, will be equal to the sum of the particles multiplied by the arch which their common centre of gravity describes; that is, the solid a D will be equal to the area of the surface multiplied by the path of its centre of gravity. In order to have a clearer illustration of this reasoning, let P, p, π, &c. be the particles of the surface ABCD; D, d, δ their distance from the centre of rotation P, and A, a, α, the arches which they describe, while GP is the distance of the centre of gravity of the surface ABCD from the centre P, and G g the arch described by it. Then by Art. 161. $\overline{P\times D}+\overline{p\times d}+\overline{\pi\times\delta}=\overline{P+p+\pi}\times GP$, but $D:d:\delta:GP=A:a:\alpha:Gg$, therefore $\overline{P\times A}+\overline{p\times a}+\overline{\pi\times\alpha}=\overline{P+p+\pi}\times Gg$. But $\overline{P\times A}+\overline{p\times a}+\overline{\pi\times\alpha}$ &c. make up the whole solid a D, and $\overline{P+p+\pi}$, &c. make up the whole surface ABCD; therefore the solid a D is equal to the generating surface ABCD multiplied by the path of its centre of gravity. Q. E. D.

Theory.

207. Cor. 1. Let us suppose the circle BACO to be generated by the revolution of the line DA round the point D; then since the centre of gravity of the line DA is in its middle point G, the path of this centre will be a circumference whose radius is DG, or a line equal to half the circumference BONAB, therefore, by the theorem, the area of the circle BONB will be equal to the radius DA multiplied by the semicircumference, which coincides with the result obtained from the principles of geometry. See Playfair's Geometry, Supp. B. I. Prop. 5. In the same way, by means of the preceding theorem, we may readily determine the area of any surface, or the content of any solid that is generated by motion. Fig. 12.

Scholium.

208. The centro-baryc method, which is one of the finest inventions of geometry, was first noticed by Pappus in the preface to the seventh book of his mathematical collections; but it is to Father Guldinus that we are indebted for a more complete discussion of the subject. He published an account of his discovery partly in 1635, and partly in 1640, in his work entitled *De Centro Gravitatis*, lib. ii. cap. 8. prop. 3. and gave an indirect demonstration of the theorem, by showing the conformity of its results with those which were obtained by other means. Leibnitz demonstrated the theorem in the case of superficies generated by the revolution of curves, but concealed his demonstration (Act. Leips. 1695, p. 493.

Theory.

493. The theorem of Leibnitz, however, as well as that of Guldinus was demonstrated by Varignon in the Memoirs of the Academy for 1714, p. 78. Leibnitz observes that the method will still hold, even if the centre round which the revolution is performed be continually changed during the generating motion. For further information on this subject, the reader is referred to Dr Wallis's work, *De Calculo Centri Gravitatis*, Hutton's Mensuration, Prony's Architecture Hydraulique, vol. i. p. 88. and Gregory's Mechanics, vol. i. p. 64.

PROP. XVIII.

209. To show the use of the doctrine of the centre of gravity in the explanation of some mechanical phenomena.

On the motion of animals.

In the equilibrium and motion of animals we perceive many phenomena deducible from the properties of the centre of gravity. When we endeavour to rise from a chair, we naturally draw our feet inwards, and rest upon their extremities, in order to bring the centre of gravity directly below our feet, and we put the body into that position in which its equilibrium is tottering, a position which renders the smallest force capable of producing motion, or of overturning the body. In this situation, in order to prevent ourselves from falling backwards, we thrust forward the upper part of the body for the purpose of throwing the centre of gravity beyond our feet: and when the equilibrium is thus destroyed, we throw out one of our feet, and gradually raise the centre of gravity till the position of the body is erect.—When we walk, the body is thrown into the position of tottering equilibrium by resting it on one foot; this equilibrium is destroyed by pushing forward the centre of gravity, and the body again assumes the position of tottering equilibrium by resting it on the other foot. During this alternate process of creating and destroying a tottering equilibrium, the one foot is placed upon the ground, and the other is raised from it; but in running, which is performed in exactly the same way, both the feet are never on the ground at the same time: At every step there is a short interval, during which the runner does not touch the ground at all.

210. When we ascend an inclined plane the body is thrown farther forward than when we walk on a horizontal one, in order that the line of direction may fall without our feet; and in descending an inclined plane, the body is thrown backward, in order to prevent the line of direction from falling too suddenly without the base. In carrying a burden, the centre of gravity is brought nearer to the burden, so that the line of direction would fall without our feet if we did not naturally lean towards the side opposite to the burden, in order to keep the line of direction within our feet. When the burden is therefore carried on the back, we lean forward; when it is carried in the right arm, we lean towards the left; when it is carried in the left arm, we lean towards the right; and when it is carried before the body, we throw the head backwards.

211. When a horse walks, he first sets out one of his fore feet and one of his hind feet, suppose the right foot; then at the same instant he throws out his left fore foot and his left hind foot, so as to be supported only by the two right feet. His two right feet are then brought up at the same instant, and he is supported only by his two left feet. When a horse pulls at a load which he can scarcely overcome, he raises both his fore feet, his hind feet become the fulcrum of a lever, and the weight of the horse collected in his centre of gravity acts as a weight upon this lever, and enables him to surmount the obstacle. See Appendix to Ferguson's Lectures, vol. ii.).

Theory.

Method in which a rope-dancer keeps his equilibrium.

212. When a rope-dancer balances himself upon the fore part of one foot, he preserves his equilibrium in two ways, either by throwing one of his arms or his elevated foot, or his balancing pole, to the side opposite to that towards which he is beginning to fall, or by shifting the point of his foot, on which he rests, to the same side towards which he is apt to fall; for it amounts to the same thing whether he brings the centre of gravity directly above the point of support, or brings the point of support directly below the centre of gravity. For this purpose the convex form of the foot is of great use, for if it had been perfectly flat, the point of support could not have admitted of small variations in its position *.

* See Dr T Young's *Natural Philosophy*, vol. i. p. 64.

The construction of mail coaches erroneous.

213. We have already seen (Art. 197.) that any body is more easily overturned in proportion to the height of its centre of gravity. Hence it is a matter of great importance that the centre of gravity of all carriages should be placed as low as possible. This may often be effected by a judicious disposition of the load, of which the heaviest materials should always have the lowest place. The present construction of our mail and post coaches is therefore adverse to every principle of science, and the cause of many of those accidents in which the lives of individuals have been lost. The elevated position of the guard, the driver, and the outside passengers, and the two boots which contain the baggage, raises the centre of gravity of the loaded vehicle to a very great height, and renders it much more easily overturned than it would otherwise have been. When any accident of this kind is likely to happen, the passengers should bend as low as possible, and endeavour to throw themselves to the elevated side of the carriage.—In two wheeled carriages where the horse bears part of the load upon its back, the elevation of the centre of gravity renders the draught more difficult, by throwing a greater proportion of the load upon the horse's back when he is going down hill, and when he has the least occasion for it; and taking the load from the back of the horse when he is going up hill, and requires to be pressed to the ground.

Fig. 24.

214. A knowledge of the laws of the centre of gravity enables us to explain the experiment represented in fig. 24. where the vessel of water CG is suspended on a rod AB, passing below its handle, and resting on the end E of the beam DE. The extremity B of the rod AB is supported by another rod BF, which bears against the bottom of the vessel; so that the vessel and the two rods become, as it were, one body, which, by Art. 199. will be in equilibrio when their common centre of gravity C is in the same vertical line with the point of support E.

A loaded cylinder may be made to ascend an inclined plane by its own weight.

215. The cylinder G may be made to ascend the inclined plane ABC by putting a piece of lead or any heavy substance on one side of its axis, so that the centre of gravity may be moved from G towards g. Hence it

it is obvious, that the centre of gravity g will descend, and by its descent the body will rise towards A. The inclination of the plane, however, must be such, that before the motion commences, the angles formed by a vertical line drawn from g with a line drawn from G perpendicularly to AB, must be less than the angle of inclination ABC, or, which is the same thing, when the vertical line drawn from g does not cut the line which lies between the point of contact and the centre of the cylinder. When the vertical line, let fall from g, meets the perpendicular line drawn from G to the plane in the point of contact, the cylinder will be in equilibrio on the inclined plane.

ouble e may made to end an lined ne by own ght. . 26.

216. Upon the same principle, a double scalene cone may be made to ascend an inclined plane without being loaded with a weight. In fig. 26. let ABC be the section of a double inclined plane, AB, BC being sections of its surfaces perpendicular to the line in which the double scalene cone ADEFC moves. Then, since the centre of gravity of a cone is in the line joining the vertex and the centre of its base, and since the axis of a scalene cone is not perpendicular to its base, the line which joins the centres of both the cones, when in the position represented in the figure, will be above the line which joins the centres of their bases. If the circle, therefore, in fig. 27. represents the base of one of the cones, and C its centre, the line which joins the centres of gravity of the two cones will terminate in some point G at a distance from the centre, and therefore the double cone will ascend the plane upon the same principles, and under the same conditions, as those mentioned in the last paragraph.

. 27.

CHAP. V. *On the Motion of Bodies along inclined Planes and Curves, on the Curve of swiftest descent, and on the Oscillations of Pendulums.*

PROP. I.

Plate CCXXI. fig. 1.

217. When a body moves along an inclined plane, the force which accelerates or retards its motion, is to the whole force of gravity as the height of the plane is to its length, or as the sine of its inclination is to radius.

Let ABC be the inclined plane, A the place of the body, and let AB represent the whole force of gravity. The force AB is equivalent to the two forces AD, DB or AE, AD, of which AD is the force that accelerates the motion of the body down the plane, while AE is destroyed by the resistance or re-action of the plane. The part of the force of gravity, therefore, which makes the body arrive at C is represented by AD, while the whole force of gravity is represented by AB; but the triangle ABD is equiangular to ABC, and AD : AB=AB : AC, that is, the accelerating force which makes the body descend the inclined plane, is to the whole force of gravity as the height of the plane is to its length, or as the sine of the plane's inclination is to radius; for when AC is radius, AB becomes the sine of the angle ACB.

218. COR. 1. Since the force of gravity, which is uniform, has a given ratio to the accelerating force, the accelerating force is also uniform; consequently the laws of accelerated and retarded motions, as exhibited in the article DYNAMICS, are also true when the bodies move along inclined planes. If H, therefore, represent the height AB of the plane, L its length AC, g the force of gravity, and A the accelerating force, we shall have, by the proposition, L : H$=g$: A, hence, $A=g\times\frac{H}{L}$, or, since g : A=radius : sin, ACB, and A $=g\times$ sin. ACB. Now, from the principles of DYNAMICS, $s=\frac{1}{2}g\,t^2$, $v=g\,t=\sqrt{2\,g\,s}$, and $t=\frac{v}{g}=\sqrt{\frac{2s}{g}}$, where s is the space described, g the force of gravity, or $32\frac{1}{4}$ feet, v the velocity, and t the time. Making φ, therefore, equal to ACB, and substituting the value of A instead of g in the preceding equation, we shall have $s'=\text{sin.}\,\varphi\times\frac{1}{2}t'$; $v'=g\,\text{sin.}\,\varphi\,t=\sqrt{2gs'\text{sin.}\,\varphi}$, and $t=\frac{v'}{g.\,\text{sin.}\,\varphi}=\sqrt{\frac{2s'}{g.\,\text{sin.}\,\varphi}}$.

219. COR. 2. If one body begins to descend through the vertical AB at the same time that another body descends along the plane AC, when the one is at any point m, the position of the other will bo n, which is determined by drawing $m\,n$ perpendicular to AC. The forces by which the two bodies are actuated, are as AB to AD, that is, as A m to A n; but forces are measured by the spaces described in the same time; therefore, the spaces described in the same time, are as A m, A n, that is, as the length of the plane is to its height; for A m : A n=AC : AB; consequently, when the body that descends along the vertical line AB is at m, the other body will be at n.—Through the three points A, m, n describe the semicircle A m n; then, since A n m is a right angle, the centre of the semicircle will be in the line A m (Playfair's Euclid, Book iv. Prop. 5.); consequently, *if two bodies descend from the point A at the same time, the one through the diameter of a circle* A m, *and the other through any chord* A n, *they will arrive at the points* m n, *the extremities of the diameter and of the chord at the same instant.* It also follows from this corollary, that if from the point A there be drawn any number of lines making different angles with the diameter A m, and if bodies be let fall from A, so as to move along these lines, they will, at the end of any given time, be found in the circumferences of circles which touch one another in the point A. If the lines are not in the same plane, the bodies will be in the circumferences of spheres which touch each other in the point A.

220. COR. 3. If any number of bodies descend from the same point A along any number of inclined planes AC, AF, their velocities at the points C, F will be equal. By Cor. 1. the velocity of a body descending the plane AC, is $v=\sqrt{2\,g\,s\,\text{sin.}\,\varphi}$, and the velocity of a body falling in the vertical line AB is $v'=\sqrt{2\,g\,s'}$. But, since $v=v'$, we have $\sqrt{2\,g\,s\,\text{sin.}\,\varphi}=\sqrt{2\,g\,s'}$ or $2\,g\,s\,\text{sin.}\,\varphi=2\,g\,s'$, and dividing by $2\,g$; $s\,\text{sin.}\,\varphi=o$, consequently s : s'=sin. φ : 1, or AB : AC=sin. DAB : radius. Therefore, when $v=v'$, that is, when the velocities of the two bodies are equal, the spaces described are as sin. DAB : radius, which can only happen when BC is perpendicular to AB. In the same way it may be shewn that the velocity at F is equal to the velocity at C, therefore the velocity at C is equal to the velocity at F.

221. COR. 4. The time of descending along AC is to

Theory.

to the time of descending along AB, as AC is to AB. From the values of s, s' in Cor. 1. we obtain $t^2 : t'^2 = \frac{s}{\sin.\varphi} : s' = \frac{AC}{\sin.\varphi} : AB$. But $\frac{AB}{AC} = \sin.\varphi$; therefore, $t^2 : t'^2 = \frac{AC^2}{AB} : AB$, and taking equal multiples of these two last terms, that is, multiplying them by AB, we have $t^2 : t'^2 = AC^2 : AB^2$, or $t : t' = AC : AB$. Hence the times of descending along AF and AC, are as AF and AC.

222. Cor. 5. The velocities acquired by descending any planes AC, AF, are as the square roots of their altitudes AB. The velocity acquired by falling through AB is, by the principles of Dynamics, as the square root of AB; and as the velocities at F, C are equal to that at B, they will also be as the square root of AB.

Prop. II.

223. If a body descend from any point along a number of inclined planes to a horizontal line, its velocity, when it reaches the horizontal line, will be equal to that which it would have acquired by falling in a vertical direction from the given point to the horizontal line.

Fig 2. Let AB, BC, CD, be a number of planes differently inclined to a horizontal line DN, and let the body be let fall from the point A, so as to move along these planes, without losing any of its velocity at the angular points; it will have the same velocity when it reaches the horizontal plane at D, which it would have acquired by falling freely from A to F. It is manifest from Art. 220. that the velocity of the body when at B will be the same as that of another body which had fallen freely from A to c in a vertical line. The two bodies set out from B and c with the same velocity, and will therefore continue to have the same velocity when they reach the points C, G, because $c\,G = B\,d$. The two bodies again set off from the points C, G with the same celerity, and since $GF = Ce$, their respective velocities will be equal when they arrive at the points D, F in the horizontal plane. The velocity, therefore, acquired by the body falling along the planes AB, BC, CD is equal to that which is acquired by the same body falling through the vertical line AF.

224. Cor. 1. As the preceding proposition holds true, whatever be the number of inclined planes which lie between the point A and the horizontal line, it will hold true also of any curve line which may be considered as made up of an infinite number of straight lines. And, since the small planes are diminished without limit, the radius is diminished without limit, and therefore the versed sine, or the velocity lost in passing from one plane to another, is diminished without limit (A), consequently, abstracting from friction, a body will ascend or descend a curve surface without losing any of its velocity from the curvature of the surface.

225. Cor. 2. If a body be made to ascend a curve surface, or a system of inclined planes, the vertical height to which it will rise, is equal to that through which it must fall in order to acquire the velocity with which it ascended, abstracting from the effects of friction, and the velocity which is lost in passing from one plane to another. This is obvious, from Dynamics, § 26, 51.; for the body experiences the same decrements of velocity in its ascent, as it received increments in its descent.

226. Cor. 3. The same thing will hold if the body is kept in the curve by a string perpendicular to the curve, for the string sustains that part of the weight which was sustained by the curve, since the reaction of the curve surface is in a line perpendicular to the curve.

Scholium.

227. It is obvious, that the body which moves along the system of inclined planes must lose a part of its velocity in passing from one plane to another. By the resolution of motion it will be found that the velocity acquired by falling through any of the planes, is to the velocity lost in passing to the succeeding one, as radius is to the versed sine of the angle formed by the two planes. Or the velocity with which the body enters upon one plane is as the cosine of the angle made by the contiguous planes, divided by the velocity which the body had when it left the preceding plane.

Prop. III.

228. The times of descending two systems of inclined planes similar and similarly situated, are in the subduplicate ratio of their lengths.

Let AB, BC, CD, and $a\,b$, $b\,c$, $c\,d$ be the similar systems of inclined planes, and let T be the time of descending ABCD, and t the time of descending $a\,b\,c\,d$. Fig. 2.

By Cor. 4. Prop. 1. we have

$$\text{Time along AB} : \text{Time along A}\,c = AB : A\,c,$$
$$\text{Time along } a\,b : \text{Time along } \alpha\,\beta, = a\,b : \alpha\,\beta,$$

But, on account of the similar triangles AB c, $a\,b\,\beta$, we have,

$$AB : A\,c = a\,b : \alpha\,\beta.$$

Hence (Euclid, Book v. Prop. 11. 16.)

$$\text{Time along AB} : \text{Time along } a\,b = \text{Time along A}\,c : \text{Time along } \alpha\,\beta.$$

In

(A) See Wood's Principles of Mechanics, p. 58. note; and also Gregory's Mechanics, vol. i. p. 112. where this corollary is demonstrated by the method of fluxions.

Theory.

In the same way it may be shewn, that

$$\text{Time along BC : Time along } bc = \text{Time along } c\,\text{G : Time along } \beta\kappa,$$
$$\text{Time along CD : Time along } cd = \text{Time along GF : Time along } \kappa f.$$

Then, by GEOMETRY, Sect. III. Theorem VIII.

$$\text{Time along AB+BC+CD : Time along } \overline{ab+bc+cd} = \text{Time along } \overline{\text{A}c+c\text{G+GF}} \text{ : Time along } \overline{a\beta+\beta\kappa+\kappa f}$$

that is,

$$\text{Time along } \overline{\text{AB+BC+CD}} \text{ : Time along } \overline{ab+bc+cd} = \text{Time along AF : Time along } af.$$

But by DYNAMICS § 37, 2.

$$\text{Time along AF : Time along } af = \sqrt{\text{AF}} : \sqrt{af}.$$

Therefore, EUCLID, B. V. Prop. 11.

$$\text{Time along } \overline{\text{AB+BC+CD}} \text{ : Time along } \overline{ab+bc+cd} = \sqrt{\text{AF}} : \sqrt{af}. \quad \text{Q. E. D.}$$

But by similar triangles, &c.

$$\sqrt{\text{AF}} : \sqrt{af} = \sqrt{\text{AB+BC+CD}} : \sqrt{ab+bc+cd}.$$

Therefore,

$$\text{Time along } \overline{\text{AB+BC+CD}} \text{ : Time along } \overline{ab+bc+cd} = \sqrt{\text{AB+BC+CD}} : \sqrt{ab+bc+cd}. \quad \text{Q. E. D.}$$

229. COR. 1. This proposition holds true of curves, for the reasons mentioned in Prop. 2. Cor. 1.

230. COR. 2. The times of descent along similar arcs of a circle are as their radii; for by the preceding corollary the times are as the arcs, and the arcs are as the radii, therefore the times are as the radii.

PROP. IV.

231. An inverted semicycloid is the curve of quickest descent, or the curve along which a body must descend in order to move between two points not in a vertical line, in the least time possible.

Fig. 4. Let q FZ be a semicycloid, and A′D′, C′F′ two parallel and vertical ordinates at an infinitely small distance. Draw the ordinate B′E′ an arithmetical mean between the ordinates A′D′ and C′F′, and from F′, E′ draw F′v, E′u perpendicular to B′F, C′E′. Make C′F′$=a$, B′E′$=b$, E′$v=c$, C′B′$=m$, B′A′$=n$. Then since F′E′ may be considered as a straight line, and since B′C′$=$F′v, we have (Euclid, B. I. Prop. 47.) F′E′$=\sqrt{m^2+c^2}$, and since F′$v=$E′u, E′D′$=\sqrt{n^2+c^2}$. Now the velocities at F′ and E′ vary as $\sqrt{a}$ and $\sqrt{b}$, and F′E′, E′D′ are the elementary spaces described with these velocities; but the times are directly as the square root of the spaces, and inversely as the velocities, therefore the time of describing F′E′ is $\frac{\sqrt{m^2+c^2}}{\sqrt{a}}$, and the time of describing E′D′ is $\frac{\sqrt{n^2+c^2}}{\sqrt{b}}$, consequently, the time of describing FD must be $\frac{\overline{m^2+c^2}|^{\frac{1}{2}}}{a^{\frac{1}{2}}}+\frac{\overline{n^2+c^2}|^{\frac{1}{2}}}{b^{\frac{1}{2}}}$

But the proposition requires that this time should be the least possible or a minimum, therefore taking its fluxion and making it equal to o, we have

$$\frac{2m\dot{m}}{2\sqrt{a\times\overline{mm+c^2}}}+\frac{2n\dot{n}}{2\sqrt{b\times\overline{nn\times c^2}}}=\text{o}.$$

But since CA is invariable $m+n$ is invariable, and therefore its fluxion $\dot{m}+\dot{n}=$o, or $\dot{m}=-n$ and $\dot{n}=-m$, therefore by transposing the second number of the preceding equation, and substituting these values of $\dot{m}$ and $\dot{n}$, it becomes $\frac{m}{\sqrt{a\times\overline{m^2+c^2}}}=\frac{n}{\sqrt{b\times\overline{n^2+c^2}}}$. Let us now call the variable abscissa q C′$=x$, the ordinate C′F′$=y$ and the arc q F′$=z$, then m and n are fluxions of x, and F′E′ is the increment of q F or z, when y is equal to a, and E′D′ the increment of q F or z, when y is equal to b, therefore by substituting these values in the preceding equation, we obtain $\frac{\dot{x}'}{\sqrt{y\dot{z}'}}=\frac{\dot{x}'}{\sqrt{y\dot{z}'}}$, which shews that this quantity is constant, and gives us the following analogy, $\dot{z}' : \dot{x}' = 1 : \sqrt{y}$. Now in the cycloid $\sqrt{y}$ is always the chord of the generating circle when the diameter is y (for by Euclid, Book I. Prop. 47, Book II. Prop 8. and Book III. Prop. 35.) AF$=\sqrt{\text{AD}\times\text{AO}}$, and since AO$=1$ and AD$=y$, we have AF$=\sqrt{y}$. Fig. 5. But since the arc of the cycloid at F is perpendicular to the chord AF, the elementary triangle FEv is similar to FDO, (for BE is parallel to AO) and consequently to AFO (Euclid. B. VI. Prop. 8.), therefore, we have FE : E′ $\dot{z}'=$AO : AF; but FE$=\dot{x}'$, E$v=v$, AO$=1$ and AF$=\sqrt{y}$, consequently $\dot{z}' : \dot{x}' = 1 : \sqrt{y}$, which coincides with the analogy already obtained, and being the property of the cycloid shews that the curve of quickest descent is an inverted cycloidal arc.

Properties of the Cycloid.

Fig. 3. Properties of the cycloid.

DEFINITION.—If a circle NOP be so placed as to be in contact with the line AD, and be made to roll along that line from D towards A, till the same point D of the circle touches the other extremity A, the point D will describe a curve DBA, called a cycloid.

The line AD is called the *base of the cycloid*; the line CB, which bisects AD at right angles and meets the curve in B, is called the *axis*, and B the *vertex*.

The circle NOP is called the generating circle.

232. 1. The

Theory.

232. 1. The base AD is equal to the circumference of the generating circle, and AC is equal to half that circumference.

2. The axis CB is equal to the diameter of the generating circle.

3. If from any point G of the cycloid, there be drawn a straight line GM parallel to AD, and meeting the circle BLC in L, the circular arc BL is equal to the line GL.

4. If the points L, B be joined, and a tangent drawn to the cycloid at the point G, the tangent will be parallel to the chord LB, and the tangent is found by joining G, E, for GE is parallel to LB.

5. The arc BG of the cycloid is double of the chord BL, and the arc BA or BD is equal to twice the axis BC.

6. If the two portions AB, DB of the cycloid in fig. 3. be placed in the inverted position AB, DB (fig. 4.), and if a string BP equal in length to BA be made to coincide with BA, and then be evolved from it, its extremity P will describe a semicycloid AF, similar and equal to BA. In the same way the semicycloid DF, produced by the evolution of the string BP from the semicycloid BD, is equal and similar to BD and to AF. Therefore, if BP be a pendulum or weight attached to the extremity of a flexible line BP, which vibrates between the cycloidal cheeks BA, BD, its extremity D will describe a cycloid AFD, equal to that which is composed of the two halves BA, BD. Fig. 4.

7. The chord CN is parallel to MP, and MP is perpendicular to the cycloid AFD, at the point P.

8. If Pp be an infinitely small arc, the perpendicular to the curve drawn from the points Pp will meet at M, and Pp may be regarded as a circular arc, whose radius is MP. An infinitely small cycloidal arc at F may likewise be considered as a circular arc whose radius is BF.

As these properties of the cycloid are demonstrated in almost every treatise on mechanics, and as their demonstrations more properly belong to geometry than to mechanics, they are purposely omitted to make room for more important matter.

233. Definition.—If a body descend from any point of a curve, and ascend in the same curve till its velocity is destroyed, the body is said to oscillate in that curve, and the time in which this descent and ascent are performed is called the time of an oscillation or vibration.

234. Definition.—A cycloidal pendulum is a pendulum which oscillates or vibrates in the arch of a cycloid.

235. Definition.—Oscillations which are performed in equal times are said to be isochronous.

Prop. V.

Fig. 4. 236. The velocity of a cycloidal pendulum BP at the point F, varies as the arch which it describes.

The velocity of the pendulum at F is that which it would have acquired by falling through EF (Prop. 2. and Cor. 3. Prop. 2.), and the velocity of a falling body is as the square root of the space which it describes (Dynamics, § 37.), therefore the velocity of the pendulum P, when it reaches F, varies as $\sqrt{EF}$. But (Geometry, Sect. IV. Theor. 23. and 8.) FE varies as $\frac{FN^2}{FC}$, and since FC is a constant quantity, FE will vary as FN^2 varies, or, to adopt the notation used in the article Dynamics, $FE \doteq FN^2$, or $\sqrt{FE} \doteq FN$, but the velocity acquired by falling through EF varies as $\sqrt{FE}$, therefore the velocity of the pendulum at F varies as FN, that is, as FP, for (Art. 232. N° 5.) FN is equal to half FP. Q. E. D.

Prop. VI.

237. If the pendulum begins its oscillation from the point P, the velocity of the pendulum at any point R varies as the sine of a circular arc whose radius is FP, and whose versed sine is PR.

Through F draw $p\,F\,q$ parallel to AD, and with a radius equal to the cycloidal arc FP, describe the semicircle $p\,o\,q$. Make $p\,r$ equal to the arc PR of the cycloid, and through r draw $r\,m$ perpendicular to p F. Through the points P, R draw PE, RT parallel to AD, and cutting the generating circle CNF in the points N, S.—By Prop. 4. the velocity at R varies as $\sqrt{ET}$, that is, as $\sqrt{EF-TF}$, or since CF is constant, as $\sqrt{CF\times EF-CF\times TF}$, that is, as $\sqrt{FN^2-FS^2}$. For, (Playfair's Euclid, Book I. Prop. 47, Book II. Prop. 7. and Book III. Prop. 35.) $FN^2=CF\times EF$, and $FS=CF\times TF$), that is, as $\sqrt{4FN^2-FS4^2}$, that is (Art. 232. N° 5.) as $\sqrt{FP^2-FR^2}$. But F p or F m was made equal to FP, and, $p\,r$ being made equal to PR, the remainder F r must be equal to FR, therefore the velocity at R varies as $\sqrt{\overline{Fm}^2-\overline{Fr}^2}$, but (Euclid, 47. 1.) $r\,m=\sqrt{\overline{Fm}^2-\overline{Fr}^2}$, and $r\,m$ is by construction equal to the sine of a circular arc, whose radius is FP, and versed sine PR, consequently, the velocity at R varies as the sine of that arc. Q. E. D. Fig. 4.

238. Corollary. The velocity of the pendulum at F is to the velocity of the pendulum at R, as F m : $r.m$, for the versed sine is in this case equal to radius, and therefore the corresponding arc must be a quadrant whose sine is also equal to radius or F m.

Prop. VII.

239. The time in which the pendulum performs one complete oscillation from P to O, is equal to the time in which a body would describe the semicircle $p\,o\,q$, uniformly with the velocity which the pendulum acquires at the point F. Fig. 4.

Take any infinitely small arc RV, and making $r\,v$ equal to it, draw $v\,o$ parallel to $r\,m$, and $m\,n$ to $r\,v$. Now, by the last proposition, and by Dynamics, Art. 28.; the velocity with which RV is described is to the velocity with which $m\,o$ is described as $r\,m$ is to F m, that

Theor.

Theory.

that is as $\frac{RV}{rm}:\frac{mo}{Fm}$, or as $\frac{mn}{rm}:\frac{mo}{Fm}$, for $mn=rv=RV$. But in the similar triangles Fmr, mno, $Fm:rm=mo:mn$, consequently $\frac{mn}{rm}=\frac{mo}{Fm}$, therefore the velocity with which RV is described is equal to the velocity with which mo is described, and the times in which these equal spaces are described must likewise be equal. The same thing may be demonstrated of all the other corresponding arcs of the cycloid and circle, and therefore it follows that the time in which the pendulum performs one complete oscillation is equal to the time in which the semicircle poq is uniformly described with the velocity acquired at F.

Prop. VIII.

240. **The time in which a cycloidal pendulum performs a complete oscillation is to the time in which a body would fall freely through the axis of the cycloid, as the circumference of a circle is to its diameter.**

Fig. 4. Since $FP=2FN$, and since the velocity acquired by falling down NF is equal to the velocity acquired by falling down PF, the body, if it continued to move uniformly with this velocity, would describe a space equal to 2PF (Dynamics, § 37. N° 6.) in the same time that it would descend NF or CF (Art. 219.). Calling T therefore the time of an oscillation, and t the time of descent along the axis, we have, by the preceding proposition,

$T=$time along poq, with the velocity at F,

and by the preceding paragraph,

$t=$time along Fp, with the same velocity; therefore

$T::t=$time along poq with velocity at V : time along Fp with the same velocity; that is, $T:t=poq:Fp$ $=2poq:2Fp=$the circumference of a circle : its diameter.

241. Cor. 1. The oscillations in a cycloid are isochronous, that is, they are performed in equal times whatever be the size of the arc which the pendulum describes. For the time of an oscillation has a constant ratio to the time of descent along the axis, and is therefore an invariable quantity.

242. Cor. 2. The oscillations in a small circular arc whose radius is BF, and in an equal arc of the cycloid, being isochronous (Art. 232. N° 8.), the time of an oscillation in a small circular arc will also be to the time of descent along the axis, as the circumference of a circle is to its diameter.

243. Cor. 3. Since the length BF of the pendulum is double of the axis CF, the time of an oscillation in a cycloid or small circular arc varies as the time of descending along CF, half the length of the pendulum, the force of gravity being constant. But the time of descent along CF varies as $\sqrt{CF}$, therefore the time of an oscillation in a small circular or cycloidal arc varies as the square root of half the length of the pendulum, or as the square root of its whole length. If T, t therefore be the times of oscillations of two pendulums, and L, l their respective lengths, we have by this corollary $T:t=\sqrt{L}:\sqrt{l}$, and $T\times\sqrt{l}=t\times\sqrt{L}$; hence $T=\frac{t\times\sqrt{L}}{\sqrt{l}}$; $t=\frac{T\times\sqrt{l}}{\sqrt{L}}$; $l=\sqrt{\frac{t\times\sqrt{L}}{T}}$, and $L=\sqrt{\frac{T\times\sqrt{l}}{t}}$, from which we may find the time in which a pendulum of any length will vibrate; a pendulum of 39.2 inches vibrating in one second.

Theory.

244. Cor. 4. When the force of gravity varies, which it does in going from the poles to the equator, the time of an oscillation is directly as the square root of the length of the pendulum, and inversely as the square root of the force of gravity. The time of an oscillation varies as the time of descent along half the length of the pendulum, and the time of descent through any space varies as $\frac{\sqrt{s}}{\sqrt{g}}$, where s is the space described and g the force of gravity; but in the present case $s=\frac{L}{2}$; therefore by substitution, the time of descent along half the length of the pendulum, or the time of an oscillation, varies as $\frac{\sqrt{\frac{1}{2}L}}{\sqrt{g}}$, or as $\frac{\sqrt{L}}{\sqrt{g}}$. Hence $T:t=\frac{\sqrt{L}}{\sqrt{g}}:\frac{\sqrt{l}}{\sqrt{g}}$, from which it is easy to deduce equations similar to those given in the preceding corollary.

245. Cor. 5. Since $T\doteq\frac{\sqrt{L}}{\sqrt{g}}$, $\sqrt{g}\times T\doteq\sqrt{L}$; and if the time of oscillation is 1 second, we have $\sqrt{g}\doteq\sqrt{L}$, or $g\doteq L$, that is, the force of gravity in different latitudes varies as the length of a pendulum that vibrates seconds.

246. Cor. 6. The number of oscillations which a pendulum makes in a given time, and in a given latitude, are in the inverse subduplicate ratio of its length. The number of oscillations n made in a given time are evidently in the inverse ratio of t, the time of each oscillation; that is $n\doteq\frac{1}{t}$; but by Corollary 3. $t\doteq\sqrt{l}$, therefore $n\doteq\frac{1}{\sqrt{l}}$, and $l\doteq\frac{1}{n^2}$, from which it is easy to find the length of a pendulum which will vibrate any number of times in a given time, or the number of vibrations which a pendulum of a given length will perform in a given time.

Prop. IX.

247. **To find the space through which a heavy body will fall in one second by the force of gravity.**

Since by Proposition 8. the time of an oscillation is to the time along half the length of the pendulum as 3.14159 is to 1, and since the spaces are as the squares of the times, the spaces described by a heavy body in the time of an oscillation will be to half the length of the pendulum as $\overline{3.14159}^2$ is to 1. Now it appears from the experiments of Mr Whitehurst, that the length of a pendulum which vibrates seconds at London at 113 feet above the level of the sea, in a temperature of

60° of Fahrenheit, and when the barometer is 30 inches, is 39.1196 inches; hence $1^2 : \overline{3.14159}|^2 = \frac{39.1196}{2} : 19.5598 \times \overline{3.14159}|^2 = 16.087$ feet the space required.

The methods of determining the centre of oscillation, gyration, and percussion, properly belong to this chapter, but they have been already given in the article ROTATION, to which we must refer the reader who wishes to prosecute the subject.

CHAP. VI. *On the Collision or Impulsion of Bodies.*

248. DEF. 1. When a body moving with a certain velocity strikes another body, either at rest or in motion, the one is said to impinge against, or to impell the other. This effect has been distinguished by the names collision, impulsion or impulse, percussion, and impact.

249. DEF. 2. The collision or impulsion of two bodies is said to be *direct* when the bodies move in the same straight line, or when the point in which they strike each other is in the straight line which joins their centres of gravity. When this is not the case, the impulse is said to be oblique.

250. DEF. 3. A *hard* body is one which is not susceptible of compression by any finite force. An *elastic* body is one susceptible of compression, which recovers its figure with a force equal to that which compresses it. A *soft* body is one which does not recover its form after compression. There does not exist in nature any body which is either perfectly hard, perfectly elastic or perfectly soft. Every body with which we are acquainted possesses elasticity in some degree or other. Diamond, crystal, agate, &c. though among the hardest bodies, are highly elastic; and even clay itself will in some degree recover its figure after compression. It is necessary, however, to consider bodies as hard, soft or elastic, in order to obtain the limits between which the required results must be contained.

251. DEF. 4. The mass of a body is the sum of the material particles of which it is composed; and the *momentum*, or *moving force*, or *quantity of motion* of any body, is the product arising from multiplying its mass by its velocity.

PROP. I.

252. **Two hard bodies B, B′ with velocities V, V′ striking each other perpendicularly, will be at rest after impulse, if their velocities are inversely as their masses.**

1. When the two bodies are equal, their velocities must be equal in the case of an equilibrium after impulse, and therefore $B : B' = V' : V$, or $BV = B'V'$; for if they are not at rest after impulse, the one must carry the other along with it: But as their masses and velocities are equal, there can be no reason why the one should carry the other along with it.

2. If the one body is double of the other, or $B = 2B'$, we should have $V' = 2V'$. Now instead of B we may substitute two bodies equal to B′, and instead of V′ we may substitute two velocities equal to V, with which the bodies B′ may be conceived to move; consequently we have $2B' \times V = B' \times 2V$, or $B' : 2B' = V : 2V$; but 2V is the velocity of B′, and V is the velocity of 2 B′, therefore when one body is double of the other, they will remain at rest when the masses of the bodies are inversely as their velocities.

In the same way the proposition may be demonstrated when the bodies are to one another in any commensurable proportion.

PROP. II.

253. **To find the common velocity v of two hard bodies B, B′ whose velocities are V, V′, after striking each other perpendicularly.**

If the bodies have not equal quantities of motion they cannot be in equilibrio after impulse. The one will carry the other along with it, and in consequence of their hardness, they will remain in contact, and move with a common velocity v.

1. In order to find this, let us first suppose B′ to be at rest and to be struck by B in motion. The quantity of motion which exists in B before impulse is BV, and as this is divided between the two bodies after impulse, it must be equal to the quantity of motion after impulse. But $v \times \overline{B + B'}$ is the quantity of motion after impulse, therefore $v \times \overline{B + B'} = BV$, and $v = \frac{BV}{B+B'}$.

2. Let us now suppose that both the bodies are in motion in the same direction that B follows B′. In order that B may impel B′, we must have V greater than V′. Now we may conceive both the bodies placed upon a plane moving with the velocity V′. The body B′, therefore, whose velocity is V′ equal to that of the plane, will be at rest upon the plane, while the velocity of B with regard to B′ or the plane, will be $V - V'$; consequently, the bodies are in the same circumstances as if B′ were at rest, and B moving with the velocity $V - V'$. Therefore, by the last case, we have the common velocity of the bodies in the moveable plane $\frac{BV - BV'}{B + B'}$; and by adding to this V′, the velocity of the plane, we shall have v, or the absolute velocity of the bodies after impulse, $v = \frac{BV + B'V'}{B + B'}$. Hence the quantity of motion, after impact, is equal to the sum of the quantities of motion before impact.

3. If the impinging bodies mutually approach each other, we may conceive, as before, that the body B′ is at rest upon a plane which moves with a velocity V′ in an opposite direction to V′, and that B moves on this plane with the velocity $V + V'$. Then, by Case 1. $\frac{BV + BV'}{B + B'}$ will be the common velocity upon the plane after impulse; and adding to this V′, or the velocity of the plane, we shall have v, or the absolute velocity of the bodies after impact, $v = \frac{BV - B'V'}{B + B'}$. Hence the quantity of motion after impact is equal to the difference of the quantities of motion before impact. It is obvious that v is positive or negative, according as BV is greater or less than B′V′, so that when BV is greater than B′V′, the bodies will move in the direction of B's

B's motion; and when BV is less than B'V', the bodies will move in the direction of A's motion.

254. All the three formulæ which we have given, may be comprehended in the following general formula, $v=\frac{BV\pm B'V'}{B+B'}$; for when B' is at rest, $V'=0$, and the formula assumes the form which it has in Case 1.

255. COR. 1. If $B=B'$, and the bodies mutually approach each other, the equation in Case 3. becomes $v=\frac{V-V'}{2}$, or the bodies will move in the direction of the quickest body, with a velocity equal to one half of the difference of their velocities.

256. COR. 2. If $V=V'$, and the bodies move in the same direction, the last formula will become $v=V\times\frac{B+B'}{B+B}$, or $v=V$; for in this case there can be no impulsion, the one body merely following the other in contact with it. When the bodies mutually approach each other, and when $V=V'$, we have $v=V+\frac{B-B'}{B+B}$.

257. COR. 3. When the bodies move in the same direction, we have, by Case 2. $v=\frac{BV+BV'}{B+B'}$. Now the velocity gained by B' is evidently $v-V'$, or $\frac{BV+B'V'}{B+B'}-V$ $=\frac{BV-BV'}{B+B'}$; hence $B+B':B=V-V':\frac{BV-BV'}{B+B'}$; but this last term is the velocity gained by B, and $V-V'$ is the relative velocity of the two bodies. Therefore, *in the impact of two hard bodies moving in the same direction*, $B+B'$: B *as the relative velocity of the two bodies is to the velocity gained by* B'. It is obvious also that the velocity lost by B is $V-v=V-\frac{BV+B'V'}{B+B'}$ or $\frac{B'V-B'V'}{B+B'}$; hence $B+B':B'=V-V':\frac{B'V-B'V'}{B+B}$; but this last term is the velocity lost by B, and $V-V'$ is the relative velocity of the bodies, therefore *in the impact of two hard bodies* $B+B'$: B' *as their relative velocity is to the velocity lost by* B. The same thing may be shewn when the bodies move in opposite directions, in which case their relative velocity is $V+V'$.

PROP. III.

258. To determine the velocities of two elastic bodies after impulse.

If an elastic body strikes a hard and immoveable plane, it will, at the instant of collision, be compressed at the place of contact. But as the elastic body instantaneously endeavours to recover its figure, and as this force of restitution is equal and opposite to the force of compression, it will move backwards from the plane in the same direction in which it advanced.—If two elastic bodies, with equal momenta, impinge against each other, the effect of their mutual compression is to destroy their relative velocity, and make them move with a common velocity, as in the case of hard bodies. But by the force of restitution, equal to that of compression, the bodies begin to recover their figure,—the parts in contact serve mutually as points of support, and the bodies recede from each other. Now, before the force of restitution began to exert itself, the bodies had a tendency to move in one direction with a common momentum; therefore, the body whose effort to recover its figure was in the same direction with that of the common momentum, will move on in that direction, with a momentum or moving force equal to the sum of the force of restitution and the common momentum; while the other body, whose effort to recover from compression is in a direction opposite to that of the common momentum, will move with a momentum equal to the difference between its force of restitution and the common momentum, and in the direction of the greatest of these momenta: After impulse, therefore, it either moves in the direction opposite to that of the common momentum, or its motion in the same direction as that of the common momentum is diminished, or it is stopped altogether, according as the force of restitution is greater, less, or equal to the common momentum.

259. In order to apply these preliminary observations, let us adopt the notation in the two preceding propositions, and let v be the common velocity which the bodies would have received after impulse, if they had been hard, and v', v'' the velocities which the elastic bodies B, B' receive after impact.

260. 1. If B follows B', then V is greater than V', and when B has reached B', they are both compressed at the point of impact. Hence, since v is the common velocity with which they would advance if the force of restitution were not exerted, we have $V-v=$ the velocity lost by B, and $v-V'=$ the velocity gained by B' in consequence of compression.—But, when the bodies strive to recover their form by the force of restitution, the body B will move backwards in consequence of this force, while B' will move onward in its former direction with an accelerated velocity. Hence, from the force of restitution, B will again lose the velocity $V-v$, and B' will, a second time, gain the velocity $v-V'$; consequently, the whole velocity lost by B is $2V-2v$, and the whole velocity gained by B' is $2v-2V'$. Now, subtracting this loss from the original velocity of B, we have $V-\overline{2V-2v}$, for the velocity of B after impact, and adding the velocity gained by B to its original velocity, we have $V'+\overline{2v-2V'}$ for the velocity of B' after impact; hence we have

$$v'=V-\overline{2V-2v}=2v-V$$
$$v''=V'+\overline{2v-2V'}=v-V.$$

Now, substituting in these equations, the value of v as found in Case 2. Prop. 2. we obtain

$$v'=\frac{BV-B'V+2B'V'}{B+B'}$$
$$v''=\frac{BV'-B'V'+2BV}{B+B'}.$$

261. 2. When the bodies move in opposite directions or mutually approach each other, the body A is in precisely the same circumstances as in the preceding case; but

but the body B′ loses a part of its velocity equal to $\overline{2v+2V'}-V'$. Hence we have, by the same reasoning that was employed in the preceding case,

$$v'=2v-V'$$
$$v''=2v+V',$$

and by substituting instead of v its value, as determined in Case 3. Prop. 2. or by merely changing the sign of V′ in the two last equations in the preceding corollary, we obtain the two following equations, which will answer for both cases, by using the upper sign when the bodies move in the same direction, and the under sign when they move in opposite directions.

$$v'=\frac{BV-B'V\pm 2B'V'}{B'+B'}$$

$$v''=\frac{\pm BV'\pm B'V'+2BV}{B+B'}.$$

From the preceding equation the following corollaries may be deduced.

262. Cor. 1. The velocity gained by the body that is struck, and the velocity lost by the impinging body, are twice as great in elastic as they are in hard bodies; for in hard bodies the velocities gained and lost were $v-V'$, and $V-v$; whereas in elastic bodies the velocities gained and lost were $2v-2V'$, and $2V-2v$.

263. Cor. 2. *If one of the bodies, suppose* B′, *is at rest*, its velocity $V'=0$, and the preceding equation becomes

$$v'=\frac{VB-VB'}{B+B'};\ v''=\frac{2VB}{B+B'}.$$

264. Cor. 3. If one of the bodies B′ is at rest, and their masses equal, we have B=B′ and $V'=o$, by substituting which in the preceding formulæ, we obtain $v'=o$, and $v''=V$; that is, the impinging body B remains at rest after impact, and the body B′ that is struck when at rest moves on with the velocity of the body B that struck it, so that there is a complete transfer of B's velocity to B′.

265. Cor. 4. If B′ is at rest and B greater than B′, both the bodies will move forward in the direction of B's motion; for it is obvious from the equations in Cor. 2. that when B is greater than B′, v', and v'' are both positive.

266. Cor. 5. If B′ is at rest, and B less than B′, the impinging body B will return backwards, and the body B′ which is struck will move forward in the direction in which B moved before the stroke. For it is evident that when B is less than B′, v' is negative, and v'' positive.

267. Cor. 6. *If both the bodies move in the same direction*, the body B′ that is struck will after impact move with greater velocity than it had before it. This is obvious from the formula in Case 1. of this proposition.

268. Cor. 7. *If the bodies move in the same direction*, and if B=B′, there will at the moment of impact be a mutual transfer of velocities, that is, B will move on with B′'s velocity, and B′ will move on with B's velocity. For in the formulæ in Case 1. when B=B, we have $v'=V'$ and $v''=V$.

269. Cor. 8. *When the bodies move in opposite directions*, or mutually approach other, and when B=B′ and $V=V'$, both the bodies will recoil or move backwards after impact with the same velocities which they had before impact. For in the formulæ in Case 2. with the inferior signs, when B=B′ and $V=V'$, we have $v'=-V$ and $v''=V'$.

270. Cor. 9. If the bodies move in opposite directions, and $V=V'$, we have $v'=V\times\frac{B-3B'}{B+B'}$, and $v''=V\times\frac{3B-B'}{B+B'}$. Hence it is obvious, that if B=3 B′, or if one of the impinging bodies is thrice as great as the other, the greatest will be stopped, and the smallest will recoil with a velocity double of that which it had before impact. For since B=3 B′, by substituting this value of B in the preceding equations, we obtain $v'=o$, and $v''=2V$.

271. Cor. 10. If the impinging bodies move in opposite directions, and if B=B′, they will both recoil after a mutual exchange of velocities. For when B=B′, we have $v'=-V'$, and $v''=V$.

272. Cor. 11. When the bodies move in opposite directions, the body which is struck, and the body which strikes it, will stop, continue their motion, or return backwards, according as $BV-B'V$ is equal to, or greater or less than $2B'V'$.

273. Cor. 12. The relative velocity of the bodies after impact, is equal to their relative velocity before impact, or, which is the same thing, at equal instants before and after impact, the distance of the bodies from each other is the same. For in the different cases we have $v'=2v-V$; $v''=2v\mp V'$. But the relative velocity before impact is in the different cases $V\mp V'$, and the relative velocity after impact is $v'-v'=V\mp V'$.

274. Cor. 13. By reasoning similar to that which was employed in Prop. 2. Cor. 3. it may be shewn that B+B′ : 2 B as their relative velocity before impact is to the velocity gained by B′ in the direction of B's motion; and B+B′ : 2 B′ as their relative velocity before impact is to the velocity lost by B in the direction of A's motion.

275. Cor. 14. This *vis viva*, or the sum of the products of each body multiplied by the square of its velocity, is the same before and after impact, that is, $Bv'^2+B'v''^2=BV^2+B'V'^2$. From the formulæ at the end of Case 2. we obtain

$$Bv'^2=\frac{\overline{B-B'}|^2\times\overline{BV^2+B'V'^2}}{\overline{B+B'}|^2}\text{ and}$$

$$B'v''^2=\frac{4BB'\times\overline{BV^2+B'V'^2}}{\overline{B+B'}|^2},\text{hence their sum }Bv'^2\times B'v''^2$$

$$=\frac{\overline{B-B'}|^2\times\overline{BV^2+B'V'^2}+4BB'\times\overline{BV^2+B'V'^2}}{\overline{B+B'}|^2}=$$

$$\frac{\overline{BV^2+B'V'^2}\times\overline{B^2-B'^2+4BB'}}{B+B'^2}=BV^2+B'V'^2.$$

276. Cor. 15. If several equal elastic bodies B, B″. B‴, B⁗, &c. are in contact, and placed in the same straight line, and if another elastic body β of the same magnitude impinges against B, they will remain at rest, except the last body B⁗, which will move on with the velocity of β. By Art. 264. B will transfer to

Theory.

to B'' all its velocity, and therefore B will be at rest, in the same way B'' will transfer to B''' all its velocity, and B'' will remain at rest, and so on with the rest; but when the last body B'''' is set in motion, there is no other body to which its velocity can be transferred, and therefore it will move on with the velocity which it received from B''', that is, with the velocity of β.

277. Cor. 16. If the bodies decrease in size from B to B'''', they will all move in the direction of the impinging body β, and the velocity communicated to each body will be greater than that which is communicated to the preceding body.

278. Cor. 17. If the bodies increase in magnitude, they will all recoil, or move in a direction opposite to that of β, excepting the last, and the velocity communicated to each body will be less than that which is communicated to the preceding body.

Prop. IV.

279. To determine the velocities of two imperfectly elastic bodies after impulse, the force of compression being in a given ratio to the force of restitution or elasticity.

Let B, B' be the two bodies, V, V' their velocities before impact, v', v'' their velocities after impact, and $1 : n$ as the force of compression is to that of restitution. It is evident from Case 1. Prop. 8. that in consequence of the force of compression alone we have,

$$\left.\begin{array}{l} V-v=\text{velocity lost by B} \\ v-V'=\text{velocity gained by B}' \end{array}\right\}\text{from compression.}$$

But the velocity which B loses and B' gains by the force of compression will be to the velocity which B loses and B' gains by the force of restitution or elasticity as $1 : n$; hence

$$\left.\begin{array}{l} 1 : n=V-v : nV-nv,\text{ the velocity lost by B} \\ 1 : n=v-V' : nv-nV'\text{ the velocity gained by B} \end{array}\right\}\text{from elasticity.}$$

therefore by adding together the two portions of velocity lost by B, and also those gained by B', we obtain

$\overline{1+n}\,V-\overline{1+n}\,v$, the whole velocity lost by B,
$\overline{1+n}\,v-\overline{1+n}\,V'$, the whole velocity gained by B.

Hence by subtracting the velocity lost by B in consequence of collision from its velocity before impact, we shall have v' or the velocity of B after impact, and by adding the velocity gained by B' after collision to its velocity before impact, we shall find v'' or the velocity of B' after impact, thus

$v'=V-\overline{1+n}V-\overline{1+n}v$ the velocity of B after impact.
$v''=V'+\overline{1+n}v-\overline{1-n}V'$ the velocity of B after impact.

Now by substituting in the place of v its value as determined in Case 2. Prop. 2. we obtain

$$v'=V-\frac{\overline{1+n}\times\overline{B'V-B'V'}}{B+B'}.$$

$$v'=V+\frac{\overline{1+n}\times BV-BV'}{B+B}.$$

280. Cor. 1. Hence by converting the preceding equation into analogies, $B+B : \overline{1+n}\times B$ as the relative velocity of the bodies before impact is to the velocity gained by B' in the direction of B's motion; and $B+B' : 1+n\times B'$ as the relative velocity of the bodies before impact is to the velocity lost by B.

Theory.

281. Cor. 2. The relative velocity before impact is to the relative velocity after impact as the force of compression is to the force of restitution, or as $1 : n$.

The relative velocity after impact is $v''-v'$, or taking the preceding values of these quantities $v''-v'=V'$ $+\dfrac{\overline{1+n\times\overline{BV-BV'}}}{B+B'}-V-\dfrac{\overline{1+n+\overline{B'V-B'V'}}}{B+B'}=V'-V+\dfrac{\overline{1+n}\times\overline{B+B'}\times\overline{V-V'}}{B+B'}$, dividing by $B+B'$ we have $v''-v'=V'-V+V-V'+n\times\overline{V-V'}=n\times\overline{V-V'}$ $=$ the relative velocity after impact. But the relative velocity before impact is $V-V'$, and $V-V' : n\times\overline{V-V'}=1 : n$. Q. E. D. The quantity V' has evidently the negative sign when the bodies move in opposite directions.

282. Cor. 3. Hence from the velocities before and after impact we may determine the force of restitution or elasticity.

Prop. V.

283. To find the velocity of a body, and the direction in which it moves after impinging upon a hard and immoveable plane.

When the body is perfectly hard. Fig. 6.

283. Case 1. *When the impinging body is perfectly hard.* Let AB be the hard and immoveable plane, and let the impinging body move towards AB in the direction CD, and with a velocity represented by CD. Then the velocity CD may be resolved into the two velocities, CM, MD, or MD, FD; CM DF being a parallelogram. But the part of the velocity FD, which carries the body in a line perpendicular to the plane, is completely destroyed by impact, while the other part of the velocity MD, which carries the body in a line parallel to the plane, will not be affected by the collision, therefore the body will, after impact, move along the plane with the velocity MD. Now, CD : MD=radius : cos.∠CDM, therefore since MD =CF the sine of the angle of incidence CDF, the *velocity before impact is to the velocity after impact, as radius is to the sine of the angle of incidence;* and since AM=CD−MD, *the velocity before impact is to the velocity lost by impact, as radius is to the versed sine of the complement of the angle of incidence.*

When the body is perfectly elastic.

285. Case 2. *When the impinging body is perfectly elastic.* Let the body move in the direction CD with a velocity represented by CD, which, as formerly, may be resolved to MD, FD. The part of the velocity MD remains after impact, and tends to carry the body parallel to the plane. The other part of the velocity FD is destroyed by compression; but the force of restitution or elasticity will generate a velocity equal to FD, but in the opposite direction DF. Consequently the impinging body after impact is solicited by two velocities, one of which would carry it uniformly from D to F in the same time that the other would carry it uniformly from M to D, or from D to N; the body will, therefore

Theory.

therefore, move along DE, the diagonal of the parallelogram DFEN, which is equal to the parallelogram DFCM. Hence the angle CDF is equal to the angle EDF, therefore, when *an elastic body impinges obliquely against an immoveable plane, it will be reflected from the plane, so that the angle of reflexion is equal to the angle of incidence.* Since CD, DE are equal spaces described in equal times, the velocity of the body after impact will be equal to its velocity before impact.

When the body is imperfectly elastic.

286. Case 3. *When the impinging body is imperfectly elastic.* In DF take a point *m*, so that DF is to D *m* as the force of compression is to the force of restitution or elasticity, and having drawn *m c* parallel to DB, and meeting NE in *c*, join D *c*; then, if the impinging body approach the plane in the direction CD, with a velocity represented by CD, D *c* will be the direction in which it will move after impact. Immediately after compression, the velocity DF is destroyed as in the last case, while the velocity MD tends to carry the body parallel to the plane. But, by the force of restitution, the body would be carried uniformly along D *m*, perpendicular to the plane, while, by the velocity MD= DN—*m c*, it would be carried in the same time along *m c*, consequently, by means of these two velocities, the body will describe D *c*, the diagonal of the parallelogram D *m e* N. The velocity, therefore, before impact is to the velocity after impact as DC : D *c*, or as DE : D *c*, or as sin. D *c* E, sin. DE *c*, or as sin. D *c m*: sin. DE *c*, or as sin. FD *c* : sin. FDE. Now, by producing D *c* so as to meet the line CE produced in G, we have, on account of the parallels FE, *m c*, D *m* : DF =*m c* : FG; but, FD being radius, FE is the tangent of FDE, or FDG the angle of incidence, and FDG is the tangent of the angle of reflexion FDG: Therefore D *m* : DF=tang. ∠CDF : tang. ∠FDG. Consequently, *when an imperfectly elastic body impinges against a plane,* it will be reflected in such a manner *that the tangent of the angle of reflexion is to the tangent of the angle of incidence, as the force of compression is to the force of restitution or elasticity; and the velocity before incidence will be to the velocity after reflexion, as the sine of the angle of reflexion is to the sine of the angle of incidence.*

Scholium.

287. When the surface against which the body impinges is curved, we must conceive a plane touching the surface at the place of incidence, and then apply the rules in the preceding proposition. The doctrine of the oblique collision of bodies is of great use both in acoustics and optics, where the material particles which suffer reflexion are regarded as perfectly elastic bodies.

Prop. VI.

288. To find the point of an immoveable plane which an elastic body moving from a given place must strike, in order that it may, after reflexion, either from one or two planes, impinge against another body whose position is given.

Fig. 7.

289. Case 1. *When there is only one reflexion.* Let C be the place from which the impinging body is to move, and let E be the body which is to be struck after reflexion from the plane AB. From C let fall CH perpendicular to AB, continue it towards C till HG=CH, and join G, E by the line GDE; the point D where this line cuts the plane, is the place against which the body at C must impinge in order that, after reflexion, it may strike the body at E. The triangles CDH, HDG are equiangular, because two sides and one angle of each are respectively equal, therefore the angles DCH, DGH are equal. But on account of the parallels FD, CG the angle EDF=DGC=DCH, and DCH= FDC, therefore the angle of incidence FDC=FDE the angle of reflexion; consequently by Prop. 4. a body moving from C and impinging on the plane at D will, after reflexion, move in the line DE, and strike the body at E.

290. Case 2. *When there are two reflexions.* Let AB, BL, be the two immoveable planes, C the place from which the impinging body is to move, and F the body which it is to strike after reflexion from the two planes, it is required to find the point of impact D. Draw CHG perpendicular to AB, so that HG=CH. Through G draw GMN parallel to AB, cutting LB produced in M, and make GM=MN. Join N, F, and from the point E, where NF cuts the plane BL, draw EG, joining the points EG: the point D will be the point of the plane, against which the body at C must impinge, in order to strike the body at F. By reasoning as in the preceding case, it may be shewn that the angle CDH=EDB, therefore DE will be the path of the body after the first reflexion. Now, the triangles GEM, EMN are equiangular, because GM =MN, and the angles at M right, therefore DEB= FEL, that is, the body after reflexion at E will strike the body placed at F. Fig. 8.

Prop. VII.

291. To determine the motions of two spherical bodies which impinge obliquely upon each other, when their motion, quantities of matter, and radii, are given.

Let A, B be the two bodies, and let CA, DB be the directions in which they move before impact, and let these lines represent their respective velocities. Join A, B the centres of the bodies, and produce it both ways to K and I. Draw LM perpendicular to IK, and it will touch the bodies at the point of impact. Now, the velocity CA may be resolved into the two velocities CI, IA, and the velocity DB into the velocities DK, KB, but CA and DB are given, and also the angles CAI, DBK, consequently CI and IA, and DK and KB may be found. The velocities CI, DK, which are parallel to the plane, will not be altered by collision, therefore IA, KB are the velocities with which the bodies directly impinge upon each other, consequently their effects or the velocities after impact may be found from Prop. 3.; let these velocities be represented by AN, BP. Take AF=CI and BH=DM, and having completed the parallelograms AFON, BPQH, draw the diagonals AO, QB. Then, since the body A is carried parallel to the line LM with a velocity CI=AF, and from the line LM by the velocity AN, it will describe AO, the diagonal of the parallelogram Fig. 9.

Theory.

rallelogram NF; and for the same reason the body B will describe the diagonal BQ of the parallelogram PH.

Fig. 10. 292. COROLLARY. If A=B, and if the body which is struck moves in a given direction and with a given velocity after impact, the direction of the impinging body, and the velocity of its motion, may be easily found. Let the body D impinge against the equal body C, and let CB be the direction in which C moves after impact, it is required to find the direction in which D will move. Draw D c, touching the ball C at c, the place where the ball D impinges; produce BC to E, and through c draw A c F perpendicular to EB, and complete the rectangle FE. The force D c may be resolved into the forces E c, c F, of which E c is employed to move the ball C in the direction CB and with the velocity E c; but the force c F has no share in the impulse, and is wholly employed in making the body D move in the direction CA, and with the velocity CF.

SCHOLIUM.

The phenomena of impulsion owing to repulsive forces which prevent bodies from coming into mathematical contact.

293. In the preceding proposition, we have endeavoured to give a short and perspicuous view of the common theory of impulsion. The limits of this article will not permit us to enter upon those interesting speculations to which this subject has given rise; but those who are anxious to pursue them will find ample assistance in the article IMPULSION, in the Supplement to the last edition of this work, where Dr Robison has treated the subject with his usual ability. It may be proper however to remark, that all the phenomena of impulse as well as pressure, are owing to the existence of forces which prevent the particles of matter from coming into mathematical contact. The body which is struck, in the case of collision, is put in motion by the mutual repulsion of the material particles at the point of impact, while the velocity of the impinging body is diminished by the same cause. Hence we see the absurdity of referring all motion to impulse, or of attempting to account for the phenomena of gravitation, electricity, and magnetism by the intervention of any visible fluid. Even if the supposition that such a medium exists were not gratuitous, it would be impossible to shew that its particles, by means of which the impulse is conveyed, are in contact with the particles of the body to which that impulse is communicated.

Don Georges Juan's physico-mathematical theory of percussion.

294. A physico-mathematical theory of percussion, in which the impinging bodies are considered as imperfectly elastic, has been lately given by Don Georges Juan, in his *Examen Maritimo*, a Spanish work which has been translated with additions by M. L'Eveque, under the title of *Examen maritime, theorique et pratique, ou Traite de mecanique, applique a la construction, et a la manœuvre des vaisseaux et autres batimens.* This theory has been embraced by many eminent French philosophers, and may be seen in Prony's *Architecture Hydraulique*, vol. i. p. 208, and in Gregory's Mechanics, vol. i. p. 291. We shall endeavour, under the article PERCUSSION, to give a short account of this interesting theory, which has been found to accord with the most accurate experiments.

295. In some cases of collision the results of experiments are rather at variance with those of theory, in consequence of the communication of motion not being exactly instantaneous. "If an ivory ball (says Mr Leslie) strikes against another of equal weight, there should, according to the common theory, be an exact transfer of motion. But if the velocity of the impinging ball be very considerable, so far from stopping suddenly, it will recoil back again with the same force, while the ball which is struck will remain at rest; the reason is, that the shock is so momentary, as not to permit the communication of impulse to the whole mass of the second ball, a small spot only is affected, and the consequence is therefore the same as if the ball had impinged against an immoveable wall. On a perfect acquaintance with such facts depends, in a great measure, the skill of the billiard player. It is on a similar principle that a bullet fired against a door which hangs freely on its hinges will perforate without agitating it in the least. Nay, a pellet of clay, a bit of tallow, or even a small bag of water, discharged from a pistol will produce the same effect. In all these instances the impression of the stroke is confined to a single spot, and no sufficient time is allowed for diffusing its action over the extent of the door. If a large stone be thrown with equal momentum, and consequently with smaller velocity, the effect will be totally reversed, the door will turn on its hinges, and yet scarcely a dent will be made on its surface. Hence likewise the theory of most of the tools, and their mode of application in the mechanical arts: the chisel, the saw, the file, the scythe, the hedge bill, &c.—In the process of cutting, the object is to concentrate the force in a very narrow space, and this is effected by giving the instrument a rapid motion. Hence, too, the reason why only a small hammer is used in rivetting, and why a mallet is preferred for driving wedges." *Enquiry into the Nature of Heat*, p. 127,8.

Successive propagation of motion illustrated. Fig. 11.

296. The successive propagation of motion may be illustrated by a very simple experiment. Take two balls A, B, of which B is very large when compared with A, and connect them by a string S passing over the pulley P. If the ball B is lifted up towards S and allowed to fall by its own weight, instead of bringing the little ball A along with it, as might have been expected, the string will break at P. Here it is evident that the motion is not propagated instantaneously, for the string is broken before the motion is communicated to the portion of the string between P and A.

Apparatus for experiments on collision. Fig. 12.

297. An apparatus for making experiments on the collision of bodies is represented in fig. 12. The impinging bodies are suspended by threads like pendulums, and as the velocities acquired by descending through the arches of circles are in the ratio of their chords, the velocities of the impinging bodies may be easily ascertained. The apparatus is therefore furnished with a graduated arch MN which is generally divided into equal parts, though it would be more convenient to place the divisions at the extremities of arcs whose chords are expressed by the corresponding numbers. The balls that are not used may be placed behind the arc as at m and n; and in order to give variety to the experiments, the balls may be of different sizes. Sometimes a dish like G is attached to the extremities of the strings, for the purpose of holding argillaceous balls, and balls of wax softened with a quantity of oil equal to one-fourth part of their weight.—See *Smeaton's Experiments on the Collision of Bodies.*

CHAP.

Theory.

Chap. VII. *On the Maximum Effects of Machines.*

298. We have already seen in some of the preceding chapters, that when two bodies act upon each other by the intervention either of a simple or compound machine, there is an equilibrium when the velocity of the power is to the velocity of the weight as the weight is to the power. In this situation of equilibrium, therefore, the velocity of the weight is nothing, and the power has no effect in raising the weight, or, in other words, the machine performs no work. When the weight to be raised is infinitely small, the velocity is the greatest possible; but in this case likewise, the machine performs no work. In every other case, however, between these two extremes, some work will be performed.—In order to illustrate this more clearly, let us suppose a man employed in raising a weight by means of a lever with equal arms; and that he exerts a force upon the extremity of the lever, equivalent to 50 pounds. If the weight to be raised is also 50 pounds, there will be an equilibrium between the force of the man and the weight to be raised, the machine will remain at rest, and no work will be performed. If the man exert an additional force of one pound, or if his whole force is 51 pounds, the equilibrium will be destroyed, the weight will rise with a very slow motion, and the machine will therefore perform some work. When the motion of the machine therefore is $=0$ the work performed is also nothing, and when the machine is in such a state that the power preponderates, the work performed increases. Let us now suppose that the weight suspended from the lever is infinitely small, the motion of the machine will then be the greatest possible; but no work will be performed. If the weight however is increased, the motion of the machine will be diminished, and work will be performed. Here then it is evident that the work performed increases from nothing when the velocity is a maximum, and decreases to nothing when the velocity is a minimum. There must therefore be a particular velocity when the work performed is a *maximum*, and this particular velocity it is our present object to determine. Sometimes, indeed, the velocities of the machine are determined by its structure, and therefore it is out of the power of the machine to obtain a maximum effect by properly proportioning them. The same object however may be obtained, by making the work to be performed, or the resistance to be overcome, in a certain proportion to the power which is employed to perform the work or overcome the resistance.

299. Def. 1.—In a machine performing work, the powers employed to begin and continue the motion of the machine, are called the *first movers*, *the movers of powers*; and those powers which oppose the production and continuance of motion are called *resistances*. The friction of the machine, the inertia of its parts, and the work to be performed, all oppose the production and continuance of motion, and are therefore the resistances to be overcome. When various powers act at the same time, and in different directions, the equivalent force which results from their combined action is called the *moving force*, and the force resulting from all the resisting forces, the *resistance*. If the machine, for example, is a lever AB moving round the centre F, by means of which, two men raise water out of two pump barrels by the chains Au, Cw attached to the pistons, and passing over the arched heads or circular sectors M, N, for the purpose of giving the pistons and chains a vertical motion. Let the force of the man at B, six feet from F, be equal to 50 pounds, or π, his mechanical energy to turn the lever is $6\times 50=300$. Let the force of the other man applied at E, four feet from F, be also equal to 50 pounds, or p. His mechanical energy will be $4\times 50=200$, so that the whole moving power is equal to $300+200=500$. But if the two forces of 50 pounds, instead of being applied at two different distances from F, had been applied at the same point G, 5 feet from F, their energy to turn the lever would have been the same, for $5\times 50+50=500$. In the present case, therefore, the *moving force* is equivalent to $P\times GF$, or a force of 100 pounds acting at a distance of five feet from the centre of motion. Now let us suppose that each piston $A\,u$, $C\,w$ raises 60 pounds of water equivalent to the weights u, w, and that $CF=2$ feet, and $AF=3$ feet, then the mechanical energy of these weights will be respectively $2\times 60=120$, and $3\times 60=180$, and the sum of their energies $=300$. But two forces of 60 pounds each, acting at the distances two feet and three feet from F, are equivalent to their sum $=120$ pounds, acting at a distance of two feet and a half from F, for $2\frac{1}{2}\times 120=300$; therefore, the resistance arising from the work to be performed, or from the water raised in the pump barrels, is equal to a weight P of 120 pounds acting at the distance $DF=2\frac{1}{2}$ feet. But in addition to the resistance arising from the work to be performed, the two men have to overcome the resistance arising from the friction of the piston in the barrels, which we may suppose equivalent to f, φ, each equal to 10 pounds, acting at the points A, C; but these forces are equivalent to 20 pounds, or $f+\varphi$ acting at D, therefore the resistance arising from the work and from friction is equal to 140 pounds, acting at the distance $DF=2$ feet and a half. While the two men are employed in overcoming these resistances, they have also to contend against the inertia of the beam AF, and that of the chains and pistons, which we may suppose equal to 20 pounds when collected in their centre of gravity g, whose distance from F is 2.2 feet; but a weight of 20 pounds acting at the distance of 2.2 feet is equivalent to a weight of $19\frac{1}{2}$ pounds, acting at the distance of 2.5 feet, or DF, consequently the sum of all the resistances when reduced to the same point D of the lever is equal to $159\frac{1}{2}$ pounds acting at the distance of 2.5 feet from F. The mechanical energy, therefore, of the sum of all the resistances will be $=2.5\times 159\frac{1}{2}=398.75$, while the energy of the moving force, or the sum of all the moving powers, is equal to 500.

Plate CCCXXII. fig. 1.

300. Def. 2.—The *impelled point* of a machine is that point to which the moving power is applied, if there is only one power, or that point to which all the moving powers are reduced, or at which the moving force is supposed to act. The *working point* of a machine is that point at which the resistance acts if it is single, or that point to which all the resistances are reduced, and at which they are supposed to act when combined. Thus in fig. 1. G is the impelled point of the machine, and D the working point. Had a single force π been applied at the point B to raise a single weight u, acting at

Fig. 1.

Theory.

at the point A, then B would have been the impelled point, and A the working point of the machine. In the wheel and axle, the point of the wheel at which the rope touches its circumference is the impelled point, while the working point is that point in the circumference of the axle where the rope which carries the weight is in contact with it.

301. Def. 3.—The velocity of the moving power, and the velocity of the resistance, are respectively the same as the velocity of the impelled point, and the velocity of the working point.

302. Def. 4.—The *effect* of a machine, or the *work performed*, is equal to the resistance multiplied by the velocity of the working point; for when any machine raises a mass of matter to a given height in a certain time, the effect produced is measured by the product of the mass, and the height through which it rises, that is, by the product of the mass by the velocity with which it moves.

303. Def. 5.—The *momentum of impulse* is equal to the moving force multiplied by the velocity of the impelled point.

Explanation of symbols.

304. In any machine that has a motion of rotation, let x be the velocity of the impelled point, and y the velocity of the working point. When the machine is a lever, x, y will express the perpendiculars let fall from the centre of motion upon the line of direction in which the forces act; and if the machine is a wheel and axle, x, y will represent the diameters of the wheel and the axle respectively. In compound machines, which may be regarded as composed of levers, (Art. 90.) x will represent the sum of all the levers by which the power acts, and y the sum of all the levers by which the resistance acts.

305. Let P be the real pressure which the moving power exerts at the impelled point of the machine, and R the actual pressure which the mere resistance of the work to be performed exerts at the working point, or which it directly opposes to the direction of the power. Let a be the inertia of the power P, or the mass of matter which the power P must move with the velocity of the impelled point, in order that P may exert its pressure at the impelled point; and let b be the inertia of the resistance R, or the mass of matter which must be moved with the velocity of the working point in the performance of the work.

306. Since the resistance arising from the friction of the communicating parts is an uniformly retarding force, it may be measured by a weight φ acting at the working point of the machine, which will oppose the same resistance to the moving power as the friction of the parts.

307. Let m be the inertia of the machine, or rather that quantity of matter, which acting at the working point of the machine will require the same part of the moving force to give it an angular motion, then since y represents the arm of the lever by which the resistance acts, or the distance of the working point from the centre of motion; and since the momentum of inertia, or the momentum with which any mass revolving round a centre resists being put in motion, is equal to its quantity of matter multiplied by the square of its distance from its centre of motion (see article Rotation), we have $m\,y^2$ for the momentum of inertia of the machine. It is obvious that every machine opposes a certain resistance to any force that endeavours to give it an angular motion, and that this resistance will increase with the inertia of its parts. It is easy, therefore, to find a quantity of matter, which, when placed at any part of the machine, will oppose the same resistance to an angular motion, as the combined inertia of the various parts of the machine. This is the quantity of matter which we have called m, and which we have supposed to act at the working point, because to that point all the other resistances have been reduced. Collecting the symbols, therefore, we have

$x=$ the velocity of the impelled point or the radius of the wheel, or the length of the lever by which the power acts.

$y=$ the velocity of the working point, or the radius of the axle, or the length of the lever by which the resistance acts against the power.

P $=$ the pressure exerted by the power at the impelled point of the machine.

R $=$ the pressure which the resistance arising from the work to be performed exerts at the working point of the machine.

$a=$ the inertia of the power P, or the quantity of matter to which it must communicate the velocity of the impelled point.

$b=$ the inertia of the resistance R, or the quantity of matter which it must move with the velocity of the working point before any work is performed.

$\varphi=$ a quantity of matter which, if placed at the working point of the machine, would oppose the same resistance to the moving power as that which arises from the friction of the communicating parts.

$m=$ the quantity of matter which, if placed at the working point of the machine, would oppose the same resistance to the production of an angular motion, that is opposed by the inertia of the various parts of which the machine is composed. Hence, by the principles of rotation, we have

$my^2=$ the momentum of inertia of the machine.

We are now prepared for determining the conditions of construction, which will enable any machine to produce a maximum effect.

Prop. I.

308. To determine the velocities which must be given to the impelled and working points of a machine, or the ratio of the levers by which the power and resistance ought to act, in order to obtain a maximum effect.

Let AB be a lever, whose fulcrum is F, and to whose extremity B is applied to the power P to overcome the resistance R, and let FB$=x$, and FA$=y$. Then, by Art. 36. we shall have, from the following analogy, the weight which, placed at B, would be in equilibrio with R; $x : y = \text{R} : \frac{\text{R}y}{x}$, the weight which will keep R in equilibrio, or the weight which is equal to Fig. 2.

Theory.

to that part of the power P which balances the resistance R. Hence, $P-\frac{Ry}{x}$ will be the effective force exerted by the power P, which, multiplied by x, its distance from the centre of motion gives $Px-Ry$ for the force which is exerted in giving an angular motion to the power and resistance. But the resistance of friction was supposed equal to the weight φ acting at the working point or at the distance FA or y; consequently, φy will be the resistance which friction opposes to the force $Px-Ry$, and therefore $Px-Ry-\varphi y$ is the motive force exerted by P. Now, the momentum of the inertia of the power P, or the force with which it resists being put in motion, is ax^2, and the momentum of inertia of the resistance R is by^2, while the momentum of inertia of the machine is my^2. Therefore, the sum of these momenta, viz. $ax^2+by^2+my^2$ is the mass to be put in motion by the power P. But, by DYNAMICS, § 167. the velocity generated in a given time is directly as the motive force, and inversely as the quantity of matter to which that force is applied. Hence the angular velocity, or the number of turns which the machine will make in a given time, is $\frac{Px-Ry-\varphi y}{ax^2+by^2+my^2}$. But in every rotatory machine the velocities of its different parts are as their distance from the axis; hence, we shall have the velocities of the impelled and working points of the machine, by multiplying the angular velocity by x, y the distances of the impelled and working points of the machine from the centre of motion. Therefore,

$\frac{Px^2-Rxy-\varphi xy}{ax^2+by^2+my^2}=$ the velocity of the impelled point,

and

$\frac{Pxy-Ry^2-\varphi y^2}{ax^2+by^2+my^2}=$ the velocity of the working point

of the machine; and multiplying by R, we have from

Def. 4. $\frac{PxyR-R^2y^2-\varphi Ry^2}{ax^2+vy^2+my^2}=$ the work performed.

309. But as forces are proportional to the velocities generated by them in equal times (DYNAMICS, § 153. Cor. 4. § 159.), the preceding quantities will represent the accelerating forces. Now, the velocities are as the forces and times jointly (DYNAMICS, § 153.), that is, $v=Ft$, or is $=gtF$; but F, the accelerating force, which generates the velocity of the impelled point, is represented by the formula $\frac{Px^2-Rxy-\varphi xy}{ax^2+by^2+my^2}$. Therefore, v, or the absolute velocity of the impelled point, is $\frac{Px^2-Rxy-\varphi xy}{ax^2+by^2+my^2}\times gt$, and the absolute velocity of the working point $\frac{Pxy-Ry^2-\varphi y^2}{ax^2+by^2+my^2}\times gt$. Again, by Def. 4. the effect of a machine, or the work performed, is equal to the resistance of the work multiplied by the velocity; consequently, since R is the work, we have for the performance of the machine,

$$\frac{PxyR-R^2y^2-\varphi Ry^2}{ax^2+by^2+my^2}\times gt.$$

Now, considering y as the variable quantity, and making the fluxion of the preceding formula $=0$, we shall find that the performance of the machine is a maximum, when

$$y=\frac{\overline{a^2\times\overline{R+\varphi}|^2+P^2a\times\overline{m+b}}|^{\frac{1}{2}}-aR-a\varphi}{Pm+Pb}\times x.$$

When $R=0$, we have

$$y=\frac{\overline{a^2\varphi^2+P^2a\times\overline{m+b}}|^{\frac{1}{2}}-a\varphi}{Pm+Pb}\times x.$$

When $\varphi=0$, the first formula becomes

$$y=\frac{\overline{a^2R^2+P^2a\times\overline{m+b}}|^{\frac{1}{2}}-aR}{Pm+Pb}\times x.$$

When both R and $\varphi=0$, we have, after reduction,

$$y=\frac{\sqrt{a}}{\sqrt{m+b}}\times x.$$

When $b=0$, the first formula becomes

$$y=\frac{\overline{a^2\times\overline{R+\varphi}|^2+P^2am}|^{\frac{1}{2}}-aR-a\varphi}{Pm}\times x.$$

When R, φ and $b=0$, we have

$$y=\frac{\sqrt{a}}{\sqrt{m}}\times x.$$

When $a:b=P:R$, we have, by substituting P and R instead of a and b,

$$y=\frac{\overline{P^2\times\overline{R+\varphi}|^2+P^3\times\overline{m+R}}|^{\frac{1}{2}}-PR-P\varphi}{Pm+PR}\times x.$$

When Pm and $\varphi=0$, the last formula becomes

$$y=\frac{\overline{P^2R^2+P^3R}|^{\frac{1}{2}}-PR}{PR}\times x=\sqrt{\frac{P^2R^2+P^3R}{P^2R^2}}-\frac{PR}{PR}\times x.$$

$$x=\sqrt{\frac{P}{R}+1}\Big|-1,$$

and when $x=1$, and $R=1$, we have

$$y=\sqrt{P+1}\Big|-1,$$

and when $P=1$, and $x=1$, we obtain

$$y=\sqrt{\frac{1}{R}+1}\Big|-1.$$

When $x=1$,

$$y=\sqrt{\frac{P}{R}+1}\Big|-1.$$

These various formulæ, the application of which to particular cases shall be shown in the practical part of this article, give us values of y for almost every species of machinery; so that the mechanic may easily determine the velocities which must be given to the impelled and working points of the machine in order to produce a maximum effect.

310. When the machine, however, is already constructed, the velocities of the impelled and working points cannot be changed, without altering the structure of the machine; and therefore we must find the ratio between the power and resistance, which will enable

Theory.

Theory.

enable us to obtain a maximum effect. The method of determining this will be shewn in the following proposition.

Prop. II.

311. To determine the ratio between the power and the resistance of a machine when its performance is a maximum.

Since the structure of the machine is given, the values of x, y are known, and therefore we have to determine the relative values of P and R, when the effect of the machine is a maximum. This would be easily done, by making R variable in the formula which expresses the performance of the machine, and making its fluxion equal to 0, if none of the other quantities varied along with R. It often happens, however, that while R varies, the mass b suffers a considerable change, though in other cases the change induced upon b is too unimportant to merit notice. This proposition, therefore, admits of two cases, 1. When the change upon b is so small that it may be safely omitted in the investigation; and, 2. When the change upon b is sufficiently great to require attention.

312. Case 1. When R is the only quantity which is variable, the fluxion of the formula

$$\frac{\mathrm{P}\,x\,y\,\mathrm{R}-\mathrm{R}^2y^2-\varphi\,\mathrm{R}\,y^2}{a\,x^2+b\,y^2+m\,y^2}$$

which represents the work performed, is equal to the fluxion of the numerator, because the denominator is constant, that is, $\mathrm{P}\,x\,y\,\dot{\mathrm{R}}-2\,\mathrm{R}\dot{\mathrm{R}}\,y^2-\varphi\,\dot{\mathrm{R}}\,y^2=0$, and, dividing by $\dot{\mathrm{R}}$; $\mathrm{P}\,xy-2\,\mathrm{R}\,y^2-\varphi\,y^2=0$, hence $2\,\mathrm{R}\,y^2=\mathrm{P}\,xy-\varphi\,y^2$, and $\mathrm{R}=\frac{\mathrm{P}\,xy-\varphi\,y^2}{2\,y^2}$, which, divided by y, gives $\mathrm{R}=\frac{\mathrm{P}\,x-\varphi\,y}{2\,y}$. Now, according to the experiments of Coulomb, the friction is, in general, proportional to the resisting pressure, or a certain part of that pressure, for example, $\frac{1}{15}\mathrm{R}$; and calling $\mathrm{Z}=\frac{1}{15}$, and omitting $\varphi\,y$, we have for the resistance $\mathrm{R}+\frac{1}{15}\mathrm{R}$, or $\frac{16}{15}\mathrm{R}=\frac{\mathrm{P}\,x-\varphi}{2\,y}$, or $\mathrm{R}=\left(\frac{\mathrm{P}x}{2\,y}\right)\div\frac{16}{15}$, and making $\mathrm{P}=1$, and $x=1$, we have $\mathrm{R}=\left(\frac{1}{2y}\right)\div\frac{16}{15}$, so that abstracting from the quotient $\frac{16}{15}$, which being little greater than 1, will not alter the result, the resistance should be one-half of the force which would keep the impelling power in equilibrio.

313. Case 2. When b varies at the same time with R, it will in most cases vary in the same proportions, and therefore may be represented by any multiple of R, as d R, where d may be either an integer or a fraction. In order to simplify the investigation, we may consider the fraction φ as a resistance diminishing the impelling power, instead of regarding it as a resistance to be added to the other resisting forces. Thus the impelling power P will become $\mathrm{P}-\varphi$. In the same way we may consider the momentum of the machine's inertia applied to the impelled point, that is, instead of my^2 it may be made $m\,x^2$. Now making $\mathrm{P}-\varphi$, or the impelling power $=1$, and making $x=1$, we shall have by these substitutions in the formula which expresses the effect of the machine, $\frac{\mathrm{R}\,y-\mathrm{R}^2y^2}{a+m+d\mathrm{R}\,y^2}$, or, for the sake of simplicity, making $a+m=q$, we have for the performance of the machine $\frac{\mathrm{R}y-\mathrm{R}^2y^2}{q+dry^2}$; then since R is the variable quantity, we shall find, after making the fluxion of this formula $=0$, that the performance is a maximum when $\mathrm{R}=\frac{\overline{q^2+q\,dy}|^{\frac{1}{2}}-q}{d\,y^2}$.

When $b=\mathrm{R}$ then $d-1$, and we shall have

$$\mathrm{R}=\frac{\overline{q^2+qy}|^{\frac{1}{2}}-q}{y^2}.$$

When $a=\mathrm{P}$ and $\mathrm{P}=1$, and when m, the inertia of the machine, $=0$, we shall have $a+m=1=q$, and then the formula becomes

$$\mathrm{R}=\frac{\overline{y+1}|^{\frac{1}{2}}-1}{y^2}.$$

When $y=x$, then $y=1$, and

$$\mathrm{R}=\frac{\overline{1+1}|^{\frac{1}{2}}-1}{1}=0.4142.$$

Scholium.

314. Those who wish to prosecute this interesting subject may consult the different papers of Euler in the *Comment. Petropol.* vol. x. p. 80, 1743, and in the *Comment. Nov. Petropol.* vol. iii. and viii. In the article Machinery in the Supplement to the last edition of this Work, the subject has been treated with great ability by Dr Robison, though he has omitted the various steps in the investigation which conduct to the leading formulæ. The subject has been also ably discussed by Professor Leslie in a paper published in the Appendix to Ferguson's Lectures, vol. ii. p. 353; and as the results of his investigations may be of great use in practice, we shall here present the reader with a short abstract of them.

If the resistance is equal to the power, is double, triple, or quadruple, &c. a maximum effect will be produced when the velocity of the power, or its distance from the centre of motion, is $1+\sqrt{2}$; $2+\sqrt{6}$; $3+\sqrt{12}$; $4-\sqrt{20}$; $5+\sqrt{30}$; $6+\sqrt{42}$, that of the weight being 1, &c. If the resistance is very great, compared with the power, the velocity should at least be double of that which would procure an equilibrium, in order that the machine will produce a maximum effect.

315. If the velocity of the power, or its distance from the centre of motion, be equal to, double, triple, quadruple, &c. &c. of the velocity of the weight or resistance, a maximum effect will be produced when the power P is equal to $\mathrm{R}\times\overline{1+\sqrt{2}}$; $\mathrm{R}\times\overline{\frac{1}{2}+\sqrt{\frac{3}{8}}}$; $\mathrm{R}\times\overline{\frac{1}{3}+\sqrt{\frac{4}{27}}}$; $\mathrm{R}\times\frac{1}{4}+\sqrt{\frac{5}{64}}$, $\mathrm{R}\times\frac{1}{5}+\sqrt{\frac{6}{125}}$, &c. where R is the resistance or weight to be raised. If the velocity of the power be very large, a maximum effect will be produced when the power B is, at least, double of that which would procure an equilibrium. It appears also from Mr Leslie's paper, that in whatever way the maximum be procured, the force which impells the

Theory.

the weight can never amount to one-fourth part of the direct action of the power; and that in machines where the velocity of the power is great, we may disregard the momenta of the connecting parts, and consider the force which ought to be employed as double of what is barely able to maintain the equilibrium.

Chap. VIII. *On the Equilibrium of Arches, Piers, and Domes.*

Fig. 3. 316. Def. 1. An arch is represented in fig. 3. by the assemblage of stones *a b*, *c d*, *c f*, &c. forming the mass ABMN, whose inferior surface is the portion of a curve. The parts A, B are called the *spring of the arch*, the line AB the *span of the arch*, C *b* its *altitude*, *b* its crown, *a b* the *keystone*, the curve or lower surface A *b* B the *intrados*, and the roadway TUV the *extrados;* PQ, RS, the *piers* when they stand between two arches, and the *abutments* when they are at the extremities of the bridge.

Fig. 4. 317. Def. 2. A catenarian curve is the curve formed by any line or cord perfectly flexible, and suspended by its extremities. Thus if the chain ACB be suspended by its extremities A, B, it will by the action of gravity upon all its parts assume the form ACB, which is called the catenary or catenarian curve.

318. There are three modes of determining the construction of arches; the first of which is to consider the arch as an inverted catenary; the second is to establish an equilibrium between the vertical pressures of all the materials between the intrados and extrados; and the third is to regard the different arch-stones as portions of wedges without friction, which endeavour by their own weight to force their way through the arch. The first of these methods was given by the ingenious Dr Hook, and is contained in the following proposition.

Prop. I.

319. To determine the form of an arch by considering it as an inverted catenary, when its span, its altitude, and the form of the roadway or extrados are given.

Fig. 5. Let *a*, *b*, *c*, *d* be a number of spheres or beads connected by a string, and suspended by their extremities A, B; they will form a catenarian curve A *a b c* B, and be in equilibrio by the action of gravity. Each sphere is acted upon by two forces; at its lower point by the weight of the spheres immediately below it, and at its upper point by the weight of the same spheres added to that of the sphere itself; that is, any sphere *c* is in equilibrio from the result of two forces, one of which is produced by the weights of *c d e* acting at the lower point of *b*, while the other force arises from the weight of *b c d e* acting at its upper point. The equilibrium of this chain of spheres is evidently of the stable kind, as it will immediately recover its position when the equilibrium is disturbed. Let us now suppose this arch inverted, so as to stand in a vertical plane as in

Fig. 6. fig. 6. It will still preserve its equilibrium. For the relative positions of the lines which mark the directions remain unchanged by inverting the curve, the force of gravity continues the same, and therefore the result of these forces will be the same, and the arch will be in equilibrio. The equilibrium, however, which the arch now possesses is of the tottering kind, so that the least disturbing force will destroy it, and it will consequently be unable to support any other weight but its own.

Theory.

320. Let us now suppose that it is required to form an equilibrated arch, whose span is AB, whose altitude is D *k*, and which will support the materials of a roadway, whose form TUV is given. It is obvious, that if the spheres *a*, *b*, *c*, *d* increase in density from *k* towards *a*, the catenarian curve will grow less concave at its vertex *c*, and more concave towards its extremities A, B. Let us then suppose that the densities of the spheres *a*, *b*, *c*, *d*, *e*, &c. are respectively as *a m*, *b n*, *c o*, *d p*, *e q*, &c. the vertical distances of their respective centres from the roadway TUV, the arch will have a form different from that which it would have assumed if the spheres were of equal density, and will be in equilibrio when inverted as in fig. 6. Now, in place of the Fig. 6. spheres *a*, *b*, *c*, *d*, *e*, &c. of different densities, let us substitute spheres of the same density, and having the same position as those of different densities; let us then load the sphere *a* with a weight which, when combined with the weight of *a*, will be equal to the weight of the corresponding sphere *a*, that had a greater density; and let us load the other spheres *b*, *c*, *d*, &c. with weights proportional to *b n*, *c o*, *d p*, &c. Then it is obvious that the pressure of each sphere when thus loaded upon that which is contiguous to it, is precisely equal to the pressure of the spheres of different densities upon each other, because the density of these spheres varied as their distances from the roadway. But the arch composed of spheres of different densities was in equilibrio when inverted, therefore since the loaded spheres of the same density have the same position and exert the same pressures, the arch composed of these spheres and supporting TUVB *k* A composed of homogeneous materials will be in equilibrio. *Hence a roadway of a given form, and composed of homogeneous materials, will be supported by an arch whose form is that of a catenary, each of whose points varies in density as their distance from the surface of the roadway;* or, which is the same thing, *A roadway of a given form, and composed of homogeneous materials, will be supported by an arch whose form is that of a catenary, each of whose points is acted upon by forces proportional to the distances of these points from the surface of the roadway.*

321. Hence we have the following practical method of ascertaining the form of an equilibrated arch, whose span is AB, and altitude D *k*, and which is to support a roadway of the form T′U′V′. Let a chain Fig. 7. A *a b c k* B, of uniform density, be suspended from the points A, B, so that it forms a catenary whose altitude is D *k*, the required height of the arch. Divide AB into any number of equal parts, suppose eight, and let the vertical lines 1 *m*, 2 *n*, 3 *o*, drawn from these points, intersect the catenary in the points *a*, *b*, *c*. From the points *a*, *b*, *c*, *k*, *r*, *s*, *t*, suspend pieces of chain of uniform density, and form them of such a length, that when the whole is in equilibrio, the extremities of the chains may lie in the line T′U′V′; then the form which the catenary A *k* B now assumes, will be the form of an equilibrated arch, which, when inverted like AKB, will support the roadway TUV, similar to T′U′V′. This

Theory. This is obvious from the last paragraph, for the pieces of chain $a\,m$, $b\,n$, $c\,o$, k U, &c. are forces acting upon the points a, b, c, k of the catenary, and are proportional to $a\,m$, b, n, c, o, &c. the distances of the points a, b, c, k, &c. from the roadway.

322. An arch of this construction will evidently answer for a bridge, in which the weight of the materials between the roadway and the arch stones is to the weight of the arch stones, as the weight of all the pieces of chain suspended from a, b, c, &c. is to the weight of the chain A k B. As the ratio, however, of the weight of the arch stones to the weight of the superincumbent materials is not known, we may assume a convenient thickness for the arch stones, and if from this assumed thickness their weight be computed, and be found to have the required ratio to the weight of the incumbent mass, the curve already found will be a proper form for the arch. But if the ratio is different from that of the weight of the whole chain to the weight of the suspended chains; it may easily be computed how much must be added to or subtracted from the pieces of chain, in order to make the ratios equal. The new curve which the catenary then assumes, in consequence of the change upon the length of the suspended chains, will be the form of an equilibrated arch, the weight of whose arch stones is equal to that which we assumed.

Scholium.

323. In most cases the catenarian curve thus determined will approach very near to a circular arc equal to 120 degrees, which springs from the piers so as to form an angle of 60 degrees with the horizon. The form of the arch, however, as determined in the preceding proposition, is suited only to those cases in which the superincumbent materials exert a vertical pressure. A quantity of loose earth and gravel exerts a pressure in almost every direction, and therefore tends to destroy the equilibrium of a catenarian arch. This tendency, however, may be removed by giving the arch a greater curvature towards the piers. This will make it approach to the form of an ellipsis, and make it spring more vertically from the piers or abutments.

324. We shall now proceed to deduce the form of an arch and its roadway, by establishing an equilibrium among the weights of all the materials between the arch and the roadway. This method was given by Emerson in his Fluxions, published in 1742, and afterwards by Dr Hutton in his excellent work on bridges.

Prop. II.

325. To determine the form of the roadway or extrados, when the form of the arch or intrados is given.

Fig. 8. Let the lines AD, DE, EB, BF, FG, GH lie in the same plane, and let them be placed perpendicular to the horizon. From the points D, E, B, &c. draw the vertical lines D d, E e, B b, &c. and taking D p of any length, make E r equal to D p, &c. and complete the parallelograms $p\,c$, $q\,r$. Again, make B s=$q\,e$, and complete the parallelogram ts; in like manner make F k=sb, and complete the parallelogram F f; and so on with all the other lines, making the side of each parallelogram equal to that side of the preceding parallelogram which is parallel to it. Let us now suppose that the lines CD, DE, EB, &c. can move round the angular points D, E, B, F, &c. the extremities A, C being immoveable; and that forces proportional to Dd, Ee, Bb, &c. are exerted upon the points D, E, B, F, &c. and in the direction D d, E e, &c. Now, by the resolution of forces, the force D d may be resolved into the forces D c, D p, the force E e into the forces E q, E r, and the force B b into the forces B s, B t, and so on with the rest. The force D c produces no other effect than to press the point A on the plane on which it rests, and is therefore destroyed by the resistance of that plane; but the remaining force Dp tends to bring the point D towards E, and to enlarge the angle ADE; this force, however, is destroyed by the equal and opposite force E q, and in the same way the forces E r, B t, F x are destroyed by the equal and opposite forces Bs, Fk, Gv, while the remaining force G w is destroyed by the resistance of the plane which supports the point C. When the lines AD, DE, &c. therefore are acted upon by vertical forces proportional to D d, E e, B b, &c. these forces are all destroyed by equal and opposite ones, and the lines will remain in equilibrio. Theory.

326. Now the force D c : Dp or E q=sin. $e\,d$ D or d Dp : sin. AD d, that is, by taking the reciprocals

$$\mathrm{D}\,c : \mathrm{E}\,q = \frac{1}{\sin.\ \mathrm{AD}d} : \frac{1}{\sin.\ d\ \mathrm{D}p},$$

and for the same reason

$$\mathrm{E}\,q : \mathrm{B}\,s = \frac{1}{\sin.\ \mathrm{E}\,e\,q} : \frac{1}{\sin.\ b\,\mathrm{B}\,s}.$$

Hence

$$\mathrm{E}\,q \doteq \frac{1}{\sin.\ \mathrm{E}\,e\,q}.$$

Now, since E q : E e=sin. E $e\,q$: sin. E $q\,e$, we have $\mathrm{E}\,e = \frac{\mathrm{E}\,q \times \sin.\ \mathrm{E}\,q\,e}{\sin.\ \mathrm{E}\,e\,q}$, that is, since DE$m$=E $q\,e$, and eEB=E $e\,q$; $\mathrm{E}\,e = \frac{\mathrm{E}\,q \times \sin.\ \mathrm{DE}m}{\sin.\ e\ \mathrm{EB}}$. But $\mathrm{E}q \doteq \frac{1}{\sin.\ \mathrm{E}eq}$ therefore, by substitution, we obtain

$$\mathrm{E}\,e \doteq \frac{\sin.\ \mathrm{DE}m}{\sin.\ \mathrm{E}eq \times \sin.\ e\ \mathrm{EB}}.$$

Now, as the same reasoning may be employed to find D d, B b, &c. we have obtained expressions of the forces which, when acting at the angular points D, E, B, &c. keep the whole in equilibrio, and these expressions are in terms of the angles which the lines DE, EB, &c. form with the direction of the forces. If the lines AD, DE, &c. be increased in number so that they may form a polygon with an infinite number of sides, which will not differ from a curve line, then the forces will act at every point of the curve, and the line m E will be a tangent to the curve at the point E, and DE m will be the angle of contact. The line E q being now infinitely small will coincide with E m, and therefore the angles c E q and e EB or E $e\,q$ will be equal to the angle e E m, and consequently their sines will be equal. Therefore by making these substitutions in the last formula, we have an expression of the force at every point of the curve, thus

$$\mathrm{E}\,e \doteq \frac{\sin.\ \mathrm{DE}\,m}{\sin.\ e\,\mathrm{E}\,m \times \sin.\ e\,\mathrm{E}m} \doteq \frac{\sin.\ \mathrm{DE}\ m}{\sin.\ e\ \mathrm{E}\,m|^2}.$$

But

Theory.

But the angle of contact DE m varies with the curvature at the point E, and the curvature varies as the reciprocal of the radius of curvature, therefore the angle of contact varies as the reciprocal of the radius of curvature; hence by substitution,

$$\mathrm{E}e \doteq \frac{1}{\text{radius of curvature} \times \overline{\sin.\, e\mathrm{E}m}^2}.$$

Fig. 9. In order to get rid of the confusion in fig. 8. where the arch is a polygon, let us suppose ABC, fig. 9. to be the curve mn a tangent to any point E, and Ee a vertical line; *then the pressure at any point of the arch is reciprocally as the radius of curvature at that point, and the square of the sine of the angle which the tangent to that point of the curve forms with a vertical line.*

327. COROLLARY. Let us now suppose that the arch ABC supports a mass of homogeneous materials lying between the roadway TUV and the arch AEBC; and the whole being supposed in equilibrio, let us determine the weight which presses on the point E. The weight of the superincumbent column Ecbd varies as E$c\times gd$, but gd=E$d\times$sin. dEg, Ed being radius, and dEg =EnB, on account of the parallels Ec, UB, therefore the weight of the column Ecbd varies as E$c\times$ E$d\times$sin. EnB, that is, as E$c\times$sin. EnB, because Ed is a constant quantity; but the pressure at E was proved to vary as $\frac{1}{\text{radius curvature}\times\overline{\sin.\, e\mathrm{E}m}^2}$, therefore the weight of the column Ecbd or E$c\times$sin. EnB varies also as this quantity, that is,

$$\mathrm{E}c\times\sin.\,\mathrm{E}n\mathrm{B} \doteq \frac{1}{\text{radius curvature}\times\overline{\sin.\, e\mathrm{E}m}^2}.$$

But as the angle EnB is equal to the angle eEm, we shall have, by substitution and division,

$$\mathrm{E}c \doteq \frac{1}{\text{radius curvature}\times\overline{\sin.\, e\mathrm{E}m}|^3},$$ that is,

When an arch supports a roadway, the pressure exerted upon any point of it, is reciprocally as the radius of curvature, and the cube of the sine of the angle which the tangent to that point forms with a vertical line.

328. Having thus obtained an expression for Ec, we shall proceed to shew the application of the formula to the case when the arch is a portion of a circle.

Fig. 10. Let EB be the arch of a circle whose centre is F. Let the radius = R, BD = versed sine, BE=x, DF=cos. BE=b, BU=m. Draw the tangent GE, and through E the vertical line cc, which will be parallel to BE. Then since GEF is a right angle, and eEF=EFB, the angle GEe is the complement of EFB, therefore, sin. GEe=cos. EFB=FD. But, in the present case, the radius of curvature is the radius of the arch, or R, therefore, E$c \doteq \frac{1}{\mathrm{R}\times\overline{\sin.\,\mathrm{GE}e}}$, or by substitution, E$c \doteq \frac{1}{\mathrm{R}\,b^3}$, that is, since R is constant, E$c \doteq \frac{1}{b^3}$. But when the point E coincides with B, the cosine b becomes equal to radius; therefore, in that case E$e \doteq \frac{1}{\mathrm{R}^3}$, and E$c$ becomes BU $= m$, hence $\frac{1}{\mathrm{R}^3} : \frac{1}{b^3} = m :$ Ec, and by GEOMETRY, Theor. 8. Sect. IV. and Division, we have E$c=\frac{m\,b^3}{b^3}$. Now, by the notation R : b=BF : DF; therefore R³ : b^3 $=\overline{\mathrm{BF}^3}$: DF³, hence $\frac{\mathrm{R}^3}{b^3}=\frac{\overline{\mathrm{BF}^3}}{\mathrm{DF}^3}$, and multiplying each side by m, we have $\frac{m\,\mathrm{R}^3}{b^3}=\frac{m\,\overline{\mathrm{BF}^3}}{\mathrm{DF}^3}$; but $\frac{m\,\mathrm{R}^3}{b^3}=Ec$, therefore the vertical distance of the surface of the roadway from the point F, or E$c=\frac{m\,\overline{\mathrm{BF}^3}}{\mathrm{DF}^3}=\frac{\mathrm{BU}\times\overline{\mathrm{BF}^3}}{\mathrm{DF}^3}$.

Theory.

When the point E coincides with B, BF=DF, and Ec=BU. When E coincides with A, the cosine DF vanishes, and therefore Ec, or the distance of the point A from the extrados or roadway, is infinite. The curve VUcT, therefore, will run up to an infinite height, approaching continually to a vertical line, drawn from A, which will be its asymptote. Such a form of the extrados, however, is inadmissible in practice; and therefore a semicircular arch is not an arch of equilibration. When the arch is less than a semicircle, as PBR, the curve terminates in the point p; and as it does not rise very much above a horizontal line, passing through U when the arch is small, we might produce a perfect equilibrium, by making the roadway horizontal as tUv, and making the density of the superincumbent columns Pn, Eo, which press upon the points P, E respectively, in the ratio of Pp, Ec, the distances of these points from the curvilineal roadway.

329. The inconvenience, however, arising from the inflexion of the extrados, may be considerably removed by throwing the point of contrary flexure to a greater distance, which may be done by diminishing BU, the thickness of the incumbent mass above the keystone. Thus, if BU is diminished to Bd, and if points a, b are taken in the lines Pp, Ec, so that Pa : Pp=Eb : Ec=Bd : BU, and so on with all the points in the arch; and if a new roadway $vdbat$ be drawn through these points, the equilibrium of the arch will still continue, for the various pressures which it sustained, though they are diminished, preserve the same proportion.

330. Let us suppose it necessary to have the extrados a horizontal line, and let it be required to find BU=m when there is an equilibrium. In this case the point H coincides with U; or rather, when the curve UcT cuts the horizontal line tUv, the point H coincides with U. By substituting BF—BD instead of DF in the value of Ec, formerly determined, and by putting BD=y, we have E$c=\frac{m\,\mathrm{R}^3}{\overline{\mathrm{R}-y}|^3}$. But when H coincides with U, c coincides with o, and therefore Eo=Ec=BD+BU $=y+m$, consequently, $\frac{m\,\mathrm{R}^3}{\overline{\mathrm{R}-y}|^3}=y+m$, and multiplying by $\overline{\mathrm{R}-y}|^3$, we have $m\mathrm{R}^3=y\times\overline{\mathrm{R}-y}|^3+m\times\overline{\mathrm{R}-y}|^3$, or $m\,\mathrm{R}^3+m\times\overline{\mathrm{R}-y}|^3=y\times\overline{\mathrm{R}-y}|^3$, and, dividing by the coefficients of m, we have

$$m=\frac{y\times\overline{\mathrm{R}-y}|^3}{\mathrm{R}^3-\overline{\mathrm{R}-y}|^3},$$ that is,

The thickness of the roadway above the keystone, when the extrados is a straight line, is equal to the quotient arising

Theory.

arising from multiplying the versed sine of half the arch by the cube of its cosine, and dividing this product by the difference between the cube of the radius, and the cube of the cosine; or, to change the expressions, *the thickness of the roadway above the keystone, when the roadway is a straight line, is equal to the quotient arising from multiplying the height of the arch, by the cube of the difference between the radius of the arch and its height, and dividing this product by the difference between the cube of the radius, and the cube of the difference between the radius and the height of the arch.*

331. When the arch is a semicircle $R-y$ vanishes, and m becomes equal 0, so that the semicircular arch is evidently inadmissible. But when the arch is less than a semicircle, the value of m will be finite. Thus, if the arches are respectively

Arch.
60°, we have $m=\frac{1}{4}$ the span,
90°, we have $m=\frac{1}{2}$ of the span, or
110°, we have $m=\frac{1}{17}$ of the span nearly.

The two first arches of 60° and 90°, manifestly give too great a thickness to the part BU or m. In the third arch of 110°, the thickness of BD is nearly what is given to it by good architects, and is therefore the best in practice; for if the arch were made greater than 110°, the thickness of BU or m would be too small. It is obvious, however, that an arch of 110° is not an arch of *perfect* equilibration, for this can be the case only when the roadway has the form U z r. When the roadway, therefore, is horizontal, as U r, there is an unbalanced pressure on both sides of the keystone, produced by the weight of the materials in the mixtilinear space r z U. It is indeed very small, and might be counteracted, by making the materials below R lighter than those below U: but the unbalanced pressure is so trifling, that it may be safely neglected. We may, therefore, conclude, *that when the arch is to be circular with a horizontal roadway, an arch of 110 degrees approaches nearest to an arch of equilibration.*

Elliptical arches superior to circular arches when their transverse axis is horizontal.

332. When the arch is elliptical, it will be found, as in the circle, that $m=\frac{y\times\overline{R-y}|^3}{R^3-\overline{R-y}^3}$. An elliptical arch, however, has the advantage of a circular one, when the transverse axis is horizontal; for as it is much flatter, the point of contrary flexure in the extrados is thrown at a greater distance, and therefore it will, with less inconvenience, admit of a horizontal roadway. Elliptical arches have also the advantage of being more elegant, and likewise require less labour and materials.

333. The cycloidal arch is likewise superior to a circular one, but inferior to those which are elliptical. Parabolic, hyperbolic, and catenarian arches, may be employed when the bridge has only one arch, and is to rise high; but in other cases they are inadmissible. The method of determining the roadway for all these forms of arches will be found in Dr Hutton's excellent work on the Principles of Bridges, p. 3. See also Emerson's Miscellanies, p. 156.; and his work on Fluxions, published in 1742.

On the mechanical curve of equilibration.

334. When the form of the roadway is given, the shape of the intrados for an arch of equilibration may be determined. As the investigation is very difficult, unless when the roadway is a horizontal line, we shall merely give the formula, which will enable any person to construct the curve. In all other curves the equilibrium of the arch is imperfect; but the curve described by the following formula is an arch of perfect equilibration, and has been called *the mechanical curve of equilibration.*

$$ED=AF\times\frac{\text{Hyperbol. log.}\ \dfrac{BU+BD+\sqrt{2\,BU\times BD+\overline{BD}^2}}{BU}}{\text{Hyperbol. log.}\ \dfrac{BU+BF+\sqrt{2\,BU\times BF+\overline{BF}^2}}{BU}}$$

From this formula, which corresponds with figure 11. Dr Hutton has computed the following table, containing the values of c U and c E, for an arch whose span AC is 100, whose height BF is 40, and whose thickness at the crown or BU is 6. The table will answer for any other arch whose span and thickness are as the numbers 100, 40, 6; only the values of c U and c E must be increased or diminished in the same ratio as these numbers.

Table for constructing the Curve of Equilibration, when the span, height, and thickness at the crown, are as the numbers 100, 40, *and* 6.

Value of cU.	Value of cE.	Value of cU.	Value of cE.	Value of cU.	Value of cE.	Value of cU.	Value of cE.	Value of cU.	Value of cE.

335. The

Theory.

335. The construction of arches has also been deduced from considering the arch-stones as frustums of polished wedges without friction, which endeavour to force their way through the arch. This principle has been adopted by Belidor, Parent, Bossut, Prony, and other French philosophers, and likewise by our ingenious countryman, the late Mr Atwood. This theory, however, is more plausible than useful. So far from the arch-stones having liberty to slide between those which are contiguous to them, without friction, they are bound together by the strongest cement, and sometimes connected by iron pins or wedges. The theory likewise requires, that the weight of the arch must regularly increase as the portion of the vertical tangent cut off by lines drawn from a given point in a direction parallel to that of the joints, and therefore either the density or the magnitude of the arch-stones must be very great at the spring of the arch, where the portion of the vertical tangent is a maximum. Those who wish to be acquainted with the mode of investigation, by which the equilibrium of arches is established in this theory, may consult Prony's *Architecture Hydraulique*, tom. i. p. 152.

On the Construction of Piers and Abutments.

336. In the construction of piers and abutments, there are two circumstances which claim our attention. 1. The strength that must be given to them, in order to resist the lateral thurst which they sustain from the adjacent semiarches, and which tend either to overset them, or make them slide upon their base. 2. The form which must be given to their extremities, so that the force of the current may be a minimum.—The adhesion of the pier to the place on which it rests is always much greater than one-third of the pressure; and as the lateral thrust of the arch which this adhesion resists, is oblique to the horizon, and may be resolved into two forces, one of which is horizontal, and the other vertical, we have the vertical portion of the lateral thrust, the weight of the pier, and the friction on its base, combined in resisting the horizontal portion of the lateral thrust, which tends to make the pier slide upon its base, so that there is no danger of the pier yielding to such a pressure. We do not here consider, that the lateral thrust which tends to give a horizontal motion to the pier, is completely counteracted by the lateral thrust of the opposite semiarch, because it is necessary that the pier should have sufficient stability to resist the lateral thrust of one semiarch, in case of the failure of the opposite one. Let us therefore consider the strength of the pier which will prevent it from being overset.

337. For this purpose, let ABC be an arch, MHTO the pier, and BUHA the loaded semiarch, whose pressure tends to overturn the pier. Let G be the centre of gravity of the mass BUHA: Join GA, and from G draw GK perpendicular to AC. Then, since the whole pressure of the arch is exerted at its spring A; and since this pressure is the same as if the whole weight of the arch were collected into the point G, GA will be the direction in which the weight of the arch and the superincumbent mass acts upon the point A. Now, by DYNAMICS, the force GA may be resolved into the two forces, GK, KA, one of which KA endeavours to give the pier a motion of rotation about the point O, while the other GK denotes the weight of the loaded arch in the direction GK. Putting W, therefore, for the weight or area of the superincumbent mass, we have $GK : KA = W : \frac{W \times KA}{GK}$, the pressure upon A. Now, as this force tends to turn the pier round O by means of the lever OA, and as ON=AM is the perpendicular from the centre of motion upon the line of direction, we have $AM \times \frac{W \times KA}{GK}$ for the force which tends to overturn the pier. Now, the force which is opposed to this is the weight of the pier MHTO collected in its centre of gravity g, which acts by the vertical lever $Om = \frac{1}{2}OM$, because g is in the centre of the rectangle TM (Art. 164.). But the weight or area of the pier may be represented by $OM \times MH$; therefore, the force which resists the lateral thrust of the loaded arch is $OM \times MH \times \frac{1}{2}OM$, or $\frac{1}{2}MH \times OM$. Now, in the case of an equilibrium between these opposing forces, we have $AM \times \frac{W \times KA}{GK} = \frac{1}{2}MH \times OM^2$, which, by reduction, becomes $OM = \sqrt{\frac{2\,AM \times W \times KA}{MH \times GK}}$. This formula gives us the breadth of the pier which is capable of balancing the lateral thrust; and therefore OM must be taken a little greater than the preceding value. In practice, OM is generally between one-fifth and one-seventh of AC, the span of the arch. The method of finding the centre of gravity G of the loaded arch, whether the arch is in perfect equilibrium or not, may be seen in Dr Hutton's work already quoted, p. 49. A very simple method of doing this is to form the part BUHA of a piece of card, and to find its centre of gravity G by the rules given in Articles 201, 202, 203. This indeed supposes all the materials to be homogeneous; but if they are of various kinds, we can load the arch made of card in a similar manner, and determine its centre of gravity as before.

338. The limits of this article will not permit us to apply the method of fluxions to the determination of the form which should be given to the ends of the pier, in order that the impulse of the current may be the least possible. The theory of the resistance of fluids, indeed, differs so widely from experiment, that such an investigation would, in this place, be of little practical utility. It may be sufficient merely to remark, that the pier should have an angular form, and that the impulse of the current will be diminished as the angle is more acute. When the ends are semicircular, the impulse of the stream is reduced to one half; and though a triangular termination of the piers reduces the impulse still more, yet semicircular ends are more pleasing to the eye, and are particularly advantageous when small vessels have occasion to pass the arch. When those vessels happen to impinge against the piers, the semicircular ends are more able to bear the shock, and do less injury to the vessel, while the additional quantity of masonry will give greater stability to the pier.

On

Theory.

On the Construction of Domes.

339. Definition. A dome, cupola, or vault, is an arched roof, either of a spherical, conoidal, or spheroidal form.

The following proposition, taken from Dr Robison's article upon this subject, in the Supplement to the late edition of the Encyclopædia Britannica, contains a very brief view of the theory of domes.

Proposition.

340. "To determine the thickness of a dome vaulting when the curve is given, or the curve when the thickness is given.

Plate CXXIII. fig. 1.

"Let B b A, figure 1. be the curve which produces the dome by revolving round the vertical axis AD. We shall suppose this curve to be drawn through the middle of all the arch-stones, and that the coursing or horizontal joints are every where perpendicular to the curve. We shall suppose (as is always the case) that the thickness KL, HI, &c. of the arch-stones is very small, in comparison with the dimensions of the arch. If we consider any portion HA h of the dome, it is plain that it presses on the course, of which HL is an arch-stone, in a direction b C perpendicular to the joint HI, or in the direction of the next superior element β b of the curve. As we proceed downwards, course after course, we see plainly that this direction must change, because the weight of each course is superadded to that of the portion above it, to complete the pressure on the course below. Through B draw the vertical line BCG, meeting β b, produced in C. We may take b c to express the pressure of all that is above it, propagated in this direction to the joint KL. We may also suppose the weight of the course HL united in b, and acting on the vertical. Let it be represented by b F. If we form the parallelogram b FGC, the diagonal b G will represent the direction and intensity of the whole pressure on the joint KL. Thus it appears that this pressure is continually changing its direction, and that the line, which will always coincide with it, must be a curve concave downwards. If this be precisely the curve of the dome, it will be an equilibrated vaulting: but so far from being the strongest form, it is the weakest, and it is the limit to an infinity of others, which are all stronger than it. This will appear evident, if we suppose that b G does not coincide with the curve A b B, but passes without it. As we suppose the arch-stones to be exceedingly thin from inside to outside, it is plain that this dome cannot stand, and that the weight of the upper part will press it down, and spring the vaulting outwards at the joint KL. But let us suppose, on the other hand, that b G falls within the curvilineal element b B. This evidently tends to push the arch-stone inward, towards the axis, and would cause it to slide in, since the joints are supposed perfectly smooth and slipping. But since this takes place equally in every stone of this course, they must all abut on each other in the vertical joints, squeezing them firmly together. Therefore, resolving the thrust b G into two, one of which is perpendicular to the joint KL, and the other parallel to it, we see that this last thrust is withstood by the vertical joints all around, and there remains only the thrust in the direction of the curve. Such a dome must therefore be firmer than an equilibrated dome, and cannot be so easily broken by overloading the upper part. When the curve is concave upwards, as in the lower part of the figure, the line b C always falls below B b, and the point C below B. When the curve is concave downwards, as in the upper part of the figure, $'b$ C$'$ passes above, or without b B. The curvature may be so abrupt, that even b' G$'$ shall pass without $'b$ B$'$, and the point G$'$ is above B$'$. It is also evident that the force which thus binds the stones of a horizontal course together, by pushing them towards the axis, will be greater in flat domes than in those that are more convex; that it will be still greater in a cone; and greater still in a curve whose convexity is turned inwards: for in this last case the line b G will deviate most remarkably from the curve. Such a dome will stand (having polished joints) if the curve springs from the base with any elevation, however small; nay, since the friction of two pieces of stone is not less than half of their mutual pressure, such a dome will stand, although the tangent to the curve at the bottom should be horizontal, provided that the horizontal thrust be double the weight of the dome, which may easily be the case if it do not rise high.

Theory.

"Thus we see that the stability of a dome depends on very different principles from that of a common arch, and is in general much greater. It differs also in another very important circumstance, viz. that it may be open in the middle: for the uppermost course, by tending equally in every part to slide in toward the axis, presses all together in the vertical joints, and acts on the next course like the key-stone of a common arch. Therefore an arch of equilibration, which is the weakest of all, may be open in the middle, and carry at top another building, such as a lantern, if its weight do not exceed that of the circular segment of the dome that is omitted. A greater load than this would indeed break the dome, by causing it to spring up in some of the lower courses; but this load may be increased if the curve is flatter than the curve of equilibration: and any load whatever, which will not crush the stones to powder, may be set on a truncate cone, or on a dome formed by a curve that is convex toward the axis; provided always that the foundation be effectually prevented from flying out, either by a hoop or by a sufficient mass of solid pier on which it is set.

"We have seen that if b G, the thrust compounded of the thrust b C, exerted by all the courses above HILK, and if the force b F, or the weight of that course, be everywhere coincident with b B, the element of the curve, we shall have an equilibrated dome; if it falls within it, we have a dome which will bear a greater load; and if it falls without it, the dome will break at the joint. We must endeavour to get analytical expressions of these conditions. Therefore draw the ordinates b δ b'', BDB$''$, C d C$''$. Let the tangents at b and b'' meet the axis in M, and make MO, MP, each equal to b c, and complete the parallelogram MONP, and draw OQ perpendicular to the axis, and produce b F, cutting the ordinates in E and e. It is plain that MN

Theory. is to MO as the weight of the arch HA h to the thrust $b\,c$ which it exerts on the joint KL (this thrust being propagated through the course of HILK); and that MQ, or its equal $b\,e$, or $\delta\,d$, may represent the weight of the half AH.

"Let AD be called x, and DB be called y. Then $b\,c = \dot{x}$, and $e\,\mathrm{C} = \dot{y}$ (because $b\,c$ is in the direction of the element $\beta\,b$). It is also plain, that if we make $\dot{y}$ constant, BC is the second fluxion of x, or $\mathrm{BC} = \ddot{x}$, and $b\,c$ and BE may be considered as equal, and taken indiscriminately for $\dot{x}$. We have also $b\,\mathrm{C} = \sqrt{\dot{x}^2+\dot{y}^2}$. Let d be the depth or thickness HI of the arch-stones. Then $d\sqrt{\dot{x}^2+\dot{y}^2}$ will represent the trapezium IIL; and since the circumference of each course increases in the proportion of the radius y, $d\,y\sqrt{\dot{x}^2+\dot{y}^2}$ will express the whole course. If $\int$ be taken to represent the sum or aggregate of the quantities annexed to it, the formula will be analogous to the fluent of a fluxion, and $\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}$ will represent the whole mass, and also the weight of the vaulting, down to the joint HI. Therefore we have this proportion, $\int d\,y\sqrt{\dot{x}^2+\dot{y}^2} : d\,y\sqrt{\dot{x}^2+\dot{y}^2} = b\,e : b\,\mathrm{F}, = b\,e : \mathrm{CG}, = \delta\,d : \mathrm{CG}, = \dot{x} : \mathrm{CG}$. Therefore $\mathrm{CG} = \frac{d\,y\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}}$

If the curvature of the dome be precisely such as puts it in equilibrium, but without any mutual pressure in the vertical joints, this value of OG must be equal to CB, or to $\ddot{x}$, the point G coinciding with B. This condition will be expressed by the equation $\frac{d\,y\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}} = \ddot{x}$, or, more conveniently, by $\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}} = \frac{\ddot{x}}{\dot{x}}$. But this form gives only a tottering equilibrium, independent of the friction of the joints and the cohesion of the cement. An equilibrium, accompanied by some firm stability, produced by the mutual pressure of the vertical joints, may be expressed by the formula $\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}} > \frac{\ddot{x}}{\dot{x}}$, or by $\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+y^2}} = \frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$, where t is some variable positive quantity, which increases when x increases. This last equation will also express the equilibrated dome, if t be a constant quantity, because in this case $\frac{\dot{t}}{t}$ is $= o$.

"Since a firm stability requires that $\frac{d\,y\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2=\dot{y}^2}}$ shall be greater than $\ddot{x}$, and CG must be greater than CB: Hence we learn, that figures of too great curvature, whose sides descend too rapidly, are improper. Also, since stability requires that we have $\frac{d\,y\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\ddot{x}}$ greater than $\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}$, we learn Theory. that the upper part of the dome must not be made very heavy. This, by diminishing the proportion of b F to b C, diminishes the angle $c\,b$ G, and may set the point G above B, which will infallibly spring the dome in that place. We see here also, that the algebraic analysis expresses that peculiarity of dome-vaulting, that the weight of the upper part may even be suppressed.

"The fluent of the equation $\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}} = \frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$ is most easily found. It is $\mathrm{L}\int d\,y\sqrt{\dot{x}^2+\dot{y}^2} = \mathrm{L}\,\dot{x} + \mathrm{L}\,t$, where L is the hyperbolic logarithm of the quantity annexed to it. If we consider $\dot{y}$ as constant, and correct the fluent so as to make it nothing at the vertex, it may be expressed thus, $\mathrm{L}\int d\,y\sqrt{\dot{x}^2+\dot{y}^2} - \mathrm{L}\,a = \mathrm{L}\,\dot{x} - \mathrm{L}\,\dot{y} + \mathrm{L}\,t$. This gives us $\mathrm{L}\int\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{a} = \mathrm{L}\frac{\dot{x}}{\dot{y}}t$, and therefore $\int\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{a} = \frac{\dot{x}}{\dot{y}}$.

"This last equation will easily give us the depth of vaulting, or thickness d of the arch, when the curve is given. For its fluxion is $\frac{d\,y\sqrt{\dot{x}^2+\dot{y}^2}}{a} = \frac{\dot{t}\,\dot{x} + t\,\ddot{x}}{\dot{y}}$, and $d = \frac{a\,\dot{t}\,\dot{x} + a\,t\,\ddot{x}}{y\,\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$, which is all expressed in known quantities; for we may put in place of t any power or function of x or of y, and thus convert the expression into another, which will still be applicable to all sorts of curves.

"Instead of the second member $\frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$ we might employ $\frac{p\,\ddot{x}}{\dot{x}}$, where p is some number greater than unity. This will evidently give a dome having stability; because the original formula $\frac{d\,y\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}}$ will then be greater than $\ddot{x}$. This will give $d = \frac{p\,a\,\dot{x}^{p-1}\,\ddot{x}}{y\,\dot{y}^p\sqrt{\dot{x}^2+\dot{y}^2}}$. Each of these forms has its advantages when applied to particular cases. Each of them also gives $d = \frac{a\,\ddot{x}}{y\,\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$ when the curvature is such as is in precise equilibrium. And, lastly, if d be constant, that is, if the vaulting be of uniform thickness, we obtain the form of the curve, because then the relation of $\ddot{x}$ to $\dot{x}$ and to $\dot{y}$ is given.

"The chief use of this analysis is to discover what curves are improper for domes, or what portions of given curves may be employed with safety. Domes are

are generally built for ornament; and we see that there is great room for indulging our fancy in the choice. All curves which are concave outwards will give domes of great firmness: they are also beautiful. The Gothic dome, whose outline is an undulated curve, may be made abundantly firm, especially if the upper part be convex and the lower concave outwards.

"The chief difficulty in the case of this analysis arises from the necessity of expressing the weight of the incumbent part, or $\int \dot{d} y \sqrt{\dot{x}^2+\dot{y}^2}$. This requires the measurement of the conoidal surface, which, in most cases, can be had only by approximation by means of infinite serieses.

"The surface of any circular portion of a sphere is very easily had, being equal to the circle described with a radius equal to the chord of half the arch. This radius is evidently $=\sqrt{\dot{x}^2+\dot{y}^2}$.

"In order to discover what portion of a hemisphere may be employed (for it is evident we cannot employ the whole) when the thickness of the vaulting is uniform, we may recur to the equation or formula $\frac{d\,y\,\dot{x}\sqrt{\dot{x}^2-\dot{y}^2}}{\ddot{x}}=\int d\,y\sqrt{\dot{x}^2+\dot{y}^2}$. Let a be the radius of the hemisphere. We have $\dot{x}=\frac{a\,y\,\dot{y}}{\sqrt{a^2-y^2}}$, and $\ddot{x}=\frac{a^2\dot{y}^2}{a^2-y^2|^{\frac{3}{2}}}$. Substituting these values in the formula, we obtain the equation $y^2\sqrt{a^2-y^2}=\int\frac{a^2 y\,\dot{y}}{\sqrt{a^2-y^2}}$. We easily obtain the fluent of the second member $=a^3-a^2\sqrt{a^2-y^2}$, and $y=a\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$. Therefore if the radius of the sphere be 1, the half breadth of the dome must not exceed $\sqrt{-\frac{1}{2}\times\sqrt{\frac{5}{4}}}$, or 0.786, and the height will be .618. The arch from the vertex is about 51° 49′. Much more of the hemisphere cannot stand, even though aided by the cement, and by the friction of the coursing joints. This last circumstance, by giving connection to the upper parts, causes the whole to press more vertically on the course below, and thus diminishes the outward thrust; but it at the same time diminishes the mutual abutment of the vertical joints, which is a great cause of firmness in the vaulting. A Gothic dome, of which the upper part is a portion of a sphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very strong, and not ungraceful.

"341. Persuaded that what has been said on the subject convinces the reader that a vaulting perfectly equilibrated throughout is by no means the best form, provided that the base is secured from separating, we think it unnecessary to give the investigation of that form, which has a considerable intricacy, and shall merely give its dimensions. The thickness is supposed uniform. The numbers in the first column of the table express the portion of the axis counted from the vertex, and those of the second column are the length of the ordinates.

AD	DB	AD	DB	AD	DB

"The curve formed according to these dimensions will not appear very graceful, because there is an abrupt change in its curvature at a small distance from its vertex; if, however, the middle be occupied by a lantern of equal or of smaller weight than the part whose place it supplies, the whole will be elegant, and free from this defect.

"The connexion of the parts arising from cement and from friction has a great effect on dome-vaulting. In the same way as in common arches and cylindrical vaulting, it enables an overload on one place to break the dome in a distant place. But the resistance to this effect is much greater in dome-vaulting, because it operates all round the overloaded part. Hence it happens that domes are much less shattered by partial violence, such as the falling of a bomb, or the like. Large holes may be broken in them without much affecting the rest; but, on the other hand, it greatly diminishes the strength which should be derived from the mutual pressure in the vertical joints. Friction prevents the sliding in of the arch-stones which produces this mutual pressure in the vertical joints, except in the very highest courses, and even there it greatly diminishes it. These causes make a great change in the form which gives the greatest strength; and as their laws of action are but very imperfectly understood as yet, it is perhaps impossible, in the present state of our knowledge, to determine this form with tolerable precision. We see plainly, however, that it allows a greater deviation from the best form than the other kind of vaulting; and domes may be made to rise perpendicular to the horizon at the base, although of no great thickness; a thing which must not be attempted in a plane arch. The immense addition of strength which may be derived from hooping largely compensates for all defects; and there is hardly any bounds to the extent to which a very thin dome-vaulting may be carried, when it is hooped or framed in the direction of the horizontal courses. The roof of the Halle du Bled at Paris is but a foot thick, and its diameter is more than 200, yet it appears to have abundant strength."

Scholium.

342. The section of the dome of St Paul's cathedral is part of an ellipse whose conjugate diameter is parallel to the horizon. It is built of wood, and confined by strong iron chains; and is supported by carpentry resting on a cone of brick work.

Chap.

Theory.

Chap. IX. *On the Force of Torsion.*

Fig. 2. 343. Definition. Let $g\,a$ be a metallic wire firmly fixed in the pincers g by means of the screw s; let the cylindrical weight P, furnished with an index $e\,o$, be suspended at the lower extremity of the wire; and let the axis of the cylinder, or the wire $g\,a$ produced, terminate in the centre of the divided circle MNO. Then, if the cylinder P is made to move round its axis so that the index $e\,o$ may describe the arch ON, the wire $g\,a$ will be twisted. If the cylinder be now left to itself, the wire will, in consequence of its elasticity, endeavour to recover its form; the index $e\,o$ will therefore move backwards from N, and oscillate round the axis of the cylinder. The force which produces these oscillations is called the *force of torsion*, and the angle measured by the arch ON is called the *angle of torsion*.

Prop. I.

344. To deduce formulæ for the oscillatory motion of the cylinder, on the supposition that the reaction of the force of torsion is proportional to the angle of torsion, or nearly proportional to it.

Fig. 3. Let PQ be a section of the cylinder P in fig. 2. and let all the elements of the cylinder be projected upon this circular section in d, d', d''. Let ACB, the primitive angle of torsion, be called A, and let this angle, after the time t, become AC b, so that it has been diminished by the angle BC b=M; then AC b=A—M= the angle of torsion after the time t.

Since the force of torsion is supposed to be proportional to the angle of torsion, the momentum of the force of torsion must be some multiple of that angle, or $n\times\overline{A-M}$, n being a constant coefficient, whose value depends on the nature, length, and thickness of the metallic wire. If, therefore, we call v the velocity of any point d at the end of the time t, when the angle of torsion becomes AC b, and r=C d the distance of the point d from the axis of rotation C, we shall have, by the principles of Dynamics,

$$n\times\overline{A-M}\times\dot{t}=\int d\,r\,\dot{v}.$$

But if CD, the radius of the cylinder, be equal a, and if u be the velocity of the point D after the time t, we have evidently $v:u=r:a$, and $v=\frac{r\,u}{a}$. Now by substituting the fluxion of this value of v in the place of $\dot{v}$ in the preceding formula, we have

$$n\times\overline{A-M}\times\dot{t}=\dot{u}\int\frac{d\,r^2}{a};$$

and since $\dot{t}=\frac{a\dot{M}}{u}$, we have by substitution

$$n\times\overline{A-M}\times\frac{a\dot{M}}{u}=\dot{u}\int\frac{d\,r^2}{a},$$

whose fluent is

$$n\times\overline{2AM-M^2}=u^2\int\frac{d\,r^2}{a^2}.$$

Taking the square root of both sides of the equation, we have

Theory.

$$\sqrt{n}\times\sqrt{\overline{2AM-M^2}}=u\times\left|\overline{\int\frac{d\,r^2}{a^2}}\right|^{\frac{1}{2}}.$$

Multiplying both sides by $\frac{a\dot{M}}{u}$, and dividing by $\sqrt{n}\times\sqrt{\overline{2AM-M^2}}$, the equation becomes

$$\frac{a\dot{M}}{u}=\frac{\frac{a\dot{M}}{u}\times u\times\left|\overline{\int\frac{d\,r^2}{a^2}}\right|^{\frac{1}{2}}}{\sqrt{n}\times\sqrt{\overline{2AM-M^2}}}=\frac{a\dot{M}\times\frac{1}{a}\times\left|\overline{\int d\,r^2}\right|^{\frac{1}{2}}}{\sqrt{n}\times\sqrt{\overline{2AM-M^2}}}$$

$$=\frac{\dot{M}\times\left|\overline{\int d\,r^2}\right|^{\frac{1}{2}}}{\sqrt{n}\times\sqrt{\overline{2AM-M^2}}}.$$

Therefore, since $\dot{t}=\frac{a\dot{M}}{u}$, we shall have

$$\dot{t}=\frac{\dot{M}\times\left|\overline{\int d\,r^2}\right|^{\frac{1}{2}}}{\sqrt{n}\times\sqrt{\overline{2AM-M^2}}},\text{ or}$$

$$\dot{t}=\frac{\dot{M}}{\sqrt{\overline{2AM-M^2}}}\times\left|\overline{\int\frac{d\,r^2}{n}}\right|^{\frac{1}{2}}.$$

But $\frac{\dot{M}}{\sqrt{\overline{2\,AM-M^2}}}$ represents an arch or angle whose radius is A and whose versed sine is M, which arch vanishes when M=0, and which becomes equal to 90° when M=A. Therefore the time of a complete oscillation will be

$$T=\left|\overline{\int\frac{p\,r^2}{n}}\right|^{\frac{1}{2}}\times 180^{\circ}.$$

345. In order to compare the force of torsion with the force of gravity in a pendulum, we have for the time of a complete oscillation of a pendulum whose length is l, g being the force of gravity,

$$T=\left|\overline{\frac{l}{g}}\right|^{\frac{1}{2}}180^{\circ}.$$

Therefore, since the time in which the cylinder oscillates must be equal to the time in which the pendulum oscillates, we have

$$\left|\overline{\int\frac{p\,r^2}{n}}\right|^{\frac{1}{2}}180^{\circ}=\left|\overline{\frac{l}{g}}\right|^{\frac{1}{2}}\times 180^{\circ}.$$

Hence dividing by 180°, and squaring both sides, we obtain

$$\left|\overline{\int\frac{p\,r^3}{n}}\right|=\frac{l}{g}.$$

We must therefore find for a cylinder the value of $\int p\,r^2$, or the sum of all the particles multiplied by the squares of their distances from the axis. Now, if we make π=6.28318 the ratio of the circumference of a circle to its radius, a= radius of the cylinder, λ= its length, d= its density; then we shall have for the area of its base $\frac{a^2\pi}{2}$, which multiplied by λ gives the solid content of the cylinder $=\frac{a^2\pi\lambda}{2}$, and this multiplied by

d

d gives $\frac{a^2 \pi \lambda d}{2}$ for the sum of all its particles. But as this is to be multiplied by the sum of the squares of all the distances of the particles from the centre C, we shall have $\int p r^2 = \frac{a^4 \pi^2 \lambda d}{4}$. But the number of particles in the cylinder, or the mass μ of the cylinder, is $\frac{a^2 \pi \lambda d}{2}$, therefore, substituting μ, instead of this value of it in the preceding equation, we have $\int p r^2 = \frac{\mu a^2}{2}$, and, dividing both sides by n, we have $\frac{\int p r^2}{n} = \frac{\mu a^2}{2n}$, and, extracting the square root and multiplying by 180, it becomes

$$\left|\frac{\int p r^2}{n}\right|^{\frac{1}{2}} \times 180° = \left|\frac{a^2}{2n}\right|^{\frac{1}{2}} \times 180°. \text{ Therefore}$$

$$T = \left|\frac{\mu a^2}{2n}\right|^{\frac{1}{2}} \times 180, \text{ and since } \int \frac{p r^2}{r} = \frac{l}{g},$$

$\frac{\mu a^2}{2n} = \frac{l}{g}$, and by reduction $n = \frac{g \mu a^2}{2l}$. But $g\,\mu$ is the weight W of the cylinder, therefore, by substituting W instead of $g\,\mu$, we obtain $n = \frac{P a^2}{2l}$, a very simple formula for determining the value of n from experiments.

If it were required to find a weight Q, which, acting at the extremity of a lever L, would have a momentum equal to the momentum of the force of torsion when the angle of torsion is A—M, we must make $Q \times L = n \times \overline{A-M}$.

346. In the preceding investigation we have supposed, what is conformable to experiment, that the force of torsion is proportional to the angle of torsion, which gives us $n \times \overline{A-M}$ for the momentum of that force. Let us now suppose that this momentum is altered by any quantity S, then the momentum of the force of torsion will become $n \times \overline{A-M} - S'$, and the general equation will assume this form

$$n \times \overline{A-M} - S \times \dot{t} = \dot{u} \int \frac{p r^2}{a};$$

and by multiplying in place of $\dot{t}$ its value $\frac{a \dot{M}}{u}$, and taking the fluent, we have

$$\overline{n \times 2\,AM - M^2} - 2 \int S\dot{M} = u^2 \int \frac{d r^2}{a^2}.$$

Now, in order to find the value of T or a complete oscillation, we must divide the oscillation into two parts, the first from B to A, where the force of torsion accelerates the velocity u, while the retarding force, arising from the resistance of the air and the imperfection of elasticity, diminishes the velocity u; and the second from A to B′, where the force of torsion, as well as the other forces, concur in diminishing u or retarding the motion.

347. *Ex.* 1. If $S = m \times \overline{A-M}^{\,\nu}$, we shall have for the state of motion in the first portion BA

$$n \times \overline{2\,AM - M^2} + \frac{2m \times \overline{A-M}|^{\nu+1}}{\nu+1} - \frac{2m A^{\nu+1}}{\nu+1} = u^2 \int \frac{p r^2}{a^2}$$

Hence, when the angle of torsion becomes equal to nothing, or $A - M = 0$, we have

$$n\,A^2 - \frac{2\,m\,A^{\nu+1}}{\nu+1} = UU \int \frac{p r^2}{a^2},$$

which dividing by $\int \frac{p r^2}{a^2}$, becomes

$$U^2 = \frac{n\,A^2 - \frac{2\,m\,A^{\nu+1}}{\nu+1}}{\int \frac{p\,r^2}{a^2}}.$$

Let us now consider the other part of the motion from A to B′, and suppose the angle AC $b' = M'$, we shall find, by calling U the velocity of the point A,

$$\frac{n\,M'^2}{2} + \frac{m\,M'^{\nu+1}}{\nu+1} = \frac{U^2 - u^2}{2} \times \int \frac{p\,r^2}{a^2}.$$

Then, by substituting instead of U its value as lately found, and taking the fluents, we shall have, when the velocity vanishes, or when the oscillation is finished,

$$A - M' = \frac{2m}{n \times \overline{\nu+2}} \times \frac{A^{\nu+1} + M'^{\nu+1}}{A + M'},$$

and if the retarding forces are such, that at each oscillation, the amplitude is a little diminished, we shall have for the approximate value of A—M′

$$A - M' = \frac{2\,m\,A\,\nu}{n \times \overline{\nu+1}},$$

and if the angle A—M′ is so small that it may be treated as a common fluxional quantity, we shall then have for any number of oscillations

$$N \times \frac{2\,m}{n \times \overline{\nu+1}} = \frac{1}{\nu-1} \times \frac{1}{M^{\nu-1}} - \frac{1}{A^{\nu-1}},$$

where M represents the angle to which A becomes equal after any number of oscillations N. Hence we obtain

$$M = \frac{1}{\left(N \times \frac{2\,m \times \overline{\nu+1}}{n \times \overline{\nu+1}} + \frac{1}{A^{\nu-1}}\right) \times^{\frac{1}{\nu-1}}},$$

which determines the value of M after any number of oscillations N.

348. *Ex.* 2. If $S = m \times \overline{A-M}|^{\nu} + m' \times \overline{A-M}|^{\nu'}$, m' and ν' being different values of m and ν, we shall obtain by following the mode of investigation in the last example,

$$n \times A - M = \frac{2\,m}{\nu+1} \times \frac{A^{\nu+1} + M^{\nu+1}}{A + M} + \frac{2\,m'}{\nu'+1} \times \frac{A^{\nu'+1} \times M^{\nu'+1}}{A + M}:$$

and if the retarding force is much less than the force of torsion, we shall have for an approximate value of $n \times \overline{A-M}$

$$n\times\overline{A-M}=\frac{2mA^{\nu}}{\nu+1}+\frac{2m'A^{\nu'}}{\nu'+1}.$$

349. *Ex.* 3. In general, if $S=m\times\overline{A-M}|^{\nu}+m'\times\overline{A-M}|^{\nu'}+m''\times\overline{A-M}|^{\nu''}+m'''\times\overline{A-M}|^{\nu'''}$, &c. we shall always have for an oscillation when S is smaller than the force of torsion.

$$n\times\overline{A-M}=\frac{2mA^{\nu}}{\nu+1}+\frac{2m'A^{\nu'}}{\nu'+1}+\frac{2m''A^{\nu''}}{\nu''+1}+\frac{2m'''A^{\nu'''}}{\nu'''+1},\ \&c.$$

350. Having thus given after Coulomb, the mode of deducing formulæ for the oscillatory motion of the cylinder, we shall proceed to give an account of the results of his experiments.

Torsion balance. Fig. 2.

In these experiments M. Coulomb employed the torsion balance represented in fig. 2. in which he suspended cylinders of different weights from iron and brass wires of different lengths and thicknesses; and by observing carefully the duration of a certain number of oscillations, he was enabled to determine, by means of the preceding formulæ, the laws of the force of torsion relative to the length, the thickness, and the nature of the wires employed. If the elasticity of the metallic wires had been perfect, and if the air opposed no resistance to the oscillating cylinder, it would continue to oscillate till its motion was stopped. The diminution of the amplitudes of the oscillations, therefore, being produced solely by the imperfection of elasticity, and by the resistance of the air, M. Coulomb was enabled, by observing the successive diminution of the amplitude of the oscillation, and by substracting the part of the change which was due to the resistance of the air, to ascertain, with the assistance of the preceding formulæ, according to what laws this elastic force of torsion was changed.

351. From a great number of experiments it appeared, that when the angle of torsion was not very great, the oscillations were sensibly isochronous; and therefore it may be regarded as a fundamental law, *That for all metallic wires, when the angles of torsion are not very great, the force of torsion is sensibly proportional to the angle of torsion.* Hence, as the preceding formulæ are founded on this supposition, they may be safely applied to the experiments.

352. In all the experiments, a cylinder of two pounds weight oscillated in twice the time employed by a cylinder which weighed only half a pound; and therefore *the duration of the oscillations is as the square root of the weights of the oscillating cylinders.* Consequently the tension of the wires has no sensible influence upon the force of torsion. If the tensions however be very great relative to the strength of the metal, the force of torsion does suffer a change; for when the weight of the cylinder, and consequently the tension of the wire, is increased, the wire is lengthened, and as this diminishes the diameter of the wire, the duration of the oscillation must evidently be affected.

353. When the lengths of the wires are varied without changing their diameters or the weights of the cylinders, *the times of the same number of oscillations are as the square roots of the lengths of the wires*, a result also deducible from theory.

354. When the diameters of the wires are varied without changing their lengths, or the weight of the cylinders, the momentum of the force of torsion varied as the fourth power of the diameters of the wires. Now this result is perfectly conformable to theory; for if we suppose two wires of the same substance, and of the same length, but having their diameters as one to two, it is obvious that in the wire whose diameter is double of the other, there are four times as many parts extended by torsion, as in the smaller wire, and that the mean extension of all these parts will be proportional to the diameter of a wire, the same as the mean arm of a lever is, relative to the axis of rotation. Hence it appears that, according to theory, the force of torsion of two wires of the same nature and of the same length, but of different diameters, is proportional to the fourth power of their diameter.

355. From this it follows in general, that in metallic wires the momentum of torsion is directly in the compound ratio of the angle of torsion and the fourth power of their diameter, and inversely as the length of the wires. If a therefore be the angle of torsion, λ the length of the thread, δ its diameter, and F the force of torsion, we shall have

$$F=\frac{ma\delta^4}{l},$$

where m is a constant coefficient for wires of the same metal, depending on the tenacity of the metal, and deducible from experiment.

356. When the angle of torsion is not great, relative to the length of the wire, the index of the cylinder returns to the position which it had before the torsion took place, or, in other words, the wire untwists itself by the same quantity by which it had been twisted. But when the angle of torsion is very great, the wire does not completely untwist itself, and therefore the centre of torsion will have advanced by a quantity equal to that which it has not untwisted.—When the angle of torsion was below 45°, the decrements of the amplitudes of the oscillations were nearly proportional to the amplitudes of the angle of torsion; but when the angle exceeded 45°, the decrements increased in a much greater ratio.—The centre of torsion did not begin to advance or be displaced till the angle of torsion was nearly a semicircle: it displacement was very irregular till the angle was one circle and 10 degrees, but beyond this angle the torsion remained nearly the same for all angles.

357. The theory of torsion is particularly useful in delicate researches, where small forces are to be ascertained with a precision which cannot be obtained by ordinary means. It has been successfully employed by Coulomb in discovering the laws of the forces of electricity and magnetism, and in determining the resistance of fluids when the velocities are very small.

PART II. ON THE CONSTRUCTION OF MACHINERY.

358. WE have already seen, when considering the maximum effects of machines, the various causes which affect their performance. It appeared from that investigation, that there must be a certain relation between the velocities of the impelled and working points of a machine, or between the power and the resistance to be overcome, before it can produce a maximum effect, and therefore it must be the first object of the engineer to ascertain that velocity, and to employ it in the construction of this machine. The performance of the machine is also influenced by the friction and inertia of its various parts; and as both these act as resistances, and therefore destroy a considerable portion of the impelling power, it becomes an object of great importance to attend to the simplification of the machinery, and to ascertain the nature of friction so as to diminish its effect, either by the application of unguents or by mechanical contrivances. Since the impelled and working points of a machine are generally connected by means of toothed wheels, the teeth must be formed in such a manner, that the wheels may always act upon each other with the same force, otherwise the velocity of the machine will be variable, and its structure soon injured by the irregularity of its motion. The irregular motion of machines sometimes arises from the nature of the machinery, from an inequality in the resistance to be overcome, and from the nature of the impelling power. In large machines, the momenta of their parts are generally sufficient to equalize these irregularities; but in machines of a small size, and in those where the irregularities are considerable, we must employ fly-wheels for regulating and rendering uniform their variable movements. These various subjects, and others intimately connected with them, we shall now proceed to discuss in their order.

Chap. I. *On the Proportion between the Velocity of the Impelled and Working points of Machines, and between the Power and Resistance, in order that they may perform the greatest work.*

359. In the chapter on the maximum effect of machines we have deduced formulæ containing x and y, the velocities of the impelled and working points of the machines, and including every circumstance which can affect their motion. The formula which exhibits the value of y, or the velocity of the working point, assumes various forms, according as we neglect one or more of the elements of which it is composed.—When the work to be performed resists only by its inertia, which is the case in urging round a millstone or heavy fly, the quantity R may be neglected, and the second formula, (Page 92. col. 2.) should be employed. In small machines, and particularly in those where the motion is conveyed by wheels with epicycloidal teeth, the friction is very trifling, and the element φ may be safely omitted. In corn and saw mills, the quantity b or the inertia of the resistance may be left out of the formula, as the motion communicated to the flour or to the saw dust is too small to be subjected to computation. In machines where one heavy body is employed to raise another merely by its weight, the inertia of the power and the resistance, viz. a, b, are proportional to P, R, the powers and resistances themselves, and consequently P, R may be substituted in the formula, in the place of a, b.—The engineer therefore must consider, before he construct his machine, what elements should enter into the formula, and what should be omitted, in order that he may adapt it to the circumstances of the case, and obtain from his machine the greatest possible effect.

360. When the inertia of the power and that of the resistance are proportional to the power and resistance themselves; and when the inertia and friction of the machine may be omitted, the formula becomes $y=\sqrt{\frac{P}{R}+1}-1$ from which the following table is computed, which contains the values of y for different values of P; R being supposed $=10$, and $m=1$. To find the relation between the velocities of the impelled and working points of a machine.

Table containing the best Proportions between the Velocities of the Impelled and Working Points of a Machine, or between the Levers by which the Power and Resistance act.

Proportional value of the impelling power, or P.	Value of the velocities of the working point or y; or of the lever by which the resistance acts, that of x being one.	Proportional value of the impelling power, or P.	Value of the velocities of the working point or y; or of the lever by which the resistance acts, that of x being 1.
1	0.048809	20	0.732051
2	0.095445	21	0.760682
3	0.140175	22	0.788854

6	0.264911	25	0.870800
7	0.303841	26	0.897300
8	0.341641	27	0.923500
9	0.378405	28	0.949400
10	0.414214	29	0.974800
11	0.449138	30	1.000000
12	0.483240	40	1.236200
13	0.516575	50	1.449500
14	0.549193	60	1.645700
15	0.581139	70	1.828400
16	0.612451	80	2.000000
17	0.643168	90	2.162300
18	0.673320	100	2.316600
19	0.702938		

In order to explain the use of this table, let us suppose that it is required to raise one cubic foot of water in a second, by means of a stream which discharges three cubic feet of water in a second; and let it be required to find the construetion of a wheel and axle for performing this work; that is, the diameter of the axle, that of the wheel being 6. Here the power is evidently 3 cubic feet, while the resistance is only one cubic foot, therefore $P=3$ R; but in the preceding table

$R=10$, consequently $P=3\times10=30$. But it appears from the table that when $P=30$, y or the diameter of the axle is 1, upon the supposition that the diameter x of the wheel is 1; but as x must be $=6$, we shall have $y=6$.

361. Instead of using the preceding table, we might find the best proportion between x and y by a kind of tentative process, from the formula $\frac{PxRy-R^2y^2}{Px^2+Ry^2}$, which expresses the work performed. This method is indeed tedious; and we mention it only for the sake of showing the conformity of the results, and of proving that there is a certain proportion between x and y which gives a maximum effect. Let $x=6$, as in the preceding paragraph, and let us suppose y to be successively 5, 6, and 7, in order to see which of these values is the best. Since $P=3$, and $R=1$, and $x=6$, we have

$$\text{When } y=5 \quad \frac{PxRy-R^2y^2}{Px^2+Ry^2}=\frac{3\times6\times1\times5-1\times5\times5}{3\times6\times6+1\times5\times5}=\frac{65}{133}=0.488$$

$$\text{When } y=6 \quad \frac{PxRy-R^2y^2}{Px^2+Ry^2}=\frac{3\times6\times1\times6-1\times6\times6}{3\times6\times6+1\times6\times6}=\frac{72}{144}=0.500$$

$$\text{When } y=7 \quad \frac{PxRy-R^2y^2}{Px^2+Ry^2}=\frac{3\times6\times1\times7-1\times7\times7}{3\times6\times6+1\times7\times7}=\frac{77}{157}=0.49045$$

It appears therefore that when $y=5, 6, 7$, the work performed is 0.488; 0.5000; 0.49045; so that the effect is a maximum when $y=6$, a result similar to what was obtained from the table.

To find the best proportion between the power and the resistance.

362. When the machine is already constructed, x and y cannot be varied so as to obtain a maximum effect. The same object however will be gained by properly adjusting the power to the work when the work cannot be altered, or the work to the power when the power is determinate. The formulæ in Prop. 2. Chap. 7. exhibit the values of R under many circumstances, and it depends on the judgment of the engineer to select such of them as are adapted to all the conditions of the case.

363. The following table is founded on the formula $R=\sqrt{\frac{y+1}{y^2}}-\frac{1}{y}$, which answers to the case where the inertia of the impelling power is the same with its pressure, and where the inertia and the friction of the machine may be safely neglected. The second column contains the different values of R corresponding to the values of y in the first column. The numbers in the third column shew the ratio of y to R, or they have the same proportion to 1, which R has to the resistance which will balance P. In the table it is supposed that $P=1$ and $x=1$.

Table containing the best proportions between the Power *and the* Resistance, *the inertia of the impelling power being the same with its pressure, and the friction and inertia of the Machine being omitted.*

Values of y, or the velocity of the working point; x being equal to 1.	Values of R, or the resistance to be overcome, P being $=1$.	Ratio of R to the resistance which would balance P.	Values of y, or the velocity of the working point; x being equal to 1.	Values of R, or the resistance to be overcome, P being $=1$.	Ratio of R to the resistance which would balance P.
$\frac{1}{4}$	1.8885	0.4724 to 1	7	0.03731	0.26117 to 1
$\frac{1}{3}$	1.3928	0.4639 ——	8	0.03125	0.25000 ——
$\frac{1}{2}$	0.8986	0.4493 ——	9	0.02669	0.24021 ——
1	0.4142	0.4142 ——	10	0.02317	0.23170 ——
2	0.1830	0.3660 ——	11	0.02037	0.22407 ——
3	0.1111	0.3333 ——	12	0.01809	0.21708 ——
4	0.0772	0.3088 ——	13	0.01622	0.21086 ——
5	0.0580	0.2900 ——	14	0.01466	0.20524 ——
6	0.0457	0.2742 ——	15	0.01333	0.19995 ——

364. To exemplify the use of the preceding table, let us suppose that we are to raise water by means of a simple pulley and bucket, with a power $=10$, and that it is required to find the resistance R, or the quantity of water which must be put into the bucket, in order that the work performed may be a maximum. In the simple pulley, x, y, the arms of the vertical levers or the velocities of the impelled and working points are equal; and since x is supposed in the table to be $=1$, we have $y=1$, which corresponds in the table with 0.4142, the value of R, P being $=1$ in the table: But in the present case $P=10$. Therefore, $10:1=0.4142:4.142$, the value of R when $P=10$.

365. The same result might be obtained in a more circuitous method by means of the formula $\frac{PxRy-R^2y^2}{Px^2+Ry^2}$, which expresses the performance of the machine. Thus, let $x=1$; $y=1$; $P=10$, and let us suppose R successively equal to 3; 4; 4.142; 5; so that we may determine which of these values gives the greatest performance.

When

When R=3, the preceding formula becomes $\frac{\overline{10\times 3}-\overline{3\times 3}}{10+3}=\frac{21}{13}=1.6154$.

When R=4, the formula becomes $\frac{10\times 4-4\times 4}{10+4}=\frac{24}{14}=1.7143$.

When R=4.142, the formula becomes $\frac{10\times 4.142-\overline{4.142}^2}{10+4.142}=\frac{24.26384}{14.142}=1.7157$.

When R=5, the formula becomes $\frac{10\times 5-5\times 5}{10+5}=\frac{25}{15}=1.6666$.

Hence it appears, that when R=3; 4; 4.142; 5; the work performed is respectively = 1.6154; 1.7143; 1.7157; 1.6666; so that the work performed is a maximum when R is =4.142, the same result which was obtained from the table.

Chap. II. *On the Simplification of Machinery.*

366. As the inertia of every machine adds greatly to the resistance to be overcome, and as the friction of the communicating parts is proportional to the pressure, it becomes a matter of great practical importance, that the different parts of a machine should be proportioned to the strains to which they are exposed. If the beam of a steam-engine, for example, is larger than what is necessary, an immense portion of the impelling power must be destroyed at every stroke of the piston, by dragging the superfluous mass from a state of rest into motion; the pressure upon the gudgeons will also be increased, and their friction in their sockets proportionally enlarged. The engineer, therefore, should be well acquainted with the strength of the materials of which the machine is to be constructed, and should frame its different parts in such a manner that they may not be heavier than what is necessary for resisting the forces with which they are urged.—When the motions of the machine are necessarily irregular, and when the machine may be exposed to accidental strains, the parts must be made considerably stronger than what is necessary for resisting its ordinary strains; but it is not often that such a precaution should be observed. The gudgeons of water-wheels, and of the beams of steam-engines, ought to be made as short and small as possible, as the friction increases with the rubbing surfaces. This is very seldom attended to in the construction of water-wheels. The diameter of the gudgeons is frequently thrice as large as what is necessary for supporting the weight of the wheel.

367. In the construction of machinery we must not only attend to the simplification of the parts, but also to the number of these parts, and the mode of connecting them. From the nature and quantity of the work to be performed, it is easy to ascertain the velocity of the working point which is most proper for performing it. Now this velocity may be procured in a variety of ways, either by a perplexing multiplicity of wheels, or by more simple combinations. The choice of these combinations must be left solely to the judgement of the engineer, as no general rules can be laid down to direct him. It may be useful, however, to remark, that the power should always be applied as near as possible to the working point of the machine, and that when one wheel drives another, the diameter of the one should never be great, when the diameter of the other is very small. The size of wheels is often determined from the strains to which they are exposed. If, for example, we are obliged to give a certain velocity to an axle by means of a wheel with 120 teeth, and if the force with which this wheel is urged, requires the teeth to be at least one inch thick in order to prevent them from breaking, we shall be obliged to make its diameter at least seven feet; for supposing the spaces between the teeth to be equal to the thickness of the teeth, the circumference of the wheel must at least be equal to 120+120=240 inches, the sum of the teeth and their intervals, which gives a diameter of six feet eight inches. There are some cases where our choice of combination must be directed by the nature of the machinery. If the work to be performed is a load raised with a certain velocity by means of a rope winding round a hollow drum, and if the simplest combination of mechanical powers for producing this velocity should give a small diameter to the drum, then this combination must give way to another which corresponds with a larger size of the drum, for, on account of the inflexibility of the ropes, a great portion of the impelling power would be wasted in winding them about the circumference of a small drum.

Description of a powerful capstane. Plate CCCXXIII. fig. 4.

368. The advantages of simplifying machinery are well exemplified in the following capstane, which unites great strength and simplicity. It is represented in fig. 4. where AD is a compound barrel composed of two cylinders of different radii. The rope DEC is fixed at the extremity of the cylinder D: and after passing over the pulley E, which is attached to the load by means of the hook F, it is coiled round the other cylinder D, and fixed at its upper end. The capstane bar AB urges the compound barrel CD about its axis, so that while the rope coils round the cylinder D it unwinds itself from the cylinder C. Let us suppose that the diameter of the part D of the barrel is 21 inches, while the diameter of the part C is only 20 inches, and let the pulley E be 20 inches in diameter. When the barrel AD, therefore, has performed one complete revolution by the pressure exerted at B, 63 inches of rope, equal to the circumference of the cylinder, will be gathered upon the cylinder D, and 60 inches will be unwinded from the cylinder C. The quantity of wound rope, therefore, exceeds the quantity that is unwound by 63—60=3 inches, the difference of their respective perimeters; and the half of this quantity, or $1\frac{1}{2}$ inches, will be the space through which the load or pulley E moves by one turn of the bar. If a simple capstane of the same dimensions had been employed, the length of rope coiled round the barrel would have been 60 inches;

Practical Mechanics.

inches; and the space described by the pulley, or load to be overcome, would have been 30 inches. Now, as the power is to the weight as the velocity of the weight is to the velocity of the power, and as the velocity of the power is the same in both capstanes, the weights which they will raise will be as $1\frac{1}{2}$ to 30. If it is wished to double the power of the machine, we have only to cover the cylinder C with lathes a quarter of an inch thick, so that the difference between the radii of each cylinder may be half as little as before; for it is obvious that the power of the capstane increases as the difference between the radii of the cylinders is diminished. As we increase the power, therefore, we increase the strength of our machine, while all other engines are proportionably enfeebled by an augmentation of power. Were we for example to increase the power of the common capstane, we must diminish the barrel in the same proportion, supposing the bar AB not to admit of being lengthened, which will not only diminish its strength, but destroy much of its power by the additional flexure of the rope.—This capstane may be easily converted into a crane, by giving the compound barrel a horizontal position, and substituting a winch instead of the bar AB. The superiority of such a crane above the common ones does not require to be pointed out; but it has this additional advantage, that it allows the weight to stop at any part of its progress, without the aid of a ratchet wheel and catch, because the two parts of the rope pull on the contrary sides of the barrel. The rope indeed which coils round the larger part of the barrel acts with a larger lever, and consequently with greater force than the other; but as this excess of force is not sufficient to overcome the friction of the machine, the weight will remain stationary in any part of its path. (*Appendix to Ferguson's Lectures*, vol. ii.).

Compound double machine on the same principle.

Fig. 5.

369. The principle on which the preceding capstane is constructed, might be applied with great advantage when two separate axles AC, BD are driven by means of the winch H and the wheels B and A. It is evident that when the winch is turned round in one direction, the rope R is unwinded from the axle BD; the wheel B drives the wheel A, so that the axle AC moves in a direction opposite to that of BD, and the rope is coiled round the axle AC. If the wheels A, B are of the same diameter and the same number of teeth, the weight W will be stationary, as the rope winded about one axle will be always equal to what is unwinded from the other. If the wheels have different diameters, or different numbers of teeth, the quantity of rope wound round the one axle will exceed what is unwound from the other, and the weight will be raised.

Chap. III. *On the Nature of Friction and the Method of diminishing its effects in Machinery; and on the Rigidity of Ropes.*

370. The friction generated in the communicating parts of machinery, opposes such a resistance to the impelling power, and is so injurious to the machine itself, that an acquaintance with the nature and effects of this retarding force, and with the method of diminishing its effects on machinery, is of infinite importance to the practical mechanic.

371. The subject of friction has been examined at great length by Amontons, Bulfinger, Parent, Euler, and Bossut, and has lately occupied the attention of our ingenious countryman Mr Vince of Cambridge.

Result of Vince's experiments.

He found that the friction of hard bodies in motion is an uniformly retarding force, and that the quantity of friction considered as equivalent to a weight drawing the body backwards is equal to $M\frac{\overline{M+W}\times S}{g\,t^2}$, where M is the moving force expressed by its weight, W the weight of the body upon the horizontal plane, S the space through which the moving force or weight descended in the time t, and $g=16.087$ feet, the force of gravity. Mr Vince also found that the quantity of friction increases in a less ratio than the quantity of matter or weight of the body, and that the friction of a body does not continue the same when it has different surfaces applied to the plane on which it moves, but that the smallest surfaces will have the least friction.

Experiments of Coulomb.

372. Notwithstanding the attempts of preceding philosophers to unfold the nature of friction, it was reserved for the celebrated Coulomb to surmount the difficulties which are inseparable from such an investigation, and to give an accurate and satisfactory view of this difficult branch of mechanical philosophy. By employing large bodies and conducting his experiments on a large scale, he has corrected several errors which arose from the limited experiments of others; he has brought to light many new and striking phenomena, and confirmed others which were hitherto but partially established. As it would be foreign to the nature of this work to follow this ingenious philosopher through his numerous and varied experiments, we shall only present the reader with the interesting results to which they led.

1. The friction of homogeneous bodies, or bodies of the same kind, moving upon one another, is generally supposed to be greater than that of heterogeneous bodies; but Coulomb has shewn that there are exceptions to this rule. He found, for example, that the friction of oak upon oak was equal to $\frac{1}{2.34}$ of the force of pression; the friction of pine against pine $\frac{1}{1.78}$, and that of oak against pine $\frac{1}{1.5}$. The friction of oak against copper was $\frac{1}{5.5}$, and that of oak against iron nearly the same.

2. It was generally supposed, that in the case of wood, the friction is greatest when the bodies are dragged contrary to the course of their fibres; but Coulomb has shewn that the friction is in this case sometimes the smallest. When the bodies moved in the direction of their fibres, the friction was $\frac{1}{2.34}$ of the force with which they were pressed together; but when the motion was contrary to the courses of the fibres, the friction was only $\frac{1}{3.76}$.

3. *The longer the rubbing surfaces remain in contact, the greater is their friction.*—When wood was moved upon

[Pr]actical [Me]chanics.

upon wood, according to the direction of the fibres, the friction was increased by keeping the surfaces in contact for a few seconds; and when the time was prolonged to a minute, the friction seemed to have reached its farthest limit. But when the motion was contrary to the course of the fibres, a greater time was necessary before the friction arrived at its maximum. When wood was moved upon metal, the friction did not attain its maximum till the surfaces continued in contact for five or six days; and it is very remarkable, that when wooden surfaces were anointed with tallow, the time requisite for producing the greatest quantity of frictiou is increased. The increase of friction which is generated by prolonging the time of contact is so great, that a body weighing 1650 pounds was moved with a force of 64 pounds when first laid upon its corresponding surface. After having remained in contact for the space of three seconds, it required 160 pounds to put it in motion; and, when the time was prolonged to fix days, it could scarcely be moved with a force of 622 pounds. When the surfaces of metallic bodies were moved upon one another, the time of producing a maximum of friction was not changed by the interposition of olive oil; it was increased, however, by employing swine's grease as an unguent, and was prolonged to five or six days by besmearing the surfaces with tallow.

4. *Friction is in general proportional to the force with which the rubbing surfaces are pressed together; and is, for the most part, equal to between* $\frac{1}{2}$ *and* $\frac{1}{4}$ *of that force.*—In order to prove the first part of this proposition. Coulomb employed a large piece of wood, whose surface contained three square feet, and loaded it successively with 74 pounds, 874 pounds, and 2474 pounds. In these cases the friction was successively $\frac{1}{2.46}$, $\frac{1}{2.16}$, $\frac{1}{2.21}$ of the force of pression; and when a less surface and other weights were used, the friction was $\frac{1}{2.36}$, $\frac{1}{2.42}$, $\frac{1}{2.40}$. Similar results were obtained in all Coulomb's experiments, even when metallic surfaces were employed. The second part of the proposition has also been established by Coulomb. He found that the greatest friction is engendered when oak moves upon pine, and that it amounts to $\frac{1}{1.78}$ of the force of pression; on the contrary, when iron moves upon brass, the least friction is produced, and it amounts to $\frac{1}{4}$ of the force of pression.

5. *Friction is in general not increased by augmenting the rubbing surfaces.*—When a superficies of three feet square was employed, the friction, with different weights, was $\frac{1}{2.28}$ at a medium; but when a small surface was used, the friction instead of being greater, as might have been expected, was only $\frac{1}{2.39}$.

[Fr]iction di[min]ished [by] increas[e of] the ve[loc]ity.

6. *Friction for the most part is not augmented by an increase of velocity.* In some cases, *it is diminished by an augmentation of celerity.*—M. Coulomb found, that when wood moved upon wood in the direction of the fibres, the friction was a constant quantity, however much the velocity was varied; but that when the surfaces were very small in respect to the force with which they were pressed, *the friction was diminished by augmenting the rapidity:* the friction, on the contrary, was increased when the surfaces were very large when compared with the force of pression. When the wood was moved contrary to the direction of its fibres, the friction in every case remained the same. If wood be moved upon metals, the friction is greatly increased by an increase of velocity; and when metals move upon wood besmeared with tallow, the friction is still augmented by adding to the velocity. When metals move upon metals, the friction is always a constant quantity; but when heterogeneous substances are employed which are not bedaubed with tallow, the friction is so increased with the velocity, as to form an arithmetical progression when the velocities form a geometrical one.

Practical Mechanics.

7. *The friction of loaded cylinders rolling upon a horizontal plane, is in the direct ratio of their weights, and the inverse ratio of their diameters.* In Coulomb's experiments, the friction of cylinders of guaiacum wood, which were two inches in diameter, and were loaded with 1000 pounds, was 18 pounds or $\frac{1}{56}$ of the force of pression. In cylinders of elm, the friction was greater by $\frac{2}{5}$, and was scarcely diminished by the interposition of tallow.

373. From a variety of experiments on the friction of the axes of pulleys, Coulomb obtained the following results.—When an iron axle moved in a brass bush the friction was $\frac{1}{6}$ of the pression; but when the bush was besmeared with very clean tallow, the friction was only $\frac{1}{11}$; when swine's grease was interposed, the friction amounted to $\frac{1}{8.5}$; and when olive oil was employed as an unguent, the friction was never less than $\frac{1}{8}$ or $\frac{1}{7.5}$, When the axis was of green oak, and the bush of guaiacum wood, the friction was $\frac{1}{26}$ when tallow was interposed; but when the tallow was removed, so that a small quantity only covered the surface, the friction was increased to $\frac{1}{17}$. When the bush was made of elm, the friction was in similar circumstances $\frac{1}{33}$ and $\frac{1}{20}$, which is the least of all. If the axis be made of box, and the bush of guaiacum wood, the friction will be $\frac{1}{23}$ and $\frac{1}{14}$, circumstances being the same as before. If the axle be of boxwood, and the bush of elm, the friction will be $\frac{1}{29}$ and $\frac{1}{20}$; and if the axle be of iron and the bush of elm, the friction will be $\frac{1}{20}$ of the force of pression.

Method of diminishing the effects of friction.

374. Having thus considered the nature and effects of friction, we shall now attend to the method of lessening the resistance which it opposes to the motion of machines. The most efficacious mode of accomplishing this is to convert that species of friction which arises from one body being dragged over another, into that which is occasioned by one body rolling upon another. As this will always diminish the resistance, it may be easily effected by applying wheels or rollers to the sockets or bushes which sustain the gudgeons of large wheels, and the axles of wheel carriages. Casatus seems to have been the first who recommended this apparatus. It was afterwards mentioned by Sturmius and Wolfius; but was not used in practice till Sully applied it to clocks in the year 1716, and Mondran to cranes in 1725. Notwithstanding these solitary attempts to introduce friction wheels, they seem to have attracted little notice till the celebrated Euler examined

Friction wheels.

and

Practical Mechanics.

and explained, with his usual accuracy, their nature and advantages. The diameter of the gudgeons and pivots should be made as small as the weight of the wheel and the impelling force will permit. The gudgeons should rest upon wheels as large as circumstances will allow, having their axes as near each other as possible, but no thicker than what is absolutely necessary to sustain the superincumbent weight. When these precautions are properly attended to, the resistance which arises from the friction of the gudgeon, &c. will be extremely trifling.

Friction may be diminished by a judicious application of the impelling power.

375. The effects of friction may likewise in some measure be removed by a judicious application of the impelling power, and by proportioning the size of the friction wheels to the pressure which they severally sustain. If we suppose, for example, that the weight of a wheel, whose iron gudgeons move in bushes of brass, is 100 pounds; then the friction arising from both its gudgeons will be equivalent to 25 pounds. If we suppose, also, that a force equal to 40 pounds is employed to impel the wheel, and acts in the direction of gravity, as in the cases of overshot wheels, the pressure of the gudgeons upon their supports will then be 140 pounds and the friction 35 pounds. But if the force of 40 pounds could be applied in such a manner as to act in direct opposition to the wheel's weight, the pressure of the gudgeons upon their supports would be 100—40, or 60 pounds, and the friction only 15 pounds. It is impossible, indeed, to make the moving force act in direct opposition to the gravity of the wheel, in the case of water mills; and it is often impracticable for the engineer to apply the impelling power but in a given way: but there are many cases in which the moving force may be so exerted, as at least not to increase the friction which arises from the wheel's weight.

376. When the moving force is not exerted in a perpendicular direction, but obliquely as in undershot wheels, the gudgeon will press with greater force on one part of the socket than on any other part. This point will evidently be on the side of the bush opposite to that where the power is applied; and its distance from the lowest point of the socket, which is supposed circular and concentric with the gudgeon, being called x, we shall have Tang. $x = \frac{H}{V}$, that is, the tangent of the arch contained between the point of greatest pressure and the lowest part of the bush, is equal to the sum of all the horizontal forces, divided by the sum of all the vertical forces and the weight of the wheel, H representing the former, and V the latter quantities. The point of greatest pressure being thus determined, the gudgeon must be supported at that part by the largest friction wheel, in order to equalize the friction upon their axles.

The application of these general principles to particular cases is so simple as not to require any illustration. To aid the conceptions, however, of the practical mechanic, we may mention two cases in which friction wheels have been successfully employed.

Plate CCCXXIII. fig. 6.

377. Mr Gottlieb, the constructor of a new crane, has received a patent for what he calls an anti-attrition axle-tree, the beneficial effects of which he has ascertained by a variety of trials. It consists of a steel roller R about four or six inches long, which turns within a groove cut in the inferior part of the axle-tree C which runs in the nave AB of the wheel. When the wheel-carriages are at rest, Mr Gottlieb has given the friction wheel its proper position; but it is evident that the point of greatest pressure will change when they are put in motion, and will be nearer the front of the carriage. This point, however, will vary with the weight of the load; but it is sufficiently obvious that the friction roller should be at a little distance from the lowest point of the axle-tree.

378. Mr Gamett of Bristol has applied friction rollers in a different manner, which does not, like the preceding method, weaken the axle-tree. Instead of fixing them in the iron part of the axle, he leaves a space between the nave and the axis to be filled with equal rollers almost touching each other. A section of this apparatus is represented in fig. 7. where ABCD is the metallic ring inserted in the nave of the wheel. The axle-tree is represented at E, placed between the friction rollers I, I, I, made of metal, and having their axes inserted into a circle of brass which passes through their centres. The circles are rivetted together by means of bolts passing between the rollers, in order to keep them separate and parallel.

Fig. 7.

379. As it appears from the experiments of Coulomb, that the least friction is generated when polished iron moves upon brass, the gudgeons and pivots of wheels, and the axles of friction rollers, should all be made of polished iron; and the bushes in which these gudgeons move, and the friction wheels, should be formed of polished brass.

Friction diminished by unguents.

380. When every mechanical contrivance has been adopted for diminishing the obstruction which arises from the attrition of the communicating parts, it may be still farther removed by the judicious application of unguents. The most proper for this purpose are swine's grease and tallow when the surfaces are made of wood, and oil when they are of metal. When the force with which the surfaces are pressed together is very great, tallow will diminish the friction more than swine's grease. When the wooden surfaces are very small, unguents will lessen their friction a little, but it will be greatly diminished if wood moves upon metal greased with tallow. If the velocities, however, are increased, or the unguent not often enough renewed, in both these cases, but particularly in the last, the unguent will be more injurious than useful. The best mode of applying it, is to cover the rubbing surfaces with as thin a stratum as possible, for the friction will then be a constant quantity, and will not be increased by an augmentation of velocity.

381. In small works of wood, the interposition of the powder of black lead has been found very useful in relieving the motion. The ropes of pulleys should be rubbed with tallow, and whenever the screw is used, the square threads should be preferred." *Appendix to Ferguson's Lectures*, vol. ii.

On the rigidity of ropes.

382. When ropes pass over cylinders or pulleys, a considerable force is necessary to bend them into the form of the circumference round which they are coiled. The force which is necessary to overcome this resistance is called the *stiffness* or *rigidity* of the ropes. This important subject was first examined by Amontons, * who contrived an ingenious apparatus for ascertaining the rigidity of ropes. His experiments were repeated and confirmed in part by subsequent philosophers, but particularly by M. Coulomb, who has investigated the subject

* *Mem. Acad.* 1699, p. 217.

ject with more care and success than any of his predecessors. His experiments were made both with the apparatus of Amontons, and with one of his own invention; and as there was no great discrepancy in the results, he was authorised to place more confidence in his experiments. The limits of this article will not permit us to give an account of the manner in which the experiments were conducted, or even to give a detailed view of the various conclusions which were obtained. We can only present the reader with some of those leading results which may be useful in the construction of machinery.

1. The rigidity of ropes increases, the more that the fibres of which they are composed are twisted.

2. The rigidity of ropes increases in the duplicate ratio of their diameters. According to Amontons and Desaguliers, the rigidity increases in the simple ratio of the diameters of the ropes; but this probably arose from the flexibility of the ropes which they employed: for Desaguliers remarks, that when he used a rope whose diameter was half an inch, its rigidity was increased in a greater proportion; so that it is probable that if they had employed ropes from two to four inches in diameter, like those used by Coulomb, they would have obtained similar results. (See N° 9.)

3. The rigidity of ropes is in the simple and direct ratio of their tension.

4. The rigidity of ropes is in the inverse ratio of the diameters of the cylinders round which they are coiled.

5. In general, the rigidity of ropes is directly as their tensions and the squares of their diameters, and inversely as the diameters of the cylinders round which they are wound.

6. The rigidity of ropes increases so little with the velocity of the machine, that it need not be taken into the account when computing the effects of machines.

7. The rigidity of small ropes is diminished when penetrated with moisture; but when the ropes are thick, their rigidity is increased.

8. The rigidity of ropes is increased and their strength diminished when they are covered with pitch; but when ropes of this kind are alternately immersed in the sea and exposed to the air, they last longer than when they are not pitched.—This increase of rigidity, however, is not so perceptible in small ropes as in those which are pretty thick.

9. The rigidity of ropes covered with pitch is a sixth part greater during frost than in the middle of summer, but this increase of rigidity does not follow the ratio of their tensions.

10. The resistance to be overcome in bending a rope over a pulley or cylinder may be represented by a formula composed of two terms. The first term $\frac{aD^n}{r}$ is a constant quantity independent of tension, a being a constant quantity determined by experiment, D^n a power of the diameter D of the rope, and r the radius of the pulley or cylinder round which the rope is coiled. The second term of the formula is $T \times \frac{bD^n}{r}$, where T is the tension of the rope, b a constant quantity, and D^n and r the same as before. Hence the complete formula is $\frac{a\,D^n}{r} + T \times \frac{b\,D^n}{r} = \frac{D^n}{r} \times a + T\,b$. The exponent n of the quantity D diminishes with the flexibility of the rope, but is generally equal to 1.7 or 1.8; or, as in N° 2. the rigidity is nearly in the duplicate ratio of the diameter of the rope. When the cord is much used, its flexibility is increased, and n becomes equal to 1.5 or 1.4.

Chap. IV. *On the Nature and Advantages of Fly Wheels.*

383. A fly, in mechanics, is a heavy wheel or cylinder which moves rapidly upon its axis, and is applied to machines for the purpose of rendering uniform a desultory or reciprocating motion, arising either from the nature of the machinery, from an inequality in the resistance to be overcome, or from an irregular application of the impelling power. When the first mover is inanimate, as wind, water, and steam, an inequality of force obviously arises from a variation in the velocity of the wind, from an increase or decrease of water occasioned by sudden rains, or from an augmentation or diminution of the steam in the boiler, produced by a variation in the heat of the furnace; and accordingly various methods have been adopted for regulating the action of these variable powers. The same inequality of force obtains when machines are moved by horses or men. Every animal exerts its greatest strength when first set to work. After pulling for some time, its strength will be impaired; and when the resistance is great, it will take frequent though short relaxations, and then commence its labour with renovated vigour. These intervals of rest and vigorous exertion must always produce a variation in the velocity of the machine, which ought particularly to be avoided, as being detrimental to the communicating parts as well as the performance of the machine, and injurious to the animal which is employed to draw it. But if a fly, consisting either of cross bars, or a massy circular rim, be connected with the machinery, all these inconveniences will be removed. As every fly wheel must revolve with great rapidity, the momentum of its circumference must be very considerable, and will consequently resist every attempt either to accelerate or retard its motion. When the machine therefore has been put in motion, the fly wheel will be whirling with an uniform celerity, and with a force capable of continuing that celerity when there is any relaxation in the impelling power. After a short rest the animal renews his efforts; but the machine is now moving with its former velocity, and these fresh efforts will have a tendency to increase that velocity. The fly, however, now acts as a resisting power, receives the greatest part of the superfluous motion, and causes the machinery to preserve its original celerity. In this way the fly secures to the engine an uniform motion, whether the animal takes occasional relaxations or exerts his force with redoubled ardour.

384. We have already observed that a desultory or variable motion frequently arises from the inequality of the resistance, or work to be performed. This is particularly manifest in thrashing mills, on a small scale, which are driven by water. When the corn is laid unequally on

Practical Mechanics.

on the feeding board, so that too much is taken in by the fluted rollers, this increase of resistance instantly affects the machinery, and communicates a desultory or irregular motion even to the water wheel or first mover. This variation in the velocity of the impelling power may be distinctly perceived by the ear in a calm evening when the machine is at work. The best method of correcting these irregularities is to employ a fly wheel, which will regulate the motion of the machine when the resistance is either augmented or diminished. In machines built upon a large scale there is no necessity for the interposition of a fly, as the *inertia* of the machinery supplies its place, and resists every change of motion that may be generated by an unequal admission of the corn.

385. A variation in the velocity of engines arises also from the nature of the machinery. Let us suppose that a weight of 1000 pounds is to be raised from the bottom of a well 50 feet, by means of a bucket attached to an iron chain which winds round a barrel or cylinder, and that every foot length of this chain weighs two pounds. It is evident that the resistance to be overcome in the first moment is 1000 pounds added to 50 pounds the weight of this chain, and that this resistance diminishes gradually as the chain coils round the cylinder, till it is only 1000 pounds when the chain is completely wound up. The resistance therefore decreases from 1050 to 1000 pounds; and if the impelling power is inanimate, the velocity of the bucket will gradually increase; but if an animal is employed, it will generally proportion its action to the resisting load, and must therefore pull with a greater or less force according as the bucket is near the bottom or top of the well. In this case, however, the assistance of a fly may be dispensed with, because the resistance diminishes uniformly, and may be rendered constant by making the barrel conical, so that the chain may wind upon the part nearest the vertex at the commencement of the motion, the diameter of the barrel gradually increasing as the weight diminishes. In this way the variable resistance will be equalized much better than by the application of a fly wheel, for the fly having no motion of its own must necessarily waste the impelling power.

386. Having thus pointed out the chief causes of variation in the velocity of machines, and the method of rendering it uniform by the intervention of fly wheels, the utility, and in some instances the necessity, of this piece of mechanism, may be more obviously illustrated by shewing the propriety of their application in particular cases.

387. In the description of Vauloue's pile engine *, the reader will observe a striking instance of the utility of fly wheels. The ram Q is raised between the guides *b b* by means of horses acting against the levers S, S; but as soon as the ram is elevated to the top of the guides, and discharged from the follower G, the resistance against which the horses have been exerting their force is suddenly removed, and they would instantaneously tumble down, were it not for the fly O. This fly is connected with the drum B by means of the trundle X, and as it is moving with a very great force, it opposes a sufficient resistance to the action of the horses, till the ram is again taken up by the follower.

* See Part III. Plate CCCXXIX fig. 1.

Practical Mechanics.

388. When machinery is driven by a single-stroke steam engine, there is such an inequality in the impelling power, that for two or three seconds it does not act at all. During this interval of inactivity the machinery would necessarily stop, were it not impelled by a massy fly wheel of a great diameter, revolving with rapidity, till the moving power again resumes its energy.

389. If the moving power is a man acting with a handle or winch, it is subject to great inequalities. The greatest force is exerted when the man pulls the handle upwards from the height of his knee, and he acts with the least force when the handle being in a vertical position is thrust from him in a horizontal direction. The force is again increased when the handle is pushed downwards by the man's weight, and it is diminished when the handle being at its lowest point is pulled towards him horizontally. But when a fly is properly connected with the machinery, these irregular exertions are equalized, the velocity becomes uniform, and the load is raised with an equable and steady motion.

390. In many cases, where the impelling force is alternately augmented and diminished, the performance of the machine may be increased by rendering the resistance unequal, and accommodating it to the inequalities of the moving power. Dr Robison observes that "there are some beautiful specimens of this kind of adjustment in the mechanism of animal bodies."

Besides the utility of fly wheels as regulators of machinery, they have been employed for accumulating or collecting power. If motion is communicated to a fly wheel by means of a small force, and if this force is continued till the wheel has acquired a great velocity, such a quantity of motion will be accumulated in its circumference, as to overcome resistances and produce effects which could never have been accomplished by the original force. So great is this accumulation of power; that a force equivalent to 20 pounds applied for the space of 37 seconds to the circumference of a cylinder 20 feet diameter, which weighs 4713 pounds, would, at the distance of one foot from the centre, give an impulse to a musket ball equal to what it receives from a full charge of gunpowder. In the space of six minutes and 10 seconds, the same effect would be produced if the cylinder was driven by a man who constantly exerted a force of 20 pounds at a winch one foot long (D).

391. This accumulation of power is finely exemplified in the *sling*. When the thong which contains the stone is swung round the head of the slinger, the force of the hand is continually accumulating in the revolving stone, till it is discharged with a degree of rapidity which it could never have received from the force of the hand alone. When a stone is projected from the hand itself, there is even then a certain degree of force accumulated, though the stone only moves through the arch of a circle. If we fix the stone in a opening at the

(D) This has been demonstrated by Mr Atwood. See his Treatise on Rectilineal and Rotatory Motion.

Practical Mechanics.

extremity of a piece of wood two feet long, and discharge it in the usual way, there will be more force accumulated than with the hand alone, for the stone describes a larger arch in the same time, and must therefore be projected with greater force.

392. When coins or medals are struck, a very considerable accumulation of power is necessary, and this is effected by means of a fly. The force is first accumulated in weights fixed in the end of the fly. This force is communicated to two levers, by which it is farther condensed; and from these levers it is transmitted to a screw, by which it suffers a second condensation. The stamp is then impressed on the coin or metal by means of this force, which was first accumulated by the fly, and afterwards augmented by the intervention of two mechanical powers.

393. Notwithstanding the great advantage of fly wheels, both as regulators of machines and collectors of power, their utility wholly depends upon the position which is assigned them relative to the impelled and working points of the engine. For this purpose no particular rules can be laid down, as their positions depend altogether on the nature of the machinery. We may observe however, in general, that when fly wheels are employed to regulate machinery, they should be near the impelling power; and when used to accumulate force in the working point they should not be far distant from it. In hand-mills for grinding corn, the fly is for the most part very injudiciously fixed on the axis to which the winch is attached; whereas it should always be fastened to the upper millstone so as to revolve with the same rapidity. In the first position indeed it must equalize the varying efforts of the power which moves the winch; but when it is attached to the turning millstone, it not only does this, but contributes very effectually to the grinding of the corn.

Description of the conical pendulum. Fig. 8.

394. A new kind of fly, called a conical pendulum has been ingeniously employed by Mr Watt for procuring a determinate velocity at the working point of his steam-engine. It is represented in fig. 8. where AB is a vertical axis moving upon pivots, and driven by means of a rope passing from the axis of the large fly over the sheave EF. The large balls M, N are fixed to the rods NG, MH, which have an angular motion round P, and are connected by joints at G and H, with the rods GK, HK attached to the extremity of the lever KL whose centre of motion is L, and whose other extremity is connected with the cock which admits the steam into the cylinder. The frames CD and QR prevent the balls from receding too far from the axis, or from approaching too near it. Now when this conical pendulum is put in motion, the centrifugal force of the balls M, N makes them recede from the axis AB. In consequence of this recess, the points C, H, K are depressed, and the other extremity of the lever is raised; and the cock admits a certain quantity of steam into the cylinder. When the velocity of the fly is by any means increased, the balls recede still farther from the axis, the extremity of the lever is raised higher, and the cock closes a little and diminishes the supply of steam. From this diminution in the impelling power, the velocity of the fly and the conical pendulum decreases, and the balls resume their former position. In this way, when there is any increase or diminution in the velocity of the fly, the corresponding increase or diminution in the centrifugal force of the balls raises or depresses the arm of the lever, admits a greater or a less quantity of steam into the cylinder, and restores to the engine its former velocity.

Chap. V. *On the Teeth of Wheels, and the Wipers of Stampers.*

395. In the construction of machines, we must not only attend to the form and number of their parts, but also to the mode by which they are to be connected. It would be easy to shew, did the limits of this article permit it, that, when one wheel impels another, the impelling power will sometimes act with greater and sometimes with less force, unless the teeth of one or both of the wheels be parts of a curve generated after the manner of an epicycloid by the revolution of one circle along the convex or concave side of another. It may be sufficient to shew, that, when one wheel impels another by the action of epicycloidal teeth, their motion will be uniform. Let the wheel CD drive the wheel AB by means of the epicycloidal teeth mp, nq, or, acting upon the infinitely small pins or spindles a, b, c; and let the epicycloids mp, nq, &c. be generated by the circumference of the wheel AB, rolling upon the convex circumference of the wheel CD. From the formation of the epicycloid it is obvious that the arch ab is equal to mn, and the arch ac to mo; for during the formation of the part nb of the epicycloid nq, every point of the arch ab is applied to every point of the arch mn, and the same happens during the formation of the part co of the epicycloid or. Let us now suppose that the tooth mp begins to act on the pin a, and that b, c are successive positions of the pin a after a certain time; then, nq, or will be the positions of the tooth mp after the same time; but $ab = mn$ and $ac = mo$, therefore the wheels AB, CD, when the arch is driven by epicycloidal teeth, move through equal spaces in equal times, that is, the force of the wheel CD, and the velocity of the wheel AB, are always uniform. Fig. 9.

396. In illustrating the application of this property of the epicycloid, which was discovered by Olaus Roemer the celebrated Danish astronomer, we shall call the small wheel the *pinion*, and its teeth the *leaves* of the pinion. The line which joins the centre of the wheel and pinion is called the *line of centres*. There are three different ways in which the teeth of one wheel may drive another, and each of these modes of action requires a different form for the teeth.

1. When the action is begun and completed after the teeth have passed the line of centres.

2. When the action is begun and completed before they reach the line of centres.

3. When the action is carried on, on both sides of the line of centres.

First mode of action. Plate CCCXXIV. fig. 1.

397. 1. The first of these modes of action is represented in fig. 1. where B is the centre of the wheel (D), A that of the pinion, and AB the line of centres. It is evident from the figure, that the part b of the tooth ab of the wheel, does not act on the leaf m of the pinion till they arrive at the line of centres AB; and that all the action is carried on after they have passed this line, and is completed when the leaf m comes into the situation n. When this mode of action is adopted, the acting faces of

(D) In figs. 1, 2, 3, 4, the letter B is supposed to be placed at the centre of the wheels.

Practical Mechanics. of the leaves of the pinion should be parts of an *interior epicycloid*, generated by a circle of any diameter rolling upon the concave superficies of the pinion, or within the circle *a d h*; and the faces *a b* of the teeth of the wheel should be portions of an *exterior epicycloid* formed by the *same* generating circle rolling upon the convex superficies *o d p* of the wheel.

398. But when one circle rolls within another whose diameter is double that of the rolling circle, the line generated by any point of the latter is a *straight line*, tending to the centre of the larger circle. Therefore, if the generating circle above mentioned should be taken with its diameter equal to the radius of the pinion, and be made to roll upon the concave superficies *a d h* of the pinion, it will generate a straight line tending to the pinion's centre, which will be the form of the faces of its leaves; and the teeth of the wheel will be exterior epicycloids, formed by a generating circle, whose diameter is equal to the radius of the pinion, rolling upon the convex superficies *o d p* of the wheel. This rectilineal form of the teeth is exhibited in fig. 2. and is perhaps the most advantageous, as it requires less trouble, and may be executed with greater accuracy, than if the epicycloidal form had been employed, though the teeth are evidently weaker than those in fig. 1.; it is recommended both by De la Hire and Camus as particularly advantageous in clock and watch-work. Fig. 2.

Fig. 1. 399. The attentive reader will perceive from fig. 1. that in order to prevent the teeth of the wheel from acting upon the leaves of the pinion before they reach the line of centres AB; and that one tooth of the wheel may not quit the leaf of the pinion till the succeeding tooth begins to act upon the succeeding leaf, there must be a certain proportion between the number of leaves in the pinion and the number of teeth in the wheel, or between the radius of the pinion and the radius of the wheel, when the distance of the leaves AB is given. But in machinery the number of leaves and teeth is always known from the velocity which is required at the working point of the machine: It becomes a matter therefore of great importance to determine with accuracy the relative radii of the wheel and pinion.

Relative size of the wheel and pinion. 400. For this purpose, let A, fig. 2. be the pinion having the acting faces of its leaves straight lines tending to the centre, and B the centre of the wheel. AB will be the distance of their centres. Then as the tooth C is supposed not to act upon the leaf A*m* till it arrives at the line AB, it ought not to quit A*m* till the following tooth F has reached the line AB. But since the tooth always acts in the direction of a line drawn perpendicular to the face of the leaf A*m* from the point of contact, the line CH, drawn at right angles to the face of the leaf A*m*, will determine the extremity of the tooth CD, or the last part of it which should act upon the leaf A*m*, and will also mark out CD for the depth of the tooth. Now, in order to find AH, HB, and CD, put a for the number of teeth in the wheel, b for the number of leaves in the pinion, c for the distance of the pivots A and B, and let x be the radius of the wheel, and y that of the pinion. Then, since the circumference of the wheel is to the circumference of the pinion, as the number of teeth in the one to the number of leaves in the other, and as the circumferences of circles are proportional to their radii, we shall have $a : b = x : y$, then by composition (Eucl. v. 18.) $a+b : b = c : y$ (c being equal to $x+y$), and consequently the radius of the pinion, viz. $y = \frac{c\,b}{a+b}$; then by inverting the first analogy, we have $b : a = y : x$, and consequently the radius of the wheel, viz. $x = \frac{a\,y}{b}$; y being now a known number.

Now, in the triangle AHC, right-angled at C, the side AH is known, and likewise all the angles (HAC being equal to $\frac{360}{b}$); the side AC, therefore, may be found by plain trigonometry. Then, in the triangle ACB, the $\angle$CAB, equal to HAC, is known, and also the sides AB, AC, which contain it; the third side, therefore, viz. CB, may be determined; from which DB, equal to HB, already found, being subtracted, there will remain CD for the depth of the teeth. When the action is carried on after the line of centres, it often happens that the teeth will not work in the hollows of the leaves. In order to prevent this, the $\angle$ CBH must always be greater than half the $\angle$ HBP. The $\angle$ HBP is equal to 360 degrees, divided by the number of teeth in the wheel, and CBH is easily found by plane trigonometry.

401. If the teeth of wheels and the leaves of pinions be formed according to the directions already given, they will act upon each other, not only with uniform force, but nearly without friction. The one tooth rolls upon the other, and neither slides nor rubs to such a degree as to retard the wheels, or wear their teeth. But as it is impossible in practice to give that perfect curvature to the faces of the teeth which theory requires, a quantity of friction will remain after every precaution has been taken in the formation of the communicating parts.

402. 2. The second mode of action is not so advantageous as that which we have been considering, and should, if possible, always be avoided. It is represented in fig. 3. where A is the centre of the pinion, B that of the wheel, and AB the line of centres. It is evident from the figure, that the tooth C of the wheel acts upon the leaf D of the pinion before they arrive at the line BA; that it quits the leaf when they reach this line, and have assumed the position of E and F; and that the tooth c works deeper and deeper between the leaves of the pinion, the nearer it comes to the line of centres. From this last circumstance a considerable quantity of friction arises, because the tooth C does not, as before, roll upon the leaf D, but slides upon it; and from the same cause the pinion soon becomes foul, as the dust which lies upon the acting faces of the leaves is pushed into the interjacent hollows. One advantage, however, attends this mode of action: It allows us to make the teeth of the large wheel rectilineal, and thus renders the labour of the mechanic less, and the accuracy of his work greater, than if they had been of a curvilineal form. If the teeth C, E, therefore of the wheel BC are made rectilineal, having their surfaces directed to the wheel's centre, the acting faces of the leaves D, F, &c. must be epicycloids formed by a generating circle, whose diameter is equal to the radius B o of the circle $o\,p$, rolling upon the circumference $m\,n$ of the pinion A. But if the teeth of the wheel and the leaves of the pinion are made curvilineal as in the figure, the faces of the teeth of the wheel must be portions of an interior epicycloid formed by any generating Second mode of action. Fig. 3.

[...actical ...hanics.] rating circle rolling within the concave superficies of the circle $o\,p$, and the faces of the pinion's leaves must be portions of an exterior epicycloid produced by rolling the same generating circle upon the convex circumference $m\,n$ of the pinion.

[...rd mode ...ction. ... 4.] 403. 3. The third mode of action, which is represented in fig. 4. is a combination of the two first modes, and consequently partakes of the advantages and disadvantages of each. It is evident from the figure that the portion $e\,b$ of the tooth acts upon the part $b\,c$ of the leaf till they reach the line of centres AB, and that the part $e\,d$ of the tooth acts upon the portion $b\,a$ of the leaf after they have passed this line. Hence the acting parts $e\,h$ and $b\,c$ must be formed according to the directions given for the first mode of action, and the remaining parts $e\,d$, $b\,a$, must have that curvature which the second mode of action requires; consequently $e\,h$ should be part of an interior epicycloid formed by any generating circle rolling on the concave circumference $m\,n$ of the wheel, and the corresponding part $b\,c$ of the leaf should be part of an exterior epicycloid formed by the same generating circle rolling upon b EO, the convex circumference of the pinion: the remaining bart $c\,d$ of the tooth should be a portion of an exterior epicycloid, engendered by any generating circle rolling upon e L, the concave superficies of the wheel: and the corresponding part $b\,a$ of the leaf should be part of an interior epicycloid described by the same generating circle, rolling along the concave side b EO of the pinion. As it would be extremely troublesome, however, to give this double curvature to the acting faces of the teeth, it will be proper to use a generating circle, whose diameter is equal to the radius of the wheel BC, for describing the interior epicycloid $e\,h$ and the exterior one $b\,c$, and a generating circle, whose diameter is equal to AC, the radius of the pinion, for describing the interior epicycloid $b\,a$, and the exterior one $e\,d$. In this case the two interior epicycloids $e\,h$, $b\,a$, will be straight lines tending to the centres B and A, and the labour of the mechanic will by this means be greatly abridged.

[...lative ...meters the ...eel and ...ion.] 404. In order to find the relative diameters of the wheel and pinion, when the number of teeth in the one and the number of leaves in the other are given, and when the distance of their centres is also given, and the ratio of ES to CS, let a be the number of teeth in the wheel, b the number of leaves in the pinion, c the distance of the pivots A, B, and let m be to n as ES to CS, then the arch ES, or $\angle$ SAE, will be equal to $\frac{360^\circ}{b}$, and LD, or $\angle$ LBD, will be equal to $\frac{360^\circ}{a}$. But ES : CS$=m:n$; consequently LD : LC$=m:n$, therefore (Eucl. vi. 16.) LC$\times m=$LD$\times n$, and LC$=\frac{\text{LD}\times n}{m}$; but LD is equal to $\frac{360}{a}$, therefore by substitution LC$=\frac{360\times n}{am}$.

Now, in the triangle APB, AB is known, and also PB, which is the cosine of the angle ABD, PC being perpendicular to DB; AP or the radius of the pinion therefore may be found by plane trigonometry. The reader will observe that the point P marks out the parts of the tooth D and the leaf SP where they commence their action; and the point I marks out the parts where their mutual action ceases (E); AP therefore is the proper radius of the pinion, and BI the proper radius of the wheel, the parts of the tooth L without the point I, and of the leaf SP without the point P, being superfluous. Now, to find BI, we have ES : CS$=m:n$, and CS$=\frac{\text{ES}\times n}{m}$; but ES was shewn to be $=\frac{360}{b}$, therefore, by substitution, CS$=\frac{360\times n}{b\,m}$. Now the arch ES, or $\angle$ EAS, being equal to $\frac{360}{b}$, and CS, or $\angle$CAS, being equal to $\frac{360\times n}{b\,m}$, their difference EC, or the angle EAC, will be equal to $\frac{360}{b}-\frac{360\times n}{b\,m}$, or $\frac{360^\circ\times\overline{m-n}}{b\,m}$. The $\angle$ EAC being thus found, the triangle EAB, or IAB, which is almost equal to it, is known, because AB is given, and likewise AI, which is equal to the cosine of the angle IAB, AC being radius, and AIC being a right angle, consequently IB the radius of the wheel may be found by trigonometry. It was formerly shewn that AC, the radius of what is called the primitive pinion, was equal to $\frac{c\,b}{a+b}$, and that BC the radius of the primitive wheel was equal to $\frac{\text{AC}\times a}{b}$. If then we subtract AC or AS from AP, we shall have the quantity SP which must be added to the radius of the primitive pinion, and if we take the difference of BC (or BL) and DE, the quantity LE will be found, which must be added to the radius of the primitive wheel. We have all along supposed that the wheel drives the pinion, and have given the proper form of the teeth upon this supposition. But when the pinion drives the wheel, the form which was given to the teeth of the wheel in the first case, must in this be given to the leaves of the pinion; and the shape which was formerly given to the leaves of the pinion must now be transferred to the teeth of the wheel.

405. Another form for the teeth of wheels, different from any which we have mentioned, has been recommended by Dr Robison. He shews that a perfect uniformity of action may be secured, by making the acting faces of the teeth involutes of the wheel's circumference, which are nothing more than epicycloids, the centres of whose generating circles are infinitely distant. Thus, in fig. 1. let AB be a portion of the wheel on which [Form of the teeth according to Dr Robison.]

(E) The letter L marks the intersection of the line BL with the arch $e\,m$, and the letter E the intersection of the arch b O with the upper surface of the leaf m. The letters D and S correspond with L and E respectively, and P with I.

Practical Mechanics.

Fig. 5.

which the tooth is to be fixed, and let A *p a* be a thread lapped round its circumference, having a loop hole at its extremity *a*. In this loop hole fix the pin *a*, and with it describe the curve or *involute a b c d e h*, by unlapping the thread gradually from the circumference A *p m*. This curve will be the proper shape for the teeth of a wheel whose diameter is AB. Dr Robison observes, that as this form admits of several teeth to be acting at the same time (twice the number that can be admitted in M. de la Hire's method), the pressure is divided among several teeth, and the quantity upon any one of them is so diminished, that those dents and impressions which they unavoidably make upon each other are partly prevented. He candidly allows, however, that the teeth thus formed are not completely free from sliding and friction, though this slide is only $\frac{1}{60}$th of an inch, when a tooth three inches long fixed on a wheel ten feet in diameter drives another wheel whose diameter is two feet. *Append. to Ferguson's Lectures.*

406. *On the Formation of Exterior and Interior Epicycloids, and on the Disposition of the Teeth on the Wheel's Circumference.*

Mechanical method of forming epicycloids.

Nothing can be of greater importance to the practical mechanic, than to have a method of drawing epicycloids with facility and accuracy; the following, we trust, is the most simple mechanical method that can be employed.—Take a piece of plain wood GH, fig. 6. and fix upon it another piece of wood E, having its circumference *m b* of the same curvature as the circular base upon which the generating circle AB is to roll. When the generating circle is large, the segment B will be sufficient: in any part of the circumference of this segment, fix a sharp pointed nail *a*, sloping in such a manner that the distance of its point from the centre of the circle may be exactly equal to its radius; and fasten to the board GH a piece of thin brass, or copper, or tinplate, *a b*, distinguished by the dotted lines. Place the segment B in such a position that the point of the nail *a* may be upon the point *b*, and roll the segment towards G, so that the nail *a* may rise gradually, and the point of contact between the two circular segments may advance towards *m*; the curve *a b* described upon the brass plate will be an accurate exterior epicycloid. In order to prevent the segments from sliding, their peripheries should be rubbed with rosin or chalk, or a number of small iron points may be fixed on the circumference of the generating segment. Remove, with a file, the part of the brass on the left hand of the epicycloid, and the remaining concave arch or gage *a b* will be a pattern tooth, by means of which all the rest may be easily formed. When an *interior epicycloid* is wanted, the concave side of its circular base must be used. The method of describing it is represented in fig. 7. where CD is the generating circle, F the concave circular base, MN the piece of wood on which this base is fixed, and *c d* the interior epicycloid formed upon the plate of brass, by rolling the generating circle C, or the generating segment D, towards the right hand. The *cycloid*, which is useful in forming the teeth of *rack-work*, is generated precisely in the same manner, with this difference only, that the base on which the generating circle rolls must be a straight line.

Fig. 6.

Fig. 7.

Practical Mechanics.

Disposition of the tooth.

In order that the teeth may not embarrass one another before their action commences, and that one tooth may begin to act upon its corresponding leaf of the pinion, before the preceding tooth has ceased to act upon the preceding leaf, the height, breadth, and distance of the teeth must be properly proportioned. For this purpose the pitch-line or circumference of the wheel, which is represented in fig. 2. and 3. by the dotted arches, must be divided into as many equal spaces as the number of teeth which the wheel is to carry. Divide each of these spaces into 16 equal parts; allow 7 of these for the greatest breadth of the teeth, and 9 for the distance between each; or the distance of the teeth may be made equal to their breadth. If the wheel drive a trundle, each space should be divided into 7 equal parts, and 3 of these allotted for the thickness of the tooth, and $3\frac{2}{7}$ for the diameter of the cylindrical stave of the trundle. If each of the spaces already mentioned, or if the distance between the centres of each tooth, be divided into three equal parts, the height of the teeth must be equal to two of these. These distances and heights, however, vary according to the mode of action which is employed. The teeth should be rounded off at the extremities, and the radius of the wheel made a little larger than that which is deduced from the rules in Art. 400, 404. But when the pinion drives the wheel, a small addition should be made to the radius of the pinion.

On the Nature of Bevelled Wheels, and the method of giving an epicycloidal form to their Teeth.

Bevelled wheels.

407. The principle of bevelled wheels was pointed out by De la Hire, so long ago as the end of the 17th century. It consists in one fluted or toothed cone acting upon another, as is represented in fig. 8. where the cone OD drives the cone OC, conveying its motion in the direction OC. If these cones be cut parallel to their bases as at A and B, and if the two small cones between AB and O be removed, the remaining parts AC and BD may be considered as two bevelled wheels, and BD will act upon AC in the very same manner, and with the same effect, that the whole cone OD acted upon the whole cone OC. If the section be made nearer the bases of the cones, the same effect will be produced: this is the case in fig. 9. where CD and DE are but very small portions of the imaginary cones ACD and ADE.

Fig. 8.

Fig. 9.

408. In order to convey motion in any given direction, and determine the relative size and situation of the wheels for this purpose, let AB, fig. 10. be the axis of a wheel, and CD the given direction in which it is required to convey the motion by means of a wheel fixed upon the axis AB, and acting upon another wheel fixed on the axis CD, and let us suppose that the axis CD must have four times the velocity of AB, or must perform four revolutions while AB performs one. Then the number of teeth in the wheel fixed upon AB must be four times greater than the number of teeth in the wheel fixed upon CD, and their radii must have the same proportion. Draw *c d* parallel to CD at any convenient distance, and draw *a b* parallel to AB at four times that distance, then the lines *i m* and *i n* drawn perpendicular to AB and CD respectively, will mark the situation and size of the wheels required. In this

Fig. 10.

Practical Mechanics.

this case the cones are O $n i$ and O $m i$, and $s r n i$, $r p m i$, are the portions of them that are employed.

On the formation of teeth.

The formation of the teeth of bevelled wheels is more difficult than one would at first imagine. The teeth of such wheels, indeed, must be formed by the same rules which have been given for other wheels; but since different parts of the same tooth are at different distances from the axis, these parts must have the curvature of their acting surfaces proportioned to that distance. Thus, in fig. 10. the part of the tooth at r must be more incurvated than the part at i, as is evident from the inspection of fig. 9.; and the epicycloid for the part i must be formed by means of circles whose diameters are $i m$ and Ff, while the epicycloid for the part r must be generated by circles whose diameters are C n and D d.

409. Let us suppose a plane to pass through the points O, A, D; the lines AB, AO, will evidently be in this plane, which may be called the *plane of centres*. Now, when the teeth of the wheel DE, which is supposed to drive CD the smallest of the two, commence their action on the teeth of CD, when they arrive at the plane of centres, and continue their action after they have passed this plane, the curve given to the teeth of CD at C, should be a portion of an interior epicycloid formed by any generating circle rolling on the concave superficies of a circle whose diameter is twice C n perpendicular to CA, and the curvature of the teeth at i should be part of a similar epicycloid, formed upon a circle, whose diameter is twice $i m$. The curvature of the teeth of the wheel DE at D, should be part of an exterior epicycloid formed by the same generating circle rolling upon the concave circumference of a circle whose diameter is twice D d perpendicular to DA; and the epicycloid for the teeth at F is formed in the same way, only instead of twice D d, the diameter of the circle must be twice Ff. When any other mode of action is adopted, the teeth are to be formed in the same manner that we have pointed out for common wheels, with this difference only, that different epicycloids are necessary for the parts F and D. It may be sufficient, however, to find the form of the teeth at F, as the remaining part of the tooth may be shaped by directing a straight ruler from different points of the epicycloid at F to the centre A, and filling the tooth till every part of its acting surface coincide with the side of the ruler. The reason of this operation will be obvious by attending to the shape of the tooth in fig. 8. When the small wheel CD impels the large one DE, the epicycloids which were formerly given to CD must be given to DE, and those which were given to DE must be transferred to CD.

Fig. 8.

Of crown wheels.

410. The wheel represented in fig. 11. is sometimes called a crown wheel, though it is evident from the figure that it belongs to that species of wheels which we have just been considering; for the acting surfaces of the teeth both of the wheel MB and of the pinion EDG are directed to C the common vertex of the two cones CMB, CEG. In this case the rules for bevelled wheels must be adopted, in which AS is to be considered as the radius of the wheel for the profile of the tooth at A, and MN as its radius for the profile of the tooth at M; and the epicycloids thus formed will be the sections or profiles of the teeth in the direction MP, at right angles to MC the surfaces of the cone. When the vertex C of the cone MCG approaches to N till it be in the same plane with the points M, G, some of the curves will be cycloids and others involutes, as in the case of rack-work, for then the cone CEG will revolve upon a plane surface. *Appendix to Ferguson's Lectures.*

Fig. 11.

Sect. II. *On the Wipers of Stampers, &c. the Teeth of Rack-work, &c. &c.*

Fig. 12.

411. In fig. 12. let AB be the wheel which is employed to elevate the rack C, and let their mutual action not commence till the acting teeth have reached the line of centres AC. In this case C becomes as it were the pinion or wheel driven, and the acting faces of its teeth must be *interior epicycloids* formed by any generating circle rolling within the circumference $p q$; but as $p q$ is a straight line, these interior epicycloids will be *cycloids*, or curves generated by a point in the circumference of a circle, rolling upon a straight line or plane surface. The acting face $o p$, therefore, will be part of a *cycloid* formed by any generating circle, and $m n$, the acting face of the teeth of the wheel, must be an *exterior* epicycloid produced by the same generating circle rolling on $m r$ the convex surface of the wheel. If it is required to make $o p$ a straight line, as in the figure, them $m n$ must be an *involute* of the circle $m r$ formed in the manner represented in fig. 5.

412. Fig. 12. likewise represents a wheel depressing the rack c when the third mode of action is used. In this case also c becomes the pinion, and DE the wheel; $e h$ therefore must be part of an interior epicycloid formed by any generating circle rolling on the concave side $e x$ of the wheel, and $b c$ must be an exterior epicycloid produced by the same generating circle rolling upon the circumference of the rack. The remaining part $e d$ of the teeth of the wheel must be an exterior epicycloid described by any generating circle moving upon the convex side $e x$, and $b a$ must be an interior epicycloid engendered by the same generating circle rolling within the circumference of the rack. But as the circumference of the rack is in this case a straight line, the exterior epicycloid $b e$ and the interior one $b a$ will be cycloids formed by the same generating circles which are employed in describing the other epicycloids. Since it would be difficult, however, as has already been remarked, to give this compound curvature to the teeth of the wheel and rack, we may use a generating circle whose diameter is equal to D x the radius of the wheel, for describing the interior epicycloid $e h$, and the exterior one $b e$; and a generating circle whose diameter is equal to the radius of the rack, for describing the interior epicycloid $a b$, and the exterior one $d e$; $a b$ and $e h$, therefore, will be straight lines, and $b e$ will be a cycloid, and $d e$ an involute of the circle $e x$, the radius of the rack being infinitely great.

413. In the same manner may the form of the teeth of rack-work be determined, when the second mode of action is employed, and when the teeth of the wheel or rack are circular or rectilineal. But if the rack be part of a circle, it must have the same form of its teeth as that of a wheel of the same diameter with the circle of which it is a part.

In

Practical Mechanics.

Proper form of wipers.

In machinery, where large weights are to be raised, such as falling-mills, mills for pounding ore, &c. or where large pistons are to be elevated by the arms of levers, it is of the greatest consequence that the power should raise the weight with an uniform force and velocity; and this can be effected only by giving a proper form to the wiper.

Now there are two cases in which this uniformity of motion may be required, and each of these demands a different form for the communicating parts. 1. When the weight is to be raised vertically, as the piston of a pump, &c. 2. When the weight to be raised or depressed moves upon a centre, and rises or falls in the arch of a circle, such as the sledge hammer in a forge, &c.

Fig. 13.

414. 1. Let AH be a wheel moved by any power which is sufficient to raise the weight MN by its extremity O, from O to *e*, in the same time that the wheel moves round one-fourth of its circumference, it is required to fix upon its rim a wing OBCDEH which shall produce this effect with an uniform effect. Divide the quadrant OH into any number of equal parts O *m*, *m n*, &c. the more the better, and *o e* into the same number *o b*, *b c*, *c d*, &c. and through the points *m*, *n*, *p*, H draw the indefinite lines AB, AC, AD, AE, and make AB equal to A*b*, AC to A*c*, AD to A*d*, and AE to A*e*; then through the points O, B, C, D, E, draw the curve OBCDE, which is a portion of the spiral of Archimedes, and will be the proper form for the wiper or wing OHE. It is evident that when the point *m* has arrived at O, the extremity of the weight will have arrived at *b*; because AB is equal to A *b*, and for the same reason, when the points *n*, *p*, H have successively arrived at O, the extremity of the weight will have arrived at the corresponding points *c*, *d*, *e*. The motion therefore will be uniform, because the space described by the weight is proportional to the space described by the moving power, O *b* being to O *c* as O *m* to O *n*. If it be required to raise the weight MN with an accelerated or retarded motion, we have only to divide the line O *e* according to the law of acceleration or retardation, and divide the curve OBCDE as before.

When the weight rises in the arch of a circle. Fig. 14.

415. 2. When the lever moves upon a centre, the weight will rise in the arch of a circle, and consequently a new form must be given to the wipers or wings. Let AB, fig. 14. be a lever lying horizontally, which it is required to raise uniformly through the arch BC into the position AC, by means of the wheel BFH furnished with the wing BNOP, which acts upon the extremity C of the lever; and let it be required to raise it through BC in the same time that the wheel BFH moves through one-half of its circumference; that is, while the point M moves to B in the direction MFB. Divide the chord CB into any number of equal parts, the more the better, in the points 1, 2, 3, and draw the lines 1 *a* 2 *b* 3 *c* parallel to AB, or a horizontal line passing through the point B, and meeting the arch BC in the points *a*, *b*, *c*. Draw the lines CD, *a* D, *b* D, *c* D, and BD cutting the circle BFH in the points *m*, *n*, *o*, *p*.

Having drawn the diameter BM, divide the semicircle BFM into as many equal parts as the chord CB, in the points *q*, *s*, *u*. Take B *m*, and set it from *q* to *r*: Take B *n* and set it from *s* to *t*: Take B *o* and set it from *u* to *v*, and lastly set B *p* from M to E. Through the points *r*, *t*, *v*, E, draw the indefinite lines DN, DO, DP, DQ, and make DN equal to D *c*; DO equal to D *b*; DP equal to D *a*; and DQ equal to DC. Then through the points Q, P, O, N, B, draw the spiral B, N, O, P, Q, which will be the proper form for the wing of the wheel when it moves in the direction EMB.

That the spiral BNO will raise the lever AC, with an uniform motion, by acting upon its extremity *c*, will appear from the slightest attention to the construction of the figure. It is evident, that when the point *q* arrives at B, the point *r* will be in *m*, because B *m* is equal to *q r*, and the point N will be at *c*, because DN is equal to D *c*; the extremity of the lever therefore, will be found in the point *c*, having moved through B *c*. In like manner, when the point *s* has arrived at B, the point *t* will be at *n*, and the point O, in *b*, where the extremity of the lever will now be found; and so on with the rest, till the point M has arrived at B. The point E will then be in *p*, and the point Q in C; so that the lever will now have the position AC, having moved through the equal heights B*c*, *c b*, *b a*, *a c*, (F) in the same time that the power has moved through the equal spaces *q* B, *s q*, *u s*, M *u*. The lever, therefore, has been raised uniformly, the ratio between the velocity of the power, and that of the weight, remaining always the same.

416. If the wheel D turn in a contrary direction, according to the letters MHB, we must divide the semicircle BH EM, into as many equal parts as the chord *c* B, viz. in the points *e*, *g*, *h*. Then, having set the arch B *m* from *e* to *d*, the arch B *n* from *g* to *f*, and the rest in a similar manner, draw through the points *d*, *f*, *h*, E, the indefinite lines DR, DS, DT, DQ: make DR equal to D *c*; DS equal to D *b*; DT equal to D *a*, and DQ equal to DC; and through the points B, R, S, T, Q, describe the spiral BRSTQ, which will be the proper form for the wing, when the wheel turns in the direction MEB. For, when the point *e* arrives at B, the point *d* will be in *m*, and R in *c*, where the extremity of the lever will now be found, having moved through B *c* in the same time that the power, or wheel, has moved through the division *e* B. In the same manner it may be shewn, that the lever will rise through the equal heights *c b*, *b a*, *a* C, in the same time that the power moves through the corresponding spaces *e g*, *g i*, *i* M. The motion of the lever, therefore, and also that of the power, are always uniform. Of all the positions that can be given to the point B, the most disadvantageous are those which are nearest the points F, H; and the most advantageous position is when the chord B *c* is vertical, and passes, when prolonged, through D, the centre

(F) The arches B *c*, *c b*, &c. are not equal; but the perpendiculars let fall from the points *c*, *a*, *b*, &c. upon the horizontal lines, passing through *a b*, &c. are equal, being proportional to the equal lines *c* 1, 1, 2. Eucl. VI. 2.

centre of the circle (G). In this particular case the two curves have equal bases, though they differ a little in point of curvature. The farther that the centre A is distant, the nearer do these curves resemble each other; and if it were infinitely distant, they would be exactly similar, and would be the spirals of Archimedes, as the extremity *c* would in this case rise perpendicularly.

It will be easily pereeived that 4, 6, or 8 wings may be placed upon the circumference of the circle, and may be formed by dividing into the same number of equal parts as the chord BC, $\frac{1}{4}$, $\frac{1}{6}$, or $\frac{1}{8}$ of the circumference, instead of the semicircle BFM.

That the wing BNO may not act upon any part of the lever between A and C, the arm AC should be bent; and that the friction may be diminished as much as possible, a roller should be fixed upon its extremity C. When a roller is used, however, a curve must always be drawn parallel to the spiral described according to the preceding method, the distance between it and the spiral being everywhere equal to the radius of the roller.

If it should be required to raise the roller with an accelerated or retarded motion, we have only to divide the chord BC, according to the degree of retardation or acceleration required, and the circle into the same number of equal parts as before.

417. As it is frequently more convenient to raise or depress weights by the extremity of a constant radius, furnished with a roller, instead of wings fixed upon the periphery of a wheel; we shall now proceed to determine the curve which must be given to the arm of the lever which is to be raised and depressed, in order that this elevation or depression may be effected with an uniform motion.

Let AB be a lever, which it is required to raise uniformly through the arch BC, into the position AC, by means of the arm or constant radius DE, moving upon D as a centre, in the same time that the extremity E describes the arch E*e*F. From the point C draw CH at right angles to AB, and divide it into any number of equal parts, suppose three, in the points 1, 2; and through the points 1, 2, draw 1 *a* 2 *b*, parallel to the horizontal line AB, cutting the arch CB in the points *a*, *b*, through which draw *a* A, *b* A. Upon D as a centre, with the distance DE, describe the arch E *i c* F, and upon A as a centre, with the distance AD, describe the arch *c* O D, cutting the arch E *i c* F in the point *c*. Divide the arches E *i c*, and F *s c*, each into the same number of equal parts as the perpendicular *c* H, in the points *k*, *i*, *s*, *m*, and through these points about the centre A, describe the arches *k z*, *i g*, *q r*, *m n*. Make *z x* and set it from *k* to *l*, and take *g f*, and set it from *i* to *h*. Take *r q* also, and set it from *s* to *t*, and set *n m* from *o* to *p*, and *d c* from *c* to O. Then through the points E, *l*, *h*, O, and O, *t*, *p*, F, draw the two curves E *l h* O, and O *t p* F, which will be the proper form that must be given to the arm of the lever. If the handle DE moves from E towards F, the curve EO must be used, but if in the contrary direction, we must employ the curve OF.

It is evident, that when the extremity E of the handle DE, has run through the arch E *k*, or rather E *l*, the point *l* will be in *k*, and the point *z* in *x*, because *x z* is equal to *k l*, and the lever will have the position A *b*. For the same reason, when the extremity E of the handle has arrived at *i*, the point *h* will be in *i*, and the point *g* in *f*, and the lever will be raised to the position A *a*. Thus it appears, that the motion of the power and the weight are always proportional. When a roller is fixed at E, a curve parallel to EO, or OF, must be drawn as formerly. See *Appendix to Ferguson's Lectures*.

Chap. VI. *On the First Movers of Machinery.*

418. The powers which are generally employed as the first movers of machines are water, wind, steam, and animal exertion. The mode of employing water as an impelling power has already been given at great length in the article Hydrodynamics. The application of wind to turn machinery will be discussed in the chapter on Windmills; and what regards steam will be more properly introduced into the article *Steam-Engine*. At present, therefore, we shall only make a few general remarks on the strength of men and horses; and conclude with a general view of the relative powers of the first movers of machinery. The following table contains the weight which a man is able to raise through a certain height in a certain time, according to different authors.

Table *of the Strength of Men, according to different authors.*

Number of pounds raised.	Height to which the weight is raised	Time in which it is raised.	Duration of the Work.	Names of the authors.
1000	180	60 minutes		Euler
60 } French.	1 } French.	1 second	8 hours	Bernouilli
25 } French.	220 } French.	145 seconds		Amontons
170 } French.	1 } French.	1 second	half an hour	Coulomb
1000	330	60 minutes		Desaguliers
1000	225	60 minutes		Smeaton
30	$3\frac{1}{2}$	1 second	10 hours	Emerson
29 or 30	2.45 feet.	1 second		Schulze

419.

(G) In the figure we have taken the point B in a disadvantageous position, because the intersections are in this case more distinct.

Practical Mechanics.

Force of men according to Amontons.

419. According to Amontons, a man weighing 133 pounds French, ascended 62 feet French by steps in 34 seconds, but was completely exhausted. The same author informs us that a sawer made 200 strokes of 18 inches French each, with a force of 25 pounds, in 145 seconds; but that he could not have continued the exertion above three minutes.

According to Desaguliers.

420. It appears from the observations of Desaguliers, that an ordinary man can, for the space of ten hours, turn a winch with a force of 30 pounds, and with a velocity of two feet and a half per second; and that two men working at a windlass with handles at right angles to each other, can raise 70 pounds more easily than one man can raise 30. The reason of this is, that when there is only one man, he exerts variable efforts at different positions of the handle, and therefore the motion of the windlass is irregular; whereas in the case of two men, with handles at right angles, the effect of the one man is greatest when the effect of the other is least, and therefore the motion of the machine is more uniform, and will perform more work. Desaguliers also found, that a man may exert a force of 80 pounds with a fly when the motion is pretty quick, and that by means of a good common pump, he may raise a hogshead of water 10 feet high in a minute, and continue the exertion during a whole day.

Results of Coulomb's experiments.

421. A variety of interesting experiments upon the force of men were made by the learned M. Coulomb. He found that the quantity of action of a man who ascended stairs with nothing but his own weight, was double that of a man loaded with 223 pounds avoirdupois, both of them continuing the exertion for a day. In this case the total or *absolute effect* of the unloaded man is the greatest possible; but the *useful effect* which he produces is nothing. In the same way, if he were loaded to such a degree that he was almost incapable of moving, the useful effect would be nothing. Hence there is a certain load with which the man will produce the greatest useful effect. This load M. Coulomb found to be 173.8 pounds avoirdupois, upon the supposition that the man is to ascend stairs, and continue the exertion during a whole day. When thus loaded, the quantity of action exerted by the labourer is equivalent to 183.66 pounds avoirdupois raised through 3282 feet. This method of working is however attended with a loss of three-fourths of the total action of the workman.—It appears also from Coulomb's experiments, that a man going up stairs for a day raises 205 chiliogrammes (a chiliogramme is equal to three ounces five drams avoirdupois) to the height of a chiliometre (a chiliometre is equal to 39571 English inches); that a man carrying wood up stairs raises, together with his own weight, 109 chiliogrammes to one chiliometre;—that a man weighing 150 pounds French, can ascend by stairs three feet French in a second, for the space of 15 or 20 seconds; —that a man cultivating the ground performs $\frac{12}{20}$ as much labour as a man ascending stairs, and that his quantity of action is equal to 328 pounds avoirdupois raised through the space of 3282 feet;—that a man with a winch does $\frac{6}{8}$ as much as by ascending stairs;—and that in a pile-engine, a man by means of a rope drawn horizontally, raised for the space of five hours $55\frac{1}{7}$ pounds French through one foot French in a second.—When men walk on a horizontal road, Coulomb found that the quantity of action was a maximum when they were loaded, and that this maximum quantity of action is to that which is exerted by a man loaded with 190.25 pounds avoirdupois as 7 to 4.—The weight which a man ought to carry in order that the *useful effect* may be a maximum, is 165.3 pounds avoirdupois. When the workman, however, returns unloaded for a new burden, he must carry 200.7 pounds avoirdupois.

422. According to Dr Robison a feeble old man raised seven cubic feet of water$=437.5$ pounds avoirdupois, $11\frac{1}{2}$ feet high, in one minute, for eight or ten hours a day, by walking backwards and forwards on a lever;—and a young man weighing 135 pounds, and carrying 30 pounds, raised $9\frac{1}{4}$ cubic feet of water $=578.1$ pounds avoirdupois, $11\frac{1}{2}$ feet high, for 10 hours a day, without being fatigued.

423. From the experiments of Mr Buchanan, it appears that the forces exerted by a man pumping, acting at a winch, ringing and rowing, are as the numbers 1742, 2856, 3883, 4095.

On the strength of horses.

424. According to Desaguliers and Smeaton, the power of one horse is equal to the power of five men. Several French authors suppose a horse equal to seven men, while M. Schulze considers one horse as equivalent to 14 men.—Two horses, according to the experiment of Amontons, exerted a force of 150 pounds French, when yoked in a plough. According to Desaguliers, a horse is capable of drawing, with a force of 200 pounds, two miles and a half an hour, and of continuing this action eight hours in the day. When the force is 240 pounds he can work only six hours. It appears from Smeaton's reports, that by means of pumps a horse can raise 250 hogsheads of water, 10 feet high, in an hour.—The most disadvantageous way of employing the power of a horse is to make him carry a load up an inclined plane, for it was observed by De la Hire, that *three* men, with 100 pounds each, will go faster up the inclined plane than a horse with 300 pounds. When the horse walks on a good road, and is loaded with about two hundred weight, he may easily travel 25 miles in the space of seven or eight hours.

425. When a horse is employed in raising coals by means of a wheel and axle, and moves at the rate of about two miles an hour, Mr Fenwick found that he could continue at work 12 hours each day, two and a half of which were spent in short intervals of rest, when he raised a load of 1000 pounds avoirdupois, with a velocity of 13 feet per minute;—and that he will exert a force of 75 pounds for nine hours and a half, when moving with the same velocity. Mr Fenwick also found that 230 ale gallons of water delivered every minute on an overshot water-wheel, 10 feet in diameter; that a common steam-engine, with a cylinder eight inches in diameter, and an improved engine with a cylinder 6.12 inches in diameter, will do the work of one horse, that is, will raise a weight of 1000 pounds avoirdupois, through the height of 13 feet in a minute. It appears from Mr Smeaton's experiments, that Dutch sails in their common position with a radius of 9 feet and a half, —that Dutch sails in their best position with a radius of eight feet, and that his enlarged sails with a radius of seven feet, perform the same work as one man; or perform

Practical Mechanics.

form one-fifth part of the work of a horse. Upon these facts we have constructed the following table, the four first columns of which are taken from Mr Fenwick's Essays on Practical Mechanics.

Table shewing the relative strength of Overshot Wheels, Steam Engines, Horses, Men, and Wind-mills of different kinds.

Number of ale gallons delivered on an overshot wheel, 10 feet in diameter, every minute.	Diameter of the cylinder in the common steam-engine, in inches.	Diameter of the cylinder of the improved steam-engine, in inches.	Number of horses working 12 hours per day, and moving at the rate of two miles per hour.	Number of men working 12 hours a-day.	Radius of Dutch sails in their common position in feet.	Radius of Dutch sails in their best position, in feet.	Radius of Mr Smeaton's enlarged sails, in feet.	Height to which these different powers will raise 1000 pounds avoirdupois in a minute.

426. Dutch sails are always constructed so that the angle of weather may diminish from the centre to the extremity of the sail. They are concave to the wind, and are in their *common position* when their extremities are parallel to the plane in which they move, or perpendicular to the direction of the wind. Dutch sails are in their *best position* when their extremities make an angle of seven degrees with the plane of their motion. Mr Smeaton's enlarged sails are Dutch sails in their best position, but enlarged at their extremities.

427. It appears from M. Coulomb's experiments on Dutch wind-mills, with rectangular sails, that when the distance between the extremities of two opposite sails is 66 feet French, and the breadth of each sail six feet, a wind moving at the rate of 20 feet per second will produce an effect equivalent to 1000 pounds raised through the space of 218 feet in a minute.

According to Watt and Boulton, one of their steam engines, with a cylinder 31 inches in diameter, and which makes 17 double strokes per minute, is equivalent to 40 horses working day and night; that is, to 101 horses working nine hours and a half, the time of constant exertion in the preceding table. When the cylinder is 19 inches in diameter, and the engine makes 25 strokes of four feet each per minute, its power is equivalent to twelve horses working constantly, or thirty horses working nine hours and a half;—and when the cylinder is 24 inches in diameter, and the engine makes 22 strokes, of five feet each, in a minute, its power is equal to that of 20 horses working constantly, or 50 horses working nine hours and a half.

Chap. VII. *On the Construction of Wind-mills.*

428. A wind-mill is represented in fig. 1. where MN is the circular building that contains the machinery, E the extremity of the windshaft, or principal axis, which is generally inclined from 8 to 15 degrees to the horizon; and EA, EB, EC, ED four rectangular frames upon which sails of cloth of the same form are stretched. At the lower extremity G of the sails their surface is inclined to the axis 72°; and at their farthest extremities A, D, &c. the inclination of the sail is about 83°. Now, when the sails are adjusted to the wind, which happens when the wind blows in the direction of the windshaft E, the impulse of the wind upon

Plate CCCXXV. fig. 1.

Practical Mechanics.

upon the oblique sails may be resolved into two forces, one of which acts at right angles to the windshaft, and is therefore employed solely in giving a motion of rotation to the sails and the axis upon which they are fixed. When the mill is used for grinding corn, a crown wheel, fixed to the principal axis E, gives motion to a lantern or trundle, whose axis carries the moveable millstone.

Methods of turning the sails to the wind.

429. That the wind may act with the greatest efficacy upon the sails, the windshaft must have the same direction as the wind. But as this direction is perpetually changing, some apparatus is necessary for bringing the windshaft and sails into their proper position. This is sometimes effected by supporting the machinery on a strong vertical axis, whose pivot moves in a brass socket firmly fixed into the ground, so that the whole machine, by means of a lever, may be made to revolve upon this axis, and be properly adjusted to the direction of the wind. Most wind-mills, however, are furnished with a moveable roof which revolves upon friction rollers inserted in the fixed kerb of the mill; and the adjustment is effected by the assistance of a simple lever. As both these methods of adjustment reqnire the assistance of men, it would be very desireable that the same effect should be produced solely by the action of the wind. This may be done by fixing a large wooden vane or weather-cock at the extremity of a long horizontal arm which lies in the same vertical plane with the windshaft. By this means when the surface of the vane, and its distance from the centre of motion, are sufficiently great, a very gentle breeze will exert a sufficient force upon the vane to turn the machinery, and will always bring the sails and windshaft to their proper position. This weather-cock, it is evident, may be applied either to machines which have a moveable roof, or which revolve upon a vertical arbor.

On the Form and Position of Wind-mill Sails.

The inclination assigned by Parent, erroneous.

430. It appears from the investigations of Parent, that a maximum effect will be produced when the sails are inclined $54\frac{2}{7}$ degrees to the axis of rotation, or when the angle of weather is $35\frac{1}{7}$ (G) degrees. In obtaining this conclusion, however, M. Parent has assumed data which are inadmissible, and has neglected several circumstances which must materially affect the result of his investigations. The angle of inclination assigned by Parent is certainly the most efficacious for giving motion to the sails from a state of rest, and for preventing them from stopping when in motion; but he has not considered that the action of the wind upon a sail at rest is different from its action upon a sail in motion; for since the extremities of the sails move with greater rapidity than the parts nearer the centre, the angle of weather should be greater towards the centre than at the extremity, and should vary with the velocity of each part of the sail. The reason of this is very obvious. It has been demonstrated by Bossut, and established by experience, that when any fluid acts upon a plain surface, the force of impulsion is always exerted most advantageously when the impelled surface is in a state of rest, and that this force diminishes as the velocity of the surface increases. Now, let us suppose with Parent, that the most advantageous angle of weather for the sails of wind-mills is $35\frac{1}{7}$ degrees for that part of the sail which is nearest the centre of rotation, and that the sail has every where this angle of weather; then, since the extremity of the sail moves with the greatest velocity, it will in a manner withdraw itself from the action of the wind, or, to speak more properly, it will not receive the impulse of the wind so advantageously as those parts of the sail which have a less degree of velocity. In order therefore to counteract this diminution of force, we must make the wind act more perpendicularly upon the sail, by diminishing its obliquity or its angle of weather. But since the velocity of every part of the sail is proportional to its distance from the centre of motion, every elementary portion of it must have a different angle of weather diminishing from the centre to the extremity of the sail. The law or rate of diminution, however, is still to be discovered, and we are fortunately in possession of a theorem of Euler's, afterwards given by Maclaurin, which determines this law of variation. Let a represent the velocity of the wind, and c the velocity of any given part of the sail; then the effort of the wind upon that part of the sail will be greatest when the tangent of the angle of the wind's incidence, or of the sail's inclination to the axis, is to radius, as $\sqrt{2+\frac{9cc}{4aa}}+\frac{3c}{2a}$ to 1.

Euler's theorem.

Fig. 2. Explanation and application of this theorem.

431. In order to apply this theorem, let us suppose that the radius or whip ED of the sail $\alpha\beta\delta\gamma$, is divided into six equal parts; that the point n is equidistant from E and D, and is the point of the sail which has the same velocity as the wind; then, in the preceding theorem, we shall have $c=a$, when the sail is loaded to a maximum; and therefore the tangent of the angle, which the surface of the sail at n makes with the axis, when $a=1$, will be $\sqrt{2+\frac{9}{4}}+\frac{3}{2}=3.561=$ tangent of 74° 19′, which gives 15° 41′ for the angle of weather at the point n. Since, at $\frac{3}{6}$ of the radius $c=a$, and since c is proportional to the distance of the corresponding part of the sail from the centre, we will have, at $\frac{1}{6}$ of the radius $s\,m$, $c=\frac{a}{3}$, at $\frac{2}{6}$ of the radius, $c=\frac{2a}{3}$; at $\frac{4}{6}$, $c=\frac{4a}{3}$, at $\frac{5}{6}$, $c=\frac{5a}{3}$; and at the extremity of the radius, $c=2a$. By substituting these different values of c, instead of c in the theorem, and by making $a=1$, the following table will be obtained, which exhibits the angles of inclination and weather which must be given to different parts of the sails.

Parts

(G) The *weather* of the sails is the angle which the surface forms with the plane in which they move, and is equal to the complement of the angle which that surface forms with the axis.

Results of Smeaton's experiments.

432. Mr Smeaton found, from a variety of experiments, that the common practice of inclining plane sails from 72° to 75° to the axis, was much more efficacious than the angle assigned by Parent, the effect being as 45 to 31. When the sails were weathered in the Dutch manner, that is, when their surfaces were concave to the wind, and when the angle of inclination increased towards their extremities, they produced a greater effect than when they were weathered either in the common way, or according to Euler's theorem. But when the sails were enlarged at their extremities, as represented at $\alpha\beta$, in fig. 2. so that $\alpha\beta$ was one-third of the radius ED, and α D to D β as 5 to 3, their power was greatest of all, though the surface acted upon by the wind remained the same. If the sails be farther enlarged, the effect is not increased in proportion to the surface; and besides, when the quantity of cloth is great, the machine is much exposed to injury by sudden squalls of wind. In Mr Smeaton's experiments, the angle of weather varied with the distance from the axis; and it appeared from several trials, that the most efficacious angles were those in the following table.

Parts of the radius EA, which is divided into 6 parts	Angle with the axis.	Angle of weather.

If the radius ED of the sail be 30 feet, then the sail will commence at $\frac{1}{6}$ ED, or 5 feet from the axis, where the angle of inclination will be 72°. At $\frac{2}{6}$ ED, or 10 feet from the axis, the angle will be 71°, and so on.

On the Effect of Wind-mill Sails.

433. The following maxims deduced by Mr Smeaton from his experiments, contain the most accurate information upon this subject.

Effects of wind-mill sails, according to Smeaton.

Maxim 1. The velocity of wind-mill sails, whether unloaded or loaded, so as to produce a maximum effect is nearly as the velocity of the wind, their shape and position being the same.

Maxim 2. The load at the maximum is nearly, but somewhat less than, as the square of the velocity of the wind, the shape and position of the sails being the same.

Maxim 3. The effects of the same sails at a maximum, are nearly, but somewhat less than, as the cubes of the velocity of the wind.

Maxim 4. The load of the same sails at the maximum is nearly as the squares, and their effects as the cubes of their number of turns in a given time.

Maxim 5. When sails are loaded, so as to produce a maximum at a given velocity, and the velocity of the wind increases, the load continuing the same: 1st, The increase of effect, when the increase of the velocity of the wind is small, will be nearly as the squares of those velocities: 2dly, When the velocity of the wind is double, the effects will be nearly as 10 : $27\frac{1}{2}$: But, 3dly, When the velocities compared are more than double of that where the given load produces a maximum, the effects increase nearly in the simple ratio of the velocity of the wind.

Maxim 6. In sails where the figure and positions are similar, and the velocity of the wind the same, the number of turns in a given time will be reciprocally as the radius or length of the sail.

Maxim 7. The load at a maximum that sails of a similar figure and position will overcome at a given distance from the centre of motion, will be as the cube of the radius.

Maxim 8. The effects of sails of similar figure and position are as the square of the radius.

Maxim 9. The velocity of the extremities of Dutch sails, as well as of the enlarged sails, in all their usual positions when unloaded, or even loaded to a maximum, are considerably quicker than the velocity of the wind.

434. A new mode of constructing the sails of wind-mills has been recently given by Mr Sutton, and fully described by Mr Hesleden of Barton, in a work exclusively devoted to the subject.

The limits of this article will not permit us to enter into any discussion respecting the principles upon which Mr Sutton's gravitated sails are constructed; but the subject shall be resumed under the article WINDMILL. It may be proper however to remark that Mr Sutton gives his sails the form represented in fig. 4. and makes the angle of weather at the point M, equidistant from A and B, equal to 22° 30′. The inclination of the sail at any other point N of the sail, is an angle whose sine is the distance of that point from the centre of motion A, the radius being the breadth of the sail at that point. Fig. 3. shews the angles at the different points of the sail; and the apparent and absolute breadth of the sail at these points. Mr Sutton's mode of regulating the velocity of the sails, and of bringing them to a state of rest is particularly ingenious. Fig. 3.

Practical Mechanics.

On Horizontal Wind-mills.

Horizontal wind-mills.

435. Various opinions have been entertained respecting the relative advantages of horizontal and vertical wind-mills. Mr Smeaton, with great justice, gives a decided preference to the latter; but when he asserts that horizontal wind-mills have only $\frac{1}{8}$ or $\frac{1}{10}$ of the power of vertical ones, he certainly forms too low an estimate of their power. Mr Beatson, on the contrary, who has received a patent for the construction of a new horizontal wind-mill, seems to be prejudiced in their favour, and greatly exaggerates their comparative value. From an impartial investigation, it will probably appear, that the truth lies between these two opposite opinions; but before entering on this discussion, we must first consider the nature and form of horizontal winds-mills.

Fig. 4.

436. In fig. 4. CK is the windshaft, which moves upon pivots. Four cross bars, CA, CD, IB, FG, are fixed to this arbor, which carry the frames APIB, DEFG. The sails AI, EG, are stretched upon these frames, and are carried round the axis CK, by the perpendicular impulse of the wind. Upon the axis CK, a toothed wheel is fixed, which gives motion to the particular machinery that is employed. In the figure, only two sails are represented; but there are always other two placed at right angles to these. Now, let the sails be exposed to the wind, and it will be evident that no motion will ensue; for the force of the wind upon the sail AI, is counteracted by an equal and opposite force upon the sail EG. In order then, that the wind may communicate motion to the machine, the force upon the returning sail EG must either be removed by screening it from the wind, or diminished by making it present a less surface when returning against the wind. The first of these methods is adopted in Tartary, and in some provinces of Spain; but is objected to by Mr Beatson, from the inconvenience and expence of the machinery and attendance requisite for turning the screens into their proper positions. Notwithtsanding this objection, however, I am disposed to think that this is the best method of diminishing the action of the wind upon the returning sails, for the moveable screen may easily be made to follow the direction of the wind, and assume its proper position, by means of a large wooden weathercock, without the aid either of men or machinery. It is true, indeed, that the resistance of the air in the returning sails is not completely removed; but it is at least as much diminished as it can be by any method hitherto proposed. Besides, when this plan is resorted to, there is no occasion for any moveable flaps and hinges, which must add greatly to the expence of every other method.

Common method of bringing back the sails against the wind.

Beatson's method.

437. The mode of bringing the sails back against the wind, which Mr Beatson invented, is perhaps, the simplest and best of the kind. He makes each sail AI to consist of six or eight flaps or vanes, AP *b* 1, *b* 1 *c* 2, &c. moving upon hinges represented by the dark lines, AP, *b* 1, *c* 2, &c. so that the lower side *b* 1, of the first flap overlaps the hinge or higher side of the second flap, and so on. When the wind, therefore, acts upon the sail AI, each flap will press upon the hinge of the one immediately below it, and the whole surface of the sail will be exposed to its action. But when the sail AI returns against the wind, the flaps will revolve round upon their hinges, and present only their edges to the wind, as is represented at EG, so that the resistance occasioned by the return of the sail must be greatly diminished, and the motion will be continued by the great superiority of force exerted upon the sails in the position AI. In computing the force of the wind upon the sail AI, and the resistance opposed to it by the edges of the flaps in EG, Mr Beatson finds, that when the pressure upon the former is 1872 pounds, the resistance opposed by the latter is only about 36 pounds, or $\frac{1}{52}$ part of the whole force; but he neglects the action of the wind upon the arms CA, &c. and the frames which carry the sails, because they expose the same surface in the position AI, as in the position EG. This omission, however, has a tendency to mislead us in the present case, as we shall now see, for we ought to compare the whole force exerted upon the arms, as well as the sail, with the whole resistance which these arms and the edges of the flaps oppose to the motion of the windmill. By inspecting fig. 4. it will appear, that if the force upon the edges of the flaps, which Mr Beatson supposed to be 12 in number, amounts to 36 pounds, the force spent upon the bars CD, DG, GF, FE, &c. cannot be less than 60 pounds. Now, since these bars are acted upon with an equal force, when the sails have the position AI, $1872+60=1932$ will be the force exerted upon the sail AI, and its appendages, while the opposite force upon the bars and edges of the flaps when returning against the wind will be $36+60=96$ pounds, which is nearly $\frac{1}{20}$ of 1932, instead of $\frac{1}{52}$ as computed by Mr Beatson. Hence we may see the probable advantages of a screen over moveable flaps, as it will preserve not only the sails, but the arms and the frame which support it, from the action of the wind.

Comparisons between vertical and horizontal wind mills.

438. We shall now conclude this chapter with a comparison of the power of horizontal and vertical wind-mills. It was already stated, that Mr Smeaton rather underrated the former, while he maintained that they have only $\frac{1}{8}$ or $\frac{1}{10}$ the power of the latter. He observes, that when the vanes of a horizontal and a vertical mill are of the same dimensions, the power of the latter is four times that of the former, because, in the first case, only one sail is acted upon at once, while, in the second case, all the four receive the impulse of the wind. This, however, is not strictly true, since the vertical sails are all oblique to the direction of the wind. Let us suppose that the area of each sail is 100 square feet; then the power of the horizontal sail will be 100, and the power of a vertical sail may be called $100 \times \overline{\text{sine } 70^{\circ}}^{2}$ (70° being the common angle of inclination) $=88$ nearly; but since there are four vertical sails, the power of them all will be $4 \times 88=352$; so that the power of the horizontal sail is to that of the four vertical ones as 1 to 3.52, and not as 1 to 4, according to Mr Smeaton. But Mr Smeaton also observes, that if we consider the farther disadvantage which arises from the difficulty of getting the sails back against the wind, we need not wonder if horizontal wind-mills have only about $\frac{1}{8}$ or $\frac{1}{10}$ the power of the common sort. We have already seen, that the resistance occasioned by the return of the sails amounts to $\frac{1}{20}$ of the whole force which they receive; by subtracting $\frac{1}{20}$, therefore, from $\frac{1}{3.52}$, we shall find that the

ractical Mechanics. the power of horizontal wind-mills is only $\frac{1.03}{4.40}$, or little more than $\frac{1}{4}$ that of vertical ones. This calculation proceeds upon a supposition, that the whole force exerted upon vertical sails is employed in turning them round the axis of motion; whereas a considerable part of this force is lost in pressing the pivot of the axis or windshaft against its gudgeon. Mr Smeaton has overlooked this circumstance, otherwise he could never have maintained that the power of four vertical sails was quadruple the power of one horizontal sail, the dimensions of each being the same. Taking this circumstance into the account, we cannot be far wrong in saying, that in theory at least, if not in practice, the power of a horizontal wind-mill is about $\frac{1}{8}$ or $\frac{1}{4}$ of the power of a vertical one, when the quantity of surface and the form of the sails is the same, and when every part of the horizontal sails has the same distance from the axis of motion as the corresponding parts of the vertical sails. But if the horizontal sails have the position AI, EG, in fig. 4. instead of the position CA $d\,m$, CD $o\,n$, their power will be greatly increased, though the quantity of surface is the same, because the part CP $3\,m$ being transferred to BI $3\,d$, has much more power to turn the sails.

Chap. VIII. *On the Construction of Wheel Carriages.*

the size carriage eels. Plate CCXXV. Fig. 6. 439. It is evident from Art. 60. that when a wheel surmounts an obstacle, it acts as a lever of the first kind, and that its power to overcome such resistances increases with its diameter. The power of the force P, for example, to raise the wheel NB over the eminence C, is proportional to the vertical lever FC, which increases with the diameter of the wheel, while the lever of resistance FA, by which the weight of the wheel acts, remains unchanged; hence we see the advantages of large wheels for overcoming such obstacles as generally resist the motion of wheel carriages. There are some circumstances, however, which, independent of the additional weight and expence of large wheels, prescribe limits to their size. If the radius AC of the wheel exceeds the height of that part of the horse to which the traces are attached, the line of traction DA will be oblique to the horizon, and part of the power P will be employed in pressing the wheel upon the ground. A wheel exceeding four and a half feet radius, which is the general distance from the ground of that part of the horse to which the traces are attached, has still the advantage of a smaller wheel; but when we consider that the traces or poles of the cart will, in this case, rub against the flanks of the horses, so that the power of the wheel is diminished by the increase of its weight, we shall be convinced that no power is gained by making the radius of the wheels greater than four and a half feet. Even this size is too great, as shall be afterwards shown, when we treat of the line of traction, so that we may safely assert, that the diameter of wheels should never be greater than six feet. The fore wheels of our carriages are still unaccountably small, and it is not uncommon to see carts moving upon wheels scarcely 14 inches in diameter. The convenience of turning is urged as the reason for diminishing the fore wheels of carriages, and the facility of loading the cart is considered as a sufficient reason for using wheels so small as 14 inches. The first of these advantages, however, may be obtained by going to the end of a street, or to a proper place for turning the carriage; and a few additional turns of a windlass will be sufficient to convey the heaviest loads into carts mounted on high wheels.

440. The next thing to be determined is the shape of the wheels. Now it is certainly a matter of surprise how the unnatural shape which is at present given to them could ever have been brought into use. A cylindrical wheel, with the spokes perpendicular to the naves, is undoubtedly the form which every mechanic would give to his wheels, before he had heard of the pretended advantages of concave or dishing wheels, or those which have inclined spokes and conical rims. It has been alleged, indeed, that the form represented in fig. 5. when A r, B s is the conical rim, and o A, p B the inclined spokes, renders the wheel stronger than it would otherwise be; that by extending the base of the carriage it prevents it from being overturned; that it hinders the fellies from rubbing against the load or the sides of the cart; and that when one wheel falls into a rut, and therefore supports more than one half of the load, the spokes are brought into a vertical position, which renders them more capable of sustaining the additional weight. Now it is evident that the second of these advantages is very trifling, and may be obtained, when required, by interposing a piece of board between the wheel and the load. Plate CCCXXV. Fig. 5.

441. The other two advantages exist only in very bad roads; and if they are necessary, which we much question, in a country like this, where the roads are so excellently made, and so regularly repaired, they can easily be procured, by making the axle-tree a few inches longer, and increasing the strength of the spokes. But it is allowed on all hands that perpendicular spokes are preferable on level ground. The inclination of the spokes, therefore, which renders concave wheels advantageous in rugged and unequal roads, renders them disadvantageous when the roads are in good order; and where the good roads are more numerous than the bad ones, as they certainly are in this country, the disadvantages of concave wheels must overbalance their advantages. It is true indeed that in concave wheels, the spokes are in their strongest position, when they are exposed to the severest strains, that is, when one wheel is in a deep rut, and sustains more than one half of the load: but it is equally true that on level ground, where the spokes are in their weakest position, a less severe strain, by continuing for a much longer time, may be equally if not more detrimental to the wheel.

Upon these observations we might rest the opinion which we have been maintaining, and appeal for its truth to the judgment of every intelligent and unbiassed mind; but we shall go a step farther, and endeavour to show that concave dishing wheels are more expensive, more injurious to the roads, more liable to be broken by accidents, and less durable in general, than those wheels in which the spokes are perpendicular to the naves. By inspecting fig. 5. it will appear that the whole of the pressure which the wheel AB sustains is exerted along the inclined spoke $p\,s$, and therefore acts obliquely upon the level ground n D, whether the rims are conical or cylindrical. This oblique action must necessarily

necessarily injure the roads, by loosening the stones more between B and D than between B and n, and if the load were sufficiently great, the stones would start up between s and D. The texture of the roads, indeed, is sufficiently firm to prevent this from taking place; but in consequence of the oblique pressure, the stones between s and D will at least be loosened, and by admitting the rain the whole of the road will be materially damaged. But when the spokes are perpendicular to the nave as pn, and when the rims mA, nB are cylindrical, or parallel to the ground, the weight sustained by the wheel will act perpendicularly upon the road; and however much that weight is increased, its action can have no tendency to derange the materials of which it is composed, but is rather calculated to consolidate them, and render the road more firm and durable.

442. It was observed that concave wheels are more expensive than plane ones. This additional expence arises from the greater quantity of wood and workmanship which the former require; for in order that dishing wheels may be of the same perpendicular height as plane ones, the spokes of the former must exceed in length those of the latter, as much as the hypothenuse oA of the triangle oAn exceeds the side om; and therefore the weight and the resistance of such wheels must be proportionably great. The inclined spokes, too, cannot be formed nor inserted with such facility as perpendicular ones. The extremity of the spoke which is fixed into the nave is inserted at right angles to it, in the direction $o\ p$, and if the rims are cylindrical, the other spoke should be inserted in a similar manner; while the intermediate portion has an inclined position. There are therefore two flexures or bendings in the spokes of concave wheels, which requires them to be formed out of a larger piece of wood than if they had no such flexures, and renders them liable to be broken by any sudden strain at the points of flexure.

443. We shall now dismiss the subject of concave wheels with one observation more, and we beg the reader's attention to it, because it appears to be decisive of the question. The obstacles which carriages have to encounter, are almost never spherical protuberances that permit the elevated wheel to resume by degrees its horizontal position. They are generally of such a nature, that the wheel is instantaneously precipitated from their top to the level ground. Now the momentum with which the wheel strikes the ground is very great, arising from a successive accumulation of force. The velocity of the elevated wheel is considerable when it reaches the top of the eminence, and while it is tumbling into the level ground, it is receiving gradually that proportion of the load which was transferred to the other wheel, till having recovered the whole, it impinges against the ground with great velocity and force. But in concave wheels the spoke which then strikes the ground is in its weakest position, and therefore much more liable to be broken by the impetus of the fall, than the spokes of the lowest wheel by the mere transference of additional weight. Whereas, if the spokes be perpendicular to the nave, they receive this sudden shock in their strongest position, and are in no danger of giving way to the strain.

444. In the preceding observations we have supposed the rims of the wheels to be cylindrical. In concave wheels, however, the rims are uniformly made of a conical form, as A r, B s, fig. 5. which not only increases the disadvantages which we have ascribed to them, but adds many more to the number. Mr Cumming, in a late Treatise on Wheel Carriages, solely devoted to the consideration of this single point, has shewn with great ability the disadvantages of conical rims, and the propriety of making them cylindrical; but we are of opinion that he has ascribed to conical rims several disadvantages which arise chiefly from an inclination of the spokes. He insists much upon the injury done to the roads by the use of conical rims; yet though we are convinced that they are more injurious to pavements and highways than cylindrical rims, we are equally convinced, that this injury is occasioned chiefly by the oblique pressure of the inclined spokes. The defects of conical rims are so numerous and palpable, that it is wonderful they should have been so long overlooked. Every cone that is put in motion upon a plane surface will revolve round its vertex, and if force is employed to confine it to a straight line, the smaller parts of the cone will be dragged along the ground and the friction greatly increased. Now when a carriage moves upon conical wheels, one part of the cone rolls while the other is dragged along, and though confined to a rectilineal direction by external force, their natural tendency to revolve round their vertex occasions a great and continued friction upon the linch pin, the shoulder of the axle-tree, and the sides of deep ruts.

445. The shape of the wheels being thus determined, we must now attend to some particular parts of their construction. The iron plates of which the rims are composed should never be less than three inches in breadth, as narrow rims sink deep into the ground, and therefore injure the roads and fatigue the horses. Mr Walker, indeed, attempts to threw ridicule upon the act of parliament which enjoined the use of broad wheels; but he does not assign any sufficient reason for his opinion, and ought to have known that several excellent and well devised experiments were lately instituted by Boulard and Margueron, which evince in the most satisfactory manner, the great utility of broad wheels. Upon this subject an observation occurs to us, which has not been generally attended to, and which appears to remove all the objections which can be urged against broad rims. When any load is supported upon two points, each point supports one half of the weight; if the points are increased to four, each will sustain one-fourth of the load, and so on; the pressure upon each point of support diminishing as the number of points increases. If a weight therefore is supported by a broad surface, the points of support are infinite in number, and each of them will bear an infinitely small portion of the load; and, in the same way, every finite portion of this surface will sustain a part of the weight inversely proportional to the number of similar portions which the surface contains. Let us now suppose that a cart carrying a load of sixteen hundred weight is supported upon wheels whose rims are four inches in breadth, and that one of the wheels passes over four stones, each of them an inch broad and equally high, and capable of being pulverized only by a pressure of four hundred pounds weight. Then as each wheel sustains one half of the load, and as the wheel which passes

over

over the stones has four points of support, each stone will bear a weight of two hundred weight, and therefore will not be broken. But if the same cart, with rims only two inches in breadth, should pass the same way, it will cover only two of the stones; and the wheel having now only two points of support, each stone will be pressed with a weight of four hundred weight, and will therefore be reduced to powder. Hence we may infer that narrow wheels are in another point of view injurious to the roads, by pulverizing the materials of which they are composed.

446. As the rims of wheels wear soonest at their edges they should be made thinner in the middle, and ought to be fastened to the fellies with nails of such a kind that their heads may not rise above the surface of the rims. In some military waggons we have seen the heads of these nails rising an inch above the rims, which not only destroys the pavement of streets, but opposes a continual resistance to the motion of the wheel. If these nails were eight in number, the wheel would experience the same resistance, as if it had to surmount eight obstacles, one inch high, during every revolution. The fellies on which the rims are fixed should in carriages be three inches and a fourth deep, and in waggons four inches. The naves should be thickest at the place where the spokes are inserted; and the holes in which the spokes are placed should not be bored quite through, as the grease upon the axle-tree would insinuate itself between the spoke and the naves, and prevent that close adhesion which is necessary to the strength of the wheel.

On the Position of the Wheels.

447. It must naturally occur to every person reflecting upon this subject, that the axle-trees should be straight and the wheels perfectly parallel, so that they may not be wider at their highest than at their lowest point, whether they are of a conical or a cylindrical form. In this country, however, the wheels are always made concave, and the ends of the axle-trees are universally bent downwards, in order to make them spread at the top and approach nearer below. In some carriages which we have examined, where the wheels were only four feet six inches in diameter, the distance of the wheels at top was fully six feet, and their distance below only four feet eight inches. By this foolish practice the very advantages which may be derived from the concavity of the wheels are completely taken away, while many of the disadvantages remain; more room is taken up in the coach-house, and the carriage is more liable to be overturned by the contraction of its base.

448. With some mechanics it is a practice to bend the ends of the axle-trees forwards, and thus make the wheels wider behind than before. This blunder has been strenuously defended by Mr Henry Beighton, who maintains that wheels in this position are more favourable for turning, since, when the wheels are parallel, the outermost when turning would press against the linch pin, and the innermost would rest against the shoulder of the axle-tree. In rectilineal motions, however, these converging wheels engender a great deal of friction both on the axle and the ground, and must therefore be more disadvantageous than parallel ones.

On the Line of Traction, and the Method by which Horses exert their strength.

449. M. Camus attempted to shew that the line of traction should always be parallel to the ground on which the carriage is moving, both because the horse can exert his greatest strength in this direction, and because the line of draught being perpendicular to the vertical spoke of the wheel, acts with the largest possible lever. M. Couplet, however, considering that the roads are never perfectly level, and that the wheels are constantly surmounting small eminences even in the best of roads, recommends the line of traction to be oblique to the horizon. By this means the line of draught HA, (which is by far too much inclined in the figure) will in general be perpendicular to the lever AC which mounts the eminence, and will therefore act with the longest lever when there is the greatest necessity for it. We ought to consider also, that when a horse pulls hard against any load, he always brings his breast nearer the ground, and therefore it follows, that if a horizontal line of traction be preferable to all others, the direction of the traces should be inclined to the horizon when the horse is at rest, in order that it may be horizontal when he lowers his breast and exerts his utmost force. The particular manner, however, in which living agents exert their strength against great loads, seems to have been unknown both to Camus and Couplet, and to many succeeding writers upon this subject. It is to M. Deparcieux, an excellent philosopher and ingenious mechanic, that we are indebted for the only accurate information with which we are furnished; and we are sorry to see that philosophers who flourished after him have overlooked his important instructions. In his memoir on the draught of horses he has shewn in the most satisfactory manner, that animals draw by their weight, and not by the force of their muscles. In four-footed animals, the hinder feet is the fulcrum of the lever by which their weight acts against the load, and when the animal pulls hard, it depresses its chest and thus increases the lever of its weight, and diminishes the lever by which the load resists its efforts. Thus, in fig. 6. let P be the load, AD the line of traction, and let us suppose FC to be the hinder leg of the horse, and AE part of its body, A its chest or centre of gravity, and CE the level road. Then AFC will represent the crooked lever by which the horse acts, which is equivalent to the straight one AC. But when the horse's weight acts downwards at A, so as to drag forward the rope AD and raise the load P, CE will represent the power of the lever in this position, or the lever of the horse's weight, and CF the lever by which it is resisted by the load, or the lever of resistance. Now if the horse lowers its centre of gravity A, which it always does when it pulls hard, it is evident that CE, the lever of its weight, will be increased, while CF the lever of its resistance will be diminished, for the line of traction AD will approach nearer to CE. Hence we see the great benefit which may be derived from large horses; for the lever AC necessarily increases with their size, and their power is always proportioned to the length of this lever, their weight remaining the same. Large horses, therefore, and other animals, will draw more than small ones, even though they have less muscular force,

Fig. 6.

force, and are unable to carry such a heavy burden. The force of the muscles tends only to make the horse carry continually forward his centre of gravity, or, in other words, the weight of the animal produces the draught, and the play and force of its muscles serve to continue it.

450. From these remarks, then, we may deduce the proper position of the line of traction. When the line of traction is horizontal, as AD, the lever of resistance is CF; but if this line is oblique to the horizon, as A d, the lever of resistance is diminished to C f, while the lever of the horse's weight always remains the same. Hence it appears, that inclined traces are much more advantageous than horizontal ones, as they uniformly diminish the resistance to be overcome. Deparcieux, however, has investigated experimentally the most favourable angle of inclination, and found, that when the angle DAF made by the trace A d and a horizontal line is fourteen or fifteen degrees, the horses pulled with the greatest facility and force. This value of the angle of draught will require the weight of the spring-tree bar, to which the traces are attached in four-wheeled carriages, to be *one-half* of the height of that part of the horse's breast to which the fore end of the trace is connected.

Fig. 7. 451. When several horses are yoked in the same carriage as represented in fig. 7. and when the declivity changes, the length of the traces has a considerable influence upon the draught. From the point E where the traces are fastened to the horse next the load, draw ER to the same point in the second horse R, and let R′ be another position of the second horse, it is required to find the difference of effect that will be produced by placing the second horse at R or at R′, or the comparative advantages of short and long traces. From R′, the point where the traces are fixed, draw R′F′E; and from E draw E m n parallel to the declivity DA. Take EF=EF′ to represent the power of the horse in the direction of the traces, which will be the same whether he is yoked at R or at R′; draw EA perpendicular to DA, F n, F′ m parallel to EA, and F φ, F′ f parallel to E n. Then since the second horse when at R pulls with a force represented by FE, in the direction FE, we may resolve this force into the two forces, E n, E φ, one of which E n is solely employed in dragging the cart up the inclined plane DA, while the other E φ is solely employed in pressing the first horse E to the ground. Let the horse be now removed from R to R′, the direction of the traces becomes RF′E, and F′E=FE is the power exerted by the horse at R′ and the direction in which it is exerted. But this force is equivalent to the forces E m, E f, the first of which acts directly against the load, while the other presses the horse against the ground. Hence we see the disadvantages of long traces, for the force which draws the load when the horse is at R′ is to the force when the horse is at R, as E m to E n, and the forces which press the horse upon the ground as E f to E φ, or as F′ m to F n. Now $\mathrm{E}\varphi = \mathrm{F}n = \mathrm{FE} \times \sin.\, n\mathrm{EF}$; hence $\mathrm{F}\varphi = \mathrm{FE} \times \sin.\, (\overline{n\mathrm{E}g' - \mathrm{FE}g'})$ (g' E being parallel to AB′) and $\mathrm{E}n = \mathrm{EF} \times \cos.\, (n\mathrm{E}g' - \mathrm{FE}g')$. In like manner we have $\mathrm{E}f = \mathrm{FE} \times \sin.\, (n\mathrm{E}g' - \mathrm{F'E}g')$, and $\mathrm{E}m = \mathrm{EF} \times \cos.\, (n\mathrm{E}g' - \mathrm{F'E}g')$. Now $\sin.\, \mathrm{FE}g' = \sin.\, \mathrm{FE}g = \frac{\mathrm{R}g}{\mathrm{ER}}$, and $\sin.\, \mathrm{FE}g' = \frac{\mathrm{R'}g'}{\mathrm{ER'}} = \frac{\mathrm{R}g}{\mathrm{ER'}}$; but $\mathrm{R}g = \mathrm{R'}g' = \mathrm{BR} - \mathrm{EQ} = \mathrm{BR} - \mathrm{BR} \times \cos.\, n\mathrm{E}g' = \mathrm{BR} \times (1 - \cos.\, n\mathrm{E}g)$. By substituting this value in the equations which contain the values of E φ, E n, E f, E m, and considering that the angles FE g', F′E g' are always so small that their arcs differ very little from their sines, we have $\mathrm{FE}g = \frac{\mathrm{BR} \times \overline{1 - \cos.\, n\mathrm{E}g}}{\mathrm{ER}}$, and

$$\mathrm{F'E}g' = \frac{\mathrm{BR} \times \overline{1 - \cos.\, n\mathrm{E}g}}{\mathrm{ER'}}.$$

By substituting these values in the preceding equations, we have

$$\mathrm{E}\varphi = \mathrm{EF} \times \sin.\, (n\mathrm{E}g - \frac{\mathrm{BR} \times \overline{1 - \cos.\, n\mathrm{E}g}}{\mathrm{ER}},$$

$$\mathrm{E}fn = \mathrm{EF} \times \sin.\, (n\mathrm{E}g - \frac{\mathrm{BR} \times \overline{1 - \cos.\, n\mathrm{E}g}}{\mathrm{ER'}},$$

$$\mathrm{E}n = \mathrm{EF} \times \cos.\, (n\mathrm{E}g - \frac{\mathrm{BR} \times \overline{1 - \cos.\, n\mathrm{E}g}}{\mathrm{ER}},$$

$$\mathrm{E}m = \mathrm{EF} \times \cos.\, (n\mathrm{E}g - \frac{\mathrm{BR} \times \overline{1 - \cos.\, n\mathrm{E}g}}{\mathrm{ER'}}.$$

If AB is horizontal, and the declivity $\mathrm{AD} = \frac{1}{6}$, we shall have $n\mathrm{E}g = 9^\circ\ 28'$, or in parts of the radius=0.16522, and $\cos.\, n\mathrm{E}g = 0.98638$. Then, if EF=200 pounds, BR=$3\frac{1}{2}$ feet, ER=8 feet, ER′=12 feet, then we shall have from the preceding formulæ, E φ=31.716 pounds, E f=32.350 pounds, E n=197.470 pounds, and E m=197.404. Hence an additional length of four feet to traces eight feet long, presses the horse E to the ground with an additional force of 32.250—31.716 =0.534 pounds, and diminishes the effect of the other horse by 0.066 pounds.

On the Position of the Centre of Gravity, and the manner of disposing the load.

452. If the axle-tree of a two-wheeled carriage pass through the centre of gravity of the load, the carriage will be in equilibrio in every position in which it can be placed with respect to the axle-tree; and in going up and down hill the whole load will be sustained by the wheels, and will have no tendency either to press the horse to the ground or to raise him from it. But if the centre of gravity is above the axle-tree, as it must necessarily be, according to the present construction of wheel-carriages, a great part of the load will be thrown on the back of the horses from the wheels when going down a steep road, and thus tend to accelerate the motion of the carriage which the animal is striving to prevent; while, in ascending steep roads, a part of the load will be thrown behind the wheels, and tend to raise the horse from the ground, when there is the greatest necessity for some weight on his back to enable him to fix his feet in the earth, and overcome the great resistance which is occasioned by the steepness of the road. On the contrary, if the centre of gravity is below the axle, the horse will be pressed to the ground in going up hill, and lifted from it when going down. In all these cases, therefore, where the centre of gravity is either on the axle-tree or directly above it or below, the

Practical Mechanics.

the horse will bear no part of the load in level ground. In some situations the animal will be lifted from the ground when there is the greatest necessity for his being pressed to it, and he will sometimes bear a great proportion of the load when he should rather be relieved of it.

453. The only way of remedying these evils, is to assign such a position to the centre of gravity, that the horse may bear some portion of the weight when he must exert great force against the load, that is, in level ground, and when he is ascending steep roads; for no animal can pull with its greatest effort unless it is pressed to the ground.—Now this may be in some measure effected in the following manner. Let BCN be the wheel of a cart, AD one of the shafts, D that part of it where the cart is suspended on the back of the horse, and A the axle-tree; then, if the centre of gravity of the load is placed at m, a point equidistant from the two wheels, but below the line DA, and before the axletree,—the horse will bear a certain weight on level ground,—a greater weight when he is going up hill and has more occasion for it, and less weight when he is going down hill, and does not require to be pressed to the ground: All this will be evident from the figure.—When we recollect that the shaft DA is horizontal, the centre of gravity will press more upon the point of suspension D the nearer it comes to it; or the pressure upon D, or the horse's back, will be proportional to the distance of the centre of gravity from A. If m, therefore, be the centre of gravity, b A will represent its pressure upon D, when the shaft DA is horizontal. When the cart is ascending a steep road, AH will be the position of the shaft, the centre of gravity will be raised to a, and a A will be the pressure upon D. But if the cart is going down hill, AC will be the position of the shaft, the centre of gravity will be depressed to n, and c A will represent the pressure upon the horse's back. The weight sustained by the horse, therefore, is properly regulated by placing the centre of gravity at m. We have still, however, to determine the proper length of $b\,a$ and $b\,m$, the distance of the centre of gravity from the axle, and from the horizontal line DA; but as these depend upon the nature and inclination of the roads, upon the length of the shaft DA, which depends on the size of the horse, on the magnitude of the load, and on other variable circumstances, it would be impossible to fix their value.—If the load, along with the cart, weighs 400 pounds; if the distance DA be eight feet, and if the horse should bear 50 pounds of the weight, then b A should be one foot, which, being one-eighth of DA, will make the pressure upon D exactly 50 pounds. If the road slopes four inches in a foot, $b\,m$ must be four inches, or the angle $b\,\mathrm{A}\,m$ should be equal to the inclination of the road; for then the point m will rise to a when ascending such a road, and will press with its greatest force on the back of the horse.

Plate CCCXXV. Fig. 5.

454. When carts are not made in this manner, we may, in some degree obtain the same end by judiciously disposing the load. Let us suppose that the centre of gravity is at O when the cart is loaded with homogeneous materials, such as sand, lime, &c. then if the load is to consist of heterogeneous substances, or bodies of different weights, we should place the heaviest at the bottom and nearest the front, which will not only lower the point o, but will bring it forward, and nearer the proper position m. Part of the load, too, might be suspended below the fore part of the carriage in dry weather, and the centre of gravity would approach still nearer the point m. When the point m is thus depressed, the weight on the horse is not only judiciously regulated, but the cart would be prevented from overturning; and in rugged roads the weight sustained by each wheel would be in a great degree equalised.

Description of different Carriages.

Carriages that move without horses. Fig. 8.

455. In figure 8. is represented a carriage invented by Mr Richard, a physician in Rochelle, which moves without horses, merely by the exertion of the passengers. The machinery by which this is effected is placed in a box behind the carriage, and is shewn in figure 9. where AA is a small axis fixed into the box, and B a pulley over which a rope passes whose two extremities are tied to the ends of the levers or treddles C, D: the other ends of the levers are fixed by joints to the cross beam MF. The cranks FF are fixed to the axle KL, and move upon it as a centre. Each of them has a detent tooth at F which catches in the teeth of the wheels H, H, so that they can move from F to H without moving the wheel, but the detent tooth catches in the teeth of the wheels when the cranks are brought backward, and therefore bring the wheel along with them. When the foot of the passenger, therefore, is placed upon the treddle D, it brings down the crank F and along with it the wheel H, so that the large wheels fixed on the same axis perform part of a revolution; but when D is depressed, the rope DA descends, the extremity C of the other treddle rises, and the crank F rising along with it, takes into the teeth of the wheel H, so that when the elevated treddle C is depressed, the wheels H, H, and consequently the wheels I, I, perform another part of a revolution. In this way, by continuing to work at the treddles, the machine advances with a regular pace. Fig. 9.

456. A carriage of this kind, where the mechanism is much more simple and beautiful than that which we have described, has been lately invented and constructed by Mr Nasmyth of Edinburgh, a gentleman whose mechanical genius is scarcely inferior to his talents as a painter. The pulley B and axle AA, are rendered unnecessary; leather straps are substituted in place of the cranks F, F, and the whole mechanism is contained in two small cylindrical boxes about six inches in diameter, and one and a half broad.

457. A carriage driven by the action of the wind is exhibited in fig. 10. It is fixed on four wheels, and moved by the impulse of the wind upon the sails C, D, being guided by the rudder E. Carriages of this kind will answer very well in a level country where the roads are good and the wind fair; and are said to be much used in China. In Holland they sometimes use similar vehicles for travelling upon the ice; but they have a sledge instead of wheels, so that if the ice should happen to break, there will be no danger of sinking. Stephinus, a Dutchman, is said to have constructed one of these carriages with wheels, which travelled at the rate of 21 miles an hour with a very strong wind. Fig. 10.

458. The carriage represented in fig. 11. is made so as to sail against the wind by means of the spiral sails Fig. 11.

Description of Machines.

E, F, G, H, one of which F, is expanded by the wind. The impulse of the wind upon the sails gives a rotatory motion to the axle M, furnished with a cog-wheel K, whose trundles act upon teeth placed on the inside of the fore-wheels.

Fig. 12.

459. A carriage which cannot be overturned is represented in figure 12. where AB is the body of the carriage, consisting of a hollow globe, made of leather or wood, at the bottom of which is placed an immoveable weight proportioned to the load which the carriage is to bear. Two horizontal circles of iron D, E, connected with bars HI, and two vertical circles F, G, surround the globe; and the wheels are fastened by a handle K to the perpendicular bars HI. Then since the body of the carriage moves freely in every direction within the iron circles, the centre of gravity will always be near C, and the carriage will preserve an upright position even if the wheels and frame were overturned.

PART III. DESCRIPTION OF MACHINES.

Chap. I. *Machines which illustrate the doctrines of Mechanics, or are connected with them.*

1. *Atwood's Machine.*

Atwood's machine, Plate CCCXXVI. Fig. 1. 2. 3. &c.

460. THE ingenious machine invented by Mr Atwood for illustrating the doctrines of accelerated and retarded motion, is represented in figs. 1, 2, 3, 4, 5, 6, and enables us to discover, 1. The quantity of matter moved. 2. The moving force. 3. The space described. 4. The time of description; and, 5. The velocity acquired at the end of that time.

461. 1. *Of the quantity of matter moved.*—In order to observe the effects of the moving force, which is the object of any experiment, the interference of all other forces should be prevented: the quantity of matter moved, therefore, considering it before any impelling force has been applied, should be without weight; for though it be impossible to abstract weight from any substance whatever, yet it may be so counteracted as to produce no sensible effect. Thus in the machine

Fig. 1.

fig. 1. A, B represent two equal weights affixed to the extremities of a very fine silk thread: this thread is stretched over a wheel or fixed pulley *a b c d*, moveable round a horizontal axis: the two weights A, B being equal, and acting against each other, remain in equilibrio; and when the least weight is superadded to either (setting aside the effects of friction), it will preponderate. When A, B are set in motion by the action of any weight m, the sum $A+B+m$, would constitute the whole mass moved, but for the inertia of the materials which must necessarily be used in the communication of motion. These materials consist of, 1. The wheel *a b c d*, over which the thread sustaining A and B passes. 2. The four friction wheels on which the axle of the wheel *a b c d* rests. 3. The thread by which the bodies A and B are connected, so as when set in motion to move with equal velocities. The weight and inertia of the thread are too small to have any sensible effect on the experiments; but the inertia of the other materials constitute a considerable proportion of the mass moved, and must therefore be taken into account. Since when A and B are put in motion, they must move with a velocity equal to that of the circumference of the wheel *a b c d* to which the thread is applied; it follows, that if the whole mass of the wheels were accumulated in this circumference, its inertia would be truly estimated by the quantity of matter moved; but since the parts of the wheels move with different velocities, their effects in resisting the communication of motion to A and B by their inertia will be different; those parts which are furthest from the axis resisting more than those which revolve nearer, in a duplicate proportion of those distances, (see Rotation). If the figures of the wheels were regular, the distances of their centres of gyration from their axes of motion would be given, and consequently an equivalent weight, which being accumulated uniformly in the circumference *a b c d*, would exert an inertia equal to that of the wheels in their constructed form, would also be given. But as the figures are irregular, recourse must be had to experiment, to assign that quantity of matter, which being accumulated uniformly in the circumference of the wheel *a b c d*, would resist the communication of motion to A in the same manner as the wheels.

In order to ascertain the inertia of the wheel *a b c d*, with that of the friction wheels, the weights AB being removed, the following experiment was made.

A weight of 30 grains was affixed to a silk thread of inconsiderable weight; this thread being wound round the wheel *a b c d*, the weight 30 grains by descending from rest communicated motion to the wheel, and by many trials was observed to describe a space of about $38\frac{1}{2}$ inches in 3 seconds. From these data the equivalent mass or inertia of the wheels will be known from this rule.

Fig. 2.

Let a weight P, fig. 2. be applied to communicate motion to a system of bodies by means of a very slender and flexible thread going round the wheel SLDIM, through the centre of which the axis passes (G being the common centre of gravity, R the centre of gravity of the matter contained in this line, and O the centre of oscillation). Let this weight descend from rest through any convenient space s inches, and let the observed time of its descent be t seconds; then if l be the space through which bodies descend freely by gravity in one second, the equivalent weight sought $=$

$$\frac{W \times SR \times SO}{SD^2} = \frac{P \times t^2 l}{s} - P.$$

Here we have $p=30$ grains, $t=3$ seconds, $l=193$ inches, $s=38.5$ inches; and $\frac{P \times t^2 l}{s} - P = \frac{30 \times 9 \times 193}{385}$ $30 = 1323$ grains, or $2\frac{3}{4}$ ounces.

This is the inertia equivalent to that of the wheel *a b c d*, and the friction wheels together: for the rule extends to the estimation of the inertia of the mass contained in all the wheels.

Fig.

The resistance to motion therefore arising from the wheel's inertia, will be the same as if they were absolutely

Description of Machines.

lutely removed, and a mass of $2\frac{1}{4}$ ounces uniformly accumulated in the circumference of the wheel *a b c d*. This being premised, let the boxes A and B be replaced, being suspended by the silk thread over the wheel or pulley *a b c d*, and balancing each other: suppose that any weight m be added to A so that it shall descend, the exact quantity of matter moved, during the descent of the weight A, will be ascertained, for the whole mass will be $A+B+m+2\frac{1}{4}$ oz..

In order to avoid troublesome computations in adjusting the quantities of matter moved and the moving forces, some determinate weight of convenient magnitude may be assumed as a standard, to which all the others are referred. This standard weight in the subsequent experiments is $\frac{1}{4}$ of an ounce, and is represented by the letter m. The inertia of the wheels being therefore $=2\frac{3}{4}$ ounces, will be denoted by $11\ m$. A and B are two boxes constructed so as to contain different quantities of matter, according as the experiment may require them to be varied: the weight of each box, including the hook to which it is suspended, $=1\frac{1}{2}$ oz. or, according to the preceding estimation, the weight of each box will be denoted by $6\ m$; these boxes contain such weights as are represented by fig. 3. each of which weighs an ounce, so as to be equivalent to $4\ m$; other weights of $\frac{1}{2}$ oz. $=2\ m$, $\frac{1}{4}=m$, and aliquot parts of m, such as $\frac{1}{2}m$, $\frac{1}{4}\ m$, may be also included in the boxes, according to the conditions of the different experiments hereafter described.

Fig. 3.

If $4\frac{3}{4}$ oz. or $19\ m$, be included in either box, this with the weight of the box itself will be $25\ m$; so that when the weights A and B, each being $25\ m$, are balanced in the manner above represented, their whole mass will be $50\ m$, which being added to the inertia of the wheels $11\ m$, the sum will be $61\ m$. Moreover, three circular weights, such as that which is represented at fig. 4. are constructed; each of which $=\frac{1}{4}$ oz. or m: if one of these be added to A and one to B, the whole mass will now become $63\ m$, perfectly in equilibrio, and moveable by the least weight added to either (setting aside the effects of friction), in the same manner precisely as if the same weight or force were applied to communicate motion to the mass $63\ m$, existing in free space and without gravity.

462. 2. *The moving force.* Since the weight of any substance is constant, and the exact quantity of it easily estimated, it will be convenient here to apply a weight to the mass A as a moving force: thus, when the system consists of a mass$=63\ m$, according to the preceding description, the whole being perfectly balanced, let a weight $\frac{1}{4}$ oz. or m, such as is represented in fig. 5. be applied on the mass A; this will communicate motion to the whole system; by adding a quantity of matter m to the former mass $63\ m$, the whole quantity of matter moved will now become $64\ m$; and the moving force being $=m$, this will give the force which accelerates the descent of $A=\frac{m}{64\ m}$, or $\frac{1}{64}$ part of the accelerating force of gravity.

Fig. 5.

By the preceding construction, the moving force may be altered without altering the mass moved; for suppose the three weights m, two of which are placed on A and one on B, to be removed, then will A balance B. If the weights $3\ m$ be all placed on A, the moving force will become $3\ m$, and the mass moved $64\ m$ as before, and the force which accelerates the descent of $A=\frac{3\ m}{64\ m}=\frac{3}{64}$ parts of the force by which gravity accelerates falling bodies.

Suppose it were required to make the moving force $2\ m$, the mass moved continuing the same. Let the three weights, each of which $=m$, be removed; A and B will balance each other; and the whole mass will be $61\ m$: let $\frac{1}{2}m$, fig. 5. be added to A, and $\frac{1}{2}\ m$ to B, the equilibrium will be preserved, and the mass moved will be $62\ m$; now let $2\ m$ be added to A, the moving force will be $2\ m$; and the mass moved $64m$ as before; wherefore the force of acceleration $=\frac{1}{32}$ part of the acceleration of gravity. These alterations in the moving force may be easily made in the more elementary experiments, there being no necessity for altering the contents of the boxes A and B: but the proportion and absolute quantities of the moving force and mass moved, may be of any assigned magnitude, according to the conditions of the proposition to be illustrated. Fig. [5.]

463. 3. *Of the space described.* The body A, fig. 1. descends in a vertical line; and a scale about 64 inches in length divided into inches and tenths of an inch is adjusted vertical, and so placed that the descending weight A may fall in the middle of a square stage, fixed to receive it at the end of the descent: the beginning of the descent is estimated from 0 on the scale, when the bottom of the box A is on a level with 0. The descent of A is terminated when the bottom of the box strikes the stage, which may be fixed at different distances from the point 0; so that by altering the position of the stage, the space described from rest may be of any given magnitude less than 64 inches. Fig. 1.

464. 4. *The time of description* is observed by a pendulum, vibrating seconds; and the experiments intended to illustrate the elementary propositions, may easily be so constructed that the time of motion shall be a whole number of seconds. The estimation of the time, therefore, admits of considerable exactness, provided the observer takes care to let the bottom of the box A begin its descent precisely at any beat of the pendulum; then the coincidence of the stroke of the box against the stage, and the beat of the pendulum at the end of the time of motion, will show how nearly the experiment and the theory agree. There might be various devices for letting the weight A begin its descent at the instant of a beat of the pendulum W; for instance, let the bottom of the box A, when at 0 on the scale, rest on a flat rod, held in the hand horizontally; its extremity being coincident with 0, by attending to the beats of the pendulum; and with a little practice, the rod which supports the box A may be removed at the moment the pendulum beats, so that the descent of A shall commence at the same instant.

465. 5. *Of the velocity acquired.* It remains only to describe in what manner the velocity acquired by the descending weight A, at any given point of its path, is made evident to the senses. The velocity of A's descent being continually accelerated will be the same in two points of the space described. This is occasioned by the constant action of the moving force; and since the velocity of A at any instant is measured by the space which

Description of Machines.

which would be described by it moving uniformly for a given time with the velocity it had acquired at that instant, this measure cannot be experimentally obtained, except by removing the force by which the descending body's acceleration was caused.

In order to show in what manner this is effected particularly, let us again suppose the boxes A and B $=25m$ each, so as together to be $=50m$; this with the wheel's inertia $11m$ will make $61m$; now let m be added to A, and an equal weight m to B, these bodies will balance each other, and the whole mass will be $63m$. If a weight m be added to A, motion will be communicated, the moving force being m, and the mass moved $64m$. In estimating the moving force, the circular weight $=m$ was made use of as a moving force: but for the present purpose of showing the velocity acquired, it will be convenient to use a flat rod, the weight of which is also $=m$. Let the bottom of the box A be placed on a level with 0 on the scale, the whole mass being as described above $=63m$, perfectly balanced. Now let the rod, the weight of which $=m$, be placed on the upper surface of A; this body will descend along the scale in the same manner as when the moving force was applied in the form of a circular weight. Suppose the mass A, fig. 6. to have descended by constant acceleration of the force of m, for any given time, or through a given space: let a circular frame be so affixed to the scale, contiguous to which the weight descends, that A may pass centrally through it, and that this circular frame may intercept the rod m by which the body A has been accelerated from rest. After the moving force m has been intercepted at the end of the given space or time, there will be no force operating on any part of the system which can accelerate or retard its motion: this being the case, the weight A, the instant after m has been removed, must proceed uniformly with the velocity which it had acquired that instant: in the subsequent part of its descent, the velocity being uniform will be measured by space described in any convenient number of seconds. (Fig. 6.)

466. Mr Atwood's machine is also useful for estimating experimentally the velocities communicated by the impact of bodies elastic and nonelastic; the quantity of resistance opposed by fluids, as well as for various other purposes. These uses we shall not insist on; but the properties of retarded motion being a part of the present subject, it may be necessary to show in what manner the motion of bodies resisted by constant forces are reduced to experiment by means of the instrument above described, with as great ease and precision as the properties of bodies uniformly accelerated. A single instance will be sufficient: Thus, suppose the mass contained in the weights A and B, fig. 6. and the wheels to be $61m$, when perfectly in equilibrio; let a circular weight m be applied to B, and let two long weights or rods, each $=m$, be applied to A, then will A descend by the action of the moving force m, the mass moved being $64m$: suppose that when it has described any given space by constant acceleration, the two rods m are intercepted by the circular frame above described, while A is descending through it, the velocity acquired by that descent is known; and when the two rods are intercepted, the weight A will begin to move on with the velocity acquired, being now retarded by the constant force m; and since the mass moved is $62m$, the force of retardation will be $\frac{1}{62}$ part of that force whereby gravity retards bodies thrown perpendicularly upwards. The weight A will therefore proceed along the graduated scale in its descent, with an uniformly retarded motion, and the spaces described, times of motion, and velocities destroyed by the resisting force, will be subject to the same measures as in the examples of accelerated motion already described.

In the preceding descriptions, two suppositions have been assumed, neither of which is mathematically true: but it might be easily shown that they are so in a physical sense; the errors occasioned by them being insensible in practice.

2. *Machine for illustrating the Theory of the Wedge.*

467. This machine is represented in fig. 7. where KILM and LMNO are two flat pieces of wood joined together by a hinge at LM; P is a graduated arch on which these pieces of wood can be moved so as to subtend any angle not greater than 60°, and a, b two screws for fixing them at the required angle. The back of the wedge will therefore be represented by IKNO, its sharp edge by LM, and its two sides by KILM, LMNO. The weight p suspended to the wedge by the hook M, and the weight of the wedge itself, may be considered as the force employed to drive the wedge. The wooden cylinders AB, CD, have their extremities made like two flat circular plates to prevent the wedge from slipping off at one side. To the pivots of these cylinders, two of which are represented at e and f, are fastened the cords eW, fU, CV, AX, which passing over the pulleys U, V, X, W are fastened to the two bars $u\,v$, $x\,w$, on which any equal weights Y, Z may be hung at pleasure. The tendency of these weights is evidently to draw the cylinders towards each other, and they may therefore be regarded as the resistance of the wood acting against the sides of the wedge. The cylinders themselves are suspended by their pivots to the threads E, F, G, H, which may be fixed to the ceiling of the room, or to the horizontal beam of a frame made on purpose.—By placing various equal weights at Y and Z, it may be easy to determine the proportion between the power and the resistance when the wedge is in equilibrio.—In this machine the impelling power is the pressure of the weight p, whereas, in the real wedge, the impelling power is always an impulsive force which is infinitely more powerful. (Plate CCCXXVI. fig. 7.)

3. *Machine far illustrating the effects of the centrifugal force in flattening the poles of the Earth.*

468. Fig. 8. represents this machine, which consists of two flexible circular hoops, AB and CD, crossing one another at right angles, and fixed to the vertical axis EF at its lower extremity, but left loose at the pole or intersection e. If this axis be made to revolve rapidly by means of the winch m, and the wheel and pinion n, o, the middle parts A, B, C, D will, by their centrifugal force, swell out and strike against the frame at F and G; if the pole e, when sinking, is not stopped by means of a pin E fixed in the vertical axis. The hoops, therefore, will have a spheroidal form; the equatoreal being larger than the polar diameter. (Fig. 8.)

Machine for trying the strength of materials.

4. *Machine for trying the Strength of Materials.*

469. The piece of wood, whose strength is to be tried,

D·ription of M·chines. Plate ·XXVII. ·g. 1.

tried, is represented by EF, and the force is applied to it by means of the winch A, which winds up the rope BC, passing over the pulley n, and below the pulley m, and attached to the point D of the beam EF. The pulleys slide on two parallel bars fixed in a frame, held down by a projecting point, at G, of the lever GR, which is graduated like a steelyard, and measures the force employed. The beam EF is held by a double vice IK with four screws, two of which are invisible. When a wire is to be torn it is fixed to the cross bar LM; and when any body is to be crushed, it must be placed beneath the lever NO, the rope BC being fixed to the hook N, and the end O being held down by the click which acts on the double ratchet OP.—The lever is double from O to Q, and acts on the body by a loop fixed to it by a pin. See *Young's Nat. Philos.* vol. i. p. 768. from which this drawing and description are taken.

5. *Machine in which all the Mechanical powers are combined.*

C·bina·ti· of all ·necha·nical pow·ers. F· 2.

470. The lever AB, whose centre of motion is C, is fixed to the endless screw DE, which drives the wheel and axle FHG. Round the axle G is coiled a rope GHI, which passes round the four pulleys K, L, m, n, and is fixed to a hook at m on the lower block, which carries the weight W. When equal weights are suspended on the lever at equal distances from the fulcrum C, the lever becomes a balance, and the wedge and inclined plane are evidently included in the endless screw DE. If the wheel F has 30 teeth, if the lever AB is equal to twice the diameter of the wheel FH, and if the diameter of the axle G is one-tenth of the diameter of the wheel, a power of 1 exerted at P will raise a weight of 2400, suspended at the lower block of the four pulleys.

6. *Fidler's Balance.*

F·er's ba·la·e. F· 3.

471. The balance represented in fig. 3. was made by Fidler for the Royal Institution, and does not differ much from those which have been constructed by Ramsden and Troughton. The middle column A can be raised at pleasure by the nut B, and supports the round ends of the axis in the forks at its upper extremity, in order to remove the pressure on the sharp edges of the axis within the forks. C and D are pillars which occasionally support the scales, and may be elevated or depresed by turning the nut E. The screw F raises or depresses a weight within the conical beam, for the purpose of regulating the position of the centre of gravity. The graduated arc G measures the extent of the vibrations. See *Young's Nat. Philos.* vol. i. p. 765.

7. *Improvement on the Balance.*

I·rove·m·t on t· ba·la·e. F· 5.

472. An improvement on the balance is represented in fig. 4. where DC is a micrometer screw fixed to the arm FA, so that when it is turned round by the nut D, it neither approaches to, nor recedes from, the centre of motion F. The screw DC works in a female screw in the small weight n, and by revolving in one direction, carries this weight from S to R, and thus gives the preponderance to the scale G. The recession of the weight n from the centre F is measured as in the common micrometer, and a weight x placed in the scale suspended at A, will be in equilibrio with n placed at any distance S n, when $x = \frac{S\,n \times n}{FA}$.—*Appendix to Ferguson's Lectures.*

Description of Machines.

8. *Machine for shewing the Composition of Forces.*

Machine for the composition of forces. Fig. 4.

473. The part BEFC is made to draw other parts into the wooden square ABCD. The pulley H is joined to BEFC so as to turn on an axis which will be at H when the square BEFC is pushed in, and at p when it is drawn out. A ball G is made to slide on the wire k which is fixed to BEFC, and the thread m attached to the ball goes over the pulley to I, where it is fixed. Now, when the piece BEFC is pulled out, the pulley, wire, and ball, move along with it, in the direction DCF, and it is evident that the ball G will slide gradually up the wire k. It is therefore acted upon by two forces: one in the direction GH, and the other in the direction GC, and will be found at the end of the motion at g, having moved in the direction G g, the diagonal of a parallelogram whose sides are GH, GC.

9. *Smeaton's Machine for experiments on Windmill Sails.*

Apparatus for windmills. Fig. 6.

474. In the experiments with this machine, the sails were carried round in the circumference of a circle, so that the same effect was produced as if the wind had struck the sails at rest with the velocity which was then given them. In the pyramidal frame ABC is fixed to the axis DE, which carries the arm FG with the sails GI. By pulling the rope Z, which coils round the barrel H, a motion of rotation is given to the sails, so that they revolve in the circumference of a circle, whose radius is DI. At L is fixed a cord which passes round the pulleys M, N, O, and coils round a small cylinder on the axis of the sails and raises the scale C, in which different weights are placed for trying the power of the sails, and which, being in the direction of the axis DE, is not affected by the circular motion of the arm DG. The scale C is kept steady by the pillars Q, R, and prevented from swinging by the chains S, T, which hang loosely round the pillars. VX is a pendulum composed of two leaden balls moveable upon a wooden rod, so that they can be adjusted to vibrate in any given time. The pendulum hangs upon a cylindrical wire, on which it vibrates as on a rolling axis.

10. *Smeaton's Machine for experiments on Rotatory Motion.*

Apparatus for rotatory motion. Plate CCCXXVIII. Fig. 1.

475. This machine is exhibited in fig. 1. where the vertical axis NB is turned by the rope M passing over the pulley R, and carrying the scale S. The axis NB carries two equal leaden weights K, D, moveable at pleasure on the horizontal bar HI. The upper part N of the axis is one half the diameter of the part M, so that when the rope is made to wind round N, it acts at half the distance from the axis, at which it acts when coiled round M.—When the rope is wound round N, the same force will produce in the same time but half the velocity which is produced when the rope coils round M, the situation of the leaden weights being the same: But when the weights K, L are removed to a double distance from the axis, a quadruple force will be required in order to produce an equal angular velocity in a given time.

CHAP.

Description of Machines.

Chap. II. *Machines for various purposes.*

1. *Prony's Condenser of Forces.*

Prony's condenser of forces. Plate CCCXXVIII. fig. 2, 3.

476. The object of this machine is to obtain a maximum effect from an impelling power which is subject to variation in its intensity. Let us suppose that wind is the first mover, and that O, O is the vertical axis of a windmill; *c*, *c*, *c*, *c*, are several radii issuing from this axis, and carrying a wiper *b d*, which acts upon the corresponding wipers *a f*, and gives a motion of rotation to the axis *a*, *a*, *a*, *a*, to which they are attached. The wipers *b d*, *a f* must be so constructed that when *b d* ceases to press on one wiper *a f*, it shall at the same moment begin to act upon the next wiper. Each of the axes, *a*, *a*, *a*, *a*, carries a drum *t t r r*, round which is coiled a cord *t p* F, passing over the pulley *p*, and supporting a weight Q which can be placed at different distances from G on the lever FG. The axes *a*, *a*, *a*, *a* also pass through the pinions *q q*, to which they are not fixed; but these pinions carry ratchet wheels that bear against the teeth *r r*, so that when the weight Q rises, the rope merely coils round the drum without moving the pinion *q q*. But when the wiper *b d* ceases to act upon *a f*, the weight Q descends, and then the toothed wheel *r r* acts against the ratchet, so that Q cannot descend without turning the pinion *q q* along with the drum. The pinion *q q* drives the wheel *a b*, which again drives the wheel CE by means of the bevelled teeth CD, and elevates the load at P. Hence, when the axis OO is put in motion by the wind acting on the sails, it will first raise a number of weights Q sufficient to put the machine in motion, and will continue to raise new weights while those before raised are fallen, so that the motion once impressed will be continued.

2. *Portable Stone Crane, for loading and unloading Carts.*

Portable stone crane. Fig. 4.

477. This crane is mounted on a wooden stage, and is so constructed that it may be taken to pieces. The frame A, A, A, A is about ten feet high, nine feet long and nine feet wide. The wheels B, B are of iron, and about three feet in diameter. The pinion D that is fixed to the axis of the first wheel B is eight inches diameter, and the other pinion C is about the same diameter. When the stones are suspended to the rope that coils round the barrel, the workman turns a winch on the axis of the wheel C, and raises or lowers the weight according to the direction in which he turns it.

3. *Portable Cellar Crane.*

Portable cellar crane. Fig. 5.

478. This crane is represented in fig. 5. where A, A are two wooden supports about six feet high, which are joined at E, and connected by the iron cylinder C and the wooden bar D. The supports A, A are fastened to the edge of the cellar by the iron prongs E, E, and the two ropes which support the barrel and pass round it are fixed to the iron clamp G, G. These ropes coil round the cylindrical bar F, which is put in motion by the winch K, driving the pinion I about four inches diameter, which gives motion to the wheel H, about three feet in diameter. The barrel, therefore, will rise or fall according to the direction in which the winch is moved.

4. *Weighing Crane.*

Plate CCCXXX. fig. 6. Andrews' weighing crane.

479. This crane represented in fig. 6. was invented by Mr Andrews, and weighs the body at the time that it is raising it. The weight W is elevated by means of the levers M, N, O, P which coil the rope HR round the barrel H. The jib ED stands on a horizontal beam moveable in a vertical plane round the centre FA, and the distance of the upright beam F from the centre of motion A is $\frac{1}{20}$ of BF. The weight of the body W is then ascertained by the weight at B, which keeps it in equilibrio. The piece of wood C projects from the vertical beam CT, in order to prevent the beam from rising too high.

5. *Gilpin's Crane.*

Gilpin's crane. Plate CCCXXIX. fig. 1, 2, 4, 5.

480. In fig. 1. where this machine is represented, AB is the perpendicular stand, formed of two oaken planks let into cast iron mortises C, D: Between these planks is fixed the barrel E with spiral grooves on its surface, on which the chain RL winds. When the winch N is put in motion it drives the pinion O, which again drives the wheel P, on whose axis is fixed the barrel F, so that the chain is coiled round the barrel and the weight raised. A section of this part of the machinery is shewn in fig. 2. Figure 3. shews an enlarged view of part of the barrel, and part of the chain lying in its proper position in the spiral grooves or channels. In order to prevent the chain from twisting when it is wound upon the barrel, the lower edge of one link lies in the groove, and the next link upon the surface of the barrel. This will be better understood from fig. 4. which is a section of the barrel F, and shews the manner in which one link lies within it, and the other link on its outside. The old method of working chains is exhibited in fig. 5. For a full account of this useful invention, see Nicholson's Journal, vol. xv. p. 126.

6. *Bramah's Jib for Cranes.*

Bramah's jib. Fig. 6.

481. The nature of this invention, for which we are indebted to the ingenious Mr Bramah, may be easily understood from a bare inspection of fig. 6. which represents a jib attached to the wall of a warehouse. The jib turns on a perforated axis or pillar. The rope by which the weight is raised, after passing over two pulleys, goes through the perforated axis, and is conducted over another pulley to the barrel of the crane, which is not represented in the figure. In jibs of the common construction which turn in two solid gudgeons, the rope passes over the upper gudgeon, and is confined between two vertical rollers; but the bending of the rope occasions a great deal of friction, and produces a constant effort to bring the arm of the jib into a position parallel to the inner part of the rope.

7. *Gottlieb's Carriage Crane.*

Plate CCCXX[illegible] fig. 7. Carriage crane.

482. This machine, which is useful for carrying large stones where carts and horses cannot be easily obtained, consists of two sorts of crane wheels applied to the two sets of wheels belonging to the carriage, so that two men, one acting at each winch A, A give motion to the loaded carriage. The pinion B, six inches in diameter turns the wheel C, three feet in diameter. The wheel C gives motion to the pinion D one foot in diameter,

meter, which works into two wheels E, E three feet six inches diameter, and are fixed on the wheels of the carriage.

8. *Common Jack.*

483. The common worm jack is represented in fig. 8. and is impelled by the weight W, which is suspended to a rope passing through the pulleys V, R, and rolling round the barrel Q. When the barrel is put in motion by the action of the weight, it drives the wheel KL of 60 teeth, by means of a catch fixed to AB, which lays hold of the cross bars in KL. The wheel KL drives the pinion M of 15 teeth, fixed on the axis of the wheel N of 30 teeth, which gives motion to the endless screw O, and the fly-wheel P. On the axis of the wheel KL is fixed the pulley DG, which, by means of a rope, gives motion to the spit. The axis ET is fixed in the barrel AC; and as this axis is hollow, both it and the barrel turn round upon the axis FD, so that the rope may be coiled round the barrel by the winch H without moving the wheel K.

9. *Loading and Unloading Machine.*

484. This portable machine, invented by Mr Davis of Windsor, is put in motion by the winch A, which drives the two endless screws C, C. These screws move the wheels E, E, and consequently the barrels connected with them, so that the ropes F, F passing over the pulleys G, G are coiled round the barrels, and the load H which these ropes support is raised into the frame R, R, which shews a part of the cart. The barrels and wheels are contained in an iron box L, the sides of which are removed in the figure.

10. *Vauloue's Pile Engine.*

485. The horses which work this engine are yoked at S, S, and by moving the wheel B and drum C, which are locked together, raise the follower GH, (carrying the ram Q by the handle R), by means of the rope HH which coils round the drum. When the follower G reaches the top of the frame, the upper legs of the tongs H are closed by pressing against the adjacent beams; and their lower legs are opened, so that they drop the ram Q, which falls and strikes the pile. When G is at the top of the frame, the crooked handle 6, of the follower G, presses against the cords *a*, *a*, which raise the end of the lever L (see fig. 2.) round *m* as a centre, and by depressing the extremity N, and consequently the bar S, S, unlock the drum C and the wheel B, so that the follower G falls by its weight and seizes the ram R. As soon as the follower drops, the horses would tumble down, having no resistance to overcome, were not this prevented by the fly O, which is moved by the wheel B and trundle X, and opposes a sufficient resistance to the horses till the follower again seizes the ram. When the follower falls, the weight L (fig. 2.) pushes up the bolt Y into the drum C, and locks the wheel and the drum;—and the same operation is afterwards repeated. See *Ferguson's Lect.* vol. i. p. 118.

Description of Machines.

11. *Bunce's Pile Engine.*

486. A side view of this engine is shewn in fig. 3, 4. It consists of two endless ropes or chains A, connected by cross pieces of iron B, B, &c. (fig. 4.) which pass round the wheel C, the cross pieces falling into corresponding cross grooves, cut in the periphery of the wheel. When the man at S, therefore, drives the wheel *m* by means of the pinion *p*, he moves also the wheel C fixed on the axis of *m*, and makes the double ropes revolve upon the wheels, C, D. The wheel D is fixed at the end of a lever DHK, whose centre of motion is H, a fixed point in the beam FT. Now, when the ram L (fig. 3, 5.) is fixed to one of the cross-pieces B by the hook M, the weight of the ram, acting by the rope, moves the lever DK round H, and brings the wheel D to G, so that, by turning the winch, the ram L (fig. 3.) is raised in the vertical line LRG. But when it reaches R, the projecting piece R disengages the ram from the cross piece B, by striking the bar Q; and as the weight is removed from the extremity D of the lever, the counterpoise I brings it back from G to its old position at F, and the ram falls without interfering with the chain. When the hook is descending, it is prevented from catching the rope by means of the piece of wood N suspended from the hook M at O; for being specifically lighter than the iron weight L, and moving with less velocity, it does not come in contact with L till the ram is stopped at the end of its path. When N, therefore, falls upon L, it depresses the extremity M of the hook, and therefore brings the hoop over one of the cross pieces B, by which the ram is again raised.

Bunce's pile engine, Fig. 3, 4.

487. For the description of a great variety of useful machines, the reader is referred to the second volume of Mr Gregory's Mechanics, and to Dr Young's Natural Philosophy, a work of great merit, which would have been more particularly noticed if it had reached us before the historical part of this article was printed off.—See also HYDRODYNAMICS, MARLY, *Machine at*, MILL, RAMSDEN, and *WATER-Works*, in this Work, and the articles ATTRACTION and BRIDGE in the Supplement.

Mechanism || Mecklenburg.

MECHANISM, either the construction or the machinery employed in any thing; as the mechanism of the barometer, of the microscope, &c.

MECHOACAN, a province of Mexico, or New Spain, in America, bounded on the north by Panuco and Guadalajara, on the east by Panuco and Mexico Proper, on the south by the Pacific ocean, and on the west by Guadalajara and the South Sea. It is about 200 miles in circumference, and its population in 1793 was 289,314. The soil is exceedingly fertile; and the climate so wholesome, that the Spaniards imagine it to be possessed of some peculiarly restorative quality; for which reason the sick and infirm flock to it from all quarters. The commodities are sulphur, indigo, sarsaparilla, sassafras, cacao, vanelloes, ambergris, hides, wool, cotton, silk, sugar, the root mechoacan or white jalap, and silver. This province formed an independent kingdom at the time Mexico was reduced by Cortez. The sovereign had long been the inveterate enemy of the Mexicans, and was considered next to the republic of Tlascala, as the most formidable barrier against the extension of the imperial frontier. However, he submitted to Cortez without striking a blow, being intimidated by the wonders he had performed with a handful of men; and thus Mechoacan became a province of the Spanish empire, and a valuable addition to Mexico. The country at that time was exceedingly populous, but the natives are now much thinned. The capital of the province, called *Mechoacan* by the natives, but *Valladolid* by the Spaniards, contained 17,093 inhabitants in 1793.

MECHOACAN, or *White Jalap*, in the materia medica, the root of an American species of convolvulus, brought from Mechoacan, a province of Mexico, in thin slices like jalap, but larger, and of a whitish colour. It was first introduced into Europe about the year 1524 as a purgative: but since jalap became known, mechoacan has been little employed.

MECKLENBURG, a duchy of Germany, containing those of Schwerin and Gustro, is bounded by Pomerania on the east, by part of the marquisate of Brandenburg and the duchy of Lunenburg on the south, the Baltic on the north, and Holstein and Saxe Lawenburg on the west. Their greatest length is about 135 miles, and greatest breadth upwards of 90. With respect to the soil, much cannot be said in favour of it, as it consists, in general, either of sand, or large and desolate heaths interspersed with moors, woods, fens, and lakes. It yields very little wheat, and not a great deal of oats, rye, and barley; but breeds a considerable number of sheep and cattle, has plenty of fish, with stone quarries, salt springs, alum, iron, and some copper. The principal rivers here are the Elde and Stor, which fall into the Elbe as it glides along the borders of this country to the south-west; the Reckenitz, which discharges itself into the Baltic; as do the Peene, the Warno, and the Stopenitz. This country has only one harbour on the Baltic, namely that of Rostock. In both duchies, exclusive of Rostock, are 45 great and small cities, with three convents, and a great number of manors and farms, belonging either to the duke, the nobility, or convents. The peasants are in a state of villenage; but the nobility enjoy very considerable privileges, The states are composed of the nobility and towns; and the diets, which are summoned annually, are held alternately at Sternberg and Malchin. The duchy of Schwerin appoints four provincial counsellors, and that of Gustro as many; who rank according to seniority, with the duke's actual privy counsellors, as their marshals do with the colonels. The lesser committee represents the whole body of the nobility and commons, by whom the members are chosen freely and without controul, and no edict relative to the whole country can be published without their consent, or in prejudice of their rights. The inhabitants of this country are mostly Lutherans, under their superintendants. There are also some Calvinists and Roman Catholics. Besides the grammar schools in the towns, there is an university at Rostock. The commodities of the duchy are corn, flax, hemp, hops, wax, honey, cattle, butter, cheese, wool, and wood, a part of which is exported; but hardly any manufactures.

Mecklenburg, Meconium.

Of the house of Mecklenburg, there are two lines still subsisting, viz. that of Schwerin and that of Strelitz. The latter commenced in Duke Adolphus Frederick II. younger brother of the duke of Schwerin, and grandfather of Adolphus Frederick IV. who entered on the government in 1752, and whose family received a great additional lustre by his Britannic majesty's taking his second sister for his consort, and by her own great merit and noble deportment in that high station. Besides the duchy of Strelitz, to this duke belong the principality of Ratzeburg, with the lordship of Stargard, the ancient commanderies of Miro and Nemero, and a yearly pension of 9000 dollars out of the Boitzenburg toll. The title assumed by both the dukes is *duke of Mecklenburg; prince of Wenden, Schwerin, and Ratzburg; count of Schwerin and the country of Rostock, and lord of Stargard*. By the agreement concluded at Wittstock in 1442, the elector of Brandenburg, on the extinction of the male line of the dukes of Mecklenburg, is entitled to their whole succession. The duke of Schwerin has two votes both in the diet of the empire and that of the circle. The matricular assessment for the duchies of Schwerin and Gustro is 40 horse and 67 foot, or 748 florins monthly, including what is paid by Sweden for Wismar, and the bailiwicks of Poll and Neukloster. To the chamber of Wetzlar, these two duchies pay each 243 rix-dollars, 43 kruitzers. For the government of Mecklenburg, the administration of justice, and the management of the revenue, there is the privy council of regency, the demesne chamber, the high and provincial court of justice, to which appeals lie in most causes, both from the consistory and the inferior civil courts, and which are common to both the dukes. As to the revenues, those of the Schwerin line must be very considerable, those arising from the demesne bailiwicks and regalia alone amounting to 300,000 rix-dollars per annum. There is a tax on land that produces no contemptible sum, and that called the *princess's tax* is fixed at 20,000 rix-dollars: besides all these, there are also free gifts. The whole revenues of the Strelitz branch are estimated at 120,000 rix-dollars. Each of these princes maintains a body of troops.

MECONIUM, the excrement contained in the intestines of an infant at its birth.

MEDALS.

Utility of them in History, &c.

MEDAL, denotes a piece of metal in the form of coin, such as was either current money among the ancients, or struck on any particular occasion, in order to preserve to posterity the portrait of some great person, or the memory of some illustrious action. Scaliger derives the word *medal* from the Arabic *methalia*; a sort of coin with a human head upon it. But the opinion of Vossius is generally received; viz. that it comes from *metallum*, "metal;" of which substance medals are commonly made.

Sect. I. *Utility of Medals in History, and various other Sciences.*

There are few studies of more importance to history than that of medals; the sole evidence we can have of the veracity of a historian being only such collateral documents as are evident to every body, and cannot be falsified. In modern times, these are found in public memoirs, instructions to ambassadors, and state papers of various kinds. Such memorials, however, are subject to various accidents, and besides commonly remain in the countries where they are first published, and cannot therefore give to the world at large that perfect and entire satisfaction which ought to be derived from genuine history; so that more durable and widely diffused monuments are still to be wished for. Such are public buildings, inscriptions, and statues; but these, excepting a few instances of the two last, are always confined to particular countries; so that medals alone remain as infallible documents of truth, capable of being diffused over all countries in the world, and of remaining through the latest ages.

1 Various writers on medals.

The first who showed the importance of medals in ascertaining the dates, and arranging the order of events, in ancient history, by means of medals, was Vaillant, in his History of the Kings of Syria, printed at Paris in 1681. By medals alone, he has been enabled to fix the chronology and important events of history, in the three most ancient kingdoms of the world, viz. Egypt, Syria, and Parthia. Many coins have been discovered since his time, which confirm the accounts he has given. He was followed in this method by Father Hardouin, though with less success. Hardouin's best work is his *Herodiades*, or Series of Successors to Herod king of Judæa. The same plan was pursued by Noris, in his learned Treatise on the Syro-Macedonian princes, and by Bayer in his History of Osrhoene, as well as by Froelich, in the work entitled *Annales Regum et Rerum Syriæ*, Vien. 1754, and another named Kevenhullers *Regum veterum Numismata Anecdota, auct. Perrara*, Vien. 1752, 4to, of which Froelich was properly the author. Corsini and Cary likewise published works of a similar nature; the former in 1744, *De Minnifari, aliorumque Armeniæ Regum, Nummis*, &c.; the latter in 1752, *Histoire des Rois de Thrace, et du Bosphore Cimmerien, eclaircie par les Medailles.*

Utility of them in History, &c.

2 Of the Greek coins.

The study of the Greek coins does not show the dates of events, though it illustrates the chronology of reigns. This defect, however, is abundantly supplied by those of Rome, which commonly mark the date of the prince's consulship, the year of his tribunician power; giving also, upon the reverse, the representation or poetical symbol of some grand event. The year of the tribunician power is sometimes imagined by antiquaries to be synonymous with that of the emperor's reign: but this is not the case; and Mr Pinkerton is at some pains to set them right in this respect. He finds fault with Julius Cæsar, when he assumed the sovereign authority, for taking upon him the title of Perpetual Dictator, as being synonymous with that of king or absolute governor, which the Romans abhorred. "He ought (says our author), under the disguise of some supreme magistrate of annual election, to have lulled the people with a dream, that they might terminate his power when they pleased; or that he himself would resign it, when the necessities of state which had required his temporary elevation had subsided." To this error Mr Pinkerton ascribes the assassination of the dictator, and commends the policy of Augustus, who, with far inferior abilities, continued in possession of the most absolute authority as long as he lived. The tribuneship was an office of annual election; and if put into the hands of any others than plebeians, must have been the supreme power of the state, as it belonged to that office to put a negative upon every public measure whatever. Augustus, being of senatorial rank, could not assume this office: but he invested himself with the tribunician power, which had the advantages of appearing to be only a temporary supremacy, though in truth it was continued during his whole lifetime. Towards the end of his reign, he frequently assumed his destined successor, Tiberius, for his colleague, though in the beginning he had enjoyed it alone. This, with his artifice of resigning his power every ten years, and reassuming it at the desire, as was pretended, of the senate, secured his sovereignty as long as he lived.—His example was followed by his successors; so that most of them have the inscription *Tribunicia Potestate* upon their medals, with the date affixed to it thus, *Tr. Pot.* VII. Yet though this date generally implies the year of the emperor's reign, it sometimes happens that the emperor, by special favour from a former prince, had been endowed with this title before he came to the throne, as being the successor to that prince, of which we have already given an instance in Tiberius. Besides the tribunician power, the emperors very frequently enjoyed that of the consuls; and the date of their consulship is frequently expressed in their coins.

3 Method used by Augustus to secure his power

The office of Pontifex Maximus was likewise assumed by the Roman emperors, in order to secure themselves in their authority; which, Mr Pinkerton observes, was one of the most efficacious artifices they could have fallen upon. "In the Greek heroic times (says lity of n in Hi- y, &c. (says he), king and priest were carefully united in one person; and when sovereigns arose in Denmark and Sweden, the same plan was followed, as appears from Snorro, and other writers. Nothing could lend more security to the person of the monarch than an office of supreme sanctity, which also confirmed his power by all the terrors of superstition. Even the Christian system was afterwards debased by a mock alliance with government; though it be clear from the whole New Testament, that such an alliance is subversive of its genuine institution, and the greatest of all its corruptions. But the Roman Catholic clergy, in the dark ages, were the authors of 'no church no king,' for their own interest; while the Roman emperors only sought to strengthen their power by the dark awe of superstition. The title of Pontifex Maximus was so important, that it was retained even by the Christian emperors till the time of Gratian. Its influence in the state was, indeed, prodigious. Cicero observes, that to this office were subject, temples, altars, penates, gods, houses, wealth, and fortune of the people.—That of augur is also borne by many emperors; and its authority was such, that by the law of the twelve tables no public business could be transacted without a declaration from the augur concerning its event.—The proconsular power was also given to Augustus and the other emperors. It conferred a direct authority over all the provinces, and implied the emperor to be chief proconsul, or governor of each, and of all. Another special power assigned to the emperors, but not occurring on coins, was the *Jus Relationis Tertiæ*, *Quartæ*, &c. or the right of making three or four motions in the senate on the same day, while the senators could only propose one.

Hence our author infers, that medals afford the most authentic documents of the Roman history, in particular, that could have been invented by man.—The histories of Nerva and Trajan are much better elucidated by medals than by authors; for the history of Suetonius ends with Domitian, and the *Historiæ Augustæ Scriptores* begin with Adrian: so that the reigns of the two emperors just mentioned are almost unknown; and Mr Pinkerton is surprised that none of the learned have attempted to supply the defect.—"Capitolinus (says he), in his life of Maximinus Junior is quite puzzled to know if Maximus and Pupienus were two emperors, or two names for the same. Had he happened on any of those coins which bear M. CL. PUPIENUS MAXIMUS AUG. he would have seen at once that Maximus was only another name for Pupienus."

4
e of me- ls in geo- aphy. Medals are useful in other sciences besides history. In geography, we find the situation of towns determined by their vicinity to some noted river, mountain, &c. Thus, ΜΑΓΝΗΤΩΝ ΣΙΠΥΛΟΥ shows that Magnesia was situated under Mount Sipylus. In like manner, it is shown from a medal, that Ephesus stood on the river Caÿster; and there is extant a medal, bearing an inscription, which signifies Alexandria on the Scamander; a name given to Troy by Alexander the Great. The reverse has upon it the famous Apollo

5
natural story. Smintheus of Homer. In natural history also, medals are useful chiefly from the coins struck on the celebration of the secular games, in which the figures of various animals are preserved; and thus it may very often be determined whether any animal be known to the ancients or not. On many of the Greek medals are several uncommon plants and animals. Thus, on most of the medals of Cyrene is the figure of the celebrated *Sylphium*; and on those of Tyre, the shell-fish from which the famous Tyrian purple was procured. By means of medals, also, the exact delineations of many noble edifices are preserved, though not even a vestige of their ruins be now existing; so that the uses of them to the architect are very considerable. To the connoisseur they are absolutely necessary; because by them alone he is enabled to ascribe ancient busts and statues to their proper persons, with multitudes of other points of knowledge which cannot be otherwise determined. The elucidations of obscure passages in ancient authors by means of medals are so numerous and well known, that it is needless to insist upon them.

Utility of them in History, &c.

6
In architecture.

7
In the fine arts.

Mr Addison has treated the connexion betwixt medals and poetry at considerable length; but Mr Pinkerton finds fault with him for preferring the Latin to the Greek poets. He observes also, that the knowledge of Greek medals is most necessary for a sculptor, and perhaps an architect: but an acquaintance with Latin ones is preferable for a poet, or perhaps a painter. The reason of this difference is, that the former generally have on the obverse the head of some king, god, or goddess, of exquisite relief and workmanship; but the reverse seldom affords much fancy of symbol in the early Greek coins; and in the imperial Greek coins, is chiefly impressed with the temples of their deities. To a person of poetical imagination, however, the Roman coins afford the greatest entertainment, from the fine personifications and symbols to be found on their reverses; of which our author gives the following instances:

8
Latin medals of use to a poet.

9
Personifications on Roman medals.

"HAPPINESS has sometimes the caduceus, or wand of Mercury, which Cicero, I. *Offic.* tells us was thought to procure every wish. She has, in a gold coin of Severus, heads of poppy, to express that our prime bliss lies in oblivion of misfortune.

"HOPE is represented as a sprightly girl, walking quickly, and looking straight forward. With her left hand she holds up her garments, that they may not impede the rapidity of her pace; while in her right hand she holds forth the bud of a flower; an emblem infinitely more fine than the trite one of an anchor, which is the symbol of Patience, and not of Hope. This personification, with some others, must have been very familiar to the ancients; for often in this, and in a few more instances, no name, as SPES AUG. or the like, is inserted in the legend.

"ABUNDANCE is imagined as a sedate matron, with a cornucopiæ in her hands, of which she scatters the fruits, and does not hold up her cornucopiæ and keep the contents to herself, as many modern poets and painters make her do.

"The emperor Titus, having cause to import a great supply of corn during a scarcity at Rome, that supply, or the ANNONA, is finely represented as a sedate lady, with a filled cornucopiæ in her left hand, which she holds upright, to indicate that she does not, however, mean to scatter it, as Abundance has a title to do, but to give it to Equity to deal out. This last particular is shown by her holding a little image of

 Equity,

Utility of them in History, &c.

Equity, known by her scales, and *hasta pura*, or pointless spear, in her right hand, over a basket filled with wheat. Behind the ANNONA is the prow of a ship decked with flowers, to imply that the corn was brought by sea (from Africa), and that the ships had had a prosperous voyage. The best poet in the world would not have given us a finer train of imagery; the best painter would have been puzzled to express so much matter in so small a compass.

"SECURITY stands leaning upon a pillar, indicative of her being free from all designs and pursuits; and the posture itself corresponds to her name. Horace, in describing the wise man, mentions his being *teres atque rotundus;* round and polished, against all the rules of chance: an idea seemingly derived from the column upon which this ideal lady reclines.

"The emblems of PIETY, MODESTY, and the like, are equally apposite and poetical.

"The happiness of the state is pictured by a ship sailing before a prosperous breeze: an image than which the superlative genius of Gray could find none more exquisite; and he has accordingly used it in his most capital production "The Bard," with due success.

"The different countries of the then known world are also delineated with great poetical imagery. It affords patriotic satisfaction in particular to a Briton, to see his native island often represented upon the earliest imperial coins, sitting on a globe, with a symbol of military power, the *labarum*, in her hand, and the ocean rolling under her feet. An emblem almost prophetic of the vast power which her dominion over the sea will always give her, provided she exerts her element of empire with due vigour and perseverance.

"Coins also present us with Achaia, Africa, Alamannia, Alexandria, Arabia, Armenia, Asia, Bithynia, Cappadocia, Dacia, Dardania, Egypt, Gallia, Hispania, Italia, Judæa, Macedon, Mauritania, Pannonia, Parthia, Phrygia, Sarmatia, Sicily, Scythia, Syria, and the rivers Danube, Nile, Rhine, Tiber. This personification of provinces seems to have arisen from the figures of provinces carried in triumphs; as the personification of our old poets sprung from the ideal persons actually represented in the mysterial plays.

"There is one colonial medal of rude execution of Augustus and Agrippa, which has a high claim to merit in displaying the ancient poetical imagery. It is inscribed IMP. and DIVI. F. and on the reverse, the conquest of Egypt is represented by the metaphor of a crocodile, an animal almost peculiar to that country, and at that period esteemed altogether so: which is chained to a palm tree, at once a native of the country, and symbolic of victory.

10.
Medals useful to a painter.

"As the reverses are so useful for knowledge of personification, symbols of countries and actions, and the like; so the portraits to be seen on old coins are no less important to a painter; the high merit of a great number of them, in every character, justly entitling them to be regarded as the best studies in the world. Not to mention, that, to an historic painter, the science of ancient medals is absolutely necessary, that he may delineate his personages with the features they really bore while in existence. This can only be attained in this way, or from statues and busts; any one of which will cost as much as hundreds of medals; and indeed a collection of such is only attainable by princes.

The same things which render the study of medals important to a painter, do still more so to a sculptor; and, in this particular, the study of the Greek coins is remarkably useful. The skill of the Greeks in the art of sculpture has always been admired throughout the world; and on their coins the heads of several deities are represented in the most exquisite *alto relievo.* Our author, therefore, thinks it strange, that the Grecian coins should have hitherto been so little attended to by men of learning and taste. They may have been looked upon, he supposes, as belonging only to the province of the antiquary; but he assures us, that the Greek medals will afford satisfaction to the persons who value them only as pieces of workmanship. In most respects, they greatly excel those of Rome even in its best times; which our author supposes to have been from the days of Augustus to Adrian. "In the days of Adrian, in particular (says he), the Roman mint seems to have been the very seat of art and genius; witness the vast number of exquisite personifications, engraven with equal workmanship, which swarm on the medals of that prince. Yet from his time down to Posthumus, coins of admirable workmanship are to be found. Those of the Faustinas and Lucilla deserve particular mention. There is one, and not an uncommon one, of the latter, in great brass, which yields to nothing of the kind. The reverse is a Venus with the name around her. The portrait of the obverse seems to spring from the field of the coin; it looks and breathes, nay talks, if you trust your eyes. The coins of Tarsus are extremely remarkable for a kind of perspective in the figures, as Froelich observes. On others are found triumphal arches, temples, fountains, aqueducts, amphitheatres, circi, hippodromes, palaces, basilicas, columns and obelisks, baths, sea-ports, pharoses, and the like. These furnish much pleasure and instruction to the architect, and serve to form his taste to the ancient manner; that manner which unites perfect simplicity with sublimity and grace; that manner which every age admires, in proportion as it has genius to imitate."

Entertainment from studying them.

11.
To a sculptor.

SECT. II. *Entertainment arising from the Study of Medals.*

BESIDES the purposes which the study of medals answers in the useful arts, a great variety of sources of entertainment are to be found in it. Mr Pinkerton observes, that the most barbarous nations are more pleased with the rudest efforts of art, than with the most admirable works of nature; and that in proportion as the powers of the mind are large and various, such are also the pleasures which it receives from those superlative productions of art, which can only be the offspring of vast genius. Hence works of art are agreeable both to the enlightened and to the ignorant. The chief amusement, therefore, which attends the study of medals, originates from the strength and spirit, the finish and beauty, which the engraver has displayed in the execution of them. It besides gives a kind of personal acquaintance with the persons of whom they are the representations. Portraits have always been ertain- t from ying em. been highly entertaining to mankind; and our author is of opinion, that the love of them gave rise both to painting and sculpture. They are nowhere to be found so ancient, so numerous, and so well preserved as in medals. Amusement is also derived even from the representations of ideal heads and persons; nay, even from the minutest symbols. Thus the Greek coins of cities present us with heads of deities of exquisite workmanship, apparently copied from statues or paintings; so that we may even guess at the works of Apelles and Praxiteles from some of the Greek medals. Their reverses afford still greater variety; there being scarce an object either in art or nature which is not represented upon some of them: and to the satisfaction arising from a view of these, we may likewise add that of beholding, in a lively manner, the dresses, manners and customs, religious and civil ceremonies, of the ancients: so that from medals we may obtain an interesting history of manners; which, though very lately cultivated, may perhaps afford the most useful and entertaining of all the provinces of history.

12 rence ixt a alist anti- y.

There is a very considerable difference betwixt the study of medals and that of a mere antiquary. The latter frequently seems to take delight in coins merely in proportion to their rust and deformity; so that it is often a recommendation of some of their pieces, that neither portrait, reverse, nor legend, can be discovered; at least in such manner as can be intelligibly explained. "The delight of the antiquarist (says Mr Pinkerton), may be called a depraved appetite of the mind, which feeds on trash, and fills itself with emptiness. It is perhaps a mere childish curiosity mingled with caprice and hypochondricism. Against this character the ridicule of Severus is particularly shot, but with little effect; for our antiquists exceed in visions and nonsense. I say *antiquists;* for the name of antiquary is sacred. By *antiquary,* in foreign countries, is implied a man who illustrates their ancient laws, manners, poetry; but especially their ancient history. There, men of the most elevated minds are antiquaries; as Muratori, Leibnitz, Montesquieu, Du Bos. Here men of talents will not stoop, forsooth, to studies the most important to their country, but leave its antiquities to chance. Every thing is important but our history; and we are profound in every ancient matter that is superficial; and superficial in what is profound. Even England cannot boast of one general historian, but trusts to the inaccuracy of Rapin, and the ignorant neatness of Hume. It is therefore no wonder that the study of antiquity is here ridiculous, though most important in other countries; none requiring greater talents, learning, or industry. But the historic antiquary has the pleasure of benefiting society, and enlightening whole nations, while the medallic has only an innocent amusement. This amusement, considered merely as rising from antiquarian objects, has not been explained, though felt by most people, and more by the learned. It seems analogical with that which we derive from an extensive prospect: for as the mind delights to expand itself into distant places, so also into distant times. We connect ourselves with these times, and feel as it were a double existence. The passions are singularly affected by minute circumstances, though mute to generalities; and the relicks of antiquity impress us more than its general history."

Sect. III. *History of Medals.*

The study of medals is not of very ancient date: None of the classic writers give any account of collections of them; though indeed many little particulars are passed without notice by them. In the times of the Greeks, a collection of such coins as then existed must have been but little regarded, as consisting only of those struck by the numerous little states which at that time used the Greek characters and language. Hence they would have had an air of domestic coinage, and no atttention would have been paid to them, however exquisite their workmanship might have been. The little intercourse at that time carried on betwixt the different provinces also, greatly impeded any communication of knowledge to those who wrote histories; so that it is no wonder to find any small collections that might then have existed altogether unnoticed by them.

Almost as soon as any communication was opened between the Greeks and Romans, the latter treated the arts of the Greeks with all due respect and applause. Their coins were imitated by the Romans, and preserved in cabinets by the senators among their choicest treasures. Suetonius informs us, that on solemn occasions Augustus was accustomed to present his friends with medals of foreign states and princes, along with other valuable testimonies of his friendship. In a more advanced period of the Roman empire, however, individuals would undoubtedly form collections of coins peculiar to their own state; for Dr Stukeley, in his Medallic History of Carausius, informs us, that a complete series of silver coins was lately found in Britain, containing all the emperors down to Carausius inclusively. From Banduri we also know, that certain Greek coins were specially preserved by the Romans; and it appears from their code, that ancient gold and silver coins were made use of instead of gems; to which distinction those of Sicily were particularly entitled. From the decline of the Roman empire till towards the end of the fifth century, almost all branches of literature were involved in darkness, and the medallic science among the rest. While the Christian dominion of Constantinople lasted, indeed, almost all the arts and sciences may be said to have been kept within its own boundaries; though the Arabs and eastern nations had some arts and sciences of their own: but after the destruction of the imperial city by the Turks, the Greeks were once more compelled to become fathers to the European science. Even before this time, indeed, some vestiges of a revival of literature had appeared in Italy; and so intimate and necessary a connexion (says Mr Pinkerton), has now the study of medals with that of ancient erudition, that on the earliest appearance of a revival of the latter, the former was also disclosed."

13 Greek coins imitated by the Romans.

14 Collectors of medals.

The first among the moderns who began to study the medallic science was Petrarch. Being desired by the emperor Charles IV. to compose a book containing the lives of eminent men, and to place him in the list, he replied, that he would do so whenever the emperor's life and conduct deserved it. In consequence of this conversation, he afterwards sent the emperor a collection of gold and silver coins bearing the representations

History.

sentations of eminent men, with an address suitable to his former declaration. A collection of coins was made in the next age by Alphonso king of Arragon; but though this monarch collected all that could be found throughout Italy, we know that there could not have been very many, as the whole were contained in an ivory cabinet, and carried always about with him. A very considerable collection was made by Anthony Cardinal St Mark, nephew to Eugene IV. who ascended the pontifical chair in 1431; and soon after the grand museum at Florence was begun by Cosmo de Medici, where a collection of ancient coins and medals had a place among other curiosities. Corvinus king of Hungary about the same time formed a noble collection of coins along with ancient manuscripts and other valuable relicks of antiquity.

Mr Pinkerton considers Agnolo Poliziano, more commonly known by the name of *Angelus Politianus*, as the first writer who adduced medals as vouchers of ancient orthography and customs. He cites different coins of the Medicean collection in his Miscellanea written about the year 1490. By means of a cabinet of medals collected by Maximilian I. emperor of Germany, Joannes Huttichius was enabled to publish a book of the lives of the emperors, enriched with their portraits, delineated from ancient coins. It is generally supposed that this book, which appeared in 1525, was the first work of the kind; but Labbé, in his *Bibliotheca Nummaria*, mentions another named *Illustrium Imagines*, by one Andreas Fulvius, printed in 1517, in which most of the portraits seem to be from medals. About the year 1512 also, Guillaume Bude, a French author, had written his treatise *De Asse*, though it was not printed till many years afterwards. M. Grollier, treasurer of the French armies in Italy, during part of the 16th century, had a great collection of coins of different kinds of metals. After his death, his brass medals were sent to Provence, and were about to be sent into Italy; when the king of France, having got information of the transaction, gave orders to stop them, and purchase the whole at a very high price for his own cabinet of antiquities. M. Grollier had an assortment of gold and silver as well as of brass medals; the cabinet in which they were contained fell two centuries afterwards into the hands of M. l'Abbe de Bothelin; and was known to have been that of Grollier from some slips of paper, on which was his usual inscription for his books, *Joannis Grollierii, et amicorum.*

15 Number of cabinets.

Cotemporary with Grollier was Guillaume de Choul, who was likewise a man of rank and fortune. He had a good collection of medals, and published many in his Treatise on the Religion of the ancient Romans in 1557. In the Low Countries we know, from the letters of Erasmus, that the study of medals was begun about the beginning of the 16th century. About the middle of that century, Hubertzus Goltzius, a printer and engraver, travelled over most countries in Europe searching for coins and medals, in order to publish books concerning them. From one of these works it appears, that there were then in the Low Countries 200 cabinets of medals; 175 in Germany, upwards of 380 in Italy, and 200 in France. It is probable, however, that there are now four times as many in these countries, besides 500 in Britain; but we are not to imagine that all these were grand collections, for of such there are not above a dozen even in Italy: most of those just mentioned were of the class named *caskets* of medals, containing from 100 to 1000 or 2000.

16 Number of coins found in Britain.

There are few countries, Italy excepted, in which a greater number of coins have been found than in Britain; though we are by no means well acquainted with the time when the study of them commenced. Mr Pinkerton suspects that Camden was one of the first, if not the very first British author, who produced medals in his works, and who must have had a small collection. Speed's Chronicle, published in the 17th century, was illustrated with coins from Sir Robert Cotton's cabinet. Gorlæus's collection was purchased by Henry prince of Wales, brother to Charles I. to whom he left it at his death. According to Joseph Scaliger, it consisted of 30,000 coins and medals. A collection of 5500 coins was purchased by Archbishop Laud for 600l. and given to the Bodleian library. Thomas earl of Arundel, earl-marshal of England, well known from the Arundelian tables and other antiquities which he imported from Greece and Italy into Britain, had a rich cabinet of medals collected by Daniel Nisum. The dukes of Buckingham and Hamilton, Sir William Paston, Sir Thomas Fanshaw of Ware-Park, Sir Thomas Hanmer, Ralph Sheldon, Esq. Mr Selden, &c. are enumerated by Evelyn as collectors of medals. Charles I. as well as his historian the earl of Clarendon, were also collectors. The king had a very fine cabinet; which, however, was dissipated and lost during the civil commotions. Oliver Cromwell had a small collection; and the cabinet of Charles II. is mentioned by Vaillant in the preface to his treatise entitled "*Nummi in Coloniis*," &c. This branch of magnificence has not been much attended to by succeeding British monarchs; though his present majesty has a very good collection of ancient gold coins.

17 British cabinets.

A great number of fine cabinets have been formed in Britain since the time of Evelyn. About the year 1720, Haym makes mention of those of the duke of Devonshire, the earls of Pembroke and Winchelsea, Sir Hans Sloane, Sir Andrew Fontaine, Mr Sadler, Mr Abdy, Mr Wren, Mr Chicheley, and Mr Kemp. At present there are many remarkable collections; but that of the late Dr William Hunter is deservedly esteemed the most remarkable in Europe, excepting that of the late French king. Is was not only formed at a great expence, but with much care and ability; many foreign medals offered to it having been rejected (A). The other remarkable collections are those of the duke of Devonshire, the earl of Pembroke, Earl Fitzwilliam, formerly the marquis of Rockingham's, the honourable Horace Walpole, the reverend Mr Crachrode, the reverend Mr Southgate, Mr Townley, Mr

R. P.

(A) This collection, as well as the rest of Dr Hunter's Museum, is now in the possession of the university of Glasgow, to which it was bequeathed by the doctor's will.

Of what constructed. R. P. Knight, Mr Edward Knight, Mr Tyson, Mr Barker, Mr Brown, and several others. The British museum and universities in England have also collections; as well as the Advocates library, the Antiquarian Society, and the universities in Scotland.

Sect. IV. *Materials of which Medals are constructed.*

Ancient gold coins. Medals are formed of gold, silver, and the various modifications of copper. The gold usually made use of in coinage is about the fineness of 22 carats; and as the art of purifying this metal was very much unknown in former times, the most ancient medals are for this reason much more impure than the modern coins. Gold is never found in its native state above 22 carats fine; and the very ancient medals are much under that standard. Many of them are composed of a mixture of gold and silver, called by the ancients *electrum*. The gold medals were made of much finer metal after Philip of Macedon became possessed of the gold mines of Philippi in Thrace, and the medals of his son Alexander the Great are equally fine; as well as those of some other princes of that age. Those of the Egyptian Ptolemies are of the fineness of 23 carats three grains, with only one grain of alloy. The Roman coins are very pure even from the earliest times; the art of refining gold being well known before any was coined at Rome. Some authors are of opinion, that the Roman coins begin to fall short of their purity after the time of Titus; but Mr Pinkerton denies that any thing of this kind takes place till the time of the emperor Severus; and even then only in a very few instances. Most of the Roman gold was brought from Dalmatia and Dacia, where that metal is still to be met with. A very remarkable circumstance is observed in the eastern part of Hungary, which belonged to the ancient Dacia. It germinates in the vines of Tokay, and is found in their stems; as it is elsewhere in the straw of corn.

Metal called electrum. Pliny informs us, and indeed it is generally known, that gold and silver are found mixed together in the earth. Where the silver amounted to one-fifth part of the gold, the metal was called *electrum*; but sometimes the quantity of silver was added artificially. The gold was in those days as well as at present refined by means of mercury; and the ancient artists had certainly attained to great perfection in this branch of metallurgy; as Bodin tells us, that the goldsmiths of Paris upon melting one of Vespasian's gold coins found only $\frac{1}{788}$ part of alloy.

Ancient silver. Most of the ancient silver, particularly that of Greece, is less pure than that of succeeding times; even the Roman silver is rather inferior to the present standard, and that from the very beginning; but in the time of Severus, the silver appears very bad, and continues so until the time of Dioclesian. Many writers upon this subject have mistaken the *denarii ærei*, "coins of brass washed with silver," for silver currency. Silver coins are extremely scarce from the time of Claudius Gothicus to that of Dioclesian, or from the year 270 to 284: in which short space no fewer than eight emperors reigned. Silver at that time was found mostly in Spain; and the commerce with that country was disturbed by the usurpers who arose in Gaul; and such were the troubles of the times, that not only the silver but also the gold coins of those eight emperors, are extremely scarce. There is still, however, some silver extant of these eight emperors; and it is certain, that copper washed was never used as silver currency, but was entirely a distinct coinage. Occasional depravations of silver had taken place long before; as Pliny tells us, that Mark Antony mixed iron with his silver denarii; and Mr Pinkerton informs us, that he had seen a denarius of Antony, which was attracted by a magnet.

21 Ancient brass. The ancient brass coins consist of two kinds: the red or Cyprian, which indeed is no other than copper; and the common yellow brass. Our author observes, that in the Roman coinage brass was of double the value of copper, and he is of opinion, that it was the same among the Greeks; and the latter is the metal most commonly made use of in the Greek coinage. The Roman sestertii was always of brass: the middling-sized kind are partly copper and partly brass; the former being double the value of the latter, which are the *ases*.

22 Mixed metals. Mr Pinkerton next proceeds to give an account of the mixed metals used among the Romans. In Britain all kinds of coins made of mixed metal are without hesitation alleged to be forgeries; although it is certain that the variety of mixed metals used in coinage was very considerable. The most valuable mixture was that of gold and silver, already mentioned, named *electrum*; the silver commonly amounting to one-fifth part of the gold made use of, or perhaps more. Of this mixture are many of the early coins of Lydia, and some other Asiatic states; also those of the kings of the Bosphorus Cimmerius, during the imperial ages of Rome. Next to the electrum were the coins of Corinthian brass: but Mr Pinkerton informs us, that

23 Corinthian brass. not a single coin was ever struck of this metal by the ancients; it having been constantly employed only in the fabrication of vases or toys. It was in use at any rate only for a very short time; being altogether unknown in the days of Pliny the Elder. Our author therefore ridicules those who pretend not only to find out imperial coins of this metal, but to discover three kinds of it; viz. one in which the gold predominates, another in which the silver prevails, and a third where the brass is most conspicuous. He gives Æneas Vico, one of the most ancient writers on medals, as the author of this idea; but whose opinions were confuted by one Savot, a writer in the 17th century. Vico mentions a coin of this kind struck under Augustus, another of Livia, and a third of Claudius. The mistake, he is of opinion, arose from the circumstance of the first propagator not being able to account for the various mixtures and modifications of brass observable in ancient coins of the large size; and which in so common a metal appear very odd to the moderns. Besides the authority of Pliny and other antiquaries of a more modern date, who all declare that they never saw a single medal of Corinthian brass, or of that metal mixed with silver and gold, our author adduces another evidence which he looks upon to be superior to either; viz. that those who have given into this supposition, imagine, that the large pieces called *sestertii*, and others called *dupondiarii*, worth about twopence or a penny, are said to have been composed of this precious metal. It is unreasonable to think, that any proportion of gold

Ancient Money.

gold or silver could have been made use of in these. The coins said to have been struck upon Corinthian brass are only done upon a modification of common brass; of which we know, that in proportion to the quantity of zinc made use of in conjunction with the copper, the metal assumes a variety of hues. On the authority of Pliny he informs us, that the coins mistaken for Corinthian brass were no other than prince's metal.

24 Egyptian silver coins.

The Egyptian silver coins struck under the Roman emperors are at first of tolerably pure silver; but afterwards degenerate into a mixture of copper and tin with a little silver. They are very thick, but many of them are elegantly struck, with uncommon reverses. There are likewise three sets of brass coins belonging to this country from the earliest times of the Roman emperors there. Some of these are of bell-metal or pot-metal; and after the time of Gallienus and Valerian, the coinage of brass with a small addition of silver, becomes authorised by the state; the coins struck upon it, being called *denarii ærei*. Those of lead or copper plated with silver have been fabricated by Roman forgers. Some coins of lead, however, have been met with of undoubted antiquity: and an ancient writer informs us, that tin money was coined by Dionysius; but none has been found. The lead coins of Tigranes king of Armenia, mentioned as genuine by Jobert, are accounted forgeries by Mr Pinkerton and other modern medallists. Plautus, however, makes mention of leaden coins, and several of them have been found; but our author looks upon them to have been chiefly essay pices, struck in order to let the artist judge of the progress of the die. Others are the plated kind already mentioned, fabricated by ancient forgers, but having the plating worn off. A great number of leaden coins are mentioned by Fricorini in a work entitled *Piombi Antichi*, in which he supposes them to have served as tickets for guests; and coins of the same kind are also mentioned by Passeri. In the work entitled *Notitia Imperii Romani*, there is mention of coins made of leather, but none of them have ever been found.

Sect. V. *Of Ancient Money.*

In considering the different sizes, values, &c. of the Greek and Roman coins, our author treats of the medals as money; a knowledge of which, he says, is essentially necessary to every reader of the classics; insomuch that it may almost dispute the preference with the studies of ancient geography and chronology. Notwithstanding all that has been written upon the subject, however, our author is of opinion, that the science is still in its infancy, in as far as it relates to the real money of the ancients. "The ideal (says he), which is indeed the most important province of discussion, has been pretty clearly ascertained; and we are almost as well acquainted with the Attic *mna* or *mina*, and the perplexing progress of the Roman *sestertia*, as with our own *pounds*. But with the actual coin of the ancients the case is different; and the ignorance even of the learned in this point is wonderful."

25 Knowledge of ancient money imperfect.

Our author now goes on, with great asperity of language, to particularize the ignorant manner in which modern authors have treated the subject of medals. "Arbuthnot and Clarke (says he), are, if possible, more ignorant of medals than Budæus the very first. The latter professes his love of medals, but quotes a consular coin with the head of Cicero; and looks upon one of the 30 pieces of silver, the reward of the treachery of Judas, and which was said to be preserved among some relicks at Paris, to be worthy of reference and commemoration. Arbuthnot, if we may judge from his book, had never seen any ancient coins; and Clarke, it is well known, was quite ignorant of them. The latter, with all his labour, seems even to have known nothing of the theoretic part of the real ancient money. Indeed Dr Mead's catalogue seems to have been almost the only *book* on medals which had undergone his perusal. On the other hand, the ignorance of medallists on this score is no less profound. To this day they look upon the *didrachms* of Ægina, so celebrated in antiquity, as *tridrachms* of Ægium; and upon the early obolus as a brass coin. In the Roman class the large brass is esteemed the *as*, while it shall be proved that it is the *sestertius*, and worth four *ases*. The *denarius* is reckoned at ten ases even in the imperial times; whereas it only went at that rate for the first 90 years after the coinage of silver at Rome. The denarius æreus is taken for silver currency; with other mistakes, which evince that medallists are as ignorant of the theory, as the others are of the practice."

26 Money coined in the east

In his account of the ancient Greek money, Mr Pinkerton observes, that the light of science, like that of the sun, has proceeded from east to west. "It is most probable (says he), that the first invention of money arose like the other arts and sciences; and spread from thence into the western parts of the world. In its first shape it appeared as mere pieces of metal without any stated form or impression; in lieu of which, it was regulated by weight. Even down to the Saxon government in England, large sums were regulated by weight; and in our own times every single piece is weighed in gold; though with regard to silver this nicety is not minded, nor indeed does it seem practicable. Among the ancients, whose commercial transactions were less important and extensive than those of the moderns, silver was weighed as well as gold; nay even brass in some cases. 27 Its first rude state

28 Greek money.

In Greece, large sums were determined by *mnæ* or *minæ*; and the most capital sums by *talents*. In every country the mina is supposed to have contained 100 drachmæ, or small silver coins, of that country, and the talent 60 minæ. The mina is supposed to be a pound weight of the country to which it belonged. The Attic pound, according to Dr Arbuthnot, contained 16 ounces, equal to our avoirdupois pound: but Mr Pinkerton looks upon this as a very absurd opinion, and accuses the doctor of having adopted it merely that he may explain a passage in Livy. He is of opinion, that the Attic pound is very nearly the same with the pound Troy. The mina of Athens had at first 73 drachms; but by Solon it was fixed at 100. The ancient drachm weighed the same which it does at present in medical weight, viz. the eighth part of an ounce. The mina or pound of 12 ounces had consequently 96 of these drachms; but four of them were given to the round sum to supply defects in the alloy; "and indeed (says our author), in consequence of a common

common practice in all ages and in all countries, of giving some addition to a large weight. Thus the pound in weight had but 96 drachmæ in fact, while the pound in tale had 100; as the Roman libra in weight had but 84 denarii, in tale 108; and as our pound in tale, by an inverse progress, is not a third of our pound in common weight.

Of the ancient talents

Notwithstanding the very severe criticism on Dr Arbuthnot just mentioned, however, we find our author adopting his account of the *talents* used in coinage in several countries. Thus, according to the doctor,

The Syrian talent had	-	15 Attic minæ
Ptolemaic	-	20
Antiochian	-	60
Eubœan	- -	60
Babylonian	- -	70
Larger Attic	-	80
Tyrian	- -	80
Egyptian	- -	80
Æginean	-	100
Rhodian	- -	100

Notwithstanding the concession made here by Mr Pinkerton to the doctor, he tells us, that he very much questions this list of talents, and that many ancient writers are little to be relied upon. "Writers on this subject confess, that the numbers in all ancient manuscripts are the parts most subject to error, as being almost always contracted. They ought to allow that the authors themselves must often be liable to wrong information.

"Herodotus mentions, that King Darius ordered gold to be paid into his treasury by the Euboic talent, and silver by the Babylonian. The Euboic is esteemed the same with that called afterwards the Attic; and as we estimate gold by carats, so it is natural to suppose, that the most precious metal would be regulated by the most minute weight. But I confess I take the Babylonic talent to be the same with that of Ægina. Mr Raper has proved the first coins of Macedon to be upon the standard of Ægina. Now the early Persian coins are upon that very scale, the largest tetradrachms weighing from 430 to 440 grains. Hence it follows, that the Persian silver coins were of the Æginean standard; and the payment was certainly to be made according to the standard of the money. The larger Attic talent was of 80 lesser minæ; because the larger Attic mina was of 16 ounces. The Alexandrian talent, according to Festus, consisted of 12,000 denarii, being the same with that used by the Egyptian kings in their coins; and is shown by Mr Raper to have been the same with the talent of Ægina. Perhaps the whole of the ancient coins of Asia, Africa, Greece, Magna Græcia, and Sicily, are reducible to three talents or standards. 1. That of Ægina, used in most of the more ancient silver coinages; as would seem in even the later of Egypt, Carthage, Cyrene, &c. 2. The Attic (being the Asiatic gold standard, afterwards used by Phidon king of Argos in estimating gold, and called Euboic from Eubœa, one of the quarters of the city of Argos), used in Athens and the greater part of the world as the standard both of gold and silver. 3. The Doric or Sicilian talent of 24 nummi, each worth an obolus and a half; whence the talent is estimated at six Attic drachms or three daries. These weights continued to be the standard of money after it began to be distinguished by impression; nay, to the fall of Greece and prevalence of the Roman empire."

Ancient Money.

30 Coinage originates in Lydia.

Coinage, according to Herodotus, was first invented by the Lydians, from whom the Greeks quickly received it. The former could not have received it from the Persians, whose empire did not begin till 570 B. C. though our author supposes that it might have proceeded from the Syrians, who carried on commerce in very ancient times. The most ancient Greek coins of silver have an indented mark upon one side, and a tortoise upon the other; and those of the greatest antiquity have no letters upon them. Those of later date have ΑΙΓΙ marked upon them, which medallists interpret of Ægium in Achaia; being led into that supposition by the tortoise, which they look upon as a sure mark of the Peloponnesus. But though our author agrees that the tortoise was so, he thinks that they are otherwise very far wrong in their conclusions. Ægium in Achaia was a place of no consequence till the times of Aratus and the Achæan league; but there are 11 of these coins in Dr Hunter's cabinet, which show that they must have been struck in times of the most remote antiquity, and that the place where they were struck was rich and flourishing at the time. The coins we speak of are not common; but those which have the name ΑΙΓΕΙΩΝ at full length, and which may perhaps belong to Ægium in Achaia, are extremely scarce; insomuch that in all Dr Hunter's vast collection there are not above one or two. They are likewise constructed upon a scale quite different from all other Grecian money; being of 8, 13, 15$\frac{1}{7}$, 90, and about 186 grains. The Grecian drachma at an average is 66 grains; and Mr Pinkerton thinks it would have been strange if pieces had been struck of eight-tenths of an obolus, of an obolus and a half, or of a drachma and a half. Ægium being originally an obscure village, could not be the first which coined money: so that Mr Pinkerton supposes the name ΑΙΓΙ to have stood for Ægialus, the ancient name of Sicyon, a wealthy and powerful city; or rather Ægina, the mint of which was much celebrated, and perhaps the most ancient in Greece.

31 Most ancient Greek coins described.

Other arguments in favour of these coins being derived from Ægina, are drawn from their weight as well as their workmanship, which are quite different from those bearing the name of Ægium at full length. The coinage of Ægina is known to have been different from that of the rest of Greece; insomuch that its drachma was worth 10 Attic oboli, while the Attic drachma was valued only at six. Hence the drachmas of Ægina were named by the Greeks παχειαν, or *thick*; a name very applicable to the coins in question. From these observations, our author is of opinion, that we may even distinguish the precise weight of the ancient coins of Ægina. According to the exact proportion, the drachma of this place should weigh exactly 100 grains; and one of them very much rubbed weighed above 90. The others of larger size, which seem to be didrachms of Ægina, weigh from 181 to 194 grains; but the latter being the only one he could meet with in good preservation, it was impossible to form any just medium. Even in those best preserved, he

Ancient Money.

he thinks that 10 grains may be allowed for a waste of the metal in so long a time, as 2400 years, which would bring the drachma of Ægina near its proper standard. The obolus of Ægina was in proportion to its drachma of six oboli. It is the piece of $15\frac{1}{2}$ grains, and 13 when very much rubbed. The hemiobolon is that of eight, but when rubbed it falls short of this weight.

32 The drachma the most general denomination.

The general denomination of the Greek money is the drachma, or eighth part of an ounce; which to this day is retained in the medical weights, the Grecian coins receiving the names they bore from their weights: though in some instances the weights received their appellations from the coins. The silver drachma, according to Mr Pinkerton, was about ninepence sterling; and he finds fault with those who make the drachma and denarius both equal to one another, the latter being no more than eightpence. The didrachm of silver, according to the same calculation, was worth 18d.; but the *tridrachm* occurs very rarely: and Mr Pinkerton is even of opinion, that medallists give this name to the didrachm of Ægina. The largest of all the Grecian coins is the tetradrachm, which on the Æginean standard is worth five shillings; but in those of the other states only four. There are, however, many subdivisions in the silver drachma; the highest being the tetraobolion or coin of four oboli; being in proportion to the drachma as our groat to a sixpence, weighing about 44 grains, and being in value about sixpence. The hemidrachm or triobolion comes next in value, weighing about 33 grains, and worth fourpence halfpenny. The silver diobolion, or third of the drachma, weighs about 22 grains, and is worth threepence. The obolus of silver weighs about 11 grains, and is worth only three halfpence. There is likewise a hemiobolion in silver, or half the obolus, of five grains and a half, value three farthings: and another called *tetraobolion dichalcos* or quarter obolus, which is the most minute coin yet met with; and by reason of its extreme smallness, weighing only two grains and a quarter, is now very scarce: but there is one in the cabinet of Dr Hunter, and some more have been lately brought from Athens by Mr Stuart. Some of them are likewise met with at Tarentum. It would appear, however, that there were some still smaller, and of value only three-fourths of a farthing. None of these have been met with; and the smallness of the size renders it improbable that any will ever be met with; as the peasants, who commonly discover coins, would probably either not observe them at all, or, if they did, would neglect them as things of no value.

33 Different names of Greek coins.

Many different names have been imposed on the coins belonging to the different states of Greece: thus Κορη, *the maiden*, was a name often applied to the tetradrachm, and which would seem to apply to those of Athens; though there are coins of other cities with the head of Proserpine, and the word Κορη, to which it would appear more applicable in our author's opinion. Χελωνε, *the shell*, was the name of another coin, from its type. A Sicilian coin was named Δημαρετιον, from Gelon's wife. A tetradrachm was named Κραπαταγους, and had eight ευθειας or hemidrachms. The Τροισηνιον, so called from its country Troizene, had Pallas on one side and a trident on the reverse. The hemiobolion was the πελανος of Lacedæmon; and the κολλυβος is supposed to have been equal to the Roman sestertius or quarter drachma. The *cystophori* were coins with the mystic chest or hamper of Bacchus upon them, out of which a serpent rises; and are much celebrated in antiquity. We are told by Livy, that Marcus Acilius, in his triumph over Antiochus and the Ætolians, carried off 248,000 of them; Cneius Manlius Vulso in that over Gallo-Græcia had 250,000; and Lucius Emilius Regillus, in his naval triumph over the fleets of Antiochus, had 131,300. Cicero likewise mentions his being possessed of a vast sum in them. The most probable opinion concerning them seems to be, that they are all silver tetradrachms; such as belong to the cities of Apamea and Laodicea in Phrygia; Pergamus in Mysia; Sardis and Tralles in Lydia; and Ephesus; but it is a mistake to ascribe any to Crete. Mr Pinkerton thinks it absurd to imagine that Crete, a small island, should strike such vast numbers of coins; though Cicero mentions his being in possession of an immense treasure in them at the time he was governor of Asia Minor. "It is most likely (says Mr Pinkerton), that his wealth should be in the coin of the country to which he belonged. But what had these triumphs of Cicero's government to do with Cretan money? But indeed the coins themselves, as above noticed, establish the fact."

34 Coins of Cyzicus.

Another set of coins famous in antiquity were those of Cyzicus in Mysia, which were of gold; but they are now almost entirely vanished by being recoined in other forms. The Αρυανδικον νομισμα, or *money of Aryandes*, who was made governor of Egypt by Cambyses, is made mention of by Hesychius; but none of them, as far as is known, have reached our times. They must have been marked with Persian characters, if with any. The coin of Queen *Philistis* is mentioned by the same writer, and many of these pieces are still extant; but we know not where this queen reigned, nor does there seem to be any method of finding it out. Mr Pinkerton inclines to believe, that she presided over Sicily; and as a confirmation of that supposition, mentions some inscriptions of ΒΑΣΙΛΙΣΣΑΣ ΦΙΛΙΣΤΙΔΟΣ on the *Gradini* of the theatre at Syracuse; but which appear not older than the Roman times. Some authors are of opinion, that she reigned in Cossara or Malta; which our author thinks much more improbable.

35 Athenian coins.

The most particular attention with regard to the names and standard of coins is due to those of Athens; and it is most remarkable, that most of them which have reached us are of a very late period, with the names of magistrates inscribed upon them. Some of these bear the name of Mithridates; and few are older than the era of that prince; who, it is well known, took the city of Athens in his war with the Romans. I suspect (says Mr Pinkerton), that no Athenian coins of silver are posterior to Sylla's infamous destruction of that city; an event the more remarkable, as Sallust tells us, that Sylla was learned in Greek. Indeed Caligula, Nero, and most of the pests of society, have been learned men, in spite of a noted axiom of Ovid,

Sed ingenuas didicisse feliciter artes
Emollit mores, nec sinit esse feros.

It is still more remarkable, that the fabric of Athenian

Ancient Money. nian coins is almost universally very rude; a singular circumstance, if we reflect how much the arts flourished there. It can only be accounted for from the excellence of their artists being such as to occasion all the good ones to be called into other countries, and none but the bad left at home. In like manner, the coins struck at Rome in the imperial times are excellent, as being done by the best Greek artists; while those of Greece, though famous at that time for producing miraculous artists, are during that period commonly of very mean execution. The opulence of Athens in her days of glory was very great; owing in an eminent degree to her rich commerce with the kingdoms on the Euxine sea, carried on chiefly from Delos, which belonged to Athens, and was the grand centre of that trade." Hence it has become matter of surprise to Neumann, that when there are so many coins of Mycene, an island even proverbially poor, there should be none of Delos. But Mr Pinkerton accounts for this from Mycene's being a free state, and Delos subject to Athens. "It may be well supposed (says he), that Athens had a mint at Delos; and such Athenian coins as have symbols of Apollo, Diana, or Latona, were struck in this island."

36 Greek copper money. The copper money of the Greeks is next in antiquity to the silver. Mr Pinkerton is of opinion, that it was not used at Athens till the 26th year of the Peloponnesian war; about 404 years before Christ, and 300 after silver was first coined there. The first copper coins were those of Gelo of Syracuse, about 490 B. C.

37 Of the chalcos. The chalcos of brass, of which eight went to the silver obolus, seems to have been the first kind of Greek coin. At first it was looked upon as of so little consequence, that it became proverbial; and to say that a thing was not worth a *chalcos*, was equivalent to saying that it was worth nothing. As the Greeks became poor, however, even this diminutive coin was subdivided into two, four, nay eight λεπτα or small coins; but our author censures very severely those who have given an account of those divisions. "Pollux, and Suidas copying from him (says he), tell us, that there were seven lepta to one chalcos; a number the most unlikely that can be, from its indivisibility and incapacity of proportion.

"Pollux lived in the time of Commodus, so was too late to be of the smallest authority: Suidas is four or five centuries later, and out of the question. Pliny tells us, that there were ten chalci to the obolus; Diodorus and Cleopatra that there were six; Isidorus says there were four: and if such writers differ about the larger denomination, we may well imagine that the smaller equally varied in different states; an idea supported by these undeniable witnesses, the coins which remain. Most of the Greek copper coin which has reached our times consists of chalci; the lepta being so small as to be much more liable to be lost." In Dr Hunter's cabinet, however, there are several of the dilepta of Athens: and from being stamped with the representation of two owls, seem to be the same with the silver diobolus: "a circumstance (says Mr Pinkerton), of itself sufficient to confute Pollux; for a dilepton can form no part of seven; a number indeed which never appeared in any coinage of the same metals, and is contradictory to common sense. It may be observed, that the whole brass coins of Athens published by Dr Combe are reducible to four sizes, which may be the *lepton*, *dilepton*, *tetralepton* or *hemichalcos*, and *chalcos*. The first is not above the size of one of King James I.'s farthing tokens; the last about that of our common farthing." The lepta was also called κερμα, as being change for the poor. The κιδαβος, perhaps so called from the figure of a wolf upon it, was the coin of a particular state, and if of brass must have weighed three chalci. The other names of the copper coins of Greece are but little known. Lycurgus ordered iron money to be coined at Sparta; but so perishable is this metal, that none of that kind of money has reached our times.

Ancient Money.

38 Lepton, dilepton, &c.

After the conquest of Greece by the Romans, most of the coins of that country diminished very much in their value, the gold coinage being totally discontinued: though some of the barbarous kings who used the Greek character were permitted to coin gold, but they used the Roman model; and the standard used by the few cities in Asia who spoke the Greek language in the times of the emperors is entirely unknown. Copper seems to have been the only metal coined at that time by the Greeks themselves; and that upon the Roman standard, then universal through the empire, that there might be no impediment to the circulation of currency. They retained, however, some of their own terms, using them along with those of the Romans. The *assarion* or *assarium* of Rome, the name of the diminished *as*, being 16 to the drachma or denarius, the obolus was so much diminished in value as to be struck in brass not much larger than the old chalcos, and valued at between two or three assaria; which was indeed its ancient rate as to the drachma. This appears from the copper coins of Chios, which have their names marked upon them. The brass obolus, at first equal in size to the Roman sestertius or large brass, lessens by degrees to about the size of a silver drachma. From the badness of the imperial coinage in Greece also, it appears that brass was very scarce in that country, as well as in all the cities using the Greek characters; being found mostly in the western countries of the Roman empire. The time of this declension in size of the Greek coins is by Mr Pinkerton supposed to have been from Augustus down to Gallienus. He is of opinion, however, that the copper obolus, at first above the size of large brass, was used in Greece about the time of its first subjection to Rome; and that the lepta ceasing, the chalci came in their room, with the dichalcus and the hemiobolion of brass.

39 Era of the declension of the Greek coinage.

40 Gold coins of Greece. With respect to the gold coins of the Greeks, Mr Pinkerton is of opinion that none of that metal was coined before the time of Philip of Macedon, as none have reached our times prior to the reign of that monarch. From a passage in Thucydides our author concludes, that in the beginning of the Peloponnesian war the Athenians had no gold coin. Mentioning the treasure in the Acropolis or citadel of Athens, at the commencement of that war, the historian mentions silver coin, and gold and silver in bullion; and had any of the gold been in coin, he would certainly have mentioned it. Philip began his reign about 68 years after the beginning of the Peloponnesian war; and we can scarce suppose that any city would have preceded

Ancient Money.

ceded the elegant and wealthy Athens in the coining of gold.

41 Gold coined early in Sicily.

Notwithstanding, however, this deficiency of gold coin among the Greeks, it is certain that the coinage of gold had taken place in Sicily long before; as we have gold coins of Gelo about 491 B. C. of Hiero I. 478, and of Dionysius I. in 404, all using the Greek characters; though not to be ranked among the gold coins of Greece, as Philip caused his to be. Gold coins of Syracuse even appear of the third class of antiquity, or with an indented square, and a small figure in one of its segments. Gold coins are used in the cities of Brettium, Tarentum, and throughout Magna Græcia; also in Panticapæa in Thrace, and likewise Cosa in that country; but not in Tuscany, as is commonly believed, though Neumann proves that they were struck by Brutus, and are unquestionably as ancient as the Greek coins. The Thebans and Athenians probably coined the first gold after Philip had set them the example, and when they were attempting to resist the projects of that enterprising monarch. The Ætolians probably coined their gold during the time of their greatest power, about a century after Philip, and when they were combating the power of Aratus and the Achæan league. "There is (says Mr Pinkerton) but one ἡμιχρυσος of Thebes, much worn, in Dr Hunter's cabinet, and weighing but 59 grains; and perhaps not above two or three χρυσοι or gold didrachms of Athens in the world; one of which is also in the collection of Dr Hunter, and weighs 132½ grains. It appears to be more modern than the reign of Philip. That monarch having got possession of the mines of Philippi in Thrace, improved them so much, that they produced him annually above a thousand talents of gold, or 2,880,000l. of our money. From this gold the first coins named from the monarch, *Philippi*, were struck. They were marked with his portrait; and for many ages after were so numerous, that they were common in the Roman empire; whence the name *Philippi* became at length common to gold, silver, and at last even brass coins of their size. Even in the time of Philip gold was very scarce in Greece: but after the Phocians had plundered the temple of Delphos, this precious metal, which had been valued as gems, and consecrated only to the decoration of the temples of the gods, began to be known among the Greeks. The comparative value of gold and silver, however, seem to have been at that time very different from what they are now. Herodotus values gold at 13 times its weight in silver; Plato in his Hipparchus at 12; and even the low value of 10 to 1 seems to have been the stated value in Greece, though in Rome the plenty of silver from the Spanish mines made the value of gold to be much higher; and there is no reason to think that it was ever valued in that city at less than 12 times its weight in silver. The *Philippus* χρυσος, gold piece, or *stater*, is a didrachm, and is the most common of all the ancient coins. Mr Pinkerton is of opinion that it went for 20 silver drachms on its first appearance; but in latter times for 25 Greek drachmæ or Roman denarii. There are proofs of the Philippi being didrachms, both from the writings of ancient authors and from numbers of the coins themselves, which remain to this day; and that the χρυσος, or principal gold coin of Greece, was of the same weight, is also evident from ancient writings. It was anciently worth about 15s. but valuing gold now at the medium price of 4l. per ounce, it is worth about 20s. The ἡμιχρυσος, or half the former coin, scarcely occurs of the coinage of Philip and Alexander, though it does of Hiero I. of Syracuse and of King Pyrrhus. It passed for ten silver drachmas, and was valued only at 7s. 6d. though now worth 10s. There was another division of this kind worth about 5s. There were besides some lesser divisions of gold coins, which could not be worth above two drachmas. These were coined in Cyrene; and there were besides several old gold coins of Asia Minor, the value of which is now unknown. Our author supposes that they were coined not with relation to their weight as parts of the drachma, but merely to make them correspond with so many silver pieces as was necessary. There are also larger coins than the χρυσος, the διχρυσος of Alexander and Lysimachus being double its value. Some others are met with of Lysimachus, Antiochus III. and some of the Egyptian monarchs, weighing four times the χρυσος, and now worth about 4l. sterling. Some weigh even more; but this our author supposes owing to a difference in the purity of the gold.

42 Roman Money.

In Rome, as well as in Greece, the money was at first estimated by weight; and the first metal coined by that people was copper, silver being long unknown in Rome; nor is it certainly known that any silver has ever been found in the Italian mines. In Rome the first valuation of money was by the *libra gravis æris*, or pound of heavy brass: and in the progress of their conquests, the little silver and gold that came in their way was regulated by the same standard, as appears from the story of Brennus. The weights made use of were the same with those which continue to this day. The pound consisted of 12 ounces of 458 grains each; but the pound by which the money was weighed appears to have consisted only of 420 grains to the ounce, or to have contained in all 5040 grains. This became the standard of copper; and when silver came to be coined, seven denarii went to the ounce as eight drachms did in Greece. Gold was regulated by the *scriptulum* or *scrupulum*, the third part of a denarius, and by the larger weights just mentioned. The number 10 was at first used by the Romans in counting their money; but finding afterwards that a smaller number was more convenient, they divided it into quarters; and as the quarter of 10 is 2½, they for this reason bestowed upon it the name of *sestertius* or "half the third;" to express that it was two of any weights, measures, &c. and half a third; whence the sestertius came at last to be the grand estimate of Roman money. The *as* being at first the largest, and indeed the only Roman coin, the word *sestertius* means *sestertius as*, or "two ases and a half." On the first coining of silver, the denarius of ten ases was struck in the most common and convenient denary division of money, or that by tens; the sestertius being of course two ases and a half. But the denarius being afterwards estimated at 16 ases, the name sestertius was still applied to a quarter of the denarius, though it now contained four ases. The term *sestertius* was applied to all sums not exceeding 1000 sestertii, or 8l. 6s. 8d.; but for greater sums the mode of the sestertius was likewise altered, though not to exclude the former. Very large sums

43 Of the Roman pound.

44 Sestertii, as, &c.

Ancient Money.

sums of money were estimated by the hundred weight of brass; for the Romans were at first unacquainted with the talent. The hundred weight, by way of eminence, was distinguished by the name of *pondus*, and *sestertium pondus* became a phrase for two hundred weight and a half. Mr Pinkerton is of opinion, that we may value the *as libralis* of ancient Rome at about eightpence English. Estimating the *as* therefore at a pound weight, the *sestertium pondus* was equal to 1000 *sestertii*, or 8l. 6s. 8d.; and by coincidence which our author supposes to have been the effect of design, as soon as the silver coinage appeared, the *sestertium centum denariorum* was always equal to 8l. 6s. 8d. also. The word *sestertium* itself, however, seems to have been unknown prior to the coinage of silver money at Rome: the *pondera gravis æris* being sufficient before that time for all the purposes of a state in which money was so scarce. But however this may be, the *pondus* or hundred weight of brass was precisely worth 100 denarii, or a pound of silver. As the great sestertium was always valued at 1000 of the smaller, or 8l. 6s. 8d. we never find one sestertium mentioned in authors, but two, three, or more; ten thousand of them being equal to 83,333l. 6s. 8d.

Whence the Romans derived their coins.

The states from which the Romans may be supposed first to have derived their coinage, were the Etruscans and the Greek colonies in Magna Græcia and Sicily. Joseph Scaliger, Gronovius, &c. contend that it was from the Sicilians that the Romans first derived their knowledge of money; but Mr Pinkerton argues that it was from the Etruscans. In confirmation of his opinion, he appeals to the state of the Roman territories in the time of Servius Tullius, who is looked upon to have been the first who coined money at Rome. At that time the whole Roman dominion did not extend beyond ten miles round the city; and was entirely surrounded by the Etruscan and Latin states; Cumæ being the next Greek colony to it that was of any consequence, and which was in the neighbourhood of Naples, at about the distance of 150 miles. Our author asks, Is it reasonable to think that the Romans received the use of money from the Etruscans and Latins who were their neighbours, or from the Greeks, who were at a distance, and at that time, as far as appears from their history, absolutely unknown to them? "If this argument (adds he), is strong with regard to the nearest Grecian colonies, what must it be with respect to Sicily, an island 300 miles distant from Rome, where it was not known, at that time, if a boat went by land or water?" Arguments, however, for this opinion have been derived from the similarity betwixt the Sicilian and Roman coins; which Mr Pinkerton now proceeds to examine. The Greek pound in Sicily was called λιτρα, and consisted, like the Roman, of 12 ουγκιαι, or ounces; and Mr Pinkerton grants that the Roman *libra* was derived from the Greek λιτρα, but denies that the *as*, or libra, a coin, was from Sicilian model. The Sicilians had indeed a coin named λιτρα; but it was of silver, and of equal value to the Æginean standard, ten of which went to the Sicilian δεκαλιτρα. He differs from Gronovius, that the standard of Ægina was used at Corinth, and of course at Syracuse; and it appears from Aristotle, that the Sicilians had a talent or standard of their own. The Sicilian obolus or λιτρα contained also 12 ounces or *chalci*, so named at first because they weighed an ounce weight; but the ουγκιαι of Hiero weigh more than a troy ounce; and the brass coins of Agrigentum are marked with cyphers as far as six: the largest weighing only 186 grains, or about one-third of the primitive ounce. Our author denies that even the Roman denarius took its rise from the Sicilian δεκαλιτρον, as many authors assert. Were this the case, it would have weighed 180 grains; whereas the Roman denarii are not above the third part of the quantity.

46 Origin of the Sicilian coins.

From all these considerations, our author is of opinion that the Sicilians borrowed the division of their λιτρα from the Etruscans, or possibly from the Romans themselves; which our author thinks is more probable than that the Romans had it from Sicily. The strongest argument, however, against the Roman coinage being borrowed from the Sicilian is, that though great numbers of Sicilian coins are to be found in the cabinets of medalists, yet none of them resemble the *as libralis* of the Romans in any degree. In most cabinets also there are Etruscan coins upon the exact scale of the *as libralis*, and several of its divisions; from whence Mr Pinkerton concludes, that "these, and these alone, must have afforded a pattern to the primitive Roman coinage." The Etruscans were a colony from Lydia, to which country Herodotus ascribes the first invention of coinage. "Those colonists (says Mr Pinkerton), upon looking round their settlements, and finding that *no* silver was to be had, and *much less* gold," supplied the mercantile medium with copper; to which the case of Sweden is very similar, which, as late as the last century, had copper coins of such magnitude, that wheelbarrows were used to carry off a sum not very considerable.

47 Of the most ancient Roman coins.

Some coins are found which exceed the *as libralis* in weight; and these are supposed to be prior to the time of Servius Tullius. Some of them are met with of 34 and of 53 Roman ounces; having upon one side the figure of a bull rudely impressed, and upon the other the bones of a fish. They are most commonly found at Tudder, or Tudertum, in Umbria; but they appear always broken at one end: so that Mr Pinkerton is of opinion, that perhaps some might be struck of the decussis form, or weighing ten pounds. These pieces, in our author's opinion, make it evident, that the Romans derived their large brass coins from the Etruscans and the neighbouring states: they are all cast in moulds; and the greater part of them appear much more ancient than the Roman ases, even such as are of the greatest antiquity.

Mr Pinkerton agrees with Sir Isaac Newton as to the time that Servius Tullius reigned in Rome, which he supposes to be about 460 B. C. His coinage seems to have been confined to the as, or piece of brass having the impression of Janus on the one side, and the prow of a ship on the other; because Janus arrived in Italy by sea. Varro, however, informs us, that the very first coins of Tullius had the figure of a bull or other cattle upon them, like the Etruscan coins, of which they were imitations. Those with the figure of Janus and the prow of a ship upon them may be supposed first to have appeared about 400 B. C. but in a short time, various subdivisions of the as were coined. The *semis*, or half, is commonly stamped with the head of

48 Subdivisions of the as.

Jupiter

Ancient Money.

Jupiter laureated; the *triens* or third, having four cyphers, as being originally of four ounces weight, has the head of Minerva; the *quadrans* or quarter, marked with three cyphers, has the head of Hercules wrapt in the lion's skin; the *sextans* or sixth, having only two cyphers, is marked with the head of Mercury with a cap and wings; while the *uncia* having only one cypher, is marked with the head of Rome. All these coins appear to have been cast in moulds, by a considerable number at a time; and in the British museum there are four of them all united together as taken out of the mould in which perhaps dozens were cast together. In process of time, however, the smaller divisions were struck instead of being cast; but the larger still continued to be cast until the as fell to two ounces. Even after this time it was still called *libra*, and accounted a pound of copper; though there

49 Larger denominations of it struck.

were now larger denominations of it coined, such as the *bissas* or double as; *tressis* and *quadrussis* of three and four ases; nay, as far as *decussis* or ten ases, marked X. Olivieri mentions one in his own cabinet weighing upwards of 25 ounces, and cast when the as was about three ounces weight. There is likewise in the Musæum Etruscum a decussis of 40 Roman ounces, cast when the as was at four ounces. There was likewise a curious decussis in the Jesuits library at Rome, for which an English medallist offered 20l.; but it was seized by the pope along with every other thing belonging to the society.

50 Decrease of the as in weight.

Mr Pinkerton contests the opinion of Pliny that the as continued of a pound weight till the end of the first Punic war. His opinion (he says), is confuted by the coins which still remain; and it appears probable to him that the as decreased gradually in weight; and from one or two of the pieces which still exist, he seems to think that the decrease was slow, as from a pound to eleven ounces, then to ten, nine, &c.; but neither the as nor its parts were ever correctly sized. During the time of the second Punic war, when the Romans were sore pressed by Hannibal, the as was reduced to a single ounce. It is said to have taken place in the 215th year before our era, being about 36 years after the former change. This as libralis, with the faces of Janus upon it, is the form most commonly met with previous to its being reduced to two ounces. Our author supposes that the as libralis continued for at least a century and a half after this coinage of Tullius down to 300 B.C. about the year of Rome 452, between which and the 502d year of Rome a gradual diminution of the as to two ounces must have taken place. The following table of the dates of the Roman coinage is given by Mr Pinkerton.

The libralis, coined by Tullius with the figures of oxen, &c. about 167 years after the building of Rome, according to Sir Isaac Newton, or about the year before Christ	460
As liberalis with Janus and the prow of a ship	400
As of ten ounces - - -	300
Eight - - - -	290
Six - - - - -	280
Four - - - - -	270
Three - - - - -	260
Two, according to Pliny - -	250
One, according to the same author -	214

About 175 B.C. also, we are informed by Pliny that the as was reduced to half an ounce by the Papyrian law, at which it continued till the time of Pliny himself, and long after.

After the Romans began to have an intercourse with Greece, a variety of elegant figures appear upon the parts of the as, though not on the as itself till after the time of Sylla. Towards the latter end of the republic also, *dupondii*, or double ases, were coined, together with the sestertii ærei, which came in place of the *quadrusses*, when the denarius began to be reckoned at 16 ases; probably at the time the latter was reduced to half an ounce. In some instances it is to be observed, that the Romans accommodated their coins to the country where their army was stationed; whence we have many coins marked as Roman, which have been coined in Magna Græcia and Sicily, and are evidently upon the Greek and not the Roman scale. In the latter part of the republican times, also, the types begin to vary; so that we have a brass coin supposed to be struck by Sextus Pompeius in Sicily, having upon it a double head of that warrior, representing a Janus. Mr Pinkerton supposes it to have been a dupondius; which indeed appears to be the case from the double head. This coin is of copper, and still weighs an ounce, notwithstanding its antiquity.

51 Coins on the Greek scale marked as Roman.

52 Of the sestertius.

The largest imperial copper coin was the sestertius, a piece worth about twopence of our money. Mr Pinkerton censures severely the opinion of other medallists, all of whom say that the sestertius was of silver. "In fact (says he), it would be as rational in any antiquary, a thousand years hence, to contend that the halfpenny and farthing are of silver, because they were so in the reign of Henry VIII." In confirmation of his own opinion, he quotes the following passage from Pliny: "The greatest glory of brass is now due to the Marian, called also that of Cordova. This, after the Livian, most absorbs the lapis calaminaris, and imitates the goodness of native orichalcum in our sestertii and dupondiarii, the ases being contented with their own copper." Gronovius confesses that he does not know what to make of this passage, and that it causes him hesitate in his opinion. The *Livian* mine mentioned here by Pliny, is supposed to have got its name from *Livia* the wife of Augustus; and it is probable that the pieces marked with her portraits, entitled Justitia, Salus, Virtus, &c. were dupondii from this very mine, the metal being exceedingly fine, and of the kind named *Corinthian brass* by the ancient medallists. "Perhaps (says Mr Pinkerton), the mine received its name from this very circumstance of her coins being struck in the metal taken from it."

53 Coinage of yellow brass.

No change took place in the Roman coinage from the time that the as fell to half an ounce to the days of Pliny: but Mr Pinkerton observes, that before the time of Julius Cæsar yellow brass began to be used, and was always looked upon to be double the value of Cyprian or red copper. There are but few coins in large brass immediately before Julius Cæsar, or even belonging to that emperor; but from the time of Augustus downward, the large coins are all found of brass, and not one of them copper. The largest of what are called the middle size are all of yellow brass; and the next size, which is the as, and weighs half an ounce, is universally copper. What the ancients named

med *orichalcum*, or what we call *brass*, was always looked upon to be greatly superior in value to the æs Cyprium. Procopius, speaking of a statue of Justinian, tells us, that brass inferior in colour to gold is almost equal in value to silver. The mines of native brass were very few in number, and were owing entirely to the singular combination of copper and lapis calaminaris in the bowels of the earth, which very seldom occurs; and the ancients were very far from being well acquainted with the method of combining these two bodies artificially; so that yellow brass was always esteemed at double the value of copper; and hence, in the ancient coinages, the brass and copper pieces were kept as distinct as those of gold and silver.

Mr Pinkerton challenges to himself the discovery that the imperial sestertius was of brass; and is at considerable pains to bring proofs of it. Besides the testimony of Pliny, which of itself would be decisive, this is supported by the strongest collateral evidence of other authors. From a passage in Julius Africanus, who wrote the Ιατρικα, or *Treatise on Medicine*, it appears that the nummus, or sestertius, weighed an ounce, and of consequence that it could not be silver but brass; and all the large imperial Roman coins weigh an ounce. We know not the age in which Julius Africanus lived; and as he makes the denarius to contain 16 ases, he must have been before the age of Gallienus, when it had 60. Gronovius supposes him to have been the same mentioned by Eusebius. This author speaks of a Julius Africanus who lived in the time of Heliogabalus, and whom Mr Pinkerton supposes to have been the same with him above mentioned.

54 Diminution of the sestertius.

The sestertius underwent no change till the time of Alexander Severus, when it was diminished by one-third of its weight. Trajanus Decius was the first who coined double sestertii, or quinarii, of brass; but from the time of Trebonianus Gallus to that of Gallienus, when the first brass ceases, the sestertius does not weigh above the third part of an ounce; the larger coins are accounted double sestertii; and after the time of Gallienus it totally vanishes. In the times of Valerian and Gallienus we find a new kind of coinage, mentioned by the name of *denarii æris*, or *Philippi ærei*. Two sizes of denarii began to be used in the time of Caracalla; the larger of six sestertii, or 24 assaria; the smaller of four sestertii, or 16 assaria as usual. In the time of Pupienus, the latter was reduced to such a small size as not to weigh more than 36 grains; though in Caracalla's time it weighed 56. After the time of Gordian III. the smaller coin fell into disuse, as breeding confusion. The larger denarius of six sestertii, though diminished at last to the size of the early denarius, still retained its value of six sestertii, or 24 assaria. The *Philippus æreus* came at length in place of the sestertius. It was also called *denarius;* from which we may learn not only their size, but that they were in value ten assaria as the first denarius. In the reign of Dioclesian, the place of the sestertius was supplied by the *follis*, that emperor having restored the silver coin to its purity, and likewise given this form to the copper; but it would seem that this restoration of the coinage only took place towards the end of his reign; whence we have but few of his silver coins, and still fewer of the *follis*, though the *denarii æerei* continue quite common down to the time of Constantine. The follis of Dioclesian seems to have weighed above half an ounce; and Mr Pinkerton is of opinion, that Dioclesian designed this coin to supply the place of the denarius æreus; which of course was worth ten assariæ, and six of them went to the silver denarius. From this time the assarium diminishes to the size of 30 grains; and soon after the follis appeared, the denarius æreus was entirely dropped, the former having gradually supplied its place. Some mints appear to have retained the use of the denarius longer than others; and in some the change was preceded, and gradually brought in, by washing the follis with silver or tin, as the denarius had formerly been. Pieces of this kind occur in the times of Dioclesian, Maximian I. and II. and Constantius I.; that is, for about ten years after the follis made its appearance. Some countries, however, retained the denarius æreus; others the follis; and some had a medium betwixt the two, or the follis washed in imitation of the denarius.

55 New coinage introduced by Constantine I.

Towards the end of the reign of Constantine I. a new coinage was introduced throughout the whole empire. The follis coined by this prince was of half an ounce weight; 24 of them going to the milliarensis, or larger silver coin. The word *follis* signifies also a purse, in which sense we sometimes find it mentioned in the Byzantine history. The common follis of silver, when it occurs by itself, means a purse of 250 milliarenses, as the sestertium was 250 denarii; and by a law of Constantine I. every man paid to the state a follis or purse according to his income. The method of counting by purses continues in Turkey to this day.

56 Of the dupondius.

The *dupondius* was only half the value of the sestertius, or about one penny sterling; and before the yellow brass appeared it seems to have been struck upon copper, and double the size of the as. There are some of this coin, struck in the time of Julius Cæsar, in yellow brass, weighing half an ounce, with a head of Venus Victrix upon one side; on the reverse, a female figure, with serpents at her feet: while others have a Victory on the reverse, with Q. Oppius Pr. After the time of Augustus, the dupondius was struck in yellow brass; which Pliny tells us was also the case in his time. The word dupondiarius seems to have been used by Pliny, and adopted, not to express that the coin was *dupondius*, but that it was of dupondiary value. Neither was the former word confined to signify double weight, but was used also for double length or measure, as in the instance of *dupondius pes*, or two feet, &c. In the imperial times, therefore, *dupondius* was used, not to signify a coin of double the weight of the as, but of double the value. It was one of the most common of the Roman coins; and seems to have been very common even in Constantinople. In the time of Justinian, it seems there was a custom of nicknaming young students of the law *dupondii*, against which the emperor made a law; but it is not known what gave rise to the name. The dupondius, though of the same size with the as, is commonly of finer workmanship, the metal being greatly superior in value. It continues to be of yellow brass, as well as the sestertius to the time of Gallienus; but the as is always in copper.

57 Of the assarium.

The imperial as, or *assarium*, was worth only a halfpenny.

halfpenny. At first it weighed half an ounce, and was always of copper till the time of Gallienus, when it was made of brass, and weighed only the eighth part of an ounce. From the time of Gallienus to that of Dioclesian, it continued to diminish still more, the size being then twenty to an ounce. This was the same with the lepta, or smallest coins but the νουμια, which weighed only ten grains.

58 Parts of the as.

The parts of the as occur but seldom: which may, indeed, be well expected, considering the low value of it; though there still occur some of those called semis, triens, quadrans, sextans, and uncia, coined in the times of Nero and Domitian. There is no small brass from the time of Pertinax to that of Gallienus, excepting that of Trajanus Decius; but in the time of Gallienus it becomes extremely common; and the coins of small brass, as well as the larger, are always marked S. C. such as want it being universally accounted forgeries; and were plated with silver, though the plating be now worn off. The small pieces struck for slaves during the time of the saturnalia, must also be distinguished from the parts of the as. The S. C. upon these most probably signifies *Saturni Consulto*, and were struck in ridicule of the true coins, as the slaves on that occasion had every privilege of irony.

59 Of the smallest Roman coins.

The sestertius diminishes from Pertinax to Gallienus so fast, that no parts of the as are struck, itself being so small. Trajanus Decius, indeed, coined some small pieces, which went for the semis of the time. The small brass coins under Gallienus were called assaria, sixty of which went to the silver denarius. They are about the size of the denarius, and some of them occur of the coinage of Gallus and his family, of half that size, which appear to have been struck during the latter part of his reign, when the assarium was diminished to a still smaller size. It is probable, however, that some of these very small coins had been struck in all ages of the empire, in order to scatter among the people on solemn occasions. Mr Pinkerton is of opinion that they are the *missilia*, though most other medallists think that they are medallions. "But if so (says our author), they were certainly called *missilia à non mittendo*; for it would be odd if fine medallions were scattered among the mob. It is a common custom just now to strike counters to scatter among the populace on such occasions, while medals are given to peers of the kingdom; and we may very justly reason from analogy on this occasion."

60 Of the missilia.

The *assarion* or *lepton* of the Constantinopolitan empire was, as we have already observed, one of the smallest coins known in antiquity, weighing no more than 20 grains; and the *noumia* were the very smallest which have reached our times, being only one half of the former. By reason of their extreme smallness, they are very scarce; but Mr Pinkerton informs us, that he has in his possesion a fine one of Theodosius II. which has on it the emperor's head in profile. Theodosius P. F. AV.; on the reverse a wreath, having in the centre VOT. XX.: MULT. XXX.

61 Coins of the lower empire.

The principal coin of the lower empire was the follis, which was divided into an half and quarter, named ἡμισοφολεος and τεταρτον; that latter of which is shown by Du Cange to have been a small brass coin, as the other is supposed to have been by Mr Pinkerton.—Besides these, the follis was divided into eight oboli, 16 assaria or lepta, and 32 noumia, though in common computation it contained 40 of these last. This coin, notwithstanding so many divisions, was of no more value than a halfpenny.

Mr Pinkerton controverts an opinion, common among medallists, that the largest brass coin or follis of the lower empire had 40 small coins, expressed by the letter M upon it; the next had 30, expressed by the letter Λ; the half by the letter K; and the quarter marked I, which contained only 10. Mr Pinkerton informs us, that he has three coins of Anastasius, all marked M in large; one of them weighs more than half an ounce; the second 40 grains less; and the third of 160 grains, or one-third of an ounce; but the size is so very unequal, that the last, which is very thick, does not appear above half the size of the first. There are pieces of Justinian which weigh a whole ounce; but the size of copper was increased as the silver became scarcer; and the value of the coinage cannot be deduced from the weight of the coins, as it is plain that our own coinage is not of half the value with regard to the metal. A great number of medallions were struck by Constantius II. but there is no other copper larger than the half ounce, excepting that of Anastasius, when the follis began to be struck larger. All medallists allow the others to be medallions.

The metal employed in these very small coins, though at first of brass, was always a base and refuse kind; but copper is generally made use of in the parts of the as from the earliest times to the latest; and if brass be sometimes employed, it is never such as appears in the sestertii and dupondiarii, which is very fine and beautiful, but only the refuse. "Yellow brass of the right sort (says Mr Pinkerton), seems totally to have ceased in the Roman coinage with the sestertius, under Gallienus, though a few small coins of very bad metal appear under that hue as late as Julian II."

Silver was coined in Rome only as late as the 485th year of the city, or 266 B. C. Varro indeed speaks of silver having been coined by Servius Tullius, and the libella having been once in silver; but Pliny's authority must be accounted of more weight than that of this author, as he mistakes the λιτρα of Sicily for Roman coins, having been current at Rome during the time of the first Punic war. Even Pliny, according to our author, very frequently mistakes with regard to matters much antecedent to his own time; and among the moderns he criticises severely Erasmus and Hume. "Erasmus (says he), who had been in England for some time, talks of leaden money being used here." Not even a leaden token was struck in the reign of Henry VIII.; yet his authority has been followed with due deference to so great a name; for how could Erasmus, who must have seen the matter with his own eyes, assert a direct falsehood? To give a later instance in a writer of reputation, Mr Hume, in Vol. VI. of his history, has these words, in treating of the reign of James I. "It appears that copper halfpence and farthings began to be coined in this reign. Tradesmen had commonly carried on their retail business by leaden tokens. The small siver penny was soon lost; and at this time was nowhere to be found." Copper halfpence and farthings were not struck till Charles II. 1672: there were small tokens for

62 Roman silver.

An...nt Mo...y.

for farthings struck in copper by James I. but not one for the halfpenny. The silver farthings had ceased with Edward VI. but the silver halfpence continued the sole coins till Edward II. It was by copper tokens that small business was carried on. The silver penny was much used till the end of the reign of George I.; and so far from being nowhere to be found, is superabundant of every reign since that period, not excepting even the present reign of George III. From these instances the reader may judge how strangely writers of all ages blunder, when treating of a subject of which they are entirely ignorant."

Dena... when ...st coine...

The first silver denarii coined at Rome, are supposed by our author to have been those which are impressed with the ROMA; and he inclines to account those the most ancient that have a double female head on the one side, and on the reverse Jupiter in a car, with Victory holding the reins, and the word ROMA indented in a rude and singular manner. The double female head seems to denote Rome, in imitation of the Janus then upon the as. There are 15 of these in the cabinet of Dr Hunter; one of the largest weighs 98¼ grains: and the rest, which seem to be of the greatest antiquity, are of various weights betwixt that and 84; the smaller and more modern weigh 58 or 59 grains; but Mr Pinkerton is of opinion, that the large ones are of the very first Roman coinage, and struck during that interval of time betwixt the coinage of the first silver denarius and the as of two ounces. He takes the indentation of the word ROMA to be a mark of great antiquity; such a mode being scarcely known any where else, except in Caulonia, Crotona, and other towns of Italy; all of them allowed to be struck at least 400 B. C. As these coins are not double denarii, they must have been struck prior to the small ones; and Nenmann has given an account of one of them recoined by Trajan, in which the indentation of ROMA is carefully preserved. The first denarius was in value 10 ases, when the as weighed three ounces; and allowing 90 grains at a medium for one of these large denarii, the proportion of copper to silver must have been as 1 to 160: but when the as fell to one ounce, the proportion was as 1 to 80; when it fell to half an ounce, so that 16 ases went to the denarius, the proportion was as 1 to 64, at which it remained. Copper with us, in coinage, is to silver as one to 40; but in actual value as 1 to 72.

Valu... of the d...rius a... its parts.

At Rome the denarius was worth 8d.; the quinarius 4d.; and the sestertius, whether silver or brass, 2d. The denarius is the coin from which our penny is derived, and was the chief silver coin in Rome for 600 years. According to Celsus, seven denarii went to the Roman ounce, which in metals did not exceed 430 grains; but as all the denarii hitherto met with weigh at a medium only 60 grains, this would seem to make the Roman ounce only 420 grains; though perhaps this deficiency may be accounted for from the unavoidable waste of metal even in the best preserved of these coins. According to this proportion the Roman pound contained 84 denarii; but in tale there was a very considerable excess; for no fewer than 100 denarii went to the Roman pound. The Greek ounce appears to have been considerably larger than that of Rome, containing about 528 grains; yet notwithstanding this apparently great odds, the difference in the coins was so small, that the Greek money went current in Rome, and the Roman in Greece. The denarius at first went for 10 ases, and was marked X: it was afterwards raised to 16; which Mr Pinkerton supposes to have been about 175 B. C. Some are met with bearing the number XVI. nay, with every number up to CCCCLXXVI. These large numbers are supposed to have been mint-marks of some kind or other. After being raised to 16 ases, it continued at the same value till the time of Gallienus; so that till that time we are to look upon its constituent parts to be 16 ases or assaria, eight dupondii, four brass sestertii, and two silver quinarii. Under the emperor Severus, however, or his successor Caracalla, denarii were struck of two sizes, one of them a third heavier than the common; which we must of consequence suppose to have borne a third more value. This large piece obtained the name of *argentus*, and *argenteus Philippus*, or the "silver Philip;" the name of Philip having become common to almost every coin. The common denarii now began to be termed *minuti* and *argenti Philippi minutuli*, &c. to express their being smaller than the rest. Some have imagined that the large denarii were of the same value with the small, only of worse metal; but Mr Pinkerton observes, that among the few which have any difference of metal, the smallest are always the worst. The first mention of the *minuti* is in the time of Alexander Severus, who reduced the price of pork from eight minuti at Rome to two and to one. The *minutus argenteus* of that age was about 40 grains; and from the badness of the metal was not worth above 4d. of our money. Thus the price of meat was by this prince reduced first to 8d. and then to 4d.

65 Restoration of the purity of the Roman coins.

According to Zozimus and other writers, the purity of the Roman coin was restored by Aurelian: but Mr Pinkerton controverts this opinion; thinking it more probable, that he only made the attempt without success; or that his reformation might be entirely confined to gold, on which there is an evident change after the time of this emperor. His successor Tacitus is said to have allowed no brass to be mixed with silver upon any account; yet the few coins of this emperor are very much alloyed. We are certain, however, that the emperor Dioclesian restored the silver to its ancient purity; the denarii struck in his reign being very small indeed, but of as fine silver as the most ancient coins of the empire. After Gordian III. the small denarius entirely vanished, while the large one was so much diminished, that it resembled the *minutus*, or small one of Caracalla, in size. Gallienus introduced the *denarii ærei* instead of the *sestertii*. The *argenteus*, though reduced more than one-third in size, contained six denarii ærei, the old standard of sestertii. According to the writers of this period, and some time afterwards, the denarius or argenteus contained 60 assaria; whence it follows, that each denarius æreus had 10; and from this it probably had its name. The assaria are of the size of the argentei already mentioned; and show the copper to have retained nearly its old proportion of value to the silver, viz. 1 to 60.

66 Reformation of the silver coin by Constantine.

A larger silver coin was introduced by Constantine I. who accommodated the new money to the pound of gold in such a manner, that 1000 of the former in tale were equal to the latter in value; so that this new piece from thence obtained the name of the *milliarensis*

Ancient Money.

milliarensis or "thousander." Its weight at a medium is 70 grains, or 70 to the pound of silver: but Mr Pinkerton is of opinion, that it might have contained 72 grains, of which two have now perished by the softness of the silver; that the pound contained 72; or that two of the number might be allowed for coinage; while the alloy alone would pay for coining gold. The code says, that 60 went to the pound; but the numbers of this are quite corrupt. The *milliarensis* was worth about a shilling sterling. The argentei or denarii, however, were still the most common currency; and having been originally rated at 100 to the pound of silver in tale, they from thence began to be called *centenionales*, or "hundreders." Those of Constantine I. and II. Constans, and Constantius, weigh from 50 grains down to 40; those of Julian and Jovian, from 40 to 30; and of the succeeding emperors from that time to Justinian, from 30 to 20. Under Heraclius they ceased entirely; and from Justinian to their total abolition, had been brought down from 15 to 10 grains. A like decrease of weight took place in the milliarensis; those of Constantine and Constans being above 70 grains in weight; those of Arcadius not above 60; and the milliarensis of Justinian not more than 30 grains; but, from the weight of those in Dr Hunter's cabinet, Mr Pinkerton deduces the medium to have been exactly $70\frac{8}{11}$ grains. These coins were also called *majorinæ*.

67 Account of the small Roman coins.

The smaller silver coins of Rome were, 1. The *quinarius*, at first called *victoriatus*, from the image of Victory on its reverse; and which it continued to bear from first to last. Its original value was five ases, but it was afterwards raised to eight, when the value of the denarius increased to 16. According to Pliny, it was first coined in consequence of the *lex Clodia*, about the 525th year of Rome. Some are of opinion, that it was called κεϱατιον under the Constantinopolitan empire, because it was worth a κεϱατιον of gold, 144 of which went to the ounce: but this is denied by Mr Pinkerton, because, at the time that the word κεϱατιον first appears in history, the denarius did not weigh above 30 grains; and of consequence, as 25 must have gone to the gold solidus, of which there were six in the ounce, 130 denarii must have gone to the ounce of gold. He is therefore of opinion, that the word κεϱατιον, was only another name for the denarius when much reduced in size; probably owing to the great scarcity of silver in Constantinople, though in the same city there was plenty of gold; and of consequence, the gold solidus was never diminished. "For Montesquieu (says our author) has well observed, that gold must be common where silver is rare. Hence gold was the common regulation of accounts in the Eastern empire." The διxεϱατιον met with in ancient authors, according to Mr Pinkerton, was merely an improper name for the *milliarensis;* when, on account of the scarcity of silver, the denarius was reduced, and no milliarenses coined: so that the current milliarensis of former reigns happened to be double to the denarius or centenionalis. The quinarius diminishes in size along with the other coins; those of Augustus weighing 30 grains, of Severus 25, of Constantine I. 20, of Justinian 12, and of Heraclius only 5. A new silver coinage seems to have taken place after the days of this emperor; as the little we then meet with, which in the best cabinets scarce exceeds a dozen of coins, consists entirely of large unshapely pieces of coarse metal.

68 Division of the denarius.

2. The consular denarius had also four silver sestertii, till the as fell to half an ounce, when it was thought proper to coin the sestertius in brass, as it continued to be ever afterwards. "The very last silver sestertius (says Mr Pinkerton) which appears, is one with a head of Mercury, and H. S.; on the reverse a caduceus P. SEPVLLIVS; who appears to be the P. SEPVLLIVS MACER of the denarii of Julius Cæsar. If so, as is most probable, the sestertius was coined in silver down to Augustus; and it is of course not to be expected that any of brass can appear till Augustus, under whom they are actually quite common. I have indeed seen no coin which could be a consular brass sestertius; and though we have certainly brass dupondii of Cæsar, yet it is reasonable to infer, that the brass sestertius was first coined by Augustus. Not one silver sestertius appears during the whole imperial period, yet we know that the sestertius was the most common of all silver coins. The consular sestertii of silver, marked H. S. are not uncommon, nor the quinarii; but the latter are very scarce of all the emperors, if we except one instance, the ASIA RECEPTA of Augustus.

69 Roman gold.

"The Roman gold coinage was still later than that of silver. Pliny tells us, that "gold was coined 62 years after silver,; and the scruple went for 60 sesterces. It was afterwards thought proper to coin 40 pieces out of the pound of gold. And our princes have by degrees diminished their weight to 45 in the pound." This account is confirmed by the pieces which still remain; for we have that very coin weighing a scruple, which went for 20 sesterces. On one side is the head of Mars, and on the other an eagle; and it is marked XX. We have another coin of the same kind, but double, marked XXXX; and its triple, marked ↓X or 60; the ↓ being the old numeral character for 50. Mr Pinkerton, the discoverer of this, treats other medallists with great asperity. Savot and Hardouin are mentioned by name; the latter (he says) is "ignorant of common sense;" and neither he nor Savot could explain it but by reading backward; putting the ↓ for the Roman V, and thus making it XV. Other readings have been given by various medallists, but none have hit upon the true one excepting our author, though the coin itself led to it; being just three times the weight of that marked XX. We have likewise half the largest coin, which is marked XXX, and which weighs 26 grains; the smallest is only $17\frac{1}{2}$; the XXXX weighs 34; and the LX or drachma 53. There is also the didrachm of this coinage, of 106 grains.

70 Account of the aurei.

The *aurei*, or Roman gold coins, were at first 48 in the pound; but they were afterwards diminished in number to 40, owing to an augmentation in the weight of each coin. In the time of Sylla, the aureus weighed no less than from 164 to 168 grains, and there were only 30 in the pound; but such confusion in the coinage was introduced by that conqueror, that no person could know exactly what he was worth. Till this time the aureus seems to have continued of the value of 30 silver denarii, about one pound sterling; for about that time it was enlarged a whole third, that

Ancient Money.

that it might still be equivalent to the full number of denarii. But after Sylla had taken Athens, and the arts and manners of Greece became objects of imitation to the Romans, the aureus fell to 40 in the pound, probably when Sylla had abdicated his dictatorship. Thus, being reduced near to the scale of the Greek χρυσος, it passed for 20 denarii, as the latter did for as many drachmas, being in currency 13s. 4d. sterling. "This (says Mr Pinkerton) is the more probable, because we know from Suetonius, that the great Cæsar brought from Gaul so much gold, that it sold for nine times its weight of silver: but the Gallic gold was of a very base sort."

In the time of Claudius, the aureus was valued at 100 sesterii, or 25 silver denarii, at which it continued till the time of Heliogabalus, when it fell to about 92 grains at a medium, or rose in number to 55 in the pound. In the reign of Philip, during which the city completed its thousandth year, the aureus was coined of two or three sizes. These are impressed with a head of Rome on one side, and various figures on the other; but the workmanship is so rude, that they are supposed to have been struck in some of the more uncivilized provinces of the empire. The practice of having different gold coins, however, continued under Valerian, Gallienus, and his successors. In the time of Gallienus, they were of 30, 65, and from 86 to 93 grains; the double aurei being from 172 to 183½ grains; but the aureus properly so called was from 86 to 93; those of 30 and 32 being the *trientes aurei* of the *Historiæ Augustæ Scriptores;* while the larger, from 62 to 65, are to be accounted double trientes, and were perhaps called *minuti aurei*. The value of these different sizes of aurei is not known.

Alteration in the gold coin by Aurelian.

That Aurelian made some alteration in the coin is certain; but Mr Pinkerton supposes it to have been only in the gold; because under him and his successor Probus, the common aureus was of 100 grains, a size confined to those emperors: there are likewise halves of about 50 grains; and double aurei, commonly of very fine workmanship, of upwards of 200 grains. In the time of Gallienus, the precious metal was so common, that this emperor vied in magnificence with Nero and Heliogabalus. Aurelian, who plundered the rich city of Palmyra, and thus became master of the treasures of the east, obtained such a profusion of gold, that he looked upon it to be produced by nature in greater plenty than silver. It is remarkable that during this emperor's reign there was a rebellion among the money coiners, which could not be quelled but by the destruction of several thousands; which Mr Pinkerton ascribes to his having ordered the gold to be restored to its former size, but to go for no more silver than it formerly did. "So very little silver (says he) occurs of this period, that it is plain no alteration in the silver produced the war with the moneyers; and in the brass he made no change; or if he had, it were strange that such commotions should arise about so trifling a metal. But if, as appears from the coins, he ordered the aureus, which had fallen to 80 grains, to be raised to about 100, it is no wonder that the contractors should be in an uproar; for a whole quarter of their coinage, amounting as would seem, to all their profits, was lost. Aurelian judged, that when he found gold so common in the east, it was equally so in the west; and that the moneyers must have made a most exorbitant profit; but his ideas on this subject were partial and unjust: and after his short reign, which did not exceed five months after the alteration, the gold returned to its former course; though a few pieces occur of Aurelian's standard, struck, as would seem, in the commencement of the reign of Probus his successor.

From this time to that of Constantine I. the aureus weighed between 70 and 80 grains; but in his reign it was changed for the solidus, of which six went to the ounce of gold, which went for 14 milliarenses, and 25 denarii as before; the value of silver being now to gold as 14 to 1. This new coin continued of the same value to the final downfall of the Constantinopolitan empire; gold being always very plentiful in that city, though silver became more and more scarce. The solidus was worth 12s. sterling. Here again our author most severely criticises Mr Clarke and Mr Raper: the former (he says) with respect to the value of gold in the time of Constantine I. "has left all his senses behind him. In page 267, he absurdly asserts, that 20 denarii went to the solidus in the time of Theodosius I. and proceeds with this deplorable error to the end of his work. He then tells us, that only 14 denarii went to the solidus under Constantine I.," &c. To Mr Raper, however, he is a little more merciful, as he owns, that "though he (Mr Raper) has strangely confounded the milliarensis with the denarius, he has yet kept common sense for his guide." Mr Pinkerton, indeed, argues with great probability, "that had any change in the coinage taken place between the time of Constantine and Theodosius I. that is, in less than 50 years, the laws of that period, which are all in the Theodosian code, must have noticed it." To this and other arguments upon the subject, Mr Pinkerton adds the following observation upon the value of gold and silver: "As a state advances to its height, gold increases in value; and as a state declines, it decreases, providing the metals are kept on a par as to purity. Hence we may argue, that gold decreased in its relation to silver perhaps four or five centuries, furnished most European kingdoms with gold in coin, which otherwise would, from their want of arts and of intercourse with the east, then the grand seminary of that metal, have almost been ignorant of what gold was. These gold coins were called *Bezants* in Europe, because sent from Byzantium or Constantinople; and were *solidi* of the old scale, six to the ounce. In Byzantine writers, the solidus is also called *nomisma*. or "the coin;" *crysinos*, because of gold; *hyperperos*, from its being refined with fire, or from its being of bright gold flaming like fire. The *solidi* also, as the *aurei* formerly, received names from the princes whose portraits they bore; as *Michelati*, *Manuelati*. *Solidus* is a term used also for the aureus by Apuleius, who lived in the time of Antoninus the Philosopher; nay, as early as the prætorian edicts of the time of Trajan. It was then a distinction from the semissis or half. In the time of Valerian, when aurei of different sizes had been introduced, it became necessary to distinguish the particular aurei meant. Hence in the Imperial Rescripts, published by the *Historiæ Augustæ Scriptores*, Valerian uses the term *Philippeos nostri vultus*, for the common aurei. Aurelian uses the same term *aurei*

U 2 *Philippei*,

Ancient Money.

Philippei, for the aurei which he had restored to their size in some degree. Gallienus uses *aurei Valeriani* for his father's coins. *Aurei Antoniniani* are likewise put by Valerian for coins of the early Antonini, of superior standard to any then used.

72
Division of the aureus.

In the first gold coinage at Rome the aureus was divided into four parts: the semissis of 60 sestertii; the tremissis or third, of 40; the fourth, the name of which is not mentioned, of 30; and the scrupulum of 20. But in a short time all of these fell into disuse, except the semissis or half, which is extremely scarce; so that it is probable that few have been struck. It is an erroneous opinion (according to Mr Pinkerton), that the semissis was called a *denarius aureus*. The aureus itself indeed had this name; but the name of *quinarius* is applied to the semissis with greater propriety than the former. Trientes, or tremisses of gold, are found of Valerian and his son Gallienus, and weigh about 30 grains. Those of Salonina the wife of Gallienus weigh 33 grains. Under the Constantinopolitan empire, tremisses again made their appearance; and from the time of Valentinian downwards, the thirds are the most common kinds of gold, being worth about 4s. sterling. The semissis is likewise mentioned, but none occur earlier than the time of Basiliscus. The gold tremissis was the pattern of the French and Spanish gold coins; as the silver denarius, in its diminished state, was of the Gothic and Saxon penny.

73
Account of the Roman method of coining.

We shall close this account of the Roman money with some remarks concerning the mint, and method of coinage. This at first seems to have been under the direction of the quæstor. About the time that silver was first coined in Rome, viz. about 266 B. C. the *triumviri monetales* were created. They were at first of senatorial rank, but were by Augustus chosen from among the equestrian; and the title of *triumviri* was continued till after the time of Caracalla; but under Aurelian there was probably but one master of the mint, called *rationalis;* and Mr Pinkerton is of opinion that the change took place under Gallienus. He seems also to have permitted the provincial cities to coin gold and silver, as well as to have altered the form of the mints in the capital, and to have ordered them all to strike money with Latin legends, and of the same forms; as in his time we first meet with coins with mint marks of cities and offices. The violent insurrection which took place in his reign has already been mentioned, as well as its probable cause; and Mr Gibbon has shown, that the concealed enemies of Aurelian took such advantage of this insurrection, that it cost 7000 of his best troops before it could be quelled. About this time the *procurator monetæ* seems to have succeeded the *rationalis* as director of the mint. In the colonies, the direction of the mint seems to have been given to the decemviri, whose names frequently occur in colonial coins; "which (says Mr Pinkerton), though generally of rude invention, and ruder execution, are yet often interesting and important."

The engraving of the ancient dies used in coinage was a work of much genius and labour; and at Rome Greek artists were generally employed in it; but it has been thought a matter of great surprise, that scarce any two ancient coins are to be found exactly the same. Hence some antiquaries have imagined that only a single coin was thrown off from each die. M. Beauvais informs us, that the only two Roman imperial coins of the first times which he had seen perfectly alike were those of the emperor Galba. It is, however, the opinion of the best judges, that a perfect similarity betwixt two medals is a very great reason for supposing one of them to be forged. "It must also be observed (says Mr Pinkerton), that the differences in coins, apparently from the same die, are often so minute as to escape an eye not used to microscopic observations of this sort. But it would be surprising if any two ancient coins were now found struck with the same die; for out of each million issued, not above one has reached us. Dies soon give way by the violence of the work, and the ancients had no puncheons nor matrices, but were forced to engrave many dies for the same coin. Even in our mint, upon sending for a shilling's worth of new halfpence, it will appear that three or four dies have been used. Sometimes the obverse of of the die gives way, sometimes the reverse; but among us it is renewed by puncheons, though with variations in the lettering or other minute strokes; while the ancients were forced to recur to another die differently engraven. The engravers of the die were called *cælatores;* other officers employed in the mint were the *spectatores*, *expectatores*, or *nummularii*. The melters were styled *fusarii*, *flatuarii*, and *flaturarii;* those who adjusted the weight were called *æquatores monetarum;* those who put the pieces into the die *suppositores*, and those who struck them *malleatores*. At the head of each office was an officer named *primicerius*, and the foreman was named *optio et exactor*."

In order to assist the high relief on the coins, the metal, after being melted and refined, was cast into bullets, as appears from the ancient coins not being cut or filed on the edges, but often cracked, and always rough and unequal. These bullets were then put into the die, and received the impression by repeated strokes of the hammer, though sometimes a machine appears to have been used for this purpose: for Boiterue informs us, that there was a picture of the Roman mintage in a grotto near Baiæ, where a machine was represented holding up a large stone as if to let it fall suddenly, and strike the coin at once. None of the ancient money was cast in moulds, excepting the most ancient and very large Roman brass, commonly called *weights*, and other Italian pieces of that sort; all the rest being mere forgeries of ancient and modern times. Some Roman moulds which have been found are a proof of this; and from these some medallists have erroneously imagined that the ancients first cast their money in moulds, and then stamped it, in order to make the impression more clear and sharp.

The ancients had some knowledge of the method of crenating the edges of their coins, which they did by cutting out regular notches upon them; and of this kind we find some of the Syrian and ancient consular coins, with a few others. The former were cast in this shape, and then struck; but the latter were crenated by incision, to prevent forgery, by showing the inside of the metal: however, the ancient forgers also found out a method of imitating this; for Mr Pinkerton informs us, that he had a Roman consular coin, of which the incisions, like the rest, were plated with silver over the copper.

SECT.

Pr rva- n.

Sect. VI. *Of the Preservation of Medals.*

We now come to consider what it is that distinguishes one medal from another, and why some are so highly prized more than others. This, in general, besides its genuineness, consists in the high degree of preservation in which it is. This, by Mr Pinkerton, is called the *conservation* of medals, and is by him regarded as *good* and as *perfect*. In this, he says that a true judge is so nice, that he will reject even the rarest coins if in the least defaced either in the figures or legend. Some, however, are obliged to content themselves with those which are a little rubbed, while those of superior taste and abilities have in their cabinets only such as are in the very state in which they came from the mint; and such, he says, are the cabinets of Sir Robert Austin, and Mr Walpole, of Roman silver, at Strawberryhill. It is absolutely necessary, however, that a coin be in what is called *good* preservation; which in the Greek or Roman emperors, and the colonial coins, is supposed to be when the legends can be read with some difficulty; but when the conservation is perfect, and the coin just as it came from the mint, even the most common coins are valuable.

4 Br and cop best pre ved by rust the overs the

The fine rust, like varnish, which covers the surface of brass and copper coins, is found to be the best preserver of them; and is brought on by lying in a certain kind of soil. Gold cannot be contaminated but by iron mold, which happens when the coin lies in a soil impregnated with iron; but silver is susceptible of various kinds of rust, principally green and red; both of which yield to vinegar. In gold and silver coins the rust must be removed, as being prejudicial; but in brass and copper it is preservative and ornamental; a circumstance taken notice of by the ancients. "This fine rust (says Mr Pinkerton), which is indeed a natural varnish not imitable by the art of man, is sometimes a delicate blue, like that of a turquoise; sometimes of a bronze brown, equal to that observable in ancient statues of bronze, and so highly prized; and sometimes of an exquisite green, a little on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour or pale yellow: which last is exquisite, and shows the impression to as much advantage as paper of cream colour, used in all great foreign presses, does copperplates and printing. The Neapolitan patina (the rust in question) is of a light green; and when free from excrescence or blemish is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of a deeper green is found; and it is sometimes spotted with the red or bronze shade, which gives it quite the appearance of the East Indian stone called the *blood-stone*. These rusts are all, when the real product of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done; concealing at the same time not the most minute particle of the impression of the coin."

Di ent kin of thi ist.

5 M ls ho limi- nis l in val

The value of medals is lowered when any of the letters of the legend are misplaced; as a suspicion of forgery is thus induced. Such is the case with many of those of Claudius Gothicus. The same, or even greater, diminution in value takes place in such coins as have not been well fixed in the die, which has occasioned their slipping under the strokes of the hammer, and thus made a double or triple image. Many coins of this kind are found in which the one side is perfectly well formed, but the other blundered in the manner just mentioned. Another blemish, but of smaller moment, and which to some may be rather a recommendation, is when the workmen through inattention have put another coin into the die without taking out the former. Thus the coin is convex on one side, and concave on the other, having the same figure upon both its sides.

Preservation.

The medals said by the judges in this science to be *countermarked* are very rare, and highly valued. They have a small stamp impressed upon them, in some a head, in others a few letters, such as AUG: N. PROBUS, &c. which marks are supposed to imply an alteration in the value of the coin; as was the case with the countermarked coins of Henry VIII. and Queen Mary of Scotland. Some have a small hole through them; sometimes with a little ring fastened in it, having been used as ornaments; but this makes no alteration in their value. Neither is it any diminution in the value of a coin that it is split at the edges; for coins of undoubted antiquity have often been found in this state, the cause of which has been already explained. On the contrary, this cracking is generally considered as a great merit; but Mr Pinkerton suspects that one of these cracked coins has given rise to an error with respect to the wife of Carausius who reigned for some time in Britain. The inscription is read ORIUNA AUG: and there is a crack in the medal just before the O of oriuna. Without this crack Mr Pinkerton supposes that it would have been read FORTUNA AUG. 77 Countermarked medals.

Some particular soils have the property of giving silver a yellow colour as if it had been gilt. It naturally acquires a black colour through time, which any sulphureous vapour will bring on in a few minutes. From its being so susceptible of injuries, it was always mixed by the ancients with much alloy, in order to harden it. Hence the impressions of the ancient silver coins remain perfect to this day, while those of modern coins are obliterated in a few years. On this account Mr Pinkerton expresses a wish that modern states would allow a much greater proportion of alloy in their silver coin than they usually do. As gold admits of no rust except that from iron above-mentioned, the coins of this metal are generally in perfect conservation, and fresh as from the mint. 78 Silver and gold how tarnished.

To cleanse gold coins from this rust, it is best to steep them in aquafortis, which, though a very powerful solvent of other metals, has no effect upon gold. Silver may be cleansed by steeping for a day or two in vinegar, but more effectually by boiling in water with three parts of tartar and one of sea salt; on both these metals, however, the rust is always in spots, and never forms an entire incrustation as on brass or copper. The coins of these two metals must never be cleansed, as they would thus be rendered full of small holes eaten by the rust. Sometimes, however, they are found so totally obscured with rust, that nothing can be discovered upon them; in which case it is best to clear them with a graver; but it may also be done by boiling them for 24 hours in water with three 79 How to cleanse them.

How to distinguish true from counterfeits.

three parts of tartar and one of alum; not sea salt as in silver coins.

The high state of preservation in which ancient coins are usually found, is thus accounted for by Mr Hancarville. He observes, that the chief reason is

80 When ancient coins are in such a high state of preservation.

the custom of the ancient always to bury one or more coins with their dead, in order to pay for their passage over the river Styx. "From Phidon of Argos (says he) to Constantine I. are 36 generations: and from Magna Græcia to the Euphrates, from Cyrene to the Euxine sea, Grecian arts prevailed, and the inhabitants amounted to above 30,000,000. There died, therefore, in that time and region, not less than ten thousand millions of people, all of whom had coins of one sort or other buried with them. The tombs were sacred and untouched; and afterwards neglected, till modern curiosity or chance began to disclose them. The urn of Flavia Valentina, in Mr Towley's capital collection, contained seven brass coins of Antoninus Pius and Heliogabalus. Such are generally black, from being burnt with the dead. The best and freshest coins were used on these occasions from respect to the dead; and hence their fine conservation. At Syracuse a skeleton was found in a tomb, with a beautiful gold coin in its mouth; and innumerable other instances might be given, for hardly is a funeral urn found without coins. Other incidents also conspire to furnish us with numbers of ancient coins, though the above-recited circumstance be the chief cause of perfect conservation. In Sicily, the silver coins with the head of Proserpine were found in such numbers as to weigh 600 French livres or pounds. In the 16th century, 60,000 Roman coins were found at Modena, thought to be a military chest hid after the battle of Bedriacum, when Otho was defeated by Vitellius. Near Brest, in the year 1760, between 20 and 30,000 Roman coins were found. A treasure of gold coins of Lysimachus was found at Deva on the Marus; and Strabo, lib. vii. and Pausan. in *Attic.* tell that he was defeated by the Getæ; at which time this treasure seems to have fallen into their hands."

81 Number of ancient coins.

Thus Mr Pinkerton, from the authority of Mr Hancarville and others: but considering these vast numbers of coins found in various places, it seems surprising how so few should now remain in the cabinets of the curious, as the same author informs us that the whole of the different ancient coins known to us amount only to about 80,000, though he owns that the calculation cannot be esteemed accurate.

Sect. VII. *How to distinguish true Medals from counterfeits.*

The most difficult and the most important thing in the whole science of medals is the method of distinguishing the true from the counterfeit. The value put upon ancient coins made the forgery of them almost coeval with the science itself; and as no laws inflict a punishment upon such forgers, men of great genius and abilities have undertaken the trade: but whether to the real detriment of the science or not, is a matter of some doubt; for if only exact copies of genuine medals are sold for the originals, the imposition may be deemed trifling: but the case must be accounted very different, if people take it upon them to forge medals which never existed. At first the forgeries were extremely gross; and medals were forged of Priam, of Aristotle, Artemisia, Hannibal, and most of the other illustrious personages of antiquity. Most of these were done in such a manner, that the fraud could easily be discovered; but others have imposed even upon very learned men. Mr Pinkerton mentions a remarkable medal of the emperor Heraclius, representing him in a chariot on the reverse, with Greek and Latin inscriptions, which Joseph Scaliger and Lipsius imagined to have been struck in his own time, but which was certainly issued in Italy in the 15th century. "Other learned men (says our author) have been strangely misled, when speaking of coins; for to be learned in one subject excludes not gross ignorance in others. Budæus, de Asse, quotes a denarius of Cicero, M. TULL. Erasmus, in one of his Epistles, tells us with great gravity, that the gold coin of Brutus struck in Thrace, ΚΟΣΩΝ, bears the patriarch Noah coming out of the ark with his two sons, and takes the Roman eagle for the dove with the olive branch. Winkelman, in his letters informs us, that the small brass piece with Virgil's head, reverse EPO, is undoubtedly ancient Roman; and adds, that no knowledge of coins can be had out of Rome: but Winkelman, so conversant in statues, knew nothing of coins. It is from other artists and other productions that any danger of deceit arises. And there is no wonder that even the skilful are misled by such

82 Coins forged by excellent artists.

artists as have used this trade; for among them appear the names of Victor Gambello, Giovani del Cavino, called the PADUAN, and his son Alessandro Bassiano, likewise of Padua, Benvenuto Cellini, Alessandro Greco, Leo Aretino, Jacobo da Frezzo, Federigo Bonzagna, and Giovani Jacopo, his brother; Sebastiano Plumbo, Valerio de Vizenza, Gorlæus, a German, Carteron of Holland, and others, all or most of them of the 16th century; and Cavino the Paduan, who is the most famous, lived in the middle of that century. The forgeries of Cavino are held in no little esteem, being of wonderful execution. His and those of Carteron are the most numerous, many of the other artists here mentioned not having forged above two or three coins. Later forgers were Dervieu of Florence who confined himself to medallions, and Cogornier who gave coins of the 30 tyrants in small brass. The chief part of the forgeries of Greek medals which have come to my knowledge are of the first mentioned, and a very gross kind, representing persons who could never appear upon coin, such as Priam, Æneas, Plato, Alcibiades, Artemisia, and others. The real Greek coins were very little known or valued till the works of Goltzius appeared, which were happily posterior to the æra of the grand forgers. Why later forgers have seldom thought of counterfeiting them cannot be easily accounted for, if it is not owing to the masterly workmanship of the originals, which set all imitation at defiance. Forgeries, however, of most ancient coins may be met with, and of the Greek among the rest.

83 Roman forgeries more conspicuous than Greek

"The forgeries are more conspicuous among the Roman medals than any other kind of coins; but we are not to look upon all these as the work of modern artists. On the contrary, we are assured that many of them were fabricated in the times of the Romans themselves, some of them being even held in more estimation than the genuine coins themselves, on account of

How to distinguish true from counterfeits.

of their being plated, and otherwise executed in a manner to which modern forgers could never attain. Even the ancients held some of these counterfeits in such estimation, that Pliny informs us there were frequently many true denarii given for one false one."—Caracalla is said to have coined money of copper and lead plated with silver; and plated coins, the work of ancient forgers, occur of many Greek cities and princes; nay, there are even forgeries of barbaric coins. "Some Roman coins (says Mr Pinkerton), are found of iron or lead plated with brass, perhaps trials of the skill of the forger. Iron is the most common; but one decursio of Nero is known of lead plated with copper. Neumann justly observes, that no historic faith can be put in plated coins, and that most faulty reverses, &c. arise from plated coins not being noticed as such. Even of the Roman consular coins not very many have ever been forged. The celebrated silver denarius of Brutus, with the cap of liberty and two daggers, is the chief instance of a consular coin of which a counterfeit is known. But it is easily rejected by this mark: in the true coin the cap of liberty is below the guard or hilt of the daggers; in the false, the top of it rises above that hilt."

84 Denarius of Brutus.

85 Imperial medals.

The imperial series of medals is the grand object of modern medallic forgeries; and the deception was at first extended to the most eminent writers upon the subject. The counterfeits are by Mr Pinkerton divided into six classes.

I. Such as are known to be imitations, but valued on account of the artists by whom they are executed. In this class the medals of the Paduan rank highest; the others being so numerous, that a complete series of imperial medals of almost every kind, nay almost of every medallion, may be formed from among them. In France, particularly, by far the greater part of the cabinets are filled with counterfeits of this kind. They are distinguished from such as are genuine by the following marks: 1. The counterfeits are almost universally thinner. 2. They are never worn or damaged. 3. The letters are modern. 4. They are either destitute of varnish entirely, or have a false one, which is easily known by its being black, shining, and greasy, and very easily hurt by the touch of a needle, while the varnish of ancient medals is as hard as the metal itself. Instead of the greasy black varnish above mentioned, indeed, they have sometimes a light green one, spotted with a kind of iron marks, and is composed of sulphur, verdigrise, and vinegar. It may frequently be distinguished by the hairstrokes of the pencil with which it was laid on being visible upon it. 5. The sides are either filed or too much smoothed by art, or bear the marks of a small hammer. 6. The counterfeits are always exactly circular, which is not the case with ancient medals, especially after the time of Trajan.

86 Paduan forgeries how known.

The Paduan forgeries may be distinguished from those of inferior artists by the following marks: 1. The former are seldom thinner than the ancient. 2. They very seldom appear as worn or damaged, but the others very frequently, especially in the reverse, and legend of the reverse, which sometimes, as in forged Othos, appear as half consumed by time. 3. The letters in moulds taken from the antique coins have the rudeness of antiquity. 4. False varnish is commonly light green or black, and shines too much or too little. 5. The sides of forged coins are frequently quite smooth, and undistinguishable from the ancient, though to accomplish this requires but little art. 6. Counterfeit medals are frequently as irregular in their form as the genuine; but the Paduan are generally circular, though false coins have often little pieces cut off, in perfect imitation of the genuine. 7. In cast coins, the letters do not go sharp down into the medal, and have no fixed outline; their minute angles, as well as those of the drapery, are commonly filled up, and have not the sharpness of the genuine kind. Where the letters or figures are faint, the coin is greatly to be suspected.

How to distinguish true from counterfeits.

87 Letters the principal criterion of medals.

The letters form the great criterion of medals, the ancient being very rude, but the modern otherwise; the reason of which, according to Cellini, is, that the ancients engraved all their matrices with the graver or burin, while the modern forgers strike theirs with a punch.

88 Vico's account of false patina.

According to Vico, the false patina is green, black, russet, brown, gray, and iron colour. The green is made from verdigrise, the black is the smoke of sulphur, the gray is made of chalk steeped in urine, the coin being left for some days in the mixture. The russet is next to the natural, by reason of its being a kind of froth which the fire forces from ancient coins; but when false, it shines too much. To make it they frequently took the large brass coins of the Ptolemies, which were often corroded, and made them red hot in the fire; put the coins upon them, and a fine patina adhered. Our author does not say in what manner the iron-coloured patina was made. "Sometimes (adds he) they take an old defaced coin, covered with real patina, and stamp it anew; but the patina is then too bright in the cavities, and too dull in the protuberances. The trial of brass coins with the tongue is not to be despised; for if modern the patina tastes bitter or pungent, while if ancient it is quite tasteless."

Mr Pinkerton informs us, that all medallions from Julius Cæsar to Adrian are much to be suspected of forgery; the true medals of the first 14 emperors being exceedingly valuable, and to be found only in the cabinets of princes.

89 Medals cast from the Paduan forgeries.

II. The second class of counterfeit medals contains those cast from moulds taken from the Paduan forgeries, and others done by eminent masters. These are sometimes more difficult to be discovered than the former, because in casting them they can give any degree of thickness they please; and, filling the small sandholes with mastic, they retouch the letters with a graver, and cover the whole with varnish. The instructions already given for the former class, however, are also useful for those of the second, with this addition, that medals of this class are generally lighter than the genuine, because fire rarefies the metal in some degree, while that which is struck is rather condensed by the strokes. In gold and silver medals there cannot be any deception of this kind; because these metals admit not of patina, and consequently the varnish betrays the imposition. The marks of the file on the margin of those of the second class are a certain sign of forgery; though these do not always indicate the forgery to be of modern date, because the Romans often filed the edges of coins to accommodate them to the purposes of ornament, as quarter guineas are sometimes

How to distinguish true from counterfeits. times put into the bottom of punch ladles. It is common to imitate the holes of medals made by time by means of aquafortis; but this destroys the sides of a coin more effectually than if it had been eat into naturally. The fraud, however, is not easily distinguished.

90 Medals cast from an antique. III. *Medals cast in moulds from an antique.*—In this mode some forgers, as Beauvais informs us, have been so very careful, that they would melt a common medal of the emperor whom they meant to counterfeit, lest the quality of the metal should betray them. "This (says Mr Pinkerton), has been done in the silver Septimius Severus, with the reverse of a triumphal arch, for which a common coin of the same prince has been melted; and in other instances." Putting medals in the fire or upon hot iron to clease them, gives them an appearance of being cast; for some spots of the metal being softer than the rest will run, which makes this one of the worst methods of cleaning medals.—The directions given for discovering the two former deceptions hold good also in this.

91 Ancient medals retouched. IV. *Ancient Medals retouched and altered.*—This is a class of counterfeits more difficult to be discovered than any other. "The art (says Mr Pinkerton) exerted in this class is astonishing; and a connoisseur is the less apt to suspect it, because the coins themselves are in fact ancient. The acute minds of the Italian artists exerted themselves in this way, when the other forgeries became common and known. With graving-tools they alter the portraits, the reverses, and the inscriptions themselves, in a surprising manner. Of a Claudius struck at Antioch they make an Otho; of a Faustina, a Titiana; of a Julia Severa, a Didia Clara; of a Macrinus, a Pescennius, &c. Give them a Marcus Aurelius, he starts up a Pertinax, by thickening the beard a little, and enlarging the nose. In short, wherever there is the least resemblance in persons, reverses, or legends, an artist may from a trivial medal generate a most scarce and valuable one. This fraud is distinguishable by the false varnish which sometimes masks it; but, above all, by the letters of the legend, which are always altered. Though this be sometimes done with an artifice almost miraculous, yet most commonly the characters straggle, are disunited, and not in a line."

In counterfeits of this kind sometimes the obverse is not touched, but the reverse made hollow, and filled with mastic coloured like the coin, and engraven with such device and legend as was most likely to bring a great price; others are only retouched in some minute parts, by which, however, the value of the coin is much diminished. "Against all these arts (says Mr Pinkerton), severe scrutiny must be made by the purchaser upon the medal itself; and the investigation and opinion of eminent antiquaries had upon its being altered, or genuine as it is issued from the mint."

92 Medals with new devices, or soldered. V. *Medals impressed with new devices, or soldered.*—In the first article of this class the reverses have been totally filed off, and new ones impressed with a die and hammer. This is done by putting the face or obverse, whichever is not touched, upon different folds of pasteboard, afterwards applying the die and striking it with a hammer. The forgery in this class is very easily discovered, as the devices and inscriptions on the counterfeits are known not to exist on true medals: as the Pons Ælius on the reverse of Adrian: the Expeditio Judaica of the same emperor, &c. The difference of fabrication in the face or reverse will be discovered at the first glance by any person of skill.

How to distinguish true from counterfeits.

The soldered medals consist of two halves belonging to different medals, sawed through the middle and then joined with solder. This mode of counterfeiting is common in silver and brass coins. "They will take an Antoninus, for example, and saw off the reverse, then solder to the obverse which they have treated in the same manner. This makes a medal, which, from an unknowing purchaser, will bring a hundred times the price of the two coins, which compose it. When the deceit is used in brass coins, they take care that the metals be of one hue; though indeed some pretenders in this way sometimes solder copper and brass together, which at once reveals the deceit. Medals which have a portrait on each side, and which are generally valuable, are the most liable to a suspicion of this fraud. To a very nice eye the minute ring of solder is always visible; and upon inserting a graver, the fabrication falls into halves."

In the same manner reverses are sometimes soldered to faces not originally belonging to them; as one mentioned by Pere Jobert, of Domitian with an amphitheatre, a reverse of Titus joined to it. Another art is sometimes made use of in this kind of counterfeits, of which there is an instance in the temple of Janus upon Nero's medals; where the middle brass is taken off, and inserted in a cavity made in the middle of a large coin of that prince. In the coins of the lower empire, however, the reverses of medals are sometimes so connected with their obverses, that a suspicion of forgery sometimes occurs without any foundation. They are met with most commonly after the time of Gallienus, when such a number of usurpers arose, that it was difficult to obtain an exact portrait of their features; the coiners had not time, therefore, to strike a medal for these as they could have done for other emperors who reigned longer. Hence, on the reverse of a medal of Marius, who reigned only three days, there is PACATOR ORBIS, which shows that at that time they had reverses ready fabricated, to be applied as occasion might require.

VI. *Plated medals, or those which have clefts.*—It has been already remarked, that many true medals are cracked in tho edges; owing to the repeated strokes of the hammer, and the little degree of ductility which the metal possesses. This the forgers attempt to imitate by a file; but it is easy to distinguish betwixt the natural and artificial cleft by means of a small needle. The natural cleft is wide at the extremity, and appears to have a kind of almost imperceptible filaments; the edges of the crack corresponding with each other in a manner which no art can imitate. 93 Plated medals, &c.

The plated medals which have been forged in ancient times were long supposed to be capable of resisting every effort of modern imitation; but of late years, "some ingenious rogues (says Mr Pinkerton), thought of piercing false medals of silver with a red-hot needle, which gave a blackness to the inside of the coin, and made it appear plated to an injudicious eye. This fraud is easily distinguished by scraping the inside of the metal." It is, however, very difficult to distinguish

distinguish the forgeries of rude money, when not cast; and our author gives no other direction than to consult a skilful medallist. Indeed, notwithstanding all the directions already given, this seems to be a resource which cannot by any means with safety be neglected. A real and practical knowledge of coins "is only to be acquired (says he) by seeing a great number, and comparing the forged with the genuine. It cannot therefore be too much recommended to the young connoisseur, who wishes to acquire some knowledge in this way, to visit all the sales and cabinets he can, and to look upon all ancient medals with a very microscopic eye. By these means only is to be acquired that ready knowledge which enables at first glance to pronounce upon a forgery, however ingenious. Nor let the science of medals be from this concluded to be uncertain; for no knowledge is more certain and immediate, when it is properly studied by examination of the real objects. A man who buys coins, trusting merely to his theoretic perusal of medallic books, will find himself wofully mistaken. He ought to study coins first, where only they can be studied, in themselves. Nor can it be matter of wonder or implication of caprice, that a medallist of skill should at one perception pronounce upon the veracity or falsehood of a medal; for the powers of the human eye, employed in certain lines of science, are amazing. Hence a student can distinguish a book among a thousand similar, and quite alike to every other eye: hence a shepherd can discern, &c.; hence the medallist can say in an instant, 'this is a true coin, and this is a false,' though to other people no distinction be perceptible."

Forgeries of modern coins and medals, Mr Pinkerton observes, are almost as numerous as of the ancient. The satiric coin of Louis XII. PERDAM BABYLONIS NOMEN, is a remarkable instance: the false coin is larger than the true, and bears the date 1512. The rude coins of the middle ages are very easily forged, and forgeries have accordingly become common. Forged coins of Alfred and other early princes of England have appeared, some of which have been done with great art. "The two noted English pennies of Rich. I. says our author, are of this stamp; and yet have imposed upon Messrs Folkes and Snelling, who have published them as genuine in the two best books upon English coins. But they were fabricated by a Mr White of Newgate-street, a noted collector, who contaminated an otherwise fair character by such practices. Such forgeries, though easy, require a skill in the history and coinage of the times, which luckily can hardly fall to the lot of a common Jew or mechanic forger. But the practice is detestable, were no gain proposed: and they who stoop to it must suppose, that to embarrass the path of any science with forgery and futility, implies no infamy. In forgeries of ancient coin, the fiction is perhaps sufficiently atoned for by the vast skill required; and the artist may plausibly allege, that his intention was not to deceive, but to excite his utmost powers, by an attempt to rival the ancient masters. But no possible apology can be made for forging the rude money of more modern times. The crime is certainly greater than that which leads the common coiner to the gallows; inasmuch as it is committed with more ease, and the profit is incomparably larger."

Value.

SECT. VIII. *Of the Value of Medals.*

ALL ancient coins and medals, though equally genuine, are not equally valuable. In medals as well as in every thing else, the scarcity of a coin stamps a value upon it which cannot otherwise be derived from its intrinsic worth. There are four or five degrees of rarity reckoned up; the highest of which is called *unique*. The cause is generally ascribed to the fewness of number thrown off originally, or to their having been called in, and recoined in another form. To the former cause Mr Pinkerton ascribes the scarcity of the copper of Otho and the gold of Pescennius Niger; to the latter that of the coinage of Caligula; "though this last (says he) is not of singular rarity; which shows that even the power of the Roman senate could not annihilate an established money; and that the first cause of rarity, arising from the small quantity originally struck, ought to be regarded as the principal."

96 Causes of the scarcity of medals in ancient cities.

In the ancient cities Mr Pinkerton ascribes the scarcity of coin to the poverty or smallness of the state; but the scarcity of ancient regal and imperial coins arises principally from the shortness of the reign; and sometimes from the superabundance of money before, which rendered it almost unnecessary to coin any money during the reign of the prince. An example of this we have in the scarcity of the shillings of George III. which shows that shortness of reign does not always occasion a scarcity of coin: and thus the coins of Harold II. who did not reign a year, are very numerous, while those of Richard I. who reigned ten, are almost unique.

97 Rare coins sometimes become common, and *vice versa.*

Sometimes the rarest coins lose their value, and become common. This our author ascribes to the high price given for them, which tempts the possessors to bring them to market; but chiefly to the discovering of hoards of them. The former cause took place with Queen Anne's farthings, some of which formerly sold at five guineas; nay, if we could believe the newspapers, one of them was some years ago sold for 960l.; the latter with the coins of Canute, the Danish king of England; which were very rare till a hoard of them was discovered in the Orkneys. As discoveries of this kind, however, produce a temporary plenty, so when they are dispersed the former scarcity returns; while, on the other hand, some of the common coins become rare through the mere circumstance of neglect.

98 Silver coins in what cases most esteemed.

As double the number of copper coins of Greek cities are to be met with that there are of silver, the latter are of consequence much more esteemed: but the reverse is the case with those of the Greek princes. All the Greek civic coins of silver are very rare, excepting those of Athens, Corinth, Messana, Dyrrhachium, Massilia, Syracuse, and some others. Of the Greek monarchic coins, the most rare are the tetradrachms of the kings of Syria, the Ptolemies, the sovereigns of Macedon and Bithynia, excepting those of Alexander the Great and Lysimachus. Those of the kings of Cappadocia are of a small size, and scarce to be met with. Of those of Numidia and Mauritania, the coins of Juba, the father, are common; but those of

Value. of the son, and nephew Ptolemy, scarce. Coins of the kings of Sicily, Parthia, and Judea, are rare; the last very much so. We meet with no coins of the kings of Arabia and Comagene except in brass; those of the kings of Bosphorus are in electrum, and a few in brass, but all of them rare; as are likewise those of Philetenis king of Pergamus, and of the kings of Pontus. In the year 1777, a coin of Mithridates sold for 26l. 5s. Didrachms of all kings and cities are scarce, excepting those of Corinth and her colonies; but the gold coins of Philip of Macedon, Alexander the Great, and Lysimachus, as has already been observed, are common. The silver tetradrachms of all kings bear a very high price. The didrachm of Alexander the Great is one of the scarcest of the smaller Greek silver coins; some of the other princes are not uncommon.

99 Greek copper coins. In most cases the copper money of the Greek monarchs is scarce; but that of Hiero I. of Syracuse is uncommonly plenty, as well as that of several of the Ptolemies.

100 Roman consular coins. The most rare of the consular Roman coins are those restored by Trajan: of the others the gold consular coins are the most rare, and the silver the most common; excepting the coin of Brutus with the cap of liberty, already mentioned, with some others. Some of the Roman imperial coins are very scarce, particularly those of Otho in brass; nor indeed does he occur at all on any coin struck at Rome: but the reason of this may with great probability be supposed to have been the shortness of his reign. His portrait upon the brass coins of Egypt and Antioch is very bad: as well as almost all the other imperial coins of Greek cities. The best likeness is on his gold and silver coins; the latter of which are very common. The Greek and Egyptian coins are all of small or middling sizes, and have reverses of various kinds: those of Antioch have Latin legends, as well as most of the other imperial coins of Antioch. They have no other reverse but the SC in a wreath; excepting in one instance or two of the large and middle brass, where the inscriptions are in Greek. Latin coins of Otho in brass, with figures on the reverse, are certainly false; though in the cabinet of D'Ennery at Paris there was an Otho in middle brass restored by Titus, which was esteemed genuine by connoisseurs.

101 Leaden Roman coins. The leaden coins of Rome are very scarce: Most of them are pieces struck or cast on occasion of the saturnalia; others are tickets for festivals and exhibitions, both private and public. The common tickets for theatres were made of lead, as were the *contorniati*; perpetual tickets, like the English silver tickets for the opera. Leaden medallions are also found below the foundations of pillars and other public buildings, in order to perpetuate the memory of the founders. From the time of Augustus also we find that leaden seals were used. The work of Ticorini upon this subject, entitled *Piombi Antiochi*, is much recommended by Mr Pinkerton.

102 Of coins blundered in the mintage. The Roman coins, which have been blundered in the manner formerly mentioned, are very rare, and undeservedly valued by the connoisseurs. The blunders in the legends of these coins, which in all probability are the mere effects of accident, have been so far mistaken by some medallists, that they have given rise to imaginary emperors who never existed. A coin of Faustina, which has on the reverse SOUSTI. S. C. puzzled all the German antiquaries, till at last Klotz gave it the following facetious interpretation: *Sine omni utilitate sectamini tantas ineptias.*

103 Heptarchic coins of England. The heptarchic coins of England are generally rare, except those called *stycas*, which are very common, as well as those of Burgred king of Mercia. The coins of Alfred which bear his bust are scarce, and his other money much more so. Those of Hardyknute are so rare, that it was even denied that they had an existence; but Mr Pinkerton informs us, that there are three in the British museum, upon all of which the name HARTHCANUT is quite legible. No English coins of King John are to be met with, though there are some Irish ones; and only French coins of Richard I. "Leake (says Mr Pinkerton) made a strange blunder, in ascribing coins of different kings with two faces, and otherwise spoiled in the stamping, to this prince; in which, as usual, he has been followed by a misled number."

104 Scottish coins. Coins of Alexander II. of Scotland are rather scarce, but those of Alexander III. are more plentiful. Those of John Baliol are rare, and none of Edward Baliol are to be found.

Sect. IX. *Of the Purchase of Medals.*

Purchase. MEDALS are to be had at the shops of goldsmiths and silversmiths, with those who deal in curiosities, &c. but in great cities there are professed dealers in them. The best method of purchasing medals, however, is that of buying whole cabinets, which are every year exposed to auction in London. In these the rare medals are sold by themselves: but the common ones are put up in large lots, so that the dealers commonly purchase them. Mr Pinkerton thinks it would be better that medals were sold one by one; because a lot is often valued and purchased for the sake of a single coin; while the others separately would sell for perhaps four times the price of the whole lot. "If any man of common sense and honesty (says Mr Pinkerton), were to take up the trade of selling coins in London, he would make a fortune in a short time. This profitable business is now in the hands of one or two dealers, who ruin their own interest by making an elegant study a trade of knavery and imposition. If they buy 300 coins for 10s. they will ask 3s. for one of the worst of them! nay, sell forged coins as true to the ignorant. The simpletons complain of want of business. A knave is always a fool."

10[5] Price of gold coins of Carthage. The gold coins of Carthage, Cyrene, and Syracuse, are worth about twice their intrinsic value as metal; but the other gold civic coins from 5l. to 30l. each. The only gold coins of Athens certainly known to exist are two lately procured by the king. One of these remains in possession of his majesty, but the other was given by the queen to Dr Hunter. There was another in the British museum, but suspected not to be genuine. Dr Hunter's coin, then, if sold, would bear the highest price that could be expected for a coin.

10[6] Of silver coins. The silver coins of Syracuse, Dyrrhachium, Massilia, Athens, and a few other states, are common; the drachmas and coins of lesser size are worth about five

Pur ase.

five shillings; the didrachms, tetradrachms, &c. from five to ten, according to their size and beauty; the largest, as might naturally be expected, being more valuable than the small ones. The tetradrachms, when of cities whose coins are common, are worth from 7s. 6d. to 1l. 1s.; but it is impossible to put a value upon the rare civic coins; ten guineas have been given for a single one.

Gre cop- er is.

The Greek copper coins are common, and are almost all of that kind called *small brass;* the middle size being scarce, and the largest in the ages prior to the Roman emperors extremely so. The common Greek coins of brass bring from 3d. to 18d. according to their preservation; but when of cities, whose coins are rare, much higher prices are given. "The want of a few cities, however, (says Mr Pinkerton), is not thought to injure a collection; as indeed new names are discovered every dozen of years, so that no assortment can be perfect. To this it is owing that the rarity of the Grecian civic coins is not much attended to."

8 Gol oins of P ip and ex- and

The gold coins of Philip and Alexander the Great being very common, bear but from five to ten shillings above their intrinsic value; but those of the other princes, being rare, sell from 3l. to 30l. each, or even more.

The tetradrachms are the dearest of the silver monarchic money, selling from five to ten shillings; and if very rare, from 3l. to 30l. Half these prices may be obtained for the drachmas, and the other denominations in proportion.

9 Gre cop- per ns mor are tha e sil

The Greek copper coins are for the most part scarcer than the silver, except the Syro-Grecian, which are common, and almost all of the size called small brass. They ought (says Mr Pinkerton), to bear a high price; but the metal and similarity to the copper civic coins, which are common, keep their actual purchase moderate, if the seller is not well instructed, and the buyer able and willing to pay the price of rarity."

The name of weights given to the ancient Roman ases is, according to our author, exceedingly improper; as that people had weights of lead and brass sides, without the least appearance of a portrait upon them. These denote the weight by a certain number of knobs; and have likewise small *fleurettes* engraved upon them. According to Mr Pinkerton, whenever we meet with a piece of metal stamped on both sides with busts and figures, we may lay it down as a certain rule that it is a coin; but when slightly ornamented and marked upon one side only, we may with equal certainty conclude it to be a weight.

o Pri of the anc tRo- ma ses.

The ancient Roman ases are worth from 2s. to 2l. according to the singularity of their devices. Consular gold coins are worth from 1l. to 5l. Pompey with his sons 21l. and the two Bruti 25l. The silver coins are universally worth from a shilling to half a crown, excepting that of the cap of liberty and a few others, which, if genuine, will bring from 10s. to 5l. The consular copper bears an equal price with the silver, but is more rare; the consular silver coins restored by Trajan are worth 20s. each.

With regard to the Roman imperial coins, it is to be observed, that some of those which belong to princes whose coins are numerous, may yet be rendered extremely valuable by uncommon reverses. Mr Pinkerton particularly points out that of Augustus, with the legend C. MARIVS TROGVS, which is worth three guineas, though the silver coins of that prince in general are not worth above a shilling. In like manner, the common gold coins of Trajan are not worth above twenty shillings; while those with *Basilica Ulpia, Forum Trajani, Divi Nerva et Trajanus, Pater, Divi Nerva et Platina Aug. Profectio Aug. Regna Assignata, Rex Parthus*, and some others, bear from three to six pounds. The ticket medals belong to the Roman senate, and are worth from three to ten shillings. The forged coins and medallions of the Paduan sell from one to three shillings each.

Arrangement, &c.

111 Barbaric coins.

Of the coins of other nations, those of Hilderic king of the Vandals are in silver, and worth 10s.; the small brass of Athanaric, 5s.; the gold of Theodoric 2l.; the second brass of Theodahat 5s.; the second brass of Baducta rare, and worth 10s.; the third brass, 3s. The British coins are very rare, and worth from ten shillings to two guineas each, sometimes much more. Medals with unknown characters are always scarce and dear. Saxon pennies of the heptarchy are rare, and worth from ten shillings to *ten pounds*, according to their scarcity and preservation. The coins of the English kings are common; those of Edward the Confessor, in particular; others are rare, and worth from ten shillings to two guineas, while two of Hardyknute are worth no less than ten guineas. The gold medals of Henry, in 1545, and the coronation of Edward, are worth 20l. each: the Mary of Trezzo, 3l.; Simon's head of Thurloe in gold is worth 12l.; his oval medal in gold upon Blake's naval victory at sea is worth 30l.; and his trial piece, if brought to a sale, would, in Mr Pinkerton's opinion, bring a still higher price. The medals of Queen Anne, which are intrinsically worth about two guineas and a half, sell for about 3l. each; the silver, of the size of a crown piece, sell for 10s. and the copper from five to ten shillings. Dassier's copper pieces sell from two to five shillings, and a few bear a higher price.

112 Gold coins of Scotland.

The Scottish gold coins sell higher than the English, but the others are on a par. The shilling of Mary with the bust is rare, and sells for no less than 30l.; the half 3l.; and the royal 5l. 5s. The French testoon of Francis and Mary brings 10l. 10s. and the Scottish one of Mary and Henry would bring 50l. as would also the medal of James IV. The coronation medal of Francis and Mary is worth 20l. Briot's coronation medal sold in 1755 only for two guineas at Dr Mead's sale; but would now bring 20l. if sold according to rarity.

113 English coins struck in Ireland.

The English coins struck in Ireland are of much the same price with those of the native country; but the St Patrick's halfpence and farthings are rather scarce, and the rare crown of white metal is worth 4l. The gun-money of James II. and all other Irish coins are very common.

SECT. X. *Arrangement of Medals, with the Instruction to be derived from them.*

HAVING thus given a full account of every thing in general relative to medals, we must now come to some particulars respecting their arrangement, and the enter-

tainment

Arrangement, &c.

tainment which a medallist may expect from the trouble and expence he is at making a collection.

It has already been observed, that one of the principle uses of medals is the elucidation of ancient history. Hence the arrangement of his medals is the first thing that must occur in the formation of a cabinet. The most ancient medals with which we are acquainted are those of Alexander I. of Macedon, who began to reign about 501 years before Christ. The series ought of consequence to begin with him, and to be succeeded by the medals of Sicily, Caria, Cyprus, Heraclia, and Pontus. Then follow Egypt, Syria, the Cimmerian Bosphorus, Thrace, Bithynia, Parthia, Armenia, Damascus, Cappadocia, Paphlagonia, Pergamus, Galatia, Cilicia, Sparta, Pæonia, Epirus, Illyricum, Gaul, and the Alps, including the space of time from Alexander the Great to the birth of Christ, and which is to be accounted the third medallic series of ancient monarchs. The last series goes down to the fourth century, including some of the monarchs of Thrace, Bosphorus, and Parthia, with those of Comagene, Edessa or Osrhoene, Mauritania, and Judæa. A most distinct series is formed by the Roman emperors, from Julius Cæsar to the destruction of Rome by the Goths; nay, for a much longer period, were it not that towards the latter part of it the coins become so barbarous as to destroy the beauty of the collection. Many series may be formed of modern potentates.

114
Diadem an ancient emblem of sovereign authority.

By means of medals we can with great certainty determine the various ornaments worn by ancient princes as badges of distinction. The Grecian kings have generally the diadem, without any other ornament; and though in general the side of the face is presented to view, yet in some very ancient Greek and Roman consular coins, full faces of excellent workmanship are met with. On several coins also two or three faces are to be seen, and these are always accounted very valuable.

The diadem, which was no more than a ribbon tied round the head with a floating knot behind, adorns all the Grecian princes from first to last, and is almost an infallible mark of sovereign power. In the Roman consular coins it is seen in conjunction with Numa and Ancus, but never afterwards till the time of Licinius, the colleague of Constantine. Dioclesian, indeed, according to Mr Gibbon, first wore the diadem, but his portrait upon coins is never adorned with it. So great an aversion had the Romans to kingly power, that they rather allowed their emperors to assume the radiated crown, the symbol of divinity, than to wear a diadem; but, after the time of Constantine, it becomes common. The radiated crown appears first on the posthumous coins of Augustus as a mark of deification, but in somewhat more than a century became common.

The laurel crown, at first a badge of conquest, was afterwards permitted by the senate to be worn by Julius Cæsar, in order to hide the baldness of his head. From him all the emperors appear with it on their medals, even to our own times. In the lower empire the crown is sometimes held by a hand above the head, as a mark of piety. Besides these, the naval, mural, and civic crowns appear on the medals both of emperors, and other eminent men, to denote their great actions. The laurel crown is also sometimes worn by the Greek princes. The Arsacidæ of Parthia wear a kind of sash round the head, with their hair in rows of curls like a wig. The Armenian kings have the *tiara*, a kind of cap which was esteemed the badge of imperial power in the east. Conical caps are seen on the medals of Xerxes, a petty prince of Armenia, and Juba the father, the former having a diadem around it.

115
Symbols of divinity on the coins of Alexander and his successors.

The impious vanity of Alexander and his successors in assuming divine honours is manifest on their medals, where various symbols of divinity are met with. Some of them have the horn behind their ear, either to denote their strength, or that they were the successors of Alexander, to whom this badge might be applied as the son of Jupiter Ammon. This, however, Mr Pinkerton observes, is the only one of these symbols which certainly denotes an earthly sovereign, it being doubted whether the rest are not all figures of gods.—According to Eckhet, even the horn and diadem belong to Bacchus, who invented the latter to cure his headaches; and, according to the same author, the only monarch who appears on coins with the horn is Lysimachus. We are informed, however, by Plutarch, that Pyrrhus had a crest of goats horns to his helmet; and the goat, we know, was a symbol of Macedon. Perhaps the successors of Alexander wore this badge of the horn in consequence. The helmet likewise frequently appears on the heads of sovereigns, and Constantine I. has helmets of various forms curiously ornamented.

The diadem is worn by most of the Greek queens, by Orodaltis, daughter of Lycomedes, king of Bithynia; and though the Roman empresses never appear with it, yet this is more than compensated by the variety of their headdresses. Sometimes the bust of an empress is supported by a crescent, to imply that she was the moon, as her husband was the sun of the state. The toga, or vail drawn over the face, at first implied that the person was invested with the pontifical office; and accordingly we find it on the busts of Julius Cæsar, while pontifex maximus. It likewise implies the augurship, the augurs having a particular kind of gown called *lana*, with which they covered their heads when observing an omen. In latter times this implies only consecration, and is common in coins of empresses. It is first met with on the coins of Claudius Gothicus as the mark of consecration of an emperor. The *nimbus*, or glory, now appropriated to saints, has been already mentioned. It is as ancient as Augustus, but is not to be met with on many of the imperial medals, even after it began to be appropriated to them. There is a curious coin, which has upon the reverse of the common piece, with the head of Rome, Urbs Roma, in large brass, Constantine I. sitting amid Victories and genii, with a triple crown upon his head for Europe, Asia, and Africa, with the legend Securitas Romæ.

Portraits upon medals

In general only the bust is given upon medals, though sometimes half the body or more; in which latter case the hands often appear with ensigns of majesty in them; such as the globe, said to have been introduced by Augustus as a symbol of universal dominion; the sceptre, sometimes confounded with the consular staff; a roll of parchment, the symbol of legislative

Arrangement, &c. tive power; and an handkerchief, expressive of the power over the public games, where the emperor gave the signal. Some princes hold a thunderbolt, showing that their power on earth was equal to that of Jupiter in heaven, while others hold an image of Victory.

Medals likewise afford a good number of portraits of illustrious men; but they cannot easily be arranged in chronological order, so that a series of them is not to be expected. It is likewise vain to attempt the formation of a series of gods and goddesses to be found on ancient coins. Mr Pinkerton thinks it much better to arrange them under the several cities or kings whose names they bear. A collection of the portraits of illustrious men may likewise be formed from medals of modern date.

117 Reverses of Greek and Roman coins. The reverses of ancient Greek and Roman coins afford an infinite variety of instruction and amusement. They contain figures of deities at full length, with their attributes and symbols, public symbols and diversions, plants, animals, &c. &c. and in short almost every object of nature or art. Some have the portrait of the queen, son, or daughter of the prince whose image appears on the face obverse; and these are esteemed highly by antiquaries, not only because every coin stamped with portraits on both sides is accounted valuable, but because they render it certain that the person represented on the reverse was the wife, son, or daughter of him who appears on the obverse; by which means they assist greatly in the adjusting of a series. Some, however, with two portraits are common, as Augustus, the reverse of Caligula; and Marcus Aurelius, reverse of Antoninus Pius.

We find more art and design in the reverses of the Roman medals than of the Greek; but on the other hand, the latter have more exquisite relief and workmanship. The very ancient coins have no reverses, excepting a rude mark struck into the metal, resembling that of an instrument with four blunt points on which the coin was struck; and was owing to its having been fixed by such an instrument on that side to receive the impression upon the other. To this succeeds the image of a dolphin, or some small animal, in one of the departments of the rude mark, or in a hollow square: and this again is succeeded by a more perfect image, without any mark of the hollow square. Some of the Greek coins are hollow in the reverse, as those of Caulonia, Crotona, Metapontum, and some other ancient cities of Magna Græcia. About 500 B. C. perfect reverses appear on the Greek coins, of exquisite relief and workmanship. "The very muscles of men and animals (says Mr Pinkerton), are seen, and will bear inspection with the largest magnifier as ancient gems. The ancients certainly had not eyes different from ours; and it is clear that they must have magnified objects. A drop of water forms a microscope; and it is probable this was the only one of the ancients. To Greek artists we are indebted for the beauty of the Roman imperial coins; and these are so highly finished, that on some reverses, as that of Nero's decursion, the *adventus* and *progressio* of various emperors, the *fundator pacis* of Severus, the features of the emperor, riding or walking, are as exact as on the obverse. But though the best Greek artists were called to Rome, yet the Greek coins under the Roman emperors are sometimes well executed, and always full of variety and curiosity. No Roman or Etruscan coins have been found of the globular form, or indented on the reverse like the early Greek. The first Greek are small pieces of silver, while the Roman are large masses of copper. The former are struck; the latter cast in moulds. The reverses of the Roman coins are very uniform, the prow of a ship, a car, or the like, till about the year 100 B. C. when various reverses appear on their consular coins in all metals. The variety and beauty of the Roman imperial reverses are well known, The medallist much values those which have a number of figures; as the *Puellæ Faustinianæ*, of Faustina, a gold coin no larger than a sixpence, which has 12 figures; that of Trajan, *regna assignata*, has four; the *congiarium* of Nerva five; the allocution of Trajan seven; of Hadrian 10; of Probus 12. Some Roman medals have small figures on both sides, as the *Apollini sancto* of Julian II. Such have not received any peculiar name among the medallists. Others have only a reverse, as the noted *spintriati*, which have numerals I. II. &c. on the obverse."

118 Of the deities represented upon ancient coins. The *names* of the deities represented on the reverses of Greek coins are never expressed; perhaps, as Mr Pinkerton supposes, out of piety, a symbolical representation of their attributes being all that they thought proper to delineate; but the Roman coins always express the name, frequently with an adjunct, as VENERI VICTRICI, &c. In others, the name of the emperor or empress is added; as PUDICITIÆ AUGUSTÆ, round an image of modesty; VIRTUS AUGUSTI, a legend for an image of virtue.

The principal symbols of the divine attributes to be met with on the Greek medals are as follow:

1. Jupiter is known on the coins of Alexander the Great by his eagle and thunderbolts; but when the figure occurs only on the obverses of coins, he is distinguished by a laurel crown, and placid bearded countenance. Jupiter Ammon is known by the ram's horn twisting round his ear; a symbol of power and strength, assumed by some of the successors of Alexander the Great, particularly by Lysimachus.

2. Neptune is known by his trident, dolphin, or being drawn by sea horses; but he is seldom met with on the Grecian coins.

3. Apollo is distinguished by an harp, branch of laurel, or tripod; and sometimes by a bow and arrows. In the character of the sun, his head is surrounded with rays; but when the bust only occurs, he has a fair young face, and is crowned with laurel. He is frequent on the coins of the Syrian princes.

4. Mars is distinguished by his armour, and sometimes by a trophy on his shoulders. His head is armed with a helmet, and has a ferocious countenance.

5. Mercury is represented as a youth, with a small cap on his head, wings behind his ears and on his feet. He is known by the cap, which resembles a small hat, and the wings. He appears also with the caduceus, or wand twined with serpents, and the *marsupium*, or purse, which he holds in his hand.

6. Æsculapius is known by his bushy beard, and his leaning on a club with a serpent twisted round it. He

Arrangement, &c.

He sometimes occurs with his wife Hygeia or Health, with their son *Telesphorus* or Convalescence between them.

7. Bacchus is known by his crown of ivy or vine, his diadem and horn, with a tyger and satyrs around him.

8. The figure of Hercules is common on the coins of Alexander the Great, and has frequently been mistaken for that of the prince himself. He appears sometimes as a youth and sometimes with a beard. He is known by the club, lion's skin, and remarkable apparent strength; sometimes he has a cup in his hand; and a poplar tree, as a symbol of vigour, is sometimes added to the portrait.

9. The Egyptian Serapis is known by his bushy beard, and a measure upon his head.

10. Apis is delineated in the form of a bull, with a flower of the lotos, the water lily of the Nile, supposed by Macrobius to be a symbol of creation; and Jamblichus tells us, that Osiris was thought to have his throne in it.

11. Harpocrates, the god of Silence, appears with his finger on his mouth; sometimes with the sistrum in his left hand; a symbol common to most of the Egyptian deities.

12. Canopus, another Egyptian deity, appears in the shape of a human head placed on a kind of pitcher. "This deified pitcher (says Mr Pinkerton), seems to refer to an anecdote of ancient superstition, which, I believe, is recorded by Plutarch. It seems some Persian and Egyptian priests had a contest which of their deities had the superiority. The Egyptian said, that a single vase, sacred to Serapis, would extinguish the whole power of the Persian deity of fire. The experiment was tried; and the wily Egyptian, boring holes in the vase and stopping them with wax, afterwards filled the vase with water; which, gushing through the holes as the wax melted, extinguished the Persian deity. Hence the vase was deified."

13. The *Holy Senate* and *Holy People*, appear frequently on the Greek imperial coins, sometimes represented as old men with beards, at others as youths.

The goddesses represented on medals are,

1. Juno, represented by a beautiful young woman, sometimes with a diadem, sometimes without any badge, which is reckoned a sufficient distinction, as the other goddesses all wear badges. Sometimes she appears as the goddess of marriage; and is then veiled to the middle, and sometimes to the toes. She is known by the peacock, a bird sacred to her from the fable of Argus.

2. Minerva is very common on the coins of Alexander the Great; and her bust has been mistaken by the celebrated painter Le Brun for the hero himself. She is very easily distinguished by the helmet. Her symbols are, her armour; the spear in her right hand and the ægis, with a Medusa's head, in her left; an owl commonly standing by her.

3. Diana of Ephesus is commonly represented on the Greek imperial coins; and appears with a great number of breasts, supposed to denote universal Nature. She is supported by two deer, and carries a pannier of fruit upon her head. The bust of this goddess is known by the crescent on her brow, and sometimes by the bow and quiver at her side.

Arrangement, &c.

4. Venus is known by an apple, the prize of beauty, in her hand. Sometimes she is distinguished only by her total want of dress; but is always to be known by her extraordinary beauty, and is sometimes adorned with pearls about the neck.

5. Cupid is sometimes met with on the Syrian coins, and is known by his infancy and wings.

6. Cybele is known by a turreted crown and lion; or is seen in a chariot drawn by lions.

7. Ceres is known by her garland of wheat, and is common on the Sicilian coins; that island being remarkable for its fertility. Sometimes she has two serpents by her, and is sometimes drawn in a chariot by them. She carries in her hands the torches with which she is fabled to have gone in search of her daughter Proserpine.

8. Proserpine herself is sometimes met with on coins, with the name of κορη, or the *girl*.

9. The Egyptian Isis has a bud or flower on her head; a symbol of the perpetual bloom of the inhabitants of heaven. She carries also a sistrum in her hand.

10. The Sidonian Astarte appears on a globe supported on a chariot with two wheels, and drawn by two horses.

These are the deities most commonly represented on the Greek coins. The more uncommon are, Saturn with his scythe, or with a hook on the Heraclian coins; Vulcan with his tongs on the reverse of a coin of Thyatira, represented at work in the presence of Minerva. Adranus, a Sicilian god, is sometimes represented on coins with a dog. Anubis, an Egyptian deity, has a dog's head. Atis is known by his Phrygian bonnet; Castor and Pollux by a star on the head of each; Dis, by his old face, dishevelled hair and beard, and a hook: Flora by her crown of flowers; Nemesis by her wheel; and Pan by his horns and ears belonging to some kind of beast. 119

Table of symbols.

There are likewise to be found on medals many different symbols by themselves; of the most remarkable of which we shall give the following table, with their signification:

Symbols.	*Significations.*
1. Vases with sprigs, -	Solemn games.
2. Small chest or hamper, with a serpent leaping out,	Mystic rites of Bacchus.
3. Anchor on Seleucian medals,	Coin struck at Antioch, where an anchor was dug up.
4. Apollo on Syrian coins, on an inverted hamper,	Covered tripod.
5. Bee, - - -	Aristeus the son of Apollo.
6. Laurel, - - -	Apollo.
7. Reed, - - -	A river.
8. Ivy and grapes, - -	Bacchus.
9. Poppy, - - -	Ceres and Proserpine.
10. Corn, - - -	Ceres.
11. Owl and olive, - -	Minerva.
12. Dove, - - -	Venus.

13.

Symbols.	Significations.
13. Torch, - - - -	Diana, Ceres, or Proserpine.
14. Mudnis, or conic stone, -	The sun, Belus, or Venus.
Symbols of Countries, &c.	
15. Pomegranate flowers, -	Rhodes.
16. Owl, - -	Athens.
17. Pegasus, - -	Corinth.
18. Wolf's head, - -	Argos.
19. Bull's head, - -	Bœotia.
20. Minotaur's head and labyrinth,	Crete.
21. Horse's head, - -	Pharsalia.
22. Lion, - - -	Marseilles.
23. Tortoise, - - -	Peloponnesus.
24. Sphinx, - -	Scio.
25. Three legs joined as in the Isle of Man money, - -	Sicily.
26. Horse, - - -	Thessaly.
27. The crescent, - -	Byzantium (A)
28. Bull, - - -	Supposed to be a river.
29. Ensign, with the letters COL.	A colony drawn from one legion.
30. Bull, - - . -	Apis, strength or security.
31. Caduceus, - - -	Peace and concord.
32. Cornucopiæ, - -	Abundance.
33. Pontifical hat, - -	Priesthood.
34. Parazonium, - -	Batoon of command.
35. Globe on an altar with three stars, - - - -	The world preserved by the gods for the three sons of Constant. I.
36. Fort and gate, -	Security.
37. Tribuli, a kind of chevaux de frize, - - -	Unknown.
38. Altar or tripod, - -	Piety.
39. Dolphin, - - -	Apollo.
40. Lectisternia, - -	Festivals.
41. Lituus, or twisted wand, -	Augurship.
42. Apex, or cap with strings,	Pontificate.
43. Thensa, or chariot employed to carry images, - -	Consecration of an empress.
44. Peacock, - - -	Ditto.
45. Eagle, - - -	Consecration of an emperor.

Arrangement, &c.

120 *Legends of medals.*

The legends put upon medals are designed as explanations of them; but as the compass of even the largest coins does not admit of any great length of inscription, it has always been found necessary to use abbreviations; and in readily decyphering these lies a considerable part of the difficulty of the science. This, however, is greater in the Roman than in the Greek medals; for the Greeks commonly insert as much of the word as is sufficient to enable us easily to understand its meaning; but it is common for those who attempt to explain letters that do not often occur, to fall into very ridiculous errors. Of this Mr Pinkerton gives a most remarkable instance in Fortunius Licetus, a learned man, who finding upon a coin of Adrian the letters, Γ. ΙΔ signifying the 14th year of that emperor's reign, imagined that they signified *Lucernas invenit Delta;* "Delta invented lanthorns;" and thence ascribed the origin of lanthorns to the Egyptians. Tables explaining the meaning of the abbreviations found upon medals have been published by Patin, Ursatus, and others.

121 *Extraordinary mistake of Fortunius Licetus.*

SECT. XI. *Of Medallions, Medalets*, &c.

BESIDES the ordinary coins of the ancients, which passed in common circulation through the country, there were others of a larger size, which are now termed *medallions*. These were struck on the commencement of the reign of a new emperor and other solemn occasions: frequently also, by the Greeks in particular, as monuments of gratitude or of flattery. Sometimes they were mere trial or pattern pieces; and those abound after the time of Maximian, with the words *Tres Monetæ* on the reverse. The common opinion is, that all the Roman pieces of gold exceeding the denarius aureus, all in silver exceeding the denarius, and all in brass exceeding the sestertius, went under the denomination of *medallions:* but Mr Pinkerton thinks that many of these large pieces went in circulation, though not very commonly, as our five and two guinea pieces, silver crowns, &c. do in this country. The finest medallions were presented by the mint-masters to the emperor, and by the emperor to his friends, as specimens of fine workmanship. The best we have at present are of brass, and many of them composed of two sorts of metal; the centre being copper, with a ring of brass around it, or the contrary; and the inscription is sometimes confined to one of the metals, sometimes not. There is a remarkable difference between the Greek and Roman medallions in point of thickness; the latter being frequently three or four lines thick, while the other seldom exceed one. Very few medallions, however, were struck by the Greeks before the time of the Roman emperors; but the Greek medallions of the emperors are more numerous than those

(A) This appears on the early coins of Byzantium, with the legend ΒΥΖΑΝΤΙΝ. ΣΩΤ. "the preserver of Byzantium." The reason of this was, that when Philip of Macedon besieged the city, and was about to storm it in a cloudy night, the moon shone out on a sudden and discovered him; by which means the inhabitants had time to collect their forces and repulse him. The Turks on entering Constantinople, found this badge in many places; and suspecting some magical power in it, assumed the symbol, and its power, to themselves; so that the crescent is now the chief Turkish ensign.

Medallions, &c. those of the Romans themselves. And all these pieces, however, are of such high price that few private persons are able to purchase them. In the last century Christina queen of Sweden procured about 300. In the king of France's collection there are 1200; a number formerly supposed not to exist; and Dr Hunter's collection contains about 400, exclusive of the Egyptian.

Besides these large pieces, there are smaller ones, of a size somewhat larger than our half-crowns; and by Italian medallists are called *medaglion cini*, or small medallions. They are still scarcer than the large kind.

122 Of medalets. There is still a third kind, which have almost escaped the notice of medallists, viz. the small coins or *missilia* scattered among the people on solemn occasions; such as those struck for the slaves on account of the saturnalia; counters for gaming; tickets for baths and feasts; tokens in copper and in lead, &c. These are distinguished by Mr Pinkerton by the name of *medalets*. Many, or perhaps almost all, of those struck for the saturnalia were satirical; as the slaves had then a license to ridicule not only their masters but any person whatever. Mr Pinkerton mentions one of the most common pieces of this kind, which has on the obverse the head of an old woman veiled, with a laurel crown; the reverse only S. C. within a wreath. Baudelot is of opinion that it is the head of Acca Laurentia, the nurse of Romulus, to whom a festival was ordained. "Perhaps (says Mr Pinkerton), it was struck in ridicule of Julius Cæsar; for the manner of the laurel crown, and its high appearance over the head, perfectly resemble that of Julius on his coins." Some have a ship upon one side; on the reverse T, or a cross, which was the image of Priapus; and occasioned many false invectives against the first Christians, who paid such respect to the cross. Some pieces have the heads of the emperors upon one side, on the reverse only numerals, III. IV. V. &c., and the noted *spintriati* of Tacitus. Both these kinds appear tickets for the baths, as the number seems to denote the particular bath. Some have the head of a girl with a vessel used at the baths in her hand. The spintriati are so immodest, that few will bear mention. But some are merely ludicrous; as one which has an ass with a bell about his neck, and a soldier riding him; another with two figures hoisting a woman in a basket into the air. Of those that will just bear mention, is a man with titles around him, as chief of the games; and a woman in ridicule of the modest bath-girl above mentioned. There is also one marked XIX, on which appears an imperator triumphing in a car: this car is placed on the back of a camel; and behind the imperator is a monkey mimicking him.

123 Of the contorniati. A fourth class of medals are called *contorniati* from the Italian *contorniato*, "encircled;" because of the hollow circle which commonly runs around them. They are distinguished from medallions by their thinness, faint relief, reverses sometimes in relief, sometimes hollow; and in general by the inferiority in their workmanship. The opinions of medallists concerning these pieces are very various; some suppose them to have been struck by Gallienus to the memory of illustrious men and celebrated *athletæ* at the time that he caused all the consecration coins of his predecessors to be restored; others ascribe their invention to Greece, &c. but Mr Pinkerton is of opinion that they were only tickets for places at public games. Many of them, notwithstanding their inferior workmanship, are very valuable on account of their preserving the portraits of some illustrious authors of antiquity, nowhere else to be found. Much dependance, however, cannot be put on the portraits of Greek authors and eminent men found upon some of them; for though we know that the busts of Sallust, Horace, &c. must have been struck when their persons were fresh in the memory of the artists, yet it was otherwise with Homer, Solon, Pythagoras, &c. which are to be found on some of them. Even these, however, are valuable, as being ancient and perhaps traditional portraits of these great men. The last whose portraits are supposed to have been delineated in this way, are Apollonius Tyaneus who flourished in the time of Domitian, and Apuleius in that of Marcus Antoninus. Mr Pinkerton thinks it a confirmation of his opinion concerning these medals, that the reverses always contain some device alluding to public games, as that of a charioteer driving a chariot, &c.

Sect. XII. *Directions for making Cabinets.*

We must now proceed to the last part of our subject, viz. that of giving directions for the formation of cabinets. As we have already seen that the formation of any one must be attended with very considerable expence, it is necessary for every one who attempts this to proportion the cabinet to his own circumstances. There are, properly speaking, three kinds of cabinets. 1. Those meant to contain a coin of every sort that has been issued from the mint in every age and country; but this, which may be called the large and complete cabinet, is not to be purchased by private persons. That of Dr Hunter already mentioned is perhaps one of the best private cabinets ever known; aud cost 23,000l. but as many duplicates were sold as cost 2000l. by which means the expence was reduced to 21,000l. The vast collection made by the king of France cost upwards of 100,000l. 2. The smaller cabinet may be supposed to consist only of middle and small Roman brass, English pennies, groats, &c. with a few medals of the more valuable kind, and may be supposed to incur an expence of from 20l. to 100l. 3. The smallest kind is called a *casket* of medals, and does not consist of above 1000 at most of various kinds; and consequently the expence must depend on the pleasure of the proprietor.

In the formation of the grand cabinet, it must be observed that the Greek medals of every denomination do not admit of any arrangement by the metals like the Roman; not any regular series of this kind being met with even in the most opulent cabinets. Hence in all collections the civic coins are ranged according to an alphabetical order; and the monarchic in a chronological one. The same rule is to be observed in the Roman consular medals; they are ranged, like the coins of the Greek cities, in an alphabetical series of the families. The Roman imperial coins are

only

Directions for making Cabinets.

only those capable of being arranged according to sizes and metals. Even from this must be excepted the minimi, or very smallest coins; which are so scarce, that the only regular series of them in the world is that belonging to the king of Spain, which was formed by a most skilful French medallist, and consists of all the metals. The arrangement of a grand cabinet, according to Mr Pinkerton, is as follows.

"I. The coins of cities and of free states in alphabetical order: whether using Greek, Roman, Punic, Etruscan, or Spanish characters.

"II. Kings in chronological series, both as to foundation of empire and seniority of reign.

"III. Heroes, heroines, founders of empires, and cities.

"IV. Other illustrious persons.

"V. Roman ases.

"VI. Coins of families, commonly called consular.

"VII. Imperial medallions.

"VIII. Imperial gold.

"IX. Imperial *minimi* of all metals.

"X. Imperial silver.

"XI. Imperial first brass.

"XII. Second brass.

"XIII. Third brass.

"XIV. Colonial coins which are all of brass.

"XV. Greek cities under the emperors, of all metals and sizes. In a smaller cabinet they may be put with the Roman, according to their metal and size. Those without the emperor's head go to Class I. though struck in Roman times.

"XVI. Egyptian coins struck under the Roman emperors, of all metals and sizes. They are mostly of a base metal called by the French *patin;* it is a kind of pot-metal or brittle brass.

"XVII. Contorniati, or ticket medals.

"XVIII. Coins of Gothic princes, &c. inscribed with Roman characters.

"XIX. Coins of southern nations using uncommon alphabets; as the Persian, Punic, Etruscan, and Spanish.

"XX. Coins of northern nations using uncommon characters; as the Runic and German.

"In the modern part no series can be formed of copper that will go back above two centuries; but sequences (chronological series) of gold and silver may be arranged of all the different empires, kingdoms, and states, as far as their several coinages will allow. Those of England and France will be the most perfect. Modern silver is commonly arranged in three sequences; the dollar, the groat, and the penny sizes. The medals of each modern country ought of course to be separated; though it is best to arrange each set in chronological order, let their size of metal be what they will. It may be remarked here, that our modern medals of the size of a tea-saucer, are only so many monuments of barbarism. The ancient medallions are almost universally but little larger than our crown-piece, though three or four of them may extend to about two inches diameter, but very many modern medals to four inches and more. A large medal always declares an ignorant prince or an ignorant artist. Into the size of a crown-piece the ancients threw more miracles in this way than will ever appear in these monstrous productions."

These directions will likewise apply to the formation of a cabinet of the second kind: but if the collector means to form a series of large Roman brass, he will find the coins of four or five emperors so scarce as not to be attainable in that series, even at any price. He must therefore supply their places with middle brass, as is allowed with regard to Otho, even in the best cabinets; there not being above three coins of that emperor in large brass known in the world: whereas of the middle brass, two or three hundred may exist. For this reason Mr Pinkerton concludes, that in cabinets of the second class, the collector may mingle the large and second brass together as he thinks proper, in order to save expence; though it would not do so well to unite such disproportionate sizes as the large and small. "In the small sequence, however (says he), there can be no harm in his mixing gold, silver, and brass, as chance or curiosity may lead him to purchase any of these metals. And though your starched bigotted medallist may sneer because such a sequence would controvert his formal and narrow way of thinking, common sense will authorize us to laugh at the pedant in our turn, and to pronounce such a series more various, rich, and interesting, than if the collector had arranged only one metal, and rejected a curious article because he did not collect gold or silver. In like manner, if, in the modern part of the smaller cabinet, any coin of a series is of high price, or of bad impression, there can be no impropriety in putting another of the same reign, which is cheaper, or better executed, though of a different denomination or of a little larger size. In short, the collector has no rules but in the Greek cities and Roman families, to observe alphabetical order and chronology in every thing else."

Ancient Coins.

TABLES of Ancient Coins.

The most ancient coins, according to Froelich, are distinguished by the following marks, which he accounts infallible. 1. Their oval circumference, and globulous swelling shape. 2. Antiquity of alphabet. 3. The characters being retrograde, or the first divisions of the legend in the common style, while the next is retrograde. 4. The indented square already described. 5. The simple structure of the mintage. 6. Some of the very old coins are hollowed on the reverse, with the image impressed on the front. 7. The dress, symbols, &c. frequently of the rudest design and execution.

TABLE I. *Ancient Greek Coins.*

1. Those without impression.

2. With one or more hollow indented marks on one side, and an impression in relief on the other.—Of Chalcedon on the Hellespont, Lesbos, Abdera in Thrace, Acanthus in Macedon, those said to belong to Egium in Achaia. This class continues from about 900 to 700 B. C.

3. With an indented square divided into segments, having a small figure in one of them; the rest blank, with a figure in relief on the obverse.—Of Syracuse and other places adjacent.—Continue from 700 to 600 B. C.

4. Coins

Ancient Coins.

4. Coins hollow on the reverse, with figures in relief on the obverse.—Of Caulonia, Crotona, Metapontum, &c. Supposed by some to be a local coinage of Magna Græcia; but probably of equal antiquity with the former.

5. Coins in which a square die is used on one or both sides.—Of Athens, Cyrene, Argos, &c.—Of Alexander I. and Archelaus I. of Macedon. Disused in the reign of the latter about 420 B. C.

6. Complete coins, both in obverse and reverse, occur first in Sicily in the time of Gelo, about 491 B. C.

7. Coins of Alexander the Great and his successors. About the time of this hero the Greek coins began to attain to perfection, and were struck of uncommon beauty. It is remarkable, that on the coins of this monarch his own image seldom occurs. The only one yet found of Alexander with his portrait upon it, and struck during his reign, is a silver hemidrachm in Dr Hunter's cabinet, which is represented Plate CCCXXXI. N° 3. After his death many coins bear his portrait. Trebellius Pollio informs us, that some coins, particularly those of Alexander, used to be worn as amulets; and many medals are met with in cabinets, bored seemingly with that intention.

8. Coins of the Successors of Alexander.—Those of the Syrian monarchs almost equal the coins of Alexander himself in beauty. Those of Antiochus VI. are supposed to be the most perfect patterns of male beauty to be met with any where. The Egyptian Ptolemies are somewhat inferior.

9. The coins of the Arsacidæ of Parthia done by Greek workmen.

10. The Greek imperial coins, being such as have the head of the emperor or empress: such as have not these impressions being classed with the civic coins, though struck under the Roman power. None of the imperial coins occur in gold. Of silver there are those of Antioch, Tyre, Sidon, Tarsus, Berytus, Cæsarea, Egyptian silver coins of base metal, Syrian silver coins, which sometimes bear on the reverse the club of Hercules, or the Tyrian shell-fish. Those of Sidon bear the image of the goddess Astarte, or her chariot. Those of Cæsarea in Cappadocia of better work than the Syrian. Lycian coins of good workmanship: on the reverse two harps and an owl sitting upon them. Silver coins of Gelon in Sarmatia resembling the Syrian. The situation of this town is very much unknown. It seems to have been situated on the north of the Euxine sea, where some Sarmatic or Sclavonic tribes were mingled with the Scythians or Goths. The Greek imperial brass coins are very numerous. A series of almost all the emperors may be had from those of Antioch, with a Latin legend on the obverse and Greek on the reverse. Those of Bithynia and Phrygia remarkable for good workmanship. The coins of Tarsus remarkable for their curious views of objects, almost in perspective. The Egyptian coins, from the time of Augustus to Nero, are worse executed than afterwards. From Nero to Commodus they are frequently of admirable workmanship, and in a peculiar style, distinct both from the Greek and Roman. From the time of Commodus they decline, and are lost after the reign of Constantius I. The Egyptian brass coins of the Roman period are likewise of excellent workmanship, especially in the time of Antoninus Pius.

Ancient Coins.

TABLE II. *Roman Coins.*

I. The consular coins, called also the coins of families, and arranged alphabetically in cabinets, according to the names of the families which appear on them. They are,

1. *Brass Coins.*—These consist chiefly of large pieces of rude workmanship without any interesting imagery. In cabinets they are generally kept in boxes apart by themselves. The as bears the head of Janus; the semis of Jupiter with S; the triens of Minerva with four cyphers; the quadrans of Hercules with three cyphers; the sextans of Mercury with two cyphers; and the uncia bears the head of Rome with one cypher. In all these pieces the prow of a ship is constantly the figure on the reverse, with very few exceptions. Sometimes indeed they have a shell, two heads of barley, a frog, an anchor or a dog, on the reverse. About the time of Julius Cæsar both the obverses and the reverses of the coins began to be altered.

2. *Silver.*—Of this the denarius was the first and principal coin. It was stamped originally with X, denoting that the value was ten ases. On the reverse was Castor and Pollux, or a chariot of Victory. Afterwards the busts of various deities make their appearance; and in the seventh century of Rome the portraits of illustrious persons deceased are met with: but till the time of Julius Cæsar no figure of any living person is to be met with; Julius himself being the first who assumed that honour. The workmanship on the best and worst silver is much the same. The reverses are very curious, and point out many remarkable events in Roman history; but none of these occur till about a century before the Christian era. The large denarii, with ROMA, are the most ancient; and some of these bear the Pelasgic A, not the Roman. The silver sestertii have a head of Mercury, with a caduceus on the reverse. The quinarii have always a head of Jupiter, with a Victory on the reverse.

3. *Gold.*—Most of these are of great value. The number of these exceeds not 100; those of brass 200; and of silver 2000. The aureus is the general gold coin; but two or three gold semisses of families likewise occur.

II. Roman imperial coins.

1. *Brass.*—This is of three sizes; large, middle, and small. The first forms a most beautiful series, but very expensive. The various colours of the patina have the finest effect. It is the most important of all the Roman coins, and exceeds even the gold in value.

The middle brass is next in value to the former; and in it are many rare and curious coins, particularly interesting to Britons, as elucidating the history of the island. Of these are the triumphal arch of Claudius; the EXERC. BRITANNICUS of Adrian; the coins of Antoninus Pius, Commodus, Severus, with a Victory, VICTORIA BRITAN.: but especially those personifying the country BRITANNIA. "The number of Roman coins relating to Britain (says Mr Pinkerton) is remarkable, more than 20 having been struck at various times: while those personifying Italy, Gaul, Spain,

Spain, and other regions of the empire, exceed not four or six at most for each country." Only one country vies with Britain, and that is Dacia on the extreme north-east of the empire, as Britain on the extreme north-west. No doubt this circumstance of remoteness in these two countries recommended them to this particular attention, as more expressive of the Roman power.

The small brass series abounds also with curious coins. They are scarce till the time of Valerian and Gallienus, but very common afterwards. Mr Pinkerton recommends, therefore, to form a series in silver as well as brass; both being the cheapest of all the Roman coins. "In this series (says he), it is a common fault to arrange many coins which have been plated with gold or silver, the forgeries of ancient times, but which time has worn off either wholly or in part." All real brass coins have the S. C. till the time of Gallienus; as the senate alone had the power of striking brass, while the emperor himself had that of gold and silver. When the S. C. therefore, is wanting, the coin was certainly once plated; as, in general, the different type and fabric, being those of gold and silver, sufficiently show themselves. With Pertinax, A. D. 192, there is a temporary cessation of small brass; nor after him do any princes occur in that series till Valerian, A. D. 254, excepting Trajanus Decius, A. D. 250 only. After Valerian the series is continuous and common. The brass coinage gradually declined in size from the time of Severus; so that parts of the as could not be struck, or at least it was held unnecessary to strike them. Trajanus Decius attempted in vain to restore the coinage; and Valerian and Gallienus were forced to issue denarii ærei and small assaria. The series of large and of middle brass are of two fixed and known sizes; the former about that of our crown, the latter of the half crown: though after Severus they gradually lessen. But the small brass takes in all parts of the as; and every brass coin not larger than our shilling belongs to this series. The *minimi*, indeed, or very smallest, it is proper to keep apart. The coins of Julius Cæsar in this size are of peculiarly fine workmanship. They bear his portrait reverse of Augustus, or the reverse has a crocodile EGYPTO CAPTA. There are several with Mark Antony, and some with Cleopatra; but the more common pieces are those with only numerals on the obverse, which go the length of XIII.; probably tickets for the baths. A great many occur in the time of Nero; of which Mr Pinkerton particularizes one which has "on the reverse a table ornamented with griffins and other devices. Upon it is placed a wreath of laurel and a beautiful vase, of which the embossed human figures are so minute, and finished so surprisingly, as to stamp these coins the most exquisite productions of the ancient mint." From the time of Nero to that of Vespasian no small brass occurs: but there are many of this emperor, and of his son Titus; while Domitian has as many as Nero, and Domitia his wife has almost as many. Succeeding emperors to the time of Pertinax have also many brass coins; but from his time to that of Valerian there are no real small brass excepting those of Trajanus Decius. After Gallienus there are a great many coins of this kind; and Mr Pinkerton mentions one in Dr Hunter's cabinet, of an unknown person named Nigrianus. The coin seems to have been struck at Carthage; and our author concludes that he was an African usurper, father to Nigrianus.

Ancient Coins.

2. *Silver*.—This series is very complete, and the cheapest of any; especially as the small brass becomes a fine supplement to it: the latter being had in plenty when the silver becomes scarce, and the silver being plentiful when the brass is scarce.

3. *Gold*.—The Roman imperial gold coins form a series of great beauty and perfection; but on account of their great price, are beyond the purchase of private persons.

4. *The colonial coins* occur only in brass; none, excepting that of Nemausus, having a right to coin silver. They begin in Spain with Julius Cæsar and Antony, and cease with Caligula, who took away the privilege of coinage from the Spanish colonies. The most beautiful are those of Corinth. The other remarkable colonial coins are those of Emerita, Ilice, Terraco, Cassandria, Babba, Berytus, Cæsarea, Patræ, Emisa, Heliopolis or Balbec, Ptolemais, Sidon, Tyre, Deulten, Dium, Troas, Rhesaina, Neapolis of Samaria, which bears a representation of Mount Gerizzim with the temple on it, Hippo in Africa, &c. On many of these coins we meet with fine representations of temples, triumphal arches, gods, goddesses, and illustrious persons. But coins with those representations are by no means common; the colonial coins till the time of Trajan bearing only a plough, or some other simple badge of a colony. Camelodunum is the only colony in Britain of which we have any coins.

5. The *minimi*.—This includes the smallest coins of all denominations, most of which do not exceed the size of a silver penny. They are the most curious of all; but no series of them was ever formed by any person except the abbe Rothelin, whose collection, formed of all metals, passed to the queen of Spain. The reason of the scarcity of these small coins is probably their diminutive size; by reason of which they are mostly lost.

It is surprising that numbers of Roman coins are found through all countries once subject to that powerful people. Some have been met with in the Orkneys, and many in the most remote parts of Europe, Asia, and Africa, known to the ancients.

TABLE III. *Coins of other Ancient Nations.*

1. The Lydians appear to have invented coinage; though, perhaps, this honour may be disputed with them by the Greeks.

2. The Assyrians, Medes, Babylonians, Phœnicians, and Egyptians, had no coins. In the mouths of the mummies, are only thin, unstamped, and round pieces of gold, to pay Charon's fare.

3. No Indian or Chinese coins are to be met with till a very late period; and even then so rude as scarce to be worth notice. Voltaire mentions a collection of ancient Chinese and Indian coins made by the emperor of China in 1700; but Mr Pinkerton supposes it to have consisted only of the Greek and Roman money which had been introduced into these countries.

4. The Lydian coins have no legends; so that mere conjecture only determines the ancient coins of electrum

and

Ancient Coins.

and silver found in Asia, and different from the Persian, to belong to Lydia. Crœsus coined gold into a form which he called *staters;* and Mr Pinkerton mentions a very ancient gold coin in Dr Hunter's cabinet, which he supposes to have been one of these. It has a globous figure, with indented marks on one side, and on the other a man kneeling, with a fish held out in the left hand, and a sword depending in the right. It weighs four drachms; which Josephus tells us was the weight of the Lydian gold coins. In the same collection are other gold coins little inferior in antiquity; the most ancient of which, our author supposes, may have been coined by the cities of Asia Minor, as coinage passed through them to Greece. They are of admirable workmanship, and as much superior to the best Sicilian coins, as the latter are to all the rest in the world. These gold coins are all extremely pale; owing to the want of knowledge in refining gold.

5. Persian coins.—These were first struck by Darius Hystaspes, whence they had the name of *darics.* They are of gold, and generally have the figure of an archer: they weigh about four drachms; and some occur with the indented mark on one side, while others have figures upon both. The silver coins have generally a king in a chariot of two horses, with a charioteer, and sometimes another figure on foot behind, on the obverse: while the reverse presents a ship, sometimes a ram, bull, or other animal. The gold coins, which only had the title of *darics,* are extremely scarce, having been melted down, as is supposed, and recoined by Alexander the Great on his conquest of Asia.

There is a second series of Persian coins beginning with Artaxares, or Artaxerxes, who overthrew the Parthian monarchy about the year 210. These are large and thin, with the king's bust on one side, and the altar of Mithras on the other; generally with a human figure on each side. These coins continue till the year 636, when Persia was conquered by the Saracens. These have only Persian letters upon them, which have never been explained by any antiquaries. Mr Pinkerton says that they seem to partake of the ancient Greek, Gothic, and Alanic.

6. The Hebrew shekels, originally didrachms, but after the times of the Maccabees tetradrachms, are almost all forgeries of modern Jews, as well as the brass coins with Samaritan characters upon them. They have all a sprig upon one side and a vase on the other. Mr Pinkerton says, that the admission of one of them into a cabinet would almost be a disgrace to it.

7. Phœnician and Punic coins are very interesting on account of the great power and wealth of these nations. The alphabets have been cleared by their relation to the Hebrew and Syriac languages.

8. The coins of Palmyra come under the same denomination with the former, Palmyra being a Syrian city.

9. The Etruscan coins have the characters of that nation, which have been explained by their affinity to the Pelasgic, or oldest Greek and Latin.

10. The Spanish coins are inscribed with two or three alphabets allied to the old Greek or Punic; but the inscriptions have not been sufficiently explained.

11. Gaulish coins.—These are numerous, but the most ancient have no legends; and even after the Greek letters were introduced into Gaul by a colony at Marseilles, the legends are very difficult to be explained.

12. British coins.—From a passage in Cæsar's Commentaries, it has been inferred that the Britons used some kind of coins even in his time. Mr Pinkerton informs us, that some rude coins of copper very much mingled with tin are frequently found in England; which, he supposes, may be some of the ancient British money. They are of the size of a didrachm, the common form of the nummus aureus among the ancients. After the time of Cæsar, coinage increased among the Britons; and there are many found of Cunobelinus mentioned in the Roman history. Most of these have on one side CUNO, with an ear of wheat, a horse, a kind of head of Janus, or other symbol; and have frequently also the letters CAMU; supposed to mean Camelodunum. Sometimes the word TASCIA occurs; the meaning of which has not yet been explained.

13. Gothic coins of France, Italy, and Spain, to the time of Charles the Great. These have the Roman characters upon them. The Italian coins are mostly of the size of small brass; and in this way we meet with coins of Athalaric, Theodahat, Witigez, and other Gothic princes. Many others occur, the inscriptions of which, though meant for Roman, are so perverted as to be illegible.

TABLE IV. *Modern Coins.*

Modern Coins.

1. Of Japan.—These are thin plates of gold and silver, of an oval figure, with small marks or figures stamped on them.

2. China.—These are only copper, about the size of a farthing, with a square hole in the middle to put them on strings. The inscriptions on them do not express the name of the sovereign, but the year of his reign; as the *happy year,* the *illustrious year,* &c.

3. The Tartarian coins are rude, having only inscriptions upon them; and they are all posterior to the time of Jenghiz khan.

4. Coins of Thibet, Pegu, and Siam, are much the same, presenting only inscriptions without any figures. They are also of late date.

5. India.—Some old coins have been found in the neighbourhood of Calcutta, of gold, silver, copper, and tin, all mixed together. These have commonly a warrior with a sword on one side, and an Indian female idol on the other, of the same form with the celebrated sculptures in the island of Elephanta; but it is impossible to tell what antiquity they are of. The modern coins are the pagoda of gold, worth little more than six shillings; the roupee of silver upwards of two shillings; and the cash, of copper. There is a remarkable set of roupees, which show the twelve signs; a lion on one, a bull on another, &c. but the occasion on which they were struck is unknown. The other coins of India have generally Persian inscriptions upon them.

6. Persia.—The Persic coins since its conquest by the Arabs continue on the Arabian model.

7. Arabia.—Some coins of the petty princes of Arabia are met with as old as the imperial ages of Rome; but till the time of Haroun Alrashid, no regular

gular coinage appears in the vast empire of the Saracens. Even then the reverse has only an inscription, and the obverse is copied from any Greek or Syrian coin which happened to fall in the moneyer's way. The later Arabian coins are mostly silver, with the name and titles of the prince on one side, and some inscription from the Koran on the other. The more modern coins of this country are in the shape of a fish-hook, with Arabic inscriptions.

8. Turkey.—No regular coinage was formed by the Turks till they became masters of Constantinople. They resemble those of Persia and Arabia, having merely inscriptions on both sides.

9. The coins of the African states, at least such as profess the Mohammedan religion, have merely inscriptions without any figures; those of the internal parts are unknown; and no coinage was used among the Mexicans and Peruvians, the only civilized nations in America; but La Hontan mentions an American savage who had a square medal of copper depending from his neck. Mr Pinkerton supposes it to have come from Japan.

10. Modern Italic coins. Besides the Gothic princes mentioned in the former table, the exarchs of Ravenna coined money with the inscription FELIX RAVENNA, &c. The Lombards issued no coins, but there are some still extant of Charlemagne. The following list shows the origin of the coinage in various Italian states.

Rome.—Papal coinage originates with Hadrian I. Size of silver pennies, with the Pope's name on one side, and SCOS PETRUS on the other. No coins appear from 975 to 1099, excepting of Leo IX. In 1303 appear pennies of the senate and people of Rome, with Peter on the one side and Paul on the other. There are groats of Clement V. with his portrait three quarters length; but the side-head begins with Sixtus V. in 1470. Gold was first coined by John XXII. in 1316. The coins of Alexander VI. Julius II. and Leo X. are remarkable for beauty and elegance.

Milan. Coinage began with Charlemagne. The first coin of the family of Visconti occurs in 1330, under Azo. The set finishes with Louis XII.

Naples. Coinage begins in 840 and 880, with Duke Sergius and Bishop Athanasius. The next coins are of Roger of Sicily, and Roger II. in 1130, William I. II. and Tancred. Naples and Sicily were subdued in 1194 by the emperor of Germany; in 1255 Manfred appears; in 1266 Charles of Provence; and others till Joan in 1414: after which follow the house of Arragon, and later kings.

Venice begins in the 10th century. The first coins are silver pennies marked VENECI. Then follow the coins of Henrico Dandulo in 1192, of Ziani in 1205, &c. Gold was first coined at Venice in 1280, and copper in 1471; but the silver groats are as old as 1192.

Florence. Silver was coined here in the 12th century, or before; but in 1252 the first gold coins struck in Europe after the 8th century made their appearance, and were named *florins* from the flower of the lily upon them. They were imitated by the popes, by France, and England. They have on one side St John the Baptist standing, on the other a large *fleur de lis*, and it is not doubted that the French *fleurs de lis* took their origin from these coins. They weigh a drachm, and are no less than 24 carats fine, according to Italian writers, and are worth about 12 shillings.

Modern Coins.

Geneva first began to coin money in 1129, under the government of Conrad. Those of the dukes of Savoy began in the same century.

Aquileia. Coins were issued from this city by the patriarchs from 1204 to 1440.

Ferrara. Coins of the marquises from 1340.

11. French coins. During the race of Clovis, from 490 till 751, the coins are chiefly gold *trientes*, with some *solidi* and *semisses*. The former are of good workmanship, with the heads of kings. The reverse has a cross, with the name of the town where they were struck.

The coins of the second race begin with Pepin in 751, and continue till Hugh Capet in 987. The coins of the first race are elegant, but those of the second entirely the reverse, being almost all silver pennies, and seldom bearing the portrait of the king. Those of Charlemagne have only CAROLUS in the field; while the reverse bears R. F. or some such inscription; though one piece struck at Rome has a rude bust of him. The coins of Louis le Debonnaire are better done.

The third race begins with Hugh Capet in 987, and extends to this time. The coinage did not begin to improve till 1226 under St Louis, when the groat appears. Its name in Italian is *grosso*, in French *grosse*, in English *groat*, or great coin; so called from its size in comparison with the penny; and it passed from Italy to France, to Germany, and to England. After the conquest of France by the English, base coins of many kinds were introduced; and in the year 1574, in the time of Henry III. copper was first introduced into the French coinage. Besides these, the other remarkable coins of France are, the blancs or billon groats first issued in 1348; the *ecus a la couronne*, or crowns of gold, so called from the crown on one side, and begun by Charles VI. in 1384; those of Ann of Bretagne in 1498: the *teston*, or piece with the king's head, of Louis XII; the *Henri* of Henry II. with Gaul sitting in armour, and a Victory in her hand. There are many coins of Cardinal Bourbon, elected king in 1589; and in 1642, Louis XIV. takes the title of CATALONIÆ PRINCEPS. The first *louis d'or* made its appearance in 1640; but such was the poverty of France, if we believe certain authors, that in 1719 the duke of Orleans regent struck copper for silver.

12. Spanish coins. The most early series of these consists almost entirely of trientes, finely done. On one side they have the head of the king with his name, and on the other a cross, with the name of the town, commonly in Bætica, or the south part of Spain, where there were a great many Roman colonies, and which was fertile to a proverb. The Moresque coins of Spain, like those of the rest of the Mohammedan states, present us only with insipid inscriptions on both sides. Indeed the Mohammedan religion by its absolute refusal to allow the representation of any living creature, has prevented the progress of coinage in any degree throughout those regions which it has overspread.

Modern Coins.

spread. The inscription on the ancient Spanish coins are in the Cufic or old Arabic characters.

13. Portugal. No description of the coins of this kingdom has yet appeared.

14. Germany. No account of the German coins has been published; though it is well known that not only the emperors, but many of the cities, particularly those called *Hanse-towns*, issued money; and many of the coins issued by the cities were superior in elegance even to those issued by the emperors.

15. Denmark. Here the coinage begins with Canute the Great in 1014. The pieces are at first extremely rude, ornamented only with rings and Runic characters. These are succeeded by copper pieces, some of which have a cross, others a pastoral staff, on one side, with the letter A on the other, Later coins have strokes IIII, &c. all round them; but those of Harold, Hardicanute, and Magnus Bonus, in 1041, are of neat workmanship, and have the portraits of the princes at half length. The coins of Nicolas, or Niel, as he is called by the Danes, are rude, as well as those of Waldemar I. and the celebrated Margaret. In 1376 Olaf caused money to be struck with a grinning full face, with a crowned O upon the other side. "The Swedes (says Mr Pinkerton) took these coins extremely ill, as they thought they grinned at them." Silver was first coined in Denmark by Philippa queen of Eric, and daughter to Henry IV. of England.

16. Sweden. The coinage of this kingdom began in 818 under Biorno, on the plan of Charlemagne. The coins are marked with a cross. Next follow those of Olaf in 1019: which Mr Pinkerton supposes to have been the first true Swedish coins; and that the art of coinage first passed from England into Denmark in the time of Canute the Great, and from Denmark into Sweden. These coins were struck on the English model. During the time that Sweden was subject to Denmark, or miserably harassed by the Danes, the coins of both kingdoms were the same; but after the time of Gustavus Vasa many elegant pieces appear. In 1634, dollars were coined with the portrait of Gustavus Adolphus, who was killed two years before: on the reverse they have the arms of Sweden, with the chemical marks of mercury and sulphur. In 1716, 1717, and 1718, Charles XII. being in extreme want of money, issued small copper coins with Saturn, Jupiter, Mars, &c. upon them, to go for dollars; and on account of this scheme, Baron Goertz, the suggestor of it, was brought to the block.

17. Norway. The coins of this country begin with Olaaf in 1006; after which time there are various coins of other princes; but copper was not coined till the year 1343.

Besides the coins already mentioned, there are ecclesiastic coins of France, Germany, Denmark, Sweden, Norway, &c. Those of Denmark and Sweden are numerous, but the Norwegian coins of this denomination are rare. Mr Pinkerton describes a silver one in his possession as having arms and a mitre, with the inscription on one side, SANCTUS OLAWS REX NORVEY; on the reverse, OLAWS DEI GRA. ARCEP. NID'SEN, meaning NIDROSIENSIS, or archbishop of *Nidros*, now Drontheim.

18. Bohemia. The coinage of this kingdom appears at a very early date, viz. in the year 909, under Duke Boleslaus I. These coins are followed by others of Boleslaus II. and Emma his wife in 970; of Boleslaus III. in 1002; Jaromir in 1020; Udalrich in 1030, and other princes. The *bracteate* money of Ottocar I. was coined in 1197.

19. Poland. The coinage of this country is nearly as ancient as that of Bohemia. The coins are on the German model, but no particular account of them has been published.

20. Russia. None of the Russian money appears to be more ancient than the 13th century. The first are the *kopecks* or silver pennies, which have upon them rude figures of animals on one side, and a man standing with a bow or spear on the other. There are likewise coins of Moscow struck by Aristoteles the architect in 1482. The *roubles* or dollars and their halfs. There are some of the impostor Demetrius in 1605, which are very scarce.

21. Prussia. The first Prussian coins were struck at Culm by the Teutonic knights in 1230. They were silver pennies, and upon the German plan. In the next century were struck shillings, groats, and *schots;* the last were the largest, and are extremely rare. They have the Prussian shield, an eagle surmounting a cross, with a rose-shaped border, MONETA DOMINORUM PRUSSIÆ: on the reverse is a cross fleurie, within a border of a similar kind, having the inscription HONOR MAGISTRI, JUSTITIAM DILIGET.—Gold coins were struck in the same century. In the time of Copernicus the money was so debased, that 12 or 13 marks were worth but one of pure silver.

22. England. The English coins are of various kinds.

1st. *Heptarchic.* These are only of two sorts, viz. the *skeatta* or penny of silver, and the *styca* of copper. Few of the pennies appear till after the year 700; though some are met with which bear the name of Ethelbert I. king of Kent, as old as 560. At first they had only rude figures of serpents, but in latter times legends were likewise added. Most of these pennies have pagan symbols upon them. The styca was only coined in Northumberland, and was a very small piece, about the value of half a farthing.

2d. Coins of the *chief monarchs* of England. Mr Pinkerton denies that an end was put to the heptarchy by Egbert in 832, as is commonly supposed; though he owns that he was *chief monarch* of the country, as several others had been before him. Edgar, who reigned in 959, according to him, was the first king of England; and the coins of the chief monarchs form almost a complete series from the time of Egbert to Edgar. The only chief monarch of whom there are no coins is Ethelbald, who reigned in 857. Most of these coins bear rude portraits; but the reverses are sometimes curious and interesting. Some have views of cathedrals and other buildings; particularly one of Edward the Elder in 900; which has the cathedral of York with three rows of windows, round arched as the other Saxon and Norman buildings: the Gothic arch being quite unknown till after the 12th century. Some coins of Anlaf king of Northumberland have the famous raven, the Danish ensign: and those

those of other princes have frequently very curious reverses.

3d. *Ecclesiastic* coins appear of the archbishops of Canterbury, Wulfred in 804, Ceolnoth, in 830, and Plegmund in 889.

4th. Coins of the *kings* of England. The silver penny, which had begun during the heptarchy, continued to be the general coin after the kingdom had been united under one head; and extends in a continued series from Egbert almost to the present reign. The only kings wanting are Edmund Ironside, Richard I. and John, At first the penny weighed $22\frac{1}{2}$ grains: but towards the close of the reign of Edward III. it fell to 18 grains; and in that of Edward IV. to 12. In the time of Edward VI. it was diminished to 8 grains; and in Queen Elizabeth's reign to $7\frac{1}{31}$; at which it still continues.

Halfpennies and farthings were first struck in silver by Edward I. in 1280; the former continued to the time of the commonwealth, but the latter ceased with Edward VI. The groat was introduced by Edward III. in 1354, and continues to this day, though not in common circulation. The half-groat or two-pence is of the same date, and also continues to the present time.

Shillings were first coined by Henry VII. in 1503. At first it was called *testoon*, from the *teste*, *tete*, or head of the king upon it; the name *shilling* being derived from the German *schelling;* under which appellation coins had been struck at Hamburgh in 1407. The crown was first coined in its present form by Henry VIII. Formerly it had appeared only in gold, whence the phrase of crowns of gold; though these indeed were the largest gold coins known for a long time in France and other countries on the continent, being worth about 10s. sterling. They had their name from the crown stamped on one side, and were first coined by Charles VI. in 1384, and continued till the time of Louis XIV. The half-crown, sixpence, and threepence, were coined by Edward VI. In 1558 Queen Elizabeth coined three halfpenny, and in 1561 three farthing pieces; but they were discontinued in 1582. From the year 1601 to the present time the coins of England remain the same.

Gold was coined in England by Henry III. in 1257; the piece was called a *gold penny*, and was larger than the silver one; and the execution is by no means bad for the time. The series of gold coinage, however, commences properly from Edward III. In 1344, this monarch first struck florins, in imitation of those in Italy; and it is remarkable, that though these coins at the time they were first issued bore only six shillings value, they are now intrinsically worth 19s.; so much has the value of gold increased since that time. The half and quarter florin were struck at the same time, but only the last has been found. The florin, however, being found inconvenient, gave place to the noble of 6s. 8d. value, and exactly half a mark. The latter had its name from being a limited sum in accounts: and was eight ounces in weight, two thirds of the money pound. It is sometimes also called *selibra*, as being one-half of the commercial pound of 16 ounces. The noble had its name from the nobility of the metal; the gold of which it was coined being of the finest sort. Sometimes it was called *rose noble*, from both sides being impaled in an undulating circle. It continued with the half and quarter noble to be the only gold coin till the angels of Edward IV. appeared in 1465. These had their name from being stamped with the image of Michael and the dragon. The angelets of 3s. 4d. value were substituted in their place. In 1527 Henry VIII. added to the gold coined the crown and half-crown at their present value; and the same year he gave *sovereigns* of 22s. 6d. and *ryals* of 11s. 3d. angels at 7s. 6d. and nobles at their old value of 6s. 8d. In 1546 he caused sovereigns to be coined of the value of 20s. and half-sovereigns in proportion. His gold crown is about the size of our shilling, and the half-crown of six-pence, but thin. All his coins, however, gold as well as silver, are much debased; and it was not without much labour and trouble that Edward VI. brought it back to its former standard. On the union of the two crowns, James gave the sovereign the name of *unite;* the value continuing of 20s. as before. He coined also rose-ryals of 30s. value, spur-ryals of 15s. angels of 10s. and angelets of 5s. Under the commonwealth, the sovereign got the name of the *twenty-shilling* piece, and continued current till the coinage of guineas. These were so called from their being coined of Guinea gold, and were at first only to go for 20s. though by an universal but tacit consent they always passed for 21s. Half-guineas, double guineas, and five guinea pieces, were also coined during the same reign; which still continue, though the two latter are not in common circulation. Quarter guineas were coined by George I. and likewise by his present majesty; but they were found so troublesome on account of their small size, that they were stopped within a year or two, when received at the bank of England, and thus are not to be met with at present. A few pieces of 7s. value have likewise been coined, and are known by the lion above the helmet; but none have been issued. In 1688 the guinea rose to 21s. 6d. and continued to increase in value till 1696, when it was as high as 30s.; but after the recoinage in 1697 and 1698 it fell by degrees, and in 1717 was at its old standard of 21s. and at that time silver was fixed at its present standard value, viz. as 1 to $15\frac{1}{2}$ in weight.

Modern Coins.

Though the first money coined in Britain, as we have already observed, was copper, yet, excepting the Northumbrian stycas, no copper coin was found in England from the time of the Saxon conquest till the year 1672. An aversion to a copper coinage it seems was prevalent throughout the nation; and Queen Elizabeth, who without hesitation used base money for Ireland, yet scrupled at coining copper for England. This want of small coin occasioned such an increase of private tokens for halfpennies and farthings that it became a serious object to government; and in 1594 a copper coinage was seriously thought of. This year a small copper coin was struck about the size of a silver twopence, with the queen's monogram on one side, and a rose on the other; the running legend on both sides being, THE PLEDGE OF A HALFPENNY. Of this there are patterns both in copper and silver, but both of them soon fell into disuse. On the 19th of May 1613, King James by royal proclamation issued farthing tokens. They are generally of the same size with the two pence, with two sceptres in saltier surmounted with

Modern Coins.

with a crown, and the harp upon the other; with an intention, as it would seem, that if they were refused in England, they might pass in Ireland. In 1635 Charles I. coined those with the rose instead of the harp; but the circulation of these was entirely stopped by the vast number of counterfeits which appeared, and by the king's death in 1648. After this the private tokens began again to be circulated, till put a stop to by the coinage of farthings in 1672. The workmanship of the tokens is quite contemptible. In 1672 the halfpence as well as the farthings which had been struck two years before began to circulate. They were of pure Swedish copper, the dies engraved by Roettier; and they continued till the year 1684, when some disputes arose about the copper lately obtained from the English mines. Tin farthings were coined with a stud of copper in the centre, and inscribed round the edge as the crown pieces, with NUMMORUM FAMULUS. 1685 or 1686. In 1686 halfpence of the same kind were coined; and the tin coinage continued till the year 1692, to the value of more than 65,000l.; but next year the tin was all called in by government, and the copper coinage recommenced. The farthings of Queen Anne are all trial pieces, excepting those of 1714, the last year of her reign. "They are (says Mr Pinkerton) of exquisite workmanship, exceeding most copper coins either ancient or modern, and will do honour to the engraver Mr Croker to the end of time." The one, whose reverse is Peace in a car, PAX MISSA PER ORBEM, is the most esteemed; and next to it the BRITANNIA under a portal. The other halfpence and farthings are less valuable.

23. Scotland. Silver pennies of Alexander I. who reigned in 1107, are believed to exist; and there certainly are some of Alexander II. in 1214. There are likewise coins of David in 1124; but perhaps none of Malcolm IV. his successor, whose reign was very short. There are many coins of William I. in 1165; and a large hoard of his pennies was found at Inverness in 1780.

The money of Scotland continued to be of the same value with that of England till the country was drained by the vast ransom of David II. after which it became necessary to reduce its size; and so much did this diminution affect England, that Edward III. found himself obliged to lessen the English coin also. The diminution of the Scottish coin, however, continued still to go on until it became impracticable to keep par with that of England. In the first year of Robert III. it passed only for one half of its nominal value in England: in 1393, Richard II. ordered it only to go for the weight of the genuine metal it contained. In 1600 it had sunk to such a degree as to pass only for a twelfth part of the English money, and continued at that low ebb till the coinage of Scotland was entirely cancelled by the union of the two kingdoms.

Of silver coins we have only pennies till the year 1293, when Edward I. having coined halfpence and farthings, Alexander III. of Scotland coined also halfpence, of which we have a few, but no farthings are to be met with; but there are silver farthings of Robert I. and David II. The latter introduced the groat and half-groat, which completed the set of Scottish silver. It continued unaltered till the time of Queen Mary, when they all ceased to be coined in silver, on account of the high price of that metal. In 1553 shillings were first coined, with the bust of the queen on one side and the arms of France and Scotland on the other. The silver crown was first coined in 1565, which went for 30s. Scots; lesser pieces of 20s. and 10s. having likewise been struck, and marks of silver, worth 3s. 4d. English, were also coined about the same time. These coins have upon them the marks XXX. XX. X. to denote their value. They are commonly called Cruickstone dollars, from the palm-tree upon them, mistaken for a remarkable yew at Cruickstone near Glasgow, where Henry Darnley resided. It is described, however, in the act as a palm, with a "shell-padoc" (a tortoise) crawling up. This alludes to Darnley's marriage with the queen, as the motto from Propertius DAT GLORIA VIRES also implies. The motto NEMO ME IMPUNE LACESSET first appears on the Scottish coins in 1578, and the invention is given to the celebrated Buchanan. In 1582, the crown of an ounce weight went for 40s. Scots, and was accordingly marked XL.; in 1597 the mark was L. the Scottish money being then only one-tenth of the English: the mark was LX. in 1601, the value being then reduced to one-twelfth, at which it has ever since continued. In the time of Charles I. half marks, 40 and 20 penny pieces, were coined. In 1675 the Scottish dollars first appeared, in value 56s. Scots, with halves and quarters of proportional value. In 1686, James VII. coined 60s. 40s. 20s. 10s. and 5s. pieces; but only those of 40s. and 10s. are known, with these numbers under the bust. At the union of the kingdoms all the Scottish coins were called in, and recoined at Edinburgh, with the mark E under the bust to distinguish it: since which there has been no coinage in Scotland. The Scottish silver coins are in general equal, if not superior, in the workmanship to the English.

Gold was first issued by Robert II. about 30 years after Edward III. of England had coined the same metal in that country. The pieces were at first called St. Andrews, from the figure of that tutelar saint upon the cross, and who appears on the obverse with the arms of Scotland, and on the reverse a lion in a shield. The lion was another name for the largest gold coin in Scotland, from the arms of the kingdom upon it. The next was the unicorn, under James III.; which were followed by the bonnet-pieces of James V. These last are of admirable workmanship, being almost equal to the ancient coins in this respect. In imitation of the French, the monarch we speak of diminished the size of the coin without lessening its weight; an improvement not adopted by the English for a whole century. The last gold coined in Scotland was the pistole and half pistole, of twelve and six pounds Scots. These coins have the sun under the head. The gold coins of Scotland fell in the same proportion with the silver.

The copper coinage of Scotland is of more early date than that of England. It was preceded by money of *billon*, or copper washed with silver, called black money. James III. first coined black farthings in 1466; and this is recorded by historians as one of his greatest faults. This kind of coinage, however, continued as late as the reign of James VI. In his time the

Modern Coins.

the true copper coinage began; but as the value of Scottish money had now declined almost to the utmost, the pieces suddenly assumed a form almost resembling that of the French coins. The *bodle*, so called from Bothwell the mintmaster, being equal in size to the *liard*, and worth two pennies Scottish, was struck. The billon coin, formerly called *bas piece*, and worth six pennies Scots, was now coined in copper, and termed the *baw-bee*. Thus it corresponded with the French half sol and English halfpenny, the Scots penny being now equivalent to the French *denier*. Some pieces named *Atkinsons* were coined by James VI. in 1582, when the Scottish money was to the English as 1 to 8; but on its being still farther reduced, they went for 8 pennies, a third more than the value of the baw-bee. Besides these there were the hardie and plack, the former being worth three and the latter four pennies Scots. This coinage continued through the reigns of Charles I. and II. but Scottish coins of the former are, perhaps, the scarcest of any.

24. Ireland. The first coins introduced into this kingdom seem to have been those of the Danes, and which have only a number of strokes around them instead of letters. In the tenth century, however, this coinage had been considerably improved; and in 930 and 994 there are pennies struck in Dublin, with the inscription ON DVFLI or DYFLI, *Duflin* or *Dyflin* being the Danish name of that city. There are likewise coins of the Irish princes themselves, and of the English monarchs, struck in Ireland as early as the ninth century; and it is asserted by some, that Ireland even in these days had been conquered by England; of which, indeed, these coins seem to be a proof. None of the Irish coins of Henry II. are to be met with, but we have some of the coins of John; and from his time to that of Henry V. the Irish coins are known by a triangle enclosing the king's head, which appears also upon the coins of other nations at this period. The harp does not appear upon the Irish coins till the time of Henry VIII. Till the time of this monarch, the English and Irish coins are the same; but the same debasement of the coin which at that time took place in England extended also to Ireland; but in 1601 copper halfpence and farthings were coined also for this kingdom. These circulated in Ireland when James VI. issued his farthing-tokens of copper, the latter being of two sizes, that if they failed in England they might be sent to Ireland as pennies and halfpence. In 1635 a mint was established in Dublin by Charles I. but it was stopped by the Irish massacre, and the many disturbances which followed; since which time the scheme has not been resumed. After the massacre, St Patrick's halfpence and farthings were coined by the Papists, bearing the legends FLOREAT REX, and on the reverse ECCE GREX; on the farthing QUIESCAT PLEBS. Copper tokens were struck by towns and tradesmen, as in England and Scotland. In 1680, halfpence and farthings were issued by authority, with the harp and date. In 1689, James II. having invaded Ireland, instituted a mint, and coined shillings and half crowns of all the refuse metal he could find, particularly some brass guns were employed, whence the coinage is commonly called *gun-money*. Even this metal, however, soon became so scarce, that a diminution in its size is quite apparent from June 1689 to July 1690; and as the month of their mintage is marked upon them, this decrease is easily perceived. In March 1690, pennies of lead mixed with tin were issued; and on the 15th of June the same year, crowns of white metal were coined; but these are now very scarce. In 1722, the patent for coining halfpence and farthings was given to William Wood, which excited such discontent in Ireland. From the small size allowed by the patent to these pieces, it was supposed that the patentee would have gained 60,000l. but as he caused them to be struck of a size still smaller, his gains were estimated at 100,000l. The coins, however, are of admirable workmanship, and very fine copper, bearing the best portrait of King George I. to be found any where. Sir Isaac Newton, at that time at the head of the mint, declared that they were superior to the English coins in every thing except the size. In 1737 the Irish halfpence and farthings, with the harp on the reverse, were coined, and continue to the present time. In 1760, there was such a scarcity of copper coin, that some private persons applied for leave to coin halfpence, which appeared with a very bad portrait of George II. and the words VOCE POPULI around it. No gold or silver has been coined in Ireland since the massacre of 1641.

TABLE V. *Modern Medals, properly so called.*

1. Scottish medals. These take the lead in the present article, the first modern medals of gold being those of David II. struck between the years 1330 and 1370. Only two of them are known to exist; one in the collection of Mr Barker of Birmingham, and the other in that of Dr Hunter. In 1487, there is a medal of James III. sent to the shrine of St Amboise in France. It is described as of two inches and a third in diameter; the weight near two ounces; having on the obverse a beardless king, with long hair, sitting on a throne, holding in one hand a naked sword; in the other a shield, with the Scottish arms. On the borders of the canopy above the throne is an inscription in Gothic letters, IN MI DEFFEN, being corrupt French for *In my defence*; a common motto in the Scottish arms. Above the canopy is VILLA BERWICHI: the reverse bears St Andrew and his cross, SALVUM FAC POPULUM TUUM DOMINE. There is also a medal of James IV. in the collar of St Michael, having on the reverse a Doric pillar surmounted by a young Janus, standing on a hill, beyond which is the sea, and land on either side. This, however, is by some suspected to be a forgery.

The most remarkable Scottish medals are those of the unfortunate Mary. The first is properly French, having been issued at her coronation as queen of France, along with her husband King Francis II. On the obverse of this piece there are portraits of Francis and Mary, face to face, with three legends around them, the outermost containing their titles; the middle one the following sentence: HORA NONA DOMINUS J. H. S. EXPIRAVIT HELLI CLAMANS; the innermost the name of the city (Paris). On the reverse are the arms of France and Scotland. Fine testoons were also coined upon the same plan, and are now so rare that Dr Hunter gave ten guineas for one which

Modern Medals.

which is in his collection. The same portraits appear on the fine crown of Mary and Henry, in 1565, which is so rare as to be esteemed a medal of the highest value; and Mr Pinkerton imagines, that if offered to sale it would bring 40 or 50 guineas.

Another remarkable medal of Mary represents her full-faced and weeping, with the inscription, O GOD GRANT PATIENCE IN THAT I SVFFER VRANG. The reverse has in the centre, QUHO CAN COMPARE WITH ME IN GRIEF, I DIE AND DAR NOCHT SEEK RELIEF; with this legend around, HOURT NOT THE (figure of a heart) QUHAIS JOY THOU ART. There are also many counters of this unfortunate princess, being thin silver pieces of the size of a shilling. "They all appear (says Mr Pinkerton) to have been done in France, by the direction of Mary, who was fond of devices. Her cruel captivity could not debar her from intercourse with her friends in France, who must with pleasure have executed her orders, as affording her a little consolation."

The coronation medal of Charles II. struck at Edinburgh for his inauguration, June 18. 1663, is remarkable as being the only one ever coined of Scottish gold, and the first in Britain struck with a legend on the edge. With respect to the workmanship, it is inferior to Simon's. Of these medals only three are known to exist, of which one is in the Museum. It is not uncommon in silver; in which case it sometimes wants the legend on the edge.

2. Italian medals. These appear in the 15th century, and from that time successively in most European countries. Vittore Pisano, a painter of Verona, is celebrated as the restorer of the art, but it remains to be accounted for how the medals of King David, already mentioned, came to exist so long before. Mr Pinkerton considers this artist rather as an inventor than a restorer, his medals having no resemblance to the ancient coins, as being large, and all cast. They were first modelled in wax, then a mould taken from the model in fine sand and other ingredients. After a good cast was procured, it was touched up, and made a model for the rest. These medals of Pisano, are almost always inscribed *Opus Pisani Pictoris*. The portraits of a great number of illustrious men were done by him in this manner; and in the British Museum is a large brass medal of Pisano by himself.—Other artists were Boldu, Marescotto, Matthæus de Pastus, Sperandes, Misaldone, &c. Towards the end of the century, however, the medals began to assume a more elegant appearance; and the papal ones are not only the most elegant but the most ancient series of all the modern medals. The improvement began in the reign of Alexander VI. so famous for his own crimes, and those of his nephew Cæsar Borgia. His successors, Julius II. Leo X. Hadrian VI. and Clement VII. had many of their medals designed by Raphael, Julio Romano, and other eminent painters, and the engraving executed by artists of equal merit. Among these were the celebrated Cellini, and the noted Paduan forgers of Roman coins, Cavino and Bassiano. In 1644, Cormanni, a medallic artist, was imprisoned on account of a piece which represented the Pope upon one side, and Olympia Maidalchina, the *relation* of his holiness, on the other. The unfortunate Cormanni poisoned himself. About this time the family of the Hamerani, originally from Germany, began to engrave the papal medals; which they did with surprising merit for several generations. Each of the daughters did a fine medal, as we are informed by Venuti.

Modern Medals.

Besides the papal medals, many have been issued by the various states of Italy. There are medals of Frederic II. of Sicily in 1501, of several Venetian generals in 1509, of Alfonso duke of Ferrara in 1511, and of the celebrated Andrew Doria in 1528.

3. French medals. Till the reign of Louis XIV. the medals of this country are neither fine nor numerous; but this monarch exceeds all modern princes in this way. Many of his pieces are well designed and executed, though objectionable on account of their falsehood.

4. Danish medals. These appear of Christian II. in 1516, of Frederic and Sophia in 1532, of Frederic I. and Christian III. in bonnets worn in the 16th century. The elephant of the house of Oldenburg is frequent upon Danish medals.

5. Swedish medals. These begin with Gustavus Vasa; and several of Christina are likewise to be met with. There are also some curious ones of Charles XII.

6. Dutch medals. These begin in 1566; and many of them are remarkable for maps and plans, which must be very interesting to posterity. "Had the Greeks and Romans (says Mr Pinkerton) given us maps and plans, what a fine system of ancient geography and topography a cabinet of medals must have been!"

7. Medals of Spain, Portugal, and Germany. The Spanish medals began with Gonsalo in 1503, many of which are curious and interesting. Under Charles V. there are many curious Spanish medals; but those of Germany begin with Frederic in 1453. They are extremely numerous; as we may easily suppose from the greatness of the empire, and various states which compose it. There is a famous medal of Sebastian king of Portugal, famous for his unfortunate expedition into Africa in 1578; with his bust, full face, and three quarters in length. On the reverse is a shell-fish in the sea, with the moon and seven stars, bearing the inscription SERENA CALSA FAVENT. There is also a curious lozenge-shaped coin of the same, with the arms of Portugal, and the king's name and title: On the reverse is a cross with the inscription IN HOC SIGNO VINCES, 1578.

8. Satiric medals. These began almost as soon as the knowledge of the art of coining medals was revived. They seem to have been almost unknown to the ancients. One indeed of the emperor Gallienus is supposed to have been satiric. It has on the front the emperor's bust, with the inscription GALLIENÆ AUG. the reverse is Peace in a car, PAX UBIQUE; but this has been proved to be only a blundered coin. Some other ancient medals, however, are not liable to this objection. The first modern satiric medal published was that of Frederic king of Sicily in 1501, against his antagonist Ferdinand king of Spain. It has on one side the head of Ferdinand, with the inscription FERDINANDUS R AR. VETUS VULPES ORBIS; on the reverse a wolf carrying off a sheep, JVGVM MEVM SVAVE EST ET ONVS MEVM LEVE. Many others have been struck, of which the wit would now perhaps be difficult

Abbreviations.

difficult to be found out: but of all nations the Dutch have most distinguished themselves in this way; and paid very dear for their conduct, as they brought upon themselves by one or two satiric medals the whole power of France under Louis XIV.

9. English medals. The first of these is in the duke of Devonshire's collection. It is of a large size, and done on the plan of the early Italian medals. It has on the reverse the arms of Kendal, with the inscription TEMPORE OBSIDIONIS TURCORUM, MCCCCLXXX. On the other side is a portrait with IO KENDAL RHODI TVRCVPELLERIVS. It was found last century in Knaresborough forest; but Mr Pinkerton has no doubt of its having been done in Italy. The next is that of Henry VIII. in 1545, and is of gold, larger than the crown-piece, with the king's head upon the obverse, and three legends within each other, including his titles, &c. The reverse contains two inscriptions, declaring him to be the head of the church; the one in Hebrew, the other in Greek. It was imitated exactly by Edward VI. whose coronation medal is the first we have. There are two medals of Philip and Mary, whose execution is tolerably good; but those of Elizabeth are very poor. There are good medals of James I. and his queen; with a fine one of Charles I. and Henrietta, though the workmanship is much inferior to the antique. There are many good medals of Charles, with various devices upon their reverses. Under the commonwealth the celebrated Simon produced medals which are deservedly reckoned the most admirable pieces of modern workmanship. There are many good medals of Charles II. James II. and William III. Some are also found of James after his abdication. Some fine gold, silver, and copper medals, were issued in the time of Queen Anne; the two last affording a series of all the great actions of the duke of Marlborough. About the year 1740, a series of medals was engraved in London by Dassier, a native of Geneva, containing all the kings of England; being 36 in number. They are done upon fine copper, and executed with great taste. There are besides many medals of private persons in England; so that it may justly be said, that this country for medals exceeds almost every other in Europe.

To this account of modern coins and medals we shall add that of another set called *siege-pieces*, and which were issued during the time of a siege in cases of urgent necessity. These were formed of any kind of metal; sometimes of no metal; and Patin mentions a remarkable one struck at Leyden in 1574, when the place was besieged by the Spaniards. It was of thick paper or pasteboard, having a lion rampant, with this inscription, PVGNO PRO PATRIA, 1574; and on the reverse, LVGDVNVM BATAVORVM. There are various siege-pieces of Charles I. both in gold and silver, some of the latter being of the value of 20 shillings.

The *nummi bracteati* are a species of modern coins somewhat between counters and money; and have their name from the word BRACTEA, a spangle or thin bit of metal. They are commonly little thin plates of silver, stamped as would seem with wooden dies upon one side only, with the rude impression of various figures and inscriptions. Most of them are ecclesiastic, and were struck in Germany, Switzerland, Denmark, Sweden, Norway, and a few in Poland. They continued to be in use in Germany till the end of the 15th century; and some are still used in Switzerland at this day.

Greek Numerals.

Α.	1.	Ι.	10.	Ρ.	100.
Β.	2.	Κ.	20.	Σ. or C	200.
Γ.	3.	Λ.	30.	Τ.	300.
Δ.	4.	Μ.	40.	Υ.	400.
Ε.	5.	Ν.	50.	Φ.	500.
ς. or ϛ	6.	Ξ.	60.	Χ.	600.
Ζ.	7.	Ο.	70.	Ψ.	700.
Η.	8.	Π.	80.	Ω.	800.
Θ.	9.	ϙ. or ϟ	90.	ϡ.	900.

Example.

Abbreviations.

Examples. I is 10: add A to I, and IA makes 11: so IB, 12; IΓ, 13, &c. K is 20, KA, 21, &c. PIA makes 111. The English word AIR marks the grand initial numerals. On coins the numerals are often placed in retrograde order; which makes no difference in the value, as every letter is appropriated to its number. Thus TAΓ or ΓAT imply the same, 333. But this advantage being unknown to the Roman numerals and Arabic cyphers, is apt to puzzle the beginner.

ROMAN COINS.

A

A. AULUS: in the exergue it implies the first mint, as ANT. A. coined at Antioch in the first mint
A. A. A. F. F. Auro, Argento, Ære, Flando, Feriundo
A. or AN. Annus
A. A. Apollo Augusti
A. F. A. N. Auli filius, Auli nepos
ABN. Abnepos
ACT. Actiacus, or Actium

Medals || Medea.

Impressions of Medals. See Casting.

MEDALLION, or Medalion, a medal of an extraordinary size, supposed to be anciently struck by the emperors for their friends, and for foreign princes and ambassadors. But, that the smallness of their number might not endanger the loss of the devices they bore, the Romans generally took care to stamp the subject of them upon their ordinary coins.

Medallions, in respect of the other coins, were the same as modern medals in respect of modern money: they were exempted from all commerce, and had no other value than what was set upon them by the fancy of the owner. Medallions are so scarce, that there cannot be any set made of them, even though the metals and sizes should be mixed promiscuously.

MEDEA, in fabulous history, a celebrated sorceress, daughter of Æetes king of Colchis. Her mother's name, according to the more received opinion of Hesiod and Hyginus, was Idyia, or, according to others, Ephyre, Hecate, Asterodia, Antiope, and Neæra. She was the niece of Circe. When Jason came to Colchis in quest of the golden fleece, Medea became enamoured of him, and it was to her well directed labours that the Argonauts owed their preservation. Medea had an interview with her lover in the temple of Hecate; where they bound themselves by the most solemn oaths to eternal fidelity. No sooner had Jason overcome all the difficulties which Æetes had placed in his way, than Medea embarked with the conquerors for Greece. To stop the pursuit of her father, she tore to pieces her brother Absyrtus, and left his mangled limbs in the way through which Æetes was to pass. This act of barbarity, some have attributed to Jason, and not to her. When Jason reached Iolchos his native country, the return and victories of the Argonauts were celebrated with universal rejoicings: but Æson the father of Jason was unable to assist at the solemnity on account of the infirmities of his age. Medea, at her husband's request, removed the weakness of Æson; and by drawing away the blood from his veins, and filling them again with the juice of certain herbs, she restored him to the vigour and sprightliness of youth. This sudden change in Æson astonished the inhabitants of Iolchos; and the daughters of Pelias were also desirous to see their father restored by the same power to the vigour of youth. Medea, willing to revenge the injuries which her husband's family had suffered from Pelias, increased their curiosity; and betrayed them into the murder of their father as preparatory to his rejuvenescence, which she afterwards refused to accomplish. This action greatly irritated the people of Iolchos; and Medea with her husband fled to Corinth to avoid their resentment. Here they lived for 10 years with mutual attachment, when the love of Jason for Glauce the king's daughter interrupted their harmony, and Medea was divorced. Medea revenged the infidelity of Jason, by causing the death of Glauce, and the destruction of her family. She also killed two of her children in their father's presence; and when Jason attempted to punish the barbarity of the mother, she fled through the air upon a chariot drawn by winged dragons. From Corinth Medea came to Athens, where, after she had undergone the necessary purification of her murder, she married King Ægeus, or (according to others) lived in an adulterous manner with him. From her conduct with Ægeus, Medea had a son who was called *Medus.* Soon after, when Theseus wished to make himself known to his father, Medea, jealous of his fame and fearful of his power, attempted to poison him at a feast which had been prepared for his entertainment. Her attempts, however, failed of success, and the sight of the sword which Theseus wore by his side convinced Ægeus that the stranger against whose life he had so basely conspired was his own son. The father and the son were reconciled; and Medea, to avoid the punishment which her wickedness deserved, mounted her fiery chariot and disappeared through the air. She came to Colchis; where, according to some, she was reconciled to Jason, who had sought her in her native country after her sudden departure from Corinth. She died at Colchis, as Justin mentions, when she had been restored to the confidence of her family. After death she married Achilles in the Elysian fields, according to the tradition mentioned by Simonides. The murder of Mermerus and Pheres, the youngest of Jason's children by Medea, is not to be attributed to the mother, according to Elian; but to the Corinthians, who assassinated them in the temple of Juno Acræa. To avoid the resentment of the gods, and to deliver themselves from the pestilence which visited their country after so horrid a massacre, they engaged the poet Euripides for five talents to write a tragedy, which cleared them of the murder, and represented Medea as the cruel assassin of her own children. And besides, that this opinion might be the better credited, festivals were appointed, in which the mother was represented with all the barbarity of a fury murdering her own sons.

Medea || Media.

MEDEOLA, Climbing African Asparagus, a genus of plants belonging to the hexandria class, and in the natural method ranking under the 11th order, *Sarmentaceæ*. See Botany *Index*.

MEDIA, now the province of Ghilan in Persia, once the seat of a potent empire, was bounded, according to Ptolemy, on the north by part of the Caspian sea; on the south by Persia, Susiana, and Assyria; on the east by Parthia and Hyrcania; and on the west by Armenia Major. It was anciently divided into several provinces, viz. Tropatene, Charomithrene, Darites, Media.

rites, Marciane, Amariace, and Syro Media. By a later division, however, all these were reduced to two; the one called *Media Magna*, the other *Media Atropatia*, or simply *Atropatene*. Media Magna was bounded by Persis, Parthia, Hyrcania, the Hyrcanian sea, and Atropatene, and contained the cities of Ecbatan, Laodicea, Apamea, Raga, Rageia or Ragea, &c. Atropatene lay between the Caspian mountains and the Caspian sea.

This country originally took its name from Madai, the third son of Japhet; as is plain from Scripture, where the Medes are constantly called *Madai*. Among profane authors, some derive the name *Media*, from one Medus the son of Jason and Medea; others from a city called *Media*. Sextus Rufus tells us that in his time it was called *Medena*, and from others we learn that it was also called *Aria*. The most probable history of the Medes is as follows:

This people lived in subjection to the Assyrians till the reign of Sennacherib, when they threw off the yoke, and lived for some time in a state of anarchy. But at last, rapine and violence, the natural consequences of such a situation, prevailed so much, that they were constrained to have recourse to some kind of government, that they might be enabled to live in safety. Accordingly, about 699 B. C. one Dejoces having procured himself to be chosen king, united the scattered tribes into which the Medes were at that time divided; and having applied himself as much as possible to the civilization of his barbarous subjects, left the throne to his son Phraortes, after a reign of 53 years.

The new king, who was of a warlike and enterprising disposition, subdued almost all the Upper Asia lying between Mount Taurus and the river Halys which runs through Cappadocia into the Euxine sea. Elated with this good success, he invaded Assyria, the empire of which was now much declined, and greatly weakened by the revolt of many nations which had followed the example of the Medes. Nebuchadonosor or Chyniladan, however, the reigning prince, having assembled what forces he could, engaged Phraortes, defeated, took him prisoner, and put him to death; after which, entering Media, he laid waste the country, took the metropolis of Ecbatan itself, and levelled it with the ground.

On the death of Phraortes, his son Cyaxares was placed on the throne. He was no less valiant and enterprising than his father, and had better success against the Assyrians. With the remains of that army which had been defeated under his father, he not only drove the conquerors out of Media, but obliged Chyniladan to shut himself up in Nineveh. To this place he immediately laid close seige; but was obliged to give over the enterprise on account of an irruption of the Scythians into his own country. Cyaxares engaged these new enemies with great resolution; but was utterly defeated; and the conquerors overran not only all Media, but the greatest part of Upper Asia, extending their conquests into Syria, and as far as the confines of Egypt. They continued masters of all this vast tract of country for 28 years, till at last Media was delivered from their yoke by a general massacre at the instigation of Cyaxares.

Media || Medicinal Springs.

After this deliverance, the Medes soon repossessed themselves of the territories they had lost; and once more extended their frontiers to the river Halys, their ancient boundary to the westward. After this we find the Medes engaged in a war with the Lydians; which, however, ended without any remarkable transaction: but on the conclusion of it, Cyaxares having entered into a strict alliance with Nebuchadnezzar king of Babylon, returned in conjunction with the Babylonians before Nineveh: which they took and levelled with the ground, putting most of the inhabitants to the sword.

After this victory the Babylonian and Median empires seem to have been united: however, after the death of Nebuchadnezzar, or rather in his lifetime, a war ensued, which was not extinguished but by the dissolution of the Babylonian empire. The Medes, under Astyages the son of Cyaxares I. withstood the power of the Babylonian monarchs: and under Cyrus and Cyaxares II. utterly destroyed their empire by the taking of BABYLON, as is related under that article. After the death of Cyaxares, the kingdom fell to Cyrus, by whom the seat of the empire was transferred to PERSIA, under which article the history of Media now falls to be considered, as also the manners, &c. of the inhabitants.

MEDIANA, the name of a vein or little vessel, made by the union of the cephalic and basilic, in the bend of the elbow.

MEDIASTINUM, in *Anatomy*, a double membrane, formed by a duplicature of the pleura; serving to divide the thorax and the lungs into two parts, and to sustain the viscera, and prevent their falling from one side of the thorax to the other. See ANATOMY, N° 117.

MEDIATE, or INTERMEDIATE, something that stands betwixt and connects two or more terms considered as extremes; in which sense it stands opposed to *immediate*.

MEDIATOR, a person that manages or transacts between two parties at variance, in order to reconcile them. The word, in Scripture, is applied, 1. To Jesus Christ, who is the only intercessor and peace-maker between God and man, (1 Tim. ii. 5.) 2. To Moses, who interposed between the Lord and his people, to declare unto them his word; (Deut. v. 5. iii. 19.).

MEDICAGO, SNAIL TREFOIL, a genus of plants belonging to the diadelphia class, and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*. For the properties and culture of LUCERN, a species of this genus, see AGRICULTURE *Index*.

MEDICINAL, any thing belonging to medicine.

MEDICINAL Springs, a general name for any fountain, the waters of which are of use for removing certain disorders. They are commonly either chalybeate or sulphureous. See SPRINGS and WATER.

MEDICINE.

Definition.

MEDICINE is the art of preventing, curing, or alleviating, those diseases to which the human species are subjected.

History of Medicine.

Origin of medicine among the Jews;

THE fabulous history of the ancients derives this art immediately from their gods; and, even among the moderns, some are of opinion that it may justly be considered as of divine revelation. But without adopting any supposition of which no probable evidence can be given, we may conclude, that mankind were naturally led to it from casual observation on the diseases to which they found themselves subjected; and that therefore, to a certain degree at least, it is as ancient as the human race. But at what period it began to be practised as an art, by particular individuals following it as a profession, is not known. The most ancient physicians we read of were those who embalmed the patriarch Jacob by order of his son Joseph. The sacred writer styles these physicians *servants* to Joseph: whence we may be assured that they were not *priests*, as the first physicians are generally supposed to have been; for in that age we know the Egyptian priests were in such high favour, that they retained their liberty, when, through a public calamity, all the rest of the people were made slaves to the prince.

It is not probable, therefore, that among the Egyptians religion and medicine were originally conjoined; and if we suppose the Jews not to have invented the art, but received it from some other nation, it is as little probable that the priests of that nation were their physicians as those of Egypt.

That the Jewish physicians were absolutely distinct from their priests is very certain. Yet as the Jews resided for such a long time in Egypt, it is probable they would retain many of the Egyptian customs, from which it would be very difficult to free them. We read, however, that when King Asa was diseased in his feet, "he sought not to the Lord, but to the physicians." Hence we may conclude, that among the Jews the medical art was looked upon as a mere human invention; and it was thought that the Deity never cured diseases by making people acquainted with the virtues of this or that herb, but only by his miraculous power. That the same opinion prevailed among the nations who were neighbours to the Jews, is also probable from what we read of Ahaziah king of Judah, who having sent messengers to inquire of Baalzebub god of Ekron concerning his disease, he did not desire any remedy from him or his priests, but simply to know whether he should recover or not.

What seems most probable on this subject therefore is, that religion and medicine came to be mixed together only in consequence of that degeneracy into ignorance and superstition which took place among all nations. The Egyptians, we know, came at last to be sunk in the most ridiculous and absurd superstition; and then, indeed, it is not wonderful that we should find their priests commencing physicians, and mingling charms, incantations, &c. with their remedies. That this was the case, long after the days of Joseph, we are very certain; and indeed it seems as natural for ignorance and barbarism to combine religion with physic, as it is for a civilized and enlightened people to keep them separate. Hence we see, that among all modern barbarians their priests or conjurors are their only physicians.

Origin of Medicine. 2 among the Egyptians;

We are so little acquainted with the state of physic among the Egyptians, that it is needless to say much concerning them. They attributed the invention of medicine, as they did also that of many other arts, to Thoth, the HERMES or MERCURY of the Greeks. He is said to have written many things in hieroglyphic characters upon certain pillars, in order to perpetuate his knowledge, and render it useful to others. These were transcribed by Agathodemon, or the second Mercury, the father of Tat, who is said to have composed books of them, that were kept in the most sacred places of the Egyptian temples. The existence of such a person, however, is very doubtful, and many of the books ascribed to him were accounted forgeries as long ago as the days of Galen; there is also great reason to suspect that those books were written many ages after Hermes, and when physic had made considerable advances. Many of the books attributed to him are trifling and ridiculous; and though sometimes he is allowed to have all the honour of inventing the art, he is on other occasions obliged to share it with Osiris, Isis, and Apis or Serapis.

After all, the Egyptian physic appears to have been little else than a collection of absurd superstitions. Origen informs us, that they believed there were 36 demons, or gods of the air, who divided the human body among them; that they had names for each of them; and that by invoking them according to the part affected, the patient was cured. Of natural medicines we hear none recommended by the father of Egyptian physic; except the herb *moly*, which he gave to Ulysses in order to secure him from the enchantments of Circe; and the herb *mercury*, of which he first discovered the use. His successors made use of venesection, cathartics, emetics, and clysters. There is no proof, however, that this practice was established by Hermes; on the contrary, the Egyptians themselves pretended that the first hint of those remedies was taken from some observations on brute animals. Venesection was taught them by the hippopotamus, which is said to perform this operation upon itself. On certain occasions, he comes out of the river, and strikes his leg against a sharp-pointed reed. As he takes care to direct the stroke against a vein, the consequence must be a considerable effusion of blood; and this being suffered to run as long as the creature thinks proper, he at last stops up the orifice with mud. The hint of clysters was taken from the ibis, a bird which is said to give itself clysters with its bill, &c. They used venesection, however, but very little, probably on account of the

Origin of Medicine. warmth of the climate; and the exhibition of the remedies above mentioned, joined with abstinence, formed the most of their practice.

3 Among the Greeks. The Greeks too had several persons to whom they attributed the invention of physic, particularly Prometheus, Apollo or Pæan, and Æsculapius; which last was the most celebrated of any. But here we must observe, that as the Greeks were a very warlike people, their physic seems to have been little else than what is now called *surgery*, or the cure of wounds, fractures, &c. Hence Æsculapius, and his pupils Chiron, Machaon, and Podalirius, are celebrated by Homer only for their skill in curing these, without any mention of their attempting the cures of internal diseases. We are not, however, to suppose that they confined themselves entirely to surgery. They no doubt would occasionally prescribe for internal disorders; but as they were most frequently conversant with wounds, we may naturally suppose the greatest part of their skill to have consisted in knowing how to cure these. If we may believe the poets, indeed, the knowledge of medicine seems to have been very generally diffused. Almost all the heroes of antiquity are reported to have been physicians as well as warriors. Most of them were taught physic by the centaur Chiron. From him Hercules received instructions in the medicinal art, in which he is said to have been no less expert than in feats of arms. Several plants were called by his name; from which some think it probable that he found out their virtues, though others are of opinion that they bore the name of this renowned hero on account of their great efficacy in removing diseases. Aristæus king of Arcadia was also one of Chiron's scholars; and is supposed to have discovered the use of the drug called *silphium*, by some thought to be asafœtida. Theseus, Telamon, Jason, Peleus, and his son Achilles, were all renowned for their knowledge in the art of physic. The last is said to have discovered the use of verdegrise in cleansing foul ulcers. All of them, however, seem to have been inferior in knowledge to Palamedes, who hindered the plague from coming into the Grecian camp after it had ravaged most of the cities of the Hellespont, and even Troy itself. His method was to confine his soldiers to a spare diet, and to oblige them to use much exercise.

The practice of these ancient Greek physicians, notwithstanding the praises bestowed on them by their poets seems to have been very limited, and in some cases even pernicious. All the external remedies applied to Homer's wounded heroes were fomentations; while inwardly their physicians gave them wine, sometimes mingled with cheese scraped down. A great deal of their physic also consisted of charms, incantations, amulets, &c. of which, as they are common to all superstitious and ignorant nations, it is superfluous to take any farther notice.

In this way the art of medicine continued among the Greeks for many ages. As its first professors knew nothing of the animal economy, and as little of the theory of diseases, it is plain, that whatever they did must have been in consequence of mere random trials, or empiricism, in the strict and proper sense of the word. Indeed, it is evidently impossible that this or almost any other art could originate from another source than trials of this kind. Accordingly, we find, that some ancient nations were accustomed to expose their sick in temples, and by the sides of highways, that they might receive the advice of every one who passed. Among the Greeks, however, Æsculapius was reckoned the most eminent practitioner of his time, and his name continued to be revered after his death. He was ranked among the gods; and the principal knowledge of the medical art remained with his family to the time of Hippocrates, who reckoned himself the seventeenth in a lineal descent from Æsculapius, and who was truly the first who treated of medicine in a regular and rational manner.

4 Æsculapius.

5 Hippocrates. Hippocrates, who is supposed to have lived 400 years before the birth of Christ, is the most ancient author whose writings expressly on the subject of the medical art are preserved; and he is therefore justly considered as the father of physic. All the accounts which we have prior to this time, if not evidently fabulous, are at the utmost highly conjectural. Even the medical knowledge of Pythagoras, so much celebrated as a philosopher, can hardly be considered as resting on any other foundation. But from the time of Hippocrates, medicine, separated from philosophy and religion, seems to have assumed the form of a science, and to have been practised as a profession. It may not, therefore, be improper, to give a particular account of the state of medical science, as transmitted to us in his writings. The writings of Hippocrates, however, it may be remarked, are even more than preserved. Many things have been represented as written by Hippocrates which are probably spurious. Nor is it wonderful that attempts should have been made to increase the value of manuscripts, by attributing them to a name of such eminence. But although what are transmitted to us under the title of his works may have been written by different hands, yet the presumption is, that most, if not all of them, are of nearly as early a date, and contain the prevailing opinions of those times.

6 His writings.

According to the most authentic accounts, Hippocrates was a native of the island of Cos, and born in the beginning of the 88th Olympiad. In the writings transmitted to us as his, we find a general principle adopted, to which he gives the name of *Nature*. To this principle he ascribes a mighty power. "Nature (says he) is of itself sufficient to every animal. She performs every thing that is necessary to them, without needing the least instruction from any one how to do it." Upon this footing, as if Nature had been a principle endowed with knowledge, he gives her the title of *just*: and ascribes virtues or powers to her, which are her servants, and by means of which she performs all her operations in the bodies of animals; and distributes the blood, spirits, and heat, through all parts of the body, which by these means receive life and sensation. And in other places he tells us, that it is this faculty which gives nourishment, preservation, and growth, to all things.

His idea of nature.

The manner in which Nature acts, or commands her subservient power to act, is by attracting what is good and agreeable to each species, and by retaining, preparing, and changing it; and on the other side in rejecting whatever is superfluous or hurtful, after she has separated it from the good. This is the foundation of the doctrine of depuration, concoction, and crisis in fevers,

Hippocrates.

fevers, so much insisted on by Hippocrates and many other physicians. He supposes also, that every thing has an inclination to be joined to what agrees with it, and to remove from every thing contrary to it; and likewise that there is an affinity between the several parts of the body, by which they mutually sympathize with each other. When he comes to explain what this principle called *nature* is, he is obliged to resolve it into *heat*, which, he says, appears to have something immortal in it.

8
Of the causes of diseases.

As far as he attempts to explain the causes of disease, he refers much to the humours of the body, particularly to the blood and the bile. He treats also of the effects of sleep, watchings, exercise, and rest, and all the benefit or mischief we may receive from them. Of all the causes of diseases, however, mentioned by Hippocrates, the most general are diet and air. On the subject of diet he has composed several books, and in the choice of this he was exactly careful; and the more so, as his practice turned almost wholly upon it. He also considered the air very much; he examined what winds blew ordinarily or extraordinarily; he considered the irregularity of the seasons, the rising and setting of stars, or the time of certain constellations; also the time of the solstices, and of the equinoxes; those days, in his opinion, producing great alterations in certain distempers.

9
His division of diseases.

He does not, however, pretend to explain how, from these causes, that variety of distempers arises which is daily to be observed. All that can be gathered from him with regard to this is, that the different causes above mentioned, when applied to the different parts of the body, produce a great variety of distempers. Some of these distempers he accounted *mortal*, others *dangerous*, and the rest easily *curable*, according to the cause from whence they spring, and the parts on which they fall. In several places also he distinguishes diseases, from the time of their duration, into *acute* or *short*, and *chronical* or *long*. He likewise distinguishes diseases by the particular places where they prevail, whether ordinary or extraordinary. The first, that is, those that are frequent and familiar to certain places, he called *endemic* diseases; and the latter, which raged extraordinarily, sometimes in one place, sometimes in another, which seized great numbers at certain times, he called *epidemic*, that is, *popular* diseases: and of this kind the most terrible is the plague. He likewise mentions a third kind, the opposite of the former; and these he calls *sporadic*, or straggling diseases: these last include all the different sorts of distempers which invade at any one season, which are sometimes of one sort, and sometimes of another. He distinguished between those diseases which are hereditary, or born with us, and those which are contracted afterwards; and likewise between those of a *kindly* and those of a *malignant* nature, the former of which are easily and frequently cured, but the latter give the physicians a great deal of trouble, and are seldom overcome by all their care.

Hippocrates remarked four stages in distempers; viz. the beginning of the disease, its augmentation, its state or height, and its declination. In such diseases as terminate fatally, death comes in place of the declination. In the third stage, therefore, the change is most considerable, as it determines the fate of the sick person; and this is most commonly done by means of a *crisis*. By this word he understood any sudden change in sickness, whether for the better or for the worse, whether health or death succeed immediately. Such a change, he says, is made at that time by *nature*, either absolving or condemning the patient. Hence we may conclude, that Hippocrates imagined diseases to be only a disturbance of the animal economy, with which Nature was perpetually at variance, and using her utmost endeavours to expel the offending cause. Her manner of acting on these occasions is to reduce to their natural state those humours whose discord occasions the disturbance of the whole body, whether in relation to their quantity, quality, mixture, motion, or any other way in which they become offensive. The principal means employed by nature for this end is what Hippocrates calls *concoction*. By this he understood the bringing the morbific matter lodged in the humours to such a state, as to be easily fitted for expulsion by whatever means nature may think most proper. When matters are brought to this pass, whatever is superfluous or hurtful immediately empties itself, or nature points out to physicians the way by which such an evacuation is to be accomplished. The crisis takes place either by bleeding, stool, vomit, sweat, urine, tumors or abscesses, scabs, pimples, spots, &c. But these evacuations are not to be looked upon as the effects of a true crisis, unless they are in considerable quantity; small discharges not being sufficient to make a crisis. On the contrary, small discharges are a sign that nature is depressed by the load of humours, and that she lets them go through weakness and continual irritation. What comes forth in this manner is crude, because the distemper is yet too strong; and while matters remain in this state, nothing but a bad or imperfect crisis is to be expected. This shows that the distemper triumphs, or at least is equal in strength to nature, which prognosticates death, or a prolongation of the disease. In this last case, however, nature often has an opportunity of attempting a new crisis more happy than the former, after having made fresh efforts to advance the concoction of the humours.—It must here be observed, however, that, according to Hippocrates, concoction cannot be made but in a certain time, as every fruit has a limited time to ripen; for he compares the humours which nature has digested to fruits come to maturity.

10
His opinion of a crisis.

The time required for concoction depends on the differences among distempers mentioned above. In those which Hippocrates calls *very acute*, the digestion or crisis happens by the fourth day; in those which are only *acute*, it happens on the 7th, 11th, or 14th day; which last is the longest period generally allowed by Hippocrates in distempers that are truly acute: though in some places he stretches it to the 20th or 21st, nay, sometimes to the 40th or 60th day. All diseases that exceed this last term are called *chronical*. And while in those diseases that exceed 14 days, he considers every fourth day as critical, or at least remarkable, by which we may judge whether the crisis on the following fourth day will be favourable or not; so in those which run from 20 to 40 he reckons only the sevenths, and in those that exceed 40 he begins to reckon by 20. Beyond the 120th he thinks that the number of days has no power over the crisis. They are

Hippocrates.

are then referred to the general changes of the seasons; some terminating about the equinoxes; others about the solstices; others about the rising or setting of the stars of certain constellations; or if numbers have yet any place, he reckons by months, or even whole years. Thus (he says), certain diseases in children have their crisis in the seventh month after their birth, and others in their seventh or even in their 14th year.

Though Hippocrates mentions the 21st as one of the critical days in acute distempers, as already noticed; yet, in other places of his works, he mentions also the 20th. The reason he gives for this in one of those places of his work is, that the days of sickness were not quite entire. In general, however, he is much attached to the odd days: insomuch that in one of his aphorisms he tells us, "The sweats that come out upon the 3d, 5th, 7th, 9th, 11th, 14th, 17th, 21st, 27th, 31st, or 34th days, are beneficial; but those that come out upon other days signify that the sick shall be brought low, that his disease shall be very tedious, and that he shall be subjected to relapses." He further says, "That the fever which leaves the sick upon any but an odd day is usually apt to relapse." Sometimes, however, he confesses that it is otherwise; and he gives an instance of a salutary crisis happening on the sixth day. But these are very rare instances, and therefore cannot, in his opinion, overthrow the general rule.

Besides the crisis, however, or the change which determines the fate of the patient, Hippocrates often speaks of another, which only changes the species of the distemper, without restoring the patient to health; as when a vertigo is turned to an epilepsy, a tertian fever to a quartan, or to a continued, &c.

11 His accuracy in prognostics;

But what has chiefly contributed to procure the great respect generally paid to Hippocrates, is his industry in observing the most minute circumstances of diseases, and his exactness in nicely describing every thing that happened before, and every accident that appeared at the same time with them; and likewise what appeared to give ease, and what to increase the malady: which is what we call *writing the history of a disease.*—Thus he not only distinguished one disease from another by the signs which properly belonged to each; but by comparing the same sort of distemper which happened to several persons, and the accidents which usually appeared before and after, he could often foretel a disease before it began, and afterwards give a right judgment of the event of it. By this way of prognosticating, he came to be exceedingly admired: and this he carried to such a height, that it may justly be said to be his master-piece; and Celsus, who lived after him, remarks, that succeeding physicians, though they found out several new things relating to the management of diseases, yet were obliged to the writings of Hippocrates for all that they knew of signs.

From the look;

The first thing Hippocrates considered, when called to a patient, was his looks.—It was a good sign with him to have a visage resembling that of a person in health, and the same with what the sick man had before he was attacked by the disease. As it varied from this, so much the greater danger was apprehended. The following is the description which he gives of the looks of a dying man.—"When a patient (says he) has his nose sharp, his eyes sunk, his temples hollow, his ears cold and contracted, the skin of his forehead tense and dry, and the colour of his face tending to a pale green, or lead colour, one may pronounce for certain that death is very near at hand; unless the strength of the patient has been exhausted all at once by long watchings, or by a looseness, or being a long time without eating." This observation has been confirmed by succeeding physicians, who have, from him, denominated it the *Hippocratic face*. The lips hanging relaxed and cold, are likewise looked upon by Hippocrates as a confirmation of the foregoing prognostic. He also took his signs from the disposition of the eyes in particular. When a patient cannot bear the light; when he sheds tears involuntarily; when, in sleeping, some part of the white of the eye is seen, unless he usually sleeps after that manner, or has a looseness upon him: these signs, as well as the foregoing ones, prognosticate danger. The eyes deadened, as it were with a mist spread over them, or their brightness lost, likewise presages death, or great weakness. The eyes sparkling, fierce, and fixed, denote the patient to be delirious, or that he soon will be seized with a frenzy. When the patient sees any thing red, and like sparks of fire and lightning pass before his eyes, you may expect an hæmorrhagy; and this often happens before those crises which are to be attended by a loss of blood.

From t posture bed;

The condition of the patient is also shewn by his posture in bed. If you find him lying on one side, his body, neck, legs, and arms, a little contracted, which is the posture of a man in health, it is a good sign: on the contrary, if he lies on his back, his arms stretched out, and his legs hanging down, it is a sign of great weakness; and particularly when the patient slides or lets himself fall down towards the feet, it denotes the approach of death. When a patient in a burning fever is continually feeling about with his hands and fingers, and moves them up before his face and eyes as if he was going to take away something that passed before them; or on his bed-covering, as if he was picking or searching for little straws, or taking away some filth, or drawing out little flocks of wool; all this is a sign that he is delirious, and that he will die. Amongst the other signs of a present or approaching delirium he also adds this: When a patient who naturally speaks little begins to talk more than he used to do, or when one that talks much becomes silent, this change is to be reckoned a sort of delirium, or is a sign that the patient will soon fall into one. The frequent trembling or starting of the tendons of the wrist, presage likewise a delirium. As to the different sorts of delirium, Hippocrates is much more afraid of those that run upon mournful subjects, than such as are accompanied with mirth.

From spirati

When a patient breathes fast, and is oppressed, it is a sign that he is in pain, and that the parts above the diaphragm are inflamed. Breathing long, or when the patient is a great while in taking his breath, shows him to be delirious; but easy and natural respiration is always a good sign in acute diseases. Hippocrates depended much on respiration in making his prognostics; and therefore has taken care in several places to describe the different manner of a patient's breathing. Continual watchings in acute diseases, are signs of present pain, or a delirium near at hand.

Hippocrates.

Hippocrates also drew signs from all excrements, whatever they are, that are separated from the body of man. His most remarkable prognostics, however, were from the urine. The patient's urine, in his opinion, is best when the sediment is white, soft to the touch, and of an equal consistence. If it continue so during the course of the distemper, and till the time of the crisis, the patient is in no danger, and will soon be well. This is what Hippocrates called *concocted urine*, or what denotes the concoction of the humours; and he observed, that this concoction of the urine seldom appeared thoroughly, but on the days of the crisis which happily put an end to the distemper. "We ought (said Hippocrates) to compare the urine with the purulent matter which runs from ulcers. As the pus, which is white, and of the same quality with the sediment of the urine we are now speaking of, is a sign that the ulcer is on the point of closing; so that which is clear, and of another colour than white, and of an ill smell, is a sign that the ulcer is virulent, and in the same manner difficult to be cured; the urines that are like this we have described are only those which may be named good; all the rest are ill, and differ from one another only in the degrees of more and less. The first never appear but when nature has overcome the disease; and are a sign of the concoction of humours, without which you cannot hope for a certain cure. On the contrary, the last are made as long as their crudity remains, and the humours continue unconcocted. Among the urines of this last sort, the best are reddish, with a sediment that is soft and of an equal consistence; which denotes, that the disease will be somewhat tedious, but without danger. The worst are those which are very red, and at the same time clear and without sediment; or that are muddy and troubled in the making. In urine there is often a sort of cloud hanging in the vessel in which it is received; the higher this rises, or the farther distant it is from the bottom, or the more different it is from the colour of the laudable sediment above mentioned, the more there is of crudity. That which is yellow, or of a sandy colour, denotes abundance of bile; that which is black is the worst, especially if it has an ill smell, and is either altogether muddy or altogether clear. That whose sediment is like large ground wheat, or little flakes or scales spread one upon another, or bran, presages ill, especially the last. The fat or oil that sometimes swims upon the top of the urine, and appears in a form something like a spider's web, is a sign of a consumption of the flesh and solid parts. The making of a great quantity of urine is the sign of a crisis, and sometimes the quality of it shows how the bladder is affected. We must also observe, that Hippocrates compared the state of the tongue with the urine; that is to say, when the tongue was yellow, and charged with bile, the urine he knew must of course be of the same colour; and when the tongue was red and moist, the urine was of its natural colour.

Among his prognostics from the excretions by stool are the following:—Those that are soft, yellowish, of some consistence, and not of an extraordinary ill smell, that answer to the quantity of what is taken inwardly, and that are voided at the usual hours, are the best of all. They ought also to be of a thicker consistence when the distemper is near the crisis; and it ought to be taken for a good prognostic, when some worms, particularly the round and long, are evacuated at the same time with them. The prognosis, however, may still be favourable, though the matter excreted be thin and liquid, provided it make not too much noise in coming out, and the evacuation be not in a small quantity nor too often; nor in so great abundance, nor so often, as to make the patient faint. All matter that is watery, white, of a pale green or red colour, or frothy and viscous, is bad. That which is blackish, or of a livid hue, is the most pernicious. That which is pure black, and nothing else but a discharge of black bile, always prognosticates very ill; this humour, from what part soever it comes, showing the ill disposition of the intestines. The matter that is of several different colours, denotes the length of the distemper; and, at the same time, that it may be of dangerous consequence. Hippocrates places in the same class the matter that is bilious or yellow, and mixed with blood, or green and black, or like the dregs or scrapings of the guts. The stools that consist of pure bile, or entirely of phlegm, he also looks upon to be very bad.

Matter ejected by vomiting ought to be mixed with bile and phlegm; where one of these humours only is observed, it is worse. That which is black, livid, green, or of the colour of a leek, indicates alarming consequences. The same is to be said of that which smells very ill; and if at the same time it be livid, death is not far off. The vomiting of blood is very often a mortal symptom.

Expectoration.

The spittings which give ease in diseases of the lungs and in pleurisies, are those that come up readily and without difficulty; and it is good if they be mixed at the beginning with much yellow: but if they apear of the same colour, or are red, a great while after the beginning of the distemper, if they are salt and acrimonious, and cause violent coughings, they are not good. Spittings purely yellow are bad; and those that are white, viscous, and frothy, give no ease. Whiteness is a good sign of concoction in regard to spittings; but they ought not at all to be viscous, nor too thick, nor too clear. We may make the same judgment of the excrements of the nose according to their concoction and crudity. Spittings that are black, green, and red, are of very bad consequence. In inflammations of the lungs, those that are mixed with bile and blood presage well if they appear at the beginning, but are bad if they arise not about the seventh day. But the worst sign in these distempers is, when there is no expectoration at all, and the too great quantity of matter that is ready to be discharged this way makes a rattling in the breast. After spitting of blood, the discharge of purulent matter then follows, which brings on a consumption, and at last death.

Sweat.

A kind good sweat is that which arises on the day of the crisis, and is discharged in abundance all over the body, and at the same time from all parts of the body, and thus carries off the fever: A cold sweat is alarming, especially in acute fevers, for in others it is only a sign of long continuance. When the patient sweats no where but on the head and neck, it is a sign that the disease will be long and dangerous. A gentle sweat in some particular part of the head and breast, for instance, gives no relief, but denotes the seat of the distemper, or the weakness of the part.

This

Hippocrates.

This kind of sweat was called by Hippocrates *ephidrosis*.

The hypochondria, or the abdomen in general ought always to be soft and even, as well on the right side as on the left. When there is any hardness or unevenness in those parts, or heat and swellings, or when the patient cannot endure to have it touched, it is a sign the intestines are indisposed.

From the pulse.

Hippocrates also inquired into the state of the pulse, or the beating of the arteries. The most ancient physicians, however, and even Hippocrates himself, for a long time, by this word understood the violent pulsation that is felt in an inflamed part, without putting the fingers to it. It is observed by Galen, and other physicians, that Hippocrates touches on the subject of the pulse more slightly than any other on which he treats. But that our celebrated physician understood something even on this subject, is easily gathered from several passages in his writings; as when he observes, that in acute fevers the pulse is very quick and very great; and when he makes mention, in the same place, of trembling pulses, and those that beat slowly. He likewise observes, that in some diseases incident to women, when the pulse strikes the finger faintly, and in a languishing manner, it is a sign of approaching death. He remarks also, in the *Coacæ Prænotiones*, that he whose vein, that is to say, whose artery of the elbow, beats, is just going to run mad, or else that the person is at that time very much under the influence of anger.

From this account of Hippocrates, it will appear, that he was not near so much taken up with reasoning on the phenomena of diseases, as with reporting them. He was content to observe these phenomena accurately, to distinguish diseases by them, and judged of the event by comparing them exactly together. For his skill in prognostics he was indeed very remarkable, as we have already mentioned, insomuch that he and his pupils were looked upon by the vulgar as prophets. What adds very much to his reputation is, that he lived in an age when physic was altogether buried in superstition, and yet he did not suffer himself to be carried away by it; on the contrary, on many occasions, he expresses his abhorrence of it.

Having thus seen in what Hippocrates makes the difference between health and sickness to consist, and likewise the most remarkable signs from whence he drew his prognostics, we must now consider the means he prescribed for the preservation of health, and the cure of diseases. One of his principal maxims was this, That, to preserve health, we ought not to overcharge ourselves with too much eating, nor neglect the use of exercise and labour. In the next place, That we ought by no means to accustom ourselves to too nice and exact a method of living; because those who have once begun to act by this rule, if they vary in the least from it, find themselvss very ill; which does not happen to those who take a little more liberty, and live somewhat more irregularly. Notwithstanding this, he does not neglect to inquire diligently into the articles which those who were in health used for food in his time. Here we cannot help taking notice of the prodigious disparity between the delicacy of the people in our days and in those of Hippocrates: for he takes great pains to tell the difference between the flesh of a dog, a fox, a horse, and an ass; which he would not have done if at that time they had not been used for victuals, at least by the common people. Besides these, however, Hippocrates speaks of all other kinds of provision that are now in use; for example, salads, milk, whey, cheese, flesh as well of birds as of four-footed beasts, fresh and salt fish, eggs, all kinds of pulse, and the different kinds of grain we feed on, as well as the different sorts of bread that are made of it. He also speaks very often of a sort of liquid food, or broth, made of barley-meal, or some other grain, which they steeped for some time, and then boiled in water. With regard to drink, he takes a great deal of pains to distinguish the good waters from the bad. The best, in his opinion, ought to be clear, light, without smell or taste, and taken out of the fountains that turn towards the east. The salt waters, those that he calls hard, and those that rise out of fenny ground, are the worst of all; he condemns also those that come from melted snow. But though Hippocrates makes all those distinctions, he advises those who are in health to drink of the first water that comes in their way. He speaks also of alum waters, and those that are hot; but does not enlarge upon their qualities. He advises to mix wine with an equal quantity of water: and this (he says) is the just proportion; by using which the wine will expel what is hurtful to the body, and the water will serve to temper the acrimony of the humours.

12 His maxims for the preservation of health.

Diet.

Exercise.

For those that are in health, and likewise for such as are sick, Hippocrates advises exercise. The books, however, which treat on this subject, M. Le Clerc conjectures to have been written by Herodicus, who first introduced gymnastic exercise into medicine, and who is said by Hippocrates himself to have killed several people by forcing them to walk while they were afflicted with fevers and other inflammatory disorders. The advices given in them consist chiefly in directions for the times in which we ought to walk, and the condition we ought to be in before it; when we ought to walk slowly, and when to run, &c.; and all this with design to bring the body down, or dissipate the humours. Wrestling, although a violent exercise, is numbered with the rest. In the same place also mention is made of a play of the hands and fingers, which was thought good for health, and called *chironomie;* and of another diversion which was performed round a sort of ball hung up, which they called *corycus*, and which they struck forward with both their hands.

Excretion.

With regard to those things which ought to be separated from, or retained in the human body, Hippocrates observes, that people ought to take great care not to load themselves with excrements, or keep them in too long; and besides the exercise above mentioned, which carries off one part of them, and which he prescribes chiefly on this account, he advises people to excite and rouse up nature when she flagged, and did not endeavour to expel the rest, or take care of the impediments by which she was resisted. For this reason he prescribed meats proper for loosening the belly; and when these were not sufficient, he directed the use of clysters and suppositories. For thin and emaciated persons he directed clysters composed only of milk and oily unctuous substances, which they mixed with a decoction

Hippocrates.

coction of chick-pease; but for such as were plethoric, they only made use of salt or sea-water.

As a preservative against distempers, Hippocrates also advised the use of vomits, which he directed to be taken once or twice a month during the time of winter and spring. The most simple of these were made of a decoction of hyssop, with an addition of a little vinegar and salt. He made those that were of a strong and vigorous constitution take this liquor in a morning fasting; but such as were thin and weakly took it after supper.—Venery, in his opinion, is wholesome, provided people consult their strength, and do not pursue it to excess; which he finds fault with on all occasions, and would have excess avoided also in relation to sleep and watching. In his writings are likewise to be found several remarks concerning good and bad air; and he makes it appear that the good or bad disposition of this element does not depend solely on the difference of the climate, but on the situation of every place in particular. He speaks also of the good and bad effects of the passions, and recommends moderation in regard to them.

From what we have already related concerning the opinions of Hippocrates, it may naturally be concluded, that for the most part he would be contented with observing what the strength of nature is able to accomplish without being assisted by the physician. That this was really the case, may be easily perceived from a perusal of his books entitled, "Of epidemical distempers;" which are, as it were, journals of the practice of Hippocrates: for there we find him often doing nothing more than describing the symptoms of a distemper, and informing us what has happened to the patient day after day, even to his death or recovery, without speaking a word of any kind of remedy. Sometimes, however, he did indeed make use of remedies; but these were exceedingly simple and few, in comparison of what have been given by succeeding practitioners. These remedies we shall presently consider, after we have given an abridgement of the principal maxims on which his practice was founded.

His maxims for the cure of diseases.

Hippocrates asserted in the first place, That contraries, or opposites, are the remedies for each other; and this maxim he explains by an aphorism; in which he says, that evacuations cure those distempers which come from repletion, and repletion those that are caused by evacuation. So heat is destroyed by cold, and cold by heat, &c. In the second place, he asserted that physic is an addition of what is wanting, and a subtraction or retrenchment of what is superfluous: an axiom which is thus explained, that there are some juices or humours, which in particular cases ought to be evacuated, or driven out of the body, or dried up; and some others which ought to be restored to the body, or caused to be produced there again. As to the method to be taken for this addition or retrenchment, he gives this general caution, That you ought to be careful how you fill up, or evacuate, all at once, or too quickly, or too much; and that it is equally dangerous to heat or cool again on a sudden; or rather, you ought not to do it: every thing that runs to an excess being an enemy to nature. In the fourth place, Hippocrates allowed that we ought sometimes to dilate, and sometimes to lock up: to dilate, or open the passages by which the humours are voided naturally, when they are not sufficiently opened, or when they are closed; and, on the contrary, to lock up or straiten the passages that are relaxed, when the juices that pass there ought not to pass, or when they pass in too great quantity. He adds, that we ought sometimes to smooth, and sometimes to make rough; sometimes to harden, and sometimes to soften again; sometimes to make more fine or supple; sometimes to thicken; sometimes to rouse up, and at other times to stupify or take away the sense; all in relation to the solid parts of the body, or to the humours. He gives also this farther lesson, That we ought to have regard to the course the humours take, from whence they come, and whither they go; and in consequence of that, when they go where they ought not, that we make them take a turn about, or carry them another way, almost like the turning the course of a river: or, upon other occasions, that we endeavour if possible to recal, or make the same humours return back again; drawing upward such as have a tendency downward, and drawing downward such as tend upward. We ought also to carry off, by convenient ways, that which is necessary to be carried off; and not let the humours once evacuated enter into the vessels again. Hippocrates gives also the following instruction, That when we do any thing according to reason, though the success be not answerable, we ought not easily, or too hastily, to alter the manner of acting, as long as the reasons for it are yet good. But as this maxim might sometimes prove deceitful, he gives the following as a corrector to it: "We ought (says he) to mind with a great deal of attention what gives ease, and what creates pain; what is easily supported, and what cannot be endured." We ought not to do any thing rashly; but ought often to pause, or wait, without doing any thing: by this way, if you do the patient no good, you will at least do him no hurt.

These are the principal and most general maxims of the practice of Hippocrates, and which proceed upon the supposition laid down at the beginning, viz. that nature cures diseases. We next proceed to consider particularly the remedies employed by him, which will serve to give us further instructions concerning his practice. 14

His maxims respecting diet.

Diet was the first, the principal, and often the only remedy made use of by this great physician to answer most of the intentions above mentioned: by means of it he opposed the moist to dry, hot to cold, &c.; and what he looked upon to be the most considerable point was, that thus he supported nature, and assisted her to overcome the malady. The dietetic part of medicine was so much the invention of Hippocrates himself, that he was very desirous to be accounted the author of it; and the better to make it appear that it was a new remedy in his days, he says expressly, that the ancients had wrote almost nothing concerning the diet of the sick, having omitted this point, though it was one of the most essential parts of the art. 15

Diet in acute diseases.

The diet prescribed by Hippocrates for patients labouring under acute distempers, differed from that which he ordered for those afflicted with chronical ones. In the former, which require a more particular exactness in relation to diet, he preferred liquid food to that which was solid, especially in fevers. For these he used a sort of broth made of cleansed barley; and to this he gave the name of *ptisan*. The manner in which the ancients prepared a ptisan was as follows:

Hippocrates.

They first steeped the barley in water till it was plumped up; and afterwards they dried it in the sun, and beat it to take off the husk. They next ground it; and having let the flour boil a long time in the water, they put it out into the sun, and when it was dry they pressed it close. It is properly this flour so prepared that is called *ptisan*. They did almost the same thing with wheat, rice, lentils, and other grain: but they gave these ptisans the name of the grain from whence they were extracted, as *ptisan of lentils*, *rice*, &c. while the ptisan of barley was called simply *ptisan*, on account of the excellency of it. When they wanted to use it, they boiled one part of it in 10 or 15 of water; and when it began to grow plump in boiling, they added a little vinegar, and a very small quantity of anise or leek, to keep it from clogging or filling the stomach with wind. Hippocrates prescribed this broth for women that have pains in their belly after delivery. "Boil some of this ptisan (says he), with some leek, and the fat of a goat, and give it to the woman in bed." This will not be thought very singular, if we reflect on what has been hinted above concerning the indelicate manner of living in those times. He preferred the ptisan to all other food in fevers, because it softened and moistened much, and was besides of easy digestion. If he was concerned in a continual fever, he would have the patient begin with a ptisan of a pretty thick consistence, and go on by little and little, lessening the quantity of barley-flour as the height of the distemper approached; so that he did not feed the patient but with what he called the *juice of the ptisan;* that is, the ptisan strained, where there was but very little of the flour remaining, in order that nature being discharged in part from the care of digesting the aliments, she might the more easily hold out to the end, and overcome the distemper, or the cause of it. With regard to the quantity, he caused the ptisan to be taken twice a-day by such patients as in health used to take two meals a-day, not thinking it convenient that those who are sick should eat oftener than when they were well. He also would not allow eating twice a-day to those who ate but once in that time when in health. In the paroxysm of a fever he gave nothing at all; and in all distempers where there are exacerbations, he forbade nourishment while the exacerbations continued. He let children eat more; but those who were grown up to man's estate, or were of an advanced age, less; making allowance, however, for the custom of each particular person, or for that of the country.

But though he was of opinion that too much food ought not to be allowed to the sick, he did not agree with some physicians who prescribed long abstinence, especially in the beginning of fevers. The reason he gave for this was, that the contrary practice weakened the patients too much during the first days of the distemper, by which means their physicians were obliged to allow them more food when the illness was at its height, which in his opinion was improper. Besides, in acute distempers, and particularly in fevers, Hippocrates made choice of refreshing and moistening nourishment; and amongst other things prescribed orange, melon, spinach, gourd, &c. This sort of food he gave to those that were in a condition to eat, or could take something more than a ptisan.

[15] Drink.

The drink he commonly gave to his patients was made of eight parts of water and one of honey. In some distempers he added a little vinegar; but besides these, they had another sort named κυκεων, or *mixture*. One prescription of this sort we find intended for a consumptive person; it consisted of rue, anise, celery, coriander, juice of pomegranate, the roughest red wine, water, flour of wheat and barley, with old cheese made of goats milk. Hippocrates did not approve of giving plain water to the sick; but though he generally prescribed the drinks above mentioned, he did not absolutely forbid the use of wine, even in acute distempers and fevers, provided the patients were not delirious nor had pains in their head. Besides, he took care to distinguish the wines proper in these cases; preferring to all other sorts white wine that was clear and had a great deal of water, with neither sweetness nor flavour.

Diet in chronical diseases.

These are the most remarkable particulars concerning the diet prescribed by Hippocrates in acute distempers; in chronical ones he made very much use of milk and whey; though we are not certain whether this was done on account of the nourishment expected from them, or that he accounted them medicines.

His m[ethod] respecting bathing.

There were many diseases for which he judged the bath was a proper remedy; and he takes notice of all the circumstances that are necessary in order to cause the patient receive benefit from it, among which the following are the principal. The patient that bathes himself must remain still and quiet in his place without speaking while the assistants throw water over his head or are wiping him dry; for which last purpose he desired them to keep sponges, instead of that instrument called by the ancients *strigil*, which served to rub off from the skin the dirt and nastiness left upon it by the unguents and oils with which they anointed themselves. He must also take care not to catch cold; and must not bathe immediately after eating and drinking, nor eat or drink immediately after coming out of the bath. Regard must also be had whether the patient has been accustomed to bathe while in health, and whether he has been benefited or hurt by it. Lastly, he must abstain from the bath when the body is too open, or too costive, or when he is too weak; or if he has an inclination to vomit, a great loss of appetite, or bleeds at the nose. The advantage of the bath, according to Hippocrates, consists in moistening and refreshing, taking away weariness, making the skin soft and the joints pliant; in provoking urine, and opening the other excretories. He allows two baths in a day to those who have been accustomed to it in health.

His [opinion] resp[ecting] exer[cise].

In chronical distempers Hippocrates approved very much of exercise, though he did not allow it in acute ones: but even in these he did not think that a patient ought always to lie in bed; but tells us, that "we must sometimes push the timorous out of bed, and rouse up the lazy."

His [opinion] resp[ecting] purg[ation].

When he found that diet and exercise were not sufficient to ease nature of a burden of corrupted humours, he was obliged to make use of other means, of which *purgation* was one. By this word he understood all the contrivances that are made use of to discharge the stomach and bowels; though it commonly signifies only

Hippocrates.

only the evacuation by stool. This evacuation he imagined to be occasioned by the purgative medicines attracting the humours to themselves. When first taken into the body, he thought they attracted that humour which was most similar to them, and then the others, one after another.—Most of the purgatives used in his time were emetics also, or at least were very violent in their operation downwards. These were the white and black hellebore; the first of which is now reckoned among the poisons. He used also the Cnidian berries, cneorum peplium, thapsia; the juice of hippophaë, a sort of rhamnus; elaterium, or juice of the wild cucumber; flowers of brass, coloquintida, scammony, the magnesian stone, &c.

As these purgatives were all very strong, Hippocrates was extremely cautious in their exhibition. He did not prescribe them in the dog-days; nor did he ever purge women with child, and very seldom children or old people. He principally used purgatives in chronical distempers; but was much more wary in acute ones. In his books entitled "Of Epidemical Distempers," there are very few patients mentioned to whom he gave purgative medicines. He also takes notice expressly, that these medicines having been given in cases of the distempers of which he was treating, had produced very bad effects. We are not, however, from this to conclude, that Hippocrates absolutely condemned purging in acute distempers; for in some places he expressly mentions his having given them with success. He was of opinion, for instance, that purging was good in a pleurisy when the pain was seated below the diaphragm; and in this case he gave black hellebore, or some peplium mixed with the juice of *laserpitium*.

The principal rule Hippocrates gives with relation to purging is, that we ought only to purge off the humours that are concocted, and not those that are yet crude, taking particular care not to do it at the beginning of the distemper, lest the humours should be disturbed or stirred up, which happens pretty often. He was not, however, the first who remarked that it would be of ill consequence to stir the humours in the beginning of an acute distemper. The Egyptian physicians had before observed the same thing. By the *beginning* of a distemper, Hippocrates understood all the time from the first day to the fourth complete.

Hippocrates imagined that each purgative medicine was adapted to the carrying off some particular humour; and hence the distinction of purgatives into hydragogue, cholagogue, &c. which is now justly exploded. In consequence of this notion, he contended that we knew if a purgative had drawn from the body what was fit to be evacuated according as the patient was found well or ill upon it. If we found ourselves well, it was a sign that the medicine had effectually expelled the offending humour. On the contrary, if we were ill, he imagined, whatever quantity of humour came away, that the humour which caused the illness still remained; not judging of the goodness or badness of a purge by the quantity of matters that were voided by it, but by their quality and the effect that followed after it.

Vomits were also pretty much used as medicines by Hippocrates. We have already seen what those were which he prescribed to people in health by way of preventives. With regard to the sick, he sometimes advised them to the same, when his intentions were only to cleanse the stomach. But when he had a mind to recal the humours, as he termed it, from the inmost recesses of the body, he made use of brisker remedies. Among these was white hellebore; and this indeed he most frequently used to excite vomiting. He gave this root particularly to melancholy and mad people; and from the great use made of it in these cases by Hippocrates and other ancient physicians, the phrase *to have need of hellebore*, became a proverbial expression for being out of one's senses. He gave it also in defluxions, which come, according to him, from the brain, and throw themselves on the nostrils or ears, or fill the mouth with saliva, or that cause stubborn pains in the head, and a weariness or an extraordinary heaviness, or a weakness of the knees, or a swelling all over the body. He gave it to consumptive persons in broth of lentils, to such as were afflicted with the dropsy called *leucophlegmatia*, and in other chronical disorders. But we do not find that he made use of it in acute distempers, except in the cholera morbus, where he says he prescribed it with benefit. Some took this medicine fasting; but most took it after supper, as was commonly practised with regard to vomits taken by way of prevention. The reason why he gave this medicine most commonly after eating was, that by mixing with the aliments, its acrimony might be somewhat abated, and it might operate with less violence on the membranes of the stomach. With the same intention also he sometimes gave a plant called *sesamoides*, and sometimes mixed it with hellebore. Lastly, in certain cases he gave what he called *soft* or *sweet* hellebore. This term had some relation to the quality of the hellebore, or perhaps the quantity he gave.

When Hippocrates intended only to keep the body open, or evacuate the contents of the intestines, he made use of simples; as, for example, the herb mercury, or cabbage; the juice or decoction of which he ordered to be drank. For the same purpose he used whey, and also cows and asses milk; adding a little salt to it, and sometimes letting it boil a little. If he gave asses milk alone, he caused a great quantity of it to be taken, so that it must of necessity loosen the body. In one place he prescribes no less than nine pounds of it to be taken as a laxative, but does not specify the time in which it was to be taken. With the same intention he made use of suppositories and clysters. The former were compounded of honey, the juice of the herb mercury, of nitre, powder of colocynth, and other sharp ingredients, to irritate the anus. These they formed into a ball, or into a long cylindrical mass like a finger. The clysters he made use of for sick people were sometimes the same with those already mentioned as preventives for people in health. At other times he mixed the decoction of herbs with nitre, honey, and oil, or other ingredients, according as he imagined he could by that means attract, wash, irritate, or soften. The quantity of liquor he ordered was about 36 ounces; from which it is probable he did not intend that it should all be used at one time.

On some occasions Hippocrates proposed to purge the head alone. This practice he employed after purging the rest of the body, in an apoplexy, inveterate pains

Hippocrates.

pains of the head, a certain sort of jaundice, a consumption, and the greatest part of chronical distempers. For that purpose he made use of the juices of several plants, as celery; to which he sometimes added aromatic drugs, making the patients snuff up this mixture into their nostrils. He used also powders compounded of myrrh, the flowers of brass, and white hellebore, which he caused them put up into the nose, to make them sneeze, and to draw the phlegm from the brain. For the same purpose also he used what he calls *tetragonon*, that is, "something having four angles;" but what this was, is now altogether unknown, and was so even in the days of Galen. The latter physician, however, conjectures it to be antimony, or certain flakes found in it.

In the distemper called *empyema* (or a collection of matter in the breast), he made use of a very rough medicine. He commanded the patient to draw in his tongue as much as he was able; and when that was done, he endeavoured to put into the hollow of the lungs a liquor that irritated the part, which raising a violent cough, forced the lungs to discharge the purulent matter contained in them. The materials that he used for this purpose were of different sorts; sometimes he took the root of arum, which he ordered to be boiled with a little salt, in a sufficient quantity of water and oil; dissolving a little honey in it. At other times, when he intended to purge more strongly, he took the flowers of copper and hellebore; after that he shook the patient violently by the shoulders, the better to loosen the pus. This remedy, according to Galen, he received from the Cnidian physicians; and it has never been used by the succeeding ones, probably because the patients could not suffer it.

20 His maxims respecting blood-letting.

Blood-letting was another method of evacuation pretty much used by Hippocrates. Another aim he had in this, besides the mere evacuation, was to divert or recal the course of the blood when he imagined it was going where it ought not. A third end of bleeding was to procure a free motion of the blood and spirits,

Hippocrates had also a fourth intention for bleeding, and this was refreshment. So in the iliac passion, he orders bleeding in the arm and in the head; to the end, says he, that the superior venter, or the breast, may cease to be overheated. With regard to this evacuation, his conduct was much the same as to purging, in respect of time and persons. We ought, says he, to let blood in acute diseases, when they are violent, if the party be lusty and in the flower of his age. We ought also to have regard to the time, both in respect to the disease and to the season in which we let blood. He also informs us, that blood ought to be let in great pains, and particularly in inflammations. Among these he reckons such as fall upon the principal viscera, as the liver, lungs, and spleen, as also the quinsy and pleurisy, if the pain of the latter be above the diaphragm. In these cases he would have the patients blooded till they faint, especially if the pain be very acute; or rather he advises that the orifice should not be closed till the colour of the blood alters, so that from livid it turn red, or from red livid. In a quinsy he blooded in both arms at once. Difficulty of breathing he also reckons among the distempers that require bleeding; and he mentions another sort of inflammation of the lungs, which he calls a swelling or tumor of the lungs arising from heat; in which case he advises to bleed in all parts of the body; and directs it particularly by the arms, tongue, and nostrils. To make bleeding the more useful in all pains, he directed to open the vein nearest the part affected; in a pleurisy he directs to take blood from the arm of the side affected; and for the same reason, in pains of the head, he directs the veins of the nose and forehead to be opened. When the pain was not urgent, and bleeding was advised by way of prevention, he directed the blood to be taken from the parts farthest off, with a design to divert the blood insensibly from the seat of pain. The highest burning fevers, which show neither signs of inflammation nor pain, he does not rank among those distempers which require bleeding. On the contrary, he maintains that a fever itself is in some cases a reason against bleeding. If any one, says he, has an ulcer in the head, he must bleed, *unless he has a fever*. He says further, those that lose their speech of a sudden must be blooded, unless they have a fever. Perhaps he was afraid of bleeding in fevers, because he supposed that they were produced by the bile and pituita, which grew hot, and afterwards heated the whole body, which is, says he, what we call *fever*, and which, in his opinion, cannot well be evacuated by bleeding. In other places also he looks upon the presence or abundance of bile to be an objection to bleeding; and he orders to forbear venesection even in a pleurisy, if there be bile. To this we must add, that Hippocrates distinguished very particularly between a fever which followed no other distemper, but was itself the original malady, and a fever which came upon inflammation. In the early ages of physic, the first only were properly called *fevers*: the others took their names from the parts affected; as *pleurisy*, *peripneumony*, *hepatitis*, *nephritis*, &c, which names signify that the pleura, the lungs, the liver, or the kidneys, are diseased, but do not intimate the fever which accompanies the disease. In this latter sort of fever Hippocrates constantly ordered bleeding, but not in the former. Hence, in his books on Epidemic Distempers, we find but few directions for bleeding in the acute distempers, and particularly in the great number of continual and burning fevers there treated of. In the first and third book we find but one single instance of bleeding, and that in pleurisy; in which too, he staid till the eighth day of the distemper. Galen, however, and most other commentators on Hippocrates, are of opinion that he generally blooded his patients plentifully in the beginning of acute disorders, though he takes no notice of it in his writings. But had this been the case, he would not perhaps have had the opportunity of seeing so many fevers terminate by crisis, or natural evacuations, which happen of themselves on certain days. Hippocrates, in fact, laid so much weight upon the assistance of nature and the method of diet, which was his favourite medicine, that he thought if they took care to diet the patients according to rule, they might leave the rest to nature. These are his principles, from which he never deviates; so that his writings on Epidemical Diseases seem to have been composed only with an intention to leave to posterity an exact model of management in pursuance of these principles.

Hippocrates.

Hippocrates.

With regard to the rules laid down by Hippocrates for bleeding, we must farther take notice, that in all diseases which had their seat above the liver, he blooded in the arm, or in some of the upper parts of the body; but for those that were situated below it, he opened the veins of the foot, ankle, or ham. If the belly was too loose, and bleeding was at the same time thought necessary, he ordered the looseness to be stopped before bleeding.

Almost all these instances, however, regard scarcely any thing but acute distempers; but we find several concerning chronical diseases. "A young man complained of great pain in his belly, with a rumbling while he was fasting, which ceased after eating: this pain and rumbling continuing, his meat did him no good; but, on the contrary, he daily wasted and grew lean. Several medicines, as well purges as vomits, were given him in vain. At length it was resolved to bleed him by intervals, first in one arm and then in the other, till he had scarcely any blood left, and by this method he was perfectly cured."

Hippocrates let blood also in a dropsy, even in a tympany; and in both cases he prescribes bleeding in the arm. In a disease occasioned by an overgrown spleen, he proposes bleeding several times repeated at a vein of the arm which he calls the *splenetic;* and in one species of jaundice, he proposes bleeding under the tongue. On some occasions he took away great quantities of blood, as appears from what we have already observed. Sometimes he continued the blooding till the patient fainted: at other times he would blood in both arms at once; at others, he did it in several places of the body, and at several times. The veins he opened were those of the arm, the hands, the ankles on both sides, the hams, the forehead, behind the head, the tongue, the nose, behind the ears, under the breasts, and those of the arms; besides which, he burnt others, and opened several arteries. He likewise used cupping-vessels, with intent to recal or withdraw the humours which fell upon any part. Sometimes he contented himself with the bare attraction made by the cupping-vessels, but sometimes also he made scarifications.

21 H[is] maxims re[spe]cting di[ure]tics a[nd] sudo[rifics].

When bleeding and purging, which were the principal and most general means used by Hippocrates for taking off a plethora, proved insufficient for that purpose, he had recourse to diuretics and sudorifics. The former were of different sorts, according to the constitution of the persons: sometimes baths, and sometimes sweet wine, were employed to provoke urine; sometimes the nourishment which we take contributes to it: and amongst those herbs which are commonly eaten, Hippocrates recommends garlic, leeks, onions, cucumbers, melons, gourds, fennel, and all other things which have a biting taste and a strong smell. With these he numbers honey, mixed with water or vinegar, and all salt meats. But, on some occasions, he took four cantharides, and, pulling off their wings and feet, gave them in wine and honey. These remedies were given in a great number of chronical distempers after purging, when he thought the blood was overcharged with a sort of moisture which he calls *ichor;* or in suppressions of urine, and when it was made in less quantity than it ought. There were also some cases in which he would force sweat as well as urine; but he neither mentions the diseases in which sudorifics are proper, nor lets us know what medicines are to be used for this purpose, except in one single passage, where he mentions sweating, by pouring upon the head a great quantity of water till the feet sweat; that is, till the sweat diffuses itself over the whole body, running from head to foot. After this he would have them eat boiled meat, and drink pure wine, and being well covered with clothes, lay themselves down to rest. The disease for which he proposes the above-mentioned remedy is a fever; which is not, according to him, produced by bile or pituita, but by mere lassitude, or some other similar cause; from whence we may conclude that he did not approve of sweating in any other kind of fever.

Other remedies which Hippocrates tells us he made use of were those that purged neither bile nor phlegm, but act by cooling, drying, heating, moistening, or by closing and thickening, resolving and dissipating. These medicines, however, he does not particularly mention; and it is probable they were only some particular kinds of food. To these he joined *hypnotics*, or such things as procure sleep; but these last were used very seldom, and, it is most probable, were only different preparations of poppies.

22 The use he made of specifics.

Lastly, besides the medicines already mentioned, which acted in a sensible manner, Hippocrates made use of others called *specifics;* whose action he did not understand, and for the use of which he could give no reason but his own experience, or that of other physicians. These he had learned from his predecessors the descendants of Æsculapius, who, being *empirics*, did not trouble themselves about enquiring into the operation of remedies, provided the patients were cured.

23 His external applications.

Of the external remedies prescribed by Hippocrates, fomentations were the chief. These were of two kinds. The one was a sort of bath, in which the patient sat in a vessel full of a decoction of simples appropriated to his malady; so that the part affected was soaked in the decoction. This was chiefly used in distempers of the womb, of the arms, the bladder, the reins, and generally all the parts below the diaphragm. The second way of fomenting was, to take warm water and put it into a skin or bladder, or even into a copper or earthen vessel, and to apply it to the part affected; as, for example, in a pleurisy. They used likewise a large sponge, which they dipped in the water or other hot liquor, and squeezed out part of the liquor before they applied it. The same use they made of barley, vetches, or bran, which were boiled in some proper liquor, and applied in a linen bag. They are called *moist* fomentations. The dry ones were made of salt or millet, heated considerably, and applied to the part. Another kind of fomentation was the vapour of some hot liquor; an instance of which we find in the first book of the Distempers of Women. He cast, at several times, bits of red-hot iron into urine, and, covering up the patient close, caused her to receive the steam below. His design in these kinds of fomentations was to warm the part, to resolve or dissipate, and draw out the peccant matter, to mollify and assuage pain, to open the passages, or even to shut them, according as the fomentations were emollient or astringent.

24 Fomentations.

Fumigations

Hippocrates.

25 Fumigations. Fumigations were likewise very often used by Hippocrates. In the quinsy, he burned hyssop with sulphur and pitch, and caused the smoke to be drawn into the throat by a funnel; and by this means he brought away abundance of phlegm through the mouth and through the nose. For this purpose he took nitre, marjoram, and cress-seeds, which he boiled in water, vinegar, and oil, and, while it was on the fire, caused the patient to draw in the steam by a pipe. In his works we find a great number of fumigants for the distempers of women, to promote the menstrual flux, to check it, to help conception, and to ease pains in the matrix, or the suffocation of it. On these occasions he used such aromatics as were then known, viz. cinnamon, cassia, myrrh, and several odoriferous plants; likewise some minerals, such as nitre, sulphur, and pitch, and caused the patient to receive the vapours through a funnel into the uterus.

26 Gargles. Gargles, a kind of fomentations for the mouth, were also known to Hippocrates. In the quinsy he used a gargle made of marjoram, savory, celery, mint, and nitre, boiled with water and a little vinegar. When this was strained, they added honey to it, and washed their mouths frequently with it.

27 Oils and ointments. Oils and ointments were likewise much used by Hippocrates, with a view to mollify and abate pain, to ripen boils, resolve tumours, refresh after weariness, make the body supple, &c. For this purpose, sometimes pure oil of olives was used; sometimes certain simples were infused in it, as the leaves of myrtle and roses; and the latter kind of oil was in much request among the ancients. There were other sorts of oils sometimes in use, however, which were much more compounded. Hippocrates speaks of one named Susinum, which was made of the flowers of the iris, of some aromatics, and of an ointment of narcissus made with the flowers of narcissus and aromatics infused in oil. But the most compounded of all his ointments was that called *netopon*, which he made particularly for women; and consisted of a great number of ingredients. Another ointment, to which he gave the name of *ceratum*, was composed of oil and wax. An ointment which he recommends for the softening a tumor, and the cleansing a wound, was made by the following receipt: "Take the quantity of a nut of the marrow or fat of a sheep, of mastic or turpentine the quantity of a bean, and as much wax; melt these over a fire, with oil of roses, for a ceratum." Sometimes he added pitch and wax, and, with a sufficient quantity of oil, made a composition somewhat more consistent than the former, which he called *cerapissus*.

28 Cataplasms. *Cataplasms* were a sort of remedies less consistent than the two former. They were made of powders or herbs steeped or boiled in water or some other liquor, to which sometimes oil was added. They were used with a view to soften or resolve tumors, ripen abscesses, &c. though they had also cooling cataplasms made of the leaves of beets or oak, fig or olive-trees, boiled in water.

29 Collyria. Lastly, To complete the catalogue of the external remedies used by Hippocrates, we shall mention a sort of medicine called *collyrium*. It was compounded of powders, to which was added a small quantity of some ointment, or juice of a plant, to make a solid or dry mass; the form of which was long and round, which was kept for use. Another composition of much the same nature was a sort of lozenge of the bigness of a small piece of money, which was burnt upon coals for a perfume, and powdered for particular uses. In his works we find likewise descriptions of powders for several uses, to take off fungous flesh, and to blow into the eyes in opthalmics, &c.

These were almost all the medicines used by Hippocrates for external purposes. The compound medicines given inwardly were either liquid, solid, or lambative. The liquid ones were prepared either by decoction or infusion in a proper liquor, which, when strained, were kept for use; or by macerating certain powders in such liquors, and so taking them together, or by mixing different kinds of liquors together. The solid medicines consisted of juices inspissated; of gums, resins, or powders, made up with them or with honey, or something proper to give the necessary consistence to the medicine. These were made up in a form and quantity fit to be swallowed with ease. The lambative was of a consistence between solid and fluid; and the patients were obliged to keep it for some time to dissolve in the mouth, that they might swallow it leisurely. This remedy was used to take off the acrimony of those humours which sometimes fall upon this part, and provoke coughing and other inconveniences. The basis of this last composition was honey. It is worth our observation, that the compound medicines of Hippocrates were but very few, and composed only of four or five ingredients at most; and that he not only understood pharmacy, or the art of compounding medicines, but prepared such as he used himself, or caused his servants prepare them in his house by his directions.

We have thus given some account of the state of medicine as practised and taught by Hippocrates, who, as we have already observed, has for many ages been justly considered as the father of physic. For when we attend to the state in which he found medicine, and the condition in which he left it, we can hardly bestow sufficient admiration on the judgment and accuracy of his observations. After a life spent in unwearied industry, he is said to have died at Larissa, a city in Thessaly, in the 101st year of his age, 361 years before the birth of Christ.

After the days of Hippocrates, medicine in ancient Greece gradually derived improvement from the labour of other physicians of eminence. And we may particularly mention three to whom its future progress seems to have been not a little indebted; viz. Praxagoras, Erasistratus, and Herophilus.

30 Praxagoras. The first physician of eminence who differed considerably in his practice from Hippocrates was Praxagoras. Cœlius Aurelianus acquaints us, that he made great use of vomits in his practice, insomuch as to exhibit them in the iliac passion till the excrements were discharged by the mouth. In this distemper he also advised, when all other means failed, to open the belly, cut the intestine, take out the indurated fæces, and then to sew up all again; but this practice has not probably been followed by any subsequent physician.

31 Erasistratus. Erasistratus was a physician of great eminence, and flourished in the time of Seleucus, one of the successors of Alexander the Great. According to Galen,

Erasistratus.

Galen, he entirely banished venesection from medicine; though some affirm that he did not totally discard it, but only used it less frequently than other physicians. His reasons for disapproving of venesection are as follow: It is difficult to succeed in venesection, because we cannot always see the vein we intend to open, and because we are not sure but we may open an artery instead of a vein. We cannot ascertain the true quantity to be taken. If we take too little, the intention is by no means answered: if we take too much, we run a risk of destroying the patient. The evacuation of the venous blood also is succeeded by that of the spirits, which on that occasion he supposes to pass from the arteries into the veins. It must likewise, he contends, be observed, that as the inflammation is formed in the arteries by the blood coagulated in their orifices, venesection must of course be useless and of no effect.

As Erasistratus did not approve of venesection, so neither did he of purgatives, excepting very rarely, but exhibited clysters and vomits; as did also his master Chrysippus. He was of opinion, however, that the clysters should be mild; and condemned the large quantity and acrid quality of those used by preceding practitioners. The reason why purgatives were not much used by him was, that he imagined purging and venesection could answer no other purpose than diminishing the fulness of the vessels; and for this purpose he assserted that there were more effectual means than either phlebotomy or purging. He asserted that the humours discharged by cathartics were not the same in the body that they appeared after the discharge; but that the medicines changed their nature, and produced a kind of corruption in them. This opinion has since been embraced by a great number of physicians. He did not believe that purgatives acted by attraction; but substituted in the place of this principle what Mr Le Clerc imagines to be the same with Aristotle's *fuga vacui*. The principal remedy substituted by him in place of purging and venesection was abstinence. When this, in conjunction with clysters and vomits, was not sufficient to eradicate the disease, he then had recourse to exercise. All this was done with a view to diminish plenitude, which, according to him, was the most frequent cause of all diseases. Galen also informs us, that Erasistratus had so great an opinion of the virtues of succory in diseases of the viscera and lower belly, and especially in those of the liver, that he took particular pains to describe the method of boiling it, which was, to boil it in water till it was tender; then to put it into boiling water a second time, in order to destroy its bitterness; afterwards to take it out of the water, and preserve it in a vessel with oil; and lastly, when it is to be used, add a little weak vinegar to it. Nay, so minute and circumstantial was Erasistratus with regard to the preparation of his favourite succory, that he gave orders to tie several of the plants together, because that was the more commodious method of boiling them. The rest of Erasistratus's practice consisted almost entirely of regimen; to which he added some topical remedies, such as catapsalms, fomentations, and unctions. In short, as he could neither endure compounded medicines, nor superstitious and fine-spun reasonings, he reduced medicine to a very simple and compendious art.

With regard to surgery, Erasistratus appears to have been very bold; and as an anatomist he is said to have been exceedingly cruel, insomuch that he is represented by some as having dissected criminals while yet alive *. In a scirrhous liver, or in tumours of that organ, Cœlius Aurelianus observes, that Erasistratus made an incision through the skin and integuments, and having opened the abdomen he applied medicines immediately to the part affected. But though he was thus bold in performing operations on the liver, yet he did not approve of the paracentesis or tapping in the dropsy; because (said he) the waters being evacuated, the liver, which is inflamed and become hard like a stone, is more pressed by the adjacent parts which the waters kept at a distance from it, so that by this means the patient dies. He declared also against drawing teeth which were not loose; and used to tell those who talked with him on this operation, That in the temple of Apollo there was to be seen an instrument of lead for drawing teeth; in order to insinuate that we must not attempt the extirpation of any but such as are loose, and call for no greater force for their extirpation than what may be supposed in an instrument of lead.

Herophilus.

* See Anatomy, *Hist.*

32 Herophilus.

Herophilus, the disciple of Praxagoras, and contemporary of Erasistratus, followed a less simple practice: he made so great use of medicines both simple and compound, that neither he nor his disciples would undertake the cure of any disorder without them. He seems also to have been the first who treated accurately of the doctrine of pulses, of which Hippocrates had but a superficial knowledge. Galen, however, affirms, that on this subject he involved himself in difficulties and advanced absurdities; which indeed we are not greatly to wonder at, considering the time in which he lived. He took notice of a disease at that time pretty rare, and to which he ascribes certain sudden deaths. He calls it a *palsy of the heart;* and perhaps it may be the same disease with what is now termed the *angina pectoris*.

According to Celsus, it was about this time that medicine was first divided into three branches, viz. the dietetic, the pharmaceutical, and the chirurgical medicine. The first of these employed a proper regimen in the cure of diseases; the second, medicines; and the third, the operation of the hands. The same author informs us, that these three branches became now the business of as many distinct classes of men; so that from this time we may date the origin of the three professions of physicians, apothecaries, and surgeons.—Before this division, those called *physicians* discharged all the several offices belonging to the three professions; and there were only two kinds of them, viz. one called αρχιτεκτονικοι, who gave only their advice to the patients, and directions to those of an inferior class, who were called δημιουργοι, and worked with their hands either in the performing operations, or in the composition and application of remedies.

33 The Empirics.

The first grand revolution which happened in the medicinal art, after the days of Herophilus and Erasistratus, was occasioned by the founding of the empiric sect by Serapion of Alexandria about 287 years before Christ. The division into dogmatists and empirics had indeed subsisted before; but about this time the latter party began to grow strong, and to have champions

34 Serapion.

Serapion.

pions publicly asserting its cause. Galen informs us, that Serapion used Hippocrates very ill in his writings, in which he discovered an excess of pride, self-sufficiency, and contempt for all the physicians that went before him. We have some sketches of his practice in Cœlius Aurelianus, from which we may infer that he retained the medicines of Hippocrates and the other physicians who went before him, though he rejected their reasoning. We know not what arguments he advanced for the support of his sentiments, since his works are lost, as well as those of the other empirics; and we should know nothing at all of any of them, if their adversaries had not quoted them in order to confute them.

The empirics admitted only one general method of obtaining skill in the medical art, which was by experience, called by the Greeks εμπειρια. From this word they took their name, and refused to be called after the founder or any champion of their sect. They defined experience a knowledge derived from the evidence of sense. It was either fortuitous, or acquired by design. For acquiring practical skill they recommended what they called τηρησις, or one's own observation, and the reading of histories or cases faithfully related by others. Hence they thought that we might be enabled to know a disease by its resemblance to others; and, when new diseases occurred, to conclude what was proper to be done from the symptoms they had in common with others that were before known. They asserted, that observation ought principally to be employed in two different ways; first, in discovering what things are salutary, and what are of an indifferent nature; and, secondly, what particular disease is produced by a certain concurrence of symptoms; for they did not call every symptom a disease, but only such a combination of them as from long experience they found to accompany each other, and produced such disorders as began and terminated in the same manner.

On the other hand, the dogmatist affirmed, that there was a necessity for knowing the latent as well as the evident causes of diseases, and that the physician ought to understand the natural actions and functions of the human body, which necessarily presupposes a knowledge of the internal parts. By secret or latent causes they meant such as related to the elements or principles of which our bodies are composed, and which are the origin of a good or bad state of health. They asserted that it was impossible to know how to cure a disease without knowing the cause whence it proceeded; because undoubtedly it behoved diseases to vary prodigiously in themselves according to the different causes by which they were produced.

35 Asclepiades.

The next remarkable person in the history of physic is Asclepiades, who flourished in the century immediately preceding the birth of Christ. He introduced the philosophy of Democritus and Epicurus into medicine, and ridiculed the doctrines of Hippocrates. He asserted, that matter considered in itself was of an unchangeable nature; and that all perceptible bodies were composed of a number of smaller ones, between which there were interspersed an infinity of small spaces totally void of all matter. He thought that the soul itself was composed of these small bodies. He laughed at the principle called *Nature* by Hippocrates, and also at the imaginary faculties said by him to be subservient to her; and still more at what he called *Attraction.* This last principle Asclepiades denied in every instance, even in that of the loadstone and steel, imagining that this phenomenon proceeded from a concourse of corpuscles, and a particular disposition or modification of their pores. He also maintained, that nothing happened or was produced without some cause; and that what was called *nature* was in reality no more than *matter* and *motion.* From this last principle he inferred that Hippocrates knew not what he said when he spoke of Nature as an intelligent being, and ascribed qualities of different kinds to her. For the same reason he ridiculed the doctrine of Hippocrates with regard to crises; and asserted that the termination of diseases might be as well accounted for from mere matter and motion. He maintained, that we were deceived if we imagined that nature always did good; since it was evident that she often did a great deal of harm. As for the days particularly fixed upon by Hippocrates for crises, or those on which we usually observe a change either for the better or the worse, Asclepiades denied that such alterations happened on those days rather than on others. Nay, he asserted that the crisis did not happen at any time of its own accord, or by the particular determination of nature for the cure of the disorder, but that it depended rather on the address and dexterity of the physician; that we ought never to wait till a distemper terminates of its own accord, but that the physician by his care and medicines must hasten on and advance the cure.—According to him, Hippocrates and other ancient physicians attended their patients rather with a view to observe in what manner they died than in order to cure them; and thus under pretence that Nature ought to do all herself, without any assistance.

According to Asclepiades, the particular assemblage of the various corpuscles above mentioned, and represented as of different figures, is the reason why there are several pores or interstices within the common mass, formed by these corpuscles; and why these pores are of a different size. This being taken for granted, as these pores are in all the bodies we observe, it must of course follow that the human body has some peculiar to itself, which, as well as those of all other bodies, contain certain minute bodies, which pass and repass by those pores that communicate with each other; and as these pores or interstices are larger or smaller, so the corpuscles which pass through them differ proportionally as to largeness and minuteness. The blood consists of the largest of these corpuscles, and the spirits, or the heat, of the smallest.

From these principles he infers, that as long as the corpuscles are freely received by the pores, the body remains in its natural state, and, on the contrary, it begins to recede from that state, when the corpuscles find any obstacle to their passage. Health therefore depends on the just proportion between the pores and the corpuscles they are destined to receive and transmit; as diseases, on the contrary, proceed from a disproportion between these pores and the corpuscles. The most usual obstacle on this occasion proceeds from the corpuscles embracing each other, and being retained in some of their ordinary passages, whether these corpus-
cles

cles arrive in too large a number, are of irregular figures, move too fast or too slow, &c.

Among the diseases produced by the corpuscles stopping of their own accord, Asclepiades reckoned phrensies, lethargies, pleurisies, and burning fevers. Pains, in particular, are classed among the accidents which derive their origin from a stagnation of the largest of all the corpuscles of which the blood consists. Among the disorders produced by the bad state and disposition of the pores, he placed deliquiums, languors, extenuations, leanness, and dropsies. These last disorders he thought proceeded from the pores being too much relaxed and opened: the dropsy in particular, he thinks, proceeds from the flesh being perforated with various small holes, which convert the nourishment received into them into water. Hunger, and especially that species of it called *fames canina*, proceeds from an opening of the large pores of the stomach and belly; and thirst from an opening of their small ones. Upon the same principles he accounted for intermittent fevers. According to him, quotidian fevers are caused by a retention of the largest corpuscles, those of the tertian kind by a retention of corpuscles somewhat smaller, and quartan fevers are produced by a retention of the smallest corpuscles of all.

The practice of Asclepiades was suited to remove these imaginary causes of disorders. He composed a book concerning common remedies, which he principally reduced to three, viz. gestation, friction, and the use of wine. By various exercises he proposed to render the pores more open, and to make the juices and small bodies, which cause diseases by their retention, pass more freely; and while the former physicians had not recourse to gestation till towards the end of long continued disorders, and when the patients, though entirely free from fever, were yet too weak to take sufficient exercise by walking, Asclepiades used gestation from the very beginning of the most burning fevers. He laid it down as a maxim, that one fever was to be cured by another; that the strength of the patient was to be exhausted by making him watch and endure thirst to such a degree, that, for the two first days of the disorder, he would not allow them to cool their mouths with a drop of water. Celsus also observes, that though Asclepiades treated his patients like a butcher during the first days of the disorder, he indulged them so far afterwards as even to give directions for making their beds in the softest manner. On several occasions Asclepiades used frictions to open the pores. The dropsy was one of the distempers in which this remedy was used; but the most singular attempt was, by this means, to lull phrenetic patients asleep. But though he enjoined exercise so much to the sick, he denied it to those in health; a conduct not a little surprising and extraordinary. He allowed wine freely to patients in fevers, provided the violence of the distemper was somewhat abated. Nor did he forbid it to those who were afflicted with a phrensy: nay, he ordered them to drink it till they were intoxicated, pretending by that means to make them sleep; because he said, wine had a narcotic quality and procured sleep, which he thought absolutely necessary for those who laboured under that disorder. To lethargic patients he used it on purpose to excite them, and rouse their senses: he also made them smell strong-scented substances, such as vinegar, castor, and rue, in order to make them sneeze; and applied to their heads cataplasms of mustard made up with vinegar.

Asclepiades, &c.

Besides these remedies, Asclepiades enjoined his patients abstinence to an extreme degree. For the first three days, according to Celsus, he allowed them no aliment whatever, but on the fourth began to give them victuals. According to Cælius Aurelianus, however, he began to nourish his patients as soon as the accession of the disease was diminished, not waiting til an entire remission; giving to some aliments on the first, and some on the second, to some on the third, and so on to the seventh day. It seems almost incredible to us, that people should be able to fast till this last-mentioned term; but Celsus assures us, that abstinence till the seventh day was enjoined even by the predecessors of Asclepiades.

The next great revolution which happened in the medicinal art, was brought about by Themison, the disciple of Asclepiades, who lived not long before the time of Celsus, during the end of the reign of Augustus, or beginning of that of Tiberius. The sect founded by him was called *methodic*, because he endeavoured to find a method of rendering medicine more easy than formerly.

36 Methodic sect.

37 Themison.

He maintained, that a knowledge of the causes of diseases was not necessary, provided we have a due regard to what diseases have in common and analogous to one another. In consequence of this principle, he divided all diseases into two, or at most three, kinds. The first included diseases arising from stricture; the second, those arising from relaxation; and the third, those of a mixed nature, or such as partook both of stricture and relaxation.

Themison also asserted, that diseases are sometimes acute, and sometimes chronical; that for a certain time they increase; that at a certain time they are at their height; and that at last they were observed to diminish. Acute diseases, therefore, according to him, must be treated in one way, and chronical diseases in another; one method must be followed with such as are in their augmentation, another with such as are at their height, and a third with such as are in their declension. He asserted that the whole of medicine consisted in the observation of that small number of rules which are founded upon things altogether evident. He said, that all disorders, whatever their nature was, if included under any of the kinds above mentioned, ought to be treated precisely in the same way, in whatever country and with whatever symptoms they happen to arise. Upon these principles, he defined medicine to be a method of conducting to the knowledge of what diseases have in common with each other.

Themison was old when he laid the foundation of the methodic sect; and it was only brought to perfection by Thessalus, who lived under the emperor Nero. Galen and Pliny accuse this physician of intolerable insolence and vanity, and report that he gave himself the air of despising all other physicians; and so intolerable was his vanity, that he assumed the title of *the conqueror of physicians*, which he caused to be put upon his tomb in the Appian way. Never was mountebank (says Pliny) attended by a greater number of spectators

38 Thessalus.

Thessalus, &c. spectators than Thessalus had generally about him; and this circumstance is the less to be wondered at, if we consider that he promised to teach the whole art of medicine in less than six months. In reality, the art might be learned much sooner if it comprehended no more than what the methodics thought necessary; for they cut off the explanation of the causes of diseases followed by the dogmatics; and substituted in the room of the laborious observations of the empiries, indications drawn from the analogy of diseases, and the mutual resemblance they bear to each other. The most skilful of all the methodic sect, and he who put

39 Soranus. the last hand to it, was Soranus. He lived under the emperors Trajan and Adrian, and was a native of Ephesus.

40 Celsus. One of the most celebrated medical writers of antiquity was Celsus, whom we have already had occasion to mention. Most writers agree that he lived in the time of Tiberius, but his country is uncertain. It is even disputed whether or not he was a professed physician. Certain it is, however, that his books on medicine are the most valuable of all the ancients next to those of Hippocrates. From the latter, indeed, he has taken so much, as to acquire the name of the *Latin Hippocrates;* but he has not attached himself to him so closely as to reject the assistance of other authors. In many particulars he has preferred Asclepiades. With him he laughs at the critical days of Hippocrates, and ascribes the invention of them to a foolish and superstitious attachment to the Pythagorean doctrine of numbers. He also rejected the doctrine of Hippocrates with regard to venesection, of which he made a much more general use; but did not take away so much blood at a time, thinking it much better to repeat the operation than weaken the patient by too great an evacuation at once. He used cupping also much more frequently, and differed from him with regard to purgatives. In the beginning of disorders, he said, the patients ought to endure hunger and thirst: but afterwards they were to be nourished with good aliments; of which, however, they were not to take too much, nor fill themselves suddenly, after having fasted long. He does not specify how long the patient ought to practise abstinence; but affirms, that in this particular it is necessary to have a regard to the disease, the patient, the season, the climate, and other circumstances of a like nature. The signs drawn from the pulse he looked upon to be very precarious and uncertain. "Some (says he) lay great stress upon the beating of the veins or the arteries; which is a deceitful circumstance, since that beating is slow or quick, and varies very much, according to the age, sex, and constitution of the patient. It even sometimes happens that the pulse is weak and languid when the stomach is disordered, or in the beginning of a fever. On the contrary, the pulse is often high, and in a violent commotion, when one has been exposed to the sun, or comes out of a bath, or from using exercise; or when one is under the influence of anger, fear, or any other passion. Besides, the pulse is easily changed by the arrival of the physician, in consequence of the patient's anxiety to know what judgment he will pass upon his case. To prevent this, the physician must not feel the patient's pulse on his first arrival: he must first sit down by him, assume a cheerful air, inform himself of his condition; and if he is under any dread, endeavour to remove it by encouraging discourse; after which he may examine the beating of the artery. This, nevertheless, does not hinder us from concluding, that if the sight of the physician alone can produce so remarkable a change in the pulse, a thousand other causes may produce the same effect." But although Celsus thought for himself, and in not a few particulars differed from his predecessors, yet in his writings, which are not only still preserved, but have gone through almost innumerable editions, we have a compendious view of the practice of almost all his predecessors; and he treats of the healing art in all its branches, whether performed *manu, victu, vel medicamentis.* His writings, therefore, will naturally be consulted by every one who wishes either to become acquainted with the practice of the ancients prior to the fall of the Roman empire, or to read medical Latin in its greatest purity.

About the 131st year after Christ, in the reign of the emperor Adrian, lived the celebrated Galen, a native of Pergamus, whose name makes such a conspicuous figure in the history of physic. At this time the dogmatic, empiric, methodic, and other sects, had each their abettors. The methodics were held in great esteem, and looked upon to be superior to the dogmatics, who were strangely divided among themselves, some of them following Hippocrates, others Erasistratus, and others Asclepiades. The empirics made the least considerable figure of any. Galen undertook the reformation of medicine, and restored dogmatism. He seems to have been of that sect which was called *eclectic,* from their choosing out of different authors what they esteemed good in them, without being particularly attached to any one more than the rest. This declaration he indeed sets out with; but, notwithstanding this, he follows Hippocrates much more than any other, or rather follows nobody else but him. Though before his time several physicians had commented on the works of Hippocrates, yet Galen pretends that none of them had understood his meaning. His first attempt, therefore, was to explain the works of Hippocrates; with which view he wrote a great deal, and after this set about composing a system of his own. In one of his books entitled, "Of the establishment of medicine," he defines the art to be one which teaches to preserve health and cure diseases. In another book, however, he proposes the following definition: "Medicine (says he) is a science which teaches what is sound, and what is not so; and what is of an indifferent nature, or holds a medium between what is sound and what is the reverse." He affirmed, that there are three things which constitute the object of medicine, and which the physician ought to consider as sound, as not sound, or of a neutral and indifferent nature. These are the body itself, the signs, and the causes. He esteems the human body sound, when it is in a good state or habit with regard to the simple parts of which it is composed, and when besides there is a just proportion between the organs formed of these simple parts. On the contrary, the body is reckoned to be unsound, when it recedes from this state, and the just proportion above mentioned. It is in a state of neutrality or indifference, when it is in a medium between soundness and its opposite state. The salutary signs

Celsus, 41 Galen.

signs are such as indicate present health, and prognosticate that the man may remain in that state for some time to come. The insalubrious signs, on the contrary, indicate a present disorder, or lay a foundation for suspecting the approach of one. The neutral signs, or such as are of an indifferent nature, denote neither health nor indisposition, either for the present, or for the time to come. In like manner he speaks of causes salutary, unsalutary, and indifferent.

These three dispositions of the human body, that is, soundness, its reverse, and a neutral state, comprehend all the differences between health and disorder or indisposition: and each of these three states or dispositions has a certain extent peculiar to itself. A seund habit of body, according to the definition of it already given, is very rare, and perhaps never to be met with; but this does not hinder us to suppose such a model for regulating our judgment with respect to different constitutions. On this principle Galen establishes eight other principal constitutions, all of which differ more or less from the perfect model above mentioned. The four first are such as have one of the four qualities of hot, cold, moist, or dry, prevailing in too great a degree; and accordingly receive their denomination from that quality which prevails over the rest. The four other species of constitutions receive their denominations from a combination of the above mentioned; so that, according to his definition, there may be a hot and dry, a hot and moist, a cold and moist, and a cold and dry, constitution. Besides these differences, there are certain others which result from occult and latent causes, and which, by Galen, are said to arise from an *idiosyncrasy* of constitution. It is owing to this idiosyncrasy that some have an aversion to one kind of aliment and some to another; that some cannot endure particular smells, &c. But though these eight last-mentioned constitutions fall short of the perfection of the first, it does not thence follow, that those to whom they belong are to be classed among the valetudinary and diseased. A disease only begins when the deviation becomes so great as to hinder the due action of some parts.

Galen describes at great length the signs of a good or bad constitution, as well as those of what he calls a *neutral habit*. These signs are drawn from the original qualities of cold, hot, moist, and dry, and from their just proportion or disproportion with respect to the bulk, figure, and situation, of the organical parts. With Hippocrates he establishes three principles of an animal body; the parts, the humours, and the spirits. By the parts he properly meant no more than the solid parts; and these he divided into similar and organical. Like Hippocrates, he also acknowledged four humours; the blood, the phlegm, the yellow bile and black bile. He established three different kinds of spirits; the natural, the vital, and the animal. The first of these are, according to him, nothing else but a subtle vapour arising from the blood, which draws its origin from the liver, the organ or instrument of sanguification. After these spirits are conveyed to the heart, they, in conjunction with the air we draw into the lungs, become the matter of the second species, that is, of the vital spirits, which are again changed into those of the animal kind in the brain. He supposed that these three species of spirits served as instruments to three kinds of faculties, which reside in the respective parts where these faculties are formed. The natural faculty is the first of these, which he placed in the liver, and imagined to preside over the nutrition, growth, and generation, of the animal. The vital faculty he lodged in the heart, and supposed that by means of the arteries it communicated warmth and life to all the body. The animal faculty, the noblest of all the three, and with which the reasoning or governing faculty was joined, according to him, has its seat in the brain; and, by means of the nerves, distributes a power of motion and sensation to all the parts, and presides over all the other faculties. The original source or principle of motion in all these faculties, Galen, as well as Hippocrates, defines to be *Nature*.

Upon these principles Galen defined a disease to be "such a preternatural disposition or affection of the parts of the body, as primarily, and of itself, hinders their natural and proper action." He established three principal kinds of diseases: the first relates to the similar parts; the second, to the organical; and the third is common to both these parts. The first kind of diseases consists in the intemperature of the similar parts; and this is divided into an intemperature *without matter*, and an intemperature *with matter*. The first discovers itself when a part has more or less heat or cold than it ought to have, without that change of quality in the part being supported and maintained by any matter. Thus, for instance, a person's head may be overheated and indisposed by being exposed to the heat of the sun, without that heat being maintained by the continuance or congestion of any hot humour in the part. The second sort of intemperature is when any part is not only rendered hot or cold, but also filled with a hot or cold humour, which are the causes of the heat or cold felt in the part. Galen also acknowledged a simple intemperature: that is, when one of the original qualities, such as heat or cold, exceeds the natural standard alone and separately; and a compound intemperature, when two qualities are joined together, such as heat and dryness, or coldness and humidity. He also established an equal and unequal temperature. The former is that which is equally in all the body, or in any particular part of it, and which creates no pain, because it is become habitual, such as dryness in the hectic constitution. The latter is distinguished from the former, in that it does not equally subsist in the whole of the body, or in the whole of a part. Of this kind of intemperature we have examples in certain fevers, where heat and cold, equally, and almost at the same time, attack the same part; or in other fevers which render the surface of the body cold as ice, while the internal parts burn with heat; or, lastly, in cases where the stomach is cold and the liver hot.

The second kind of disorders, relating to the organical parts, results from irregularities of these parts, with respect to the number, bulk, figure, situation, &c. as when one has six fingers, or only four; when one has any part larger or smaller than it ought to be, &c. The third kind, which is common both to the similar and the organical parts, is a solution of continuity, which happens when any similar or compound part is cut, bruised, or corroded.

Like

Galen.

Like Hippocrates, Galen distinguished diseases into acute and chronical; and, with respect to their nature and genius, into benign and malignant; also into epidemic, endemic, and sporadic.

After having distinguished the kinds of diseases, Galen comes to explain their causes; which he divides into external and internal. The external causes of diseases, according to him, are six things, which contribute to the preservation of health when they are well disposed and properly used, but produce a contrary effect when they are imprudently used or ill disposed. These six things are, the air, aliments and drink, motion and rest, sleeping and watching, retention and excretion, and lastly the passions. All these are called the *procatarctic* or *beginning* causes, because they put in motion the internal causes; which are of two kinds, the *antecedent* and the *conjunct*. The former is discovered only by reasoning; and consists for the most part in a peccancy of the humours, either by plenitude or cacochymy, i. e. a bad state of them. When the humours are in too large a quantity, it is called a *plethora;* but we must observe, that this word equally denotes too large a quantity of all the humours together, or a redundance of one particular humour which prevails over the rest. According to these principles, there may be a sanguine, a bilious, a pituitous, or a melancholy plenitude: but there is this difference between the sanguine and the three other plenitudes, that the blood, which is the matter of the former, may far surpass the rest: whereas, if any of the three last-mentioned ones do so, the case is no longer called *plenitude*, but *cacochymia;* because these humours, abounding more than they ought, corrupt the blood. The causes he also divides into such as are manifest and evident, and such as are latent and obscure. The first are such as spontaneously come under the cognizance of our senses when they act or produce their effects: the second are not of themselves perceptible, but may be discovered by reasoning: the third sort, i. e. such as he calls *occult* or *concealed*, cannot be discovered at all. Among this last he places the cause of the hydrophobia.

He next proceeds to consider the symptoms of diseases. A symptom he defines to be "a preternatural affection depending upon a disease, or which follows it as a shadow does a body." He acknowledged three kinds of symptoms: the first and most considerable of these consisted in the action of the parts being injured or hindered; the second in a change of the quality of the parts, their actions in the mean time remaining entire: the third related to defects in point of excretion and retention.

After having treated of symptoms, Galen treats of the *signs* of diseases. These are divided into *diagnostic* and *prognostic*. The first are so called because they enable us to know diseases, and distinguish them from each other. They are of two sorts, *pathognomonic* or *adjunct*. The first are peculiar to every disease, make known its precise species, and always accompany it, so that they begin and end with it. The second are common to several diseases, and only serve to point out the difference between diseases of the same species. In a pleurisy, for instance, the pathognomonic signs are a cough, a difficulty of breathing, a pain of the side, and a continued fever; the adjunct signs are the various sorts of matter expectorated, which is sometimes bloody, sometimes bilious, &c.— The diagnostic signs were drawn from the defective or disordered disposition of the parts, or from the diseases themselves; secondly, from the causes of diseases; thirdly, from their symptoms; and lastly, from the particular dispositions of each body, from things which prove prejudicial and those that do service, and from epidemical diseases.—The prognostic signs he gathered from the species, virulence, and peculiar genius of the disease: but as we have already spoken so largely concerning the prognostics of Hippocrates, it is superfluous to be particular on those of Galen.— His method of cure differed little from that of Hippocrates: but from the specimen already given of Galen's method of teaching the medical art, it is evident that his system was little else than a collection of speculations, distinctions, and reasonings; whereas that of Hippocrates was founded immediately upon facts, which he had either observed himself, or had learned from the observation of others.

Oribasi &c.

The system of Galen, however, notwithstanding its defects and absurdities, remained almost uncontradicted for a very long period. Indeed it may be considered as having been the prevailing system till the inundation of the Goths and Vandals put an almost entire stop to the cultivation of letters in Europe. But during the general prevalence of the system of Galen, there appeared some writers to whom medicine was indebted for improvements, at least in certain particulars. Among the most distinguished of these we may mention Oribasius, Ætius, Alexander, and Paulus.

4 Oriba

Oribasius flourished about the year 360, and was physician to the emperor Julian. He speaks very fully of the effects of bleeding by way of scarification, a thing little taken notice of by former writers; from his own experience he assures us that he had found it successful in a suppression of the menses, defluxions of the eyes, headach, and straitness of breathing even when the person was extremely old. He tells his own case particularly, when the plague raged in Asia and he himself was taken ill. On the second day he scarified his leg, and took away two pounds of blood; by which means he entirely recovered, as did several others who used it. In this author also we find the first description of a surprising and terrible distemper, which he termed λυκανθρωπια, a species of melancholy and madness, which he describes thus. "The persons affected get out of their houses in the night-time, and in every thing imitate wolves, and wander among the sepulchres of the dead till day-break. You may know them by these symptoms: Their looks are pale; their eyes heavy, hollow, dry, without the least moisture of a tear; their tongue exceedingly parched and dry, no spittle in their mouth, extreme thirst; their legs, from the falls and the bruises they receive, full of incurable sores and ulcers."

4 Ætiu

Ætius lived very near the end of the fifth, or in the beginning of the sixth century. Many passages in his writings serve to shew us how much the actual and potential cautery were used by the physicians of that age. In a palsy, he says, that he should not at all hesitate to make an eschar either way, and this in several places; one in the nape, where the spinal marrow takes its rise, two on each side of it; three or four

Alexander. four on the top of the head, one just in the middle, and three others round it. He adds, that in this case, if the ulcers continue running a considerable time, he should not doubt of a perfect recovery. He is still more particular when he comes to order this application for an inveterate asthma, after all other remedies have been tried in vain. One, he says, should be made on each side near the middle of the joining of the clavicle, taking care not to touch the wind-pipe: two other little ones are then to be made near the carotids under the chin, one on each side, so that the caustic may penetrate no further than the skin: two others under the breasts, between the third and fourth ribs; and again, two more backwards towards the fifth and sixth ribs. Besides these there ought to be one in the middle of the thorax, near the beginning of the xiphoid cartilage, over the orifice of the stomach; one on each side between the eighth and ninth ribs; and three others in the back, one in the middle, and the two others just below it, on each side of the vertebræ. Those below the neck ought to be pretty large, not very superficial, not very deep: and all these ulcers should be kept open for a very long time.

Ætius takes notice of the worms bred in different parts of the body, called *dracunculi*, which were unknown to Galen. He seems also to be the first Greek writer among the Christians, who gives us any specimen of medicinal spells and charms; such as that of a finger of St Blasius for removing a bone which sticks in the throat, and another in relation to a fistula. He gives a remedy for the gout, which he calls the *grand drier;* the patient is to use it for a whole year, and observe the following diet each month. "In September, he must eat and drink milk: In October he must eat garlic; in November, abstain from bathing; in December, he must eat no cabbage; in January, he is to take a glass of pure wine in the morning; in February, to eat no beef; in March, to mix sweet things both in eatables and drinkables; in April, not to eat horse-radish, nor in Mayt he fish called *polypus;* in June, he is to drink cold water in a morning; in July, to avoid venery; and lastly, in August, to eat no mallows." This may sufficiently show the quackery of those times, and how superstition was beginning to mix itself with the art.

44 Alexander. Alexander, who flourished in the reign of Justinian, is a more original author than either of the two former. He confines himself directly to the describing the signs of diseases, and the methods of cure, without meddling with anatomy, the materia medica, or surgery, as all the rest did. He employs a whole book in treating of the gout. One method he takes of relieving this disease is by purging; and in most of the purges he recommends hermodactyls, of which he has a great opinion. In a causus, or burning fever, where the bile is predominant, the matter fit for evacuation, and the fever not violent, he prefers purging to bleeding, and says that he has often ordered purging in acute fevers with surprising success. In the causus also, if a syncope happens from crude and redundant humours, he recommends bleeding. In a syncope succeeding the suppression of any usual evacuation, he recommends bleeding, with frictions. The diagnostics upon which he founds this practice are the following: viz. a face paler and more swelled than usual, a bloated habit of body, with a small sluggish pulse, having long intervals between the strokes. In tertian, and much more in quartan fevers, he recommends vomits above all other remedies, and affirms that by this remedy alone he has cured the most inveterate quartans. On the bulimus, or canine appetite, he makes a new observation, viz. that it is sometimes caused by worms. He mentions the case of a woman who laboured under this ravenous appetite, and had a perpetual gnawing at her stomach and pain in her head: after taking *hiera* she voided a worm above a dozen of cubits long, and was entirely cured of her complaints.—He is also the first author who takes notice of *rhubarb;* which he recommends in a weakness of the liver and in dysentery.—Alexander is recommended by Dr Freind as one of the best practical writers among the ancients, and well worthy the perusal of any modern. Arabian Physicians.

45 Paulus. Paulus was born in the island Ægina, and lived in the 7th century. He transcribes a great deal from Alexander and other physicians. His descriptions are short and accurate. He treats particularly of women's disorders; and seems to be the first instance upon record of a professed *man-midwife*, for so he was called by the Arabians: and accordingly he begins his book with the disorders incident to pregnant women. He treats also very fully of surgery, and gives some directions, according to Dr Freind, not to be found in the more ancient writers.

46 Arabian physicians. After the downfal of the Roman empire, and when the inundation of Goths and Vandals had almost completely exterminated literature of every kind in Europe, medicine, though a practical art, shared the same fate with more abstract sciences. Learning in general, banished from the seat of arms, took refuge among the eastern nations, where the arts of peace still continued to be cultivated. To the Arabian physicians, as they have been called, we are indebted both for the preservation of medical science, as it subsisted among the Greeks and Romans, and likewise for the description of some new diseases, particularly the small-pox. Among the most eminent of the Arabians, we may mention Rhases, Avicenna, Albucasis, and Avenzoar. But of their writings it would be tedious, and is unnecessary, to give any particular account.—They were for the most part, indeed, only copiers of the Greeks. We are, however, indebted to them for some improvements. They were the first who introduced chemical remedies, though of these they used but few, nor did they make any considerable progress in the chemical art. Anatomy was not in the least improved by them, nor did surgery receive any advancement till the time of Albucasis, who lived probably in the 12th century. They added a great deal to botany and the materia medica, by the introduction of new drugs, of the aromatic kind especially, from the east, many of which are of considerable use. They also found out the way of making sugar; and by help of that, syrups; which two new materials are of great use in mixing up compound medicines. 47 Rhases.

With regard to their practice, in some few particulars they deviated from the Greeks. Their purging medicines were much milder than those formerly in use; and even when they did prescribe the old ones, they gave them in a much less dose than the Greek and Roman physicians. The same reflection may be made concerning

Arabian Physicians.

concerning their manner of bleeding, which was never to that excessive degree practised by the Greeks. They deviated from Hippocrates, however, in one very trivial circumstance, which produced a violent controversy. The question was, Whether blood in a pleurisy ought to be drawn from the arm of the affected side or the opposite? Hippocrates had directed it to be drawn from the arm of the affected side; but the Arabians, following some other ancient physicians, ordered it to be drawn from the opposite one. Such was the ignorance of those ages, that the university of Salamanca in Spain made a decree, that no one should dare to let blood but in the contrary arm; and endeavoured to procure an edict from the emperor Charles V. to second it; alleging that the other method was of no less pernicious consequence to medicine, than Luther's heresy had been to religion.

In consequence of the general decay of learning in the western parts of the world, the Greek writers were entirely neglected, because nobody could read the language; and the Arabians, though principally copiers from them, enjoyed all the reputation that was due to the others. The Arabian physic was introduced into Europe very early, with the most extravagant applause: and not only this, but other branches of their learning, came into repute in the west; insomuch that in the 11th century, the studies of natural philosophy and the liberal arts were called *the studies of the Saracens*. This was owing partly to the crusades undertaken against them by the European princes; and partly to the settlement of the Moors in Spain, and the intercourse they and other Arabians had with the

48 College of Salernum.

Italians. For, long before the time of the crusades, probably in the middle of the 7th century, there were Hebrew, Arabic, and Latin professors of physic settled at Salernum: which place soon grew into such credit, that Charles the Great thought proper to found a college there in the year 802; the only one at that

49 Constantine.

time in Europe. Constantine the African flourished there towards the latter end of the 11th century. He was a native of Carthage; but travelled into the east, and spent 30 years in Babylon and Bagdad, by which means he became master of the oriental languages and learning. He returned to Carthage; but being informed of an attempt against his life, made his escape into Apulia, where he was recommended to Robert Guiscard, created in 1060 duke of that country, who made him his secretary. He was reputed to be very well versed in the Greek, as well as in the eastern tongues; and seems to have been the first who introduced either the Greek or Arabian physic into Italy. His works, however, contain nothing that is new, or material; though he was then accounted a very learned man.

50 State of medicine in the 15th and 16th centuries.

From this time to the end of the 15th and beginning of the 16th century, the history of physic furnishes us with no interesting particulars. This period, however, 'is famous for the introduction of chemistry into medicine, and the description of three new distempers, the sweating sickness, the venereal disease, and the scurvy. The sweating sickness began in 1485

51 Sweating sickness in England.

in the army of Henry VII. upon his landing at Milford-haven, and spread itself at London, from the 21st of September to the end of October. It returned there five times, and always in summer; first in 1495, then in 1506, afterwards in 1517, when it was so violent that it killed many in the space of three hours, so that numbers of the nobility died, and of the commonalty in several towns often the one-half perished. It appeared the fourth time in 1528, and then proved mortal in six hours; many of the courtiers died of it, and Henry VIII. himself was in danger. In 1529, and only then, it infested the Netherlands and Germany, in which last country it did much mischief. The last return of it was in 1551, and in Westminster it carried off 120 in a day. Dr Caius describes it as a pestilent contagious fever, of the duration of one natural day; the sweat he reckoned to be only a natural symptom, or crisis of the distemper. It first affected some particular part, attended with inward heat and burning, unquenchable thirst, restlessness, sickness at stomach, but seldom vomiting, headach, delirium, then faintness, and excessive drowsiness. The pulse was quick and vehement, and the breath short and laborious.—Children, poor and old people, were rarely subject to it. Of others, scarce any escaped the attack, and most of them died. Even by travelling into France or Flanders they did not escape; and what is still more strange, the Scots were said not to be affected; abroad the English only were seized, and foreigners in England were free. At first the physicians were much puzzled how to treat this disease. The only cure they ever found, however, was to carry on the sweat for a long time; for, if stopped, it was dangerous or fatal. The way, therefore, was for the patient to lie still, and not expose himself to cold. If nature was not strong enough to force out the sweat, it was necessary to assist her by art, with clothes, wine, &c. The violence of the distemper was over in 15 hours; but there was no security for the patient till 24 were passed. In some strong constitutions there was a necessity to repeat the sweating, even to 12 times. The removing out of bed was attended with great danger; some who had not sweated enough fell into very bad fevers.—No flesh-meat was to be allowed in all the time of the distemper; nor drink for the first five hours. In the seventh, the distemper increased; in the ninth the delirium came on, and sleep was by all means to be avoided. However terrible this distemper appeared at first, it seldom proved obstinate, if treated in the above-mentioned manner.

Para[...]

In the beginning of the 16th century, the famous chemist Paracelsus introduced a new system into medicine, founded on the principles of chemistry. The Galenical system had prevailed till his time; but the practice had greatly degenerated, and was become quite trifling and frivolous. The physicians in general rejected the use of opium, mercury, and other efficacious remedies. Paracelsus, who made use of these, had therefore greatly the advantage over them; and now all things relating to medicine were explained on imaginary chemical principles. It will easily be conceived that a practice founded in this manner could be no other than the most dangerous quackery. At this time, however, it was necessary; for now a new disease overran the world, and threatened greater destruction than almost all the old ones put together, both by the violence of its symptoms, and its baffling the most powerful remedies at that time known.—This was the venereal disease, which is supposed to have been imported derns.

imported from the West Indies by the companions of Christopher Columbus. Its first remarkable appearance was at the siege of Naples in 1494, from whence it was soon after propagated through Europe, Asia, and Africa. The symptoms with which it made the attack at that time were exceedingly violent, much more so than they are at present; and consequently were utterly unconquerable by the Galenists. The quacks and chemists, who boldly ventured on mercury, though they no doubt destroyed numbers by their excessive use of it, yet showed that a remedy for this terrible distemper was at last found out, and that a proper method of treating it might soon be fallen upon. Shortly after, the West Indian specific, guaiacum, was discovered: the materia medica was enriched with that and many other valuable medicines, both from the East and West Indies: which contributed considerably to the improvement of the practice of physic. At this period, as sea voyages of considerable duration were more frequent, the scurvy became a more common distemper, and was of course more accurately described. But probably, from supposed analogy to the contagions which at that time were new in Europe, very erroneous ideas were entertained with regard to its being of an infectious nature: And it is not impossible, that from its being attended also with ulcers, it was on some occasions confounded with syphilitic complaints.

53 [A]ppearance [of th]e ve[ner]eal dis[eas]e.

54 P[rog]ress of m[edic]ine in th[e 1]7th a[nd 1]8th ce[ntu]ries.

The revival of learning, which now took place throughout Europe, the appearance of these new distempers, and the natural fondness of mankind for novelty, contributed greatly to promote the advancement of medicine as well as other sciences. While at the same time, the introduction of the art of printing rendered the communication of new opinions as well as new practices so easy a matter, that to enumerate even the names of those who have been justly rendered eminent for medical knowledge would be a very tedious task. It was not, however, till 1628 that Dr William Harvey of London demonstrated and communicated to the public one of the most important discoveries respecting the animal economy, the circulation of the blood. This discovery, more effectually than any reasoning, overturned all the systems which had subsisted prior to that time. It may justly be reckoned the most important discovery that has hitherto been made in the healing art: for there can be no doubt that it puts the explanation of the phenomena of the animal body, both in a state of health and disease, on a more solid and rational footing than formerly. It has not, however, prevented the rise of numerous fanciful and absurd systems. These, though fashionable for a short time, and strenuously supported by blind adherents, have yet in no long period fallen into deserved contempt. And notwithstanding the abilities and industry of Stahl, Hoffman, Boerhaave, and Cullen, we may confidently venture to assert that no general system has yet been proposed which is not liable to innumerable and unsurmountable objections. Very great progress has indeed been made in explaining the philosophy of the human body, from ascertaining by decisive experiment the influence of the circulating, the nervous, and the lymphatic systems in the animal economy. But every attempt hitherto made to establish any general theory in medicine, that is, to conduct the cure of every disease on a few general principles, has equally deviated from truth with those of Hippocrates and Galen; and has equally tended to mislead those who have adopted it. Many systems of our own days, such for example as that of Brown, though adopted with enthusiasm by the young and inexperienced, have evidently been attended with the most pernicious consequences in practice. Indeed we may with confidence venture to assert, that from the very nature of the subject itself, medicine does not admit of such simplicity. No one can deny that the human body consists of a very great number of different parts, both solids and fluids. It is, however, equally certain, that each of these is from many different causes liable to deviations from the sound state. And although some slight changes may take place without what can be called a morbid affection, yet we well know, that every change taking place to a certain degree in any one part will necessarily and unavoidably produce an affection of the whole. Hence we may without hesitation venture to affirm, that every general theory which can be proposed, attempting to explain the phenomena, and conduct the cure of all diseases on a few general principles, though for some time it may have strenuous advocates, will yet in the end be found to be both ill-grounded and pernicious.

55 Di[sco]very of [cir]cu[lati]on.

Moderns.

The art of medicine has been much more usefully improved by careful attention to the history, theory, and practice of particular diseases, and by endeavouring to ascertain from cautious observation the symptoms by which they are to be distinguished, the causes by which they are induced, and the means by which they are to be prevented, alleviated, or cured. On this footing, therefore, we shall endeavour to give a brief account of at least the most important affections to which the human body is subjected, delivering what appear to us to be the best established facts and observations respecting each.

But before entering on the consideration of particular diseases, or what has commonly been styled the practice of medicine, it is necessary to give a general view of the most important functions of the animal body, and of the chief morbid affections to which they are subjected; a branch which has usually been named the *Theory* or *Institutions of Medicine*.

Theory of Medicine, or an Account of the Principal Functions of the Animal Body.

WHILE the functions of living animals, but particularly of the human species, are very numerous, the accounts given of these both in a state of health and disease are very various. Without, therefore, pretending to enumerate the contradictory opinions of different authors, we shall here present the reader with a view of this subject, Functions of the Body.

subject, chiefly extracted from the *Conspectus Medicinæ Theoreticæ* of Dr James Gregory, who has collected from other writers the opinions at present most generally adopted.

56 Division of the functions into animal, vital, and natural.

In this work, which was first published in 1780, and afterwards reprinted under an enlarged form in 1782, Dr Gregory introduces his subject by observing, that some functions of the human body relate to itself only, and others to external things. To the latter class belong those which by physicians are called the *animal functions;* to which are to be referred all our senses, as well as the power of voluntary motion, by which we become acquainted with the universe, and enjoy this earth. Among the functions which relate to the body, some have been named *vital*, such as the circulation of the blood and respiration; because, without the constant continuance of these life cannot subsist; others, intended for repairing the waste of the system, have been termed the *natural functions:* for by the constant attrition of the solids and the evaporation of the fluid parts of the body, we stand in need of nourishment to supply the waste; after which the putrid and excrementitious parts must be thrown out by the proper passages. The digestion of the food, secretion of the humours, and excretion of the putrid parts of the food, are referred to this class; which, though necessary to life, may yet be interrupted for a considerable time without danger. This division of the functions into animal, vital, and natural, is of very ancient date, and is perhaps one of the best that has yet been proposed.

57 Distinction of diseases into simple and compound.

A *disease* takes place, when the body has so far declined from a sound state, that its functions are either quite impeded, or performed with difficulty. A disease therefore may happen to any part of the body either solid or fluid, or to any one of the functions: and those may occur either singly, or several of them may be diseased at the same time; whence the distinction of diseases into *simple* and *compound*.

We have examples of the most simple kinds of diseases, in the rupture or other injury of any of the corporeal organs, by which means they become less fit for performing their offices; or, though the organs themselves should remain sound, if the solids or fluids have degenerated from a healthy state; or if, having lost their proper qualities, they nave acquired others of a different, perhaps of a noxious nature; or, lastly, if the moving powers shall become too weak or too strong, or direct their force in a way contrary to what nature requires.

58 Symptoms.

The most simple diseases are either productive of others, or of *symptoms*, by which alone they become known to us. Every thing in which a sick person is observed to differ from one in health is called a *symptom;* and the most remarkable of these symptoms, which most commonly appear, define and constitute the disease.

The causes of diseases are various; often obscure, and some times totally unknown. The most full and perfect proximate cause is that which, when present, produces a disease, when taken away removes it, and when changed, changes it.—There are also remote causes, which physicians have been accustomed to divide into the *predisponent* and *exciting* ones. The

59 Predisponent cause.

former are those which only render the body fit for a disease, or which put it into such a state that it will readily receive one. The exciting cause is that which immediately produces the disease in a body already disposed to receive it.

Causes of Disease.

60 Exciting cause.

The predisponent cause is always inherent in the body itself, though perhaps it originally came from without; thus heat or cold, a very sparing or a very luxurious diet, and many other particulars, may operate as causes of predisposition, inducing plethora, inanition, or the like. But the exciting cause may either come from within or without.

61 Proximate cause.

From the combined action of the predisponent and exciting causes comes the *proximate* cause, which neither of the two taken singly is often able to produce.—A body predisposed to disease therefore has already declined somewhat from a state of perfect health, although none of its functions are impeded in such a manner that we can truly say the person is diseased. Yet sometimes the predisponent cause, by continuing long, may arrive at such a height, that it alone, without the addition of any exciting cause, may produce a real disease.—The exciting cause also, though it should not be able immediately to bring on a disease; yet if it continues long, will by degrees destroy the strongest constitution, and render it liable to various diseases; because it either produces a predisponent cause, or is converted into it, so that the same thing may sometimes be an exciting cause, sometimes a predisponent one, or rather a cause of predisposition; of which the inclemencies of the weather, sloth, luxury, &c. are examples.

Hereditary diseases.

Diseases, however, seem to have their origin from the very constitution of the animal machine; and hence many diseases are common to every body when a proper exciting cause occurs, though some people are much more liable to certain diseases than others. Some are hereditary; for as healthy parents naturally produce healthy children, so diseased parents as naturally produce a diseased offspring. Some of these diseases appear in the earliest infancy; others occur equally at all ages; nor are there wanting some which lurk unsuspected even to the latest old age, at last breaking out with the utmost violence. Some diseases are born with us even though they have no proper foundation in our constitution, as when a fœtus receives some hurt by an injury done to the mother; while others, neither born with us nor having any foundation in the constitution, are suckled in with the nurse's milk. Many diseases accompany the different stages of life; and hence some are proper to infancy, youth, and old age. Some also are proper to each of the sexes: especially the female sex, proceeding, no doubt, from the general constitution of the body, but particularly from the state of the parts subservient to generation. Hence the diseases peculiar to virgins, to menstruating women, to women with child, to lying-in women, to nurses, and to old women. The climate itself, under which people live, produces some diseases; and every climate has a tendency to produce particular diseases, either from its excess of heat or cold, or from the mutability of the weather. An immense number of diseases also may be produced by impure air, or such as is loaded with putrid, marshy, and other noxious vapours. The same

Diseases from age and sex.

Diseases from climate.

...s of ...ses. same thing may happen likewise from corrupted aliment, whether meat or drink; though even the best and most nutritious aliment will hurt if taken in too great quantity; not to mention poisons, which are endowed with such pernicious qualities, that even when taken in a very small quantity they produce the most grievous diseases or perhaps even death itself. Lastly, from
5 ...ses ...acci- innumerable accidents and dangers to which mankind are exposed, they frequently come off with broken limbs, wounds, and contusions, sometimes quite incurable; and these misfortunes, though proceeding from an external cause at first, often terminate in internal diseases.

Hitherto we have mentioned only the dangers which come from without; but those are not less, nor fewer in number, which come from within. At every breath, man pours forth a deadly poison both to himself and others. Neither are the effluvia of the lungs alone hurtful: there flows out from every pore of the body a most subtile and poisonous matter, perhaps of a putrescent nature, which being long accumulated, and not allowed to diffuse itself through the air, infects the body with most grievous diseases; nor does it stop here, but produces a contagion which spreads devastation far and wide among mankind. From too much or too little exercise of our animal powers also no small danger ensues. By inactivity either of body or mind, the vigour of both is impaired; nor is the danger much less from too great employment. By moderate use, all the faculties of the mind, as well as all the parts of the body, are improved and strengthened; and here nature has appointed certain limits, so that exercise can neither be too much neglected, nor too much increased, with impunity. Hence those who use violent exercise, as well as those who spend their time in sloth and idleness, are equally liable to diseases; but each to diseases of a different kind: and hence also the bad effects of too great or too little employment of the mental powers.

6 ...ses ...pas- ...of the Besides the dangers arising from those actions of the body and mind which are in our own power, there are others arising from those which are quite involuntary. Thus, passions of the mind, either when carried to too great excess, or when long continued, equally destroy the health; nay, will even sometimes bring on sudden death. Sleep also, which is of the greatest service in restoring the exhausted strength of the body, proves noxious either from its too great or too little quantity. In the most healthy body, also, many things always require to be evacuated. The retention of these is hurtful, as well as too profuse an evacuation, or the excretion of those things either spontaneously or artificially which nature directs to be retained. As the solid parts sometimes become flabby, soft, almost dissolved, and unfit for their proper offices; so the fluids are sometimes inspissated, and formed even into the hardest solid masses. Hence impeded actions of the organs, vehement pain, various and grievous diseases. Lastly, some animals are to be reckoned among the causes of diseases: such, particularly, as support their life at the expence of others; and these either invade us from without, or take up their residence within the body, gnawing the bowels while the person is yet alive, not only with great danger and distress to the patient, but sometimes even producing death itself.

Man, however, is not left without defence against so many and so great dangers. The human body is possessed of a most wonderful power, by which it preserves itself from diseases, keeps off many, and, in a very short time, cures some already begun, while others are by the same means more slowly brought to a happy conclusion. This power, called the *autocrateia*, or *vis medicatrix naturæ*, is well known both to physicians and philosophers. This alone is often sufficient for curing many diseases, and is of service in all. Nay, even the best medicines operate only by exciting and properly directing this force; for no medicine will act on a dead carcase. But though physicians justly put confidence in this power, and though it generally cures diseases of a slighter nature, it is not to be thought that those of the more grievous kind are to be left to the unassisted efforts of the *vis medicatrix*. Physicians therefore have a twofold error to avoid, either despising the powers of nature too much, or putting too great confidence in them; because in many diseases these efforts are either too feeble or too violent, insomuch that sometimes they are more to be dreaded than even the disease itself. So far therefore is it from being the duty of a physician always to follow the footsteps of nature, that it is often necessary for him to take a directly contrary course, and oppose her efforts with all his might. 67 *Vis medicatrix naturæ.*

After a general view of the functions of the animal body, of the nature and causes of disease, and of the powers by which these are to be combated, Dr Gregory proceeds to treat of the solid materials of which the body is formed. He tells us, that the animal solid, when chemically examined, yields earth, oil, salt, water, phlogiston or inflammable air, and a great quantity of mephitic air. These elements are found in various proportions in the different parts of the body; and hence these parts are endowed with very different mechanical powers, from the hardest and most solid bone to the soft and almost fluid retina. Nay, it is principally in this difference of proportion between the quantities of the different elements, that the difference between the solid and fluid parts of the animal consist, the former having much more earth and less water in their composition than the latter. The cohesion, he thinks, is owing to something like a chemical attraction of the elements for one another; and its cause is neither to be sought for in the gluten, fixed air, nor earth. This attraction, however, is not so strong but that even during life the body tends to dissolution; and immediately after death putrefaction commences, provided only there be as much moisture in it as will allow an intestine motion to go on. The greater the heat, the sooner does putrefaction take place, and with the greater rapidity does it proceed; the mephitic air flies off, and together with it certain saline particles; after which, the cohesion of the body being totally destroyed, the whole falls into a putrid colluvies, of which at length all the volatile parts being dissipated, nothing but the earth is left behind. 68 Chemical analysis of the animal solids.

This analysis, he owns, is far from being perfect, and is by no means in the language of modern chemistry.

Animal Solids.

try. But no modern chemist has ever been able, by combining the chemical principles of flesh, to reproduce a compound any thing like what the flesh originally was; yet, however imperfect the analysis may be, it still has the advantage of showing in some measure the nature and causes of certain diseases, and thus leads physicians to the knowledge of proper remedies.

69 Qualities of the animal solids.

The solid parts are fitted for the purposes of life in three several ways; namely, by their cohesion, their flexibility, and their elasticity, all of which are various in the various parts of the body. Most of the functions of life consist in various motions. In some the most violent and powerful motions are required; and therefore such a degree of cohesion is necessary in these parts as will be sufficient for allowing them to perform their offices without any danger of laceration. It is therefore necessary that some of the solid parts should be more flexible than others; and it is likewise necessary that these parts, along with their flexibility, should have a power of recovering their former shape and situation, after the removal of the force by which they were altered.

These variations in flexibility, within certain limits, seldom produce any material consequence with regard to the health: though sometimes, by exceeding the proper bounds, they may bring on real and very dangerous diseases; and this either by an excess or diminution of their cohesion, flexibility, or elasticity. By augmenting the cohesion, the elasticity is also for the most part augmented, but the flexibility diminished; by diminishing the cohesion, the flexibility becomes greater, but the elasticity is diminished.

The cause of these affections, though various, may be reduced to the following heads. Either the chemical composition of the matter itself is changed; or, the composition remaining the same, the particles of the solid may be so disposed, that they shall more or less strongly attract one another. As to the composition, almost all the elements may exist in the body in an undue proportion, and thus each contribute its share to the general disorder. But of many of these things we know very little; only it is apparent, that the fluid parts, which consist chiefly of water, and the solid, which are made up of various elements, are often in very different proportions: the more water, the less is the cohesion or elasticity, but the greater the flexibility; and the reverse happens, if the solid or earthy part predominates.

70 Causes affecting the solids.

The remote causes of these different states, whether predisponent or exciting, are very various. In the first place, idiosyncrasy itself, or the innate constitution of the body, contributes very much to produce the above-mentioned effects. Some have naturally a much harder and drier temperament of the body than others; men, for instance, more than women; which can with the utmost difficulty, indeed scarce by any means whatever, admit of an alteration. The same thing takes place at different periods of life; for, from first to last, the human body becomes always drier and more rigid. Much also depends on the diet made use of, which always produces a corresponding state of the solids in proportion to its being more or less watery. Neither are there wanting strong reasons for believing, that not only the habit of the body, but even the disposition of the mind, depends very much on the diet we make use of. The good or bad concoction of the aliment also, the application of the nourishment prepared from it, and likewise the state of the air with regard to moisture and dryness, affect the temperament of the body not a little; and hence those who inhabit mountains or dry countries, are very different from the inhabitants of low marshy places. Lastly, the manner of living contributes somewhat to this effect: Exercise presses out and exhales the moisture of the body, if in too great quantity; on the contrary, sloth and laziness produce an effect directly opposite, and cause a redundancy of fluid.

But, putting the chemical composition of the solid parts out of the question altogether, they may be affected by many other causes. The condensation, for instance, or compression of the particles, whether by mechanical causes or by means of cold or heat, makes a considerable alteration in the strength and elasticity of every solid body. How much mechanical pressure contributes to this may be understood from the experiments of Sir Clifton Wintringham: and hence also are we to deduce the reason of many facts of the highest importance in the animal economy; namely, the growth, state, decrease of the body; its rigidity daily increasing; and at last the unavoidable death incident to old age from a continuance of the same causes.

Perhaps the different density of the solids is in some measure owing to Nature herself; but it seems to depend more on the powers of exercise or inactivity in changing the state of the solids, the effects of which on the body, whether good or bad, may hence be easily understood.

Heat relaxes and expands all bodies, but cold renders them more dense and hard; the effects of which on the human body are well known to most people. Though the body is found to preserve a certain degree of heat almost in every situation, yet its surface must unavoidably be affected by the temperature of the circumambient atmosphere; and we have not the least reason to doubt that every part of the body may thus feel the effects of that temperature. What a difference is there between one who, exposed to the south wind, becomes lazy and languid, scarce able to drag along his limbs; and one who feels the force of the cold north wind, which renders the whole body alert, strong, and fit for action?

That these various causes, each of which is capable of affecting the constitution of the body when taken singly, will produce much greater effects when combined, is sufficiently evident. The experiments of Bryan Robinson, the effects of the warm bath, and indeed daily experience, show it fully.

It is not yet certainly known what is the ultimate structure of the minutest parts of the animal-solid; whether it consists of straight fibres or threads, whose length is very considerable in proportion to their breadth, variously interwoven with one another, as Boerhaave supposes; or of spiral ones, admirably convoluted and interwoven with one another, as some microscopical experiments seem to show; or whether the cellular texture be formed of fibres or *laminæ*, and from thence the greatest part of the body, as the celebrated Haller hath endeavoured to prove.

The

Animal Solids.

Cellular texture.

The cellular texture is observed throughout the whole body: it surrounds and connects the fibres themselves, which are sufficiently apparent in many of the organs; and slightly joins the different parts which ought to have any kind of motion upon the neighbouring ones. By a condensation of this substance also, the strongest, and what seem the thinnest, membranes are formed; the most simple of which being accurately examined, discover the cellular structure. This cellular substance sometimes increases to a surprising degree, and all parts formed of it, membranes, vessels, &c. especially by a gentle distension; for a sudden and violent distension either breaks it altogether, or renders it thinner. Sometimes also it grows between neighbouring parts, and joins those which nature has left free. Preternatural concretions of this kind are often observed after an inflammation of the lungs or of the abdominal viscera; and these new membranes are found to be truly cellular. This substance, when cut, or by any other means divided, grows together of its own accord; but if, by reason of very great inflammation and suppuration, a large portion of the cellular texture has been destroyed, it is never again completely renewed, and an ugly scar is left. It is even said, that this substance, in certain cases, is capable of joining the parts either of the same body with one another, or of a foreign body with them; and upon this, if on any foundation, rests the art of Taliacotius and that of transplanting teeth, lately so much talked of.

The cellular texture is in some places merely a kind of net-work, in others filled with fat. Wherever too great bulk or compression would have been inconvenient or dangerous, as in the head, lungs, eyes, eyebrows, penis, scrotum, &c. there it collects no fat, but is lax, and purely reticulated; but between the muscles of the body and limbs below the skin, in the abdomen, especially in the omentum and about the kidneys, very much fat is secreted and collected.

Animal fat.

The fat is principally a pure animal oil, not very different from the expressed and mild vegetable ones; during life it is fluid, but of different degrees of thickness in different parts of the body. It is secreted from the blood, and is often suddenly reabsorbed into it, though pure oil is very rarely observed in the blood. It is indeed very probable, that oil, by digestion, partly in the primæ viæ, and partly in the lungs, is converted into gluten, and this again into oil by means of secretion; though no glandular organs secreting the fat can be shown by anatomists. It is, however, probable, that there are such organs; and that the cellular texture has some peculiar structure in those parts which are destined to contain the fat already secreted, without suffering it to pass into other places; for it never passes into those parts which are purely reticulated, although the cellular texture is easily permeable by air or water over the whole body from head to foot.

The fat is augmented by the use of much animal-food, or of any other that is oily and nourishing, provided the digestion be good; by the use of strong drink, especially malt-liquor; by much rest of body and mind, much sleep and inactivity, castration, cold, repeated blood-letting, and in general by whatever diminishes the vital and animal powers. Much, however, depends on the constitution of the body itself; nor is it possible to fatten a human creature at pleasure like an ox. A certain degree of fatness, according to the age of the person, is a sign and effect of good health; but when too great, it becomes a disease of itself, and the cause of other diseases. It may always be very certainly removed by strong exercise, little sleep, and a spare diet. The fat commonly makes up a considerable part of the bulk of the body, and sometimes by far the greatest part. Its use seems to be to make the motion of the body more easy and free, by lessening the friction of the moving parts, and thus preventing the abrasion of the solids, which would otherwise happen. It is also of use to hinder the parts from growing together, which sometimes happens, when by an ulcer or any other accident a part of the cellular texture containing the fat is destroyed. Besides all this, the fat contributes not a little to the beauty of the body, by filling up the large interstices between the muscles, which would otherwise give the person a deformed and shocking appearance. It is thought to be nutritious, when absorbed from its cells into the blood; but of this we have no certain proof. It seems to have some power of defending from the cold; at least, nature has bestowed it in very great quantity on those animals which inhabit the colder regions, as whales, bears, &c.

73
Vital solids.

Those parts of the body which enjoy sense and mobility, are called *living* or *vital* solids. They are the brain, cerebellum, medulla oblongata, spinal marrow, the nerves arising from these and diffused throughout the whole body, and which are distributed through the various organs of sense and through the muscles, and lastly the muscles themselves. Sensation is much more general than mobility, as being common to all the parts already mentioned. Mobility is proper to the muscular fibres alone: wherever there is sensation, therefore, we may believe that there are nerves; and wherever there is mobility, we may believe that muscular fibres exist. Nay, even mobility itself seems to originate from the connection which the muscles have with the nerves; for soon after the nerves are compressed, or tied, or cut, the muscles to which they are distributed lose their faculties; which happens too when the brain itself, or the origin of the nerves, is affected. Some reckon that the muscles are produced from the nerves, and consist of the same kind of matter. Both indeed have a similar structure, as being fibrous and of a white colour: for the muscles, when well freed from the blood, of which they contain a great abundance, are of this colour as well as the nerves; neither can the nervous fibres by any means be distinguished from the muscular fibres themselves. Both have also sensation; and both stimulants and sedatives act in the same manner, whether they be applied to the muscles themselves or to the nerves. These circumstances have led Dr Cullen and many others to consider the muscular fibre as being merely a continuation of nerve. But to this opinion there are many strong objections; though there can be no doubt that the contraction of the muscular fibre is intimately connected with nervous influence.

It is difficult for us to discover the origin of many parts of the body, or to ascertain whether they are produced all at the same time or one after another: yet it must be owned, that many of the muscular parts are observed to have attained a remarkable degree of

External Senses.

strength, while the brain is still soft and almost fluid: and that the action of these muscular parts is required for the action and growth of the brain. The muscles are also of a much firmer contexture than the nerves; and enjoy a power of their own, namely, that of irritability, of which the nerves never participate. Of necessity, therefore, either the muscles must be constructed of some kind of matter different from that of the nerves; or if both are made of the same materials, their organization must be exceedingly different. But if the substance of the muscles and nerves be totally different, we may easily be convinced that much of the one is always mixed with the other; for it is impossible to prick a muscle, even with the smallest needle, without wounding or lacerating many nervous fibres at the same time. Since, therefore, there is such a close connection between the muscles and nerves both as to their functions and structure, they are deservedly reckoned by physiologists to be parts of the same genus, called the *genus nervosum*, or *nervous system*.

74 Sense of feeling.

After treating of sense in general, Dr Gregory proceeds to consider particularly each of the senses both external and internal. He begins with the sense of feeling, as being the most simple, and at the same time in common to every part of the nervous system. In some places, however, it is much more acute than in others; in the skin, for instance, and especially in the points of the fingers. These are reckoned to have *nervous papillæ*, which by the influx of the blood are somewhat erected in the action of contact, in order to give a more acute sensation; though indeed this opinion seems rather to be founded on a conjecture derived from the structure of the tongue, which is not only the organ of taste, but also a most delicate organ of touch, than upon any certain observations.

75 Pain.

From the sense of feeling, as well as all the other senses, either pain or pleasure may arise; nay, to this sense we commonly refer both pain and almost all other troublesome sensations, though in truth pain may arise from every vehement sensation. It is brought on by any great force applied to the sentient part; whether this force comes from within or from without. Whatever, therefore, pricks, cuts, lacerates, distends, compresses, bruises, strikes, gnaws, burns, or in any manner of way stimulates, may create pain. Hence it is so frequently conjoined with so many diseases, and is often more intolerable than even the disease itself. A moderate degree of pain stimulates the affected part, and by degrees the whole body; produces a great flux of blood to the part affected, by increasing the action of its vessels; and it seems also to increase the sensibility of the part affected to future impressions. It often stimulates to such motions as are both necessary and healthful. Hence, pain is sometimes to be reckoned among those things which guard our life. When very violent, however, it produces too great irritation, inflammation and its consequences, fever, and all those evils which flow from too great force of the circulation; it disorders the whole nervous system, and produces spasms, watching, convulsions, delirium, debility, and fainting. Neither the mind nor body can long bear very vehement pain: and indeed Nature has appointed certain limits beyond which she will not permit pain to be carried, without bringing on delirium, convulsions, syncope, or even death, to rescue the miserable sufferer from his torments.

Long-continued pain, even though in a more gentle degree, often brings on debility, torpor, palsy, and rigidity of the affected part. But if not too violent, nor accompanied with fever, sickness, or anxiety, it sometimes seems to contribute to the clearness and acuteness of the judgment, as some people testify who have been afflicted with the gout.

76 Anxiety.

Anxiety is another disagreeable sensation, quite different from pain, as being more obtuse and less capable of being referred to any particular part, though frequently more intolerable than any pain. But we must take care to distinguish between this anxiety of which we treat in a medical sense, and that which is spoken of in common discourse. The latter does not at all depend on the state of the body, but belongs entirely to the mind; and arises from a sense of danger, or a foresight of any misfortune. The former is truly corporeal; and derives, no less than pain, its origin from a certain state of the body. Notwithstanding this difference, however, it is very possible for both these kinds of anxiety to be present at the same time, or for the one to be the cause of the other. A very great bodily anxiety will strike fear and despondency into the most resolute mind; and mental anxiety, on the contrary, if very violent and long-continued, may induce the former, by destroying the powers of the body, especially those which promote the circulation of the blood.

Anxiety, in the medical sense of the word, arises in the first place from every cause disturbing or impeding the motion of the blood through the heart and large vessels near it. Anxiety, therefore, may arise from many diseases of the heart and its vessels, such as its enlargement, too great constriction, ossification, polypus, palpitation, syncope, inflammation, debility, and also some affections of the mind. It is likewise produced by every difficulty of breathing, from whatever cause it may arise; because then the blood passes less freely through the lungs: anxiety of this kind is felt deep in the breast. It is said also to arise from the difficult passage of the blood through the liver or other abdominal viscera.

A certain kind of anxiety is very common and troublesome to hypochondriacal people; and arises from the stomach and intestines being either loaded with indigested and corrupted food, or distended with air produced by fermentation and extricated from the aliments. By such a load, or distention, the stomach, which is a very delicate organ, becomes greatly affected. Besides, the free descent of the diaphragm is thus hindered, and respiration obstructed. Anxiety of this kind is usually very much and suddenly relieved by the expulsion of the air; by which, as well as by other signs of a bad digestion, it is easily known. In these cases the anxiety is usually, though with little accuracy, referred to the stomach.

Anxiety also frequently accompanies fevers of every kind, sometimes in a greater and sometimes in a lesser degree. In this case it arises as well from the general debility as from the blood being driven from the surface of the body and accumulated in the large vessels: as in the beginning of an intermittent fever. Or it may arise from an affection of the stomach, when

when overloaded with crude, corrupted aliment; or distended and nauseated with too much drink, especially medicated drink. As the fever increases, the anxiety of the patient becomes greater and greater; remarkably so, according to the testimony of physicians, either immediately before the crisis or on the night preceding it; as before the breaking out of exanthemata, hæmorrhagy, sweat, or diarrhœa, which sometimes remove fevers. The patient feels likewise an anxiety from the striking in of any eruption or critical metastasis. This sensation also accompanies fevers and most other diseases, when the vital power is exhausted, and death approaches, of which it is the forerunner and the sign. It happens at that time, because the vital powers, unable to perform their functions, cannot make the blood circulate. But what kind of anxiety this is, the other signs of approaching death show very evidently. Moreover, even in the time of sleep, anxiety may arise from the same causes: hence frightful dreams, which frequently disturb our repose with surprise and terror.

77 Itching.

Itching, an uneasy sensation, with a desire of scratching the place affected, is often very troublesome, although it seems to be more a-kin to pleasure than to pain. As pain proceeds from too great an irritation, either chemical or mechanical, so does itching proceed from a slight one. Titillation, or friction, of a woollen shirt, for instance, upon the skin of a person unaccustomed to it, and of a delicate constitution, excites itching; as do also many acrid fossils, vegetables, and animals. Hence an itching is the first sensation after the application of cantharides, although the same, when augmented becomes painful. The same effect is produced by any thing acrid thrown out upon the skin; as in exanthematic fevers, the disease called the *itch*, &c. Lice, worms, especially ascarides, irritating either the skin or the intestines, excite a troublesome itching.

Too acute a sensation over the whole body is very rarely if ever observed. In a particular part the sense of feeling is often more acute than it ought to be, either from the cuticle itself being too thin and soft, or being removed; or from the part itself being inflamed, or exposed to too great heat. It becomes obtuse, or is even quite destroyed over the whole body, or in great part of it, from various affections of the brain and nerves; as when they are wounded, compressed, or defective in vital power. This is called *anæsthesia*, and sometimes accompanies palsy.

This sense may be deficient in a particular part, either from the nerve being diseased, or from its being compressed or wounded, or from the part itself being exposed to too great a degree of cold;—or from the scarf-skin which covers it being vitiated, either becoming too thick or hard, by the handling of rough, or hard, or hot bodies, as is the case with glass-makers and smiths; or from the elevation of the cuticle from the subjacent cutis, or true skin itself, by the interposition of blood, serum, or pus; or from the cutis being macerated, relaxed, or become torpid, which sometimes happens to hydropic persons; or lastly, from the whole organ being corrupted by gangrene, burning, cold, or contusion. This sense is very rarely depraved, unless perhaps in the case of delirium, when all the functions of the brain are disturbed in a surprising manner.

External Senses.

78 Taste.

The sense next to be considered is that of taste, the principal organ of which is the tongue; the nearer the tip of it, the more acute is the sense, and the nearer the glottis so much the more obtuse. It must be owned, however, that some kind of acrid substances, the taste of which is scarcely perceived upon the tip of the tongue, excite a most vehement sensation about its roots, or even in the throat itself. The tongue is endowed with many large and beautiful nervous papillæ, which seem to be the chief seat of this sense, and in the act of tasting are elevated and erected, in order to give the more acute sensation.

Nothing can be tasted which is not soluble in the saliva, that, being applied in a fluid form, it may pervade the involucra of the tongue, and affect its nervous pulp; and hence insoluble earths are quite insipid. Neither is it sufficient for a body to be soluble that it may be tasted: it must also have something in it saline, or at least acrid, in order to stimulate the nervous substance; and hence, whatever has less salt than the saliva is totally insipid.

The taste is rarely found to be too acute, unless through a fault in the epidermis which covers the tongue. If this be removed or wounded, or covered with ulcers, aphthæ, &c. then the taste, becoming too acute, is painful: or sometimes, no other sensation than that of pain is felt. It may be impaired, as well as the sense of feeling, from various diseases of the brain and nerves; of which, however, the instances are but rare. In some people it is much more dull than in others; and in such the sense of smelling is usually deficient also. The taste is most commonly deficient on account of the want of saliva; for a dry tongue cannot perceive any taste: hence this sense is very dull in many diseases, especially in fevers, catarrhs, &c. as well on account of the defect of saliva as of appetite, which is of so much service in a state of health; or by reason of the tongue being covered with a viscid mucus.

The taste is frequently depraved; when, for example, we have a perception of taste without the application of any thing to the tongue; or if any thing be applied to it, when we perceive a taste different from what it ought to be. This happens for the most part from a vitiated condition of the saliva, which is itself tasted in the mouth. Hence we may perceive a sweet, saline, bitter, putrid, or rancid taste, according to the state of the saliva: which may be corrupted either from the general vitiated condition of the mass of humours, or the glands which secrete it; of the mouth itself; or even of the stomach, the vapours and eructations of which rise into the mouth, especially when the stomach is diseased.

Besides the faults of the saliva, however, the taste may be vitiated from other causes; as, for instance, the condition of the nervous papillæ. This, however, is as yet but little known to us; for the taste is sometimes plainly vitiated, when at the same time the saliva appears quite insipid when tasted by other people.

Physicians, in almost every disease, but especially in fevers, inquire into the state of the tongue; not, indeed, without the greatest reason: for from this they can judge of the condition of the stomach; of the thirst, or rather the occasion the patient has for drink, when, on account of his delirium or stupor, he neither feels his thirst,

External Senses.

thirst, nor is able to call for drink. And, lastly, from an inspection of the tongue, physicians endeavour to form some judgment concerning the nature, increase, and remission of the fever.

79 Smell.

After the sense of taste, we shall next treat of that of that smell. Its seat is in that very soft and delicate membrane, filled with nerves and blood-vessels, which covers the internal parts of the nose, and the various sinuses and cavities proceeding from thence. This sense is more acute about the middle of the septum, and the *ossa spongiosa*, where the membrane is thicker and softer, than in the deeper cavities, where the membrane is thinner, less nervous, and less filled with blood-vessels; although even these do not seem to be altogether destitute of the sense of smelling.

As by our taste we judge of the soluble parts of bodies, so by our smell we judge of those very volatile and subtile parts which fly off into the air; and like the organ of taste, that of smell is kept moist, that it may have the more exquisite sensation, partly by its proper mucus, and partly by the tears which descend from the eyes.

Some kinds of odours greatly affect the nervous system, and produce the most surprising effects. Some gratefully excite it, and immediately recruit the spirits when almost sinking; while some produce fainting, nay, as it is alleged, even sudden death. To this head also are we to refer those antipathies, which, though truly ridiculous, are often not to be subdued by any force of mind.

This sense is sometimes too acute, as well from some disease in the organ itself, which happens more rarely, as from the too great sensibility of the nervous system in general, as is sometimes observed in nervous fevers, phrenitis, and hysteria. It is more frequently, however, too dull, either from diseases of the brain and nerves, as from some violence done to the head, or from some internal cause; or it may proceed from a dryness of the organ itself, either on account of the customary humours being suppressed or turned another way, or from the membranes being oppressed with too great a quantity of mucus or of tears. Of both these cases we have instances in the cattarh, where at first the nostrils are dry, but afterwards are deluged with a thin humour, or stopped up with a thick one. But in these, and many other examples, the membrane of the nose itself is affected with inflammation, relaxation, or too great tension, by which the nerves, which constitute a great part of it, must be vitiated. It is evident also, that whatever obstructs the free entrance of the air into the nostrils, or impedes its passage through them, must prove detrimental to the sense of smelling.

80 Hearing.

The sense of hearing is more frequently vitiated than almost any of the rest, as having a more delicate organ, and one composed of many and very small parts, of which an account is given under the article ANATOMY.—It frequently becomes too acute; either from the general habit of the body being too irritable, such as often happens to hysterical and lying-in-women; or from too great a sensibility of the brain itself, which is not unfrequently observed in fevers, as well as in phrenitis, and sometimes in the true mania; or it may be from a disease of the ear itself, as when it is affected with inflammation, pain, or too great tension.—It may be rendered dull, or even be altogether destroyed, so that the person shall become totally deaf, from the same causes acting with different degrees of force. This happens especially from the want of the external ear; or from the meatus auditorius being stopped up with mucus, wax, or other matters; or from the sides of the canal growing together, as sometimes happens after suppuration or the small-pox; or by the membrane of the tympanum becoming rigid or relaxed, or being eroded or ruptured; or the tympanum itself, or the Eustachian tube, may from certain causes be obstructed; or some of the little bones or membranes, or some of the muscles of the labyrinth, may be affected with concretion, spasm, palsy, or torpor; or, lastly, it may happen from diseases of the brain and nerves, all the organs of hearing remaining sound. Hence deafness is often a nervous disease, coming suddenly on, and going off spontaneously. Hence also it is common in old people, all of whose solid parts are too rigid, while their nervous parts have too little sensibility.

Persons labouring under fevers, especially of the typhus kind, often become deaf. When this comes on along with other signs of an oppressed brain, and a great prostration of health, it may be a very bad symptom; but for the most part it is a very good one, even though accompanied with some degree of torpor or sleepiness.

A very common disease in the sense of hearing is when certain sounds, like those of a drum, a bell, the falling of water, &c. are heard without any tremor in the air, or without a sound person's hearing any thing. This disease is called *tinnitus aurium*, of which various kinds have been observed. For the most part it is a very slight transient disorder; but sometimes it is most obstinate, long-continued, and troublesome. It often arises from the slightest cause, such as any thing partially stopping up the meatus auditorius or Eustachian tube itself, so that access is in part denied to the air; whence it happens that the latter strikes the membrane of the tympanum, or perhaps the interior parts, unequally, and with too much force. Hence *bombi*, a kind of tinnitus, are heard even by the most healthy when they yawn.

A much more frequent and troublesome species of tinnitus accompanies many diseases both of the febrile and nervous kind. This is occasioned partly by the increased impetus of the blood towards the head, with an increase of sensibility in the nervous system itself, so that the very beatings of the arteries are heard; and partly from the increased sensation and mobility of the nerves and muscles of the labyrinth: whence it happens, that the parts which ought to be at rest until excited by the tremor of the air, begin to move of their own accord, and impart their motion to other parts which are already in a morbid state of too great sensibility.

A tinnitus sometimes arises from any vehement affection of the mind; sometimes from a disorder in the stomach; sometimes from a rheumatic disorder affecting the ears and head; or from a catarrh, which commonly affects the Eustachian tube. Sometimes, however, the tinnitus alone affects the patient; and even this is a disease of no small consequence. These various causes, however, both of this and other disorders of the hearing,

hearing, are often very difficult to be distinguished, as well on account of the inaccessible situation of the organ, as on account of the little knowledge we have of its action. But from whatever cause it arises, both this and the other affections of the hearing can neither be cured certainly nor easily, but by the removal of the cause whatever it may be.

Of sight.

Concerning the nature of the sense of sight, the reader may consult the articles ANATOMY and OPTICS. Of this sense some slight disorders, or rather varieties, are often observed. Those persons are called *short-sighted* who cannot see distinctly unless the object be very near them. This disorder arises from too great a refraction of the rays by reason of their being too soon collected into a focus by the crystalline lens, and diverging again before they fall upon the retina, by which means they make an indistinct picture upon it. The most common cause is too great a convexity of the eye or some of its humours, as too prominent a cornea. It is a disorder common to young people, which is sometimes removed when they grow older. As soon as the first approaches of short-sightedness are observed, it is supposed it may be obviated by the person's accustoming himself to view remote objects, and keeping his eyes off very small and near ones: as, on the contrary, it may be brought on by the opposite custom; because the eye accommodates itself somewhat to the distances of those objects which it is accustomed to view. But a concave glass, which causes the rays of light to diverge more than naturally they would before falling upon the cornea, is the most simple and certain remedy.

Long-sighted people are those who cannot see an object distinctly unless it be at a considerable distance from them. This arises from causes contrary to the former; namely, the eye being too flat, so that there is no room for refracting the rays and bringing them into a focus. Hence this defect is common in old people, and remedied by the use of convex glasses.

Those are called *nyctalopes* who see better with a very weak than with a strong light. It is a defect very seldom to be met with in the human race, though every person is sensible of it who hath been long kept in the dark and is then suddenly brought into the light. The disease arises from too great a sensibility of the retina, and the pupil being too open.

The sight is liable to many and grievous disorders. It is sharpened beyond measure, so that the person either perceives nothing distinctly or with great pain, from the same causes that induce a similar disorder in the other senses; namely, excessive sensibility in the general habit of body; or a particular state of the brain common in phrenitis, or even in those afflicted with fevers arising from inflammation or too great excitement; though more frequently from the condition of the eye itself, one becomes unable to bear the light. The inflammation of the tunica adnata, and the forepart of the sclerotica, is communicated to the back parts of it, and from thence to the choroides and retina itself. Hence the light becomes intolerable, and vision is attended with pain and great irritation, sometimes inducing or augmenting a delirium.

The sense of seeing is made dull, or even totally abolished, by age; the aqueous humour not being supplied in sufficient quantity, and the cornea and lens, or the vitreous humour, becoming shrivelled or decayed. It may likewise happen from the cornea becoming dry and opaque; which is to be imputed to the languid motion of the blood, and to great numbers of the small vessels being obstructed or having their sides concreted;—or from the crystalline lens becoming yellow like amber, and the retina itself less sensible, for old age diminishes every sensation. It is totally abolished by injuries of the brain, the optic nerve, or the retina, even though the structure of the organ should remain sound. This disease is called an *amaurosis;* and is easily known by the dilatation and immobility of the pupil, the humours of the eye remaining clear. It is commonly owing to congestion of blood; and sometimes, where no congestion of blood can be discovered, to mere torpor of the nerves. If it be only a torpor of part of the retina, we see black spots in those things at which we look; or flies seem to pass before our eyes, a very bad sign in fevers, and almost always mortal. The sight is abolished also by the obscurity or opacity of any of the parts through which the rays ought to pass and be refracted; as if the cornea lose its transparency by being covered with spots; or the aqueous humours become corrupted with blood, serum, or pus; or the lens (which often happens, and which is called a *cataract*) becomes of a gray or brown colour, or the vitreous humour be in like manner corrupted; or, lastly, when all the humours being dissolved, confused and mixed together, by inflammation and suppuration, either do not suffer the light to pass at all, or to pass imperfectly and unequally; whence either no image is formed on the retina, or it appears obscure, distorted, imperfect, and ill-coloured.

The sight is also depraved, when things appear to it of a colour different from their own, or even in another situation and of another shape than they ought to have. This happens from the humour being tinctured with any unusual colour, as is said to happen in some instances of jaundice; or from an extravasation and mixture of the blood with the aqueous humour. A surprising depravation also, or constant and perpetual defect of vision, is not unfrequently observed in men otherwise very healthy, and who see quite clearly; namely, that they cannot distinguish certain colours, green, for example, from red. Another depravation is, when, without any light being admitted to the eyes, sparks, small drops of a flame or gold colour, and various other colours, are observed to float before us. This is generally a very slight and transient disorder, common to those whose constitutions are very irritable; and arises from the slight impulse, as it would seem, on the retina, by the vessels beating more vehemently than usual. A fiery circle is observed by pressing the eye with the finger after the eyelids are shut. The same reason, perhaps, may be given for those sparks which are seen by persons labouring under the falling sickness, and increasing to the size of an immense and luminous beam before they fall down in convulsions. A similar beam those who have recovered from hanging or drowning testify that they have observed: for by reason of the respiration being suppressed, the vessels of the head swell and compress the whole brain and nervous parts of the head. Sparks of the same kind, and these too of no good omen,

External Senses.

omen, are observed in patients labouring under a fever, where a phrenitis or fierce delirium is at hand; and likewise in those who are threatened with palsy, apoplexy or epilepsy.—A distinct but false perception, namely of visible things which do not exist, is to be imputed to some injury of the brain, to madness or a delirium, not to any disease of the eye.

A very frequent defect of vision remains to be mentioned, namely, squinting. A person is said to squint who has the axes of the eyes more oblique than usual, and directed to different points. Hence a great deformity, and often an imperfect and confused vision by which the objects are sometimes seen double. It is an evil for the most part born with the person, and often corrected by those attempts which an infant makes to see more pleasantly and distinctly; and this even without being conscious of its own defects. It is also easily learned, especially in infants, even without their own knowledge, by that kind of imitation which has a great influence over the human race, especially in their tender years.—It is by no means, however, so easily unlearned.

Squinting is frequently occasioned by a spasm, palsy, rigidity, &c. of the muscles which manage the eye; by epilepsy; by certain diseases of the head, the hydrocephalus especially; or by any great injury done to the head. Sometimes, though very rarely, it comes on suddenly without any known cause. It is very probable, however, that squinting often arises from a fault of the retinæ, when their central points, for instance, and those similarly placed with respect to the centre, do not agree. In this case there must be a contortion of the eye, that the object may not be seen double. This seems also to be the reason why squinting is much increased when the person brings the object near his eye in order to view it more perfectly. Or if the central point of either, or both, of the retinæ be insensible, or nearly so, it is necessary for the person to distort his eyes that he may have any distinct vision of objects. If the optic nerve had not entered the retina obliquely, but passed directly through its centre, we would all either have squinted or seen double.

82 Vertigo.

Physicians have referred to the sense of vision that most troublesome sensation which we call a *vertigo;* though it seems rather to belong to that of feeling, or of consciousness; for in many instances the disorder is not removed either in the dark or by shutting the eyelids. The vertigo takes place when external objects really at rest seem to reel, to whirl round, to tremble, or to move in any manner of way. If the disorder be very violent, the person is neither able to see, on account of a dimness of sight; nor can he stand, as the powers fail which ought to govern the limbs. A nausea also usually accompanies the vertigo, and the one generally produces the other.

This disorder is observed to be both the symptom and forerunner of some dangerous diseases; such as apoplexy, epilepsy, hysteria; hæmorrhages from the nose and other parts; suppressions of the menses; plethora; fevers, as well such as are accompanied with debility as those in which there is an increased impetus of the blood towards the head. An injury done to the head also, but rarely one done to the eyes, unless as it affects the whole head, brings on a vertigo. A vertigo may be likewise produced by a very great and sudden loss of blood or other fluid; by debility; syncope; various diseases of the alimentary canal, of the stomach especially; poisons admitted into the body, particularly of the narcotic kind, as opium, stramonium, wine, &c. and hence vertigo is a symptom of every kind of drunkenness. Various motions also, either of the head or the whole body, being tossed in a ship, especially if the vessel be small and the sea runs high, produce a vertigo. In these and similar examples, the unusual and inordinate motions of the blood are communicated to the nervous parts which are in the head; or these being affected by sympathy from the neighbouring parts, produce a confused sensation as if of a rotatory motion. Nay, it is often produced from an affection of the mind itself, as from beholding any thing turned swiftly round, or a great cataract, or looking down a precipice, or even by intense thought without looking at any thing.

Though a vertigo be for the most part a symptom and concomitant of other diseases, yet it is sometimes a primary disease, returning at intervals, increasing gradually, and equally impeding and destroying the functions of the body and mind.

83 Memory.

After having treated of the external senses, we shall next proceed to consider those properly called *internal;* which are the *memory*, the *imagination*, and the *judgement*. The first is lessened, disturbed, or even totally destroyed, in many diseases, especially those which affect the brain; as in apoplexy, palsy, internal tumours of the head, external violence applied, fevers, especially those in which there is an increased motion of the blood towards the head, or where the brain is any other way very much affected. It is very rarely, however, depraved in such a manner that ideas are not represented to the mind in their proper order; or if at any time such a disorder occurs, it is considered rather as a disorder of the imagination, or as a delirium, than a failure of the memory. The mind is said to be disordered when the perceptions of memory or imagination are confounded with those of sense, and of consequence those things believed to be now present which are really past or which never existed; or when the sense of the person concerning ordinary things is different from that of other people. The general name for such disorders is *vesania:* if from fever, it is called *delirium*. A general fury without a fever, is called *mania* or *madness:* but a partial madness, on one or two points, the judgment remaining sound in all other respects, is called *melancholia*. There is, however, no exact and accurate limits between a sound mind and madness. All immoderate vivacity borders upon madness; and, on the other hand, a sorrowful and gloomy disposition approaches to melancholy.

84 Delirium.

Delirium accompanies fevers of many different kinds. Sometimes it is slight, easily removed, and scarce to be accounted a bad sign. Often, however, it is very violent, and one of the very worst of signs, requiring the utmost care and attention.

A delirium is either fierce or mild. The fierce delirium is preceded and accompanied by a redness of the countenance, a pain of the head, a great beating of the arteries, and noise in the ears; the eyes in the mean time looking red, inflamed, fierce, shining, and unable to bear the light; there is either no sleep at all, Delirium.

all; or sleep troubled with horrid dreams; the wonted manners are changed; an unusual peevishness and ill-nature prevail. The depravation of judgment is first observed between sleep and waking, and by the person's crediting his imagination, while the perceptions of sense are neglected, and the ideas of memory occur in an irregular manner. Fury at last takes place, and sometimes an unusual and incredible degree of bodily strength, so that several attendants can scarce keep a single patient in his bed.

The mild delirium, on the contrary, is often accompanied with a weak pulse, a pale collapsed countenance, and a vertigo when the patient sits in an erect posture; he is seldom angry, but often stupid, and sometimes remarkably grieved and fearful. The loss of judgment, as in the former kind, is first perceived when the patient is half awake; but a temporary recovery ensues upon the admission of the light and the conversation of his friends. The patient mutters much to himself, and attends little to the things around him; at last, becoming quite stupid, he neither feels the sensations of hunger or thirst, nor any of the other propensities of nature, by which means the urine and excrements are voided involuntarily. As the disorder increases, it terminates in subsultus tendinum, tremors, convulsions, torpor, and death. The other species of delirium also frequently terminates in death, when the spirits and strength of the patient begin to fail.

The symptoms accompanying either of these kinds of delirium show an unusual, inordinate, and unequal motion of the blood through the brain, and a great change in that state of it which is necessary to the exercise of the mental powers. It is very probable, that an inflammation of the brain, more or less violent and general, sometimes takes place, although the signs of universal inflammation are frequently slight. This we learn from the dissection of dead bodies, which often show an unusual redness of the brain or of some of its parts, or sometimes an effusion or suppuration.

The state of the brain, however, may be much affected, and delirium induced, by many other causes besides the motion of the blood. In many fevers, typhus, for instance, the nervous system itself is much sooner and more affected than the blood's motion; and though the morbid affections of the nervous system are as invisible to the senses as the healthy state of it, the symptoms of its injuries plainly show that its action, or *excitement*, as some call it, is unequal and inordinate. In this way, too, delirium is produced by several poisons.

Melancholy and mania.

The pathology of melancholy and mania is much more obscure; as coming on without any fever, or disturbance in the blood's motion. Often also they are hereditary, depending on the original structure of the body, especially of the brain; the fault of which, however, cannot be detected by the nicest anatomist. But it is well known, that various diseases of the brain, obstructions, tumors, either of the brain itself, or of the cranium pressing upon it, any injury done to the head, and, as some physicians relate, the hardness and dryness of the brain, and some peculiar irritations affecting the nervous system, are capable of bringing on this malady. And indeed so great are the irritations affecting the nervous system in mad people, that they often sleep little or none for a long time.—Yet even this so defective and imperfect knowledge of the diseases of the brain and nerves, is by no means free from difficulties. For though we know that the brain, or a certain part of it, is hurt, or that it is irritated by a swelling, or a pointed bone growing into it, nobody can foretel how great, or what may be the nature of the malady from such a hurt: for examples are not wanting of people who, after losing a large part of the brain, have recovered and lived a long time; there are many instances also of persons who have perceived no inconvenience from a large portion of that viscus being corrupted, until at length they have fallen suddenly down and died in convulsions.

86 Idiotism.

Another disease of the internal senses, quite different from these, is *fatuity* or *idiotism*. Those are called *idiots* who are destitute either of judgment or memory, or else have these faculties unequal to the common offices of life. A weak memory, however, is by no means essential to idiotism. For there are some instances of idiots who have had very correct and very extensive memories. A kind of idiotism is natural and common to all infants; neither is it to be accounted a disease; but if it last beyond the state of infancy, it is a real disease, and for the most part incurable. It has the same causes with the other diseases of the internal senses; although these can scarcely be detected by the eye or by the knife of the anatomist. It frequently accompanies, or is the effect of, epilepsy. Hence, if the epilepsy derives its origin from causes not seated in the head, as from worms lodging in the intestines, the fatuity may be cured by dislodging these, and removing the epilepsy. It is not unlikely that the fatuity of children, and the dotage of old men, may arise from the brain being in the former too soft and in the latter too hard; or perhaps in the one case not evolved, and in the other somewhat decayed.

87 Disorders in the muscular power.

The muscular power may be diseased in a great number of ways. The mobility itself may be too great; but this must be carefully distinguished from vigour. By mobility is meant the ease with which the muscular fibres are excited into contraction. The vigour, on the other hand, is that power with which the contraction is performed. They are sometimes joined, but more frequently separate, and for the most part the excesses of each are owing to contrary causes.

88 Mobility.

Too great mobility is when motions are excited by a very slight stimulus, or when very violent motions are produced by the customary stimulus. A certain habit of body, sometimes hereditary, renders people liable to this disease. Women have a greater share of mobility than men. Infants have a great deal of mobility, often too great; youth has less than infancy, but more than man's estate; though old age has commonly too little. A lazy, sedentary life, full diet, a suppression of the usual evacutions, fulness of the blood-vessels, and sometimes their being suddenly emptied, laxity, flaccidity of the solids in general, but sometimes too great a tension of the moving fibres, the use of diluents, especially when warm, or heat applied in any manner, produce too great mobility. And this may be either general or particular, according as the causes have been applied to the whole body, or only to a part of it.

89 Vigour.

Vigour in general is rarely morbid; although sometimes certain muscular parts appear to have too great strength. In maniacs and phrenitics, an immense strength

Disorders in the Muscular Power.

strength is observed in all the muscles, especially in those which serve for voluntary motion; this is not unjustly reckoned morbid. The reason of this excess is very obscure; however, it is plainly to be referred to a diseased state of the brain.

A more frequent and more important excess of vigour is observed in those muscular fibres that do not obey the will, such as those which move the blood. Its circulation is thus often increased, not without great inconvenience and danger to the patient. But a slighter excess of this kind, pervading the whole body, renders people apt to receive inflammatory diseases, and is usually called a *phlogistic diathesis*. But this is better observed when local, as in inflammation itself.

Too great vigour of the muscular fibres may arise from the nervous power increased beyond measure, as in mania, phrenitis, or violent affections of the mind; from too great a tension of the fibres, by which they more easily and vehemently conceive motions, as of the arteries when filled with too much blood; from catching cold, by being exposed either to cold or heat, as usually happens in the spring; or, lastly, though the nervous power and tension of the fibres should not at all be changed, their action may become too great, from a stimulus more violent than usual being applied, or from the usual stimulus, if the fibres themselves have already acquired too great a share of mobility.

90 Torpor.

The opposite to too great mobility is torpor, and to too great vigour is debility. Torpor is such a diminution of mobility as renders the parts unequal to their functions. It arises from causes directly opposite to mobility; such as, a harder and more rigid contexture of the parts themselves, or even sometimes from one too lax and flaccid; from old age; from some peculiar temperament of body, such as one phlegmatic, frigid, or insensible; too great and incessant labour, cold, spare diet, and an exhausted body. This evil is the more to be dreaded, because, the powers of the body being deficient, nature is neither able to make any effort of herself, nor are the remedies, in other cases the most efficacious, capable of affording her any assistance.

91 Debility.

Debility takes place, when the motion of the muscles, either voluntary or involuntary, is not performed with sufficient strength. A greater or lesser share of debility, either general or of some particular part, accompanies almost all diseases, and is indeed no small part of them: for it is hardly possible that a disease can subsist for any length of time without inducing some degree of debility. When a state of debility is induced, it renders a man obnoxious to innumerable disorders, and throws him as it were defenceless in their way. It often depends on the original structure of the body, so that it can be corrected neither by regimen nor medicines of any kind. A different degree of strength also accompanies the different ages of mankind; and thus, in some cases, debility cannot be reckoned morbid. But a truly morbid and unusual debility arises from the nervous energy being diminished; from diseases of the brain and nerves, or of the muscles through which they are distributed; from a decay of the nerves themselves; from a want of the due tension of the fibres, or the fibres themselves becoming torpid; from the body exhausted by spare diet, want, evacuations; or, lastly, from diseases affecting the whole body, or some particular parts of it.

92 Palsy.

The highest degree of debility, namely, when the strength of the muscles is altogether or nearly destroyed, is called *paralysis* or *palsy*; and is either universal, or belonging only to some particular muscles. An universal palsy arises from diseases of the brain and nerves, sometimes very obsure, and not to be discovered by the anatomist; for the nervous power itself is often deficient, even when the structure of the nerves remains unhurt; yet often a compression, obstruction, or injury of the vesssels, extravasation of blood or serum, collections of pus, swellings, &c. are discovered. It frequently arises from certain poisons acting on the nerves; from the fumes of metals; from the diseases of parts, and affections of the muscles, very remote from the brain, as in the colic of Poictou. A palsy of single muscles, but less perfect, often arises without any defect of the brain or nerves, from any violent and contained pain, inflammation, too great tension, relaxation, rest, or destruction of the texture of the parts, such as commonly happens after the rheumatism, gout, luxations, fractures of the bones, and ischuria.

An *universal* palsy, however, as it is called, seldom affects the whole body, even though it should originate from a disease of the brain. We most commonly see those who are paralytic affected only on one side, which is called an *hemiplegia*. It is said that the side of the body opposite to the diseased side of the brain is most commonly affected. If all the parts below the head become paralytic, it is called a *paraplegia*. In these diseases the senses for the most part remain; though sometimes they are abolished, and at others rendered dull. Sometimes, though rarely, and which is an exceeding bad symptom, the motion, sensation, pulse, and heat of the paralytic limbs are lost; in which case the arteries themselves become paralytic. A palsy of the whole body, as far as regards the voluntary motions, with anæsthesia and sleep, is called an *apoplexy*. This proceeds from some injury of the brain: though a state very similar to it is induced by narcotics. opium, wine itself, or any generous liquor taken to excess; and lastly, by breathing in air corrupted by noxious impregnations, such as a large proportion of carbonic acid, hydrogenous gas, or similar active aeriform fluids.

Another disease to which muscular motion is liable, and that neither slight nor unfrequent, is called *spasm*. This is a violent and irregular motion of the muscles. Of spasms there are two kinds, the tonic and clonic. The latter is frequently called a *convulsion;* in order to distinguish it from the other, which is more peculiarly called *spasm*. Spasm.

Spasm, therefore, is a violent, constant and preternatural contraction of the muscular fibres; but a convulsion is an unusual and violent contraction alternated with relaxation. People are rendered liable to spasm by too sensible a habit of body, or too great mobility; and hence it is a disease common in women, in infants, and in weak, luxurious, lazy, and plethoric people. It is brought on those already predisposed to it, by any kind of stimulus applied to the brain, or to any nerve, muscle, or nervous part connected with it:

of

of which we have examples in dentition; worms lodged in the intestines, and irritating them; any acrid matter infecting the blood, or much affecting the stomach and intestines; the irritation of any nerve, or of the brain itself, by an exostosis, swelling, too great fulness of the vessels, pain, vehement affections of the mind, sudden evacuation, or poisons admitted into the body. Frequently, however, the malady originates from slight causes, little known, and not easily observed.

Spasm is both the cause and effect, and frequently constitutes the greatest part, of many diseases. It is often very difficult either to be known or cured; because it is so multiform, and produces as many different symptoms as there are organs affected; of which it surprisingly disturbs, impedes, or increases the functions. It is a disease seated in the original stamina of the constitution; and neither to be removed by slight remedies, nor in a short time.

With regard to sleep, its use is sufficiently apparent from the effects which it produces in the body. It restores the powers both of mind and body when exhausted by exercise, giving vigour to the one, and restoring its wonted alacrity to the other. It renders the muscles again active and moveable, after they have become wearied, rigid, painful, and trembling by hard labour. It moderates the quickness of the pulse, which usually increases at night, and brings it back to its morning standard. It seems also to assist the digestion of the aliment; lessens both the secretions and excretions; and renders the fluids thicker than otherwise they would be, especially in a body endowed with much sensibility and mobility. Hence sleep is not only useful, but absolutely necessary for preserving life and health; and is a most excellent remedy both for alleviating, and totally removing, many diseases.

Want of sleep is hurtful in many different ways, especially to the nervous system. It renders the organs of sense both external and internal, as well as those of every kind of motion, unfit for performing their offices. Hence the sensations are either abolished, or become imperfect or depraved; and hence imbecility of mind, defect of memory, a kind of delirium, mania itself, pain of the head, weakness of the joints, an imperfect or inordinate action of the vital organs, quickness of pulse, heat, fever, depraved digestion, atrophy, leanness, and an increase or perturbation of the secretions and excretions.

Sleep may be prevented both in healthy and sick people from various causes; such as strong light, noise, pain, anger, joy, grief, fear, anxiety, hunger, thirst, vehement desire, motion of the body, memory, imagination, intense thought, &c. On the other hand, sleep is brought on by a slight impression on the organs of sense, or none at all; by the humming of bees, the noise of falling water, cold and insipid discourse; or lastly, by such an exercise of the memory as is neither too laborious nor disturbing to the mind.—Too great an impulse of the blood towards the head, such as often happens in fevers, prevents sleep; but a free and equal distribution of the blood through the whole body, especially the extreme parts, frequently brings it on. Whatever weakens the body also favours sleep; and hence various kinds of evacuations, the warm bath, fomentations, sometimes heat itself, are useful for promoting it. It also comes on easily after taking food, or indulging venery; the violent sensation being then quieted, and the body itself somewhat weakened. Cold produces a deep sleep of long continuance, not easily disturbed, and often terminating in death. Lastly, There are certain substances which, when applied to the body, not only do not excite the nervous system, but plainly lay us asleep, and render us unfit for sensation; of this kind are those called *narcotics*, as opium and the like; among which also we may reckon wine taken in too great quantity. Lastly, Watching itself is often the cause of sleep; because while a man is awake he always more or less exercises the organs of his body, by which the nervous influence is diminished, and thus the more violently the body is exercised, in the same proportion is the person under a necessity of sleeping.

Sleep is deficient in many diseases; for there are few which do not excite pain, anxiety, or uneasiness, sufficient to prevent the approach of sleep, or to disturb it. Fevers generally cause those who labour under them to sleep ill; as well on account of the uneasiness which accompanies this kind of disease, as by reason of the impetus of the blood towards the head being frequently increased; and likewise from the stomach being disordered, loaded with meat, or distended with drink. Hence also we may see the reason why many hypochondriac and hysteric patients sleep so ill; because they have a bad digestion, and their stomach is disposed to receive many though frequently slight disorders; the slightest of which, however, is sufficient to deprive the patient of rest, provided the body be already irritable, and endowed with too great a share of mobility.

Want of sleep will hurt in diseases as well as in health; and for the same reason; but in a greater degree, and more quickly, in the former than in the latter; and is therefore not only a very troublesome symptom of itself, but often produces other very dangerous ones.

Too much sleep, on the other hand, produces many mischiefs, rendering the whole body languid, torpid, and lazy; and it even almost takes away the judgment. It also disturbs the circulation, and diminishes most of the secretions and excretions. Hence plethora, fatness, flaccidity, and an inability for the common offices of life.—The causes of this excess are, either the usual causes of sleep above mentioned increased beyond measure, or some fault in the brain, or a compression of it by an extravasation of the humours; or sometimes, as it would seem, from great debility produced by an unusual cause, as in those who are recovering from typhous fevers and other diseases. In these examples, however, this excess of sleep is by no means hurtful; nor even, perhaps, in those cases where an excess of grief continued for a long time, or a great fright, have produced a surprising and unexpected somnolency. Lastly, Many people have accustomed themselves, and that not without a great deal of hurt to their constitutions, to sleep too much. Nor are there examples wanting of some who have passed whole days, and even months, in sleep almost uninterrupted.

95 Circulation.

With regard to the manner in which the circulation of the blood is performed, and the various principles of which it is composed, see the articles Blood, and Anatomy. As for the disorders to which the blood and its circulation are subject, it has been observed, that

Disorders of Circulation.

that in our younger years the veins are much more dense, firm, and strong, than the arteries; but the latter, by reason of the continual pressure upon them, and the strength which they exert, become daily more firm, hard, and strong, until at last they equal or exceed the veins themselves in strength; and it is not uncommon in old men to find some part of the arteries converted into a horny substance, or even into a solid bone. Hence in the state of infancy the greatest part of the blood is contained in the arteries, and in old age in the veins; an affair indeed of no small moment, as it shows the reason, in some measure, of the state of increase and decrease of the body. Besides, if any disease happens from too great a quantity of blood, it thence appears that it must show itself in young subjects in the arteries, and in old ones in the veins; and this is the reason of many diseases which accompany certain periods of life.

In most, if not in all species of animals, the arteries of the females are much more lax and capacious when compared with the veins, and the veins much less, than in the males of the same genus. The design of nature in this conformation, is probably that they may be the better able to nourish the fœtus in their womb. The same likewise seems to be the reason why women are more inclined to plethora than men; and to this greater capacity of the arteries and smallness of the veins are we to ascribe that beauty and elegant shape of the arms in women, not disfigured or livid with veins as in men.

The blood is also distributed in various proportions to the different parts of the body, and that proportion too differs at different periods of our lives. At first a great quantity is sent to the head, because that part of the body is first to be evolved and fitted for its offices; but as soon as the parts begin to make a considerable resistance to the efforts of the blood, and the vessels cannot easily be further dilated, it is necessarily sent off to other parts; by which means the rest of the body increases in bulk, and becomes fitted for performing its proper functions. The effect of this change is also very soon observed, namely, when none of the blood passes through the navel, and of consequence a greater quantity is sent by the iliac arteries to the inferior extremities. These, though so small and slender in the fœtus, increase very suddenly; so that often in not many months, the child can not only stand on its feet, but even walk tolerably well. And during the earliest periods of infancy, the inferior extremities grow more rapidly than any other part of the body.

96
Pulsation of the arteries

Physicians are wont to judge of the state of the circulation by the pulse, which indeed is very various, as well with regard to its frequency, as to the strength and equality of its strokes and intervals.—Its common quickness in a healthy adult is about 70 strokes in a minute. In a fœtus, perhaps, it is more than double; and in an infant a few months old, hardly less than 120. As we grow up, this quickness gradually diminishes; so that in extreme old age it sometimes does not exceed 50, or is even slower. This rule, however, is not without exceptions: for many, especially those of an irritable habit, have the pulse much quicker; while others, even in the vigour of their age, have their pulse remarkably slow. It is for the most part somewhat quicker in women than in men.

The pulse is also rendered quicker, both in a healthy and diseased body, by the application of stimuli of many different kinds. Exercise especially, by accelerating the return of the blood through the veins, increases the quickness of the pulse to a surprising degree. Various kinds of irritations affecting the nervous system, as intense thinking, passions of the mind, pain, heat, stimulating medicines, wine, spices, &c. likewise produce the same effect. The acrimony of the blood itself also is thought to quicken the pulse.

When a person first awakes in the morning, the pulse is slow, but becomes quicker by degrees on account of the many irritating matters applied to the body. Its quickness is increased after taking food, especially of the animal kind, or such as is hot or seasoned with spices. In the evening a slight fever comes on, for which rest and sleep are the remedy. These things, however, are scarcely to be observed in a healthy person, but are very evident in one that is feverish, especially when the fever is a hectic.—Again, even debility itself often renders the pulse quicker than usual; because the ventricle of the heart not being quite emptied, it is the sooner dilated again, and of consequence contracts the sooner. For this reason a physician can never judge of the strength of the circulation from the frequency of the pulse.

Lastly, In all fevers, however different from one another, the pulse is found to be too quick, partly perhaps from debility, partly from the acrimony of the fluids, and partly from the repulsion of the blood from the surface of the body, and the accumulation of it in the large vessels where it acts as a stimulus; though it must be owned, that a great deal of this is obscure, if not totally unknown; nor in truth are we able to understand in what manner the *autocrateia* acts with regard to the frequency of the pulse.

The pulse is seldom observed too slow, unless when the mobility of the body is much diminished, as in decrepid old age, or from a compression or disease of the brain, as is exemplified in the second stage of hydrocephalus; but a greater compression of the brain usually produces a still more remarkable slowness of the pulse, as in the third stage of hydrocephalus.—Sometimes also the pulse is too slow in those who are recovering from tedious fevers. But this is a matter of little moment, and seems to be owing to some kind of torpor. Indeed it has generally been considered as a mark of a thorough and complete solution of the fever; for it is commonly observed, that when this state of the pulse takes place, the patient seldom suffers a relapse.

While the frequency of the pulse continues the same, its strokes may be either full, great, strong, and hard; or soft, small, and weak. A full, great, and strong pulse takes place when the ventricle strongly and completely empties itself; throwing out a great quantity of blood into the arteries, which fully distends them and stimulates them to a strong contraction. A pulse of this kind is common in strong healthy men, and is seldom to be accounted a symptom of disease. But if it be too strong, and strike the finger of the person who feels it violently and sharply, it is called a *hard pulse*. This hardness is produced by a sudden and violent contraction of the heart and arteries, which distends even the remote branches, as those of the wrist, too suddenly and

Disorders of Circulation.

and smartly, and excites them also to sudden and violent contractions.

A hard pulse therefore denotes too great an action of the heart and arteries. It may arise from various causes: in the first place, from too great a tension of the vessels; for instance, from their being too full, and by that means more prone to motion, and the more fit for receiving violent motions. It may arise also from too great a density and firmness of the solids; and hence it is most frequent in cold countries, among strong robust people and such as are accustomed to hard labour. It may likewise arise from various causes irritating the whole nervous system, or only the heart and arteries. Lastly, It accompanies many fevers, as well as most inflammatory disorders, whether the inflammation arises from a general stimulus applied to the whole body, or from the irritation of particular parts, by degrees extended over the whole body. In such a state of the circulation, the patient frequently stands in need of blood-letting, and almost always bears it well.

A small, weak, and soft pulse is generally owing to causes opposite to the former, and indicates a contrary state of the circulation and nervous system. It frequently requires stimulants; nor does it generally require blood-letting, or easily bear it. Sometimes, however, a pulse of this kind is observed even in the case of a dangerous inflammation, of the stomach for instance, or intestines. But in these and the like examples we ought to attend to the nature of the malady, much more than to the state of the pulse.

The pulse is said to intermit, when the stroke does not return after the usual interval, and perhaps not till after twice, thrice, or four times the usual space. A pulse of this kind seems to be almost natural and constant in some animals, and is common to some men even in the most perfect health; and if these happen to be seized with a fever, the pulse sometimes becomes regular, nor can the disease be removed before the intermission has returned.

Moreover, in some people, though their pulse beats equally while in health, yet the slightest illness makes it intermit; and in others, especially those who have a great deal of mobility in their constitution, such as hypochondriac and hysteric people, the intermission of the pulse is felt, without applying the finger to the artery, merely by the uneasiness which they perceive in their breasts during those intervals in which the pulse is deficient. An intermittent pulse likewise occurs in many diseases of the breast, especially when water is collected in it; and the like happens in the end of all diseases, especially fevers, when the strength is nearly exhausted, and death approaches, of which it is frequently the forerunner.

An intermitting pulse therefore seems to arise from an unequal influx of the nervous power into the heart, or from the decay and exhaustion of the nervous power, by which means the heart is not able to contract till it has been distended beyond its due pitch. Or, lastly, It may arise from diseases of the organ itself, or the neighbouring parts; from swellings, water, &c. pressing upon them, and impeding the action of the heart: which is indeed is a very dangerous disorder, and almost always mortal.

Many other variations of the pulse are enumerated by physicians, but most of them are uncertain, and not confirmed by experience. We shall therefore now consider the motion of the blood, which may be either too great, too small, or irregular.

A quick pulse, *cæteris paribus*, produces a more rapid circulation, because the sooner that the ventricle of the heart is emptied, the more quickly is the blood thrown into the arteries; and their actions must answer to this stronger stimulus. Hence exercise, heat, stimulants, plethora, every kind of irritation, passions of the mind, and fever, increase the circulation. The effect of this increase is a distention of the vessels, a stimulus applied to the whole body, an increase of heat, and often a debility. The secretion of sweat is increased while the other secretions are diminished, and the various functions of the body impeded; thirst comes on, the appetite is lost, the fat consumed, and a disposition to putrescency introduced. Sometimes the smaller vessels are burst; whence effusions of blood and hæmorrhages. But we are by no means to forget, that this violent motion of the blood, however hurtful it may seem, is among the best remedies made use of by nature in curing many diseases.

The motion of the blood is diminished, especially by debility, torpor, the want of irritation, or of exercise; the same thing happens to all the fluids, if there be any obstruction in the vessels, or any cause by which their return is hindered or rendered more difficult. Thus, from the very weight of the blood itself, if a person has stood long on his feet, the humours return more slowly from the inferior extremities. Any disease of the heart and arteries also, as an aneurism, contraction, ossification, must necessarily obstruct the circulation. The same thing happens from obstructions of the veins, or interrupted respiration, by which the passage of the blood through the lungs to the left side of the heart is impeded.

But, from whatever causes this diminution of the circulation takes place, the bad consequences are perceived chiefly in the veins, because in them the blood always moves more slowly than in the arteries. Hence varices, and congestions of blood, especially in those parts of the body where the veins are destitute of valves, and of consequence where the motion of the muscles cannot assist the circulation. Hence also arise dropsies from an impeded or languid motion of the blood; because the resistance of the veins being increased, the blood is received into them with the greater difficulty, and more of the thin humour is driven into the exhaling vessels, and by them deposited in such quantities as cannot be reabsorbed by the lymphatics. These diseases, as well as all others proceeding from defects of the circulation, are also more difficult of cure than others, because all the vital powers are weakened at the same time.

Another disorder of the circulation is where the blood is carried to one part of the body in too great quantity, by which means the other parts are deprived of their due proportion. This irregular distribution of the vital fluid frequently arises from a stimulus applied to the part itself, or to the brain, or at length acting on the mind, which, according to the laws of sympathy, produces a certain definite distribution of the

Disorders of Circulation.

the blood. It arises also not unfrequently from a spasm taking place in some other parts, which drives the blood out of its ordinary course.

In proportion to this irregularity of the circulation are the consequences; heat, swelling, redness, inflammation, rupture of vessels, hæmorrhages, effusions, destruction, corruption, and suppuration of the cellular texture and adjoining parts, &c. Even this evil, however, nature often converts into an excellent remedy; and physicians, following her steps, frequently attempt to direct the distribution of the blood in particular diseases, well knowing that a change in the distribution of the blood is frequently efficacious either for radically curing some diseases, or relieving their most urgent symptoms.

97 Palpitation.

Lastly, Some disorders in the motion of the heart itself, and those of no small consequence, remain yet to be taken notice of, namely, palpitation and syncope. A palpitation is a violent and irregular action of the heart, such as for the most part is perceived by the patient himself, and that not without a great deal of uneasiness and oppression at his breast; and it is also manifest to the by-standers, if they apply their hands, or look at his naked breast; the pulse of the arteries in the mean time being weak, unequal, and intermittent. This is a spasmodic disorder; and is induced by various causes affecting either the nervous system in general, or the heart in particular. Every disease of the organ itself, such as a constriction of its valves and blood-vessels, an ossification, enlargement, or polypus, hindering the free action of the heart, and evacuation of blood from it, are capable of exciting it to violent and unusual contractions. The same effect will also follow plethora, or too violent an impulse of the blood. The heart will likewise frequently palpitate from a violent excitement of the nervous system, especially where the constitution is endowed with a great deal of mobility. Hence palpitations arise from any affection of the mind, and in hysteric women. Palpitation may likewise arise from an affection of the stomach, occasioned by worms, a surfeit, flatus, or stimulation by various acrid substances. It frequently also accompanies the gout when repelled, or even when a fit is coming on. Sometimes it arises from debility, whatever may be the cause; frequently from any difficulty in breathing; and many of these causes may be joined at the same time, or some of them produce others.

Hence we may see why the evil is sometimes slight and of short continuance; at other times altogether incurable, and certainly mortal in a longer or shorter time; why it sometimes returns at intervals, often coming on and being increased by every kind of irritation and exercise, and sometimes relieved or totally removed by stimulants or exercise.

98 Syncope.

A syncope takes place when the action of the heart, and along with it that of the arteries, is suddenly and very much lessened; whence the animal powers, the senses, and voluntary motions, immediately cease. This may be produced by almost all the causes of palpitation; because whatever can disturb and disorder the motion of the heart, may also weaken or suspend it. The vitiated structure of the heart itself therefore, violent passions of the mind, whether of the depressing kind, or those which suddenly and vehemently excite, various kinds of nervous diseases, those of the stomach, every kind of debility and evacuation, especially a great loss of blood, excessive and unremitting labour, long watching, heat, pain, many kinds of poisons, &c. produce fainting.

Hence we see, that whatever weakens the motion of the blood through the brain tends to produce fainting; and, on the contrary, whatever tends to augment that motion, also tends to refresh, and to prevent the person from fainting. Hence also we see how the mere posture of the body may either bring on or keep off fainting, or remove it after it has already come on. We likewise see how this disorder may sometimes be of little consequence and easily removed; at others very dangerous, not only as a symptom, but even of itself, as sometimes terminating in death; and lastly, how it may be used as a remedy by a skilful physician, and artificially induced, either to free the patient from violent pain, or to stop an immoderate effusion of blood scarce to be restrained by any other method.

99 Buff-coloured c[rust] on the blood.

With regard to the disorders of the blood itself, the glutinous part of it, or, more properly, its fibrine separated from the red particles, produces that buff-coloured appearance often seen upon blood drawn from people afflicted with inflammatory disorders, and even sometimes when no such diseases are present. This crust indeed is nothing else than the fibrine of the blood taking longer time than usual to coagulate, by which means the red particles have an opportunity of falling to the bottom. This indicates no lentor, density, thickness, or tenacity of the blood, as was formerly thought; but rather its thinness, or at least a less tendency in it to coagulate. It arises for the most part from a violent agitation and conquassation of the blood within the body; and hence it accompanies many fevers, all inflammations, sometimes hæmorrhages, exanthemata, plethora, pain, and many irritations. It must, however, be allowed that in several of these diseases it is rendered highly probable at least, from experiments apparently accurate, that the quantity of the fibrine of the blood is really increased in the proportion which it bears to the other parts. This crust, however, is not always to be accounted morbid, as it often happens to the most healthy; and may even be produced or destroyed by the slightest causes while the blood is running from the vein, so that frequently we shall see a very thick and tenacious crust on the blood flowing into one cup, while that which runs into another has little or none at all. In general, however, the appearance of this crust shows, that the patient will bear blood-letting well, though those have been in a great mistake who have directed this operation to be repeated till no more crust appeared on the blood.

The coagulable part of the blood also frequently produces those masses called *polypi*, which sometimes take place during life, but more frequently after death, in the large vessels near the heart, or even in the cavities of that organ. Similar masses also are frequently formed in the uterus, and are called *moles*.

10[0] Pleth[ora].

The quantity of blood contained in a healthy body is very various, and difficult to be ascertained. Many diseases, however, may arise from its being either too scanty or too abundant. Too great a quantity of blood is produced by the use of rich, nourishing diet, strong drink, accompanied with a good digestion; from a lazy, sedentary life, or much sleep, especially in

Disorders of the Blood.

in those who have been formerly accustomed to much exercise; with many other causes of the same kind. It renders the person dull and languid, and sometimes almost totally oppresses him; nor are those organs destined for moving the blood sufficient for driving forward such a load. The pulse sinks; and sometimes a syncope, vertigo, or palpitation takes place. More frequently, however, the vessels are too much distended, and ready to be thrown into violent and irregular motions. Hence a disposition to fevers, inflammations, an unequal distribution of the blood, unusual congestions, rupture of the vessels, and hæmorrhages. Besides this, in consequence of the close connection between the sanguiferous and the nervous system, a fulness of blood produces a disposition to spasm and other diseases of that kind.

Hence we may understand why a plethora is sometimes accompanied with a weak and sometimes with a strong and hard pulse, why it is the cause as well as a part of so many distempers, why it is the effect of a high state of health, &c.

[1]01 [Defect] or Inanition.

The want of a due quantity of blood is no less pernicious than too great an abundance of it. It debilitates the person, and renders him unable to perform the proper duties of life; produces a languid circulation, syncope, spasms, and at last death itself. In a slighter degree of the disease the body is emaciated through want of nourishment, and its functions are vitiated in various ways. It may arise from want, bad food, or such as affords little nourishment: from bad digestion, or the chyle being hindered from passing into the blood: from fevers, or other diseases which exhaust the body and hinder nutrition: or lastly, from various evacuations, particularly of blood; and that the more especially if they are sudden, for in slow evacuations the vessels accommodate themselves surprisingly to the quantity left in them. Besides, if the body be slowly exhausted, the excretions are lessened by reason of the deficiency of the vital power; so that the unusual expence is easily compensated by the unusual retention. But if the evacuation happens to be very sudden and great, it may either prove mortal in a short time, or break the constitution to a degree beyond recovery.

[1]02 Morbid thinness of the blood.

By a great and long-continued deficiency of blood the quality of it also is impaired; because the thin part of it is easily and soon made up; but the glutinous, and red part, not so easily. Hence the blood becomes thin, pale, scarcely capable of coagulation, or of affording a proper support to the body. Too great thinness of the blood also proceeds from using much drink, especially of the aqueous kind, slender and unnutritious diet, a bad digestion in the stomach; from diseases of the lungs and those organs which elaborate the red part; or from suppression of the usual evacuations of thin humours, as sweat or urine, induced by cold, a fault of the secreting organs, or from putrescency. But along with this, other disorders of the blood concur.

A too thin and watery blood makes the face pale, the body weak and languid. The solid parts become flaccid from want of nourishment, and having too great a quantity of water in their composition. It brings on hydropic effusions of water in all parts of the body, by reason of the increased exhalation of that thin fluid which moistens all the inward parts; partly by reason of the vessels being relaxed beyond their usual pitch, and not making a proper resistance. Besides, in this case, the lymphatics are so far from absorbing more than usual, that, partaking likewise of the general debility, they are scarcely fitted for performing their proper offices.

Nature, however, has taken care, by the most simple means, to provide against so many and so great evils; for neither does the blood so easily become thin as some have imagined, nor when this quality takes place does it want a proper remedy. For almost instantly, if the person be otherwise in health, the excretions of watery matters are greatly augmented, and the whole mass of blood in a short time becomes as thick as formerly.

103 Morbid thickness of the blood.

The opposite to this, namely, too great a thickness of the blood, though often spoken of by physicians, is very rarely if ever observed; and those fevers and inflammations which have been thought to arise from thence, are now found to originate from other causes. The following would seem to be the law of the human constitution. As soon as the blood has attained the due degree of thickness, or gone in the least beyond it, the excretions are either suppressed or diminished, the body attracts more moisture from the air, the person is thirsty, and drinks as much as is necessary for diluting the blood. But if water be wanting, and the person cannot satisfy his thirst, then the blood is so far from being thickened, that by reason of a putrescency begun or augmented, it is much dissolved, becomes acrid, and is with difficulty contained in the vessels.

104 Acrimony of the blood.

The acrimony of the fluids has afforded a large field for declamation to speculative physicians, and upon this slender foundation many perplexed and intricate theories have been built. It is certain indeed, that the blood in a state of health has some small share of acrimony; and this acrimony, from certain causes, may be a little increased so as to produce various diseases of a dangerous nature. This we are assured of from the increase of motion in the heart and arteries, and the similar augmentation of the action of the secretory organs, when certain acrid substances are taken inwardly. The same thing also appears from the unusual acrimony of the secreted fluids in such cases, by which the vessels are sometimes greatly stimulated, and sometimes even quite eroded. Very many acrid substances, however, are daily taken into the stomach; so that these must either be corrected in the *primæ viæ*, or changed by digestion before they pass into the blood; or at least by dilution with much water, or being blunted by an admixture with gluten, oil, or different gases, they must deposit much of their acrimony, and at last be thrown out of the body as noxious substances. Thus a vast quantity of salts, acid, alkaline, and neutral, may pass through the body, without in the least affecting the health; though these salts, if taken in very large quantity, undiluted, or not thrown out of the body, will do much hurt.

Moreover, even while life continues, putrefaction is going on, and produces much of that substance called *animal* salt; for into this a great part of our food is converted, and passes off by urine. But if this putrescent disposition be too great, it will produce too large a quantity of animal salt; especially if much of any saline substance is otherwise thrown into the body without

Disorders of the Blood.

without proper dilution: and this kind of disease is well known to sailors who have been long at sea, without having an opportunity of getting fresh provisions.

For this spontaneous putrescency, nature has suggested a proper remedy, namely, fresh meat, especially of the vegetable and acescent kind, and such as is much impregnated with acid, which it may impart to the body. But where this kind of food is wanting, the putrefaction goes on apace, and a very great thinness and acrimony of the juices take place; especially if there be also a scarcity of urine, or the excretions which ought to carry the putrid matters out of the body languish, either from cold, sloth, torpor, depressing passions of the mind, or from the constitution being broken by diseases; or, lastly, from too great heat, which always favours putrefaction.

Besides, it would seem, that sometimes a disposition to putrefaction is much increased by the reception of a putrid ferment into the body; of which we have examples in some infectious fevers, where the contagion is very much assisted by heat, animal diet, certain kinds of salts, debility and nastiness.

Lastly, Any single part of the body may putrefy from various causes, as from inflammation, cold, &c. and thus may the whole body be infected; although for the most part the disease proves fatal before the corruption has spread over the whole body.

But when the mass of blood begins to putrefy greatly, it not only becomes very acrid, but thin, also, so that it either will not coagulate at all, or shows only a slight and very loose crassamentum. Nay, even the red globules are broken down and destroyed; in which case it necessarily follows, that the blood must become very acrid, as well on account of the evolution of the salt, as by reason of the rancid and putrid gluten, which stimulates, and frequently even erodes, the vessels; producing spots, first red, then livid and black, tumours, and ulcers scarce possible to be cured, without first removing the putrescent disposition of the humours. From the same causes proceed hæmorrhages from every part of the body, hardly to be restrained; a most intolerable fetor of the breath and all the excrements; the highest debility and laxity of the solids; the putrefaction acting as a poison to the nervous system, and at length bringing on death.

An acrimony of the acid kind never takes place in the human blood, nor in any of the humours secreted from it; though one of them, namely the milk, turns acid spontaneously in a very short time after it is drawn from the breast. Neither does an alkaline acrimony seem ever to take place in the blood. Putrescency indeed tends this way, and at last terminates in it; but scarcely while the person lives, though the nature of the urine, even while recent, seems to be but little distant from that of an alkali.

Many kinds of acrimony may exist in the blood from too liberal an use of spices, wine, spirits, &c. but of these we know nothing certain. We well know, however, that the body is often infected with various kinds of morbid acrimony, which bring on many and dangerous diseases, as the small-pox, measles, cancers, lues venerea, &c. of which the origin and manner of acting are very little understood, though the effects are abundantly evident. In most cases, nature has taken no less care to provide against the *acrimony* than against the too great *viscidity* of the blood. Sometimes an antidote is afforded, either by the excitement of thirst, that the acrid substance may be diluted with plenty of drink; or by increasing the evacuations, that it may be thrown out of the body; or lastly, by exciting various motions and actions of the vital powers, by which it may be either subdued, changed, rendered innocent, or expelled from the body by new and unwonted passages.

Disorders of Respiration.

105 Respiration.

With regard to respiration, it may be obstructed from various causes seated either in the lungs themselves or the surrounding parts. But from whatever cause this obstruction may arise, it undoubtedly produces all those diseases which proceed from an interrupted circulation. The lungs themselves also being at length compressed, and not suffered to dilate sufficiently, cannot throw off the vapour which arises from them; and hence they are frequently oppressed with moisture. At the same time they are irritated, so that a greater quantity of mucus, and that of a thicker kind than usual, is secreted; by which means the passages through which the air enters them are stopped up, till a violent cough at length throws off the load.

The respiration is also subjected to some other disorders, as a cough and sneezing, which, though at first sight they may seem very dangerous, are not destitute of use, and may even be reckoned among the most salutary attempts of nature to relieve the patient. Often, however, they are attended with danger, or very great uneasiness; namely, when they are either too violent or exerted in vain. At any rate, it is necessary for a physician to know the nature, causes, and effects of these, that he may be enabled to promote them when necessary, to moderate them when too violent, and to stop them when noxious or of no use.

10 Cough.

A cough is a violent, frequently involuntary, and sonorous exspiration, suddenly expelling the air with great force through the glottis somewhat contracted. The convulsion of the muscles serving for exspiration, gives a great force to the air, while the contraction of the glottis produces the sound. It is often long continued, being repeated at certain intervals, during each of which the inspiration is imperfect and obstructed by reason of the contraction of the glottis. It is excited by any kind of acrid substance, either chemically or mechanically applied to those passages through which the air enters. These are lined with a membrane so exceedingly delicate and impatient of stimulus, that it cannot even bear the touch of the mildest substance, such as a small drop of water, without throwing the muscles serving for exspiration into a violent convulsion; the glottis at the same time contracting by means of the sympathy between it and the neighbouring parts. Thus the air is thrown out with such violence, that it drives the irritating substance along with it; and thus a cough becomes not only useful, but absolutely necessary for the preservation of life, as being able to free the lungs from every kind of irritating substance or foulness, which might soon bring on a suffocation. Hence a cough is almost an inseparable companion of every inflammation of the lungs, as well as every difficulty in respiration; and even frequently accompanies the entrance of the purest air when the

trachea

Disorders of Respiration.

trachea and bronchiæ are excoriated, or become too sensible. Examples also are not wanting, where a violent and troublesome cough has arisen from an irritability of the nervous system, or even of some particular part, of the ear, for instance, the stomach and intestines, the liver by inflammation, &c.

Coughing may also be voluntarily excited, and may then be managed at pleasure. Even when involuntary, it may be moderated, or suppressed, by a contrary effort: though a violent fit of coughing cannot by any means be resisted. When it is once excited, the cough goes on till the irritating substance be expelled, or the sense of irritation abolished, or perhaps overcome by a more uneasy sensation than even the cough itself; after which the irritation again returning at a certain interval, the cough also returns. Hence we are taught a method of allaying and quieting this most troublesome malady, though frequently it is not in our power to remove the cause of it altogether.

A very violent cough is often dangerous: For by the retention of the breath, and the strong efforts made in coughing, a great quantity of blood is collected in the lungs, of which the vessels are distended, and frequently broken; and hence there sometimes happens a violent and even fatal hæmorrhage. More frequently, however, it is the cause of a slower, though equally fatal, disease. Nay, a frequent and troublesome cough, without any great hæmorrhage, or even without any hæmorrhage at all, may injure the lungs to such a degree, especially if they be of a more tender structure than usual, as to lay the foundation of a phthisis almost always incurable.

Again, by a long-continued and violent cough, the passage of the blood through the lungs being impeded, it must necessarily flow through the veins towards the head: hence redness and lividness in the countenance, hæmorrhages, palsies, apoplexies, and sometimes fatal convulsions. Lastly, by a violent cough the abdominal viscera are compressed with remarkable violence; and if any part happens to be weaker than usual, a hernia, prolapsus uteri, abortion, or similar accidents, may happen.

Even when the cough is more gentle, if it happens to be importunate and frequent, although we have nothing of this kind to fear, yet the patient is by no means free from danger; as he is thereby agitated, fatigued, has his constitution broken, is deprived of rest, has a fever brought upon him, his lungs are shaken and irritated, digestion and all the other functions are impeded, till at last he sinks under a complication of maladies.

107 Sneezing.

Sneezing is somewhat similar to cough, as consisting of a very full inspiration, to which succeeds a most violent exspiration, by which the air is driven out through the nostrils with immense violence, and sweeps the passage through them as it goes out. It is a convulsion much more violent than a cough, and is besides very difficult to be stopped when once a propensity to it has taken place. As a cough proceeds from an irritation of the glottis, trachea, bronchia, and lungs, so sneezing arises from an irritation of the membrane of the nostrils, but rarely from sympathy with any distant part. It is sometimes of service, as well as a cough; though it is also sometimes prejudicial, for the reasons which have been already assigned.

Disorders of Digestion.

The last affections of which we shall here speak, are those arising from a bad digestion, disordered motion of the intestines, and some of the principal secretions. The first of these are sometimes very troublesome, though seldom dangerous. The principal symptoms are oppression, anxiety, pain at the stomach; eructations, by reason of air extricated from the fermenting aliments, and irritating the stomach; nausea and vomiting, from the irritation and distention of the same organ; the belly sometimes too costive, and sometimes too loose; a defect of nourishment; a general debility; relaxation of the solid parts; too great thinness of the fluids; all the functions impeded; pain of the head; vertigo, syncope, asthma, palpitation; great sinking of the spirits, especially if the patient has been of a peculiar constitution; sometimes the gout, sometimes a dropsy, or a slow fever which may prove fatal. 108 Digestion.

109 Costiveness.

The motion of the intestines may be either too great or too little; and hence proceeds either costiveness or looseness. The former is frequently not to be accounted morbid; but, when it is, it may arise from the structure of the intestines being injured, or from their being shut up or obstructed by spasm or otherwise, or from a deficiency of those humours which moisten the intestines; or, it may arise from mere debility, from a palsy of the fibres, perhaps, or from a deficiency of the usual stimulus, of the bile, for instance, or from too dry or slender a diet.

The consequences of long-continued costiveness, are, first, an affection of the alimentary canal, and then of the whole body. The stomach is diseased, and does not digest the aliments properly; the whole body is left destitute of its usual stimulus; the blood is corrupted, perhaps from the resorption of the putrid matter into it. The circulation through the abdominal viscera is impeded; hence frequent and irregular congestions, varices of the veins, hæmorrhoids, &c. Nay, the intestines themselves being overloaded, distended and irritated by an heavy, acrid, and putrid load of aliment or other matters, are excited to new and unusual contractions, which, if they do not get the better of the obstruction, bring on tormina, colic, or an iliac passion, inflammation and gangrene, fatal in a very short time.

110 Looseness.

Looseness, or diarrhœa, is a malady extremely common; being sometimes a primary disease, and sometimes only a symptom or an effect of others. Sometimes it is a salutary effort of nature, such as the physician ought to imitate and bring on by art. It is also familiar to infants, and to people of a certain constitution; and to them costiveness is very prejudicial. It may arise, in the first place, from something taken into the body, or generated in the intestines; from a fermentation and corruption of the mass of aliments; from the bile being too abundant and acrid, or from blood or pus poured into the intestines; from the intestines themselves being eroded, or deprived of their natural mucus; from the humours being driven from the surface of the body towards the inward parts, as by cold, especially when applied to the feet; or from a general corruption of the whole body, as in the phthisis, hectic, or putrid fever, especially towards the end of these disorders. In fevers it is sometimes salutary, or even puts an end to the disease altogether, or at

Disorders of the Alimentary Canal.

at least renders it milder; more frequently, however, deriving its origin from putrescency, it is of no service, but rather exhausts the strength of the patient. A diarrhœa likewise, almost incurable, and often fatal in a short time, frequently arises after the operation for the fistula in ano. Some have their intestines so extremely weak and moveable, that from the slightest cause, such as catching cold, any violent commotion of the mind, &c. they are subject to a violent diarrhœa. Lastly, whatever be its origin, if it has continued for a long time, the viscera are rendered so weak and irritable, that the disease, though often removed, still returns from the slightest causes, and even such as are not easily discovered.

A diarrhœa proves very pernicious, by hindering digestion and the nourishment of the body; for the stomach is commonly affected, and the aliments pass through the intestines so quickly, that they can neither be properly digested, nor are the lacteals able to absorb the chyle from them as they go along. Such a violent evacuation is also hurtful by exhausting the body, and carrying off a great quantity of the nutritious matter from the blood. Neither indeed, is it only the alimentary mass which is thrown out sooner than it ought to be; but at the same time, a great quantity of the fluids secreted in the intestines, so that the whole body quickly partakes of the debility.

Sometimes a violent and long-continued diarrhœa rises to such a height, that the aliment is discharged with little or no alteration. Sometimes also, though rarely, from a similar cause, or from the obstruction of the mesenteric glands, and its other passages into the blood, the chyle itself is thrown out like milk along with the excrements; and this disease is called
111 the *fluxus cœliacus*.

Dysentery.

A dysentery is attended with very severe gripes in the belly, a frequent desire of going to stool, and vain efforts, when nothing is excreted besides the mucus of the intestines mixed with a little blood; it is also accompanied with excessive debility, and frequently with putrescency and fever. It is thought to arise from the constriction of some part of the intestines, of the colon especially: by which means the bowels, though ever so much irritated, can pass nothing; neither can the disease be removed, until the belly has been well
112 purged by proper medicines.

Tenesmus.

A tenesmus is a frequent and insatiable propensity to stool, without being able to pass any thing, notwithstanding the most violent efforts. It may be occasioned by any kind of irritation, either of the rectum itself or of the neighbouring parts, by acrid substances taken into the body; by some of the stronger purges, especially aloes, a substance very difficult of solution, which will pass even to the rectum with very little alteration; by a violent and obstinate diarrhœa, dysentery, hæmorrhoids, worms, fistula, calculus, ulcer in the bladder, urethra, &c. It is often very pernicious, both from the excessive uneasiness it occasions to the patient, and from its exhausting his strength, by the frequent and vain efforts bringing on a prolapsus ani, and communicating the violent irritation to the neigh-
113 bouring parts, as the bladder, &c.

Nausea and vomiting.

A nausea and vomiting are disorders very common, and owing to almost innumerable causes; not only to affections of the stomach itself, but also to affections and irritations of the remotest parts of the body which may act upon the stomach by sympathy. Every irritation and distention of that viscus therefore, a load of crude aliment, an obstruction about the pylorus, all acrid substances taken into it, diseases of the liver, intestines, kidneys, uterus, the head, the feet, the skin, or indeed the whole body, inflammation, the stone, king's evil, schirrus, apoplexy, compression of the brain, fracture of the skull, vertigo, syncope, violent pain, the gout, especially when repelled, fevers, passions of the mind, disagreeable imaginations or discourses, frequently induce nausea and vomiting.

These affections are often serviceable by freeing the stomach from something with which it was overloaded; promoting spitting in some cases where the lungs are overcharged with mucus, blood, pus, or water; producing sweat, and a free and proper distribution of blood to the surface of the body; partly, perhaps, by the great straining which accompanies vomiting, but rather by that wonderful sympathy which takes place between the stomach and skin: and hence, in many diseases, vomiting is a most excellent remedy. It is however in some cases hurtful, if too violent or too frequently repeated, partly by debilitating and making the stomach more easily moved; and partly by fatiguing the patient with violent strainings, which occasion hernias, abortions, &c. 11

Iliac passion.

Sometimes we find the motion of the intestines totally inverted, from the anus to the mouth; a most dangerous distemper, which hath obtained the name of the *iliac passion*. It most frequently arises from some obstruction in the alimentary canal hindering the descent of the excrements, as schirrus, spasm, inflammation, &c.: though the most perfect iliac passion takes place without any obstruction, so that clysters will be vomited; and even after this has continued for several days, the patients have at length recovered.

A slighter degree of the iliac passion, namely the inversion of the peristaltic motion of the duodenum, always takes place in long-continued and violent vomiting, as in sea-sickness, or when a person has taken too large a dose of an emetic; by which means a vast quantity of bile frequently ascends into the stomach, and is discharged by vomiting. 1

Chol

An excessive vomiting with looseness is called a *cholera*, when the matter discharged has a bilious appearance. It arises from a very great irritation of the alimentary canal without any obstruction; and is for the most part occasioned by too great a quantity, or from an acrimony of the bile, from whence it takes its name. It may originate from several causes, as too strong a dose of an emetic and cathartic medicine, eating too great a quantity of summer-fruits, &c. and is a very violent malady, often killing the patient in a few hours, unless proper remedies be applied in time.

Obstructed perspiration.

From a suppression of any of the secretions, or a disorder of any of the secretory organs, many mischiefs may arise. A diminution of perspiration produces plethora, lassitude, languor, depression of mind, bad digestion, loss of appetite, and even a general corruption of the humours from the retention of such a quantity of putrescent matter.—The more suddenly the diminution or suppression of the perspiration takes place, Di ders of ere- t i. place, the sooner the mischief is produced, and the greater it is; not only by retaining the matter which ought to be thrown out, but by repelling the humours from the surface of the body, and directing them to other parts; whence fevers, inflammations, congestions of the blood, &c. frequently take place.

This suppression of perspiration may arise from many different causes; as from cold suddenly applied to the body when very hot: sometimes from very violent passions of the mind; or from spasmodic diseases, as the hysterics, &c. It may be suppressed also by that kind of constriction of the vessels of the skin which is produced by various kinds of fevers, the nature of which has hitherto been but little known.

7 Ex sive per a- tion Excessive perspiration or sweating is injurious by debilitating the body, relaxing the skin, and exposing the patient to all the evils which arise from catching cold. It may even be carried to such a height as to produce fainting and death; though it must be owned that we cannot easily bring examples of people having, from this cause, their blood inspissated, corrupted, or being thence made liable to inflammations and fevers.

8 Su ession of u e. A suppression of urine is still more dangerous than that of perspiration, and unless relieved in a short time will certainly prove fatal. This disorder, which is called *ischuria*, may arise from various diseases of the kidneys, ureters, bladder, urethra, &c. Thus any obstruction or irritation of one or other of the kidneys or ureters, by a stone, gravel, mucus, blood, inflammations, spasm, suppuration, schirrus, swellings of the neighbouring parts, &c. may either prevent the urine from being secreted, or may give rise to a scanty or depraved secretion, or, finally, may obstruct its passage into the bladder after it is secreted.

The urine also, after it has entered the bladder, is there frequently suppressed, by reason of various disorders to which that organ is liable, as an irritation or inflammation, spasm, acrid substances injected, or sympathy with the neighbouring parts; or by reason of the texture of the bladder itself being destroyed, or from a palsy, schirrus, ulcer, &c. in the bladder. Or, lastly, the urine may be retained in the bladder from a general stupor, as from a disease of the brain, which happens in some fevers, when the patient is neither sensible of the usual stimulus, nor even of one much greater, so that the fibres can scarcely be excited to contraction by any means whatever. This, in fevers, is always a bad sign, and sometimes even proves fatal.

A suppression of urine for any length of time produces an immense distention of the bladder, oppression, uneasiness, and pain, not only of the part itself, but of the surrounding ones, and even of the whole body; a spasm, or insuperable constriction of the sphincter; an inflammation, gangrene, or laceration of the bladder itself; a violent irritation of the whole habit; then a nausea, vomiting, vertigo, general stupor, and an impregnation of the whole mass of blood with a humour of an urinous nature, which at last being poured out into various cavities of the body, especially of the head, soon brings on a deep sleep, convulsions, and death.

9 Dy a. From the same causes, but acting with less force, proceeds that disease called a *dysuria*, when the urine passes with difficulty and pain, and is frequently red, black, bloody, purulent, mucous, and sandy; the reason of all which appearances is very much unknown.—The most frequent complaint, however, in making water, is where the patient has a continual and violent desire of passing his urine, while at the same time only two or three drops can be passed at once, and that not without some pain. This may be occasioned even in healthy people, by some acrid substance taken into the stomach; and is very common to old people, who are generally subject to disorders of the kidneys and bladder. It arises also frequently from a stone irritating the bladder, or from an inflammation of it, or of its being deprived of its mucus, or this last being somehow or other corrupted; or lastly, from certain diseases, or some particular state of the neighbouring parts, as of the uterus, vagina, urethra, prostate gland, &c. Disorders of Secretion. 120 Strangury.

Akin to the strangury is an incontinence of urine, when the patient's water either comes away against his will, or altogether without his knowledge. This disorder may arise from debility, palsy, an ulcer or wound, or any long-continued and violent irritation of the bladder, especially of its sphincter, as from a stone, a general palsy, or in females difficult labour, injuring the neighbouring parts.—This symptom occurs in a great number of diseases, especially in the hydrocephalus.—Sometimes the urine is expelled with violence, either by reason of universal spasms, or by violent contractions of the muscles of respiration, as in sneezing, laughter, &c. 121 Incontinence of urine.

Among the disorders incident to the urine we may reckon the production of calculi, which frequently bring on the most excruciating and dangerous diseases.—The urine, besides the water and salts, contains no small share of the glutinous part of the blood already somewhat corrupted, and still inclined to farther corruption. Hence the urine even of the most healthy people deposits a sediment after it has stood for some time; and though none of this sediment be formed in a healthy body, yet if the smallest particle of foreign matter be introduced into the bladder, a crust soon gathers round it, and it is sure to become the basis of a concretion, which by degrees grows to a very great size. It is not unlikely, also, that some unknown faults of the fluids may contribute to the production of those calculi, as the stone is well known to be an hereditary disease, and to be born with the patient. Calculous persons also are commonly subject to complaints of the stomach, especially to an acidity of it; and many have received no little relief from alkalescent or alkaline medicines.—From the same causes may calculi be formed in the kidneys; from which proceed a horrid train of symptoms described in the subsequent part of this treatise. 122 Urinary calculi.

It is now found, by accurate experiments of the most able chemists, that urinary calculi do not, as was once supposed, consist almost entirely of an earthy matter. Their principal constituent is a peculiar acid, approaching more nearly to the phosphoric found in the bones than to any other. But the acid of calculus being in some respects peculiar in its nature, has among modern chemists obtained a peculiar name, and been distinguished by the appellation of the *lithic* or *uric acid*. It is highly probable that this acid present in the circulating mass, is precipitated and disengaged by the

Disorder of the Glands. introduction of other acids, and thus thrown off in greater quantities by the kidneys. Thus, then, we can understand the influence of acids as tending to the generation of calculus, and of alkalies as tending to prevent it.

123 Schirrus. The last disorder here to be taken notice of is a disorder of the glands themselves, owing to some kind of obstruction, and is one of the most dreadful diseases incident to human nature. Hence happens a great swelling and surprising hardness, not only without pain, but sometimes even with a diminution of sensation in the part affected; and when the gland is thus affected, it is called a *schirrus*. Sometimes it remains in this state for a long time; but sooner or later produces the most excruciating torment. By degrees it is infected with a slow and malignant suppuration, degenerating into an horrid ulcer, consuming not only the part itself, but eating away the neighbouring ones, and corrupting the whole body with the most acrid and incurable poison. This disease is called a *cancer*, of which the causes are very little known.

Versatility of the Human Constitution. Of the organs in both sexes concerned in the function of generation, and of that function as far as we yet know any thing respecting it, an account has already been given in ANATOMY; and after what has been said of the different functions, and of the morbid affections, to which these are subjected, we may conclude our remarks on the theory of medicine, with mentioning the remarkable versatility of the human constitution; which more than that of any other animal, is capable of accommodating itself to every climate and to all kinds of diet. Hence we may conclude, that a large proportion of the diseases to which we are subjected are produced by ourselves.

PRACTICE of MEDICINE, or an Account of the principal Diseases to which the Human Body is subjected.

124 General arrangement of diseases. WE have already defined medicine to be the art of preventing, curing, and alleviating, those diseases to which mankind are subjected. While these affections, however, are in number almost infinite, each in its progress is subjected to almost endless varieties from differences in climate, constitution, treatment, and a variety of other particulars. Hence we may readily explain both the difficulty of distinguishing morbid affections from each other in actual practice, and the diversity of names which have been affixed to them in the writings of ancient physicians. It may readily be supposed, that in this, as well as other subjects, there has been a gradual improvement from the progressive labours of industrious and ingenious men. And although much yet remains to be done in the proper arrangement and distinction of diseases, or what has been called *methodical nosology*, yet there cannot be a doubt, that during the course of the 18th century, this subject has received very great improvements. For these, we are, in the first place, highly indebted to the labours of Franciscus Boissier de Sauvages, an eminent professor of medicine at Montpelier, who, following out an idea suggested by the sagacious Dr Sydenham of England, first successfully attempted to arrange diseases, as botanists had done plants, into classes, orders, genera, and species. Since the publication of the *Nosologia Methodica* of Sauvages, this subject has been successfully cultivated by several ingenious men, particularly by Sir Charles Linnæus of Upsal, to whose genius for arrangement every branch of natural history, but botany in particular, has been so highly indebted; by Rudolphus Augustus Vogel, an eminent professor at Gottingen; and by John Baptist Sagar, a distinguished physician at Iglaw in Moravia: But of all the systems of arrangement yet presented to the medical world, that published by the late illustrious Dr William Cullen of Edinburgh, may justly be considered as the best. In treating, therefore, of the principal diseases to which the human body is subjected, we shall follow his plan, endeavouring to deliver the best established observations respecting the history, theory, and practice of each. In treating of particular genera of disease, although we follow the arrangement of Dr Cullen, yet for the satisfaction of the reader, we shall often point out the classes to which the same affection is referred by the other eminent writers whom we have mentioned. And on this account, it may not be improper briefly to enumerate the general classes to which each of them have referred the affections of the human body.

The Classes of Sauvages are,

1. Vitia.	6. Debilitates.
2. Febres.	7. Dolores.
3. Phlegmasiæ.	8. Vesaniæ.
4. Spasmi.	9. Fluxus.
5. Anhelationes.	10. Cachexiæ.

The Classes of Linnæus are,

1. Exanthematici.	7. Motorii.
2. Critici.	8. Suppressorii.
3. Phlogistici.	9. Evacuatorii.
4. Dolorosi.	10. Deformes.
5. Mentales.	11. Vitia.
6. Quietales.	

The Classes of Vogel are,

1. Febres.	7. Hyperæstheses.
2. Profluvia.	8. Cachexiæ.
3. Epischeses.	9. Paranoiæ.
4. Dolores.	10. Vitia.
5. Spasmi.	11. Deformitates.
6. Adynamiæ.	

The Classes of Sagar are,

1. Vitia.	8. Anhelationes.
2. Palgæ.	9. Debilitates.
3. Cachexiæ.	10. Exanthemata.
4. Dolores.	11. Phlegmasiæ.
5. Fluxus.	12. Febres.
6. Suppressiones.	13. Vesauiæ.
7. Spasmi.	

Besides

General Arrangement of Diseases.

Besides these, two other systems have been presented to the public, which may be considered as deserving attention; those, viz. of the late learned Dr M'Bride of Dublin, and of the late ingenious Dr Darwin.

The Classes and Orders of M'Bride.

Class. I. *Universal Diseases.*

Or. 1. Fevers.
2. Inflammations.
3. Fluxes.
4. Painful diseases.
5. Spasmodic diseases.
6. Weaknesses or privation.
7. Asthmatic disorders.
8. Mental disorders.

Class II. *Local Diseases.*

Or. 1. Of the internal senses.
2. Of the external senses.
3. Of the appetites.
4. Of the secretions and excretions.
5. Impeding different actions.
6. Of the external habit.
7. Dislocations.
8. Solutions of continuity.

Class III. *Sexual Diseases.*

Or. 1. General proper to men.
2. Local proper to men.
3. General proper to women.
4. Local proper to women.

Class IV. *Infantile Diseases.*

Or. 1. General.
2. Local.

The Classes and Orders of Darwin.

Class I. *Diseases of Irritation.*

Or. 1. Increased irritation.
2. Decreased irritation.
3. Retrograde irritative motions.

Class II. *Diseases of Sensation.*

Or. 1. Increased sensation.
2. Decreased sensation.
3. Retrograde sensitive motions.

Class III. *Diseases of Volition.*

Or. 1. Increased volition.
2. Decreased volition.

Class IV. *Diseases of Association.*

Or. 1. Increased associated motions.
2. Decreased associated motions.
3. Retrograde associated motions.

After this short view of different classifications, we shall next present to our readers a more particular account of the arrangement of Dr Cullen; which, although it can by no means be represented as free from errors or imperfections, is yet in many respects the best that has hitherto been published.

Cullen's *Arrangement.*

Class I. PYREXIÆ. A frequent pulse coming on after a horror; considerable heat; many of the functions injured; the strength of the limbs especially diminished.

Order I. Febres. Pyrexia without any primary local affection, following languor, lassitude, and other symptoms of debility.

Sect. I. *Intermittentes.* Fevers arising from the miasma of marshes; with an apyrexia, or at least a very evident remission; but the disease returns regularly, and for the most part with a horror or trembling.

Genus I. Tertiana. Similar paroxysms after an interval of about 48 hours, coming on most commonly at mid-day. A tertian hath either;

I. An apyrexia interposed.

1. Varying in the duration of the paroxysms.

A, The tertian whose paroxysms are not extended beyond 12 hours.

B, The tertian with paroxysms extended beyond 12 hours.

2. Varying in the return of paroxysms.

C, The tertian returning every day with unequal paroxysms alternately similar to one another.

D, The tertian returning every third day with two paroxysms on the same day.

E, The tertian returning every day, with two paroxysms on every third day, and only one on the intermediate ones.

F, The tertian returning every day, with an evident remission interposed between the odd and the even days, but a less remarkable one between the even and the odd days.

3. Varying in its symptoms.

G, The tertian accompanied with a disposition to sleep.

H, Accompanied with spasms and convulsive motions.

I, Accompanied with an efflorescence on the skin.

K, With phlegmasia.

4. Varying in being complicated with other diseases.

5. Varying as to its origin.

II. With the interposition only of a remission between the paroxysms.

Genus II. Quartana. Similar paroxysms, with an interval of about 72 hours, coming on in the afternoon.

I, With the interposition of an apyrexia.

1. Varying in the type.

A, The quartan with single paroxysms, returning every fourth day, none on the other days.

B, With two paroxysms every fourth day, and none on the other days.

C, With three paroxysms every fourth day, and none on the intermediate days.

D, Of the four days having only the third free from fever, with similar paroxysms every fourth day.

E, The quartan coming on every day, with similar paroxysms every fourth day.

2. Varying in its symptoms.

3. Varying in being complicated with other diseases.

II. With a remission only between the paroxysms.

Genus III. Quotidiana. Similar paroxysms with an

General Arrangement of Diseases.

an interval of about 24 hours, coming on commonly in the morning.

I. With the interposition of an apyrexia.

1. Varies in being solitary.

A, Universal.

B, Partial.

2. Complicated with other diseases.

II. With a remission only between the paroxsyms.

Sect. II. *Continuæ*. Fevers without evident intermission, and not occasioned by marsh miasmata; but attended with exacerbations and remissions, though not always very remarkable.

Genus IV. Synocha. Great heat; a frequent, strong, and hard pulse; high-coloured urine; the functions of the sensorium a little disturbed.

Genus V. Typhus. A contagious disease; the heat not much above the natural; the pulse small, weak, and for the most part frequent; the urine little changed; the functions of the sensorium very much disturbed, and the strength greatly diminished.

The species are,

I. Typhus *petechialis*. Typhus for the most part with petechiæ.

Varying in degree. 1. Mild typhus. 2. Malignant typhus.

II. Typhus *icterodes*. Typhus with a yellowness of the skin.

Genus VI. Synochus. A contagious disease. A fever compounded of synocha and typhus; in the beginning a synocha, but towards the end a typhus.

Order II. PHLEGMASIÆ. A synocha fever, with inflammation or topical pain, the internal function of the parts being at the same time injured; the blood drawn and concreted exhibiting a white coriaceous surface.

Genus VII. Phlogosis. Pyrexia; redness, heat, and painful tension, of some external part.

The species are,

I. Phlogosis (*phlegmone*) of a vivid red colour; a swelling well defined, for the most part elevated to a point, and frequently degenerating into an abscess, with a beating or throbbing pain.

The variations are, 1. In the form. 2. In the situation.

II. Phlogosis (*erythema*) of a reddish colour, vanishing by pressure; of an unequal and creeping circumference, with scarce any swelling; ending in the scaling off of the cuticle, in pustules, or blisters.

The variations are, 1. In the degree of violence. 2. In the remote cause. 3. In being complicated with other diseases.

The consequences of a phlogosis are, an imposthume, gangrene, sphacelus.

Genus VIII. Ophthalmia. A redness and pain of the eye, with an inability to bear the light; for the most part with an effusion of tears.

The species and varieties of the ophthalmia are,

I. Idiopathic.

1. Ophthalmia (*membranarum*), in the tunica adnata, and the membranes lying under it, or the coats of the eye.

A, Varying in the degree of the external inflammation.

B, In the internal coats affected.

2. Ophthalmia (*tarsi*), of the eye-lids, with swelling, erosion, and glutinous exudation.

II. Symptomatic.

1. From a disease of the eye itself.

2. From diseases of other parts, or of the whole body.

Genus IX. Phrenitis. Violent pyrexia; pain of the head; redness of the face and eyes; inability to endure the light or any noise; watchfulness; a furious delirium, or typhomania.

I. Idiopathic.

II. Symptomatic.

Genus X. Cynanche. Pyrexia sometimes inclining to a typhus; difficulty of swallowing and breathing; with a sensation of narrowness in the fauces.

The species are,

I. Cynanche (*tonsillaris*) affecting the mucous membrane of the fauces, but especially the tonsils, with redness and swelling, accompanied with a synocha.

II. Cynanche (*maligna*) affecting the tonsils, and mucous membrane of the fauces with swelling, redness, and mucous crusts of a whitish or ash-colour, creeping, and covering ulcers; with a typhous fever and exanthemata.

III. Cynanche (*trachealis*) attended with difficult respiration, noisy and hoarse inspiration, loud cough, without any apparent tumour in the fauces, somewhat difficult deglutition, and a synocha.

IV. Cynanche (*pharyngæa*) attended with redness in the bottom of the fauces, very difficult and painful deglutition, respiration sufficiently free, and a synocha.

V. Cynanche (*parotidæa*) when great swelling in the parotids and maxillary glands appearing on the outside; the respiration and deglutition but little injured; a synocha, for the most part mild.

Diseases of this genus are symptomatic, either from external or internal causes.

Genus XI. Pneumonia. Pyrexia, with a pain in some part of the thorax, difficult respiration, and cough. The species are,

I. Peripneumony, with a pulse not always hard, but sometimes soft; an obtuse pain of the breast; the respiration always difficult; sometimes the patient cannot breathe unless in an upright posture; the face swelled, and of a livid colour; the cough for the most part moist, frequently bloody.

1. Simple idiopathic peripneumonics.

Varying in degree.

2. Idiopathic peripneumonies complicated with fever.

3. Symptomatic peripneumonies.

II. Pleurisy, with a hard pulse; for the most part attended with a pungent pain of one side, augmented chiefly during the time of inspiration; an uneasiness when lying on the side; a most painful cough, dry in the beginning of the disease, afterwards moist, and frequently bloody.

1. Simple idiopathic pleurisies.

2. Pleurisies, complicated, (1.) With fever. (2.) With catarrh.

3. Symptomatic pleurisies.

4. False pleurisies.

The consequences of pleurisy are a vomica or empyema.

Genus XII. Carditis. Pyrexia; pain about the heart; anxiety; difficulty of breathing; cough; unequal pulse; palpitation of the heart, and fainting.

I. Idiopathic.

II. Symptomatic.

Genus XIII. Peritonitis. Pyrexia; pain of the belly, exasperated by an upright posture, without the proper signs of other abdominal phlegmasiæ.

I. Peritonitis (*propria*), situated in the peritonæum, properly so called, surrounding the inside of the abdomen.

II. Peritonitis (*omentalis*), in the peritonæum extended through the omentum.

III. Peritonitis (*mesenterica*), in the peritonæum spread through the mesentery.

Genus XIV. Gastritis. Pyrexia inclining to a typhus; anxiety; pain and heat of the epigastrium, augmented when any thing is taken into the stomach; an inclination to vomit, and an immediate rejection of every thing swallowed; an hiccough.

I. Idiopathic.

1. From external causes.

A, Gastritis (*phlegmonodæa*), attended with acute pain and violent pyrexia.

2. From external causes.

B, Gastritis (*erysipelatosa*), with a less violent fever and pain: an erysipelatous redness appearing on the fauces.

II. Symptomatic.

Genus XV. Enteritis. Pyrexia of a typhous nature; pungent pain of the belly, stretching and twisting about the navel; vomiting; the belly obstinately bound.

I. Idiopathic.

1. Enteritis (*phlegmonodæa*), with acute pain, violent fever, vomiting, and constipation of the belly.

2. Enteritis (*erysipelatosa*), with less acute fever and pain, without vomiting; but accompanied with a diarrhœa.

II. Symptomatic.

Genus XVI. Hepatitis. Pyrexia; tension and pain of the right hypochondrium; sometimes pungent like that of a pleurisy, but more frequently obtuse; a pain reaching to the clavicle and top of the right shoulder; a difficulty of lying on the left side; dyspnœa; dry cough, vomiting, and hiccough.

Genus XVII. Splenitis. Pyrexia; tension, heat, and swelling of the left hypochondrium, the pain increasing by pressure; without the signs of nephritis.

Genus XVIII. Nephritis. Pyrexia; pain in the region of the kidney, often following the course of the ureter: frequent discharge of urine, either thin and colourless, or very red; vomiting; stupor of the thigh; with a retraction or pain of the testicle of the same side. The species are,

I. Idiopathic. Spontaneous.

II. Symptomatic.

Genus XIX. Cystitis. Pyrexia; pain and swelling of the hypogastrium: frequent and painful discharge of urine, or ischuria; and tenesmus. The species are,

I. Those arising from internal causes.

II. Those from external causes.

Genus XX. Hysteritis. Pyrexia; heat, tension, swelling, and pain of the hypogastrium; the os uteri painful when touched; vomiting.

Genus XXI. Rheumatismus. A disease arising from an external and frequently very evident cause; pyrexia; pain about the joints, frequently following the course of the muscles; infesting the knees and other large joints rather than those of the feet or hands; increased by external heat.

The species are either idiopathic or symptomatic. The former varies in situation.

A, In the muscles of the loins.

B, In the muscles of the coxendix.

C, In the muscles of the breast.

Genus XXII. Odontalgia; a rheumatism of the jaws from a caries of the teeth.

Genus XXIII. Podagra. An hereditary disease, arising without any evident external cause, but for the most part preceded by an unusual affection of the stomach; pyrexia; pain of a joint for the most part of the great toe of the foot, at least infesting chiefly the wrists and ankles; returning by intervals; and often alternated with affections of the stomach and other internal parts.

I. Podagra (*regularis*), with a pretty violent inflammation of the joints remaining for some days, and by degrees going off with swelling, itching, and desquamation of the affected part.

II. Podagra (*atonica*), with an atony of the stomach, or some other internal part; and either without the usual inflammation of the joints, or only with slight and wandering pains; and frequently alternated with dyspepsia, or other symptoms of atony.

III. Podagra (*retrograda*), with the inflammation of the joints suddenly disappearing, and an atony of the stomach and other parts immediately following.

IV. Podagra (*aberrans*), with the inflammation of an internal part either preceding or not, and suddenly disappearing.

Genus XXIV. Arthropuosis. Deep, obtuse, and long-continued pains of the joints or muscular parts, frequently following contusions; with either no swelling, or a moderate and diffused one; no phlogosis; pyrexia, at first gentle, afterwards hectic, and at length an imposthume.

Order III. Exanthemata. Contagious diseases; affecting a person only once in his life; beginning with fever; after a certain time appear phlogoses, for the most part small and in considerable number, and dispersed over the skin.

Genus XXV. Erysipelas. A synocha of two or three days, for the most part attended with drowsiness, often with a delirium. In some parts of the skin, most frequently the face, appears a phlogosis. The species are,

I. Erysipelas (*vesiculosum*), with erythema, redness creeping, occupying a large space, and in some parts ending in large blisters.

II. Erysipelas (*phlyctænodes*), with an erythema formed of a number of papulæ, chiefly occupying the trunk of the body, ending in phlyctenæ or small blisters.

The disease is also symptomatic.

Genus XXVI. Pestis. An exceedingly contagious typhus, with the highest debility. On an uncertain day of the disease buboes and carbuncles break forth. It is various in degree, but the species are uncertain.

Genus

General Arrangement of Diseases.

Genus XXVII. Variola; a contagious synocha, with vomiting, and pain on pressing the epigastrium. On the third day begins, and on the fifth is finished, the eruption of inflammatory pustules, which suppurate in the space of eight days, and at last go off in crusts; frequently leaving depressed cicatrices or pockpits in the skin. The species are,

I. Variola (*discreta*), with few distinct, turpid pustules, having circular bases; the fever ceasing immediately after the eruption.

II. Variola (*confluens*), with numerous, confluent, irregularly shaped pustules, flaccid and little elevated; the fever remaining after the eruption.

Genus XXVIII. Varicella. Synocha; papulæ breaking out after a short fever, similar to those of the small-pox, but hardly ever coming to suppuration; after a few days going off in small scales, without leaving any mark.

Genus XXIX. Rubeola. A contagious synocha, with sneezing, epiphora, and dry hoarse cough. On the fourth day, or a little later, break forth small, clustered, and scarcely elevated papulæ; after three days going off in very small branny scales.

I. Rubeola (*vulgaris*), with very small confluent corymbose papulæ, scarcely rising above the skin.

Varying,

1. In the symptoms being more severe, and the course of the disease less regular.

2. In being accompanied with a cynanche.

3. With a putrid diathesis.

II. Rubeola (*variolodes*), with distinct papulæ, raised above the skin.

Genus XXX. Miliaria. Synochus with anxiety, frequent sighing, unctuous sweat, and a sense of pricking as of pin points in the skin. On an uncertain day of the disease, break out red, small, distinct papulæ, spread over the whole body as well as the face; the apices of which, after one or two days, become very small white pustules, remaining for a short time.

Genus XXXI. Scarlatina. A contagious synocha. On the fourth day of the disease the face swells a little; at the same time an universal redness occupies the skin in large spots, at length running together; after three days going off in branny scales; frequently succeeded by an anasarca. The species are,

I. Scarlatina (*simplex*), not accompanied with cynanche.

II. Scarlatina (*cynanchica*), with an ulcerous cynanche.

Genus XXXII. Urticaria. A quotidian fever. On the second day of the disease, red spots resembling the stinging of nettles, almost vanishing during the day, but returning during the evening with the fever, and after a few days going off altogether in very small scales.

Genus XXXIII. Pemphigus. A contagious typhus. On the first, second, or third day of the disease, blisters break out in several parts of the body, of the bigness of a bean, remaining for many days, and at last pouring out a thin ichor.

Genus XXXIV. Aphtha. Synochus; the tongue somewhat swelled and of a livid colour, as well as the fauces; eschars first appearing in the fauces, but at length occupying the whole internal parts of the mouth, of a white colour, sometimes distinct, often running together, quickly growing again when taken off; and remaining for an uncertain time.

The species are, 1. Idiopathic. 2. Symptomatic.

Order IV. Hæmorrhagiæ. Pyrexia, with a discharge of blood, without any external violence: the blood drawn from a vein hath the same appearance as in phlegmasiæ.

Genus XXXV. Epistaxis. Pain or weight of the head, redness of the face; a discharge of blood from the nose.

I. Idiopathic.

Varying according to the time of life.

1. Epistaxis of young people, with symptoms of an arterial plethora.

2. Epistaxis of old people, with symptoms of a venous plethora.

II. Symptomatic.

1. From internal causes.

2. From external causes.

Genus XXXVI. Hæmoptysis. Redness of the cheeks; a sensation of uneasiness, or pain, and sometimes of heat in the breast; difficulty of breathing; tickling of the fauces; either a severe or less violent cough, bringing up florid and frequently frothy blood.

The idiopathic species are,

1. Hæmoptysis (*plethorica*), without any external violence, and without being preceded by any cough or suppression of any customary evacuation.

2. Hæmoptysis (*violenta*), from external violence applied.

3. Hæmoptysis (*phthisica*), after a long-continued cough, with a leanness and debility.

4. Hæmoptysis (*calculosa*), in which some calculous molecules, for the most part of a calcareous nature, are thrown up.

5. Hæmoptysis (*vicaria*), after the suppression of a customary evacuation.

Besides these, there are a number of symptomatic species mentioned by different authors. The consequence of an hæmoptysis is, a

Phthisis. A wasting and debility of the body, with a cough, hectic fever, and for the most part a purulent expectoration. The species are,

I. An incipient phthisis, without any expectoration of pus.

II. A confirmed phthisis, with an expectoration of pus.

Both species vary, 1. As to their remote cause. 2. As to the origin of the purulent matter.

Genus XXXVII. Hæmorrhois. Weight and pain of the head; vertigo; pain of the loins; pain of the anus; livid painful tubercles, from which for the most part blood flows out; which sometimes also drops out of the anus, without any apparent tumor. The species are,

1. Hæmorrhois (*tumens*), external from mariscæ.

Varying,

A, Bloody.

B, Mucous.

2. Hæmorrhois (*procidens*), external from a *procidentia ani*.

3. Hæmorrhois (*fluens*), internal, without any swelling, or *procidentia ani*.

4. Hæmorrhois

4. Hæmorrhois (*cæca*), with pain and swelling of the anus, without any profusion of blood.

Genus XXXVIII. Menorrhagia. Pains of the back, belly, and loins, like those of child-birth; an unusually copious flux of the menses or blood from the vagina. The species are,

1. Menorrhagia (*rubra*), bloody in women neither with child nor in child-birth.

2. Menorrhagia (*abortus*), bloody in women with child.

3. Menorrhagia (*lochialis*), bloody in women after delivery.

4. Menorrhagia (*vitiorum*), bloody from some local disease.

5. Menorrhagia (*alba*), serous, without any local disease, in women not pregnant.

6. Menorrhagia (*Nabothi*), serous in women with child.

Order V. Profluvia. Pyrexia, with an increased excretion, naturally not bloody.

Genus XXXIX. Catarrhus. Pyrexia, frequently contagious; an increased excretion of mucus, at least efforts to excrete it.

The species are,

1. From cold.

2. From contagion.

Genus XL. Dysenteria. Contagious pyrexia; frequent mucous or bloody stools, while the alvine fæces are for the most part retained; gripes; tenesmus.

Varying,

1. Accompanied with worms.

2. With the excretion of small fleshy or sebaceous bodies.

3. With an intermittent fever.

4. Without blood,

5. With a miliary fever.

Class II. NEUROSES. A preternatural affection of sense and motion, without an idiopathic pyrexia or any local affection.

Order I. Comata. A diminution of voluntary motion, with sleep, or a deprivation of the senses.

Genus XLI. Apoplexia. Almost all voluntary motion abolished, with sleep more or less profound; the motion of the heart and arteries remaining.

The idiopathic species are,

1. Apoplexia (*sanguinea*), with symptoms of universal plethora, especially of the head.

2. Apoplexia (*serosa*), with a leucophlegmatia over the whole body, especially in old people.

3. Apoplexia (*hydrocephalica*), coming on by degrees; affecting infants, or those below the age of puberty, first with lassitude, a slight fever and pain of the head, then slowness of the pulse, dilatation of the pupil of the eye, and drowsiness.

4. Apoplexia (*atrabiliaria*), taking place in those of a melancholic constitution.

5. Apoplexia (*traumatica*), from some external injury mechanically applied to the head.

6. Apoplexia (*venenata*) from powerful sedatives taken internally or applied externally.

7. Apoplexia (*mentalis*), from an affection or emotion of the mind.

8. Apoplexia (*cataleptica*), the muscles remaining contractile, by external motion of the limbs.

9. Apoplexia (*suffocata*), from some external suffocating power.

The apoplexy is frequently symptomatic.

1. Of an intermittent fever. 2. Continued fever. 3. Phlegmasia. 4. Exanthema. 5. Hysteria. 6. Epilepsia. 7. Podagra. 8. Worms. 9. Ischuria. 10. Scurvy.

Genus XLII. Paralysis. Only some of the voluntary motions impaired, frequently with sleep.

The idiopathic species are,

1. Paralysis (*partialis*) of some particular muscles only.

2. Paralysis (*hemiplegica*) of one side of the body. Varying according to the constitution of the body.

a, Hemiplegia in a plethoric habit.

b, In a leucophlegmatic habit.

3. Paralysis (*paraplegica*) of one half of the body taken transversely.

4. Paralysis (*venenata*) from sedative powers applied either internally or externally.

A symptom either of an Asthenia or Palsy is,

Tremor; an alternate motion of a limb by frequent strokes and intervals.

The species are, 1. Asthenic. 2. Paralytic. 3. Convulsive.

Order II. Adynamiæ. A diminution of the involuntary motions, whether vital or natural.

Genus XLIII. Syncope; a diminution, or even a total stoppage, of the motion of the heart for a short time.

I. Idiopathic.

1. Syncope (*cardiaca*), returning frequently without any manifest cause, with violent palpitations of the heart during the intervals.—From a fault of the heart or neighbouring vessels.

2. Syncope (*occasionalis*) arising from some evident cause.—From an affection of the whole system.

II. Symptomatic; of diseases either of the whole system, or of other parts besides the heart.

Genus XLIV. Dyspepsia. Anorexia, nausea, vomiting, inflation, eructation, rumination, cardialgia, gastrodynia, more or fewer of those symptoms at least concurring; for the most part with a constipation of the belly, and without any other disease either of the stomach itself, or of other parts.

I. Idiopathic.

II. Symptomatic.

1. From a disease of the stomach itself.

2. From a disease of other parts, or of the whole body.

Genus XLV. Hypochondriasis. Dyspepsia, with languor, sadness and fear, without any adequate causes, in a melancholy temperament.

Genus XLVI. Chlorosis. Dyspepsia, or a desire of something not used as food; a pale or discoloured complexion; the veins not well filled: a soft tumor of the whole body; asthenia; palpitation; suppression of the menses.

Order III. Spasmi. Irregular motions of the muscles or muscular fibres.

Sect. I. *In the animal functions.*

General Arrangement of Diseases.

Genus XLVII. Tetanus. A spastic rigidity of almost the whole body.

Varying according to the remote cause, as it rises either from something internal, from cold, or from a wound. It varies likewise, from whatever cause it may arise, according to the part of the body affected.

Genus XLVIII. Trismus. A spastic rigidity of the lower jaw.—The species are,

1. Trismus (*nascentium*), attacking infants under two months old.

2. Trismus (*traumaticus*), attacking people of all ages either from a wound or cold.

Genus XLIX. Convulsio.—An irregular clonic contraction of the muscles without sleep.

I. Idiopathic.

II. Symptomatic.

Genus L. Chorea, attacking those who have not yet arrived at puberty, most commonly within the 10th or 14th year, with convulsive motions for the most part of one side in attempting the voluntary motion of the hands and arms, resembling the gesticulations of mountebanks; in walking, rather dragging one of their feet than lifting it.

Genus LI. Raphania. A spastic contraction of the joints, with a convulsive agitation, and most violent periodical pain.

Genus LII. Epilepsia. A convulsion of the muscles, with sleep.

The idiopathic species are,

1. Epilepsia (*cerebralis*), suddenly attacking without any manifest cause, without any sense of uneasiness preceding, excepting perhaps a slight vertigo or dimness of sight.

2. Epilepsia (*sympathica*), without any manifest cause, but preceded by the sensation of a kind of air rising from a certain part of the body towards the head.

3. Epilepsia (*occasionalis*), arising from a manifest irritation, and ceasing on the removal of that irritation.

Varying according to the difference of the irritating matter. And thus it may arise,

From injuries of the head; pain; worms; poison; from the repulsion of the itch, or an effusion of any other acrid humour; from crudities in the stomach; from passions of the mind; from an immoderate hæmorrhagy; or from debility.

Sect II. *In the vital functions.*

In the action of the heart.

Genus LIII. Palpitatio. A violent and irregular motion of the heart.

In the action of the lungs.

Genus LIV. Asthma. A difficulty of breathing returning by intervals, with a sense of straitness in the breast, and a noisy respiration with hissing. In the beginning of the paroxysm there is either no cough at all, or coughing is difficult; but towards the end the cough becomes free, frequently with a copious spitting of mucus.—The idiopathic species are,

1. Asthma (*spontaneum*), without any manifest cause or other concomitant disease.

2. Asthma (*exanthematicum*), from the repulsion of the itch or other acrid effusion.

3. Asthma (*plethoricum*), from the suppression of some customary sanguineous evacuation, or from a spontaneous plethora.

Genus LV. Dyspnœa. A continual difficulty of breathing, without any sense of straitness, but rather of fulness and infarction in the breast; a frequent cough throughout the whole course of the disease.

The idiopathic species are,

1. Dyspnœa (*catarrhalis*), with a frequent cough, bringing up plenty of viscid mucus.

2. Dyspnœa (*sicca*), with a cough for the most part dry.

3. Dyspnœa (*aëria*), increased by the least change of weather.

4. Dyspnœa (*terrea*), bringing up with the cough an earthy or calculous matter.

5. Dyspnœa (*aquosa*), with scanty urine and œdematous feet; without any fluctuation in the breast, or other signs of an hydrothorax.

6. Dyspnœa (*pinguedinosa*), in very fat people.

7. Dyspnœa (*thoracica*), from an injury done to the parts surrounding the thorax, or from some malconformation of them.

8. Dyspnœa (*extrinseca*), from evident external causes.

The symptomatic species of dyspnœa are consequences,

1. Of diseases of the heart or large vessels.

2. Of a swelling in the abdomen.

3. Of various other diseases.

Genus LVI. Pertussis. A contagious disease; convulsive strangulating cough reiterated with noisy inspiration; frequent vomiting.

Sect. III. *In the natural functions.*

Genus LVII. Pyrosis. A burning pain in the epigastrium, with plenty of aqueous humour, for the most part insipid, but sometimes acrid, belched up.

Genus LVIII. Colica. Pain of the belly, especially twisting round the navel; vomiting; and a constipation.

The idiopathic species are,

1. Colica (*spasmodica*), with retraction of the navel, and spasms of the abdominal muscles.

Varying, by reason of some symptoms superadded. Hence,

a, Colica, with vomiting of excrements, or of matters injected by the anus.

b, Colica, with inflammation supervening.

2. Colica (*pictonum*), preceded by a sense of weight or uneasiness in the belly, especially about the navel; then comes on the colic pain, at first slight and interrupted, chiefly augmented after meals: at length more severe and almost continual, with pains of the arms and back, at last ending in a palsy.

Varying according to the nature of the remote cause; and hence,

a, From metallic poison.

b, From acids taken inwardly.

c, From cold.

d, From a contusion of the back.

3. Colica (*stercorea*), in people subject to costiveness.

4. Colica (*accidentalis*), from acrid matter taken inwardly.

5. Colica (*meconialis*), in new-born children from a retention of the meconium.

6. Colica

6. Colica (*callosa*), with a sensation of stricture in some parts of the intestines, and frequently of a collection of flatus with some pain; which flatus also passing through the part where the stricture is felt, gradually vanishes; the belly slow, and at last passing only a few liquid fæces.

7. Colica (*calculosa*), with a fixed hardness in some part of the abdomen, and calculi sometimes passed by the anus.

Genus LIX. Cholera. A vomiting of bilious matter, and likewise a frequent excretion of the same by stool; anxiety; gripes; spasms in the calves of the legs.

I. Idiopathic.

1. Cholera (*spontanea*), arising in a warm season, without any manifest cause.

2. Cholera (*accidentalis*), from acrid matters taken inwardly.

II. Symptomatic.

Genus LX. Diarrhœa. Frequent stools; the disease not infectious; no primary pyrexia.

I. Idiopathic.

1. Diarrhœa (*crapulosa*), in which the excrements are voided in greater quantity than naturally.

2. Diarrhœa (*biliosa*), in which yellow fæces are voided in great quantity.

3. Diarrhœa (*mucosa*), in which either from acrid substances taken inwardly, or from cold, especially applied to the feet, a great quantity of mucus is voided.

4. Diarrhœa (*cœliaca*), in which a milky humour of the nature of chyle is discharged by stool.

5. Diarrhœa (*lienteria*), in which the aliments are discharged with little alteration soon after eating.

6. Diarrhœa (*hepatirrhœa*), in which a bloody serous matter is discharged without pain.

II. Symptomatic.

Genus LXI. Diabetes. A chronical profusion of urine, for the most part preternatural, and in immoderate quantity.

I. Idiopathic.

1. Diabetes (*mellitus*), with urine of the smell, colour, and taste of honey.

2. Diabetes (*insipidus*), with limpid, but not sweet, urine.

II. Symptomatic.

Genus LXII. Hysteria. Rumbling of the bowels; a sensation as of a globe turning itself in the belly, ascending to the stomach and fauces, and there threatening suffocation; sleep; convulsions; a great quantity of limpid urine; the mind involuntarily fickle and mutable.

The following are by Sauvages reckoned distinct idiopathic species; but, by Dr Cullen, only varieties of the same species.

A, From a retention of the menses.

B, From a menorrhagia cruenta.

C, From a menorrhagia serosa, or fluor albus.

D, From an obstruction of the viscera.

E, From a fault of the stomach.

F, From too great salacity.

Genus LXIII. Hydrophobia. A dislike and horror at any kind of drink, as occasioning a convulsion of the pharynx; induced, for the most part, by the bite of a mad animal. The species are,

I. Hydrophobia (*rabiosa*), with a desire of biting the bystanders, occasioned by the bite of a rabid animal.

II. Hydrophobia (*simplex*), without madness, or any desire of biting.

Order IV. Vesaniæ. Disorders of the judgment, without any pyrexia or coma.

Genus LXIV. Amentia; an imbecility of judgement, by which people either do not perceive, or do not remember, the relations of things. The species are,

I. Amentia (*congenita*), continuing from birth.

II. Amentia (*senilis*), from the diminution of the perceptions and memory through extreme old age.

III. Amentia (*acquisita*), occurring in people formerly of a sound mind, from evident external causes.

Genus LXV. Melancholia; a partial madness, without dyspepsia.

Varying according to the different subjects concerning which the person raves; and thus it is,

1. With an imagination in the patient concerning his body being in a dangerous condition, from slight causes; or his affairs in a desperate state.

2. With an imagination concerning a prosperous state of affairs.

3. With violent love, without satyriasis or nymphomania.

4. With a superstitious fear of a future state.

5. With an aversion from motion and all the offices of life.

6. With restlessness, and an impatience of any situation whatever.

7. With a weariness of life.

8. With a deception concerning the nature of the patient's species.

Dr Cullen thinks that there is no such disease as that called *dæmonomania*, and that the diseases mentioned by Sauvages under that title are either,

1. Species of melancholy or mania; or

2. Of some disease by the spectators falsely ascribed to the influence of an evil spirit; or

3. Of a disease entirely feigned; or

4. Of a disease partly true and partly feigned.

Genus LXVI. Mania; universal madness.

1. Mania (*mentalis*), arising entirely from passions of the mind.

2. Mania (*corporea*), from an evident disease of the body.

Varying according to the different disease of the body.

3. Mania (*obscura*), without any passion of mind or evident disease of the body preceding.

The symptomatic species of mania are,

1. Paraphrosyne from poisons.

2. Paraphrosyne from passion.

3. Paraphrosyne febrilis.

Genus LXVII. Oneirodynia. A violent and troublesome imagination in time of sleep.

1. Oneirodynia (*activa*), exciting to walking and various motions.

2. Oneirodynia (*gravans*), from a sense of some weight incumbent, and pressing on the breast especially.

General Arrangement of Diseases.

Class III. CACHEXIÆ; a depraved habit of the whole or greatest part of the body, without primary pyrexia or neurosis.

Order I. Marcores; emaciation of the whole body.

Genus LXVIII. Tabes. Leanness, asthenia, hectic fever. The species are,

1. Tabes (*purulenta*) from an external or internal ulcer, or from a vomica.

Varying in its situation: hence,

2. Tabes (*scrophulosa*), in scrophulous constitutions.

3. Tabes (*venenata*), from poison taken inwardly.

Genus LXIX. Atrophia. Leanness and asthenia, without hectic fever. The species are,

1. Atrophia (*inanitorum*), from too great evacuation.

2. Atrophia (*famelicorum*), from a want of nourishment.

3. Atrophia (*cacochymica*), from corrupted nourishment.

4. Atrophia (*debilium*), from the function of nutrition being depraved, without any extraordinary evacuation or cacochymia having preceded.

Order II. Intumescentiæ. An external swelling of the whole or greatest part of the body.

Sect. I. *Adiposæ*.

Genus LXX. Polysarcia; a troublesome swelling of the body from fat.

Sect. II. *Flatuosæ*.

Genus LXXI. Pneumatosis; a tense elastic swelling of the body, crackling under the hand. The species are,

1. Pneumatosis (*spontanea*), without any manifest cause.

2. Pneumatosis (*traumatica*), from a wound in the breast.

3. Pneumatosis (*veneneta*), from poison injected or applied.

4. Pneumatosis (*hysterica*), with hysteria.

Genus LXXII. Tympanites; a tense, elastic, sonorous swelling of the abdomen; costiveness: a decay of the other parts. The species are,

1. Tympanites (*intestinalis*), from a tumor of the abdomen frequently unequal, and with a frequent evacuation of air relieving the tension and pain.

2. Tympanites (*abdominalis*), with a more evident noise, a more equable tumor, and a less frequent emission of flatus, which also gives less relief.

Genus LXXIII. Physometra; a slight elastic swelling in the epigastrium, having the figure and situation of the uterus.

Sect. III. *Aquosæ* or *Dropsies*.

Genus LXXIV. Anasarca. A soft, inelastic swelling of the whole body, or some part of it. The species are,

1. Anasarca (*serosa*), from a retention of serum on account of the suppression of the usual evacuations, or from an increase of the serum on account of too great a quantity of water taken inwardly.

2. Anasarca (*oppilata*), from a compression of the veins.

3. Anasarca (*exanthematica*), arising after exanthemata, especially succeeding after erysipelas.

4. Anasarca (*anæmia*), from the thinness of the blood produced by hæmorrhagy.

5. Anasarca (*debilium*), in weak people after long diseases, or from other causes.

Genus LXXV. Hydrocephalus. A soft inelastic swelling of the head, with the sutures of the cranium opened.

Genus LXXVI. Hydrorachitis. A soft, slender tumour above the vertebræ of the loins; the vertebræ gaping from each other.

Genus LXXVII. Hydrothorax. Dyspnœa, paleness of the face; œdematous swellings of the feet; scanty urine; difficult lying in a recumbent posture; a sudden and spontaneous starting out of sleep, with palpitation; water fluctuating in the breast.

Genus LXXVIII. Ascites. A tense, scarce elastic, but fluctuating swelling of the abdomen. The species are,

1. Ascites (*abdominalis*), with an equal swelling of the whole abdomen, and with a fluctuation sufficiently evident.

Varying according to the cause.

A, From an obstruction of the viscera.

B, From debility.

C, From a thinness of the blood.

2. Ascites (*saccatus*), with a swelling in the abdomen, in the beginning at least, partial, and with a less evident fluctuation.

Genus LXXIX. Hydrometra. A swelling of the hypogastrium in women, gradually increasing, keeping the shape of the uterus, yielding to pressure, and fluctuating; without ischuria or pregnancy.

Genus LXXX. Hydrocele. A swelling of the scrotum, not painful; increasing by degrees, soft, fluctuating, and pellucid.

Sect. IV. *Solidæ*.

Genus LXXXI. Physconia. A swelling chiefly occupying a certain part of the abdomen, gradually increasing, and neither sonorous nor fluctuating. The species are,

Physconia hepatica.
Physconia splenica.
Physconia renalis.
Physconia uterina.
Physconia ab ovario.
Physconia mesenterica.
Physconia intestinalis.
Physconia omentalis.
Physconia polysplachna.
Physconia visceralis.
Physconia externa lupialis.
Physconia externa schirrhodea.
Physconia externa hydatidosa.
Physconia ab adipe subcutaneo.
Physconia ab excrescentia.

Genus LXXXII. Rachitis. A large head, swelling most in the fore part, the ribs depressed; abdomen swelled, with a decay of the other parts.

Varying,

1. Simple, without any other disease.

2. Joined with other diseases.

Order III. Impetigines. Cachexies chiefly deforming the skin and external parts of the body.

Genus

Genus LXXXIII. Scrophula. Swelling of the conglobate glands, especially in the neck; swelling of the upper lip and of the nose; the face florid, skin, thin, abdomen swelled. The species are,

1. Scrophula (*vulgaris*), simple, external and permanent.

2. Scrophula (*mesenterica*), simple, internal, with paleness of the face, want of appetite, swelling of the abdomen, and unusual fetor of the excrements.

3. Scrophula (*fugax*), most simple, appearing only about the neck; for the most part proceeding from the resorption of the matter of ulcers in the head.

4. Scrophula (*Americana*), joined with the yaws.

Genus LXXXIV. Syphilis. A contagious disease; ulcers of the tonsils, after impure venery, and a disorder of the genitals: clustered pimples of the skin, especially about the margin of the hair, ending in crusts and crusty ulcers; pains of the bones; exostoses.

Genus LXXXV. Scorbutus; in cold countries attacking after putrescent diet, especially such as is salt and of the animal kind, where no supply of fresh vegetables is to be had: asthenia; stomacace; spots of different colours on the skin, for the most part livid, and appearing chiefly among the roots of the hair.

Varying in degree.

a, Scorbutus incipiens.

b, Scorbutus crescens.

c, Scorbutus inveteratus.

Varying also in symptoms.

d, Scorbutus lividus.

e, Scorbutus petechialis.

f, Scorbutus pallidus.

g, Scorbutus ruber.

h, Scorbutus calidus.

Genus LXXXVI. Elephantiasis; a contagious disease; thick, wrinkled, rough, unctuous skin, destitute of hairs, anæsthesia in the extremities, the face deformed with pimples, the voice hoarse and nasal.

Genus LXXXVII. Lepra; the skin rough, with white, branny, and chopped eschars, sometimes moist beneath, with itching.

Genus LXXXVIII. Frambœsia; swellings resembling fungi, or the fruit of the mulberry or raspberry, growing on various parts of the skin.

Genus LXXXIX. Trichoma; a contagious disease; the hairs thicker than usual, and twisted into inextricable knots and cords.

Genus XC. Icterus; yellowness of the skin and eyes; white fæces; urine of a dark red, tinging what is put into it of a yellow colour.

The idiopathic species are,

1. Icterus (*calculosus*), with acute pain in the epigastric region, increasing after meals: biliary concretions voided by stool.

2. Icterus (*spasmodicus*), without pain, after spasmodic diseases, and passions of the mind.

3. Icterus (*hepaticus*), without pain, after diseases of the liver.

4. Icterus (*gravidarum*), arising during the time of pregnancy, and going off after delivery.

5. Icterus (*infantum*), coming on in infants a few days after birth.

Class IV. LOCALES. An affection of some part, but not of the whole body.

Order I. Dysæsthesiæ. The senses depraved or destroyed, from a disease of the external organs.

Genus XCI. Caligo. The sight impaired or totally destroyed, on account of some opaque substance interposed between the objects and the retina, inherent in the eye itself or the eyelids. The species are,

1. Caligo (*lentis*), occasioned by an opaque spot behind the pupil,

2. Caligo (*corneæ*), from an opacity of the cornea.

3. Caligo (*pupillæ*), from an obstruction of the pupil.

Varying according to the different causes from which it proceeds.

4. Caligo (*humorum*), from a disease or defect of the aqueous humour.

Varying according to the different state of the humour.

5. Caligo (*palpebrarum*), from a disease inherent in the eyelids.

Varying according to the nature of the disease in the eyelids.

Genus XCII. Amaurosis. The sight diminished, or totally abolished, without any evident disease of the eye; the pupil for the most part remaining dilated and immoveable. The species are,

1. Amaurosis (*compressionis*), after the causes and attended with the symptoms of congestion in the brain.

Varying according to the nature of the remote cause.

2. Amaurosis (*atonica*), after the causes and accompanied with symptoms of debility.

3. Amaurosis (*spasmodica*), after the causes and with the signs of spasm.

4. Amaurosis (*venenata*), from poison taken into the body or applied outwardly to it.

Genus XCIII. Dysopia. A depravation of the sight, so that objects cannot be distinctly perceived, except at a certain distance, and in a certain situation.

The species are,

1. Dysopia (*tenebrarum*), in which objects are not seen unless they be placed in a strong light.

2. Dysopia (*luminis*) in which objects are not distinctly seen unless by a weak light.

3. Dysopia (*dissitorum*), in which distant objects are not perceived.

4. Dysopia (*proximorum*), in which the nearest objects are not perceived.

5. Dysopia (*lateralis*), in which objects are not perceived unless placed in an oblique posture.

Genus XCIV. Pseudoblepsis; when the sight is diseased in such a manner that the person imagines he sees things which really do not exist, or sees things which do exist after some other manner than they really are. The species are,

1. Pseudoblepsis (*imaginaria*), in which the person imagines he sees things which really do not exist.

Varying according to the nature of the imagination.

2. Pseudoblepsis (*mutans*), in which objects really existing appear somehow changed.

Varying

General Arrangement of Diseases.

Varying according to the change perceived in the objects, and according to the remote cause.

Genus XCV. Dysecœa. A diminution or total abolition of the sense of hearing. The species are,

1. Dysecœa (*organica*), from a disease in the organs transmitting sounds to the internal ear.

Varying according to the nature of the disease and of the part affected.

2. Dysecœa (*atonica*), without any evident disease of the organs transmitting the sounds.

Varying according to the nature of the cause.

Genus XCVI. Paracusis; a depravation of the hearing. The species are,

1. Paracusis (*imperfecta*), in which though sounds coming from external objects are heard, yet it is neither distinctly nor in the usual manner.

Varying,

a, With a dulness of hearing.

b, With a hearing too acute and sensible.

c, When a single external sound is doubled by some internal causes.

d, When the sounds which a person desires to hear are not perceived, unless some other violent sound is raised at the same time.

2. Paracusis (*imaginaria*), in which sounds not existing externally are excited from internal causes.

Varying according to the nature of the sound perceived, and according to the nature of the remote cause.

Genus XCVII. Anosmia; a diminution or abolition of the sense of smell. The species are,

1. Anosmia (*organica*), from a disease in the membrane lining the internal parts of the nostrils.

Varying according to the nature of the disease.

2. Anosmia (*atonica*), without any evident disease of the membrane of the nose.

Genus XCVIII. Agheustia; a diminution or abolition of the sense of taste.

1. Agheustia (*organica*), from a disease in the membrane of the tongue, keeping off from the nerves those substances which ought to produce taste.

2. Agheustia (*atonica*), without any evident disease of the tongue.

Genus XCIX. Anæsthesia; a diminution or abolition of the sense of feeling. The species from Sauvages, adopted by Dr Cullen, are,

1. Anæsthesia à spina bifida.
2. Anæsthesia plethorica.
3. Anæsthesia nascentium.
4. Anæsthesia melancholica.

Order II. Dysorexiæ; error or defect of appetite.

Sect. I. *Appetitus erronei.*

Genus C. Bulimia; a desire for food in greater quantities than can be digested.

The idiopathic species are,

1. Bulimia (*helluonum*), an unusual appetite for food, without any disease of the stomach.

2. Bulimia (*syncopalis*), a frequent desire of meat, on account of a sensation of hunger threatening syncope.

3. Bulimia (*emetica*), an appetite for a great quantity of meat, which is thrown up immediately after it is taken.

Genus CI. Polydipsia; an appetite for an unusual quantity of drink.

The polydipsia is almost always symptomatic, and varies only according to the nature of the disease which accompanies it.

Genus CII. Pica; a desire of swallowing substances not used as food.

Genus CIII. Satyriasis; an unbounded desire of venery in men. The species are,

1. Satyriasis (*juvenilis*), an unbounded desire of venery, the body at the same time being little disordered.

2. Satyriasis (*furens*), a vehement desire of venery with a great disorder of the body at the same time.

Genus CIV. Nymphomania; an unbounded desire of venery in women.

Varying in degree.

Genus CV. Nostalgia; a violent desire in those who are absent from their country of revisiting it.

1. Nostalgia (*simplex*), without any other disease.

2. Nostalgia (*complicata*), accompanied with other diseases.

Sect. II. *Appetitus deficientes.*

Genus CVI. Anorexia. Want of appetite for food. Always symptomatic.

1. Anorexia (*humoralis*), from some humour loading the stomach.

2. Anorexia (*atonica*), from the tone of the fibres of the stomach being lost.

Genus CVII. Adipsia; a want of desire for drink. Always a symptom of some disease affecting the sensorium commune.

Genus CVIII. Anaphrodisia; want of desire for, or impotence to, venery.

The true species are,

1. Anaphrodisia paralytica.
2. Anaphrodisia gonorrhoica.

The false ones are,

1. Anaphrodisia à mariscis.
2. Anaphrodisia ab urethræ vitio.

Order III. Dyscinesiæ. An impediment, or depravation of motion from a disorder of the organs.

Genus CIX. Aphonia; a total suppression of voice without coma or syncope. The species are,

1. Aphonia (*gutturalis*), from the fauces or glottis being swelled.

2. Aphonia, (*trachealis*), from a compression of the trachea.

3. Aphonia (*atonica*), from the nerves of the larynx being cut.

Genus CX. Mutitas; a want of power to pronounce words. The species are,

1. Mutitas (*organica*), from the tongue being cut out or destroyed.

2. Mutitas (*atonica*), from injuries done to the nerves of the tongue.

3. Mutitas (*surdorum*), from people being born deaf, or the hearing being destroyed during childhood.

Genus CXI. Paraphonia; a depraved sound of the voice. The species are,

1. Paraphonia (*puberum*), in which, about the time of puberty, the voice from being acute and sweet, becomes more grave and harsh.

2. Paraphonia

2. Paraphonia (*rauca*), in which, by reason of the dryness or flaccid tumor of the fauces, the voice becomes rough and hoarse.

3. Paraphonia (*resonans*), in which, by reason of an obstruction in the nostrils, the voice becomes hoarse, with a sound hissing through the nostrils.

4. Paraphonia (*palatina*), in which, on account of a defect or division of the uvula, for the most part with a hare-lip, the voice becomes obscure, hoarse, and unpleasant.

5. Paraphonia (*clangens*), in which the voice is changed to one acute, shrill, and small.

6. Paraphonia (*comatosa*), in which, from a relaxation of the velum palati and glottis, a sound is produced during inspiration.

Genus CXII. Psellismus; a defect in the articulation of words. The species are,

1. Psellismus (*hæsitans*), in which the words, especially the first ones of a discourse, are not easily pronounced, and not without a frequent repetition of the first syllable.

2. Psellismus (*ringens*), in which the sound of the letter R is always aspirated, and, as it were, doubled.

3. Psellismus (*lallans*), in which the sound of the letter L becomes more liquid, or is pronounced instead of R.

4. Psellismus (*emolliens*), in which the hard letters are changed into the softer ones, and thus the letter S is much used.

5. Psellismus (*balbutiens*), in which, by reason of the tongue being large, or swelled, the labial letters are better heard, and often pronounced instead of others.

6. Psellismus (*acheilos*), in which the labial letters cannot be pronounced at all, or with difficulty.

7. Psellismus (*lagostomatum*), in which, on account of the division of the palate, the guttural letters are less perfectly pronounced.

Genus CXIII. Strabismus; the optic axes of the eyes not converging. The species are,

1. Strabismus (*habitualis*), from a bad custom of using only one eye.

2. Strabismus (*commodus*), from the greater debility or mobility of one eye above the other; so that both eyes cannot be conveniently used.

3. Strabismus (*necessarius*), from a change in the situation or shape of the parts of the eye.

Genus CXIV. Dysphagia; impeded deglutition, without phlegmasia or the respiration being affected.

Genus CXV. Contractura; a long-continued and rigid contraction of one or more limbs. The species are,

1 Contractura (*primaria*), from the muscles becoming contracted and rigid.

a, From the muscles becoming rigid by inflammation.

b, From muscles becoming rigid by spasm.

c, From muscles contracted by reason of their antagonists having become paralytic.

d, From muscles contracted by an irritating acrimony.

2. Contractura (*articularis*), from stiff joints.

Order IV. Apocenoses. A flux either of blood or some other humour flowing more plentifully than usual, without pyrexia, or an increased impulse of fluids.

Genus CXVI. Profusio; a flux of blood.

Genus CXVII. Ephidrosis; a preternatural evacuation of sweat.

Symptomatic ephidroses vary according to the nature of the diseases which they accompany, the different nature of the sweat itself, and sometimes the different parts of the body which sweat most.

Genus CXVIII. Epiphora; a flux of the lachrymal humour.

Genus CXIX. Ptyalismus; a flux of saliva.

Genus CXX. Enuresis; an involuntary flux of urine without pain. The species are,

1. Enuresis (*atonica*), after diseases injuring the sphincter of the bladder.

2. Enuresis (*irritata*), from a compression or irritation of the bladder.

Genus CXXI. Gonorrhœa; a preternatural flux of humour from the urethra in men, with or without a desire of venery. The species are,

1. Gonorrhœa (*pura*), in which, without any impure venery having preceded, a fluid resembling pus, without dysuria or propensity to venery, flows from the urethra.

2. Gonorrhœa (*impura*), in which, after impure venery, a mucous humour flows from the urethra with dysuria. The consequence of this is,

Gonorrhœa (*mucosa*), in which, after an impure gonorrhœa, a mucous humour flows from the urethra with little or no dysuria.

3. Gonorrhœa (*laxorum*), in which an humour for the most part pellucid, without any erection of the penis, but with a propensity to venery, flows from the urethra while the person is awake.

4. Gonorrhœa (*dormientium*), in which the seminal liquor is thrown out, with erection and desire of venery, in those who are asleep and have lascivious dreams.

Order V. Epischeses; suppressions of evacuations.

Genus CXXII. Obstipatio; the stools either suppressed, or slower than usual. The species are,

1. Obstipatio (*debilium*), in lax, weak, and for the most part dyspeptic persons.

2. Obstipatio (*rigidorum*), in people whose fibres are rigid, and frequently of an hypochondriac disposition.

3. Obstipatio (*obstructorum*), with symptoms of the colica, 1st, 2d, 4th, and 7th, above-mentioned.

Genus CXXIII. Ischuria; an absolute suppression of urine. The species are,

1. Ischuria (*renalis*), coming after a disease of the kidneys, with pain, or troublesome sense of weight in the region of the kidneys, and without any swelling of the hypogastrium, or desire of making water.

2. Ischuria (*ureterica*), coming after a disease of the kidneys, with a sense of pain or uneasiness in some part of the ureter, and without any tumour of the hypogastrium, or desire of making water.

3. Ischuria (*vesicalis*), with a swelling of the hypogastrium, pain at the neck of the bladder, and a frequent stimulus to make water.

4. Ischuria (*urethralis*), with a swelling of the hypogastrium, frequent stimulus to make water, and pain in some part of the urethra.

All these species are subdivided into many varieties, according to their different causes.

Genus CXXIV. Dysuria; a painful, and somehow impeded emission of urine. The species are,

1. Dysuria

General Arrangement of Diseases.

1. Dysuria (*ardens*), with heat of urine, without any manifest disorder of the bladder.

2. Dysuria (*spasmodica*), from a spasm communicated from the other parts to the bladder.

3. Dysuria (*compressionis*), from the neighbouring parts pressing upon the bladder.

4. Dysuria (*phlogistica*), from an inflammation of the neighbouring parts.

5. Dysuria (*irritata*), with signs of a stone in the bladder.

6. Dysuria (*mucosa*), with a copious excretion of mucus.

Genus CXXV. Dyspermatismus; a slow, impeded, and insufficient emission of semen in the venereal act. The species are,

1. Dyspermatismus (*urethralis*), from diseases of the urethra.

2. Dyspermatismus (*nodosus*), from knots on the corpora cavernosa penis.

3. Dyspermatismus (*præputialis*), from too narrow an orifice of the prepuce.

4. Dyspermatismus (*mucosus*), from mucus infarcting the urethra.

5. Dyspermatismus (*hypertonicus*), from too strong an erection of the penis.

6. Dyspermatismus (*epilepticus*), from a spasmodic epilepsy happening during the time of coition.

7. Dyspermatismus (*apractodes*), from an imbecility of the parts of generation.

8. Dyspermatismus (*refluus*), in which there is no emission of semen, because it returns from the urethra into the bladder.

Genus CXXVI. Amenorrhœa. The menses either flowing more sparingly than usual, or not at all, at their usual time, without pregnancy. The species are,

1. Amenorrhœa (*emansionis*), in those arrived at puberty, in whom, after the usual time, the menses have not yet made their appearance, and many different morbid affections have taken place.

2. Amenorrhœa (*suppressionis*), in adults, in whom the menses which had already begun to flow are suppressed.

3. Amenorrhœa (*difficilis*), in which the menses flow sparingly, and with difficulty.

Order VI. Tumores; an increased magnitude of any part without phlogosis.

Genus CXXVII. Aneurisma; a soft tumor, with pulsation, above an artery.

Genus CXXVIII. Varix; a soft tumour, without pulsation, above a vein.

Genus CXXIX. Ecchymoma; a diffused, little eminent, and livid tumour.

Genus CXXX. Schirrus; an hard tumour of some part, generally of a gland, without pain, and difficultly brought to suppuration.

Genus CXXXI. Cancer; a painful tumor of a schirrous nature, and degenerating into an ill conditioned ulcer.

Genus CXXXII. Bubo; a suppurating tumor of a conglobate gland.

Genus CXXXIII. Sarcoma; a soft swelling, without pain.

Genus CXXXIV. Verruca; a harder scabrous swelling.

Genus CXXXV. Clavus; a hard, lamellated thickness of the skin.

Genus CXXXVI. Lupia. A moveable, soft tumor below the skin, without pain.

Genus CXXXVII. Ganglion. A hard moveable swelling, adhering to a tendon.

Genus CXXXVIII. Hydatis; a cuticular vesicle filled with aqueous humour.

Genus CXXXIX. Hydarthrus; a most painful swelling of the joints, chiefly of the knee, at first scarce elevated, of the same colour with the skin, diminishing the mobility.

Genus CXL. Exostosis; a hard tumor adhering to a bone.

Order VII. Ectopiæ; tumors occasioned by the removal of some part out of its proper situation.

Genus CXLI. Hernia; an ectopia of a soft part as yet covered with the skin and other integuments.

Genus CXLII. Prolapsus; a bare ectopia of some soft part.

Genus CXLIII. Luxatio; the removal of a bone from its place in the joints.

Order VIII. Dialyses. A solution of continuity; manifest to the sight or touch.

Genus CXLIV. Vulnus; a recent and bloody solution of the unity of some soft part by the motion of some hard body.

Genus CXLV. Ulcus. A purulent or ichorous solution of a soft part.

Genus CXLVI. Herpes; a great number of phlyctenæ or small ulcers, gathering in clusters, creeping, and obstinate.

Genus CXLVII. Tinea; small ulcers among the roots of the hair of the head, pouring out a fluid which changes to a white friable scurf.

Genus CXLVIII. Psora. Itchy pustules and little ulcers of an infectious nature, chiefly infecting the hands.

Genus CXLIX. Fractura; bones broken into large fragments.

Genus CL. Caries; an ulceration of a bone.

Having thus presented to our readers Dr Cullen's general systematic view of all the diseases to which the human body is subjected, we next come to give a more particular account of the more important affections, treating of them in the order in which Dr Cullen has arranged them.

Genus I. TERTIANA; the TERTIAN FEVER.

(*Tertiana*, Sauv. G. 88. Lin. 16. Hoffm. Stahl. Cleghorn. Senac.)

The *Genuine* TERTIAN.

26 (Tertiana legitima, *Senert. Hoffm. Cleghorn*, Minorc. *Sauv.* Sp. I.)

1. *Description.* This disease, in its most regular form, consists of repeated paroxysms, returning every second day, the patient during the intermediate period enjoying apparently a state of good health. This is the most common form of ague, as it is commonly called in Britain. Each paroxysm consists of three parts, the cold, the hot, and the sweating stages. The paroxysm commonly begins with a remarkable shivering, increasing frequently to a convulsive shaking of the limbs. The extremities are always cold, sometimes remarkably so. The cold for the most part is first perceived about the lumbar regions, from thence ascending along the spine it turns towards the pit of the stomach. Sometimes it begins in the first joint of the fingers and tip of the nose. Sometimes it attacks only a particular part of the body, as one of the arms, the side of the head, &c. This cold is often preceded by a heavy and sleepy torpor, languor, and lassitude, which we are partly to ascribe to real weakness and partly to mere languor. To these symptoms succeed yawning and stretching; after which the cold comes on as above described, not unfrequently with a pain of the back, and a troublesome sensation of tension in the precordia and hypochondria. To this succeed nausea and vomiting: and the more genuine the disease, the more certainly does the vomiting come on; by which a great deal of tough mucous matter, and sometimes bilious stuff or indigested food, is evacuated during the first paroxysm. In some there is only a violent straining to vomit, without bringing up any thing; sometimes, instead of these symptoms, a diarrhœa occurs, and this chiefly in weak, phlegmatic, and aged people, or where an indigested mucous saburra has long remained in the primæ viæ.

When these symptoms have continued for an hour or two, the cold begins to go off, and is succeeded by a lassitude, languor, and flaccidity of the whole body, but chiefly in the limbs, with an uneasy soreness as if the parts had been bruised; excepting in those cases where the nausea continues for a longer time. After this languor, a heat comes on, the increase of which is generally slow, but sometimes otherwise, with pain of the head, thirst, and bitterness in the mouth. The pulse is quick and unequal; sometimes beating 130 strokes in a minute. As soon as this heat has abated, a little moisture or sweat is observed to break forth; not always indeed in the first, but always in the succeeding paroxysms, and the urine lets fall a quantity of lateritious sediment. The whole paroxysm is seldom over in less than six hours, more frequently eight, and in violent cases it extends to 12 hours; but that which exceeds 12 hours is to be reckoned a spurious kind, and approaching to the nature of continued fevers. All these symptoms, however, are repeated every second day, in such a manner that the patient is quite free from fever for at least 24 hours. The paroxysms return much about the same time, though sometimes a little sooner or later. Tertiana.

2. *Causes of this disease and persons subject to it.* The genuine tertian attacks men rather than women, young people rather than old: the latter being more subject to anomalous tertians. It likewise seizes the lusty and active, rather than the lazy and indolent. Those, however, who are apt to nauseate their meat fall easily into a tertian fever. The cause, according to Dr Cullen, is the miasma of marshes, and that only. Other physicians have taken in many more causes, almost every thing indeed which debilitates the body: but the Doctor denies that any of these, though they may dispose the body for receiving the disease, or may augment it, can by any means produce it without the concurrence of the marsh miasma, and it cannot be denied, that it is a disease almost peculiar to marshy situations. Thus we find it very frequent in the fenny counties of Britain, although in other parts of this island it may be considered as a very rare disease; nay, in many it may perhaps be said that it never occurs. And it is also well known that intermittents have almost entirely disappeared in many parts of Britain, in which they were very common before the marshes of these places were drained.

3. *Prognosis.* The genuine simple tertian, unless improper medicines be administered, is generally very easily cured; nay, the vulgar reckon it of such a salutary nature, that after it they imagine a person becomes more strong and healthy than before. Hippocrates has observed, that these fevers terminate of their own accord after seven or nine paroxysms. Juncker tells us, that it frequently terminates before the seventh paroxysm, but rarely before the fourth. He also denies that any thing critical is to be observed in its going off; but in this he differs from Vogel, who tells us, that the urine, for some days after the fever is quite gone off, appears slimy, and lets fall much sediment. The latter also informs us, that besides the common crisis by sweat and urine, the tertian hath one peculiar to itself, namely, dry scabby ulcers breaking out upon the lips. These sometimes appear about the third or fourth paroxysm; and then we may venture to foretel that the disease will go off spontaneously after the seventh. But though the disease be never dangerous, in cold climates, at least, when properly treated; yet the improper use of hot and stimulating medicines may change it into a continued fever, more or less dangerous according to the quantity of medicines taken and the constitution of the patient; in which case the prognosis must be regulated by the particular symptoms which occur. In warm climates, however, the tertian fever may be considered as a much more alarming disease; and unless the most powerful remedies be employed, the patient is in danger of falling a victim to every paroxysm.

A variety of theories have been proposed for explaining the phenomena of this affection; but we may assert, that every thing hitherto said upon the subject is highly unsatisfactory. For although it be now almost universally admitted, that this fever does arise from the effluvia of marshes, yet in what manner the

Febres.

action of those effluvia induces fever, and particularly why this fever returns in regular paroxysms, are questions with regard to which we are still totally in the dark. Dr Cullen, with much ingenuity, attempted to prove, that the remote causes of this, as well as of other fevers, operate by inducing a state of debility; that this debility gives rise to spasm, which induces increased action, from which the phenomena are to be explained. But this theory is liable to no less numerous and unsurmountable objections than the exploded hypotheses which had before been proposed by others. For it is an undeniable truth, that debility often exists, even to the highest imaginable degree, without any fever; nay, that when fever has taken place, the debility is often much greater after it is entirely gone than at any period during its course. When spasm and increased action do take place, we have no reason to view them in any other light than merely as symptoms of the disease; and while they are often absent in this affection, they frequently occur in others where the sickness, anxiety, and other characterizing symptoms of fever are entirely absent: and, upon the whole, a probable or rational theory of intermittents, as well as of other fevers, still remains to be discovered.

Cure. The treatment of all genuine intermittents, whether *tertians*, quotidians, or quartans, being almost precisely the same, the general method of cure applicable to all of them may be here given, to which it will be easy to refer when we come to describe the others.

In treating intermittent fevers, physicians have formed indications of cure according to their different theories. The followers of Boerhaave, Stahl, &c. who imagined that the disease proceeded from a lentor or other disorders in the blood, always thought it necessary to correct and evacuate these peccant humours by emetics and purgatives, before they attempted to stop the disease by the Peruvian bark or any other medicine. Cinchona indeed, among some, seems to be held in very little estimation: since Vogel affirms, that this medicine, instead of deserving to have the preference of all other febrifuge medicines, ought rather to be ranked among the lowest of the whole; and for this reason he ascribes the cures, said to be obtained by the use of the Peruvian bark, entirely to nature.

According to Dr Cullen, the indications of cure in intermitting fevers may be reduced to the following:

1. In the time of intermission, to prevent the return of the paroxysms.

2. In the time of paroxysms, to conduct these in such a manner as to obtain a final solution of the disease.

3. To take off certain circumstances which might prevent the fulfilling of the two first indications.

The first indication may be answered in two ways: 1. By increasing the action of the heart and arteries some time before the period of accession, and supporting that increased action till the period of accession be over, and thus preventing the recurrence of that atony and spasm of the extreme vessels, which he thinks give occasion to the recurrence of paroxysms. 2. By supporting the tone of the vessels, and thereby preventing atony and the consequent spasm, without increasing the action of the heart and arteries, the recurrence of paroxysms may be prevented.

The action of the heart and arteries may be increased, 1. By various stimulant remedies internally given or externally applied, and that without exciting sweat. 2. By the same remedies, or by others, managed in such a manner as to excite sweating, and to support that sweating till the period of accession be for some time past. 3. By emetics, supporting for the same time the tone and action of the extreme vessels.

Tertiana.

The tone of the extreme vessels may be supported without increasing the action of the heart and arteries, by various tonic medicines; as, 1. Astringents alone. 2. Bitters alone. 3. Astringents and bitters conjoined. 4. Astringents and aromatics conjoined. 5. Certain metallic tonics; and, 6. Opiates. A good deal of exercise, and as full a diet as the condition of the patient's appetite and digestion allow, will be proper during the time of intermission, and may be considered as belonging to this head. Although many particulars in this plan of cure are deduced from Dr Cullen's theory, yet there can be no doubt that the object chiefly to be aimed at is to employ such remedies during the intermissions as will prevent a recurrence of the paroxysm. Of all the remedies hitherto employed with this intention, the most celebrated, perhaps the most certainly effectual, is the Peruvian bark; or, to speak more properly, the bark of the *Cinchona officinalis* of Linnæus. But it must be observed, that good effects are only to be expected from this medicine when employed in substance and in large quantity; and for its use the following rules or observations have been given:

1. The cinchona may with safety be employed at any period of intermitting fevers, providing that at the same time there be neither a phlogistic diathesis prevailing in the system, nor any considerable or fixed congestion present in the abdominal viscera.

2. The proper time for exhibiting the cinchona in intermittent fevers is during the time of intermission, and it is to be abstained from in the time of paroxysms.

3. In the case of genuine intermittents, while a due quantity of cinchona is employed, the exhibition of it ought to be brought as near to the time of accession as the condition of the patient's stomach will allow.

4. In all cases of intermittents, it is not sufficient that the recurrence of paroxysms be stopped for once by the use of the cinchona; a relapse is commonly to be expected, and should be prevented by the exhibition of the cinchona repeated at proper intervals.

The advantage of administering the medicine as early as possible, was fully ascertained by Dr Lind in the years 1765, 1766, and 1767, during an uncommon prevalence of intermittents. When the disease was stopped by the cinchona immediately after the first or second fit, which was the case with 200 of the Doctor's patients as well as himself, neither a jaundice nor dropsy ensued; whereas, when the cinchona could not be administered, on account of the imperfect intermission of the fever, or when the patient had neglected to take it, either a dropsy, jaundice, or constant headach, were the certain consequences, and the violence of the disease was in proportion to the number of the preceding fits, or to the continuance of the fever. By every paroxysm the dropsical swellings were visibly increased, and the colour of the skin rendered of a deeper yellow. When the fever continued a few days without intermission, the belly and legs generally swelled; a violent headach, likewise, and vertigo, for the most part distressed the patient;

Fres. Tertiana.

patient; so that some, even after the fever had left them, were not able to walk across their chamber for a fortnight or three weeks. When the returns of the fever were regular and even, but slight, four or five fits of a simple tertian were sometimes followed by the most dangerous symptoms; especially in the year 1765, when these fevers raged with the greatest violence. If, as frequently happened, a dropsical patient relapsed into the intermittent, there was an absolute necessity for putting an immediate stop to it by the cinchona; and in upwards of 70 such patients, Dr Lind observed the most beneficial effects to accrue from this practice. Without regard to a cough, or any other chronical indisposition, he ordered it to be given in large doses.

Cinchona has been often observed to fail in removing intermittents, from not continuing the use of it for a sufficient length of time, from administering it in too small a dose, or from giving it in an improper form. It was a prevailing opinion, that an ounce, or an ounce and a half, taken during one intermission, was sufficient to prevent the return of another paroxysm. But this is not always the case; for a severe fit will often attack a patient who has taken such a quantity. When this happens, the patient ought to persevere during the following intermissions, with an increase of the dose, till five or six ounces at least have been taken. The medicine also ought not to be omitted as soon as one fit is stopped, but should be continued in a smaller dose, and after longer intervals, for at least ten days or a fortnight. Even for several months after the disease is entirely removed, it would be advisable to take a little occasionally in damp weather, or during an easterly wind, to prevent a relapse. Where the intervals between the fits are short, as in quotidians and double tertians, from one to two drams of it ought to be taken every two or three hours.

The form in which this medicine is administered is of some consequence. Mucilages and syrups have been recommended to conceal the taste of it; but, from various experiments, Dr Lind found nothing more effectual for this purpose than small beer or milk, especially the latter. A dram of bark mixed with two ounces of milk, and quickly drank, may easily be taken by a person of the most delicate taste, and by washing the mouth afterwards with milk, there will not remain the least flavour of the bark; but if the mixture be not drank immediately, the bark will impart a bitter taste to the milk. This medicine is commonly given in electuaries or boluses; but Dr Lind observes, that in these forms it proves much less efficacious than when administered in juleps or draughts, with the plentiful addition of wine or spirits. He has remarked, that six drams of powdered bark, given in a julep, consisting of one-fourth or one-third of brandy, is as effectual as an ounce of the powder in the form of an electuary, and proves less disagreeable to the stomach. For patients unaccustomed to wine or spirits, each draught should be warmed with spiritus ammoniæ, or tinct. myrrh. by both of which the efficacy of the bark is he thinks increased. Dr Lind is also fully convinced that wine or spirits improve the virtues of the bark much more than elixir vitrioli, tinct. rosar. or such other medicines as have been recommended by different physicians.

For those who nauseate cinchona from a weakness of the stomach or other cause, he advises it to be given in clysters, in which form it is, he tells us, as efficacious as when taken by the mouth. For this purpose the extract is most proper with the addition of a sufficient quantity of the tinctura thebaica, in order to its being longer retained. For children labouring under intermitting fevers, Dr Lind orders the spine of the back to be anointed, at the approach of the fit, with a liniment composed of equal parts of tinctura thebaica and liniment. sapon. which has often prevented it. If this should not produce the desired effect, he informs us that two or three tea-spoonfuls of syrup. è mecon. given in the hot fit, will generally mitigate the symptoms. But for the entire removal of the disease, after purging with magnesia alba, he prescribes a dram of the extract. cinchonæ with a few drops of tinct. thebaic. in a clyster, to be repeated every three hours for a child of about a year old. When the stomach is oppressed with phlegm, the magnesia frequently occasions vomiting, which should be promoted with warm water. The constant heaviness of the head occasioned by those fevers in such tender constitutions is best relieved by the application of a blister to the back.

Cinchona has also proved effectual for the cure of intermittents in children, even when externally applied, by putting the powder of it into a quilted waistcoat. Of its efficacy in this way several instances are related by Dr Samuel Pye in the second volume of Medical Observations and Inquiries. In short, so effectual was it found in removing these fevers when properly applied, that of between four and five hundred afflicted with them in the year 1765, Dr Lind lost only two, neither of whom had taken this medicine.

In all these cases, a vomit was administered whenever the patient complained of a sickness and retching to vomit, or was seized with a spontaneous vomiting; and cinchona was never given till this sickness was removed, or a purgative taken to clear more perfectly the whole alimentary canal. In those patients who were troubled with a cough, attended with a pain in the side affecting the breathing, when the pain was not relieved by warm fomentations, the balsamum anodynum, or by a blister, Dr Lind generally ordered a few ounces of blood to be taken away, and endeavoured to stop the fever as soon as possible by the administration of cinchona; having found that every return of the fever increased all such pains.—When the headach was very violent, and harassed the patient during the intermissions, the success of cinchona was rendered more complete by the application of a blister to the back.—A giddiness of the head, which is the symptom most commonly remaining after even a slight intermitting fever, was generally relieved by the sal C. C. and cinchona in wine. The former of these was administered in the following manner.

℞. Aq. Alex. Simp. ℥vii.
Sal C. C. ʒss.
Syr. è Cort. Aurant. ℥i. M. f. julep. Cap. cochlear. ij. subindè.

If from the continuance of the fever the patient was distressed with a flatulence, a distention of the abdomen, and a swelling of the legs, a spoonful of tinctura sacra, with the addition of 30 drops of the spirit. lavend. compos. was ordered to be taken every night.—A continuance

Febres. continuance of cinchona, a change of air, and the cold bath, were often found requisite to prevent a relapse.

Such is the method of cure recommended by this experienced author, who has also discovered the efficacy and success of opium in intermitting fevers. He informs us, that he has prescribed an opiate to upwards of 300 patients labouring under this disease; and he observed, that, if taken during the intermission, it had not the least effect either in preventing or mitigating the succeeding paroxysm: when given in the cold fit, it once or twice seemed to remove it; but when given half an hour after the commencement of the hot fit, it generally gave immediate relief.—When given in the hot fit, the effects of opium are as follow: 1. It shortens and abates the fit; and this with more certainty than an ounce of cinchona is found to remove the disease. 2. It generally gives a sensible relief to the head, takes off the burning heat of the fever, and occasions a profuse sweat. This sweat is attended with an agreeable softness of the skin, instead of the burning sensation which affects patients sweating in the hot fit, and is always much more copious than in those who have not taken opium. 3. It often produces a soft and refreshing sleep to a patient tortured in the agonies of the fever, from which he awakes bathed in sweat, and in a great measure free from all complaints.

Dr Lind has always observed, that the effects of opium are more uniform and constant in intermitting fevers than in any other disease, and are then more quick and obvious than those of any other medicine. An opiate thus given soon after the commencement of the hot fit, by abating the violence and lessening the duration of the fever, preserves the constitution so entirely uninjured, that, since he used opium in agues, a dropsy or jaundice has seldom attacked any of his patients in those diseases. When opium did not immediately abate the symptoms of the fever, it never increased their violence. On the contrary, most patients reaped some benefit from an opiate given in the hot fit, and many of them bore a larger dose at that time than they could do at any other. He assures us, that even a delirium in the hot fit is not increased by opium, though opium will not remove it. Hence he thinks it probable, that many symptoms attending these fevers are spasmodic; but more especially the headach. However, if the patient be delirious in the fit, the administration of the opiate ought to be delayed until he recovers his senses, when it will be found greatly to relieve the weakness and faintness which commonly succeed the delirium. Dr Lind is of opinion, that opium in this disease is the best preparative for cinchona; as it not only produces a complete intermission, in which case alone that remedy can be safely administered; but occasions such a salutary and copious evacuation by sweat, as generally to render a much less quantity of cinchona requisite. He commonly prescribes the opiate in about two ounces of tinctura sacra, when the patient is costive, who is to take the cinchona immediately after the fit. By these means the paroxysm is shortened, and the intestines are cleansed, previous to the administration of cinchona; as the opiate doth not prevent, but only somewhat retards, the operation of the purgative. When a vomit is given immediately before the paroxysm, the administration of the opiate should be postponed till the hot fit be begun.

Tertian. In the administration of cinchona, care should be taken that it be of a good quality. And different opinions have been entertained with respect to the choice, even where there is no reason to believe that it has been adulterated by the mixture of other articles. For a long time, the preference was given to small quilled pieces of pale-coloured bark; but of late the red bark, which is generally in larger masses, of an apparently coarser texture, and evidently of a more resinous nature, has been highly celebrated by Dr Saunders and others. And in cases where it does not disagree with the stomach or excite looseness, it is admitted by the most accurate observers to be more powerful in preventing the return of intermittents. Whether the red bark be the product of a different species of the cinchona, or be obtained as well as the pale quilled bark from the cinchona officinalis, is not yet ascertained with sufficient accuracy. Cinchona of a yellow colour has lately been imported into Britain and highly extolled. Its botanical history is not ascertained. It contains more bitter extractive matter, and more tannin and gallic acid, than either the pale or red; but less gum than the pale, and less resin than the red. It seems to produce the same medical effects in smaller doses. And it has sometimes succeeded in the cure of intermittents where the pale and red cinchona have before been employed in vain.

A species of cinchona, distinguished by the title of *cinchona Jamaicensis*, has been discovered in Jamaica and other islands in the West Indies. A very accurate description of it has been given by Dr Wright of Jamaica in the Philosophical Transactions of London. The bark of this species also has been recommended in the cure of intermittents; but the advantages of it have not hitherto been sufficiently confirmed by experience.

The barks of various trees readily cultivated in Britain, particularly different species of the salix, the prunus, the fraxinus, and the quercus, have by some been represented as no less efficacious than the cinchona. But we may safely venture to assert, that although several of them may possess some power in stopping intermittents, yet that none hitherto tried can be considered as in any degree approaching to the cinchona in point of efficacy.

But although the Peruvian bark be the best cure for intermittents hitherto discovered, yet while it can by no means be represented as the only cure, it is very certain that other remedies have in different cases succeeded after the cinchona has failed. Cures have often been obtained by the use of different aromatics, bitters, and astringents. Many articles from the mineral kingdom also have been employed with advantage. And intermittents have unquestionably been in certain cases stopped by different preparations of iron, zinc, copper, lead, and mercury. But of all the articles of this nature, arsenic of late has been the most celebrated. Arsenic is on good grounds conjectured to be the basis of an article much employed in the cure of intermittents in some of the countries where they are most prevalent, and sold under the title of the *tasteless ague drop*. The great success attending the use of this article, led Dr Fowler, an ingenious physician of Stafford, to examine it with particular attention. And in a treatise which he has lately published, entitled *Medical Reports* on the effects of arsenic in the cure of agues, he has given a formula for an arsenical solution,

solution, which he has found very successful in affections of this kind, and which is probably very nearly the same with the tasteless ague drop. Dr Fowler's mineral solution, as he styles it, is formed by dissolving 64 grains of arsenic and as much fixed vegetable alkaline salt in a pound of distilled water. This solution is given in doses from three to 12 drops, varied according to the condition of the patient, and repeated two or three times a-day. And where the cinchona has failed in stopping intermittents, it seems to be one of the most powerful remedies yet discovered. But after all remedies prove ineffectual, intermittents are often stopped by a change of season and of situation.

But besides the remedies employed in tertians and other intermittents, with the view of preventing the return of paroxysms, it is often also necessary to employ powerful articles with other intentions, particularly to mitigate and shorten the paroxysm when present; to obviate urgent symptoms, especially those of an inflammatory or putrid nature; and to obtain a complete apyrexia or intermission from fever after the paroxysm has ceased. With these intentions, recourse is not unfrequently had to emetics, laxatives, blood-letting, opium, diluents, or sudorifics, as the circumstances of the case may require.

The *Irregular* or *Spurious* TERTIAN.

Sp. I. var. 1. B.

Tertiana notha sive spuria, *Sauv.* sp. 2. *Sennert. Cleghorn. Hoffman.*

The characteristic marks of this fever are, that its paroxysms last longer than 12 hours, and consequently it inclines more to the quotidian or continued fever than the former. Its paroxysms have no stated hour of attacking. The cure, however, is precisely the same with that above described, observing the proper cautions already mentioned with regard to the use of the cinchona.

The *Double* TERTIAN. Sp. 1. var. 2. C.

Tertiana duplex, *Sauv.* sp. 13. *Vog.* G. 12. *Sennert. Cleghorn.*
Duplicata, *Lin.* 18.

The double tertian comes on every day; but differs from the quotidian in this, that its paroxysms do not answer to each other singly, but alternately. The first day, for instance, the fit will come on in the forenoon, in the second in the afternoon, the third in the forenoon, and the fourth in the afternoon.

Of these fevers we shall give the following description from Cleghorn's treatise on the diseases of Minorca: "They are called *double tertians* when there are two fits and two intervals within the time of each period. But commonly there is some difference between the two fits, either in respect of the hour they come at, the time of their duration, or the nature and violence of their concomitant symptoms. Some double tertians begin in this manner.—On the evening of Monday, for example, a slight fit comes on, and goes off early next morning; but on Tuesday, towards the middle of the day, a more severe paroxysm begins, and continues till night. Then there is an interval to Wednesday evening, when a slight fit commences a new period of the fever, which proceeds in the same manner as the first; so that according to the way physicians calculate the days of diseases, (by beginning to reckon from the first hour of their invasion,) both paroxysms happen on the odd days, while the greatest part of the even days is calm and undisturbed. But in most double tertians the patient has a fit every day of the disease; the severe one commonly appearing at noon upon the odd days, the slight one towards evening on the even days; though sometimes the worst of two fits happen on the even days.

"There is a tertian fever sometimes to be met with, during each period of which there are three different fits, and as many intervals. For example, towards Monday noon the patient is seized with a paroxysm, which declines about five or six o'clock the same evening; a few hours after, another fit begins, and continues until morning; from which time there is an interval to Tuesday evening, when a third fit comes on, and lasts most part of the night. On Wednesday there are again two paroxysms, as on Monday, and on Thursday like that of Tuesday; and thus the fever goes on with a double fit on each of the odd days, and a single fit on the even days.

"In double tertians, that interval is the most considerable which follows the severe fit; for the slight fit oftener ends in a remission than intermission, and frequently lingers till the other approaches: Hence it is, that the night preceding the vehement fit is much more restless than that which comes after it, as has been observed by Hippocrates. In double tertians, the vehement fit often comes on a little earlier in each period, while the slight fit returns at the same hour, or perhaps later and later every second day: so that the motions of one have no influence on those of the other; from whence it appears that each of these fits hath its own proper independent causes."

Duplicated TERTIAN. Sp. I. var. 2. D. 129

Tertiana duplicata, *Sauv.* sp. 14. *Jones. River.*

This hath two fits on the same day, with an intermediate day on which there are none. This also does not differ in any remarkable particular from those already described.

The *Triple* TERTIAN. Sp. I. var. 2. D. 130

Tertiana triplex, *Sauv.* sp. 15. *Cleghorn.*
Semitertiana, *Hoffman.*
Semitertiana primi ordinis, *Spig.*

This differs from the former in having a single and double fit alternately: thus, for instance, if there be two fits the first day, there is only one the second, two the third, one the fourth, &c. Its cure is the same as before.

The *Semi*-TERTIAN. Sp. I. var. 2. F. 131

Hemitritæus, *Cels.*
Semitertiana, *Cleghorn.*
Semitertiana secundi ordinis, *Spig.*
Amphimerina hemitritæus, *Sauv.* sp. 8.
Amphimerina pseudo-hemitritæus, *Sauv.* sp. 9.

The semitertian is described by Dr Cullen as having only an evident *remission* between its paroxysms; more remarkable between the odd and even day, but less so between the even and odd one. For this reason, he adds, that possibly some semitertians ought rather to

Febres. to be classed among the remittents; and owns that it is difficult to settle the boundaries between them. But Cleghorn, whom he quotes, describes it in the following manner. "A fit begins on Monday noon, for example, and goes off the same night. On Tuesday afternoon a second fit comes on, and gradually increases till Wednesday night, when it terminates. On Thursday morning there is such another interval as happened on Tuesday morning: But on Thursday afternoon another long fit like the preceding commences; and returning regularly every second day, leaves only a short interval of ten or twelve hours during the eight and forty.

Concerning the cure of these fevers Dr Cullen observes, that though no entire apyrexia occurs, cinchona may be given during the remissions: and it should be given even though the remissions be inconsiderable; if, from the known nature of the epidemic, intermissions or considerable remissions are not to be expected, and that great danger is apprehended from repeated exacerbations.

132 The *Sleepy* TERTIAN. Sp. I. var. 3. G.

Tertiana carotica, *Sauv.* sp. 10. *Werlhof.*
Tertiana hemiplegica, *Sauv.* sp. 20. *Werlhof.*
Quotidiana soporosa, *Sauv.* sp. 8. *Car. Pis.*
Febris caput impetens, *Sydenham*, ep. ad. R. Brady.

This, according to Vogel, is a most dangerous species, and very commonly fatal; for which reason he ranks it amongst those intermittents which he calls *malignant*. Sometimes he tells us the alarming symptom of a sleepiness comes on, not at the beginning of the disease, but will unexpectedly occur during the third, fourth, fifth, or sixth paroxysm. It commonly begins with the cold fit, and continues during the whole time of the paroxysm, and, becoming stronger at every succeeding one, at last terminates in a mortal apoplexy. Sometimes fevers of this kind rage epidemically. Vogel relates, that he saw a simple tertian changed into one of these dangerous fevers. The patient was a woman of a delicate constitution, and the symptoms appeared in consequence of her being put in a violent passion: however, it occurred but once, and she recovered. Hoffman mentions a carus in a double tertian occurring seven times without proving mortal; though Vogel says, that the powers of nature are very seldom sufficient to conquer the disease.

In 1678, Dr Sydenham tells us that intermittents raged epidemically at London, where none had appeared before from 1664. Of them "it is to be noted (says he), that though quartans were most frequent formerly, yet now tertians or quotidians were most common, unless the latter be entitled double tertians: and likewise, that though these tertians sometimes began with chilness and shivering, which were succeeded first by heat, and soon after by sweat, and ended at length in a perfect intermission, returning again after a fixed time; yet they did not keep this order after the third or fourth fit, especially if the patient was confined to his bed and used hot cardiacs, which increase the disease. But afterwards this fever became so unusually violent, that only a remission happened in the place of an intermission; and approaching every day nearer the species of continued fevers, it seized the head, and proved fatal to abundance of persons."

From this description of Sydenham's we may have an idea of the nature of the disease. As to its cure he strongly recommends cinchona; telling us, that, e en in the *most continued* kind of intermittents, "the nearer the intermittent approaches to a continued fever, either spontaneously, or from using too hot a regimen, so much the more necessary is it to exhibit a larger quantity of the bark; and that he took advantage of a remission, though ever so small."

The *Spasmodic* or *Convulsive* TERTIAN. Sp. I. var. 3. H.

Tertiana asthmatica, *Sauv.* sp. 6. *Bonnet.*
Tertiana hysterica, *Sauv.* sp. 8. *Wedel.* A. N. C. Dec. I. A. II. obs. 193.

Tertiana tetanodes Med. Beobacht I. Band.
Tetanus febricosus, *Sauv.* G. 122. sp. 10. *Stork.* Ann. Med. II.

Tertians of this kind occur with very different symptoms from those of the true ones, and sometimes even with those which are very extraordinary. In some they are attended with symptoms of asthma, in others with those of hysterics, in others with convulsions. Where the symptoms of asthma occur, the disease must be treated with diuretics and antispasmodics joined with cinchona. In the hysteric asthma the fit comes on with cold, yawning, cardialgia, terror and dejection of mind. The disease is to be removed by mild aperients and antihysterics joined with cinchona.

Of the convulsive tertian we have a most remarkable instance in the Edinburgh Medical Essays, vol. v. The patient was a farmer's son about 26 years of age, of a strong plethoric habit of body. He had laboured under an ague half-a year, and had taken a great deal of Peruvian bark. While he was telling his case to the surgeon (Mr Baine of Pembroke), he was suddenly taken with a violent stamping of his feet; and the convulsions gradually ascended from the soles of the feet to his legs, thighs, belly, back, and shoulders. His head was then most violently convulsed, with a total deprivation of speech; but he had a most dismal vociferation, which might have been heard at a considerable distance, his abdomen and thorax working and heaving violently and unusually in the mean time. This fit having lasted half an hour, a profuse sweat broke out over all his body, which relieved him; and he then became capable of answering such questions as were put. These extraordinary fits, he said, had been occasioned by a fright, and his neighbours had concluded that he was bewitched. They returned sometimes twice a-day, and always at the times the ague used to return. During the paroxysm his pulse was very high and quick, his face much inflamed, and his eyes ready to start out of his head. After the

the fit was over, he complained of a most torturing pain of the bowels. His tongue was generally moist, and he had a suppression of urine.—This formidable disease, however, was totally subdued by the use of cinchona, mercurials, antispasmodics, opiates, and saline draughts.

The *Eruptive* TERTIAN. Sp. I. var. 3. I.

Tertiana petechialis, *Sauv.* sp. 4. *Donat. Lautter.*

Tertiana scorbutica, *Wedel.* A. N. C. Dec. I. A. II. obs. 193.

Tertiana urticata, *Sauv.* sp. 22. *Planchon.* Journ. de Med. 1765. *Cleghorn.*

Tertiana miliaris, *Sauv.* sp. 21. *Walthieri* de Med. Ger.

This species of tertian is accompanied with red or livid blotches on the skin, or an eruption like that occasioned by the stinging of nettles. In the latter case Dr Cleghorn says the disease is very dangerous; and as the former indicates an incipient dissolution and putrefaction of the blood, it must also be reckoned of very dangerous tendency.

The *Inflammatory* TERTIAN. Sp. I. var. 3. K.

Tertiana pleuritica, *Sauv.* sp. 4. *Vales. Lautt.*

Pleuritis periodica, *Sauv.* G. 103. sp. 14.

Tertiana arthritica, *Sauv.* sp. 5. *Morton. Lautt.*

Sauvages informs us, that he has seen a true and genuine pleurisy having all the pathognomic signs of the disease, but assuming the form of an intermittent; that is, the patient is one day affected with the pleurisy, and the next seemingly in perfect health. He also tells us, that in the month of May 1760, a tertian raged epidemically, which after the third fit imitated a pleurisy, the pain of the side, and difficulty of breathing coming regularly on, and the fever from an intermittent becoming remittent; the blood had also the same appearance with that of pleuritic persons, and the distemper yielded to bleeding and gentle cathartics.—Morton also informs us, that he has observed similar disorders an hundred times, which were always certainly and safely cured by the Peruvian bark.

The TERTIAN *complicated* with other *Disorders.* Sp. I. var. 4.

Tertiana scorbutica, *Sauv.* sp. 9. *Etmuller, Timæus.*

Tertiana syphilitica, *Sauv.* sp. 17. *Deidier.*

Tertiana verminosa, *Sauv.* sp. 18. *Stisser.* in act. Helmstad. *Lancis.* de noxiis palud. *Pringle. Ramazzini. Van den Bosch.* de const. vermin.

The scorbutic tertian, according to Sauvages, is exceedingly anomalous, its periods being sometimes much anticipated, and sometimes much postponed. It is exceedingly obstinate, and will return if the body be not cleared of its scorbutic taint. The patient is affected with lancinating pains of a wandering nature. The urine lets fall a dusky red sediment, or a thick branny matter is copiously scattered up and down in it, seemingly tinged with blood. The usual symptoms of scurvy, viz. livid spots, and rotten fetid gums, also frequently occur. For this the Peruvian bark is very useful, both as a febrifuge and antiscorbutic.

A tertian accompanied with worms is taken notice of by Sir John Pringle in his treatise on the diseases of the army. The worms, he tells us, were of the round kind; and though we are by no means to reckon them the cause of the fever, they never failed to make it worse, occasioning obstinate gripings or sickness at stomach. In these cases stitches were frequent; but, being flatulent, were not often relieved by bleeding. The worms were discharged by vomiting as well as by stool. For discharging these worms, he commonly gave half a dram of rhubarb with 12 grains of calomel; without observing any inconvenience from such a large dose of mercury. Anthelmintics, which act slowly, had little chance of doing good; for though worms will sometimes lie long in the bowels without giving much uneasiness to a person otherwise well, yet in a fever, especially one of a putrid kind (to which his intermittents always seemed to incline), the worms being disturbed by the increase of heat, and the corruption of the humours in the *primæ viæ*, begin to move about, and struggle to get out. Lancisius, who makes this remark, adds, that upon opening the bodies of some who had died at Rome of fevers of this kind, wounds were found in the intestines made by the biting of the worms; nay, that some of them had even pierced through the coats of the guts, and lay in the cavity of the abdomen. Pringle never had any instance of this; but knew many cases in which the worms escaped by the patient's mouth, though there had been no previous retching to bring them up. One soldier was thrown into violent convulsions, but was cured by the above-mentioned powder.

The TERTIAN *varied* from its *Origin.* Sp. I. var. 5. 137

Tertiana accidentalis, *Sauv.* sp. 12. *Sydenham.*

Tertiana à scabie, *Sauv.* sp. 12. *Juncker*, tab. 80. *Hoffman*, II. p. 12.

The existence of fevers of this kind, as we have already observed, is denied by Dr Cullen; the accidental fever of Sauvages was said to arise from any slight error in the non-naturals, and consequently was very easily cured. That which arose from the repulsion of the itch, was cured as soon as the eruption returned.

Tertia

The remittent fevers are much more dangerous than the true intermittents, as being generally attended with much greater debility of the nervous system and tendency to putrescency in the fluids than the latter. Sauvages divides his tritæophya, a remittent tertian, into the following species:

1. *Tritæophya syncopalis*, or that attended with fainting. It begins like a tertian, with cold succeeded by heat and profuse sweating; but attended with much more dangerous symptoms, such as cardialgia, enormous vomiting, great weakness, small contracted pulse, coldness of the extremities, and, unless timely assistance be given, kills during the second or third paroxysm.

2. The *causus*, or burning fever of Hippocrates, returns every third day without any new sensation of cold; and is attended with great thirst, heat, but without diarrhœa or sweat, and continues only for one week or two at the utmost. It attacks chiefly young people of a robust and bilious habit of a body, who have been accustomed to much exercise, and exposed to the sun during the heats of summer, and have also used a phlogistic regimen. The tongue is dry, sometimes black; the urine of a red or flame colour; together with pain of the head, anxiety, and sometimes other symptoms still more dangerous.

3. *Tritæophya Vratislaviensis*, was a pestilential disease occasioned by famine, during which the people fed on putrid aliments: the air was infected by the vast number of bodies of those slain in battle, and the inhabitants were also dejected by reason of being deprived of their harvest, and other calamities; to all which was added the continuance of a calm in the atmosphere for a long time. It began with an acute fever, leipyria or coldness of the external parts and a sensation of burning heat inwardly; general weakness; pain of the head and præcordia; serous or bilious diarrhœa; a delirium, in some furious, and accompanied with a dread of being exposed to the air; on the second day the thirst was violent, attended with a bilious vomiting, as well as diarrhœa, tough viscid spitting, fainting, burning heat in the bowels, the tongue dry and seeming as if burnt with a hot iron, a suppression of the voice, anxiety, stupor, after which quickly followed convulsions and death. In some fevers leipyria came on with an exceeding great cold of the extremities, presently followed by an intolerable heat of the viscera, with symptomatic sweats, violent diarrhœa, followed by a very itchy miliary eruption. On the fourth day came on copious sweats, spasms of the lower jaw, nausea, involuntary passing of urine, slight delirium, a flux of ichorous matter from the nostrils, an exceeding tough spitting, an epilepsy, and death. Professor Hahn, who gives

Tertiana.

gives the history of this disease, was himself attacked by it, and suffered in the following manner: On the first day was a violent feverish paroxysm without rigor, a sharp pain in the occiput, and immediately an inflammatory pain over the whole head; the feet were extremely cold, and the extremities rigid with spasms. The pain continued to increase daily to such a degree, that the contact of the air itself became at last intolerable; a dejection of mind and incredible weakness followed; he passed restless nights with continual sweating, heavy and pained eyes, and an universal sensation of rheumatism over the whole body. On the third day the pains were assuaged, but he had a very bad night. On the fourth day all the symptoms were worse, the feet quite chilled, the hands very red and agitated with convulsive motions; he was terrified with apprehensions of death, and had a vomiting every now and then: this day sponges dipped in cold water were applied over the whole body, and he used cold water for his drink. On the eighth day the pulse was convulsive; and the pains were so violent that they made him cry out almost continually. On the ninth day he was delirious, and threw up some grumous blood. On the 11th his pulse was more quiet, and he had a sweat; a decoction of cinchona was given: his voice was broken, his speech interrupted, and his teeth chattered upon one another. On the 12th his jaw was convulsed, he had a risus sardonicus, and deafness; after which the paroxysms returned less frequently, and only towards night. On the 14th he had a chilling cold over the whole body, a cold sweat; frequent lotions were applied, and all the symptoms became milder. On the 18th he had a quick delirium, but fainted as soon as taken out of bed; a sensation of hunger, followed by copious sweats; profound sleep; an aversion from noise; every thing appeared new and extraordinary. On the 36th a cholera; on the 48th a scaling off of the skin, and falling off of the nails. This epidemic carried off above 3000 people at Warsaw. Frequent lotion of the body either cold or tepid, watery glysters, and the copious introduction of watery fluids under the form of drink, were of service. But the most favourable crisis was under the form of some cutaneous eruption.

142 4. *Tritæophya typhodes.* The principal symptom of this fever was a continual sweat with which the patients were almost always wet; with paroxysms returning every third day. Sauvages tells us, that he had twice an opportunity of observing this fever; one was in the teacher of an academy, about 40 years of age, and of a melancholic temperament. He sweated every second night so plentifully, that he was obliged to change his linen nine times; and even on the intermediate days was never perfectly free of fever, and had his skin moistened with sweat. The other was of a woman who went about in man's clothes, and was discovered only after her death. The disease began with a slight sensation of cold, after which she sweated for eight hours. It was attended with the highest debility, anxiety, and at the same time an insatiable hunger.

143 5. *Tritæophya elodes*, was an inflammatory epidemic, but not contagious, terminating about the 13th or 21st day. The disease came on in the night time, with disturbed rest, universal weakness, watchings, great heat and sweat, redness of the face and almost of the whole body, sparkling eyes, the tongue dry and white; a hard, tense, and turgid pulse: about the third day a kind of frenzy frequently came on with the feverish paroxysm, the forerunner of an universal miliary eruption; or, what was worse, with purple spots so close together, that they looked like an erysipelas of the whole body. Sometimes blisters of the size of small pearls, filled with acrid serum, appeared on the neck, armpits, and trunk of the body, which were of all the symptoms the most dangerous. There was a variety of the disease, which Sauvages calls the *humoralis*, and in which the pulse was soft and feeble, with greater weakness over the whole body, and the disposition to sleep more frequent than in the other; the eyes languid; the tongue very white, but not dry; and worms were sometimes discharged.

6. *Tritæophya assodes.* This species arose from a foulness of the primæ viæ, and the effluvia of waters in which hemp had been steeped. It began with rigor, followed by great heats, restlessness, tossing of the limbs, faintings, immoderate thirst, dryness of tongue, delirium, and at length excessive watchings; these last, however, were less dangerous than vertigo or a comatose disposition, which brought on convulsions or apoplexies. 144

7. *Tritæophya carotica.* This had exacerbations every other evening; and its distinguishing symptom was an excessive inclination to sleep, preceded by a severe headach, and followed by delirium, and sometimes convulsions; the tongue was black, and the patient insensible of thirst after the delirium came on. In those cases where the disease proved fatal, a subsultus tendinum and other alarming symptoms, came on. 145

8. *Tritæophya leipyria* is only a variety of the tritæophya causus, already described. 146

9. *Tritæophya deceptiva.* This species at first assumes the appearance of a continued fever; but afterwards degenerates into a remittent, or even an intermittent. It is described by Sydenham, but attended with no remarkable symptoms. 147

10. The last of Sauvages's species of Tritæophya belonging to the remitting tertian is the *Americana.* This, according to Sauvages, is the ardent fever with which the Europeans are usually seized on their first arrival in America, and generally carries off one half of them. Of this there are two varieties, the *very acute* and the *acute*. The very acute ends before the seventh day. It comes on a few days after the person's arrival, with loss of appetite, with dyspnœa and sighing from weakness, headach, lassitude, and pain of the loins: a pyrexia succeeds, with great thirst, sweat, and heat; the sickness increases, nausea comes on, with vomiting of porraceous bile; the tongue rough, the extremities often cold; watching, furious delirium; and the patient frequently dies on the third day. Copious sweats, and a plentiful hæmorrhagy from the nose on the fifth day, but not sooner, are serviceable; but a bilious diarrhœa is the best crisis of all. 148

The acute kind terminates most frequently on the ninth, but very rarely goes beyond the fifteenth day. Death frequently comes on between the fourth and seventh days. It begins with headach, pain in the loins, and sometimes shivering; great lassitude, dyspnœa, Febres. pnœa, thirst; burning fever, increasing every third day; inflation of the abdomen, pain at the pit of the stomach, nausea, and bilious vomiting. Such is the state of the disease within twenty-four hours. The eyes are red, and full of tears; the urine pellucid; there is a low delirium, and continual anxiety; the tongue is dry and red, and sometimes, though rarely, black, which is a still worse sign; the pulse, formerly strong and full, sinks about the fourth day, and becomes tense and spasmodic: if a carus then comes on, the patient dies the fifth or sixth day; but if the pulse keeps up, and no carus comes on, a crisis is to be expected by sweat, by a copious hemorrhagy from the nose, or, which is still more safe, by a bilious diarrhœa, which is never salutary if it comes on before the fifth day.

To the remitting tertian also belong the following species mentioned by Sauvages, viz.

149 1. *Tertiana subcontinua.* This begins like a genuine tertian, and at first hath distinct paroxysms; but these grow gradually more and more obscure, the disease acquiring daily more of the appearance of continued fever, by which it is to be distinguished from the other varieties of this species. It is not unfrequently joined with those symptoms which attend the fatal fever already mentioned; as cardialgia, cholera, syncope, &c. but in a much less degree. The disease commonly begins with little or no sense of cold, but rather a sensation of heat; when the tertian is doubled, it has first a slighter and then a more severe fit; and thus goes on with an exacerbation on the even days: and though it should change from a double into a single tertian, we are still to suspect it, if a weak fit is the forerunner of a very strong one. This change of the tertian into a continued fever is also to be prognosticated if a heat remarkable to the touch is perceived on the day of intermission, together with some disturbance of the pulse, thirst, and dryness of the tongue; all of which show a tendency to inflammation: the same is foretold by the urine being in small quantity, and very red, or of a saffron colour; also an ulcerous or aphthous inflammation of the throat, with difficulty of swallowing, or any very severe symptom coming on in the beginning of the disease, excepting only a delirium, which is easily removed.

150 2. *Quotidiana deceptiva.* This is a disorder of an inflammatory kind, with a strong tendency to putrescency, and sometimes assumes the form of a quotidian. In it the patient frequently complains of cold when he really is hot, and the remission is very indistinct. The disease is known by the great languor of the patient and the foulness of his tongue.

3. *Amphimerina cardiaca* is an acute malignant fever,
151 with daily exacerbations, attended with fainting and vomiting of green bile. Afterwards, the weakness increasing, the patient's extremities grow cold, and a profuse sweat comes on, which is frequently succeeded by death on the fourth day. Another species resembling this Sauvages calls the *syncopalis;* but the cardiaca differs from it in being attended with cardialgia.

4. *Amphimerina paludosa.* This is the fever described
152 by the British physicians under many different names, and appearing under various forms, according to the different constitutions of the patients. This fever in the East Indies, according to Dr Lind of Windsor, generally comes on suddenly, and begins with a sense of debility and a very great lowness of spirits. These symptoms are attended with a greater or less degree of chilliness, vertigo, nausea, very acute pains in the head and loins, and a trembling of the hands; the countenance is pale, the skin commonly very dry and corrugated, the eyes dull and heavy, the pulse quick and small, the breath generally difficult, and interrupted with hiccough.

Tertian.

As the paroxysm increases, the chilliness now and then gives way to irregular heats, which soon become violent and permanent; the nausea likewise increases; and in some there comes on a vomiting, in which they throw up a great deal of bile. Sometimes bile is likewise voided by stool. The skin grows red; the eyes appear small, and sometimes not a little inflamed. The pulse becomes fuller, and the breath more difficult, attended with great restlessness and a troublesome thirst; notwithstanding which (so great is the nausea) the patient cannot endure any kind of liquids. The tongue becomes foul, and the pain of the head and loins more violent; a delirium then follows; a slight moisture appears on the face, and from thence spreads to the other parts; whilst the violence of the other symptoms abates, and shows the beginning of a remission, which is completed by plentiful sweats.

On the fever's remitting, the pulse returns almost to its natural state; the pains of the head and loins still continue, though somewhat less violent, as likewise the nausea and want of appetite. When the disease gains strength, the remission is scarcely obvious, and is immediately followed by another paroxysm; which begins, not indeed with so great a shivering, but is attended with a greater pain of the head, the greatest anxiety, a heartburn, nausea, vomiting, and bilious stools. The matter most commonly evacuated by vomit and stool is whitish like chalk and water, or curdled milk which is vomited by sucking children, when the curd is much broke down. A heat, immoderate thirst, and delirium now come on. The tongue becomes more foul; the teeth and inside of the lips are covered with a black crust; the breath grows hot and fetid: another remission ensues, attended with a sweat; but this remission is both shorter and less obvious than the first.

This second remission is succeeded by a paroxysm, in which the symptoms are far more violent than in the former; that which the patient discharges by vomiting and purging is more fetid; the mouth, teeth, and inside of the lips, are not only covered with a black crust, but the tongue becomes so dry and stiff, that the patient's voice can scarce be heard. Violent delirium, with restlessness and anxiety, come on chiefly during the paroxysm; nor do these symptoms abate till the fever remits, and the patient sweats.

When the fever becomes so violent, during the third fit, as to end in death, which is often the case, some of the sick have a coma; in others the delirium becomes more violent. The discharges now become more fetid, and have a cadaverous smell; the stools are involuntary; the pulse is so quick, small, and irregular, that it is scarce to be counted, or even felt; a cold sweat is diffused over the whole body, especially the head and neck: the face becomes Hippocratic and convulsed; the patient picks the bed-clothes; a subsultus tendinum comes on; the sick lie constantly on their backs, and insensibly

Fevers. Tertiana.

insensibly slide down to the foot of the bed; their extremities grow cold; they are then seized with convulsions, with which the scene closes.

In this fever, the urine, which at the beginning is pale, becomes of a deeper colour by degrees, but without depositing any sediment. There seldom or never appear any petechiæ, and the prickly heat which was before on the skin vanishes on the first appearance of the fever. But though these were the general symptoms of this disorder, they varied in the different subjects, and at different seasons of the same year. The pulse, for example, in some, was quick in the beginning of the disorder; in others, it varied with the other symptoms. The skin was generally dry in the beginning of the fit; but in some it was moist, and covered with sweat from the very beginning of the disease. In the month of September, when the disorder raged most, the remissions were very imperfect and obscure; but, on the return of winter and the healthy season, they became more regular, and the disease assumed the appearance of an intermitting fever, to such a degree as at length not to be distinguished from it. In some the remissions could scarce be perceived, and the fever continued for two weeks without any material change for the better or the worse. At this time numbers were seized with it. When the disorder continued for any time without a change, it generally ended in death; while the weather grew better, it sometimes, in the space of a few days, from a common fever became an intermitting one, and the patient recovered, unless his liver, which was sometimes the case, happened to be affected. The cure of an inflammation of the liver proved uncertain and tedious; as it was commonly followed by a colliquative diarrhœa, which generally endangered the patient's life.—Every succeeding paroxysm was observed to be more dangerous than the preceding; the third generally proved fatal; some died during the first. When this happened, the fever, in the language of the country, was called a *puca*, that is a strong fever.

This disease, according to Dr Lind of Haslar hospital, is the autumnal fever of all hot countries, the epidemic disease between the tropics, and the disease most fatal to Europeans in all hot and unhealthy climates. All authors agree that intermittents in general, but particularly this dangerous kind of them, are produced by heat and moisture, but particularly the evaporation of moisture from marshes. Dr Lind of Windsor remarks, that the European seamen are very subject to the fever above mentioned when they happen to arrive at Bengal in autumn. They are predisposed to it from the nature of their food, their confinement on board, the very great heats to which they are exposed during the voyage, and their lying for hours together exposed to the night colds.

Most of the meat used by the crews of those ships is salted, and often in a putrid state, without any fresh vegetables, they having only biscuits, and some other farinaceous matters. The quantity of the vinous or spirituous liquors allowed them is, in his opinion, by far too small to subdue the putrescent disposition of their animal-food. Their fluids consequently become, from day to day, more and more putrescent, and of course more apt to breed and contract this disorder. This disposition is likewise induced by their being stowed very close together, and that for a considerable length of time, and in a foul air, especially when the weather happens to be too stormy to permit the hatches and portholes to be kept open.

Though the heats they endure in the voyage to India are less considerable than those of the country itself, yet they are too much for an European constitution to bear. The general heat at sea within the tropics is about 84° of Fahrenheit's thermometer, which is sufficient to relax them, and promote a corruption of their humours, especially when it coincides with the above causes. It likewise creates a languor and indolence, which alone are sufficient to increase that putrescence. These causes are apt to be considerably aggravated by the men's being often exposed, when on duty, for hours together, to rain, damp, and cold air; a circumstance which frequently happens to them when working their ships up the river Ganges in the night-time. Hence the perspiration is checked, and the excrementitious fluid which used to be discharged by the skin being retained in the body, contributes, he thinks, very much towards the predisposition to this disease.

But the most powerful of all the remote causes is justly thought to be the effluvia of marshes replete with putrid animal-substances. We have not, however, been able to determine from what kind of putrid animal-substances these effluvia derive their virus. For that every kind of putrefaction has not such an effect appears from this, that neither practical anatomists, nor those who by their trades are exposed to the putrid effluvia of animals, for instance such tanners and butchers as keep their shops and stalls very dirty, are more subject than others to putrid diseases. Nor are the ship-stewards and their servants, whose business it is to deliver out the provisions to the ships crews, and who spend the most of their time amongst the putrid and rancid effluvia of the places in which those provisions are kept, more subject to putrid fevers than their ship-mates. But whatever be in this, we are well assured that some particular putrid fermentations produce noxious vapours, which, united with those of marshes, render them more pernicious. Hence evidently proceeds the extreme unhealthfulness of a place called *Culpi*, on the eastern bank of the Ganges. The shores about it are full of mud, and the banks covered with trees. Opposite to the place where the ships lie there is a creek, and about a mile from its entrance stands the town of Culpi: the ships lie about a mile from the shore. None of the sailors on board the ships stationed at this place enjoyed their health. The burying ground also contributed not a little to spread the infection. The ground being marshy, the putrid water flowed from the old graves into the new ones, which infected the grave-diggers and those that attended the funerals; and from this cause many were suddenly seized while they were performing the last duty to their companions. This place has ever been remarkable for the unhealthfulness of its air. It was once customary to send some of the Company's servants here to receive the cargoes of the ships, and send them to Calcutta; but so many of them died on this duty, that the Company was at length obliged to dispense with it.

Hence it plainly appears, how apt putrid animal and vegetable substances are to render the effluvia of fenny

Febres.

fenny places more pernicious than they would otherwise be. The reason why great inundations of the Nile and Ganges are followed by a healthy season is, that by this means the putrid animal and vegetable substances dispersed over the contiguous countries are carried off into the sea.—The noxious vapours arising from fens spread but a little way. Dr Lind has often known ships crews at a very little distance from the shore quite free from this disorder. But although these marsh miasmata first bring on the disease, yet contagion particularly spreads it, and renders it more epidemic. Thus the Drake East Indiaman continued free from the disorder for two weeks together, when she had no communication with the other ships; but as soon as the disorder was brought on board, many were seized with it within a few days in such a manner as to leave no room to entertain the least doubt concerning its contagious nature.

Dr Lind of Haslar hospital has given a very curious and learned account of the appearance of this fever throughout the various parts of the globe. It was very common in England in the years 1765 and 1766, one obvious cause of which was the prevalence of the eastern wind. This wind in England is often said to bring with it a fog from the sea; but the truth of the matter is, that in many places of this island the east-wind frequently raises a copious vapour from water, mud, and all marshy or damp places. To this exhaling quality of the eastern wind Dr Lind has often been an eye-witness. When the wind changes to the east, the mud sometimes sends up a vapour as thick as smoke; and the doctor has observed two fish-ponds in his neighbourhood, one of fresh and the other of salt-water, which on the approach of an easterly wind sometimes also emit a dense vapour, as from a pot of boiling water. In order to view this phenomenon distinctly, the person should stand at about 100 yards distance from the mud or ponds. If the sun shines when the wind changes to the east, he will observe a constant steam of vapours arising out of the ponds, from about five to ten yards in height, while the air about him remains serene. As the vapour or fog arising from other bodies glides along the surface of the earth, and is brought by the easterly wind to the ponds, he will still be able, for some time, to distinguish the vapours ascending perpendicularly out of the ponds from those which are carried in an horizontal direction by the wind; especially if the sun continues to shine, though faintly.

This evaporating quality of the east-wind seems to manifest itself also by its effects both on the thermometer and the human body; for a thermometer hung over a damp piece of ground during the fogs or exhalations arising from it, will often indicate a degree of cold below the freezing point. The chilliness of the body, so sensibly perceived when in this situation, seems to proceed from the same cause, and to produce nearly the same sensations, which the damp arising from the wet floor of a chamber communicates to those who happen to be in it.

Winds are not constant in their effects. As we have sometimes warm weather with a north-wind, and sometimes very little heat with one blowing from the south; so the fogs attending an east-wind are not constant, neither is the evaporation above-mentioned at all times to be perceived. It is possible, however, that in all this there may be a deception; and that instead of supposing the quantity of vapours exhaled to be increased by an easterly wind, the coldness of that wind may only condense and render visible the vapours in the air at that time. But even this supposition is liable to great objections, as our coldest north-winds seldom or never produce such an effect, but on the contrary are attended with dry and serene weather.

Tertii.

Be this as it will, however, an east-wind is usually accompanied with a cold, damp, and unwholesome vapour, which is observed to affect the health both of animals and vegetables, and in many places to produce obstinate intermitting fevers, and also to occasion frequent relapses. In particular spots of the low damp island of Portsea, the ague frequently prevails during the autumnal season, and in some years is much more frequent and violent than in others. It is also observable, that this disease always attacks strangers, or those who have formerly lived on a drier soil, and in a more elevated situation, with greater severity than those who are natives of the island.

The year 1765 was remarkable, not only for the long continuance of the easterly winds, but for an excessive degree of heat, which produced a more violent and general appearance of those diseases than had been known for many years before. In the month of August the quicksilver in Fahrenheit's thermometer often rose to 82° in the middle of the day. This considerable addition of heat, together with the want of refreshing rains, greatly spread the fever, increased its violence, and even changed its form in many places. At Portsmouth, and throughout almost the whole island of Portsea, an alarming continual or remitting fever raged, which extended itself as far as Chichester. At the same time, the town of Gosport, though distant only one mile from Portsmouth, enjoyed an almost total exemption from sickness of every kind; whereas in the neighbouring villages and farm-houses, a mild regular tertian ague affected whole families. The violence of the fever, with its appearances in a continued, remitting, or intermitting form, marked in some measure the nature of the soil. In Portsmouth the symptoms were bad, worse at Kingston, and still more dangerous and violent at a place called *Half-way Houses*; a street so named, about half a mile from Portsmouth, where scarcely end in a family escaped this fever, which generally made its first attack with a delirium. In the large suburb of Portsmouth called the *Common*, it seemed to rage with more violence than in the town, some parts excepted; but even whole streets of this suburb, together with the houses in the dock-yard, escaped its attack.

The marines, who were three times a week exercised early in the morning on South-sea beach, suffered much from the effect of the stagnant water in an adjoining morass. Half a dozen of them were frequently taken ill in their ranks when under arms; some being seized with such a giddiness of their head, that they could scarcely stand; while others fell down speechless, and upon recovering their senses complained of a violent headach. When such patients were received into the hospital, it was observed that some few had a regular ague, but that far the greater number laboured under a remitting fever, in which sometimes indeed there was

Fevers. was no perceptible remission for several days. A constant pain and giddiness of the head were the most inseparable and distressing symptoms of this disease. Some were delirious, and a few vomited up a quantity of bile; but in all the countenance was yellow. A long continuance of the fever produced a dropsy or jaundice, or both. Even a slight attack reduced the most robust constitution to a state of extreme debility; and this weakness, together with the giddiness, continued for a long time after the fever. A scabby eruption now and then made its appearance on the lips and the corners of the mouth: but dry itchy spots over the whole body, resembling much the common itch, and seeming to partake of the nature of that disease, were more frequently observed in the patients at Portsmouth, where there was not the least reason to suspect any infection.

Such is the appearance of the remitting fever occasioned by marsh miasmata in England. In the Netherlands its symptoms are not much different. Dr Lind informs us, that at Middleburg, the capital of West Zealand, a sickness generally reigns towards the latter end of August, or the beginning of September, which is always most violent after hot summers. It commences after the rains which fall in the end of July; the sooner it begins the longer it continues, and it is only checked by the coldness of the weather. Towards the end of August and beginning of September it is a continual burning fever, attended with a vomiting of bile, which is called the *gall-sickness*. This fever, after continuing three or four days, intermits, and assumes the form of a double tertian; leaving the patient in a fortnight, or perhaps sooner. Strangers that have been accustomed to breathe a dry pure air do not recover so quickly. Foreigners in indigent circumstances, such as the Scots and German soldiers, who are garrisoned in the adjacent places, are apt after those fevers to have a swelling in their legs and a dropsy; of which many die.

These diseases, the doctor observes, are the same with the double tertians common within the tropics. Such as are seized with the gall-sickness have at first some flushes of heat over the body, a loss of appetite, a white foul tongue, a yellow tinct in the eyes, and a pale colour of the lips. Such as live well, drink wine, and have warm clothes and good lodgings, do not suffer so much during the sickly season as the poor people; however, these diseases are not infectious, and seldom prove mortal to the natives.

Sir John Pringle observes, that the prevailing epidemic of autumn in all marshy countries, is a fever of an intermitting nature, commonly of a tertian form, but of a bad kind; which, in the dampest places and worst seasons, appears as a double tertian, a remitting, or even an ardent fever. But however these fevers may vary in their appearance according to the constitution of the patient and other circumstances, they are all of a similar nature. For though, in the beginning of the epidemic, when the heat or rather the putrefaction in the air is the greatest, they assume a continued or a remitting form, yet by the end of autumn they usually terminate in regular intermittents.

In Zealand where the air is more corrupted than in other parts of the Netherlands, this distemper is called the *gall-sickness;* and indeed both the redundance and depravation of the bile is sometimes so great, that it has been generally ascribed to the corruption and overflowing of that humour. But though it cannot with justice be said to originate from corrupted bile, it is certain that the disease may be continued, and the symptoms aggravated, by an increased secretion and putrefaction of the bile occasioned by the fever. In proportion to the coolness of the season, to the height and dryness of the ground, this distemper is milder, remits or intermits more freely, and removes further from the nature of a continued fever. The higher ranks of people in general are least liable to the diseases of the marshes; for such countries require dry houses, apartments raised above the ground, moderate exercise, without labour in the sun or evening damps, a just quantity of fermented liquors, plenty of vegetables, and fresh meats. Without such helps, not only strangers, but the natives themselves, are sickly, especially after hot and close summers. The hardiest constitutions are very little excepted more than others; and hence the British in the Netherlands have always been liable to fevers.

Tertiana.

By this distemper the British troops were harassed throughout the whole of the war from 1743 to 1747. It appeared in the month of August 1743; the paroxysms came on in the evening, with great heat, thirst, a violent headach, and often a delirium. These symptoms lasted most of the night, but abated in the morning, with an imperfect sweat, sometimes with a hæmorrhagy from the nose or a looseness. The stomach from the beginning was disordered with a nausea and sense of oppression, frequently with a bilious and offensive vomiting. If evacuations were either neglected, or too sparingly used, the patient fell into a continued fever, and sometimes grew yellow as in a jaundice. When the season was further advanced, this fever was attended with a cough, rheumatic pains, and sizy blood. The officers being better accommodated than the common men, and the cavalry who had cloaks to keep them warm, were not so subject to it; and others who belonged to the army, but lay in quarters, were least of all affected; and the less in proportion to their being little exposed to heats, night-damps, and the other fatigues of the service.

In this manner did the remitting fever infest the army for the remaining years of the war; and that exactly in proportion to their distance from the marshy places, of which we have several notable instances in Pringle's observations. In Hungary the same disease appears with still more violence, and is readily complicated with fevers of a truly pestilential nature, by which means it becomes extremely dangerous. Hungary is acknowledged to be the most sickly climate in Europe, and indeed as bad as any in the world. Here it was where the crusaders in only marching through the country to invade Asia, often lost half their number by sickness; and where the Austrians not long since buried, in a few years, above 40,000 of their best troops, who fell a sacrifice to the malignant disposition of the Hungarian air. The reason of this uncommon malignity is, that Hungary abounds with rivers, which, by often overflowing, leave that low flat country overspread with lakes and ponds of stagnating water, and with large unwholesome marshes. So great is the impurity of these stagnated waters, that by them the rivers, even the Danube, whose course is slow, become in some places corrupted and offensive. The air is moist, Febres. moist, and in summer quite sultry. In the nights of harvest, Kramer tells us, it was so very damp, that the Austrian soldiers could not secure themselves from the moisture even by a triple tent-covering. Here epidemical distempers begin constantly to rage during the hottest months of the year; which are July, August, and September: and these complaints, according to the observations of the physician above mentioned, are the same with those which are epidemic upon the coast of Guinea, and in the sickly climates of the East and West Indies, of which malignant fevers of the remitting and intermitting kind are the most common and dangerous.

The heat of the sun in Hungary is more intense than in any other country of Eurpe; and in proportion to the heat is the pestilential quality of the marshy exhalations. It is constantly observed, that the nearer any city or fort is to a morass or a large river with foul aud oozy banks, the more unhealthy are the inhabitants. At such seasons and places, the air swarms with numberless insects and animalcules, a sure sign of its malignant disposition; and the hotter the summer, the more frequent and mortal are the diseases. In short, this country, on account of its unhealthiness, has been termed *the grave of the Germans;* and in Italy, the Campania of Rome is almost equally unhealthy. Lancisius, physician to Pope Clement XI. furnishes us with a very striking instance of the malignant quality of the air of Campania. Thirty gentlemen and ladies of the first rank in Rome having made an excursion, upon a party of pleasure, towards the mouth of the Tyber, the wind suddenly shifting, blew from the south over the putrid marshes, when 29 were immediately seized with a tertian fever, only one escaping.

The island of Sardinia is annually visited with an epidemical sickness, which rages from June to September, and is called by the natives the *intemperies.* In some years there is a want of rain for four or five months; and then it is that this sickness exerts its utmost violence, being always more fatal in some places than in others, and in particular to strangers. Of this the British had a severe proof in 1758.—Admiral Broderick, in the Prince ship of war, anchored in the bay of Oristagni, where 27 of his men, sent ashore on duty, were seized with the epidemical distemper of this island; twelve of them in particular, who had slept on shore, were brought on board delirious. All of them in general laboured under a low fever, attended with great oppression at the breast and at the pit of the stomach, a constant retching, and sometimes a vomiting of bile; upon which a delirium often ensued. These fevers changed into double tertians, and terminated in obstinate quartan agues. It is worthy of remark, that in this ship, which lay only two miles from the land, none were taken ill but such as had been on shore, of whom seven died. The prior of a convent, making a visit to the English officers, informed them, that the intemperies of the island were a remitting or intermitting fever, and that he himself had suffered several attacks of it. Sardinia was formerly so remarkable for its unwholesome air, that the Romans used to banish their criminals thither; and it is at present but thinly peopled, owing to the mortality occasioned by this annual sickness. For although it is about 140 miles long, and in several places 75 miles broad, yet it is computed that the whole number of its inhabitants does not exceed 250,000: an inconsiderable number, when compared with the inhabitants of the lesser, but comparatively more healthful, island of Corsica; though even there the French lost a number of their troops by intermitting and remitting fevers. In the island of Minorca, too, Dr Cleghorn informs us, that fevers of this kind prevail exceedingly; that their types are various, their symptoms violent, the intermissions fallacious, and that they frequently and suddenly prove fatal. It is more than probable, he adds, from the accounts of several physicians and travellers, that epidemical tertians are not wholly confined to the coasts and islands of the Mediterranean, but that they are equally frequent and destructive in many other parts of the globe; and perhaps may be deemed the anniversary autumnal distempers of most hot countries in the world. And though in the mild climate of Britain, a tertian may easily be cured when it is discovered; yet in warm climates, such is the rapid progress of the distemper, that it is necessary to know it in the very beginning, which is very difficult for those who have never seen any but the tertians usually met with in Britain.

Tertiana.

From Dr Cleghorn's account of Minorca, however, it doth not appear why that island shonld be so much infested with fevers of this kind, since it is far from being a marshy country; nay, on the contrary, is very dry. The south wind, he observes, is very unhealthy; and it is the prevalence of this wind which brings on the fever: but still the difficulty is not removed, because the sea air is so far from bringing on such dangerous diseases, that it is one of the greatest preservatives against them. As to the moisture which must necessarily accompany an insular situation, that cannot reasonably be admitted as a cause of this or any other disease. In the London Medical Observations we find a paper on a subject very similar to the present, namely, the mischiefs produced by lying in damp sheets, or being exposed to moist vapour. The author tells us, that he hardly knows a distemper the origin of which has not by some been ascribed to lying in a damp bed, or sitting in a wet room; and yet he does not know any one which will certainly be produced by these causes, and people frequently expose themselves to such causes without suffering any ill effects. "It must be owned indeed, (says he), that the vapours arising from the bilge-water of ships tend to produce a scurvy. The swampy plains also near the mouths of great rivers which are often overflowed, and low grounds which cannot readily be drained, and those tracts of land where the thickness and extent of the woods keep the ground moist and half putrid for want of ventilation, are destructive to the neighbouring inhabitants, by occasioning obstinate intermittents in the colder climates, and pestilential fevers in the hotter regions. But all this mischief arises not merely from moisture, but from an unventilated and putrid moisture; for the inoffensiveness of mere wetness, untainted with putridity, may be reasonably inferred from the following considerations. The air is often fully saturated with moisture; and yet neither is any epidemical distemper produced by it, nor are those remarkably aggravated with which the sick happen at that time to be afflicted. The air from rivers and from the sea is probably more replenish-

ed

Fevers. ed with vapours than inland countries cleared of their woods: yet the most celebrated of the ancient physicians recommended the bank of a running river for the situation of a house, on account of its peculiar healthfulness; and many invalids are sent by the modern physicians to the sea side, only for the benefit of the sea air.

"Where the sailors are cleanly, and not too much crowded, they are often as healthy during long voyages at sea, as they would have been on any part of the land. Venice is not observed to be less healthy than London or Paris.

"Those who are much disposed to sweat, lie many hours in bedclothes impregnated probably with a less wholesome moisture than would have been left in the sheets half-dried after washing; and there is no reason to think that any remarkable injury was done to the health by the continuance of such sweats almost every night for weeks, and for months, except what arose from the too great copiousness of this evacuation.

"Children, and such as are troubled with the stone, and those who, from other infirmities or age, constantly wet their beds with their urine, do not appear to suffer in their health on this account.

"It is a common practice, in some disorders, to go to bed with the legs or arms wrapped in linen cloths thoroughly soaked in Malvern water, so that the sheets will be in many places as wet as they can be; and I have known these patients and their bedfellows receive no harm from a continuance of this practice for many months. Nor can it be said that the Malvern water is more innocent than any other water might be, on account of any ingredients with which it is impregnated; for the Malvern water is purer than that of any other spring in England which I ever examined.

"The greatest valetudinarians do not scruple to sprinkle lavender-water upon their sheets; and yet, when the spirit is flown off, there is left what is as truly water as if it had been taken from the river.

"Is it observed, that laundresses are peculiarly unhealthy above other women, though they live half their time in the midst of wet linen, in an air fully saturated with vapours? Many other employments might be mentioned, the persons occupied in which are constantly exposed to wet floors or pavements, or to be surrounded with watery vapours, or to have their clothes often wet for many hours together.

"Is it the coldness of wet linen which is to be feared? But shirts and sheets, colder than any unfrozen water can be, are safely worn and lain in by many persons, who, during a hard frost, neither warm their shirts nor their sheets.—Or does the danger lie in the dampness? But then, how comes it to pass, that a warm or cold bath, and long-continued fomentations, can be used, without the destruction of those who use them? Or is it from both together? Yet we have long heard of the thickness and continuance of the cold fogs in the seas north-west of England, but have never yet been told of any certain ill effect which they have upon those that live in these countries."

With regard to the causes of fevers, however, Dr Lind is of opinion, that noxious vapours arising from the earth are for the most part to be blamed. Even in countries seemingly dry, and where violent rains are not frequent, he thinks the air may load itself with putrid exhalations from the ground; and that, except in the burning deserts of Arabia or Africa, people are nowhere exempt from diseases occasioned by putrid moisture. In most of the hot countries the pernicious effects of the putrid vapours are by no means equivocal. In Guinea, they seem to be more extraordinary than anywhere else in the world; neither indeed can it be supposed, that a hot and moist atmosphere can be without putrescency. It may in general be remarked, that in sultry climates, or during hot weather, in all places subject to great rains, where the country is not cleared and cultivated, but is overrun with thickets, shrubs, or woods, especially if there are marshes or stagnating waters in the neighbourhood, sickness may be dreaded, and particularly the remitting fever of which we now treat. The fens, even in different counties of England, are known to be very prejudicial to the health of those who live near them, and still more so to strangers; but the woody and marshy lands in hot countries are much more pernicious to the health of Europeans. In all those unhealthy places, particularly during fogs or rains, a raw vapour, disagreeable to the smell, arises from the earth, and especially in the huts or houses. But of all the vapours which infest the torrid zone, the most malignant and fatal are *harmattans*: They are said to arise from the conflux of several rivers in the king of *Dormeo's* dominions at Benin (the most unwholesome part of Guinea), where travellers are obliged to be carried on men's backs for several days journey, through swampy grounds, and over marshes, amidst stinking ooze, and thickets of mangrove trees which are annually overflown. These vapours come up the coast to a surprising distance, with the south-east and north-east winds: and it has been observed, that in their progress they have often changed both the course of the winds and of the sea-currents. The times of their appearance at Cape Coast are the months of December, January, or February. The north-east and south-east winds are always unhealthy, but particularly so during the harmattan season. In some years this vapour is scarce perceptible; but in others it is thick, noxious, and destructive to the blacks as well as whites.—The mortality is in proportion to the density and duration of the fog. It has a raw putrid smell; and is sometimes so thick, that a person or house cannot be discerned through it at the distance of 15 or 20 yards: and it continues so for 10 or 14 days; during which it opens the seams of ships, splits or opens the crevices of wood as if shrunk or dried with a great fire, and destroys both man and beast.—In the year 1754 or 1755, the mortality occasioned in Guinea by this stinking fog was so great, that in several negro towns the living were scarce sufficient to bury the dead.—Twenty women brought from Holland by a new governor to the Castle *del Mina*, perished, together with most of the men in the garrison. The gates of Cape Coast castle were shut up for want of centinels to do duty; the blacks dying at this time as well as the white people. It is lucky that it is only in some years that *harmattans* are so very thick and noxious, otherwise that part of the country would be depopulated. It is observed that all fogs are extremely unhealthy in those parts, particularly before and after the rainy seasons; but the above account of the *harmattans* appeared so very extraordinary and incredible to some of Dr Lind's readers, that he thought proper to publish

Tertiana.

Febres.

publish a further corroboration of the facts above mentioned. "A gentleman (says he) who had long resided at Cape Coast castle, informed me, that during the time of this fog, being in the upper chambers of the fort, the boards of the floor shrunk so much, that he could discern the candles burning in the apartments below him (there are no plaster ceilings used in those hot countries), and that he could then even distinguish what people were doing in the apartments below; the seams of the floor having opened above half an inch while the fog lasted, which afterwards, upon its being dispelled, became close and tight as before."

In Africa the rains and dews seem to be possessed of qualities almost equally pernicious with the fogs. This much is certain, that in Guinea, many of the principal negroes, and especially of the mulatto Portuguese, take the utmost precaution to avoid being wet with those rains, especially such as fall first. At the setting in of the rainy season, they generally shut themselves up in a close well-thatched hut, where they keep a constant fire, smoke tobacco, and drink brandy, as preservatives against the noxious quality of the air at that time. When wet by accident with the rain, they immediately plunge themselves into salt water, if near it. Those natives generally bathe once a-day, but never in the fresh water rivers when they are overflown with the rains: at such times they prefer for that purpose the water of springs. The first rains which fall in Guinea are commonly supposed to be the most unhealthy. They have been known, in 48 hours, to render the leather of the shoes quite mouldy and rotten, they stain clothes more than any other rain; and soon after their commencement, even places formerly dry and parched swarm with frogs. At this time skins, part of the traffic of Senegal, quickly generate large worms; and it is remarked, that the fowls, which greedily prey on other insects, refuse to feed on these. It has been farther observed, that woollen cloths wet in those rains, and afterwards hung up to dry in the sun, have sometimes become full of maggots in a few hours.—It is also probable, that as in some of those countries the earth, for six or eight months of the year, receives no moisture from the heavens but what falls in dews, which every night renew the vegetation, the surface of the ground in many places becomes hard and incrustated with a dry scurf, which pens up the vapours below; until, by the continuance of the rains for some time, this crust is softened, and the long pent up vapours set free. That these dews do not penetrate deep into the earth is evident from the constant dryness and hardness of such spots of ground in those countries as are not covered with grass and other vegetables. Thus the large rivers in the dry season being confined within narrow bounds, leave a great part of their channel uncovered, which having its moisture totally exhaled, becomes a solid hard crust; but no sooner the rains fall than by degrees this long parched up crust of earth and clay gradually softens, and the ground, which before had not the least smell, begins to emit a stench, which in four or five weeks becomes exceedingly noisome, at which time the sickness is generally most violent.

This sickness, however, is not different from the remitting fever which has been described under so many various forms and names. An inflammatory fever is seldom observed, during the season of sickness, in this part of the world; and we shall conclude our description of the *amphimerina paludosa* with some extracts from the surgeon's journal in a ship that sailed up the rivers of Guinea.

Tertiana.

"On the 5th of April we sailed up the river of Gambia, and found all the English in the fort in perfect health. The surgeons of the factory informed me, that a relaxation of the stomach, and consequently a weakened digestion, seemed to bring on most of the diseases so fatal to Europeans in the sickly season. They were generally of a bilious nature, attended with a low fever, sometimes of a malignant, at other times of a remitting kind.—On the 12th of April, after sailing 30 miles up the river St Domingo, we came to Catchou, a town belonging to the Portuguese in Lat. 20° N. In this town were only four white people, the governor, and three friars. The number of whites in the trading ships was 51. One morning towards the latter end of April, a little rain fell. On the 13th of May there was a second shower, accompanied with a tornado. On the 18th of May it rained the whole day; and the rain continued, but with short intervals, until the beginning of October.

"In the month of June almost two-thirds of the white people were taken ill. Their sickness could not be well characterised by any denomination commonly applied to fevers: it however approached nearest to what is called a *nervous fever*, as the pulse was always low, and the brain and nerves seemed principally affected. It had also a tendency to frequent remissions. It began sometimes with a vomiting, but oftener with a delirium. Its attack was commonly in the night; and the patients, being then delirious, were apt to run into the open air. I observed them frequently recover their senses for a short time, by means of the heavy rain which fell upon their naked bodies. But the delirium soon returned: they afterwards became comatose, their pulse sunk, and a train of nervous symptoms followed; their skin often became yellow; bilious vomitings and stools were frequent symptoms. The fever reduced the patient's strength so much, that it was generally six weeks or two months before he was able to walk abroad. A consuming flux, a jaundice, a dropsy or obstructions in the bowels, were the consequences of it. Of 51 white men, being the companies of four ships which were at Catchou, one-third died of the fever, and one-third more of the flux, and other diseases consequent upon it; and of these not one was taken ill till the rains began.

"I believe, on the whole face of the earth, there is hardly to be found a more unhealthy country than this during the rainy season: and the idea I then conceived of our white people was by making a comparison of their breathing such a noxious air, with a number of river-fish put into stagnating water; where, as the water corrupts, the fish grow less lively, they droop, pine away, and many die.

"Thus some persons became dull, inactive, slightly delirious, at intervals; and, without being so much as confined to their beds, they expired in that delirious and comatose state in less than 48 hours after being in apparent good health. The white people in general became yellow; their stomach could not receive much food without loathing and retchings. Indeed it is no wonder that this sickness proved so fatal, that recoveries

Fevers. Tertiana.

ries from it were so tedious, and that they were attended with fluxes, dropsies, the jaundice, ague-cakes, and other dangerous chronical distempers. It seems more wonderful to me that any white people ever recover, while they continue to breathe so pestiferous an air as that at Catchou during the rainy season. We were, as I have already observed, 30 miles from the sea, in a country altogether uncultivated, overflowed with water, surrounded with thick impenetrable woods, and overrun with slime. The air was vitiated, noisome, and thick; insomuch that the lighted torches or candles burnt dim, and seemed ready to be extinguished: even the human voice lost its natural tone. The smell of the ground and of the houses was raw and offensive; but the vapour arising from putrid water in the ditches was much worse. All this, however, seemed tolerable, when compared with the infinite numbers of insects swarming every where, both on the ground and in the air; which, as they seemed to be produced and cherished by the putrefaction of the atmosphere, so they contributed greatly to increase its impurity. The wild bees from the woods, together with millions of ants, overran and destroyed the furniture of the houses; at the same time, swarms of cockroaches often darkened the air, and extinguished even candles in their flight; but the greatest plague was the musquettoes and sand-flies, whose incessant buzz and painful stings were more insupportable than any symptom of the fever. Besides all these, an incredible number of frogs on the banks of the river made such a constant and disagreeable croaking, that nothing but being accustomed to such an hideous noise could permit the enjoyment of natural sleep. In the beginning of October, as the rains abated, the weather became very hot; the woods were covered with abundance of dead frogs, and other vermin, left by the recess of the river; all the mangroves and shrubs were likewise overspread with stinking slime."

After so particular a description of the remitting fever in many different parts of the world, we presume it will be needless to take notice of any little varieties which may occur in the warm parts of America, as both the nature and cure of the distemper are radically the same: neither shall we lengthen out this article with further descriptions of remitting fevers from the works of foreign authors, as, from what we have already said, their nature cannot easily be mistaken.

Cure. The great difficulty in the cure of remitting fevers arises from their not being simple diseases, but a complication of several. Fevers, properly speaking, have but three or four different appearances which they can assume without a complication. One is, when they are attended with a phlogistic diathesis; another is, when they assume the form of genuine intermittents; a third is, when they produce a great debility of the nervous system; and the fourth is, when along with this debility there is also a rapid tendency to putrefaction. If, therefore, all these species happen to make an attack at once, the most dangerous fever we can imagine will be produced; and however contrary it may be to our theories to admit the possibility of such an attack, the truth of the fact is too often confirmed by fatal experience. In the beginning of remittent fevers, for instance, the symptoms indicate a high degree of inflammation: but if the practitioner attempts to remove this inflammation by blood-letting or other evacuations, the pulse sinks irrecoverably, and the person dies with such symptoms as show that the nervous system has been from the beginning greatly affected; at the same time the high stimulants and cordials, or cinchona, which would have conquered the nervous part of the disease, increase the inflammatory part of it to such a degree, that, by a too early exhibition of them, the patient also dies, but after another manner.

In the remitting fever of the East Indies, Dr Lind of Windsor formed the following indications of cure. 1. To allay the violence of the fever. 2. To evacuate the putrid humours, and take great care to prevent the body from inclining to putrefaction. 3. To keep up the strength of the patient as much as possible during the disorder. 4. To lose no time in preventing the return of the paroxysms.

To allay the violence of the fever, every thing that can contribute to increase it ought to be carefully avoided or removed; such as great heat, too strong a light falling on the eyes, noise, and motion. If during the paroxysm the head and loins be affected with violent pains, the pulse be full and hard, and the heat intense, bleeding may be used, but with the greatest caution: for, however useful this operation may be in cold climates, the success of it in warm ones is so far from being certain, that the lives of the patients have been often very much endangered, nay even destroyed by it. Dr Badenoch, and the surgeon of the Ponsborne, endeavoured each of them to relieve two patients by blood-letting; and the consequence was, that each of them lost one patient. Dr Lind bled two patients; one of whom was Mr Richardson, the first mate of the ship, who complained of a most violent pain in his head, with a full hard pulse. About four or five ounces of blood were taken from him, by which he was greatly relieved: nor was the cure retarded by it; nay, the fever afterwards became less irregular. At the time the other patient was bled, the disease was exceedingly frequent and violent. He was so earnest for bleeding, that he fired all the rest with the same desire, swearing, that by refusing them this only remedy, every one of them would be sent to their graves. To quiet them, therefore, and get quit of their importunities, the doctor complied with their request, and took about five or six ounces from him who had been the first to require it. The consequence was, that he immediately lost his strength; and in less than an hour, during which time he made his will, was carried off by the next fit. It is necessary, however, to observe, and indeed the doctor himself makes the observation, with regard to this patient, that he was bled at an improper time, namely, between the fits; whereas, had he been bled in the hot fit, it is possible he might have been relieved.

In support of the advantages to be derived from bleeding under proper circumstances, we have the authority both of Cleghorn and Pringle. As Dr Cleghorn practised in a very hot country, his observations must in the present case have greater weight than those of Pringle, who practised in a colder one. The former acquaints us, that if he was called in early enough, unless there was a strong contra-indication, he always used to take away some blood from people

Febres. people of all ages; namely, from robust adults, ten or twelve ounces; from others a smaller quantity, in proportion to their strength and years. And further, if a violent headach, obstinate delirium, and heat or pains of the bowels, were urgent, the bleeding was repeated within a day or two. By this seasonable evacuation, he found the vehemence of all the paroxysms somewhat diminished; the apyrexia became more complete; the operation of emetics and cathartics rendered safer and more successful; and the terrible symptoms which happened about the height of the distemper, such as raving *sopor*, difficulty of breathing, inflammations of the abdominal viscera, &c. were either prevented or mitigated. But if the fever had continued for some time before he was called, and the mass of blood appeared to be too much melted down or inclined to a putrid dissolution, he either abstained from bleeding entirely, or took away a very small quantity, though some urgent symptoms might seem to require a larger evacuation. As to the time of performing the operation, he acquaints us, that it is safe enough, except when the cold fit lasts or is soon expected, or while the skin is covered with critical sweats; and that he usually opened a vein in the beginning of the hot fit; by which means the sick were relieved, the immoderate heat of the body, which is often productive of fatal effects, was diminished, and the critical sweats brought on sooner and in greater abundance.

But though Dr Lind found venesection to be of such pernicious tendency in his patients, cooling acidulated liquors were of the utmost service, as they corrected the putrid humours, lessened the heat and thirst, and of course prevented the fever from arriving at so great an height as it would otherwise have done. Those cooling liquors are the best which are made up with some farinaceous substance, as they most easily unite with other fluids. Fossil acids too, and crystals of tartar, especially the latter, are of considerable use, not only in this, but in other fevers. The neutral salts, prepared with the juice of lemons, were likewise given with success during the heat of the fever. They lessen the nausea, the fits become more regular, and the remissions more full; and they are particularly grateful when given in a state of effervescence. The good effects of these draughts we are in a great measure to ascribe to the antiseptic quality of the fixed air extricated from them during the effervescence.

During the remission, it is proper to evacuate the putrid humours, by small doses of ipecacuanha, or rather tartar emetic. The tartar emetic indeed appears to be endowed with some kind of febrifuge virtue, which Dr Cullen thinks is owing to its relaxing the febrile spasm taking place in the capillary vessels. But should there appear any symptoms of a topical inflammation in some of the abdominal viscera, a thing which never happens unless the disorder has been of some standing, vomiting is to be avoided, and we are to depend upon purgatives alone for the evacuation of the putrid bile. These are always useful in the cure of this disorder. But all acrid and strong purgatives are to be carefully avoided, and only the mild antiseptic ones made use of, such as crystals of tartar, or tamarinds made up with manna or with Glauber's salt.

Tertian. Though in these diseases there is a great quantity of putrescent bile collected in the body, yet it seems much more probable that this is the *effect* than the *cause* of the disorder; and therefore, though we carry off the quantity collected ever so often, more of the same kind will still be produced by the putrescent disposition of the other fluids, at the same time that the strength of the patient must necessarily be diminished by repeated evacuations, when it ought rather to be kept up by all possible means. We ought well to observe, however, that the mineral acids have not that property of sweetening putrid bile which the vegetable ones have: and therefore the same relief will not be given by them which might reasonably be expected from vinegar or lemon juice.

In order to keep up the strength of the patient, good food is absolutely necessary. Dr Lind allowed the sick small messes of panada made with boiled rice and barley mixed with currants or raisins and prunes, seasoned with sugar and a little wine, especially claret. During the paroxysms, they had gruel made of flour and rice, with sugar and the juice of acid fruit; and when the fit went off, a little wine was added to this mixture.

The shirts and bedding must be very often changed and well aired; their stools, and all filth and nastiness, are to be immediately removed; the places where they are lodged should be well aired and frequently sprinkled with vinegar; and, in the last place, the sick must be exceedingly well nursed. Blisters, according to Dr Lind, should never be used till the fever has been of long continuance, or the spirits and pulse of the patient have begun to flag. But here our author has implicitly followed Dr Huxham, whose theory concerning the use of blisters is now found to be erroneous. According to that celebrated author, blisters are capable of doing considerable hurt in all cases where there is a tendency to inflammation, by increasing the motion of the fluids and the oscillatory power of the vessels, both of which are already too great. They are also improper, according to him, when there is a considerable tendency of the fluids to putrefaction; because he supposes the salts of these flies to operate in the same manner with volatile alkalies, that is, by dissolving and putrefying the blood still farther. But Sir John Pringle has shown, that, in inflammatory fevers as well as those of the putrid kind, both blisters and volatile salts may be of service; the latter, particularly, he hath experimentally proved to be so far from promoting putrefaction, that they are exceedingly strong antiseptics.

In the East Indies, Dr Lind found it absolutely necessary to exhibit the Peruvian bark in large quantities, and as early as possible. By this method he not only secured the patient from the imminent danger of death to which he was exposed at every fit, but likewise conquered those obstructions which were apt to ensue in the abdominal viscera, and which are to be attributed to the continuance of the disorder, and not to the bark employed to cure it. He always gave the cinchona during the second remission, as all his care was during the first to cleanse the primæ viæ. He observes, however, that it is to no purpose to give the bark till the necessary purgations are over; but assures us, that it never fails, unless from the coming on of a vomiting or

Febres.

Tertiana.

or diarrhœa it cannot be taken in sufficient quantities before the return of a paroxysm. To prevent the medicine from vomiting or purging, he mixed a few drops of liquid laudanum with every dose of it. Half a dram was given every half hour in some convenient vehicle, beginning as soon as the fever had considerably abated, and the pulse was returned nearly to its natural state; both which generally happened before the sweats were over. An ounce of the bark was sometimes found too little to check the fever, but an ounce and a half never failed. It must be continued daily in small doses till the patient has recovered his strength, and then a greater quantity must be given, especially at the season when the rivers overflow the country.

Dr Pringle found the autumnal remittents in the Netherlands complicated with a great many inflammatory symptoms; for which reason it was generally found necessary to open a vein in the beginning. The vernal and later autumnal remitting fevers are accompanied with pleuritic and rheumatic pains from the coldness of the weather, and on that account require more bleeding. A physician unacquainted with the nature of the disease, and attending chiefly to the paroxysms and remissions, would be apt to omit this evacuation entirely, and give the cinchona too soon, which would bring on a continued inflammatory fever. In these countries a vein may be safely opened either during the remission or in the height of a paroxysm; and our author also found good effects resulting from bleeding in the hot fits of the marsh fever, even after it had almost come to regular intermissions. After bleeding, a purgative was usually exhibited, of which he gives us the following formula.

℞. Infusi senæ commun. ℥iij.
Elect. Lenitiv. ℥ss.
Nitr. pur. ʒi.
Tinct. sen. ʒvi. M.

Of this only one half was taken at once; and if it did not operate twice in four hours, the remainder was then taken. This potion agreed with the stomach, purged plentifully, and therefore was a very useful composition. Next morning, when there was almost always some remission, he gave one grain of emetic tartar rubbed with 12 grains of crabs-eyes, and repeated the dose in two hours, if the first had little or no effect; or at any rate in four hours. This medicine was intended not only to vomit, but also to operate by stool, and excite a sweat. If these evacuations were procured, the fever generally became easier, and was even sometimes cured. This he prefers to the ipecacuanha, and therefore in the latter years of his practice disused that root entirely. The same medicine was repeated next day or the day following; or if not, a laxative clyster was thrown up: and this method was continued till the fever either went off altogether, or intermitted in such a manner as to be cured by the cinchona.

A similar method was followed by Dr Huck in the remitting fevers of the West Indies and North America. In the beginning he let blood; and in the first remission gave four or five grains of ipecacuanha, with from half a grain to two grains of emetic tartar. This powder he repeated in two hours, taking care that the patient should not drink before the second dose; for then the medicine more readily passed into the bowels after it had operated by vomiting. If, after two hours more, the operation either way was small, he gave a third dose, which commonly had a good effect in opening the first passages; and then the fever either went quite off, or intermitted in such a manner as to yield to the bark. On the continent, he found little difficulty after the intermission; but in the West Indies, unless he gave the cinchona upon the very first intermission, though imperfect, the fever was apt to assume a continued and dangerous form.

In the remitting fevers of hot countries, however, it must be observed, that the lancet must in all cases be much more sparingly used than in similar diseases of the colder regions; and we must also be sparing of venesection in those countries where the marsh effluvia are very strong and prevail much. For this reason Dr Lind of Haslar greatly condemns the practice of indiscriminate bleeding when people first arrive in hot climates. The first diseases indeed which occur in a voyage to the southward are, for the most part, of an inflammatory nature, and owing to a sudden transition from cold to hot weather. This occasions a fulness and distention of the vessels; whence all Europeans, on their first arrival under the tropic, bear evacuations much better than afterwards. The practice of indiscriminately bleeding, however, a number of the ship's company when they first come into a warm latitude, is by no means found to answer the purpose of a preventive. In such cases, indeed, as plainly indicate a plethoric disposition brought on by the heat, blood-letting is certainly useful. The signs of this are a pain and giddiness in the head; a heaviness and dulness of the eyes, which sometimes appear slightly inflamed: there is also commonly a sense of weight and fulness in the breast, the pulse at the same time being quick and oppressed.

But the case is quite different after a longer continuance of sultry weather, and when the constitution is in some measure habituated to the hot climate. For it is then observed, that the symptoms of inflammations in the bowels, even the most dangerous, are not near so severe in such climates as in cold countries; nor can the patients bear such large evacuations. The physician, however, must take care not to be misled by the apparent mildness of the symptoms; for he will find, notwithstanding such deceitful appearances, that the inflammation makes a more rapid progress in hot countries than in cold, suppurations and mortifications being much more suddenly formed; and that in general all acute distempers come sooner to a crisis in the warm than in colder regions. Hence it is an important rule of practice in those climates, to seize the most early opportunity, in the commencement of all threatening inflammations, to make frequent though not copious evacuations by blood-letting. For by delay the inflammation quickly passes from its first to its last or fatal stage; at least, an imperfect crisis in such inflammatory fevers ensues, which fixes an obstruction in the viscera extremely difficult to remove.

It is indeed a general maxim with some physicians in the West Indies, that in most acute distempers bleeding in that country is prejudicial. This is founded upon a supposition that the crassamentum of the blood is

Febres. is thinned, and the solids greatly weakened, by the heat of the climate. It is therefore objected, that bleeding in such an habit of body weakens the powers of nature, and withdraws the strength which is requisite to support the patient until the crisis of the fever.

This reasoning is partly just; but, like all general maxims, will admit of exceptions. First, with regard to sailors, it is to be remembered, that they are more exposed to quick vicissitudes of heat, cold, damps, and to various changes of the air and weather, than most of the other inhabitants of the Torrid Zone. Add to this, that their intemperance, and the excesses they are apt to fall into whenever it is in their power to commit them, render them more liable to inflammations than any other set of people. Hence their diseases require more plentiful evacuations than the land-inhabitants of those parts of the world, and generally they bear them better. But with regard to the natives of the country, or those who have remained long there, it must be proper to bleed them very sparingly, making allowance for the different seasons of the year, the temperature of the air, and the situation of the places where they reside. Thus, in some parts, even on the island of Jamaica, at particular seasons, the weather is cool; wherefore, in these places, and at such seasons, the inhabitants having their fibres more rigid, and a firmer crasis of their blood, bear venesection much better.

In cold countries the state of the air greatly assists in restoring the impaired spring of the fibres; whereas every thing almost in warm weather, such as heat, moisture, &c. concur to relax and weaken the habit of body. Thus we may daily see persons in Britain, after having suffered a most severe fit of sickness, recover their strength and spirits in a few days, and in a very short time their natural constitution. But the case is very different in the sultry regions of the Torrid Zone, or indeed in any part of the world where the heat of the season causes the mercury to stand for any length of time at the 77th degree and upward of Fahrenheit's thermometer. During such an excess of heat, debility after fevers is apt to remain with European constitutions for several months. In Jamaica, the convalescents are sent to the cool summits of the mountains; but a retreat to a more northern climate is often absolutely necessary to recover their wonted tone and vigour of body. It is a well-established observation, that the negroes and aborigines of the Torrid Zone cannot bear plentiful evacuations by the lancet. They commonly mix the most stimulating poignant spices with their ordinary light food, and this is found by experience suitable to their constitutions.

As proper preventives for the dangerous fevers of which we are treating, Dr Lind on all occasions recommends the avoiding of stagnant water, or putrid marshes; the use of proper food, cleanliness, and sobriety. Of the propriety of removing from the neighbourhood of those places whose pestilential effluvia produce the disorders, we cannot possibly entertain a doubt; and of the efficacy of proper food in preventing putrid disorders he gives a remarkable instance in the Sheerness man of war, bound to the East Indies. As they went out, the men being apprehensive of sickness in so long a voyage, petitioned the captain not to oblige them to take up their salt provisions, but rather to permit them to live upon the other species of their allowance. It was therefore ordered, that they should be served with salt-meat only once a-week; and the consequence was, that after a passage of five months and one day, the ship arrived at the Cape of Good Hope without having a single person sick on board. As the use of Sutton's pipes had been then newly introduced into the king's ships, the captain was willing to ascribe part of such an uncommon healthfulness to their beneficial effects; but it was soon discovered, that, by the neglect of the carpenter, the cock of the pipes had all this while been kept shut. This ship remained in India some months, where none of the men, except the boats crew, had the benefit of going on shore; notwithstanding which, the crew continued to enjoy the most perfect state of health; they were, however, well supplied with fresh meat. On leaving India, knowing they were to stop at the Cape of Good Hope, and trusting to a quick passage, and the abundance of refreshments to be had there, they ate their full allowance of salt meats, during a passage of only 10 weeks; and it is to be remarked the air-pipes were now opened. The effect of this was, that when they arrived at the Cape, 20 of them were afflicted in a most miserable manner with scorbutic and other disorders. These, however, were speedily recovered by the refreshments they met with on shore. Being now thoroughly sensible of the beneficial effects of eating, in these southern climates, as little salt meat as possible when at sea, they unanimously agreed, in their voyage home from the Cape, to refrain from their too plentiful allowance of salt flesh. And thus the Sheerness arrived at Spithead, with her full complement of 160 men in perfect health and with unbroken constitutions, having in this voyage of 14 months and 15 days buried but one man, who died in a mercurial salivation.

Tertian. Thus we see, that a free and pure air is not a sufficient preservative against a putrescent state of the fluids, without proper food; and, on the other hand, we have a very remarkable instance of the inefficacy of the most salutary food to prevent putrid diseases, in a very noxious state of the atmosphere. In the year 1717, at the siege of Belgrade in Hungary, the fever of the country, and the flux, occasioned a most extraordinary mortality among the troops. The dread of these diseases caused every one, as may naturally be supposed, to have recourse to different precautions for self-preservation. Prince Eugene, the commander in chief, had water and the provisions for his table sent him twice a week from Vienna. The pure stream of the river Kahlenberg was regularly brought to him: he avoided all excesses, and lived regularly or rather abstemiously; refreshed himself often by eating a cool melon; and mixed his usual wine, which was Burgundy, with water. Yet, notwithstanding his utmost care, he was seized with a dysentery; which would have quickly put an end to his life, had not the speedy conclusion of that campaign permitted him to make a quick retreat.

At this unhealthy season, when hardly one imperial officer, much less their several domestics, escaped those malignant diseases, the renowned Count Bonneval and his

Fevers. Quartana.

his numerous retinue continued in perfect health, to the surprise, or to use the words of Dr Kramer, to the *envy*, of all who beheld them. The only precaution he used, was to take, two or three times a-day, a small quantity of brandy in which the Peruvian bark was infused; and he obliged all his attendants and domestics to follow his example. It is no less remarkable that the count, placing his certain preservation in the use of this single medicine, lived for many years afterwards in the most unhealthy spots of Hungary, without any attack or apprehension of disease; and continued to enjoy a perfect state of health during the hottest and most sickly seasons. And thus, with an unbroken and sound constitution, which is seldom the case of those who reside long in such climates, he lived to a great age. There is an instance produced by the same author, of a whole regiment in Italy having been preserved by the use of cinchona from the attack of these malignant diseases, viz. the flux, and *bilious* fever as it is frequently called, when the rest of the Austrian army, not pursuing that method, became greatly annoyed with them.

The intemperance and irregular living of those Europeans who visit the hot climates is frequently accused as the cause of their destruction; but, our author thinks, without sufficient reason; for though intemperance will make the body more liable to receive such diseases, it will not bring them on. It must by no means, however, be imagined, that in those climates Europeans may with impunity be guilty of excesses in eating or drinking: for the least error in that way will often prove fatal by debilitating the body, whose utmost strength in time of full health was perhaps scarce sufficient to resist the pestilential miasmata of the atmosphere.

It appears, therefore, from the concurrent testimony of the most eminent physicians, that the most proper medicine to be used, either as a preventive or cure for remitting and intermitting disorders, is the Peruvian bark, administered with proper precautions and after the *primæ viæ* have been evacuated of the putrid bilious matter collected in them. In those species of *tritæophya*, &c. belonging to this class, enumerated by Sauvages, the same remedies only were useful; but in that pestilential distemper which he calls *tritæophya Vratislaviensis*, he tells us, that washing the body with water sometimes hot, sometimes cold, watery clysters, and plenty of aqueous drink, were likewise of use.

GENUS II. QUARTANA; the QUARTAN FEVER.

Quartana auctorum, *Sauv.* Gen. 89. *Lin.* 17. *Vog.* 3. *Sag.* 711. *Hoffm.* II. p. 23. *Junck.* tab. 81.

The *Genuine* QUARTAN. Sp. I. var. I. A.
Quartana legitima, *Sauv.* sp. 1. *Sydenham* de morb. acut. cap. v.

Description. The genuine quartan, according to Juncker, keeps its form more exactly than other intermittents; scarcely coming on at any other time than four or five in the afternoon. The cold is less violent than in the tertian; but is very perceptible, though it doth not proceed to such a height as to make the limbs shake; it continues for about two hours. It is preceded and accompanied by a languor both of body and mind. There is seldom any vomiting unless when the stomach is manifestly overloaded with aliment; neither is there any diarrhœa, but the belly in general is rather bound, not only on the days on which the paroxysm takes place, but also on the intermediate ones. The heat, which slowly succeeds the cold, is less troublesome to the patient by its violence than by the uneasy dryness of the skin, which is scarcely ever moistened with sweat. This heat rarely continues longer than four or five hours, unless perhaps at the first or second paroxysm. It is accompanied also with a giddiness and dull pain of the head. On the termination of the paroxysm, the patient returns to a middling state of health, and continues in the same for the rest of the intermediate days; only there remains somewhat of a loathing, and a deep-seated pain as if the person was all over bruised or broken, which kind of sensation the physicians are wont to call *osteocopus*. The fit returns every fourth day, and precisely at the same hours, being rarely postponed.

Causes of, and persons subject to, this disorder. The same general causes concur in producing this as other intermittents, namely marsh miasmata, and whatever can dispose the body to be easily affected by them. Studious people, and those of a melancholic turn, are said to be particularly subject to quartans; but what are the immediate causes which produce a return of the fits every fourth day, instead of every day, or every third day, must probably lie for ever concealed, as depending upon the secret and inexplicable mechanism of the human body.

Prognosis. A simple quartan, where there is no reason to dread any induration of the viscera, may very certainly admit of a cure; and the prognosis can never be unfavourable, unless in cases of extreme weakness, or where the distemper hath been unskilfully treated.

Cure. This does not in the least differ from that which hath been fully laid down for the simple tertian, and which it is therefore needless to repeat here.

The *Duplicated* QUARTAN. Sp. I. var. I. B.

Quartana duplicata, *Sauv.* sp. 4. *Bonet.* 153

This is entirely similar to the duplicated tertian already mentioned; proper allowance being made for the difference between the type of a tertian and quartan.

The *Triplicated* QUARTAN. Sp. I. var. I. C.

Quartana triplicata, *Sauv.* sp. 16. 154

This hath three paroxysms every fourth day, while the intermediate days are entirely free from fever.

The *Double* QUARTAN. Sp. I. var. I. D.

Quartana duplex, *Sauv.* sp. 3. *Vog.* sp. 13. 155

In the double quartan, the fits come on every day except the third; but so that the first paroxysm answers to the third, the second to the fourth, and so on.

The *Triple* QUARTAN. Sp. I. var. I. E.

Quartana triplex, *Sauv.* sp. 5. *Vog.* sp. 14. *Bartholin.* H. anat. c. I. 95. 156

This comes on every day, but the quartan type is still

Febres.

still preserved by the times of accession; that is, the time of the fourth paroxysm's coming on answers to that of the first, the fifth to the second, the sixth to the third, &c.

7. Tetartophya hepatalgica, *Sauv.* 3. *Cor. Pis.* in prefat. p. 33.
8. Amphimerina spasmodica, *Sauv.* sp. 16.

To the tertian or quartan fevers also belong the *Erraticæ* of authors. As all those above mentioned differ only in the slight circumstance of the type from the intermitting and remitting tertians already described at length, it is unnecessary here to take up time in describing every minute circumstance related by physicians concerning them, especially as it could contribute nothing towards the laying down a better method of cure than what hath been already suggested.

GENUS III. QUOTIDIANA; the QUOTIDIAN FEVER. Quotidia

Quotidiana auctorum, *Sauv.* gen. 86. *Lin.* 15. *Vog.* I. *Hoffm.* II. 33. *Junck.* tab. 79.

The *Genuine* QUOTIDIAN. Sp. I. var. 1. A.

Quotidiana simplex, *Sauv.* sp. 1. 16
Quotidiana legitima, *Sennert.* de febr. cap. 18.

Description. This kind of fever generally comes on about six or seven o'clock in the morning, beginning with a considerable degree of cold and shivering, which lasts for about an hour; and is often accompanied with vomiting or spontaneous diarrhœa, or both. It is succeeded by a pretty strong heat, accompanied with thirst, restlessness, and pain of the head. When the heat abates a little, a spontaneous sweat commonly follows, and the whole paroxysm rarely exceeds six hours. It returns, however, every day almost always at the same hour, unless it be evidently disturbed.

Causes of, and persons subject to, the disease. The same general causes are to be assigned for the quotidian as for other intermittents. This kind occurs but rarely; and it is said to attack people of a phlegmatic temperament rather than any other: also old people rather than young, and women rather than men.

The prognosis and method of cure are not different from those of tertians and quartans.

The *Partial* QUOTIDIAN, Sp. I. var. 1. B.

Quotidiana partialis, *Sauv.* sp. 16. *Cnoffel*, E. N. C. D. I. A. III. obs. 205. Edin. Med. Ess. vol. i. art. 31. vol. ii. art. 16. 16
Quotidiana cephalalgica, *Suav.* sp. 6. Mort. pyretol. exerc. i. hist. 27. *Van Swieten in Boerh.* p. 534.
Cephalalgia intermittens, *Sauv.* sp. 7.
Cephalæa febricosa, *Sauv.* sp. 4.
Quotidiana ophthalmica, *Morton*, ibid. hist. 17. *Van Swieten*, ibid.
Ophthalmia febricosa, *Sauv.* sp. 23.

These distempers attack only some particular part of the body, as the head, the eye, arm, &c. producing periodical affections of those parts returning once in 24 hours; they are to be cured by cinchona, as other intermittents. They are known to belong to this class, by the evident intermission of the pain or other affection of the part. The *quotidiana hysterica*, *Sauv.* sp. 3. *quotidiana catarrhalis*, *Sauv.* sp. 9. and *quotidiana stranguriosa*, *Sauv.* sp. 11. seem to be symptomatic disorders.

The *Remitting* QUOTIDIAN. Sp. II.

Amphimerina, *Sauv.* gen. 84. *Lin.* 20. 16

Diaria, *Lin.* 11.
Febris inflammatoria auctorum.

Description. The most simple kind of synocha is the ephemera or diary fever. It begins without any sensation of cold or shivering, unless there be some internal inflammation, or the smallpox or measles happen to be present. A continual heat without any intermission constitutes the essence of this disease. The heat, however, is more tolerable than in the synocha properly so called. In some, the pains of the head are pungent and throbbing, answering to the pulsations of the arteries; but in others they are dull and heavy. The face is red and bloated; and there is a remarkable lassitude of the limbs, with a strong, full, and frequent pulse. The urine is red, and deposits a sediment almost of the colour of orange-peel; and in the very first day of the disease, signs of concoction (according to the Hippocratic phrase) appear. The fever commonly goes off with a gentle sweat; but sometimes, though more rarely, with a hemorrhagy by the nose. Its shortest period is 24 hours: but if it goes beyond the fourth day, it is then a *synocha* properly so called.

The simple synocha, according to Vogel, begins with cold and shivering, succeeded by vehement heat, redness, and dryness of the skin. The face, especially, is very red, and the thirst intense. The head is either pained or heavy. The patient either doth not sleep at all, or is disturbed with dreams. A moist sweat then breaks out all over the skin. The pulse is full, quick, and frequent; the judgment is sometimes a little disturbed; young people are apt to be terrified with imaginations; and they for the most part incline to sleep; the respiration is difficult, and the belly costive; at the same time that a tensive kind of lassitude is perceived over the whole body. A complete crisis takes place either on the fourth or at the farthest on the eleventh day. The characteristic marks of the simple synocha, therefore, are, A redness of the face, moisture of the skin, a strong and frequent pulse.

Causes of, and persons subject to, this disease. As we have already remarked of intermittents, so must we also now remark of continued fevers, that it is impossible to discover those minute causes which occasion the difference of type betwixt one inflammatory fever and another, though most authors pretend to enumerate these with great certainty. Thus Juncker tells us, that the cause of the simple ephemera is plethora, together with any immoderate agitation and commotion of the fluids while in that state. Vogel reckons among the causes of his *febris diaria*, passions of the mind, pain, want, exposure to the sun, &c.; a repulsion or absorption of certain humours; wounds, fractures, luxations, &c.; so that in general we may reckon every thing tending to increase the action of the arterial system to be in certain circumstances a cause of inflammatory fever.—Hence we find those are most subject to the synocha whose constitution is either naturally robust, or who are exposed to those causes which tend to produce an increased action of the arterial system; such as hard labour, high living, &c.

Prognosis. The most simple kind of synocha, that is, the ephemera or diary fever, is commonly cured without the assistance of medicine, and therefore the prognosis is for the most part favourable: yet, if it be improperly treated by heating medicines, it may easily be converted into the other kind; or, if there be a putrid disposition of the fluids, into a fever of a very dangerous nature. The same thing is to be understood even of the most violent kind; for simple inflammatory fevers are not dangerous unless complicated with an affection of some particular part, as the pleura, stomach, &c.

Cure. Dr Cullen objects to the plan of those who are for leaving the cure of continued fevers to the operations of nature; because these operations are neither certain in themselves, nor are they so well understood as to enable us to regulate them properly; and it is likewise possible to supersede them by art. The plan therefore on which he proceeds is, to form his indications of cure upon the means of obviating the tendency to death in fevers; and these he reduces to three. 1. To moderate the violence of reaction.—2. To remove or obviate the causes of debility; and, 3. To obviate or correct the tendency of the fluids to putrefaction.

The *first* indication may be answered, 1. By all those means which diminish the action of the heart and arteries. 2. By those which take off the spasm of the extreme vessels, which, according to his theory, is the chief cause of violent reaction.

I. The action of the heart and arteries may be diminished, 1. By avoiding or moderating those irritations which, in one degree or other, are almost constantly applied to the body. 2. By the use of certain sedative powers. 3. By diminishing the tension or tone of the arterial system.

[1.] The irritations above mentioned are the impressions made upon our senses, the exercise of the body and mind, and the taking in of aliments. The avoiding of these as much as possible, or the moderating their force, makes what is properly called the *antiphlogistic regimen*, proper to be employed in *almost* every continued fever. This regimen is to be directed in the following manner.

1. Impressions on the external senses, as stimulant to the system, and a chief support of its activity, should be avoided as much as possible; especially such as are of a stronger kind, and which give pain and uneasiness. No impression is to be more carefully guarded against than that of external heat; and at the same

Febres. same time every other means of increasing the heat of the body is to be shunned. Both these precautions are to be taken as soon as a hot stage is fully formed; and to be attended to during its continuance, except in certain cases, where a determination to sweating is necessary, or where the stimulant effects of heat may be compensated by circumstances which determine it to produce relaxation and revulsion.

2. All motion of the body is to be avoided as much as possible, and that posture only chosen which employs the fewest muscles, and keeps none of them long in a state of contraction. Speaking, as it accelerates respiration, is particularly to be avoided. It must also be observed, that every motion of the body is more stimulant in proportion as the patient is weaker.

3. The exercise of the mind is also to be avoided, as being a stimulus to the body; but here an exception is to be made in the case of a delirium coming on, when the presenting of accustomed objects may divert the irregular train of ideas then arising in the mind.

4. The presence of recent aliment in the stomach proves always a stimulus to the system, and ought therefore to be as moderate as possible. A total abstinence for some time may be of service; but as this cannot be long continued with safety, we must avoid the stimulus of aliment by choosing that kind which gives the least. Alimentary matters are also to be accounted more stimulant in proportion to their alkalescent qualities; and this leads us to avoid all animal, and use only vegetable food. For the same reason, aromatic and spirituous liquors are to be avoided; and in answering the present indication, we must abstain from all fermented liquors except those of the lowest quality. Other stimuli are, the sensation of thirst, crudities or corrupted humours in the stomach, a preternatural retention of the fæces in the intestines, and a general acrimony of all the humours, which is in most fevers to be suspected. These are to be removed by such methods as the urgency of the symptoms require, by diluting liquors, vomiting, the use of acids, laxative elysters, and large quantities of antiseptic drinks.

[2.] The second method of moderating the violence of reaction is by the employment of certain sedative powers, with a view to diminish the activity of the whole body, and particularly that of the sanguiferous system. The first of these to be mentioned is the application of cold. Heat is the chief support of the activity of the animal-system; and the system is therefore provided with a power of generating heat: but at the same time we may observe, that this would go to excess, were it not constantly moderated by a cooler temperature in the surrounding atmosphere. When, therefore, the generating power of heat in the system is increased, as is commonly the case in fevers, it is necessary not only to avoid all further means of increasing it, but also to apply air of a cooler temperature; or at least to apply it more entirely and freely than in a state of health. This is shown, from some late observations, to be a very powerful means of moderating the violence of re-action: but what is the mode of its operation, to what circumstances of fever it particularly applies, or what limitations it requires, are not yet fully ascertained.

Synocha. Another sedative power very frequently employed in fevers, is that of certain medicines known in the materia medica by the name of *refrigerants*. The chief of these are acids of all kinds when sufficiently diluted, and which are, in several respects, remedies adapted to continued fevers. Those especially in use are the sulphuric and vegetable; and on many accounts the latter are to be preferred. Another set of refrigerants are the neutral salts formed of the sulphuric, nitrous or vegetable acids, with alkalies either fixed or volatile. All these neutrals, while they are dissolved in water, generate cold; but as that cold ceases soon after the dissolution is finished, and as the salts are generally exhibited in a dissolved state, their refrigerant power in the animal body does not all depend upon their power of generating cold with water. Nitre is the refrigerant chiefly employed; but all the others, compounded as above mentioned, partake more or less of the same quality. Besides these neutrals, some metallic salts have also been employed in fevers, particularly the acetite of lead: but the refrigerant powers of this salt are by no means ascertained, and its deleterious qualities are too well known to admit of its being freely used.

[3.] The third general method of diminishing the reaction, is by lessening the tension, tone, and activity of the sanguiferous system. As the activity of the system in a great measure depends upon the tone, and this again upon the tension, of the vessels, given to them by the quantity of fluids they contain, it is evident, that the diminution of the quantity of these must diminish the activity of the sanguiferous system. The most efficacious means of diminishing the quantity of fluids is by the evacuations of blood-letting and purging. The former is evidently one of the most powerful means of diminishing the activity of the whole body, and especially of the sanguiferous system; and it must therefore be the most effectual means of moderating the reaction in fevers. When the violence of reaction, and its constant attendant a phlogistic diathesis, are sufficiently evident; when these constitute the principal part of the disease, and may be expected to continue through the whole of it, as in the cases of synocha; then blood-letting is the principal remedy, and may be employed as far as the symptoms of the disease may seem to require, and the constitution of the patient will bear. It must, however, be remarked, that a greater evacuation than is necessary may occasion a slower recovery, and render the person more liable to a relapse, or bring on other diseases. It is also to be observed, that this evacuation is the more effectual, as the blood is more suddenly drawn off, and as the body is at the same time more free from all irritation, and therefore when it is in a posture in which the fewest muscles are in action.

With regard to purging, when we consider the quantity of fluids constantly present in the cavity of the intestines, and the quantity which may be drawn off from the innumerable excretories that open into this cavity, it will be obvious, that a very great evacuation may be made in this way; and if this be done by a stimulus that is not at the same time communicated to the rest of the body, it may, by emptying both the cavity of the intestines and the arteries which furnish

Fevers. Synocha.

furnish the excretions poured into it, induce a considerable relaxation in the whole system; and is therefore suited to moderate the violence of reaction in fevers. But it is to be observed, that as the fluid drawn from the excretories opening into the intestines is not all drawn immediately from the arteries, and as what is even more immediately drawn from these is drawn off slowly; so the evacuation will not, in proportion to its quantity, occasion such a sudden depletion of the red vessels as blood-letting does; and therefore cannot act so powerfully in taking off the phlogistic diathesis of the system.

At the same time this evacuation may induce a considerable degree of debility; and therefore, in those cases in which a dangerous state of debility is likely to occur, purging is to be employed with a great deal of caution; and this caution is more difficult to be observed than in the case of blood-letting: and it is further to be noticed, that as purging takes off in some measure the determination of the blood to the vessels on the surface of the body, it seems to be less adapted to the cure of fevers.

II. The other method of moderating the violence of reaction in fevers is by the exhibition of those remedies suited to take off the spasm of the extreme vessels, supposed to be the irritation which chiefly supports the reaction. The means to be employed for this purpose are either internal or external.

First, The internal means are, 1. Those which determine the force of the circulation to the extreme vessels on the surface of the body, and by restoring the tone and activity of those vessels, overcome the spasm on their extremities. 2. Those medicines which have the power of taking off spasm in any part of the system, and which are known under the title of ANTISPASMODICS.

(1.) Those remedies which are fit to determine to the surface of the body are, 1. Diluents. 2. Neutral salts. 3. Sudorifics. 4. Emetics.

1. Water enters, in a large proportion, into the composition of all animal fluids, and a large quantity of it is always diffused through the whole of the common mass. In a sound state, the fluidity of the whole mass depends upon the quantity of water present in it. Water therefore is the proper diluent of our mass of blood, and other fluids are diluent only in proportion to the quantity of water they contain.

In a healthy state, also the fulness of the extreme vessels and the quantity of excretion are in proportion to the quantity of water present in the body. But in fever, though the excretions be in some measure interrupted, they continue in such quantity as to exhale the more fluid parts of the blood; and, while a portion of them is at the same time necessarily retained in the larger vessels, the smaller, and the extreme vessels, both from the deficiency of fluid and their own contracted state, are less filled, and therefore allowed to remain in that condition. To remedy this contracted state, nothing is more necessary than a large supply of water or watery fluids taken in by drinking or otherwise; for as any superfluous quantity of water is forced off by the several excretories, such a force applied may be a means of dilating the extreme vessels, and of overcoming the spasm affecting their extremities. Accordingly, the throwing in a large quantity of watery fluids, has been, at all times, a remedy much employed in fevers; and in no instance more remarkably than by the Spanish and Italian physicians, in the use of what they call the *diæta aquea*. This practice consists in taking away every other kind of aliment and drink, and in giving, in divided portions, every day for several days together, six or eight pounds of plain water, generally cold, but sometimes warm. This, however, is to be done only after the disease has continued for some time, and at least for a week.

2. A second mean of determining to the surface of the body, is by the use of neutral salts. These neutrals, in a certain dose, taken into the stomach, produce soon after a sense of heat upon the surface of the body; and, if the body be covered close and kept warm, a sweat is readily brought out. The same medicines taken during the cold stage of a fever, very often put an end to it, and bring on the hot one; and they are also remarkable for stopping the vomiting which so frequently attends the cold stage of fevers. All this shows, that neutral salts have a power of determining the blood to the surface of the body, and may therefore be of use in taking off the spasm which subsists there in fevers. The neutral most commonly employed in fevers, is that formed of an alkali with the native acid of vegetables. But all the other neutrals have more or less of the same virtue; and perhaps some of them, particularly the ammoniacal salts, possess it in a stronger degree. As cold water taken into the stomach often shows the same diaphoretic effects with the neutral salts, it is probable that the effect of the latter depends upon their refrigerant powers.

3. A third method of determining to the surface of the body, and taking off the spasm subsisting there, is by the use of sudorifics and by sweating. The propriety of this practice has been much disputed; and many specious arguments may be adduced both for and against it. In its favour may be urged, 1. That in healthy persons, in every case of increased action of the heart and arteries, a sweating takes place, and is, seemingly, the means of preventing the bad effects of such increased action. 2. That, in fevers, their most usual solution and termination is by spontaneous sweating. 3. That, even when excited by art, it has been found useful at certain periods and in certain species of fever.—On the other hand, it may be urged against the practice of sweating, 1. That in fevers, as a spontaneous sweating does not immediately come on, there are some circumstances different from those in a state of health, and which may render it doubtful whether the sweating can be safely excited by art. 2. That in many cases the practice has been attended with bad consequences. The means commonly employed have a tendency to produce an inflammatory diathesis; which, if not taken off by the sweat succeeding, must be increased with much danger. Thus sweating employed to prevent the accessions of intermitting fevers has often changed them into a continued form, which is always dangerous. 3. The utility of the practice is doubtful; as sweating, when it happens, does not always give a final termination, as must be manifest in the case of intermittents, and in many continued fevers which are sometimes in the beginning attended with sweatings which do not prove final; and, on the contrary, whether they be spontaneous

Febres. Synocha.

neous or excited by art, they seem often to aggravate the disease.

From these considerations, it is doubtful if the practice of sweating can be admitted very generally; but, at the same time, it is also very doubtful if the failure of the practice, or the mischiefs said to arise from it, hath not been owing to the improper conduct of the practitioner. With respect to the last, it is almost agreed among physicians, 1. That sweating has been generally hurtful when excited by stimulant, heating, and inflammatory medicines. 2. That it has been hurtful when excited by much external heat, and continued with a great increase of the heat of the body. 3. That it is always hurtful when it does not relieve; and rather increases the frequency and hardness of the pulse, the anxiety and difficulty of breathing, the headach, and delirium. 4. That it is always hurtful if it be urged when the sweat is not fluid, and when it is partial and on the superior parts of the body only.

In these cases, it is probable, that either an inflammatory diathesis is produced, which increases the spasm on the extreme vessels; or that, from other causes, the spasm is too much fixed to yield easily to the increased action of the heart and arteries: and upon either supposition it must be obvious, that urging the sweat may produce determinations to some of the internal parts, with very great danger.

Notwithstanding these doubts, however, it still remains true, 1. That sweating has been often useful in preventing the accessions of fevers when they have been certainly foreseen, and a proper conduct employed. 2. That even after fevers have in some measure come on, sweating has interrupted their progress when properly employed, either at the very beginning of the disease, or during its approach and gradual formation. 3. That even after pyrexiæ have continued for some time, sweating has been successfully employed in curing them, as is particularly exemplified in the case of a rheumatism. 4. That certain fevers produced by a very powerful sedative contagion, have been generally treated most successfully by sweating.

These instances are in favour of sweating, but give no general rule; and it must be left to farther experience to determine how far any general rule can be established in this matter. In the mean time, if the practice of sweating is to be attempted, the following rules may be laid down for the conduct of it: 1. That a sweat should be excited without the use of stimulant inflammatory medicines. 2. That it should be excited with as little external heat, and with as little increase of the heat of the body, as possible. 3. That, when excited, it should be continued for a due length of time; not less than 12 hours, and sometimes for 24 or 48 hours; always, however, supposing that it proceeds without the dangerous circumstances already mentioned. 4. That for some part of the time, and as long as the person can easily bear, it should be carried on without admitting of sleep. 5. That it should be rendered universal over the whole body; and therefore particularly that care should be taken to bring the sweating to the lower extremities. 6. That the practice should be rendered safer by moderate purging excited at the same time. 7. That it should not be suddenly checked by cold anyhow applied to the body.

When attention is to be given to these rules, the sweating may be excited, 1. By warm bathing, or a fomentation of the lower extremities. 2. By frequent draughts of tepid liquors, chiefly water, rendered more grateful by the addition of a light aromatic, or more powerful by that of a small quantity of wine. 3. By giving some doses of neutral salts. 4. Most effectually, and perhaps most safely, by a large dose of an opiate, joined with a portion of neutral salts, and of an emetic.

The fourth mean of determining to the surface of the body, and thereby taking off the spasm affecting the extreme vessels, is by the use of emetics. These, particularly of the antimonial kind, have been employed in the cure of fevers ever since the introduction of chemical medicines; but though of late their use has become very general, their efficacy is still disputed, and their manner of operating is differently explained.

Vomiting is in many respects useful in fevers: as it evacuates the contents of the stomach, as it emulges the biliary and pancreatic ducts, and evacuates the contents of the duodenum, and perhaps also of a large portion of the intestines; as it agitates the whole of the abdominal viscera, it expedes the circulation in them, and promotes their several secretions; and, lastly, as it agitates also the viscera of the thorax, it has like effects there.

It is not to this cause, however, that we are to impute the effect vomiting has in determining to the surface of the body. This must be attributed to the particular operation of emetics upon the muscular fibres of the stomach, whereby they excite the action of the extreme arteries on the surface of the body, and by this means effectually determine the blood to these vessels, remove the atony, and take off the spasm affecting them. For this purpose they are exhibited in two different ways; that is, either in such doses as may excite full and repeated vomitings, or in such doses as may excite sickness and nausea only, with little or no vomiting at all.

Full vomiting is well suited to determine to the surface of the body, and thereby to obviate the atony and spasm which lay the foundation of fever. Thus, vomiting, excited a little before the expected accession of the paroxysm of an intermittent, has been found to prevent the paroxysm altogether. It has been observed also, that when contagion has been applied to a person, and first discovers its operation, an emetic given has prevented the fever which might otherwise have been expected.

These are the advantages to be obtained by exciting vomiting at the first approach of fevers, or of the paroxysm of fevers; and they may also be applied after fevers are formed, to take off, perhaps entirely, the atony and spasm, or at least to moderate these, so that the fever may proceed more gently and safely. It is seldom, however, that vomiting is found to produce a final solution of fevers; and after they are once formed, it it commonly necessary to repeat the vomiting several times; but this is attended with inconveniency, and sometimes with disadvantage. The operation of full

full vomiting is transitory, and the exercise of vomiting is a debilitating power; and therefore, when the vomiting does not remove the atony and spasm very entirely, it may give occasion to their recurrence with greater force. For these reasons, after fevers are fully formed, some physicians have thought proper to employ emetics in nauseating doses only. These are capable of exciting the action of the extreme vessels, and their operation is more permanent. At the same time they often show their power by exciting some degree of sweat, and their operation is rendered more safe by their commonly producing some evacuation by stool. But nausea continued for any great length of time, is to most patients a sensation highly distressing, and almost insufferable.

The emetics chiefly in use at present are, ipecacuanha and antimony. The former may be employed for determining to the surface of the body: but, even in very small doses, it so readily excites vomiting, that it is with difficulty employed for the purpose of nauseating only; and in whatever manner employed, there is reason to suspect that its effects are less permanent, and less powerfully communicated from the stomach to the rest of the system, than those of antimony. This last is therefore generally preferred; and its preparations, seemingly various, may all be reduced to two heads; one comprehending those in which the reguline part is in a condition to be acted upon by acids, and therefore on meeting with acids in the stomach it becomes active; and another, comprehending those preparations in which the reguline part is already joined with an acid, rendering it active. Of each kind there are great numbers, but not differing essentially from one another; the two most worthy of notice are, the *calx nitrata antimonii*, and *emetic tartar*, or *tartrite of antimony*, of the Edinburgh Dispensatory. Both these are very efficacious medicines; but the latter seems preferable, because its dose is capable of being better ascertained; though the former, on account of its slower operation, may have some advantages, and in certain cases be more efficacious as a purgative and sudorific.

The *calx nitrata antimonii*, when first introduced into the pharmacopœia of the Edinburgh college was supposed to be very nearly, if not precisely, the same with a medicine which has of late been highly celebrated in the cure of fevers, Dr James's powder. But from more accurate observations, there is now reason to believe that the pulvis antimonialis of the London Pharmacopœia, formed by the calcination of antimony with hartshorn, approaches more nearly to that celebrated arcanum. But at any rate, the calx antimonii nitrata, the pulvis antimonialis, and James's powder, are probably not essentially different from each other. The two latter, however, have the most near resemblance; and accordingly the Edinburgh college, in their Pharmacopœia, have introduced an article under the title of *antimonium calcarco-phosphoratum*, which they consider as so much similar to James's powder, that they have used as a synonyme for it, the title of *pulvis Jacobi*.

The time most proper for exhibiting those medicines is a little before the accession, when that can be certainly known. In continued fevers the exacerbations are not always very observable; but there is reason to believe, that one commonly happens about noon or soon after it; and that these, therefore, are the most proper times for exhibiting emetics.

With respect to the manner of administration, that of the *calx nitrata* is simple, as the whole of what is thought a proper dose may be given at once; and no more can be properly given till the next accession. The administration of the emetic tartar is different. It is to be given in small doses, not sufficient to excite vomiting; and these doses are to be repeated after short intervals for several times, till sickness, nausea, and some, though not much, vomiting come on. The difference of administration must depend upon the dose, and the length of the interval at which it is given. If it be intended that the medicine should certainly operate by stool, the doses are made small, and the intervals long. On the contrary, when vomiting is proper, or when much purging ought to be avoided, and therefore some vomiting must be admitted, the doses are made larger, and the intervals shorter. With respect to both kinds of preparations, the repetition is to be made at the times of accession, but not very often: for if the first exhibitions, duly managed, have little effect, it is seldom that the after exhibitions have much; and it sometimes happens that the repeated vomiting, and especially repeated purging, does harm by weakening the patient.

(2.) The other set of internal medicines which are supposed useful in taking off the spasm of the extreme vessels, are those named *antispasmodics*. But whatever may be the virtues of some of them in this way, such is their power of stimulating at the same time, that very few of them can with safety be administered in fevers of an inflammatory nature. Almost the only one which can with safety be exhibited in these cases is camphor; and the operations of this are by no means well ascertained. Dr Huxham mentions it as a corrector of the acrimony of cantharides; and assures us, that it very effectually promotes a diaphoresis. But from the remarks of other practitioners, we have no just reason to suppose that it acts perceptibly in a dose of five or six grains, though in 15 or 20 it produces a particular kind of intoxication.

Secondly, The external means suited to take off the spasm of the extreme vessels, are blistering and warm bathing.

1. What are the effects of blistering so frequently employed in fevers is not yet agreed among physicians. Dr Cullen is of opinion, that the small quantity of cantharides absorbed from a blistering plaster, is not sufficient to change the consistence of the mass of blood; and therefore, that such a quantity can neither do good by resolving phlogistic lentor if it exists, nor do harm by increasing the dissolution of the blood arising from a putrid tendency in it. The effects of cantharides upon the fluids, therefore, may be entirely neglected. The inflammation produced by the application of cantharides to the skin, affords a certain proof of their stimulant power: but in many persons the effect of that stimulus is not considerable; in many it is not communicated to the whole system; and even when it does take place in the whole system, it seems to be taken off very entirely by the effusion and evacuation of serum from the blistered part. It may be concluded, therefore, that neither much good is to be expected,

 nor

Febres.

nor much harm to be apprehended, from the stimulant power of blistering; and the certainty of this conclusion is established by the great benefit arising from the proper practice of blistering in inflammatory diseases. Much has been imputed to the evacuation made by blistering; but it is never so considerable as to affect the whole system; and therefore can neither, by a sudden depletion, relax the sanguiferous system, nor by any revulsion affect the general distribution of the fluids. The evacuation, however, is so considerable as to affect the neighbouring vessels; and the manifest utility of blistering near the part affected in inflammatory diseases leads us to think, that blistering, by deriving to the skin, and producing an effusion there, relaxes the spasm of the deeper seated vessels. It is in this manner, most probably, that the tumor of a joint, from an effusion into the cellular texture under the skin, takes off the rheumatic pain formerly affecting that joint. Analogous to this, probably, is the good effect of blistering in continued fevers, arising from the relaxation of the spasm of the extreme vessels by a communication of the blistered part with the rest of the skin. A blister may be employed at any period in continued fevers; but it will be of most advantage in the advanced state of such fevers, when, the reaction being weaker, all ambiguity from the stimulating power of blistering is removed, and when it may best concur with other circumstances tending to a final solution of the spasm.

From this view of the matter, it will appear that the part of the body to which blisters ought to be applied is indifferent, except upon the suspicion of topical affection, when the blistering is to be made as near as possible to the part affected. Whether sinapisms and other *rubefacientia* act in a manner analogous to what has been supposed of blistering may be doubtful; but their effects in rheumatism and other inflammatory diseases render it probable.

2. The other external means of taking off the spasm of the extreme vessels is warm bathing. This was frequently, and in different circumstances, employed by the ancients; but has, till very lately, been neglected by modern physicians. As the heat of the bath stimulates the extreme vessels, and, with the concurrence of moisture, also relaxes them, it seems to be a safe stimulus, and well suited to take off the spasm affecting these vessels. It may be applied to the whole body by immersion; but this is in many respects inconvenient. From extensive experience it appears, that most of the purposes of warm bathing can be obtained by a fomentation of the legs and feet, it properly administered, and continued for a due length of time, not less than an hour. The marks of the good effects of such a fomentation are, the patient's bearing it easily, its relieving delirium, and inducing sleep.

Typhi

Description. Of all the descriptions we have of the nervous fever, that of Dr Huxham is perhaps the best. According to him, the patient at first grows somewhat listless, and feels slight chills and shudders, with uncertain flushes of heat, and a kind of weariness all over, like what is felt after great fatigue. This is always attended with a sort of heaviness and dejection of spirit, and more or less of a load, pain, or giddiness of the head; a nausea or disrelish of every thing soon follows, without any considerable thirst, but frequently with retching to vomit, though little but insipid phlegm is brought up. Though a kind of lucid interval of several hours sometimes intervenes, yet the symptoms return with aggravation, especially towards night; the head grows more giddy or heavy; the heat greater; the pulse quicker, but weak; with an oppressive kind of breathing. A great torpor, or obtuse pain and coldness, affects the hinder part of the head frequently, and oftentimes a heavy pain is felt on the top all along the *coronary suture*; this, and that of the back part of the head, generally attend nervous fevers, and are commonly succeeded by some degree of a delirium. In this condition the patient often continues for five or six days, with a heavy, pale, sunk countenance; seemingly not very sick, and yet far from being well; restless, anxious, and commonly quite void of sleep, though sometimes very drowsy and heavy; but although he appears to those about him actually to sleep, he is utterly insensible of it. The pulse during all this time is quick, weak, and unequal; sometimes fluttering, and sometimes for a few moments slow; nay, even intermitting, and then with a sudden flush in the face, immediately very quick, and perhaps soon after surprisingly calm and equal; and thus alternately. The heats and chills are as uncertain and unequal; sometimes a sudden colour and glow arise in the cheeks, while the tip of the nose and ears is cold, and the forehead at the same time in a cold dewy sweat. Nay, it is very common, that a high colour and heat appear in the face, when the extremities are quite cold. The urine is commonly pale, and often limpid; frequently of a whey colour, or like vapid small beer, in which there is either no manner of sediment, or a kind of loose matter like bran irregularly scattered up and down in it. The tongue at the beginning is seldom or never dry or discoloured, but sometimes covered with a thin whitish mucus: at length, indeed, it often appears very dry, red, and chapped, or of the colour of pomegranate rind; but this chiefly at the close of the disease: yet, however dry the tongue and lips seem, the patient seldom complains of thirst, though sometimes of a heat in the tongue. About the seventh or eighth day, the giddiness

Fevers. Typhus.

giddiness, pain, or heaviness of the head become much greater, with a constant noise in it, or *tinnitus aurium;* which is very disturbing to the sick, and frequently brings on a delirium. The load on the præcordia, anxiety and faintness, grow much more urgent; and patients often fall into an actual deliquium, especially if they attempt to sit up; cold sweats suddenly come out on the forehead, and on the backs of the hands (though at the same time there be too much heat in the cheeks and palms), and as suddenly go off. If the urine now grow more pale and limpid, a delirium is certainly to be expected, with universal tremors and *subsultus tendinum;* the delirium is seldom violent, but as it were a confusion of thought and action, muttering continually and faltering in their speech. Sometimes they awake only in a hurry and confusion, and presently recollect themselves, but forthwith fall into a muttering dozy state again. The tongue grows often very dry at the height, especially in its middle part, with a yellowish list on each side, and trembles greatly when the sick attempts to put it out. Frequently profuse sweats pour forth all at once, about the ninth, tenth, or eleventh day, commonly coldish and clammy on the extremities; oftentimes very thin stools are discharged, and then nature sinks apace; the extremities grow cold, the nails pale or livid; the pulse may be said to tremble and flutter, rather than to beat, the vibrations being so exceedingly weak and quick that they can scarce be distinguished; though sometimes they creep on surprisingly slow, and very frequently intermit. The sick become quite insensible and stupid, scarce affected with the loudest noise or the strongest light; though, at the beginning, strangely susceptible of the impressions of either. The delirium now ends in a profound coma, and that soon in death. The stools, urine, and tears, run off involuntarily, and denounce a speedy dissolution, as the tremblings and twitchings of the nerves and tendons are preludes to a general convulsion, which at once snaps the thread of life. In one or other of these ways are the sick carried off, after having languished for 14, 18, or 20 days; nay, sometimes much longer. Most patients grow deaf and stupid towards the end of this disease (some extremely deaf), though too quick and apprehensive at the beginning; insomuch that the least noise or light greatly offended them. Many from their immoderate fears seem to hurry themselves out of life, where little danger is apparent at the beginning: nay, some will not allow themselves to sleep, from a vain fear of dozing quite away; and others from the vast hurry, anxiety, and confusion of which they are sensible either during sleep or at their waking.

Causes of, and persons subject to, this disorder. The nervous fever is most frequently the consequence of contagion. It most commonly attacks persons of weak nerves, a lax habit of body, and a poor thin blood; those who have suffered great evacuations, a long dejection of spirits, immoderate watchings, studies, fatigue, &c.; also those who have used much crude unwholesome food, vapid impure drinks, or who have been confined long in damp foul air; who have broken the vigour of their constitutions by salivations, too frequent purging, immoderate venery, &c. Hence we see how the disease is connected with an extreme debility of the nervous system; for when people are prepared for this fever by having their nerves already weakened, the contagious particles immediately attack the nervous system, without so much affecting the state of the blood or juices, though the latter are greatly affected in the putrid malignant fevers.

Prognosis. In nervous fevers, the prognosis is very much the same with that of the putrid malignant kind. And although death be not so frequent as in that modification of fever, yet it may justly be considered as a very fatal disease.

Cure. As this fever is produced by contagion affecting the nervous system of a person already debilitated, and thus producing weakness in an extreme degree, we have now occasion to consider Dr Cullen's *two indications* of cure omitted under the *Synocha;* namely, to remove the cause and obviate the effects of debility, and to correct the putrescent tendency of the fluids; for though, in the beginning of nervous fevers, the tendency to putrefaction be not remarkable, it becomes exceedingly great towards their conclusion.

[1.] In answering the first indication, Dr Cullen observes, that most of the sedative powers inducing debility cease to act soon after they have been first applied; and therefore the removing them is not an object of the present indication. There is only one which may be supposed to continue to act for a long time, and that is the contagion applied; but we know nothing in the nature of contagion that can lead us to any measures for removing or correcting it. We know only its effects as a sedative power inducing debility, or as a ferment inducing a tendency to putrefaction in the fluids, the former of which at present falls under our consideration.—The debility induced in fevers by contagion, or other causes, appears especially in the weaker energy of the brain; but in what this consists, or how it may be restored, we do not well know; but as nature, seemingly for this purpose, excites the motion of the heart and arteries, we must ascribe the continuance of the debility to the weaker re-action of the sanguiferous system: the means, therefore, which we employ for obviating debility, are immediately directed to support and increase the action of the heart and arteries; and the remedies employed are tonics or stimulants.

In contagious diseases we know, both from the effects which appear, and from dissections, that the tone of the heart and arteries is considerably diminished; and that tonic remedies are therefore properly indicated. We are to consider these remedies as of two kinds; 1. The power of cold; 2. That of tonic medicines.

The power of cold as a tonic in fevers may be employed in two ways: either as thrown into the stomach, or as applied to the surface of the body. As we have already observed that the power of cold may be communicated from any one part to every other part of the system, so it will be readily allowed that the stomach is a part as fit as any other for this communication, and that cold drink taken into the stomach may prove an useful tonic in fevers. This the experience of all ages has confirmed, but at the same time it has been frequently observed, that, in certain circumstances, cold drink taken into the stomach has proved very hurtful; and therefore that its use in fevers requires some limitations,

Febres.

tations. What these limitations should be, and what are all the circumstances which may forbid the use of cold drink, it is difficult to determine; but it seems, clearly forbidden in all cases where a phlogistic diathesis prevails in the system, and more especially when there are topical affections of an inflammatory nature.

The other method of employing cold as a tonic, is by applying it to the surface of the body, as a refrigerant power fit to moderate the violence of reaction; but probably it may here also be considered properly as a tonic, and useful in cases of debility.—Not only cool air, but cold water also may be applied to the surface of the body as a tonic. The ancients frequently applied it with advantage to particular parts as a tonic; but it is a discovery of modern times, that, in the case of putrid fevers attended with much debility, the body may be washed all over with cold water. This was first practised at Breslaw in Silesia, as appears from a dissertation under the title of *Epidemia Verna, quæ Wratislaviam, anno* 1737 *afflixit*, to be found in the *Acta Nat. Curios.* vol. x. And from other writers it appears, that the practice has passed into some of the neighbouring countries. But in Britain the use of cold water externally applied has of late been more extensively introduced than into any other country of Europe. For this we are chiefly indebted to the late ingenious Dr Currie of Liverpool. He has recommended the dashing cold water over the whole surface of the body, as a means not only of obviating heat, delirium, and other symptoms most urgent; but of putting an immediate stop to the disease. And there can be no doubt that the practice has often been attended with the most salutary consequences. But it is by no means so generally advantageous as Dr Currie and some others are inclined to believe. It is in but very rare instances that an artificial termination of fever can thus be obtained; and even as obviating symptoms, it is not unfrequently attended with bad consequences. It can never be employed with safety unless where the heat is very urgent. And perhaps all the advantages of cold immersion may be obtained merely from cold washing, a practice now very common in Britain.

The medicines which have been employed in fevers as tonics are various. If the acetite of lead hath been found useful, it is probably as a tonic rather than as a refrigerant; and the *ens veneris*, or rather preparations of iron which have been employed, can act as tonics only. The preparations of copper, from their effects in epilepsy, are presumed to possess a tonic power; but whether their use in fevers be founded on their tonic or emetic powers, is uncertain. And upon the whole there may no doubt occur some instances of fevers being cured by tonics taken from the fossil kingdom; but the vegetable tonics are the most efficacious, and among these the cinchona certainly holds the first place.

The cinchona has commonly been considered as a specific, or a remedy of which the operation was not understood. We must observe, however, that, as in many cases the effects of the bark are perceived soon after its being taken into the stomach, and before it can possibly be conveyed to the mass of blood, we may conclude, that its effects do not arise from its operating on the fluids; and must therefore depend upon its acting on the nerves of the stomach, and being thereby communicated to the rest of the nervous system. This operation seems to be a tonic power, the bark being a remedy in many cases of debility, particularly in gangrene; and if its operation may be explained from its possessing a tonic power, we may easily perceive why it is improper when a phlogistic diathesis prevails; and from the same view we can ascertain in what cases of continued fever it may be admitted. These cases are either where considerable remissions have appeared, when it may be employed to prevent the return of exacerbations, on the same footing as it is used in intermitting fevers; or in the advanced state of fevers, when all suspicion of an inflammatory condition is removed, and a general debility prevails in the system; and its being then employed is sufficiently agreeable to the present practice.

Typhus.

Another set of medicines to be employed for obviating debility and its effects, are the direct stimulants. These, in some measure, increase the tone of the moving fibres; but are different from the tonics, as they more directly excite and increase the action of the heart and arteries. This mode of operation renders their use ambiguous; and when an inflammatory diathesis is present, the effects of the stimulants may be very hurtful; but it is still probable, that in the advanced state of these fevers, when debility prevails, they may be useful.

Of all the stimulants which may be properly employed, wine seems to be the most eligible. It has the advantage of being grateful to the palate and stomach, and of having its stimulant parts so much diluted, that it can be conveniently given in small doses; and therefore it may be employed with sufficient safety.—It may be suspected that wine has an operation analogous to that of opium; and on good grounds. But we can distinctly remark its stimulant power only; which renders its effects in the phrenetic delirium manifestly hurtful; and in the mild delirium depending on debility, as remarkably useful.

[2.] We must now proceed to the other indication of cure, namely, to correct or obviate the tendency in the fluids to putrefaction. This may be done, 1. By avoiding any new application of putrid or putrescent matter. 2. By evacuating the putrid or putrescent matter already present in the body. 3. By correcting the putrid or putrescent matter remaining in the body by diluents and antiseptics. 4. By supporting the tone of the vessels, and thereby resisting further putrefaction, or obviating its effects. 5. By moderating the violence of reaction, considered as a means of increasing putrefaction.

The further application of putrid or putrescent matter may be avoided, 1. By removing the patient from places filled with corrupted air. 2. By preventing the accumulation of the patient's own effluvia, by a constant ventilation, and by a frequent change of bedclothes and body linen. 3. By the careful and speedy removal of all excremental matters from the patient's chamber. 4. By avoiding animal food.

The putrid or putrescent matter already present in the body, may be evacuated partly by frequent evacuations of the contents of the intestines; and more effectually still by supporting the excretions of perspiration

ration and urine by the plentiful use of diluents. That which remains in the body may be rendered more mild and innocent by the use of diluents, or may be corrected by the use of antiseptics. These last are of many and various kinds; but which of them are conveniently applicable, or more particularly suited to the case of fevers, is not well ascertained. Those most certainly applicable and useful are acescent aliments, particularly fruits, acids of all kinds, and neutral salts.

The progress of putrefaction may be considerably retarded, and its effects obviated, by supporting the tone of the vessels; and this may be done by tonic medicines, of which the chief are cold, and the Peruvian bark, as already mentioned. The violence of reaction increasing the tendency to putrefaction, may be moderated by the means already mentioned under *Synocha*.

These are the proper indications to be observed in the cure of the slow nervous fever; and they are chiefly fulfilled by cleanliness, cool air, and diluents; which, perhaps, upon the whole, are more useful in fevers, than all other practices put together. Dr Huxham observes, that evacuations (especially bleeding), are improper even at the beginning. Even a common purgative given at this time hath been followed by surprising languors, syncope, and a train of other ill symptoms. It may, however, sometimes be necessary to cleanse the stomach and primæ viæ by a gentle emetic, or a mild laxative. Indeed, where nausea, sickness and load at stomach are urgent, as is frequently the case in the beginning of this fever, a vomit is necessary. Clysters of milk, sugar, and salt, may be injected with safety and advantage every second or third day, if nature wants to be prompted to stool. The temperate, cordial, diaphoretic medicines, are certainly, according to our author, most proper in these fevers; and a well-regulated, supporting, diluting diet is necessary. The latter of itself, judiciously managed, will go a great way in the cure, especially if assisted by well-timed and well-applied blisters, and a due care to keep the patient as quiet as possible both in body and mind. But it should be noted, that strong opiates are commonly very pernicious, however much the want of sleep and restlessness may seem to demand them. Mild diaphoretics, such as neutral draughts or elixir paregoricum, have much better effects; which, by raising a gentle easy sweat, or at least a plentiful perspiration, calm the hurry of the spirits, and a refreshing sleep ensues. Where the confusion and dejection of spirits are very considerable, blisters have been advised to be applied to the neck, occiput, or behind the ears; and during all this a free use of thin wine whey, some pleasant ptisan or gruel, with a little pure wine, must be directed. Indeed the patients, in this case, should drink frequently; though such quantities may not be necessary as in the ardent or even putrid malignant fevers; yet they should be sufficient to carry on the work of dilution, support the sweats, and supply the blood with fresh and wholesome fluids, in place of that noxious matter which is continually passing off. In this view also a thin chicken broth is of service, both as food and physic, especially towards the decline of the disease; and for the same reason thin jellies of hartshorn, sago, and panada, are useful, adding a little wine to them, and the juice of orange or lemon.

Typhus.

It is observable, that the sick are never so easy as when they are in a gentle sweat; for this soon removes the hurry of spirits, exacerbations of heat, &c. But profuse sweats should never be encouraged, much less induced, by very strong heating medicines, especially in the beginning or advance of the fever; for they too much exhaust the vital powers, and are followed by a vast dejection of spirits, tremors, startings of the tendons, and sometimes end in rigors, cold clammy sweats, syncope, or a comatose disposition. Sometimes irregular partial heats and flushes succeed, with great anxiety, restlessness, delirium, difficulty of breathing, and a vast load and oppression in the præcordia, so as to incline the less cautious observer to think there may be something pneumonic in it; but even here we must beware of bleeding, as the pulse will be found very small and unequal, though very quick. Nor is bleeding contraindicated only by the weakness and fluttering of the pulse, but also by the pale, limpid, and watery urine which is commonly attendant. These symptoms denote the load, anxiety, and oppression on the præcordia to proceed from an affection of the nervous system, and not from a pneumonic obstruction or inflammation. The breathing in this case, though thick and laborious, is not hot, but a kind of sighing or sobbing respiration, nor is there often any kind of cough concomitant; so that it has been conjectured to proceed from some spasm on the vitals. Here therefore the nervous cordial medicines are indicated, and blisters to the thighs, legs, or arms.

The above-mentioned difficulty of breathing, anxiety, and oppression, many times precede a miliary eruption, which often appears on the seventh, ninth, or eleventh day of the fever, and sometimes later. Indeed great anxiety and oppression on the præcordia always precede pustular eruptions of any kind in all sorts of fevers. This eruption should be promoted by soft easy cordials and proper diluents; to which should be sometimes added some gentle aromatics. These tend to calm the universal uneasiness commonly complained of, and also very effectually promote a diaphoresis, with which the miliary eruptions freely and easily advance. But however advantageous these commonly are, profuse sweats are seldom or never so, even though attended with a very large eruption. Two or three crops of these miliary pustules have been known to succeed one another, following profuse sweats, not only without advantage, but with great detriment to the patients, as they were thereby reduced to an extreme degree of weakness; so that they justly may be reckoned symptomatic rather than any thing else, and the consequent eruption is often merely the symptom of a symptom.

In these profuse colliquative sweatings a little generous red wine (diluted somewhat, if necessary) may be given with the greatest advantage; as it presently moderates the sweats, supports the patient, and keeps up the miliary papulæ if they happen to attend. Towards the decline of the fever also, where the sweats are abundant and weakening, small doses of the tincture of cinchona with saffron and snakeroot may be given with the greatest advantage, frequently interposing a dose of rhubarb to carry off the putrid colluvies in the first passages; which withal makes the remissions or intermissions that often happen in the decline of nervous fevers

Febres. fevers more distinct and manifest, and gives a fairer opportunity of throwing in the bark; for in the proper exhibition of this medicine we are to place our chief hope of curing both the nervous and putrid malignant fevers.

Typhus.

Description. This disease has been supposed to differ from the former in degree only; and there are many circumstances which would lead us to conclude, that both frequently originate from a contagion precisely of the same nature. In the same manner we see, during different seasons, and in different circumstances, various degrees of malignity in smallpox. Though every instance of the disease depends on the introduction of a peculiar and specific contagion into the body, yet this contagion in particular epidemics evidently possesses peculiar malignancy. The same is probably the case with the typhoid fever: But whether this observation be well founded or not, there cannot be a doubt that the typhus gravior or putrid fever is a disease of the most dangerous nature, as, besides the extreme debility of the nervous system, there is a rapid tendency of the fluids to putrefaction, which sometimes cuts off the patient in a few days, nay, in the warm climates, in 12 or 14 hours; or if the patient recovers, he is for a long time, even in this country, in an exceeding weak state, and requires many weeks to recover his former health.

The putrid fevers, according to Huxham, make their attack with much more violence than the slow nervous ones; the rigors are sometimes very great, though sometimes scarce felt; the heats much sharper and permanent; yet, at first, sudden, transient, and remittent: the pulse more tense and hard, but commonly quick and small; though sometimes slow, and seemingly regular for a time, and then fluttering and unequal. The headach, nausea, and vomiting, are much more considerable even from the beginning. Sometimes a severe fixed pain is felt in one or both temples, or over one or both eyebrows; frequently in the bottom of the orbits of the eyes. The eyes always appear very dull, heavy, sometimes yellowish, and very often a little inflamed. The countenance seems bloated, and more dead-coloured than usual. Commonly the temporal arteries throb much, and a tinnitus aurium is very troublesome: a strong vibration also of the carotid arteries frequently takes place in the advance of the fever, though the pulse at the wrist may be small, nay even slow: this is a certain sign of an impending delirium,

rium, and generally proceeds from some considerable obstructions in the brain.

The prostration of spirits, weakness, and faintness, are often surprisingly great and sudden, though no inordinate evacuation happens; and this too sometimes when the pulse seems tolerably strong. The respiration is most commonly laborious, and interrupted with a kind of sighing or sobbing, and the breath is hot and offensive.

Few or none of these fevers are without pain in the back and loins; always an universal weariness or soreness is felt, and often much pain in the limbs. Sometimes a great heat, load, and pain, affect the pit of the stomach, with perpetual vomiting of porraceous or black bile, and a most troublesome singultus; the matter discharged is frequently of a very nauseous smell. The tongue, though only white at the beginning, grows daily more dark and dry; sometimes of a shining livid colour, with a kind of dark bubble at top; sometimes exceeding black; and so continues for many days together; nor is the tinct to be got off many times for several days, even after a favourable crisis: at the height of the disease, it generally becomes very dry, stiff, and black, or of a dark pomegranate colour. Hence the speech is very inarticulate, and scarce intelligible. The thirst in the increase of the fever is commonly very great, sometimes unquenchable; and yet no kind of drink pleases, but all seem bitter and mawkish; at other times, however, no thirst is complained of, though the mouth and tongue are exceedingly foul and dry; this is always a dangerous symptom, and ends in a frenzy or coma. The lips and teeth, especially near the height, are covered with a very black tenacious sordes. At the commencement of the fever, the urine is often crude, pale, and vapid, but grows much higher coloured in the advance, and frequently resembles a strong lixivium, or citrine urine, tinged with a small quantity of blood; it is without the least sediment or cloud, and so continues for many days together: by degrees it grows darker, like dead strong high-coloured beer, and smells very rank and offensive. In petechial fevers, the urine has often been seen almost black and very *fetid*. The stools, especially near the height, or in the decline of the fever, are for the most part intolerably fetid, green, livid, or black, frequently with severe gripes and blood. When they are more yellow or brown, the less is the danger; but the highest when they run off insensibly, whatever their colour may be. It is likewise a very bad symptom when the belly continues tense, swollen, and hard, after profuse stools; for this is generally the consequence of an inflammation or mortification of the intestines. A gentle diarrhœa is often very beneficial, and sometimes seems to be the only way which nature takes to carry off the morbific matter.

Sometimes black, livid, dun, or greenish spots appear on different parts of the skin, particularly on the breast, which always indicate a high degree of malignity; but the more florid the spots are, the less danger is to be feared. It is also a good sign when the black or violet petechiæ become of a brighter colour. The large, black, or livid spots, are almost always attended with profuse hæmorrhagies; and the small, dusky, brown spots, like freckles, are not much less dangerous than the livid or black; though they are seldom accompanied with fluxes of blood: excessively profuse, cold, clammy sweats are often concomitant, by which also they sometimes vanish, though without any advantage to the patient. The eruption of the petechiæ is uncertain; sometimes they appear on the fourth or fifth day, though sometimes not till the eleventh, or even later. The *vibices*, or large dark blue or greenish marks, seldom appear till very near the fatal period. Frequently also we meet with an efflorescence like the measles in malignant fevers, but of a much more dull and livid hue; in which the skin, especially on the breast, appears as it were marbled or variegated. This in general is an ill symptom, and is often attended with fatal consequences.

Sometimes about the 11th or 14th day, on the occurrence of profuse sweats, the petechiæ disappear, and vast quantities of white miliary pustules break out. This is seldom found of any considerable advantage; but an itching, smarting, red rash, commonly gives great relief; and so do the large, fretting, watery bladders, which many times rise upon the back, breast, shoulders, &c. A scabby eruption likewise about the lips and nose is one of the salutary symptoms; and the more hot and angry it is, so much the better. But of much more uncertain and dangerous event are the brown-coloured aphthæ; nor are those that are exceeding white and thick, like lard, of a very promising aspect. They are soon succeeded by great difficulty of swallowing, pain and ulceration of the fauces, œsophagus, &c. and with an incessant singultus: the whole *primæ viæ* become at last affected; a bloody dysentery comes on, followed by a sphacelation of the intestines; as is evident from the black, sanious, and bloody stools, extremely fetid and infectious. Vibices, or large black and bluish marks resembling bruises, are frequently seen towards the close of the fever; and, when attended with lividity and coldness of the extremities, are certain tokens of approaching death. In some cases, the blackness has been known to reach almost to the elbows, and the hands have been dead-cold for a day or two before the death of the patient.

Such are the general appearances of the putrid malignant fever in this country, among those who enjoy a free air, and are not crowded together, or exposed to the causes of infection: but in jails, hospitals, or other places where the sick are crowded, and in some measure deprived of the benefit of the free air, the symptoms are, if possible, more terrible. Sir John Pringle, who had many opportunities of observing it, tells us, that the jail or hospital fever, in the beginning, is not easy to be distinguished from a common fever. The first symptoms are slight interchanges of heat and cold, a trembling of the hands, sometimes a sense of numbness in the arms, weakness of the limbs, loss of appetite; and the disorder increasing towards night, the body grows hot, the sleep is interrupted, and not refreshing. With these symptoms, for the most part, there is some pain or confusion in the head; the pulse at first is a little quicker than natural, and the patients find themselves too much indisposed to go about business, though too well to be wholly confined. When the fever advances, the above-mentioned symptoms are in a higher degree; and in particular the patient

Febres. Typhus.

patient complains of a lassitude, nausea, pains in his back, a more constant pain and confusion in his head, attended with an uncommon dejection of spirits. At this time the pulse is never sunk, but beats quick, and often varies in the same day both as to strength and fulness. It is little affected by bleeding, if a moderate quantity of blood be taken away; but if the evacuation be large, and especially if it be repeated, to answer a false indication of inflammation, the pulse, increasing in frequency, is apt to sink in force, and often irrecoverably, whilst the patient becomes delirious. But we must observe, that, in every case, independent of evacuations, the pulse sooner or later sinks, and then gives certain evidence of the nature of the disease. The appearance of the blood is various; for though it be commonly little altered, yet sometimes it will be sizy, not only on the first attack, but after the fever is formed. The worst appearance is when the crassamentum is dissolved; though this does not happen till the advanced state of the fever: indeed this seems not easy to be ascertained, as blood has been so seldom taken away at that time. The urine is also various. Sometimes it is of a reddish or flame colour, which it preserves a long time; but it is oftener pale, and changes from time to time in colour as well as crudity, being sometimes clear, sometimes clouded: towards the end, upon a favourable crisis, it becomes thick, but does not always deposit a sediment. If the sick lie warm, and have had no preceding flux, the belly is generally bound; but when they lie cold, as they often do in field-hospitals, the pores of the skin being shut, a diarrhœa is a common symptom, but is not critical. In the worst cases, a flux appears in the last stage; then the stools are involuntary, colliquative, ichorous, or bloody, and have a cadaverous smell; the effects of a mortification of the bowels, and the sign of approaching death. When the hospitals are filled with dysenteric patients, some of the nurses will be infected with the flux only, and others with this fever, ending in these bloody and gangrenous stools.

In the beginning the heat is moderate; and even in the advanced state, on first touching the skin, it seems inconsiderable: but upon feeling the pulse for some time, we are sensible of an uncommon heat (the *calor mordicans*, as it has been called), leaving an unpleasant sensation on the fingers for a few minutes. A day or two before death, if care be not taken, the extremities become cold, and the pulse is then hardly to be felt. The skin is generally dry and parched; though sometimes there are longer or shorter sweats, especially in the beginning. Such as are produced by medicine are of no use, except on the first attack, at which time they will often remove the fever; and natural sweats are never critical till the distemper begins to decline. These last are rarely profuse, but gentle, continued, and equally diffused over the body: sometimes the disease will terminate by an almost imperceptible moisture of the skin; the sweats are usually fetid, and offensive even to the patient himself.

The tongue is commonly dry; and, without constant care of the nurse, becomes hard and brown, with deep chops: but this symptom is common to most fevers. At other times, though rarely, the tongue is soft and moist to the last, but with a mixture of a greenish or yellowish colour. The thirst is sometimes great, but more frequently moderate. In the advanced state, the breath is offensive, and a blackish furring gathers about the roots of the teeth.

Some are never delirious, but all lie under a stupor or confusion; few retain their senses till death: many lose them early, and from two causes; either from immoderate bleeding, or the premature use of warm and spirituous medicines. They rarely sleep; and, unless delirious, have more of a dejected and thoughtful look than what is commonly seen in other fevers. The face is late in acquiring either a ghastly or a very morbid appearance; yet the eyes are always muddy, and generally the white is of a reddish cast as if inflamed. The confusion of head commonly rises to a delirium, especially at night; but, unless by an unseasonable hot regimen, it seldom turns to rage, or to those high flights of imagination common in other fevers. When the delirium comes to that height, the face is flushed, the eyes red, the voice is quick, and the patient struggles to get up. But when that symptom is owing to large evacuations, or only to the advanced state of the disease, the face appears meagre; the eye-lids in slumbers are only half shut; and the voice, which is commonly low and slow, sinks to a degree scarce to be heard. From the beginning there is generally a great dejection and failure of strength. A tremor of the hands is more common than a starting of the tendons; and if the subsultus occurs, it is in a lesser degree than in many other fevers. In every stage of the disease, as the pulse sinks, the delirium and tremors increase; and in proportion as the pulse rises, the head and spirits are relieved. Sometimes in the beginning, but for the most part in the advanced state, the patient grows dull of hearing, and at last almost deaf. When the fever is protracted, with a slow and low voice, the sick have a particular craving for something cordial, and nothing is so cordial or so acceptable as wine. They long for no food, yet willingly take a little panada if wine be added. But such as are delirious, with a quick voice, wild looks, a subsultus tendinum, or violent actions, though their pulse be sunk, yet bear neither hot medicines, wine, nor the common cordials.

Vomiting, and complaints of a load and sickness at stomach, though usual symptoms, are not essential to the disease; nor are pleuritic stitches, difficulty in breathing, or flying pains, to be referred so much to it as to the constitution of the patient, or to a preceding cold.

A petechial efflorescence is a frequent, though not an inseparable, attendant of this fever. It sometimes appears of a brighter or paler red, at other times of a livid colour, but never rises above the skin. The spots are small; but generally so confluent, that at a little distance the skin appears only somewhat redder than ordinary, as if the colour was uniform; but upon a nearer inspection interstices are seen. For the most part this eruption is so little conspicuous, that unless it be looked for attentively, it may escape notice. The spots appear thickest on the back and breast, less on the legs and arms, and Sir John Pringle never remembers to have seen any on the face. As to the time of their appearance, he agrees entirely with Dr Huxham. These spots are never critical, nor are they reckoned among the mortal symptoms; but only concur with other signs to ascertain the nature of the disease. The nearer they

they approach to purple, the more they are to be dreaded. In a few cases, instead of spots, purple streaks and blotches were observed. Sometimes the petechiæ did not appear till after death; and there was one case in which, after bleeding, the petechiæ were seen only on the arm below the ligature, and nowhere else on the skin.

The hospital fever, though accounted one of the continued kind, yet has generally some exacerbations at night, with a remission and often partial sweats in the day; and after a long continuance it is apt to change into a hectic, or an intermitting form. The length of the disease is uncertain. Sometimes it was terminated, either in death or recovery, in seven days after the patient took to his bed: but in the hospitals it generally continued from 14 to 20, and some died or recovered after four weeks. From the time of the sinking of the pulse until death or a favourable crisis, there is perhaps less change to be seen from day to day in this than in most other fevers. When its course is long, it sometimes terminates in suppurations of the parotid or axillary glands; and when these do not appear, it is probable that the fever is kept up by the formation of some internal abscess. The parotid glands themselves do not suppurate, but only some of the lymphatic glands that lie over them. Sir John Pringle observed one instance of a swelling of this kind on both sides, without any previous indisposition, when the person, not suspecting the cause, and applying discutient cataplasms, was, upon the tumour subsiding, seized with the hospital-fever. Many patients after the crisis of this fever complain of a pain in the limbs and want of rest; and almost all of them mention great weakness, confusion in their head, vertigo, and a noise in their ears.

Ten of the bodies of those who died of this distemper in Houghton's regiment were opened. In some, all the cavities were examined; in others, only the brain and the bowels. In some of them, the brain appeared to be suppurated. The first of this kind Sir John Pringle met with at Ghent; but the man being brought into the hospital from the barracks no earlier than two days before he died, he could only conjecture from the symptoms and the imperfect accounts he had of him, that his death was owing to a fever of this kind, after lingering near a month in it. About three ounces of purulent matter were found in the ventricles of the brain, and the whole cortical and medullary substance was uncommonly flaccid and tender; nay, some of the same kind of matter was found in the substance of the upper part of the cerebellum: yet this person, with some stupor and deafness, had his senses till the night before he died; so far, at least, that he answered distinctly when roused and spoken to; but about that time the muscles of his face began to be convulsed. Of two other instances of men who undoubtedly died of this fever, in one the cerebrum was suppurated, in the other the cerebellum. In the former case, the patient was under a stupor, with deafness from the beginning; but was never delirious, nor altogether insensible. His pulse sunk early; and about ten days before his death his head began to swell, and continued very large till within two days before he died, when it subsided a little. For several days before his end, he would taste nothing but cold water, and during his illness he lay constantly upon one side. The head being opened, an abscess as large as an egg was found in the substance of the fore-part of the right hemisphere of the brain, full of thin matter like whey. At that time five more, ill of the same fever, had the like swelling of their heads, but recovered. In the other case, the abscess in the cerebellum was about the size of a small pigeon's egg, and contained also a thin ichorous matter; nor had this patient ever been so thoroughly insensible as not to answer reasonably when spoken to. Two days before he died his urine turned pale.

These suppurations, however, were not constant; for another who died about the same time, and had been ill about the same number of days with the like symptoms, the pale water excepted, had no abscess either in the brain or cerebellum. Two were opened afterwards, in whom the cortical substance of the brain had an inflammatory appearance, but no suppuration. In one of them the large intestines were corrupted; that man went off with a looseness; and just before he died, an ichorous matter was discharged from his nose. In the military hospital at Ipswich, one who unexpectedly died of this fever after having been seemingly in a fair way of recovery, had no suppuration in his brain; but in another, who died after an abscess in both orbits, the brain was found flaccid, and about tw ounces of a thin serum in the ventricles.

Causes of, and persons subject to, this disorder. The cause of this fever, as well as that of the slow nervous fever, is an infection or contagion from some diseased animal-body, or from corrupted vegetables; and therefore is very little, if at all, different from those pestilential disorders which have arisen after battles, where great numbers of dead bodies were allowed to lie above ground, and infect the air with their effluvia. This is confirmed by an observation of Forestus, who was eye-witness to a distemper of this kind (which indeed he calls a *plague*) owing to the same cause, attended with buboes and a high degree of contagion. The same author also gives an account of a malignant fever breaking out at Egmont in North-Holland, occasioned by the rotting of a whale which had been left on the shore. We have a like observation of a fever affecting the crew of a French ship, by the putrefaction of some cattle which they had killed on the island of Nevis in the West Indies. These men were seized with a pain in their head and loins, great weakness, and a disorder of the stomach, accompanied with fever. Some had carbuncles; and on others purple spots appeared after death.

Galen assigns two causes for pestilential fevers: 1. The great heat of the weather, when the humours happen to be in a more putrescent state than usual. 2. A putrid state of the air, arising either from a multitude of dead bodies left unburied, as after a battle, or from the evaporation of corrupted lakes and marshes.

One of the most remarkable diseases incident to an army is related by Diodorus, as breaking out among the Carthaginians at the siege of Syracuse. That author not only relates some of its most distinguishing symptoms, but reasons well about its cause. He observes, that pains in the back and eruptions (φλυκταιναι) were common; that some had bloody stools; that others were seized with a delirium, so as to run about and beat all that came in their way; that the physi-

cians

Febres.

cians knew no cure; and that it was the more fatal as the sick were abandoned by every body on account of the contagion. As to the cause, the author takes notice of the multitude of people confined within a narrow compass; of the situation of the camp in low and wet ground; of the scorching heats in the middle of the day, succeeded by the cold and damp air from the marshes in the night time; to these he adds, the putrid steams arising from the marshes, and afterwards from the bodies of those who lay unburied.—This distemper seems to have been a compound of the marsh and pestilential fever.

Forestus remarks, that, from the putrefaction of the water only, the city of Delft, where he practised, was scarce ten years together free from the plague or some pestilential distemper. He adds, that the magistrates, upon his representation of the cause, erected a wind-mill for moving and refreshing the water. At that time Holland was much more subject to inundations and the stagnation of water than at present. In 1694, a fever broke out at Rochfort in France, which, on account of the uncommon symptoms and great mortality, was at first believed to be the plague. But M. Chirac, who was sent by the court to inquire into its nature, found the cause to arise from some marshes that had been made by an inundation of the sea; and observed, that the corrupted steams, which smelled like gun-powder, were carried to the town by the wind, which had long blown from that quarter. About two thirds of those who were taken ill died. In such as were opened, the brain was found either inflamed or loaded with blood; the fibres of the body were uncommonly tender; and the bowels had either suppurated or were mortified.

It is needless to mention more instances of pestilential fevers being brought on by the steams of corrupted substances, whether animal or vegetable. In general it may be remarked, that the putrefaction of these substances in a dry air is more apt to bring on a fever of the continued form; but in a moist air has a greater tendency to produce remitting fevers. But it must also be observed, that, even in cases where the most malignant fevers prevail, all persons are not equally disposed to receive the infection, though equally exposed to it with others. Some, through mere vigour of body and mind, cannot be infected with the most contagious diseases; while, on the other hand, those whose bodies are debilitated by a former disease, by study, low diet, or want, or those who have laboured under any of the depressing passions of the mind for some time, seldom or never escape. Men, therefore, who have been weakened by accidents (as those who have undergone a mercurial salivation) are very apt to fall into this distemper. Those who are taken into crowded hospitals, ill of the smallpox, however good the sort may be, fall readily into this fever, and run a greater risk of dying of it than others. The second fever is attended with double danger, seeing the patient has been so much weakened by the first. A sure sign of the corruption of the air in an hospital is when many of the nurses fall sick.

Prognosis. In these fevers we cannot draw a prognostic from any symptom by itself; and perhaps all of them together are more fallible than in others. Generally the following are good: To have little delirium; the strength little impaired; turbid urine in the decline of the disease; and at that time a gentle sweat or moisture diffused over the body, or even the skin soft and the tongue moist; or to have some loose stools succeeded by a diaphoresis; the pulse to rise by wine or cordials, with an abatement of the stupor, tremor, and other affections of the brain. Deafness is rather a good sign. A sediment in the urine, without other changes for the better, is no sure sign of recovery; and some have recovered in whose urine there was no sediment.—The bad signs are, a subsultus tendinum; the eyes much inflamed and staring; the speech quick, and the sound of the voice altered; a high delirium; perpetual watchfulness; constant sickness at the stomach, and vomitings; frequent stools, with a sinking pulse, and the disorder of the head increased; coldness of the extremities, and a tremulous motion of the tongue. It is observed to be among the worst signs when the patient complains of blindness; when he swallows with difficulty, or cannot put out his tongue when desired to do it; when he can lie on his back only, and pulls up his knees; or when insensible he endeavours to uncover his breast, or makes frequent attempts to get out of bed without assigning any reason. If to any of these are added ichorous, cadaverous, and involuntary stools, it is a sign of a mortification of the bowels and approaching death. It will not seem strange to find most of these prognostics common to the advanced state of other fevers, when we consider, that from whatever cause fevers begin, by a long continuance the humours are corrupted, and the brain and nerves affected much in the same manner as in those which arise from infection.

Typhus.

Prevention and cure. As distempers of the putrid kind never arise without an infection received from some quarter or other, the method of prevention must evidently be reduced to two general heads. 1. To avoid receiving the infection into the body; and, 2. To put the body in such a situation as may enable it to resist the infection when received. On both these methods scarce any writer hath equalled Dr Lind of Haslar, whose opinions and directions therefore we shall give pretty fully.

As putrid diseases are very common and violent in the hot countries, it is very necessary for Europeans who visit these climates to be well informed, in the first place, of the signs of an unhealthy country, that they may be upon their guard as soon as they enter any foreign region. These signs are by this author enumerated as follows.

1. A sudden and great alteration in the air, at sunset, from intolerable heat to a chilling cold. This is perceived as soon as the sun is down, and is for the most part accompanied with a very heavy dew: it shows an unhealthy swampy soil, the nature of which is such that no sooner the sun-beams are withdrawn, than the vapours emitted from it render the air damp, raw, and chilling, in the most sultry climates; so that even under the equator, in some unhealthy places, the night-air is very cold to an European constitution.

2. Thick noisome fogs, chiefly after sunset, arising from the valleys, and particularly from the mud, slime, or other impurities. In hot countries, the smell of these

these fogs may be compared to that of a new-cleaned ditch. Diseases, therefore, arising from this cause, generally take place in the night, or before sunrising.

3. Numerous swarms of flies, gnats, and other insects which attend stagnated air and unhealthy places covered with wood.

4. When all butchers meat soon corrupts, and in a few hours becomes full of maggots; when metals are quickly corroded on being exposed to the air; and when a corpse becomes intolerably offensive in less than six hours; these are proofs of a close, hot, and unwholesome country. And in such places, during excessive heats and great calms, it is not altogether uncommon for Europeans, especially such as are of a gross habit of body, to be seized at once with the most alarming and fatal symptoms of what is called the *yellow-fever*, without even any previous complaint of sickness or other symptoms of the disease. There has first been perceived an uneasy itching sensation, commonly in the legs; and upon pulling down the stockings, streams of thin dissolved blood followed, a ghastly yellow colour quickly diffused itself over the whole body, and the patient has been carried off in less than forty-eight hours.

5. A sort of sandy soil, commonly a small, loose, white sand, as that at Pensacola, Whydah, and the island of Bonavista, which is found by experience to be injurious to health. The pestiferous vapour arising, during the summer months and in the heat of the day, from such a sandy soil, is best characterized by its effects in the extensive deserts of Asia and Africa. It there constitutes what is called the *Samiel-wind;* a blast which, in the parched desert, proves instantly fatal both to man and beast; but when it passes over a soil well covered with grass and vegetables, has its effects greatly mitigated; it is, however, even then, productive of sickness: thus the southerly winds, while they blow from the deserts of Libya during the summer, at Algiers, Tunis, and Tripoli, produce an unhealthy season; and at Madras the winds, which, in the months of April and May, pass over a large tract of sand, are always hot, disagreeable, and unwholesome.

During these land-winds, sudden gusts of a more hot and suffocating nature are often observed to come from these sands once or twice, or even more frequently, in a day, which seem to be this vapour in a purer form. These gusts pass very quickly, and affect persons who happen to stand with their faces towards them in the same manner as the hot air which issues from a burning furnace, or from a heated oven, and obliges them immediately to turn away from it in order to recover breath. The effect of this hot suffocating blast or vapour on the human body, even when mitigated by passing through a moist atmosphere, is the same as that of intense cold; it shuts up every pore of the skin, and entirely stops the perspiration of such as are exposed to it. These blasts come only in the daytime, and always from the deserts. Water is the only known corrector or antidote against them: hence, coarse thick cloths, kept constantly wet, and hung up at the windows or doors, greatly mitigate their violence. A house so built as to have no windows or doors towards the deserts, is an excellent protection against their pernicious effects. The hot land-winds constantly blow at Madras and other places on the coast of Coromandel, at that season, from midnight till noon; the sea-breezes then begin, which relieve the difficulty in breathing, and the obstructed perspiration, which the former occasioned.

That the heat of these land-winds, as also of the sudden gusts which accompany them, proceeds from large tracts of sand heated by the sun, is evident from the increased heat and suffocating quality of those winds, in proportion as the day advances, and as the heat of the season is increased. The opposite winds, blowing from each side of the Balagate mountains, are a further proof of this. These mountains running from north to south, divide the Hither Peninsula of India into two equal parts, and separate what is called the *Malabar* from the *Coromandel* coast. To the former they are very near, but at a great distance from the latter. The winds blowing from those hills are on the Malabar coast always remarkably cool; but on the coast of Coromandel, in the months of April, May, June, and July, are extremely hot and suffocating, as they pass over a large tract of intermediate sand, heated during those months by an almost vertical sun. Hence the Malabar coast is always covered with an agreeable verdure; whereas the Coromandel coast, during the continuance of these hot winds, seems a barren wilderness, nothing appearing green except the trees. On the contrary, the winds that pass over these sands, after being wet with the rains, are the coldest which blow at Madras. Bottles of liquor inclosed in bags of coarse cloth, kept constantly wet, and suspended in the shade, where those hot winds may have access to them, become as cold as if they had been immersed in a solution of nitre; an effect owing undoubtedly to the constant evaporation of water from the surface.

It is an observation of the natives on the coast of Coromandel, which is confirmed by the experience of many Europeans, that the longer the hot land-winds blow, the healthier are the ensuing months; these winds, as they express it, purifying the air. Are not the winds therefore the cause why the air on the coast of Coromandel, except during their continuance, is more healthy than in other parts of India where these winds do not blow? Does not this also suggest a very probable reason, why the plague in Egypt generally ceases in the beginning of June; the periodical hot winds which come from the deserts of Nubia and Ethiopia having then rendered the air of Egypt pure and wholesome? Many have ascribed that effect to the north winds; as the plague not only ceases when they blow, but all infected goods, household-furniture, and wearing apparel, are then said to become entirely free from the contagion: these, however, cannot be the cause, as the most destructive plague is abated in its violence, if not wholly eradicated, before they set in. With equal propriety we may reject the opinion that the overflowing of the Nile is productive of that salutary effect, as the plague generally ceases before the increase of that river is perceptible.

Thus the plague, the greatest calamity which can afflict mankind, seems to be destroyed by those hot winds, which are otherwise so pernicious to animal and vegetable life. And although, during the continuance of these winds, the most fruitful fields wear the

Febres.

the aspect of a parched desert, yet no sooner the rains fall, but vegetation is restored, the plants revive, and a beautiful verdure is again spread over the face of the country.

Having thus given an account of the signs of an unhealthy country, Dr Lind next proceeds to mention such employments as are particularly dangerous to Europeans on their first arrival. One of these is the cutting down of trees, shrubs, &c. or *clearing the ground*, as it is called. Of the unhealthiness of this employment he gives two instances. At the conclusion of the late peace, the captain of a ship of war went on shore at the island of Dominica, with 12 of his men, to cut down the wood, and to clear a piece of ground which he intended to have purchased: but, in a few days, sickness obliged him to desist from this dangerous work; the captain and 11 of his men being seized with violent fevers, which terminated in obstinate intermittents, and of which several died. The survivors suffered so much in their constitutions, that, even after they came to England, the return of an east-wind was apt to bring on a violent fit of the ague. The Ludlow-Castle, a ship of war of 40 guns, in a voyage to the coast of Guinea, also lost 25 of her men at Sierra Leona, who were employed in cutting down wood for the ship. This is an occupation which has often proved destructive to Europeans in those climates, and in which they ought never to be employed, especially during the rainy season; there being numberless instances of white persons, when cutting down the woods at that season, who have been taken ill in the morning, and dead before night.

Another evil, less known, and less suspected, but no less dangerous, is the sending Europeans in open boats after sunset, where the soil is swampy, or where there are great night-fogs. The single duty alone of fetching fresh-killed butchers meat at night for the use of our ships companies in the East and West Indies, has destroyed every year several thousand seamen. In those parts of the world, butchers meat must be brought on board at night immediately after it is killed, otherwise it will not be fit for use the next day; but a contract made with the natives to send it on board at that time, which might be done for a trifling sum, would be the means of preserving many useful lives. During the sickly season at Batavia, a boat belonging to the Medway, which attended on shore every night, was three times successively manned, not one having survived that service. They were all taken ill in the night, when on shore, or when returning on board; so that at length the officers were obliged to employ none but the natives on that business. Great numbers of men have perished from being employed in this manner at Bengal, where the European ships often anchor in the most unhealthy spots of the river; and even when the great night-fogs arise, after the rainy season, the men are often obliged to perform such night-services in boats. Now since it is so dangerous for Europeans in unhealthy countries, particularly during a season of sickness, to be exposed in an open boat to the foggy night-air, it must appear that sending them unsheltered, in open boats, far up rivers, in unhealthy southern climates, for the sake of wood, water, trade, or other purposes, must be attended with the most destructive and fatal consequences.

Typhus.

Burying the dead in swampy countries is another occupation which has proved fatal to many, and which ought to be entrusted to negroes or the natives of the country. The effluvia from the ground when newly opened, whether from graves or ditches, are far more dangerous than from the same swampy soil when the surface is undisturbed; nay, in some places, it has been found almost certain death for an European to dig a grave, unless long seasoned to the country. In such a place, the attendance of friends at funerals ought to be dispensed with.

In all cases where it is practicable, the ships which visit these unhealthy countries should anchor at as great a distance as possible from shore; or if obliged to anchor near marshy grounds or swamps, especially during summer or in hot weather, and when the wind blows directly from thence, the gun-ports which would admit the noxious land-breeze ought to be kept shut, especially at night. Or if the ship rides with her head to the wind, a thick sail ought to be put upon the fore-mast, along which the smoke from the fire-place might be made constantly to play and ascend. If the sail should occasion a little smoke between decks, this inconvenience will be sufficiently compensated by its keeping off the direct stream of the swampy shore effluvia; which now being obliged to form a curve before they reach the more distant parts of the vessel, must needs be greatly diverted and scattered.

The best preservative against the mischievous impressions of a putrid fog, or of a marshy exhalation, is a close, sheltered, and covered place; such as the lower apartments in a ship, or a house in which there are no doors or windows facing the swamps. If in such places a fire be kept either at the doors and other inlets to a house, or in the chambers, as is practised in some unhealthy countries during the rainy or foggy season, it will prove an excellent and effectual protection against the injuries of a bad air. On board of ships also fires may be made at the hatchways; and of the good effects of this we have the following example. When the Edgar, a ship of war of 60 guns, was upon the coast of Guinea in the year 1768, her men were very sickly, and many of them died: however it was observed, that in a sloop of war, which was constantly in company with her, few were taken ill, and not one died during the whole voyage. This could be ascribed to no other cause, but that in the sloop the fire-place for cooking victuals was on the same level with the deck where the men lay; and every morning when the fire was lighted, especially when there was but little wind, the smoke from the cook-room spread itself all over the ship, and particularly over those parts where the men lay; but from the construction of the fire-place of the Edgar, no smoke from it ever came between her decks.

Persons on board any ship whatever, are much more safe, and their situation is much preferable to that of those who make distant inland excursions in small boats upon the rivers, and who are for the most part ignorant of the cause of those maladies which destroy them. The intolerable heat at noon often obliges such persons to go in a manner half naked; while a free and plentiful perspiration issues from every pore. A near approach to putrid swamps at this time is apt to produce an immediate sickness, vomiting, and afterwards

afterwards a low nervous or malignant fever. If they happen to pass them at night, or lie near them in an open boat, the air from those swamps is perceived to be quite chill and cold; in so much that warm thick clothing becomes absolutely requisite to guard the body against the impressions of so great an alteration in the air, and against its cold and inclement quality: for the effects of it then, even on the most healthy and vigorous constitution, is frequently a chilling cold fit of an ague, terminating in a fever with delirium, bilious vomitings, and purging, or even death itself.

Where such exposure becomes unavoidable, the only method is to defend the body as much as possible against the pernicious miasmata with which the air abounds.—All those who are employed in cutting down woods, or in other laborious and dangerous services in hot climates, during the heat of the day, ought to have their heads covered with a bladder dipt in vinegar, and to wash their mouths often with the same liquor; never to swallow their spittle, but rather to chew a little rhubarb or some other bitter, and spit it out frequently; to stop their nostrils with a small bit of linen or tow dipped in camphorated vinegar; and to infuse some Peruvian bark, garlic, and rhubarb, in brandy, of which a dram is to be taken, either by itself or diluted with water, morning and evening.

In the evening before sunset they should leave off work, and not return to their labour in the morning till the sun has dispersed the unwholesome dews and vapours. Those who must of necessity remain on shore, and sleep in dangerous places, should take care not to sleep upon the ground exposed to the dews, but in hammocks in a close tent, standing upon a dry sand, gravel, or chalk, near the sea shore, and where there is no subterraneous water for at least four feet below the surface of the ground. The door of this tent should be made to open towards the sea; and the back part of it, which receives the land breeze, must be well secured by double canvas, or covered with branches of trees. But in such circumstances, a hut, when it can be procured, is preferable to a tent, especially if it be well thatched, so as to prove a defence both against the excessive heat of the sun by day, and the noxious dews which fall at night. Here the men may be enjoined to smoke tobacco. When the air is thick, moist, and chill, the earth being overspread with cold dew, a constant fire must be kept in and about the tent or hut, as the most excellent means of purifying such unwholesome air, and of preserving the health of those who either sleeping or waking are exposed to its influence. The centinels who guard the water-casks, ought likewise at such a time to have a fire burning near them. All old and forsaken habitations, natural caves and grottos in the earth, where the men may be induced to take up their abode, must before their admission be perfectly dried and purified with sufficient fires. Fire and smoke are undoubtedly the great purifiers of all tainted and unwholesome air, and the most excellent preservatives against its noxious influence. It is the custom of the negroes in Guinea, and also of some Indians (who both sleep for the most part on the ground), to have a fire, producing a little smoke, constantly burning in their huts where they sleep. This not only corrects the moisture of the night, but also, by occasioning more smoke than heat, renders the damp from the earth less noxious; of which Dr Lind gives the following remarkable instance. A Guinea ship being up one of the rivers for the sake of trade, it was found to be very dangerous to sleep on shore: without which their trade could not be so conveniently carried on. First the captain, then the mate, and two or three of the seamen, were taken ill; each of them the morning after they had lain on shore. By these accidents the men were greatly intimidated from lying ashore; till the surgeon boldly offered to try the experiment on himself. Next morning when he waked, he found himself seized, as the rest, with a giddiness and pain in the head. He immediately acquainted one of the negroes with his condition, who carried him to his hut, and set him down in the smoke of it; when his shiverings and giddiness soon left him. He then took a dram of the bark bitter; and found himself greatly relieved, especially by breathing some time in the smoke.—Thus instructed by the negro, he ordered a large fire to dry the hut he slept in; and afterwards had every night a small fire sufficient to raise a gentle smoke without occasioning a troublesome heat: and by this means he and several others, using the same precautions, slept many nights on shore without any inconvenience.

Fire and smoke indeed are found to be certain correctors, or rather destroyers, of infection in all cases, whether arising from the noxious effluvia of marshes, or from the contagion of diseased bodies. Even those most extraordinary and fatal damps called *harmattans*, are unable to resist the salutary effects of smoke. In other cases, Dr Lind remarks, that, under some circumstances, the source of an infection in a sick chamber, or any other place, may be removed or destroyed by accidental means, for which we cannot account, and which we often cannot ascertain. But it oftener happens, that it is very difficultly rooted out; and, that exact cleanliness, with the benefit of a pure air, often proves insufficient to remove the evil. Smoke, however, has never been known to fail. It is not to be doubted, that, excepting the true plague, there has been an infection fully as pestilential and as mortal in some ships as in any other place whatever; yet it has never been heard, that any ship, after having been carefully smoked, did not immediately become healthy: and if afterwards they turned sickly, it was easy to trace that sickness from other infected ships, jails, and the like places.

There are three methods practised for purifying vessels after the men have been removed out of them. The first is by burning of tobacco. A quantity of tobacco is spread on several fires, made with such old pieces of rope as are called *junk*. These are dispersed into different places of the ship, and their heat and smoke afterwards closely confined below for a considerable time.—The second method is by charcoal fires strewed with brimstone. The heat and steam of these burning materials must also be long and close shut up: but although this fume, properly applied, has been found by experience to purify most effectually tainted apartments, ships, clothes, &c. yet there are some kinds of vermin which it will not destroy, particularly lice. The third method of purification is performed by the addition of arsenic to the materials of the second process, Febres. cess in the following manner. After carefully stopping up all the openings and every small crevice of the ship (as was also necessary in the preceding processes), a number of iron pots, properly secured, are to be placed in the *hold*, *orlope*, *gun-deck*, &c. Each of these is to contain a layer of charcoal at the bottom, then a layer of brimstone, and so alternately three or four layers of each, upon which the arsenic is to be sprinkled, and on the top of it some oakum dipped in tar is to be laid to serve as a match. The men, upon setting fire to the oakum, must speedily leave the place, shutting close the hatchway by which they came up.

From the known and experienced efficacy of these processes, it appears, that fire and smoke are powerful agents for annihilating infection; and it may be presumed, even the plague itself. This is in some measure agreeable to what we learn from the ancient records of physic. But the preposterous use, or rather abuse, of fire on such occasions, has caused its effects to be disregarded by some, and to be suspected of mischief by others. The modern practice of burning large fires in the open air, in the streets, and about the walls of towns infected with the plague or other contagion, is founded on principles groundless and erroneous; and has therefore been found by experience not only unsuccessful, but hurtful. But though this must be allowed, it does not thence by any means follow, that when once a house has been infected, and the patients removed from it, the doors and windows at the same time being shut, that such fires will then prove hurtful; or that, by this method of purification, all the seeds of contagion may not be effectually destroyed. Whenever, therefore, persons die of a spotted fever, a malignant sore throat, the small pox, or any distemper found to be communicable from the sick to the sound, the corpse ought quickly after death to be removed into another room; that in which the person died should be well aired, by having the windows opened, till a charcoal fire be kindled, with some rolls of sulphur upon it; after which, both doors and windows should be kept shut for a considerable time, not less than eight or ten hours, till the room be thoroughly smoked. In several ships, where there are the fairest opportunities of trying and judging things of this nature, the contagion of the small pox has been entirely stopped by wood-fires, sprinkled with brimstone, kept burning and closely confined in the infected place. In a word, a judicious and proper application of fire and smoke is a powerful agent for the destruction and utter extinction of the most malignant sources of disease; and they are besides great purifiers of all bad and tainted air.

Next to the smoke of wood for purifying a tainted air, that of gun-powder is to be esteemed the best; and it has this further good property, that it is entirely inoffensive to the lungs. The cascarilla bark, when burning, gives a most agreeable scent to the chamber of the sick; thus it is at least an elegant preservative, and may prevent bad smells from taking effect. The steam of camphorated vinegar, warmed, is still more powerful for this purpose. But, besides correcting the ill quality of the air, and purifying the chamber, another good effect is produced from such steams and smoke as are inoffensive to the lungs. As soon as the vapour becomes dense, the nurses and patients become desirous of the admission of fresh air by the doors or windows. Now it is certain, that the air in the chambers of the sick cannot be too often changed, provided the patient be well covered, and the curtains of his bed, if necessary, be drawn close. No argument is so forcible to obviate the danger of foul air in a room or ward (occasioned by the obstinacy of nurses and relations), as ordering it to be frequently fumigated or smoked: A practice more frequent in other countries than in this, but of great benefit to the sick.

Typhus.

Lastly, with regard to the method of purifying goods, moveables, clothes, &c. which are supposed to harbour infection, it must be observed, that the usual custom of only unpacking and exposing such materials to the open air, is in many instances insufficient to destroy the latent seeds of disease. It is certain indeed, that in most cases the contagious particles are more readily and fatally communicated from the clothes of a sick person than from his body. The spreading abroad, therefore, of contaminated clothes to dry or to be aired, without a previous fumigation of them, may be of dangerous and fatal consequences. All such suspected substances should be first fumigated in a close place, and in the same manner as an infected chamber, after which they may be spread abroad and exposed to the air. In infectious diseases, especially fevers, the linen of the sick, or such clothes about them as will admit of being washed, ought never at first to be put in warm water, as it is dangerous to receive the steam that may hence arise. It is necessary to steep them first either in cold water or in cold soap-lees for several hours, that the filth may be washed off.

But although the destruction of contagion by smoke is unquestionably a very important practice, yet it cannot now be said, that it is the most powerful agent for this purpose. By the ingenious observations and experiments of M. Morveau in France, and of Dr Smyth Carmichael in England, it is now ascertained, that we possess still more powerful means of destroying contagions, either in the muriatic or nitrous acid gas. The former may easily be detached from common sea salt, and the latter from nitre, by means of the sulphuric acid. Rooms may, with the utmost safety and ease, be filled with these fumes, although the sick be not removed from them. But for disinfecting a room, ward, or ship, when empty, the most powerful article yet discovered is the oxygenated muriatic acid gas, detached from a mixture of manganese and sea salt, by means of the sulphuric acid.

We must now proceed to give an account of the method of cure, after these means of preventing the infection from being received into the body have either been neglected or proved ineffectual. Here it is of the utmost importance to take the disease in the very beginning, before it has time to corrupt the fluids to such a degree as to endanger life. In slight degrees of infection, a vomit properly administered, especially if succeeded by a blister, never fails to remove the disorder, and prevent the fever which would otherwise unavoidably follow. Of this Dr Lind gives the following instances. A lady afflicted with the bilious cholic, had intolerably fetid discharges of corrupted matters upwards and downwards. A gentlewoman, only in passing the room, was immediately seized with a retching and sickness, which continued 24 hours. The nurse who attended was suddenly seized

Fevers. zed with a giddiness and vomiting from the bad smell, which, as she expressed it, reached into her stomach. The vomiting became more severe at night, accompanied with a purging and frequent shiverings. By means of an emetic both evacuations were stopped: notwithstanding which, for some days afterwards, she continued to have frequent tremors, and a violent headach, with a low irregular pulse; and did not recover so soon as the patient.

Such slight degrees of infection have been often observed to be derived from patients of a gross habit of body when labouring under inflammatory distempers, and even other complaints. A man was sent to Haslar Hospital, supposed to have a fever. He was furiously delirious, with a quick full pulse. Notwithstanding plentiful evacuations, this delirium continued for two months with short intervals: when the case was found to be plainly maniacal. A nurse, upon raising this person up in her arms, perceived an intolerably bad smell, and was instantly seized with shiverings, sickness, and headach. Finding herself very ill, she took a vomit in six hours afterwards, and passed the night in profuse sweats by means of a sudorific draught. Next morning the violence of the headach was but little abated; upon every attempt to move, she complained of a burning heat and pain in her forehead, and became giddy. Her inclination to drink was frequent, and her pulse low and quick. A blister was immediately applied to the back; as soon as the blister took effect, the headach and thirst entirely left her, and the pulse was calm. Next day she arose and was well.

Many similar instances of infection have been observed from putting the dead into their coffins. In particular, one man, from performing that duty to his messmate, was so ill, even after the operation of the vomit, as to require a blister. In the course of one week two nurses were infected by a person in the smallpox. Both were seized in like manner with shiverings, sickness, and headach; the one upon receiving the patient's breath, the other upon making his bed. In one, a pain darted into her breast; in the other, into the breast and into the small of the back. The complaints of the former were speedily removed by a vomit, though she continued to have irregular returns of shiverings for three days afterwards. But in the latter, though the headach, sickness, and rigors, were greatly abated by the vomit, yet a constant heat and thirst, with a low pulse, and a violent pain in the breast, indicated the necessity of applying a blister to the affected parts, which next morning removed all her complaints.

A person is often immediately sensible of his having received infection from the first attack: they generally compare the first impression to an earthy disagreeable smell, reaching down, as they express it, into their stomach, as from a grave newly opened, but not quite so raw as the cadaverous stench; and the effects of it, shivering and sickness, are instantaneous. It is a smell difficult to describe; but it is well known to the nurses and attendants upon the sick, as it usually accompanies fevers of extreme malignity, and, with the peculiar discharges from the blistered parts, may be reckoned among the most constant symptoms of a bad fever. Some compare the smell to that of rotten straw. It often resembles the disagreeable smell of a person labouring under the confluent smallpox at their turn, though not so strong. One person, on receiving the infection, was sensible of something like an electric shook through his body. But many are not sensible of any effect from infection at first; and an infection from a fever will sometimes continue for many days, nay weeks, discovering itself chiefly by irregular shiverings, sometimes so severe as to oblige the patients to have recourse to their beds once or twice a-day; sometimes every other day. Among a number thus affected, it also appears, that such as are put into unseasoned chambers, or have sat down on the cold ground, lain in raw damp apartments, &c. are immediately seized with a sickness at stomach, sometimes with a dangerous purging, and often with fevers accompanied with bad symptoms, which others have entirely escaped.

Typhus. It now remains to consider the proper method of curing putrid fevers, on the supposition that the infection has been allowed to operate till the blood becomes radically tainted, and of consequence the nervous system affected to such a degree, that its power cannot be restored by any of the simple practices above mentioned. Here all authors agree, that a change of air, when it can be effected, is highly advantageous, and often contributes more towards the removing the disease than all the medicines that can be exhibited. The utility of this change will appear from what has been formerly said; and we shall only further mention one instance from Dr Lind, in which the effects of bad air appear to a degree almost incredible. "It is remarkable (says he), that, in the last war, the English ships which touched at Batavia suffered more by the malignant and fatal diseases of that climate, than they did in any other part of India, if we except a fatal scurvy which once raged in that fleet at sea. Soon after the capture of Manilla, the Falmouth, a ship of 50 guns, went to Batavia, where she remained from the latter end of July to the latter end of January; during which time she buried 100 soldiers of the 79th regiment, and 75 of the ship's company; not one person in the ship having escaped a fit of sickness, except her commander Captain Brereton. The Panther, a ship of 60 guns, was there in the years 1762 and 1764; and both times during the rainy season. In the former of these years, she buried 70 of her men; and 92 of them were very ill when she left the place. In the year 1764, during a short stay, 25 of her men died. The Medway, which was in company with her, lost also a great number of men. Nor was the sickness at that time confined to the ships: the whole city afforded a scene of disease and death: streets crowded with funerals, bells tolling from morning to night, and horses jaded with dragging the dead in herses to their graves. At that time a slight cut of the skin, the least scratch of a nail, or the most inconsiderable wound, turned quickly to a spreading putrid ulcer, which in 24 hours consumed the flesh even to the bone. This fact is so extraordinary, that upon a single testimony, credit would hardly be given to it; yet on board the Medway and Panther they had the most fatal experience of it, and suffered much from it."

But where a change of air is impracticable or ineffectual, and where the fever has already made some progress, Sir John Pringle generally took away some blood if the pulse was full. When the symptoms run high,

Febres.

high, a plentiful evacuation of that kind seemed indicated; yet it was observed, that large bleedings generally did harm, by sinking the pulse, and affecting the head. Nor was a moderate bleeding to be repeated without caution; even those whose blood was sizy, unless their lungs were inflamed, were the worse for a second bleeding. If the head only suffered, it was much safer to use leeches than to open a vein in the arm; but in the delirium with a sunk pulse, even leeches were hurtful. Many recovered without letting blood, but few who lost much of it.

Emetics also must be used with caution; for though they may be of service by way of prevention, yet in the advanced state of the disease, when the patient has all along complained of a sickness at stomach, they are evidently unsafe. Here the antiseptic quality of fixed air is of much use, and the neutral draughts given in the act of effervescence are generally attended with happy effects. Nay, clysters of fixed air itself have been found serviceable. Even in very bad stages of the distemper, where a putrid and colliquative looseness has taken place, clysters of fixed air have been known to alleviate the symptoms. We must not, however, put too much confidence in medicines of this kind. Mild tonic cordials, especially wine and cinchona, are the only resources in these disorders. Concerning the former, Sir John Pringle observes, in the low state of these fevers, and in great sinkings, which either come after unseasonable bleedings or long want of nourishment, it was a most grateful and efficacious cordial, to which nothing was comparable. The common men had an allowance, from a quarter to half a pint in a day, of a strong kind made into whey, or added to the panada which was their ordinary food. But to others out of the hospital, he usually prescribed Rhenish or a small French wine, whereof some consumed near a quart per day, and part of that undiluted. Nay, so great was the virtue of wine in this stage of the fever, that several were known to recover from the lowest condition, when, refusing the bark on account of its taste, they took nothing but a little panada with wine, and a volatile diaphoretic mixture, every two or three hours by turns. Perhaps there is no rule more necessary in this state, than not to let the patient when low remain long without taking something cordial and nourishing; as many have been observed past recovery, by being suffered to pass a whole night without any support about the time of the crisis. In the advanced state of this fever the sick are remarkably low; and therefore Hoffman advises in such cases, that they should be constantly kept in bed, and not permitted even to sit up in it. In the last stage of this fever, as well as in that of the sea-scurvy, it would seem that the force of the heart was too small to convey the blood to the brain, except when the body is in a horizontal posture.

But, however necessary wine and cinchona may be in the low stage of this fever, we must remember, that these remedies are to be administered only as antiseptics and supporters of the *vis vitæ*, without aiming at thoroughly raising the pulse or relieving the head, or at forcing a sweat by them, before nature points that way, and which Sir John Pringle seldom observed before the 14th day.

In the low state of the hospital fever, a stupor was a constant attendant, which was very apt, in the evening, to change to a slight delirium. If this was all, nothing was done. But if the delirium increased upon using wine, if the eyes looked wild, or the voice became quick, there was reason to apprehend a phrenitis; and accordingly it was observed, that at such times all internal heating medicines aggravated the symptoms; and in these cases, blisters were of the greatest service. Fomentations of vinegar and warm water for the feet, Sir John Pringle is of opinion, would answer better than either sinapisms or blisters, provided they were long enough and often enough applied. In the inflammatory fevers, he has known these fomentations have little effect for the first hour, and yet succeed afterwards. For internal medicine, cinchona was omitted for some time, but the patient was continued with an acidulated drink, viz. barley-water and vinegar; and treated also with camphire, *pulvis contrayervæ compositus*, and nitre, as was usual in the beginning of the fever. If the delirium was of the low kind, a decoction of cinchona and wine were the only remedies; for in no instance was the delirium perfectly removed till the time of the crisis. It must also be observed, that a delirium may arise in putrid fevers from two opposite errors; one from large and repeated bleedings, and the other from wine and cordial medicines being taken too early. It appears, therefore, how nice the principles are that regard the cure; as neither a hot nor a cool regimen will answer with every patient, or in every state of the disease.

Typhus.

If a diarrhœa came on in the decline of the fever, it was moderated, but not suppressed, by adding an opiate to the usual medicines. For though the looseness may be considered as critical; yet as the sick were too low to bear evacuations, there was a necessity for restraining it in some measure; and it has often been observed, that when it has been treated in this manner, about the usual time of the crisis, the patient has fallen into a gentle sweat, which has carried off the disease. In the worst cases of this fever, and especially when it coincides with the dysentery, the stools are frequently bloody; in which dangerous state, if any thing could be done, it was attempted by medicines of the same kind. In proportion to the putrid nature of the stools, opiates and astringents were used with the greater caution.

If the disease terminate in a suppuration upon one of the parotid glands, the abscess was opened without waiting for a fluctuation, which might never happen; the pus being often here so viscid, that after it was ripe the part felt nearly as hard as if the suppuration had not begun.

Almost every patient, after the fever, complained of want of rest, frequently of a vertigo or confusion of the head, of a continuation of the deafness, or of other symptoms commonly called *nervous*. An opiate was then given at night; and in the day some strengthening medicines, such as cinchona and the sulphuric acid. In these cases, the bark was found not only to be the best strengthener, but the surest preservative against a return of the disease. For this last intention the convalescent was ordered about three drams a-day for six or seven days together; and afterwards, if he remained longer in the hospital, some smaller quantity daily. But if there was any appearance of a hectic

Fevers. Typhus.

tic fever from an inward abscess, the case was treated accordingly. Upon comparing some of the remaining symptoms of those who recovered, with the condition of the brain in those who died and were opened, Sir John Pringle was induced to think, that some part even of that substance might suppurate, and yet the person recover.

Sometimes the patient falls into an irregular intermittent; which, if not of a hectic nature from an internal abscess, may proceed from neglecting to clear the *primæ viæ*. For it is easy to conceive, that after a long fever of such a putrid nature, often attended with languor of the bowels, the fæces may be so much accumulated, and so corrupted, as to occasion new disorders. In such cases, after proper evacuation by a purge, cinchona was almost an infallible remedy.

The Yellow Fever.

Typhus cum flavedine cutis.

Typhus icteroides, *Sauv.* sp. 7.

7 *Febris flava Indiæ Occidentalis*, *Warren.* Malignant Fever of Barbadoes, *Hillary's* Diseases of Barbadoes. *Lining* on the Yellow Fever of South Carolina, Edin. Phys. and Liter. Essays, vol. ii. *M'Kittrick* de Febre Flavâ Indiæ Occidentalis, Edin. 1766.

Description. This is one of the most fatal diseases to which the inhabitants of warm climates are subject, and is the same with that called, from one of its worst symptoms, the *black vomit*, which is so terribly destructive in some of the warm parts of America, particularly at Carthagena; and which of late has proved so fatal in Philadelphia, New York, and the British West India islands, as described by Drs Rush, Chisholm, Clerk, and other late writers. This, though by some considered as a new disease, is evidently from the same contagion which has produced fatal fevers on many former occasions.

The yellow or putrid bilious fever has been in particular minutely described by Dr Hillary. It most commonly seizes the patient at first with a faintness, then with a sickness at stomach, accompanied in general with a giddiness of the head; and soon after with a slight chilness and horror, very rarely with a rigor. These symptoms are soon followed by a violent heat and high fever, attended with acute darting pains in the head and back. A flushing in the face, with an inflamed redness and a burning heat in the eyes, great anxiety and oppression about the præcordia, are the pathognomonic signs of the distemper, especially when attended with sickness at stomach, violent retchings, and bilious yellow vomitings, with frequent sighing. The pulse is now generally very quick, high, soft, and sometimes throbbing, but never hard: in some it is very quick, soft, low, and oppressed; the respiration quick, full, and sometimes difficult; the skin very hot, and sometimes dry, though more frequently moist. Blood taken from the patient, even at the very beginning of the disease, is often of an exceeding florid red colour, without the least appearance of size; and the crassamentum, when it has stood till it is cold, will scarce cohere, but fluctuates; the serum is often yellow.

Most of the above-mentioned symptoms continually increase, and are much aggravated: the retching and vomiting become almost incessant; the anxiety great, and sighing frequent; great restlessness; continual tossing; no ease in any posture; little sleep, and that disturbed and uneasy, and without any refreshment to the sick. When they are fainting, they turn yellow about the face and neck, instead of turning pale; and as the fainting goes off, they recover their natural colour. These symptoms generally continue till the third day, though sometimes not longer than the first or second; in others to the end of the fourth: the first shows the greater dissolution of the blood, and the greater malignity of the disease; the last, the contrary; which the improper manner of treating the disease sometimes hastens and increases, or the proper method retards. This may be called the first stadium of the disease, and generally ends on the third day.

Blood taken from the sick on the second or third day, is much more dissolved, the serum more yellow, and the crassamentum florid, loose, scarcely cohering, but undulates like sizy water when shaken, and sometimes has dark blackish spots on its surface, showing a strong gangrenescent diathesis.

About the third day, the pulse, which was quick and full before, now generally sinks greatly, and becomes very low: though sometimes it remains very quick, yet in others it is not much quicker than when the patient was in health, but is always low; the vomiting becomes almost incessant if not so before, and the matter thrown up is black; the patient then becomes comatose, with interrupted delirium. The thirst in some is very great, in others but little; the pulse still low and quick, attended with cold clammy sweats, and sometimes with deliquium. The eyes, which were inflamed and red before, and began to be of a more duskish colour, now turn yellow; and this yellowness also soon after appears round the mouth, eyes, temples, and neck, and in a short time diffuses itself all over the body. But this yellowness is so far from being always an encouraging prognostic, as some would have it, that it most commonly proves a mortal symptom. Sometimes indeed, though seldom, this suffusion of bile upon the surface has proved critical; but then it did not come on till the eighth or ninth day, nor appear till the coma and all the other bad symptoms began to abate; and then in proportion as the yellowness increases, all the bad symptoms decrease. But the case is most commonly quite the reverse; especially when the yellowness comes soon on: and then it ushers in the most fatal symptoms of the disease, viz. a deep coma, a low, vermicular, and intermitting pulse, great hæmorrhages from various parts of the body, a delirium with laborious and interrupted respiration, great anxiety, deep sighing, restlessness, a subsultus tendinum, coldness of the extreme parts first, and then all over the body, a faltering of the speech, tremors, and convulsions, which are soon after followed by death. So that from the first appearance of the yellowness we may say the patient is in the last stage of the disease, whether it terminates in death or recovery.

It has been observed, that, in some strong sanguine constitutions, when the patients have not been bled to a sufficient quantity in the beginning of the disease, the pulse has continued full, strong, and rapid, but never hard; the face flushed, eyes inflamed; the tongue dry, with great thirst and heat, till the second or last stage of the fever is come on, when the pulse has

Febres. suddenly sunk, and death soon after ensued. Yet in others, who seemed to be of a plethoric habit, the tongue has been moist all along, though they have been delirious most of the time, and the heat of their skin and the strength and quickness of their pulse have continued, after the first stage of the disease was over, pretty near to that of their natural state in health, till within a few hours of death; and when they have had a coma on them, one who is not well acquainted with the nature of this disease would, from the pulse, heat, breathing, and other symptoms, have taken them to be in a natural sleep. Others, when the pulse has begun to sink, and the fatal period seemed to be just approaching, to the great surprise of all present have recovered their senses, sat up and talked pretty cheerfully for an hour or two, and in the midst of this seeming security have been suddenly seized with convulsions which carried them off immediately.

In the latter stage of this fever, the blood is so attenuated and dissolved, that we frequently see it flowing not only out of the nose and mouth, but from the eyes, and even through the pores of the skin; great quantities also of black, half-baked, or half-mortified blood, are frequently voided both by vomiting and by stool, with great quantities of yellow and blackish putrid bile by the same passages; and the urine, which was before of a high ictcritious colour, is now almost black, and is frequently mixed with a considerable quantity of half-dissolved blood. The pulse, which was much sunk before, now becomes very low, unequal, and intermitting; the breathing difficult and laborious; and the anxiety inexpressible; an oppression with a burning heat about the præcordia comes on, though the extremities are cold, and often covered with cold clammy sweats; a constant delirium follows; and then a total loss of the outward senses as well as the judgment, with livid spots in many parts of the body, especially about the præcordia; and sometimes gangrenes in other parts of the body, which are very soon succeeded by death.

In a short time after death, the body appears much more full of livid, large, mortified spots, particularly about the præcordia and hypochondres, especially the right; which parts seem, even from the first seizure, to be the principal seat of this terrible disease; and, upon opening the bodies of those who die of it, we generally find the gall-bladder and biliary ducts turgid, and filled with a putrid blackish bile; and the liver, stomach, and adjoining parts, full of livid or blackish mortified spots; and the whole corpse soon putrefies after death, and can be kept but a few hours above ground.

Dr Lind is of opinion, that the remarkable dissolution of the blood, the violent hæmorrhages, black vomit, and the other symptoms which characterize the yellow fever, are only accidental appearances in the common fever of the West Indies; that they are to be esteemed merely as adventitious, in the same manner as purple spots and bloody urine are in the smallpox, or as an hiccough in the dysentery: like these they only appear when the disease is attended with a high degree of malignity, and therefore always indicate great danger. This opinion, he thinks, is confirmed by an observation of Dr Wind's, that in 1750 the crew of a Dutch ship of war were distressed by the yellow fever, accompanied with the black vomit; but when the ship left the harbour, and changed the noxious land air for one more healthy, the fever continued, but was not accompanied with the black vomit.

Diseases similar to this fever, Dr Lind informs us, may arise in any part of the world where the air is intensely hot and unwholesome; and therefore he treats as chimerical the notion of its being imported from one part of the world to another. An example of this happened at Cadiz in Spain, in the months of September and October 1764, when excessive heat, and want of rain for some months, gave rise to violent, epidemic, bilious disorders, resembling those of the West Indies, of which 100 persons often died in a day. At this time the winds blew principally from the south, and after sunset there fell an unusual and very heavy dew. But his opinion on this subject is liable to strong objections. And however the disease may originate, yet the late introduction of it from Spain into the fortress of Gibraltar, from which, by proper attention, it had been excluded in former epidemics, demonstrates the contagious nature of this fever beyond all possibility of doubt.

It has been a matter of much dispute, whether the yellow fever is of an infectious nature or not. Some time ago it became an object of consideration before the Right Hon. the Lords Commissioners of Trade and Plantations, where it was urged, among other reasons for not removing the seat of government and justice in the island of Jamaica, from Spanish Town to Kingston, that there was danger from Greenwich hospital, situated near Kingston, of an infection from the yellow fever being frequently communicated to that town. On this affair a physician was consulted, who had long practised in that island, and who gave it as his opinion, that from the yellow fever in that island there was no infection. This was the opinion not only of that gentleman, but of many others who had an opportunity of being well acquainted with this fever in Jamaica. But this opinion probably only arose from these practitioners having confounded the ordinary remittent fever of the West Indies, which is often accompanied with bilious symptoms, and is from thence often denominated the yellow fever, with the typhus icteroides, a disease essentially different from the bilious remittent which often prevails both in the West and East Indies. Dr Lind gives a remarkable instance of its being of an infectious nature.—A gentleman dying at Barbadoes of a yellow fever, his wearing apparel and linen, packed up in a chest, were sent to his friends at Philadelphia; where, upon opening the chest, the family was taken ill; and the clothes being unluckily hung abroad to be aired, they presently diffused the contagion of the yellow fever over the whole town, by which 200 persons died.

In the description of the same fever by Dr Lining, as it appeared in South Carolina, there are several particulars considerably different from that by Dr Hillary. According to the former, people complained for a day or two before the attack, of a headach, pain in the loins and extremities, especially in the knees and calves of the legs, loss of appetite, debility, and a spontaneous lassitude. Some, however, were seized suddenly, without any such previous symptoms. After a chilliness and horror, with which this disease generally invades, a fever succeeded. The pulse was very frequent, till near the termination of the fever, and was generally full,

Fevers. Typhus.

full, hard, and consequently strong: in some, it was small and hard; in others, soft and small; but in all those cases, it frequently varied in its fulness and hardness. Towards the termination of the fever, the pulse became smaller, harder, and less frequent. In some there was a remarkable throbbing in the carotids and in the hypochondria; in the latter of which it was sometimes so great, that it caused a constant tremulous motion of the abdomen. The heat generally did not exceed 102 degrees of Fahrenheit's thermometer; in some it was less; it varied frequently, and was commonly nearly equal in all parts, the heat about the præcordia being seldom more intense than in the extremities when these were kept covered. On the first day of the disease, some had frequent returns of a sense of chilliness, though there was not any abatement of the heat. In a few, there happened so great a remission of the heat for some hours, when at the same time the pulse was soft and less frequent, and the skin so moist, that one from these circumstances might reasonably have hoped that the fever would only prove a remittent or intermittent. About the end of the second day, the heat began to abate. The skin was sometimes (though rarely) dry; but oftener, and indeed generally, it was moist, and disposed to sweat. On the first day, the sweating was commonly profuse and general; on the second day, it was more moderate: but on both these, there happened frequent and short remissions of the sweatings; at which times the febrile heat increased, and the patient became more uneasy. On the third day, the disposition to sweat was so much abated, that the skin was generally dry; only the forehead and backs of the hands continued moist. The respiration was by no means frequent or difficult; but was soon accelerated by motion, or the fatigue of drinking a cup of any liquid. The tongue was moist, rough, and white, even to its tip and edges. On the second day, its middle in some was brown. On the third day, the whiteness and roughness of the tongue began to abate. The thirst in very few was great. A nausea, vomiting, or frequent retchings to vomit, especially after the exhibition of either medicines or food, came on generally the third day, as the fever began to lessen; or rather as the fulness of the pulse, heat, and disposition to sweat, began to abate. Some indeed, but very few, on the first day, had a vomiting, either bilious or phlegmatic. Very few complained of anxiety or oppression about the præcordia or hypochondria, nor was there any tension or hardness about the latter. On the first day they generally dozed much, but were afterwards very watchful. Restlessness and almost continual jactations came on the second day. A great despondency attended the sick, and the strength was much prostrated from the first attack. The pain in the head, loins, &c. of which they had complained before the attack, was much increased, and in some the pain in the forehead was very acute and darting; but those pains went generally off the second day. The face was flushed; and the eyes were hot, inflamed, and unable to bear much light. On the first day, many of them at times were a little delirious, but afterwards not until the recess of the fever. The blood drawn by venesection had not any inflammatory crust; in warm weather, it was florid like arterial blood, and continued in one soft homogeneous-like mass, without any separation of the serum after it was cold. When there was any separation, the crassamentum was of a very lax texture. The stools, after the first day, were fetid, inclined to a black colour, and were very rarely bilious, soft, or liquid, excepting when forced by art; for an obstinate costiveness attended the febrile state. The urine was discharged in a large quantity, was pale, sometimes limpid, and rarely of a higher than a straw colour, except when the weather was very warm, and then it was more saturated, of a deep colour, and discharged in smaller quantities. It had a large cloud, except when it was very pale or limpid; but more generally it had a copious white sediment, even on the first day of the fever. On the second day, the urine continued to be discharged very copiously; in some it was then turbid, and deposited a more copious sediment than on the first day; this sediment was sometimes of a brownish colour; in which case it was generally followed by bloody urine, either about the end of the second or beginning of the third day.—The colour and quantity of the urine, discharged in equal times, were remarkably variable, being now limpid, then of a deeper colour; now discharged in a larger, then in a smaller quantity; which could not be ascribed to any change made either in the quantity or quality of the drink.

The fever accompanied with those symptoms terminated on the third day, or generally in less than 72 hours from the first attack, not by any assimilation or coction and excretion of the morbid matter: for if by the latter, there would have been some critical discharge by sweat, urine, stool, or otherwise, none of which happened; and if by the former, nothing then would have remained but great debility. This fever, however, did not terminate in either of these salutary ways, excepting in some, who were happy enough to have the disease conquered in the beginning by proper evacuations, and by keeping up a plentiful sweat, till the total solution of the fever, by proper mild diaphoretics and diluents. But in those who had not that good fortune, however tranquil things might appear, yet the face of affairs was quickly changed: for this period was soon succeeded by the second *stadium*; a state, though without any fever, much more terrible than the first: the symptoms in which were the following. The pulse, immediately after the recess of the fever, was very little more frequent than in health, but hard and small. However, though it continued small, it became, soon afterwards, slower and very soft; and this softness of the pulse remained as long as the pulse could be felt. In many, in this stage of the disease, the pulse gradually subsided, until it became scarce perceptible; and this, notwithstanding all the means used to support and fill it; and when this was the case, the icteritious-like suffusion, the vomiting delirium, restlessness, &c. increased to a great degree. In some, the pulse, after being exceedingly small and scarce perceptible, recovered considerably its fulness; but that favourable appearance was generally of but short continuance. The heat did not exceed the natural animal heat; and when the pulse subsided, the skin became cold, and the face, breast, and extremities acquired somewhat of a livid colour. The skin was dry when the weather was cold, but was moist and clammy when the weather was hot, the respiration was

Febres.

was natural, or rather slow. The tongue was moist, and much cleaner than in the former stage; its tip and edges, as also the gums and lips, were of a more florid red colour than usual. Very few complained of thirst, though they had a great desire for cold liquors. The vomiting or retching to vomit increased, and in some was so constant that neither medicines nor aliment of any kind were retained. Some vomited blood; others only what was last exhibited mixed with phlegm; and others again had what is called the black vomit. The retching to vomit continued a longer or shorter time according to the state of the pulse; for as that became fuller, and the heat greater, the retching to vomit abated, and *è contra*. The inquietude was very obstinate; and when they dozed their slumbers were but short and unrefreshing. There were some who were drowsy; but these always awaked, after the shortest slumbers, with a great dejection of spirits and strength. The jactations or restlessness were surprising: it was frequently scarce possible to keep the patients in bed; though at the same time, they did not complain of any anxiety or uneasiness; but if asked how they did? the reply was, *Very well*. The debility was so great, that, if the patient was raised erect in the bed, or, in some, if the head was only raised from the pillow, while a cup of drink was given, the pulse sunk immediately, and became sometimes so small, that it could scarce be felt; at this time, they became cold, as in a horripilatio, but without the anserine-like skin: their lips and skin, especially about the neck, face, and extremities, together with their nails, acquired a livid colour. The delirium returned and increased; it was generally constant in those whose pulse was small and subsiding. The inflammation of the tunica conjunctiva or white of the eyes increased much, but without pain. A yellowness in the white of the eyes, if it did not appear before in the febrile state, became now very observable, and that icteritious tinct was soon diffused over the whole surface of the body, and was continually acquiring a deeper saffron-like colour. In some, indeed, no yellowness was observable, excepting in the white of the eyes, until a little before death, when it increased very quickly, especially about the breast and neck. There were many small specks, not raised above the skin, which appeared very thick in the breast and neck, but less so in the extremities, and were of a scarlet, purple, or livid colour. In women the menstrua flowed, and sometimes excessively, though not at their regular period.

There was such a putrid dissolution of the blood in this stadium of the disease, that there were hæmorrhages from the nose, mouth, ears, eyes, and from the parts which were blistered with cantharides. Nay, in the years 1739 and 1745, there were one or two instances of an hæmorrhage from the skin, without any apparent puncture or loss of any part of the scarf-skin.

An obstinate costivenes continued in some; in others, the stools were frequent and loose: in some they were black, liquid, large, and greatly fatiguing; in others, when the stools were moderate, even though they were black, they gave great relief; in others, again, the stools nearly resembled tar in smoothness, tenacity, colour, and consistence.

The urine was discharged in a large quantity, in proportion to the drink retained by the patient: it was pale if the patient was not yellow; but if yellow, then it was of a deep saffron-colour: in either case, it had a sediment, or at least a large cloud, which remained at the bottom of the glass; in some, it was very turbid; in others it was bloody: and the quantity of blood discharged with the urine bore always some proportion to the state of the pulse; when that became fuller, the quantity of blood in the urine was diminished; when the pulse subsided, the bloody urine increased, and even returned after it had ceased some days, soon after the pulse became smaller. This stage of the disease continued sometimes seven or eight days before the patient died.

Typhus.

When this stadium of the disease terminated in health, it was by a recess or abatement of the vomiting, hæmorrhages, delirium, inquietude, jactations, and icteritious-like suffusion of the skin and white of the eyes; while, at the same time, the pulse became fuller, and the patient gained strength, but very slowly. But when it terminated in death, those symptoms not only continued, but sooner or later increased in violence, and were succeeded with the following, which may be termed the third *stadium* of the disease, which quickly ended in death. The pulse, though soft, became exceedingly small and unequal; the extremities grew cold, clammy, and livid; the face and lips, in some, were flushed; in others, they were of a livid colour; the livid specks increased so fast, that in some the whole breast and neck appeared livid; the heart palpitated strongly; the heat about the præcordia increased much; the respiration became difficult, with frequent sighing; the patient now became anxious, and extremely restless; the sweat flowed from the face, neck, and breast; blood flowed from the mouth, or nose, or ears, and in some from all those parts at once; the deglutition became difficult; the hiccoughs and subsultus tendinum came on, and were frequent; the patients trifled with their fingers, and picked the naps of the bedclothes; they grew comatose, or were constantly delirious. In this terrible state, some continued eight, ten or twelve hours before they died, even after they had been so long speechless, and without any perceptible pulsation of the arteries at the wrists; whereas, in all other acute diseases, after the pulse in the wrists ceases, death follows almost immediately. When the disease was very acute, violent convulsions seized the unhappy patient, and quickly brought this stadium to its fatal end. After death, the livid blotches increased fast, especially about the face, breast, and neck, and the putrefaction began very early, or rather increased very quickly.

Such was the progress of this terrible disease through its several stadia. But in hot weather, and when the symptoms in the first stage were very violent, it passed through those stages with such precipitation that there was but little opportunity of distinguishing its different stadia, the whole tragedy having been finished in less than 48 hours. It was remarkable, that, 1. The infection was increased by warm and lessened by cold weather. 2. The symptoms in the several stadia were more or less violent, according to the heat or coolness of the weather. In hot days, the symptoms were not only more violent, but in those who seemed in moderate weather to be on the recovery, or at least in no danger, the symptoms were all so greatly heightened, when

 when the weather grew considerably warmer, as frequently to become fatal. In cool days, the symptoms were not only milder, but many who were apparently in great danger in hot days were saved from the very jaws of death by the weather becoming happily cooler. 3. The disease was generally more fatal to those who lay in small chambers not conveniently situated for the admission of fresh air, to those of an athletic and full habit, to strangers who were natives of a cold climate, to those who had the greatest dread of it, and to those who before the attack of the disease had overheated themselves by exercise in the sun, or by excessive drinking of strong liquors; either of which indeed seemed to render the body more susceptible of the infection. Lastly, The disease proved most certainly fatal to valetudinarians, or to those who had been weakened by any previous disease.

Causes of, and persons subject to, this disease. The yellow fever attacks principally Europeans, especially those who have but lately arrived in the hot climates. Negroes are entirely exempt from it, though the mulattoes and tawnies are as liable to be seized with it as the whites themselves. The cause of the disease seems to be a particular kind of contagion; but Dr Lind seems to be of opinion, that the immediate cause of the symptoms is a disposition in the glutinous part of the blood to separate from the others, and to become putrescent. In some persons who have been bled in the yellow fever, the blood has been observed very viscid; the crassamentum covered with a yellow gluten half an inch in thickness, and impenetrable to the finger unless cut by the nail; the serum being at the same time of the consistence of a thin syrup, and of a deep yellow tinct. This serum tasted bitter, and resembled a composition of soot. The appearances on dissection, with his conclusions from them, we shall give in his own words: "In a man who died on the eleventh day of a yellow fever, whose body emitted no bad smell 36 hours after death, and was still yellow, I found all the bowels of the abdomen sound; the liver and spleen were remarkably so; as also the stomach and intestines. There was no suffusion of the bile either in the intestines or stomach. The gall-bladder, of the natural size, contained the usual quantity of bile, somewhat thicker than common, and grumous (B).

"Upon examining further, this disease was found to have lain wholly on the left side, where, within the breast, was found near a quart of yellowish water, in which were many large flakes of yellowish gluten, appearing, by comparison, precisely the same with the thick pellicle which had covered the blood taken from his arm. These flakes bore in several places a resemblance to a membranous substance beginning to be converted into a purulent jelly. The pleura, both on its inside and outside, as also its continuation, the investing membrane of the lungs, were covered with cakes of this gluten, hanging in some places loosely, in others adhering more strongly: and all in different states of yellow or purulent corruption. The right cavity of the breast, and all the other parts of his body, were found entirely free from disease.

"His complaints had been chiefly in his breast; and a small quantity of blood taken from him two days before his death, was covered with an impenetrable, yellow, thick gluten; the red portion below it being quite loose.

"In those fevers, I have also seen (says Dr Lind) the disease entirely confined to the heart and pericardium. In one who died on the tenth day of the fever, without having been yellow, a quantity of pus and purulent crusts was found mixed with the water of the pericardium. The heart in different places was excoriated; and, together with the inside of the pericardium, was lined with a thick membranous cake, similar to that already mentioned on the lungs and pleura. In some places this cake had a purulent, in others a gelatinous appearance, exactly resembling the coagulum of the blood. His complaints had been, a great oppression on the breast, and an extreme difficulty of breathing. In a third person, who died on the thirteenth day of the fever, above two quarts of pus and purulent jelly were found in the cavity of the belly. The source of such an extraordinary quantity of matter was not from any preceding inflammation, nor any imposthume, that we could discover; but from innumerable ulcerations on the surface of the intestines, omentum, mesentery, and peritoneum. Neither did those ulcerations (or excoriations, as they rather appeared in several places) seem to be the primary fountains of the matter, but to have been occasioned by its acrimony.

"This purulent appearance seems to arise merely from an extravasation of one of the component parts of the blood, the gluten or fibrine as it is now called. Blood taken from persons in a fever, and frequently even from persons in perfect health, after standing in a clean vessel for a short time, commonly separates into three distinct portions; viz. the serum, or water of the blood, the red concreted mass, and a viscid pellicle termed the *size*, which spreads itself on the top of the red concretion. Some time ago, when making experiments with the blood taken from persons in the scurvy, I was surprised to find it often covered with that sizy crust. This induced me to extend my experiments to large quantities of blood from different subjects, which I had opportunities of inspecting at once in so large an hospital. For this purpose I one morning ordered ten patients in the scurvy to be bled, taking two ounces from each. A larger quantity was taken, for its inspection, from two men in health. That day I had occasion to prescribe bleeding to a woman in labour, two hours before her delivery; to a girl of sixteen years of age afflicted with a lunacy proceeding from the chlorosis; to three patients in the rheumatism; and to a person labouring under an obstruction of the liver.

"From a nice comparison, and an examination of the blood in these cases, I found in general, that the more

(B) In others who died in this yellow state, the bile in the gall-bladder was found of a thick ropy consistence like pitch, but the liver never appeared in the least affected. Dr Lind at first in several bodies opened the head only; but afterwards judged that all the cavities ought to be inspected.

Febres.

more size there was on the top, and the thicker and more viscid this white pellicle showed itself, the concretion below it was of a more loose coherence. This was not so observable when only some slight white streaks appeared on the top. But when much size had separated itself, the red mass became very soft at the bottom of the vessel, and less compact in its different parts, in proportion to their distance from the surface, towards which this whitish portion had ascended.

"From this and from other experiments it appears, that this crust or pellicle is the natural gluten, which becomes strongly disposed, in certain circumstances and diseases, to separate itself. And wheras the serum and red concretion are easily incorporated together, it will be found, that this glue, after its separation, becomes immiscible with either. We have, by gentle drying, converted it into a perfectly tough elastic membrane; and, by the means of a small portion of the red mass being left adhering to it, into a substance resembling muscular flesh; and it is capable of undergoing various changes into corruption, in the same manner as either of these.

"Now, I can see no reason why this gluten, in its morbid state, may not separate itself from the circulating blood, and be deposited in the cavities of the body, as readily as the serum does in dropsies; the former having always a less disposition than the latter to incorporate with the mass.

"In dissecting persons who died of fevers in London and Minorca, and where no infection was suspected, appearances similar to these have also fallen under the inspection of those accurate anatomists Drs Hunter and Cleghorn. Hence it may be presumed very difficult to distinguish fevers that are produced by infection, from some others. I cannot, however, be induced to think, as those gentlemen seem to do, that these preternatural substances which were found in the cavities of the body are the consequence, but rather that they are the cause, of the inflammation and excoriations. I believe these substances to be at first diseased extravasated gluten, and conjecture their different states greatly to depend upon the different times at which they were deposited.

"I have remarked, in a variety of dead bodies, three different kinds of extravasation; these occurred in such as had died of the scurvy, of consumption, and of fevers. In the former of those diseases, red coagulated blood is found extravasated in almost all parts of the body, not only into the tela cellulosa, but into the bellies of the muscles, particularly of the legs and thighs, which often become quite stuffed and even distorted with large grumous masses. The intestines and mesentery are often spotted also with extravasated blood; and I have seen large ecchymoses on the stomach. Those appearances at first sight resembled so many distinct mortifications; and by this appearance some anatomists have been deceived; but, upon a nice examination, the texture of the parts is found to be sound and firm. There is likewise, in that disease, sometimes an extravasation of water, chiefly collected in the tela cellulosa.

"But as, in the limbs of scorbutic persons, it is extremely difficult to make a good dissection by reason of such quantities of extravasated blood that everywhere obstruct the operator; so, on the contrary, the lower extremities of those who have died consumptive, with swelled legs, are, of all subjects, in the best state to afford a satisfactory view of the muscles. The water enclosed in their legs having insinuated itself, by passing the tela cellulosa, into the spaces between the muscles, the muscles are easily separated from each other; and their several origins and insertions may be distinctly traced by means of their having been cleansed and washed by the water in the investing cellular membrane. Thus there are extravasations of three sorts; viz. First, The grumous mass in the scurvy; and this I have often remarked where no serum was observed. Secondly, The serum alone in anasarcous swellings. The third and last is what was taken notice of in those who died of fevers, being the gluten of the blood, accompanied for the most part with some serum; both of them altogether confined to the large cavities of the body.

Typhus.

"I conjecture, that in those fevers there is always an ulcerous or purulent disposition in the blood: and that the gluten is greatly diseased. I have frequently seen it have a true purulent appearance soon after it was drawn off, when the patient seemed not very ill.

"And I further conjecture, that the mischief often lies within the breast; as also that the great benefit derived from the very early application of blisters, in a great measure flows from so many ulcerations and vents being timely provided for the free discharge of those purulent and tainted particles from the body.

"If an infection depends, as many have imagined, on the admission of certain foreign particles into the blood, this gluten seems to be primarily affected by it; and a discharge of this, by washing those particles out of the body, tends in a great measure to remove that disease.

"It is an observation of the best practical writers, that issues and setons are most excellent preservatives against receiving an infection, even that of the plague itself. And indeed a suppuration and plentiful discharge from a proper ulcer, whether produced by nature or by art, seems to open a channel the best appropriated for an exit out of the body to some of the most malignant poisons. Thus the most favourable crisis in the plague, and in most pestilential fevers, happens when nature excites tumors kindly suppurating in the groin or armpits, by whose beneficial and plentiful discharge the deadly poison is expelled from the constitution.

"I have observed it to be amongst the most certain characteristics of the worst fevers, that the blisters either do not rise and fill, or discharge such yellow, greenish, fetid, and highly offensive stuff, that even experienced nurses could give a pretty certain conjecture from the blisters of the different degrees of malignity in the fever. We have more than once endeavoured to conceal the bad state of some patients in the hospital; but a discovery was always made of their condition in the washhouse, from the linen sent there stained with the discharges from the blistered parts. And indeed a careful inspection of the state and discharge from the blisters, together with their effects, furnishes us, in those diseases, with some of the most certain diagnostics of their nature, and prognostics of their event."

Prognosis. This distemper, where it attacks with violence,

violence, is generally fatal; the prognosis therefore must be commonly unfavourable, and always uncertain; neither can any thing more be said on this subject, than that an abatement of the symptoms already enumerated affords a favourable prognostic, and an increase of them the contrary.

Cure. The cure of this terrible disease, according to Dr Hilary, is very easy and simple. His indications are, 1. To moderate the too great and rapid motion of the fluids, and abate the too great heat and violence of the fever in the two first days of the disease, as much and as safely as we can. 2. To evacuate and carry out of the body as much of the putrid bile and other humours, and as expeditiously and safely as possible. 3. To put a stop to the putrescent disposition of the fluids, and to prevent the gangrenes from coming on, by suitable antiseptics.

The first indication is answered by bleeding, which, in the first stage of this fever, is sometimes absolutely necessary in some degree: the quantity to be taken away must be determined by the age and strength of the patients, the degree of plethora, fulness of the pulse, &c. When called at the beginning, he orders 12, 14, 16, 18, or 20 ounces of blood to be taken away on the first or second day; and if the patient's pulse rise after the first bleeding, or if the fever still continue high and the pulse full, he repeats the bleeding once on the days above mentioned. But bleeding a third time is seldom or never required; neither is bleeding on the third day almost ever necessary; and when it is performed on that day, it ought to be done with the greatest caution and judgment: neither should a vein be opened after the third day in this fever, unless some very extraordinary symptoms and circumstances require it; which seldom or never happen. On that day, indeed, the pulse generally sinks, and the blood is in such a dissolved state, that bleeding must be accounted highly pernicious. Nevertheless, it is indispensably necessary in the beginning of the distemper; and if omitted at that time, the violent heat and motion of the blood increase the putrescence of the humours to such a degree as to bring on fatal consequences much sooner than would otherwise have happened. If blood-letting be thus advised by Dr Hilary, it has been still more strongly recommended by Dr Rush, who, in his first publication on the subject of the dreadful yellow fever which proved so fatal at Philadelphia, represented it as an almost infallible remedy for the disease. But the observations and experience of others have by no means confirmed the practice which he recommended.

After bleeding, we come to the second indication of cure, namely, to evacuate as much of the bilious and putrid humours as soon and as safely as we can. The great irritation of the stomach, by the putrid bilious humours constantly attending this fever, with almost continual retchings and violent vomitings, seem to indicate the giving of an emetic: but the stomach is always observed to be so violently stimulated and irritated, and most commonly inflamed, by the acrimony of the putrescent bile, that any emetic, even the most mild and gentle, given in the smallest dose, brings on an incessant vomiting, which continues in spite of all remedies, till a mortification and death ensue. Instead of this, it is proper to give large draughts of warm water, which, without any additional stimulus to the stomach, evacuates its acrid and putrid contents, commonly with great relief to the patient: the warm water also acts as an emollient fotus to the inflamed coats of the stomach; and thus abates the inflammation, and prevents gangrene and mortification from coming on.

After the patient has by this means vomited seven or eight times, or oftener, and discharged a great quantity of yellow and blackish bilious matter, a grain or a grain and a half of thebaic extract is given, in order to procure some respite from the violent retching, vomiting, and anxiety. The person is desired to take nothing into his stomach for two hours after this, by which means it is seldom or never rejected; and thus all the symptoms are considerably abated, the retching and vomiting either totally cease or are very much lessened, so that medicines may now be exhibited which the stomach would not have retained before. These are cooling acid juleps, or other antiseptic remedies; but neither nitre nor any of its preparations will commonly be found to stay on the stomach, nor, according to Dr Hilary, are the nitrous medicines, or even the common antiemetic draughts, proper to be given in this disease, even though they should agree with the stomach, on account of their attenuating property.

If the patient has not a stool or two after drinking the warm water and vomiting, it is necessary to give a gentle purging clyster; and when six or eight hours rest have been obtained, a gentle antiphlogistic and antiseptic purge, in order to evacuate by stool as much of the bilious matter as we possibly can. Or if the patient has a purging before, which sometimes though very rarely happens, a dose of toasted rhubarb is given, and an antiseptic anodyne after it has operated, to abate and check the too great purging, but not to stop it, as this evacuation has been always observed to be of service, provided it be not very violent.

After this indication is completely answered, the next is to exhibit such proper antiseptic medicines as may stop the putrescent disposition of the fluids. Here the cinchona would seem to be the most proper remedy; but unluckily the stomachs of the patients in this disease are so much irritated, and so apt to reject every thing, that it cannot be retained in any form whatever. In this case Dr Percival recommends columbo root, the infusion of which is found to be a powerful antiemetic and antiputrescent medicine, and might perhaps so far alter the state of the stomach as to make it bear the bark. Dr Hilary, however, who was ignorant of the virtues of columbo, substituted the *radix serpentariæ Virginianæ* with success. A slight infusion of this root not only sat easily on the stomach of the patients, but moderately raised the pulse and fever, both of which are now too low. The following receipt was found the most agreeable and efficacious:

℞ Rad. serpent. Virginian. ℥ij.
Croc. Ang. ʒss. M. et infunde vase clauso in aq. bul. q. per horam unam ut col. ℥vj. Adde aq. menth. simp. ℥ij. Vin. Maderiens. ℥iv. Syr. croc. vel syr. è mecon. ℥i. Elix. vitriol. acid. q. s. ad grat. acid. sap. Exhibe cochlearia duo vel tria singulis horis vel bihoris, vel sæpius pro re nata.

By the use of this medicine, and soft light nourishment taken in small quantities, the pulse is usually kept up

Febres.

up and the distemper goes off. But if, after taking this a little while, we find that the pulse does not rise, but on the contrary that a coldness of the extreme parts comes on, the medicines must be made more warming, by increasing the quantity of the snakeroot and saffron, or by adding *vinum croceum*, *confectio cardiaca*, or the like, but not by the use of volatile spirits and salts, which hurt by their stimulating and dissolving qualities. Blisters Dr Hilary reprobates in the strongest terms, and affirms that he has seen the place where a blister was applied turned perfectly black and sphacelated; so that if the spine and end of the ribs had not hindered, a large square passage would have been opened into the cavity of the thorax, had the patient lived a few hours after it.

At the same time that the strength of the patient is kept up by the medicines above mentioned, or by others similar, he gave repeated gentle purgatives every second or third day, and sometimes, when the symptoms were very urgent, every day, for four or five days successively. But if proper methods be taken in the beginning of the disease, it is seldom that such a repetition of purging is necessary.

Dr Hilary's plan of treating the yellow fever is, in our opinion, as judicious as any that has yet been proposed. But, among the late writers, some have recommended mercury, particularly under the form of calomel, as the most efficacious remedy which can be employed. In some cases it has certainly been given to an almost incredible extent, in a very short time, without exciting either purging or salivation. And it cannot be denied, that patients have not unfrequently recovered under the use of it. But calomel can no more be reckoned an infallible remedy for this disease than blood-letting.

Since the introduction of cold affusion, in the cure of typhus fevers, by Dr Currie, it has been imagined by some, that this practice would afford a very efficacious remedy in the typhus icteroides, as well as in the typhus mitior. But experience has not yet confirmed the utility of this practice.

Some have suggested the internal use of the oxygenated muriatic acid, properly diluted, as an article from which great benefit may be expected in the yellow fever. This practice deserves, we think, a fair trial: but the utility of it still remains to be determined by experience.

To the genus of *typhus* also belong all those fevers attended with very profuse and debilitating sweats, and which have sometimes, not without good reason, been accounted plagues; such as the English sweating-sickness, Miliaris sudatoria, *Sauv.* sp. 5. Ephemera sudatoria, *Sauv.* sp. 7. Ephemera Britannica, *Caius de ephem. Britan.*

168

Genus VI. SYNOCHUS.

Synochus, *Sauv.* gen. 81. *Lin.* 13.
Lenta, *Lin.* 14.
Phrenitis, *Vog.* 18.
Febris continua putrida, *Boerh.* 730.

This is a contagious distemper, being a complication of a synocha and typhus; for the description and cure of which, we must of consequence refer to what hath been already said concerning these diseases.

The *Hectic* Fever.

Hect

Hectica, *Sauv.* gen. 83. *Lin.* 24. *Vog.* 80. *Sag.* 684. 16

This disease is reckoned by Dr Cullen to be merely symptomatic; as indeed seems very probable, since it generally accompanies absorption of pus into the blood from internal suppurations, or indeed from such as are external, provided they be very large or of a bad kind.

Description. The best, perhaps the only proper, description of this disorder we have is that by Dr Heberden. According to him, the appearance of the hectic fever is not unlike that of the genuine intermittent; from which, however, the disease is very different in its nature, while at the same time it is much more dangerous. In the true intermittent, the three stages of cold, heat, and sweat, are far more distinctly marked, the whole fit is much longer, the period which it observes is more constant and regular, and the intermissions are more perfect, than in the hectic fever. For in the latter, even during the clearest remission, there is usually a feverish quickness perceptible in the pulse, which seldom fails to exceed the utmost limit of a healthy one by at least 10 strokes in a minute.

The chilness of the hectic fever is sometimes succeeded by heat, and sometimes immediately by a sweat without any intermediate state of heat. The heat will sometimes come on without any remarkable chilness preceding; and the chilness has been observed to go off without being followed either by heat or sweat. The duration of these stages is seldom the same for three fits together; and as it is not uncommon for one of them to be wanting, the length of the whole fit must vary much more than in the true intermittent; but in general it is much shorter.

A patient subjected to hectic fever is little or nothing relieved by the occurrence of the sweat; but is often as anxious and restless under it as during the chilness or heat. When the sweat is over, the fever will sometimes continue; and in the middle of the fever the chilness will return; which is a most certain mark of this disease.

The hectic fever will return with great exactness, like an intermittent, for two or perhaps three fits; but Dr Heberden informs us, that he does not remember ever to have known it keep the same period for four fits successively. The paroxysm will now and then keep off for 10 or 12 days; and at other times, especially when the patient is very ill, it will return so frequently on the same day, that the chilness of a new fit will follow immediately the sweat of the former. It is not unusual to have many threatenings of a shivering in the same day; and some degree of drowsiness is apt to attend the cessation of a fit.

The urine in a true intermittent is clear during the fits and turbid during the intervals; but in the hectic fever it is liable to all kinds of irregularity. It will be equally clear or turbid in both stages; or turbid in the fits and clear in the intervals; and sometimes it will be, as in a true intermittent, clear during the fever, and thick at the going off.

Hectic patients often complain of pains like those of the rheumatism, which either affect by turns almost every

every part of the body, or else return constantly to the same part; which is often at a great distance from the seat of the principal disorder, and, as far as is known, without any peculiar connection with it. Those pains are so violent in some patients, as to require a large quantity of opium. As far as Dr Heberden has observed, they are most common where the hectic arises from some ulcer open to the external air, as in cancers of the face, breast, &c. Joined with this fever, and arising probably from one common cause, he has been surprised to see swellings of the limbs, neck, or trunk of the body, rise up almost in an instant, as if the part was all at once grown fatter. These swellings are not painful, hard, or discoloured, and they continue for several hours.

Dr Heberden has seen this fever attack those who seemed in tolerable health, in a sudden and violent manner, like a common inflammatory one; and like that, also, in a very short time bring them into imminent danger of their lives; after which it has begun to abate, and to afford hopes of a perfect recovery. But though the danger might be over for the present, and but little of a fever remain; yet that little has soon demonstrated, that it was kept up by some great mischief within, and, proving unconquerable by any remedies, has gradually undermined the health of the patient, and never ceased except with his life. This manner of its beginning, however, is a rare occurrence. It much oftener dissembles its strength at first; and creeps on so slowly, that the subjects of it, though they be not perfectly well, yet for some months hardly think themselves ill; complaining only of being sooner tired with exercise than usual, of want of appetite, and of falling away. But gentle as the symptoms may seem, if the pulse be quicker than ordinary, so as to have the artery to beat 90 times and perhaps 120 times in a minute, there is the greatest reason to be apprehensive of the event. In no disorder, perhaps, is the pulse of more use to guide our judgment than in the hectic fever: yet even here we must be upon our guard, and not trust entirely to this criterion; for one in about twenty patients, with all the worst signs of decay from some incurable cause, which irresistibly goes on to destroy his life, will show not the smallest degree of quickness, nor any other irregularity of the pulse, to the day of his death.

Causes, &c. This fever will supervene whenever there is a great collection of matter formed in any part of the body; but it more particularly attends upon the inflammation of a scirrhous gland, and even upon one that is slight and only just beginning; the fever growing worse in proportion as the gland becomes more inflamed, ulcerated, or gangrenous. And such is the lingering nature of those glandular disorders, that the first of those stages will continue for many months, and the second for some years.

If this scirrhous inflammation be external, or in the lungs, or some of the abdominal viscera, where the disturbance of their functions plainly points out the seat of the disorder, no doubt can be entertained concerning the cause of the fever. But if the part affected be not obvious to the senses, and its precise functions be not known, the hectic, which is there only part of the train of another disease, may be mistaken for the primary or only affection.

Hectica.

Lying-in-women, on account of the violence sustained in delivery, generally die when affected with this fever. Women of the age of near 50 and upwards are particularly liable to it. For, upon the cessation of their natural discharge, the glands of the breasts, ovaries, or womb, too commonly begin to grow scirrhous, and proceed to be cancerous. Not only these, but the glandular parts of all the abdominal viscera, are supposed to be affected at this particular time, and to become the seats of incurable disorders.

The injuries done to the stomach and liver by hard drinking are attended with similar symptoms, and terminate in the same manner.

Dr Heberden observes, that the slightest wound by a fine-pointed instrument is known upon some occasions to bring on the greatest disturbances, and the most alarming symptoms, nay even death itself. For not only the wounded part will swell and be painful, but by turns almost every part of the body; and very distant parts have been known to come even to suppuration. These symptoms are constantly accompanied with this irregular intermittent, which lasts as long as any of them remain.

Prognosis. This anomalous fever is never less dangerous than when it originates from a kindly suppuration, into which all the diseased parts are melted down, and for which there is a proper outlet.

The symptoms and danger from some small punctures, with their concomitant fever, most frequently give way in a few days; though in some persons they have continued for two or three months, and in others have proved fatal.

The inflammation of internal scirrhous glands, or of those in the breasts, sometimes goes off, and the fever, which depended upon it, ceases; but it much oftener happens, that it proceeds to cancerous and gangrenous ulcers, and terminates only in death. Death is also, almost universally, the consequence of hectic fever from tubercles of the lungs, which have in general at least been considered as glandular bodies in a scirrhous state.

Cure. It is not to be expected that the same remedies will in every case be adapted to a fever which, arising from very different causes, is attended with such a variety of symptoms. A mixture of asafœtida and opium has insome persons seemed singularly serviceable in this fever, when brought on by a small wound; but in most other cases the principal if not the sole attention of the physician must be employed in relieving the symptoms, by tempering the heat, by preventing both costiveness and purging, by procuring sleep, and by checking the sweats. If, at the same time, continues Dr Heberden, he put the body into as good general health as may be, by air, exercise, and a proper course of mild diet, he can perhaps do nothing better than to leave all the rest to nature. In some few fortunate patients, nature appears to have such resources, as may afford reason for entertaining hopes of cure, even in very bad cases. For some have recovered from this fever attended with every symptom of an abdominal viscus incurably diseased, after all probable methods of relief from art had been tried in vain, and after the flesh and strength were so exhausted as to leave scarce any hopes from nature. In those deplorable

Phlegmasiæ.

ble circumstances, there has arisen a swelling not far from the probable seat of the disorder, and yet without any discoverable communication with it. This swelling has come to an abscess; in consequence of which the pulse has soon returned to its natural state, as have also the appetite, flesh, and strength. What nature has performed in those rare cases, Dr Heberden acquaints us, he has often endeavoured to imitate, by making issues or applying blisters near the seat of the disease; but he cannot say with the same success.

It seems at present, Dr Heberden observes, to be the opinion of many practitioners, that gangrenes will be stopped, and suppuration become more kindly, by the use of Peruvian bark; and therefore this remedy is always either advised or permitted in the irregular fever joined with suppurations and gangrenes. But he affirms he does not remember ever to have seen any good effect from cinchona in this fever unattended with an apparent ulcer; and even in gangrenes it so often fails, that in successful cases, where it has been administered, there must be room for suspicion that the success was owing to another cause. Dr Heberden acknowledges, at the same time, that he never saw any harm from cinchona, in these, or indeed in any other cases, except a slight temporary purging or sickness, where it has happened to disagree with the stomach, or where the latter has been loaded by taking the medicine too fast, especially in dry boluses wrapped in wafer-paper.

In hectic illnesses, where all other means have proved ineffectual, a journey to Bath is usually proposed by the friends, and wished for by the sick; but Dr Heberden justly observes, that, besides the fatigue and many inconveniences of a journey to a dying person, the Bath waters are peculiarly hurtful in this fever, which they never fail to increase, and thereby aggravate the sufferings and hasten the death of the patient.

170

ORDER II. PHLEGMASIÆ.

Phlegmasiæ membranosæ et parenchymatosæ, *Sauv.* Class III. Ord. I. II. *Sag.* 605.
Morbi febriles phlogistici, *Lin.* Class III.
Febres continuæ compositæ inflammatoriæ, *Vog.*
Morbi acuti febriles, *Boerh.* 770.
Febres inflammatoriæ, *Hoffm.* II. 105. *Junck.* 61.

The phlegmasiæ, or topical inflammations, are a very numerous assemblage of diseases. Their great characteristics are, the general symptoms of fever, and a topical inflammation, attended with the lesion of some important function. In most instances, when blood is drawn, it is found upon coagulation to be covered with a buffy coat. Under this order, many important genera are comprehended, each requiring a separate consideration.

171

GENUS VII. PHLOGOSIS.

172

Sp. I. PHLOGOSIS PHLEGMONE.

Phlegmone auctorum, *Sauv.* gen. 15. *Lin.* 39. *Vog.* 351.
Inflammatio, *Lin.* 231. *Boerh.* 370. *Junck.* 20.

This disease is a synocha fever, accompanied with an inflammation of some particular part either external or internal, and consequently it varies very much in its form and the degree of danger attending it, according to the situation and functions of the part affected with topical inflammation. To this species, therefore, belong the following diseases:

Phlogosis.

Furunculus, *Sauv.* gen. 18. *Vog.* 352.
Terminthus, *Vog.* 381.
Pupula, *Lin.* 275. *Sauv.* p. 6.
Varus, *Vog.* 436. *Lin.* 269. *Sauv.* p. 7.
Bacchia, *Lin.* 270.
Gutta rosea, *Sauv.* gen. 4.
Gutta rosacea, *Vog.* 437.
Hordeolum, *Sauv.* gen. 27. *Lin.* 276. *Vog.* 434.
Otalgia, *Sauv.* gen. 197. *Lin.* 44. *Vog.* 148.
Dolor otalgicus, *Hoffm.* II. 336.
Parulis, *Vog.* 362.
Mastodynia, *Sauv.* gen. 210. *Vog.* 153.
Paronychia, *Sauv.* gen. 21. *Lin.* 258. *Vog.* 345.
Arthrocace, *Sauv.* gen. 78. *Lin.* 256.
Pædarthrocace, *Vog.* 419.
Spina ventosa, *Boerh.* 526.
Phimosis, *Sauv.* gen. 22. *Lin.* 297. *Vog.* 348.
Paraphimosis, *Vog.* 349.

For the cure of inflammations, Dr Cullen lays down the following indications. 1. To remove the remote causes when they are evident and continue to operate. 2. To take off the phlogistic diathesis affecting the whole system, or the particular part. 3. To take off the spasm of the particular part, by remedies applied to the whole system, or to the part itself.

The means of removing the remote causes will readily occur, from considering the particular nature and circumstances of the different kinds. Acrid matters must be removed, or their action must be prevented, by the application of demulcents. Compressing and overstretching powers must be taken away; and from their several circumstances, the means of doing so will be obvious.

The means of taking off the phlogistic diathesis of the system are the same with those already mentioned under the cure for synocha. The means of taking off the spasm also from the particular part, are much the same with those already mentioned. Only it is to be remembered, that topical bleedings, such as cupping with scarifications, applying leeches, &c. are in this case much more indicated; and that some of the other remedies are to be directed more particularly to the part affected, as shall be more fully considered when we treat of those diseases attended with particular inflammations.

When a tendency to suppuration is perceived, the proper indication is to promote the production of perfect pus as much as possible. For this purpose various remedies, supposed to possess a specific power, have been proposed: but it does not appear that any of them are possessed of a virtue of this kind; and, in Dr Cullen's opinion, all that can be done is to favour the suppuration by such applications as may support a moderate heat in the part, by some tenacity confine the perspiration, and by an emollient quality may weaken the cohesion of the teguments, and favour their erosion. As all abscesses are occasioned by the effusion of fluids, and as in the case of certain effusions a suppuration becomes

comes not only unavoidable but desirable, it may be supposed that most of the means of procuring a resolution, by diminishing the force of circulation, &c. ought to be avoided. But as we observe, on the one hand, that a certain degree of increased impetus, or of the original symptoms of inflammation, is necessary to produce a proper suppuration; so it is then especially necessary to avoid those means of resolution which may diminish too much the force of circulation. And on the other hand, as the impetus of the blood, when violent, is found to prevent the proper suppuration; so, in such cases, though a tendency to suppuration may have begun, it may be proper to continue those means of resolution which moderate the force of the circulation. With respect to the opening of abscesses when completely formed, see the article SURGERY.

When an inflammation has taken a tendency to gangrene, that event is to be prevented by every possible means; and these must be different according to the nature of the several causes: but after a gangrene has in some degree taken place, it can be cured only by the separation of the dead from the living parts. This in certain circumstances can be performed, and most properly, by the knife. In other cases it can be done by exciting a suppuratory inflammation on the verge of the living part, whereby its cohesion with the dead part may be everywhere broken off, so that the latter may fall off by itself. While this is doing, it is proper to prevent the further putrefaction of the part, and its spreading wider. For this purpose various antiseptic applications have been proposed: but Dr Cullen is of opinion, that while the teguments are entire, these applications can hardly have any effect; and therefore that the fundamental procedure must be to scarify the part so as to reach the living substance, and, by the wounds made there, to excite the suppuration required. By the same incisions also we give access to antiseptics, which may both prevent the progress of the putrefaction in the dead, and excite the inflammation necessary on the verge of the living parts.

When the gangrene proceeds from loss of tone, and when this, communicated to the neighbouring parts, prevents that inflammation which, as we have said, is requisite to the separation of the dead parts from the living, it will be necessary to obviate this loss of tone by tonic medicines given internally; and for this purpose cinchona has been found to be most effectual. But when the gangrene arises from the violence of inflammation, the bark may not only fail of proving a remedy, but may do harm: for its power as a tonic is especially suited to those cases of gangrene which proceed from an original loss of tone, as in the case of palsy and œdema; or in those cases where a loss of tone takes place after the original inflammatory symptoms are removed.

On the other hand, Mr Bell is of opinion, that incisions made with a view to admit the operation of antiseptic remedies in gangrenes, as well as the remedies themselves, must be pernicious from the irritation they occasion, and from the danger of wounding bloodvessels, nerves, or tendons, and also by allowing a free passage for the putrescent fluids into the parts not yet affected. And unless they be carried so deep as to reach the sound parts, applications of the antiseptic kind can never have any effect in answering the purpose for which they were intended. The same author also remarks, that all the advantages commonly observed from the great number of applications recommended for gangrene, are obtained with more ease, and generally too with more certainty, from the use of some gentle stimulating embrocation; which, by exciting a slight irritation upon the surface, especially when assisted by a free use of cinchona, produces for the most part such a degree of inflammation as is wished for. With this view he has frequently known a weak solution of sal ammoniac, a dram of the salt to two ounces of vinegar and six of water, form a mixture of very proper strength for every purpose of this kind. But the degree of stimulus can easily be either increased or diminished according to circumstances, by using a larger or smaller proportion of the salt.

Whenever, either by the means recommended, or by a natural exertion of the system, a slight inflammation appears between the diseased and sound parts, we may in general, with tolerable certainty, expect, that in due time the parts will be separated; and when a full suppuration is once fairly established, there can be little doubt that the mortified parts will be soon and easily removed.

A complete separation being effected, the sore is to be treated in the manner described under the article SURGERY; with a proper attention, at the same time, to the support of the general system by the continuance of nourishing diet, and cinchona with such quantities of wine as may seem necessary.

With regard to the bark, however, it is proper to take notice of another case of mortification in which it is likewise unsuccessful, as well as in that attended with a high degree of inflammation; and that is, in those mortifications of the toes and feet, common in old people, or which arise from any cause increasing the rigidity of the vessels to such a degree as to prevent the motion of the fluids through them. In this case Mr Pott has discovered, that all kinds of warm applications are very unsuccessful; but by the free use of opium, together with sedatives and relaxants externally applied, he has frequently seen the tumefaction of the feet and ankles subside, the skin recover its natural colour, and all the mortified parts separate in a very short time, leaving a clean sore. But as to scarifications, or any other attempt to separate artificially the mortified from the sound parts, he thinks them very prejudicial, by giving pain; which is generally of itself violent in this disease, and which seems to have a great share in producing the other evils.

The other terminations of inflammation either do not admit of any treatment except that of preventing them by resolution, or properly belong to the article SURGERY.

The word *erythema* does not apply to any primary disease, but to a great number of those cutaneous inflammations denominated by another general term, viz. the *erysipelas*, or "St Anthony's fire;" and which being commonly symptomatic of some other inflammation or disorder, are to be removed only by removing the primary disease: the erythema is found scarcely to bear any kind of warm application to itself; and is very apt, if treated as a primary disease, to terminate in a gangrene of the part affected, or some other disorder still more dangerous. The difference between the *phlegmon* or preceding species, and *erythema*, according to Dr Cullen, is, that, in the former, the inflammation seems particularly to affect the vessels on the internal surface of the skin, communicating with the lax adjacent cellular texture; whence a more copious effusion, and that too of serum convertible into pus, takes place. In the erythema the affection is of the vessels on the external surface of the skin communicating with the *rete mucosum*. This affection does not admit of any effusion but what separates the cuticle, and gives occasion to the formation of a blister, while the smaller size of the vessels admits only of the effusion of a thin fluid very seldom convertible into pus. For the cure of the fever attended with erythema or *erysipelas*, see below; and for the external treatment of erythema, see Surgery.

Ophthalmia scrophulosa, *Sauv.* sp. 9.
Ophthalmia siphylitica, *Sauv.* sp. 11.
Ophthalmia febricosa, *Sauv.* sp. 23.

From reading this long list of distinctions which authors have invented in the ophthalmia, it is evident, that by far the greatest part of them are symptomatic, or merely the consequence of other disorders present in the habit; and therefore the remedies must be directed towards the removal of these primary disorders; and when they are gone the ophthalmia will be removed of course. Dr Cullen observes, that the inflammation of the eye may be considered as of two kinds; according as it is seated in the membranes of the ball of the eye, when it is named *ophthalmia membranarum;* or as it is seated in the sebaceous glands placed in the tarsus, or edges of the eyelids, in which case it may be termed *ophthalmia tarsi*. These two kinds are very frequently connected together, as the one may excite the other; but they are still to be distinguished according as the one or the other may happen to be the primary affection.

1. The inflammation of the *membranes* of the eye affects especially, and most frequently, the adnata, and appears in a turgescence of its vessels; so that the red vessels which are naturally there, become not only increased in size, but many more appear than in a natural state. This turgescence of the vessels is attended with pain, especially upon the motion of the ball of the eye; and this irritation, like every other, applied to the surface of the eye, produces an effusion of tears from the lachrymal gland.

The inflammation commonly, and chiefly, affects the adnata spread on the anterior part of the bulb of the eye; but usually spreads also along the continuation of the adnata on the inside of the palpebræ; and as that is extended on the tarsus palpebrarum, the excretories of the sebaceous glands opening there are also frequently affected. When the affection of the adnata is considerable, it may be communicated to the subjacent membranes of the eye, and even to the retina itself; which thereby acquires so great sensibility, that every impression of light becomes painful. The inflammation of the membranes of the eye is in different degrees, according as the adnata is more or less affected, or according as the inflammation is either of the adnata alone, or of the subjacent membranes also; and upon these differences, different species have been established; but they seem all to differ only in degree, and are to be cured by the same remedies more or less employed.

The proximate cause of ophthalmia is not different from that of inflammation in general; and the different circumstances of ophthalmia may be explained

by

by the difference of its remote causes, and by the different parts of the eye which it happens to affect; as may be understood from what has been already said. We shall therefore proceed to give an account of the method of cure.

The great objects to be aimed at in the treatment of ophthalmia, are, in the first place, the resolution of the inflammation which has already taken place; and, secondly, the removal of those consequences which frequently arise from the inflammation, especially if it have been of long standing. But besides these, while it has appeared from former observation, that there is a peculiar disposition to the disease, practices may often be successfully employed to combat this disposition, and thus prevent the return of the affection.

The ophthalmia membranarum requires the remedies proper for inflammation in general; and when the deeper-seated membranes are affected, and especially when a pyrexia is present, large general bleedings may be necessary. But this last is seldom requisite, and, for the most part, the ophthalmia is an affection merely local, accompanied with little or no pyrexia. General bleedings therefore have little effect upon it, and the cure is chiefly to be obtained by topical bleedings, that is, blood drawn from the vessels near the inflamed part; and opening the jugular vein, or the temporal artery, may be considered as in some measure of this kind. It is commonly sufficient to apply a number of leeches round the eye; but it is perhaps still better to draw blood by cupping and scarifying from the temples. In many cases, the most effectual remedy is to scarify the internal surface of the inferior eyelid, and to cut the turgid vessels upon the adnata itself.

Besides blood-letting, purging, as a remedy suited to inflammation in general, has been considered as peculiarly adapted to inflammation in any part of the head, and therefore to ophthalmia; and it is sometimes useful: but, for the reasons given before with respect to general bleeding, purging in the case of ophthalmia does not prove useful in any proportion to the evacuation excited.—For relaxing the spasm in the part, and taking off the determination of the fluids to it, blistering near the part has commonly been found useful. When the inflammation does not yield to the application of blisters after topical bleeding, great benefit is often obtained by supporting a discharge from the blistered part, under the form of an issue, by which means a more permanent determination of blood from the part is obtained.

It is probably also on the same principle that the good effects obtained from the use of errhine medicines in obstinate cases of ophthalmia are to be accounted for. By these errhines, in particular, which occasion and support for some time a great discharge from the nose, great benefit has often been obtained. The powder of asarabacca, or the infusion of hippocastanum, snuffed up the nose at bedtime in proper doses, are often productive of the best effects, when many other remedies have been tried in vain.

Ophthalmia, as an external inflammation, admits of topical applications. All those, however, which increase the heat and relax the vessels of the part, prove hurtful; and the admission of cool air to the eye, and the application of cooling and astringent medicines, which at the same time do not produce irritation, prove useful. Of all these the solution of acetite of lead, assiduously applied, is perhaps the best. In the cure of this distemper, indeed, all irritation must carefully be avoided, particularly that of light; and the only certain means of doing this is by keeping the patient in a very dark chamber.

2. In the *ophthalmia tarsi*, the same medicines may be necessary, as have been already recommended for the ophthalmia membranarum. However, as the ophthalmia tarsi may often depend upon an acrimony deposited in the sebaceous glands of the part, so it may require various internal remedies according to the variety of the acrimony in fault; for which we must refer to the consideration of scrophula, siphylis, or other diseases with which this ophthalmia may be connected; and where these shall not be evident, certain remedies more generally adapted to the evacuation of acrimony, such as mercury, may be employed. In the ophthalmia tarsi, it almost constantly happens that some ulcerations are formed on the tarsus. These require the application of mercury and copper, which alone may sometimes cure the whole affection: and they may be useful even when the disease depends upon a fault of the whole system.

Both in the ophthalmia membranarum, and in the ophthalmia tarsi, it is necessary to obviate that gluing together of the eyelids which commonly happens in sleep; and which may be done by insinuating a little of any mild unctuous medicine between the eyelids before the patient shall go to sleep.

The slighter kinds of inflammations from the dust or the sun, may be removed by fomenting with warm milk and water, adding a small portion of brandy; and by anointing the borders of the eyelids with *unguentum tutiæ*, or the like, at night, especially when those parts are excoriated and sore. But in bad cases, after the inflammation has yielded a little to evacuations, the *cataplasma aluminis* of the London Pharmacopœia spread on lint, and applied at bedtime, has been found the best external remedy. Before the use of the latter, the solution of sulphate of zinc is prescribed with advantage; and in violent pains it is of service to foment frequently with a decoction of white poppy-heads. One of the most common and most disagreeable consequences of ophthalmia, is an offuscation of the cornea, so far obstructing the passage of light as to diminish or prevent vision. This is sometimes so considerable as to admit of removal by operation: but in slighter cases it may often be removed by the application of different gentle escharotics; and in this way, without the least danger of any inconvenience, goods effects are often obtained, from gently introducing into the eye at bedtime a powder consisting of equal parts of supertartrite of potass and sugar, reduced together to a fine powder.

Where there is a disposition to frequent returns of this affection, cinchona is often employed with success in combating it: But nothing in general answers better than frequent and regular cold bathing of the eyes.

Besides the various species of ophthalmia which were before known in Britain, another has lately been introduced, that contagious ophthalmia, viz. with which the British

Phlegmasiæ. British troops were affected in Egypt, and which they have imported into this island on their return from thence.

Of this affection many interesting accounts have been published. Perhaps the best is an elaborate treatise by Mr Edmonston, who has had many opportunities of witnessing the affection, and extensive practice in the treatment of the disease, both in Egypt and in Britain. To his work therefore we may refer those who wish for the most full information respecting it. We shall only observe, that now, no doubt can be entertained respecting the contagious nature of the disease; and that therefore the first great object necessary in the treatment is the complete separation of the diseased from the sound.

175 GENUS IX. PHRENITIS.

PHRENSY, or *Inflammation of the BRAIN*.

Phrenitis, *Sauv.* gen. 101. *Lin.* 25. *Sag.* gen. 301. *Boerh.* 771. *Hoffm.* II. 131. *Junck.* 63.
Phrenismus, *Vog.* 45.
Cephalitis, *Sauv.* gen. 109. *Sag.* gen. 310.
Sphacelismus, *Lin.* 32.
Phrenitis vera, *Sauv.* sp. 1. *Boerh.* 771.
Phrenitis idiopathica, *Junck.* 63.
Cephalalgia inflammatoria, *Sauv.* sp. 9.
Cephalitis spontanea, *Sauv.* sp. 3.
Cephalitis siriasis, *Sauv.* sp. 4.
Siriasis, *Vog.* 34.
Cephalitis Littriana, *Sauv.* sp. 5.

Dr Cullen observes, that the true phrenitis, or inflammation of the membranes or substance of the brain, is very rare as an original disease: but, as a symptom of others, much more frequent; of which the following kinds are enumerated by different authors:

Phrenitis synochi pleuriticæ, *Sauv.* sp. 2.
Phrenitis synochi sanguineæ, *Sauv.* sp. 4.
Phrenitis calentura, *Sauv.* sp. 11.
Phrenitis Indica, *Sauv.* sp. 12.
Cephalitis Ægyptiaca, *Sauv.* sp. 1.
Cephalitis epidemica anno 1510, *Sauv.* sp. 6.
Cephalitis verminosa, *Sauv.* sp. 7.
Cephalitis cerebelli, *Sauv.* sp. 8.
Phrenitis miliaris, *Sauv.* sp. 3.
Phrenitis variolosa, *Sauv.* sp. 5.
Phrenitis morbillosa, *Sauv.* sp. 6.
Phrenitis à plicâ, *Sauv.* sp. 8.
Phrenitis aphrodisiaca, *Sauv.* sp. 9.
Phrenitis à tarantismo, *Sauv.* sp. 14.
Phrenitis hydrophobica, *Sauv.* sp. 15.
Phrenitis à dolore, *Sauv.* sp. 13.
Cephalitis traumatica, *Sauv.* sp. 2.

Description. The signs of an impending phrenitis are, immoderate and continual watchings; or if any sleep be obtained, it is disburbed with dreams, and gives no refreshment; acute and lasting pains, especially in the hind part of the head and neck; little thirst; a great and slow respiration, as if proceeding from the bottom of the breast; the pulse sometimes small and slow, sometimes quick and frequent; a suppression of urine; and forgetfulness. The distemper when present may be known by the following signs: The veins of the head swell, and the temporal arteries throb much; the eyes are fixed, sparkle, and have a fierce aspect; the speech is incoherent, and the patient behaves very roughly to the bystanders, with furious attempts to get out of bed, not indeed continually, but returning as it were by paroxysms: the tongue is dry, rough, yellow, or black; there is a coldness of the external parts; a proneness to anger; chattering of the teeth; a trembling of the hands, with which the sick seem to be gathering something, and actually do gather the naps off the bed-clothes.

Phrenitis. *Causes of, and persons subject to, this disorder.* People of a hot and bilious habit of body, and such as are of a passionate disposition, are apt to be affected with phrenitis. In the same danger are those who make much use of spices, or are given to hot and spirituous liquors; who have been exposed more than usual to the sun, or obliged to undergo immoderate studies or watchings; who are subject to headachs, or in whom some customary hemorrhages have been stopped; or the disease may arise from some injury offered to the head externally. Sir John Pringle observes, that the phrenitis, when considered as an original disease, is apt to attack soldiers in the summer season when they are exposed to the heat of the sun, and especially when asleep and in liquor. A symptomatic phrenitis is also more frequent in the army than elsewhere, on account of the violence done to all fevers when the sick are carried in waggons from the camp to the hospital, where the very noise or light alone would be sufficient, with more delicate natures, to raise a phrensy. From these and similar causes, a state of active inflammation, affecting some parts within the cranium, is produced: and there can be no doubt, that from this all the symptoms of the disease arise, and particularly that peculiar delirium which characterizes it. But in what manner local diseases, even of the brain itself, produce affections of the mind, we are still totally in the dark.

Prognosis. Every kind of phrenitis, whether idiopathic or symptomatic, is attended with a high degree of danger; and, unless removed before the fourth day, a gangrene or sphacelus of the meninges readily takes place, and the patient dies delirious. The following are the most fatal symptoms: A continual and furious delirium, with watching; thin watery urine, white fæces, the urine and stools running off involuntarily, or a total suppression of these excretions; a ready disposition to become stupid, or to faint; trembling, rigor, chattering of the teeth, convulsions, hiccough, coldness of the extremities, trembling of the tongue, shrill voice, a sudden cessation of pain, with apparent tranquillity. The following are favourable: Sweats, apparently critical, breaking out; a seeming effort of nature to terminate the disease by a diarrhœa; a large hemorrhagy from the nose; swellings of the glands behind the ears; hæmorrhoids.

Cure. From what has been said of the theory of this disease, the cure must entirely depend on obtaining a resolution of the inflammation. The objects chiefly to be aimed at with this view are, 1. The removal of such exciting causes as continue to operate. 2. The diminution of the momentum of the blood in the circulating system in general. 3. The diminution of impetus at the brain in particular: and, 4. The avoiding

Cynanche.

ing circumstances which tend either to accelerate the motion of the blood or to give determination to the head.

Different practices may be used with these intentions; but the most powerful remedies are to be immediately employed. Large and repeated bleedings are especially necessary; and these too taken from vessels as near as possible to the part affected. The opening the temporal artery has been recommended, and with some reason: but as the practice is attended with inconveniences, perhaps the opening of the jugular veins may in general prove more effectual; with which, however, may be joined the drawing of blood from the temples by cupping and scarifying. It is also probable, that purging may be of more use in this than in some other inflammatory affections, as it may operate by revulsion. For the same purpose of revulsion, warm pediluvia are a remedy, but rather ambiguous. The taking off the force of the blood in the vessels of the head by an erect posture is generally useful. Blistering is also useful, but chiefly when applied near to the part affected. In short, every part of the antiphlogistic regimen is here necessary, and particularly the admission of cold air. Even cold substances applied to the head have been found useful; and the application of such refrigerants as vinegar is certainly proper. Opiates are thought to be hurtful in every inflammatory state of the brain. On the whole, however, it must be remarked, that practitioners are very uncertain with regard to the means proper to be used in this disease; and the more so, that the symptoms by which the disease is commonly judged to be present, appear sometimes without any internal inflammation; and on the other hand, dissections have shown that the brain has been inflamed, where few of the peculiar symptoms of inflammation had appeared before death.

Sp. I. Cynanche tonsillaris.
7 The *Inflammatory* Quinsy.

Cynanche tonsillaris, *Sauv.* sp. 1.
Angina inflammatoria, sp. 5. *Boerh.* 805.

Description. This is an inflammation of the mucous membrane of the fauces, affecting principally that congeries of mucous follicles which forms the tonsils; and from thence spreading along the velum and uvula, so as frequently to affect every part of the mucous membrane. The disease appears by some tumour and redness of the parts; is attended with a painful and difficult deglutition; a troublesome clamminess of the mouth and throat; a frequent but difficult excretion of mucus; and the whole is accompanied with pyrexia. The inflammation and tumour are commonly at first most considerable in one tonsil; and afterwards, abating in that, increase in the other. This disease is not contagious.

Causes of, and persons subject to, this disorder. This disease is commonly occasioned by cold externally applied, particularly about the neck. It affects especially the young and sanguine; and a disposition to it is often acquired by habit. It occurs especially in the spring and autumn, when vicissitudes of heat and cold frequently take place.

Prognosis. This species of cynanche terminates frequently by resolution, sometimes by suppuration, but hardly ever by gangrene; though in some cases sloughy spots appear on the fauces: the prognosis therefore is generally favourable.

Cure. As the principal morbid affection in this disease, on which all its characterising symptoms immediately depend, is the active inflammation in the tonsils and neighbouring parts, the object first and principally to be aimed at in the cure is to obtain a resolution of this inflammation. Sometimes, however, it is necessary to have recourse to practices, with the view of obviating urgent symptoms before a resolution can be effected: and in other cases, where a resolution cannot be obtained, it must be the aim of the practitioner to promote a speedy and favourable suppuration. After suppuration has taken place, the proper means of promoting a discharge of the purulent matter will conclude the cure. Here some bleeding may be necessary; but large and general evacuations are seldom beneficial. The opening of the ranular veins is an insignificant remedy, according to Dr Cullen, but is recommended as efficacious by Sir John Pringle: more benefit, however, may in general be derived from leeches to the external fauces. The inflammation may be often relieved by moderate astringents, and particularly by acids applied to the parts affected. In many cases, nothing has been found to give more relief than the vapour of warm water received into the fauces.

Besides these, blistering, and still more frequently rubefacient medicines, are applied with success, as well as antiphlogistic purgatives; and every part of the antiphlogistic regimen is to be observed, except the application of cold. Sir John Pringle recommends a thick piece of flannel moistened with two parts of common sweet oil, and one of spirit of hartshorn (or in a larger proportion, if the skin will bear it), to be applied to the throat, and renewed once every four or five hours. By this means the neck, and sometimes the whole body, is put into a sweat, which after bleeding either carries off or lessens the inflammation. When the disease has a tendency to suppuration, nothing will be more useful than receiving into the fauces the steams of warm water. Benefit is also obtained from poultices applied to the external fauces. When the abscess is attended with much swelling, if it break not spontaneously, it ought to be opened by a lancet; and this does not require much caution, as even the inflammatory state may be relieved by some scarification of the tonsils. When this disease runs very rapidly to such a height as to threaten suffocation, it is sometimes necessary to have recourse to bronchotomy as the only means of saving the life of the patient. But there is reason to believe that this operation has sometimes been employed where it was not necessary: and we may safely venture to say, that it is but seldom requisite; insomuch that Dr Cullen tells us, he has never in his practice seen any case requiring bronchotomy.

History and Description. This distemper is not particularly described by the ancient physicians; though perhaps the Syrian and Egyptian ulcers mentioned by Aretæus Cappadox, and the pestilent ulcerated tonsils we read of in Aetius Amideus, were of this nature. Some of the scarlet fevers mentioned by Morton seem also to have approached near to it. In the beginning of the last century, a disease exactly similar to this is described by the physicians of that time, as raging with great violence and mortality in Spain and some parts of Italy; but no account of it was published in this country till the year 1748, when a very accurate one was drawn up by Dr Fothergill, and in 1752 by Dr Huxham. The latter observes, that this disease was preceded by long, cold, and wet seasons; by which probably the bodies of people were debilitated, and more apt to receive contagion, which possibly also might be produced by the stagnant and putrid waters.

The attack of this disease was very different in different persons. Sometimes a rigor, with fulness and soreness of the throat, and painful stiffness of the neck, were the first symptoms complained of. Sometimes alternate chills and heats, with some degree of giddiness, drowsiness, or headach, ushered in the distemper. It seized others with more severe feverish symptoms; great pain of the head, back, and limbs; a vast oppression of the præcordia, and continual sighing. Some grown persons went about for days in a drooping state, with much uneasiness and anxiety, till at last they were obliged to take to their beds.—Thus various was the disease, says Dr Huxham, at the onset. But it commonly began with chills and heats, load and pain of the head, soreness of throat, and hoarseness; some cough, sickness at stomach, frequent vomiting and purging, in children especially, which were sometimes very severe; though a contrary state was more common to the adult. There was in all a very great dejection of spirits, very sudden weakness, great heaviness on the breast, and faintness, from the very beginning. The pulse in general was quick, small, and fluttering, though sometimes heavy and undulating. The urine was commonly pale, thin, and crude; however, in many grown persons, it was passed in small quantities and high coloured, or like turbid whey. The eyes were heavy, reddish, and as it were weeping; the countenance very often full, flushed, and bloated, though sometimes pale and sunk.

Cynanche.

How slight soever the disorder might appear in the day-time, at night the symptoms became greatly aggravated, and the feverish habit very much increased, nay, sometimes a delirium occurred on the very first night; and this exacerbation constantly returned through the whole course of the disease. Indeed, when it was considerably on the decline, our author says he has been often pretty much surprised to find his patient had passed the whole night in a phrensy, whom he had left tolerably cool and sedate in the day.

Some few hours after the seizure, and sometimes cotemporary with it, a swelling and soreness of the throat was perceived, and the tonsils became very tumid and inflamed, and many times the parotid and maxillary glands swelled very much, and very suddenly, even at the very beginning; sometimes so much as even to threaten strangulation. The fauces also very soon appeared of a high florid red, or rather of a bright crimson, colour, very shining and glossy; and most commonly on the uvula, tonsils, velum palatinum, and back part of the pharynx, several whitish or ash-coloured spots appeared scattered up and down, which oftentimes increased very fast, and soon covered one or both the tonsils, uvula, &c.: those in the event proved sloughs of superficial ulcers (which sometimes, however, ate very deep into the parts). The tongue at this time, though only white and moist at the tip, was very foul at the root, and covered with a thick, yellowish or brown coat. The breath also now began to be very nauseous: which offensive smell increased hourly, and in some became at length intolerable, and that too sometimes even to the patients themselves.

The second or third day every symptom became much more aggravated, and the fever much more considerable; and those that had struggled with it tolerably well for 30 or 40 hours, were forced to submit. The restlessness and anxiety greatly increased, as well as the difficulty in swallowing. The head was very giddy, pained, and loaded; there was generally more or less of a delirium; sometimes a pervigilium and perpetual phrensy, though others lay very stupid, but often starting and muttering to themselves. The skin was very hot, dry, and rough; there was very rarely any disposition to sweat. The urine was pale, thin, crude; often yellowish and turbid. Sometimes vomiting was urgent, and sometimes a very great looseness, in children particularly. The sloughs were now much enlarged, and of a darker colour, and the surrounding parts tended much more to a livid hue. The breathing became much more difficult; with a kind of a rattling stertor, as if the patient was actually strangling, the voice being exceeding hoarse and hollow, exactly resembling that from venereal ulcers in the fauces: this noise in speaking and breathing was so peculiar, that any person in the least conversant with the disease might easily know it by this odd noise; from whence indeed the Spanish physicians gave it the name of *garrotillo,* expressing the noise made by persons when they are strangled with a rope. Dr Fothergill never observed in one of them the shrill barking noise that we frequently hear in inflammatory cynanche. The breath

Phlegmasiæ. breath of all the diseased was very nauseous; of some insufferably fetid, especially in the advance of the distemper to a crisis; and many about the fourth or fifth day spit off a vast quantity of stinking purulent mucus tinged sometimes with blood: and sometimes the matter was quite livid, and of an abominable smell. The nostrils likewise in many were greatly inflamed and excoriated, continually dripping down a very sharp ichor or sanious matter, so excessively acrid, that it not only corroded the lips, cheeks, and hands of the children that laboured under the disease, but even the fingers and arms of the very nurses that attended them: as this ulceration of the nostrils came on, it commonly caused an almost incessant sneezing in the children; but few adults were affected with it, at least to any considerable degree. It was surprising what quantities of matter some children discharged this way, which they would often rub on their face, hands, and arms, and blister them all over. A sudden stoppage of this rheum from the mouth and nostrils actually choaked several children; and some swallowed such quantities of it, as occasioned excoriations of the intestines, violent gripings, dysentery, &c. nay, even excoriations of the anus and buttocks. Not only the nostrils, fauces, &c. were greatly affected by the extremely sharp matter, but the wind-pipe itself was sometimes much corroded by it, and pieces of its internal membrane were spit up, with much blood and corruption; and the patients lingered on for a considerable time, and at length died tabid; though there were more frequent instances of its falling suddenly and violently on the lungs, and killing in a peripneumonic manner.

Dr Huxham was astonished sometimes to see several swallow with tolerable ease, though the tumour of the tonsils and throat, the quantity of thick mucus, and the rattling noise in breathing, were very terrible; which he thinks pretty clearly shows, that this malignant angina was more from the acrimony and abundance of the humours than the violence of the inflammation.

Most commonly the angina came on before the exanthemata; but many times the cuticular eruption appeared before the sore-throat, and was sometimes very considerable, though there was little or no pain in the fauces: on the contrary, a very severe angina seized some patients that had no manner of eruption; and yet, even in these cases, a very great itching and desquamation of the skin sometimes ensued; but this was chiefly in grown persons, very rarely in children. In general, however, a very considerable efflorescence broke out on the surface of the body, particularly in children; and it most commonly happened the second, third, or fourth day: sometimes it was partial, sometimes it covered almost the whole body, though very seldom the face: sometimes it was of an erysipelatous kind; sometimes more pustular: the pustules frequently eminent, and of a deep fiery red colour, particularly on the breast and arms; but oftentimes they were very small, and might be better felt than seen, and gave a very odd kind of roughness to the skin. The colour of the efflorescence was commonly of a crimson hue, or as if the skin had been smeared over with juice of raspberries, and this even to the fingers ends; and the skin appeared inflamed and swollen, as it were; the arms, hands, and fingers, were often evidently so, and very stiff, and somewhat painful. This crimson colour of the skin seemed indeed peculiar to this disease. Though the eruption seldom failed of giving some manifest relief to the patient, as to anxiety, sickness at stomach, vomiting, purging, &c. yet there was observed an universal fiery eruption on some persons, without the least abatement of the symptoms, nay almost every symptom seemed more aggravated, particularly the fever, load at breast, anxiety, and delirium; Dr Huxham knew more than one or two patients die in the most raging phrensy, covered with the most universal fiery rash he ever saw: so that, as in the highly confluent smallpox, it seemed only to denote the quantity of the disease, as he terms it.

Cynanche.

He had under his care a young gentleman, about 12 years of age, whose tongue, fauces, and tonsils, were as black as ink, and he swallowed with extreme difficulty; he continually spit off immense quantities of a black, sanious, and very fetid matter, for at least eight or ten days:—about the seventh day, his fever being somewhat abated, he fell into a bloody dysentery, though the bloody, sanious, fetid expectoration still continued, with a most violent cough. He at length indeed got over it, to the very great surprise of every one that saw him. Now, in this patient, a severe and universal rash broke out upon the second and third day; and the itching of his skin was so intolerable, that he tore it all over his body in a most shocking manner; yet this very great and timely eruption very little relieved his fever and phrensy, or prevented the other dreadful symptoms mentioned.

An early and kindly eruption, however, was most commonly a very good omen; and, when succeeded by a very copious desquamation of the cuticle, one of the most favourable symptoms that occurred: but when the eruption turned of a dusky or livid colour, or prematurely or suddenly receded, every symptom grew worse, and the utmost danger impended, especially if purple or black spots appeared up and down, as sometimes happened; the urine grew limpid, and convulsions came on, or a fatal suffocation soon closed the tragedy.

The disease was generally at the height about the fifth or sixth day in young persons, in the elder not so soon; and the crisis many times was not till the 11th or 12th, and then very imperfect; some adults however, were carried off in two or three days; the distemper either falling on the lungs, and killing in a peripneumonic manner; or on the brain, in which case the patient either died raving or comatose. In some, the disease brought on a very troublesome cough, purulent expectoration, hæmoptoë, and hectic fever; in which they lingered on for several weeks, and then died tabid.

If a gentle easy sweat took place on the third or fourth day; if the pulse became more slow, firm, and equal; if the sloughs of the fauces cast off in a kindly manner, and appeared at the bottom tolerably clean and florid; if the breathing was more soft and free, and some degree of vigour and quickness returned in the eyes; all was well, and a salutary crisis followed soon by a continuance of the sweat, and a turbid, subsiding, farinaceous urine, a plentiful expectoration, and a very large desquamation of the cuticle. But if a rigor came on, and the exanthemata suddenly disappeared or turned livid;

Phlegmasiæ.

livid; if the pulse grew very small and quick, and the skin remained hot and parched as it were, the breathing more difficult, the eyes dead and glassy, the urine pale and limpid, a phrensy or coma succeeded, with a coldish clammy sweat on the face or extremities; life was despaired of, especially if a singultus and choaking or gulping in the throat attended, with sudden, liquid, involuntary, livid stools, intolerably fetid. In some few patients, Dr Huxham observed, some time before the fatal period, not only the face bloated, sallow, shining and greasy as it were, but the whole neck very much swollen, and of a cadaverous look; and even the whole body became in some degree œdematous; and the impression of a finger would remain fixed in a part, the skin not rising again as usual; an indication that the blood stagnated in the capillaries, and that the elasticity of the fibres was quite lost.

Medical writers are still much divided in opinion, whether the cynanche maligna is to be considered as the same disease with the scarlatina anginosa, afterwards to be treated of, or not. This question will afterwards come to be more fully discussed. At present we may only observe, that although ulcerous sore throats of a malignant nature often appear sporadically, yet that the disease above described appears only as an epidemic, and is always the consequence of contagion.

We have, therefore, no doubt that the cynanche maligna of Huxham, Fothergill, and Cullen, is precisely the same disease with the scarlatina anginosa of Sauvage, Withering, and other late writers. This is abundantly demonstrated by the diversities which take place in the appearance of the disease among children of the same family during the same epidemic.

Prognosis. This may be easily gathered from the above description. The malignant and putrid tendency of the disease is evident, and an increase of the symptoms which arise from that putrescent disposition of the body must give an unfavourable prognostic. On the contrary, a decrease of these, and an apparent increase of the *vis vitæ*, are favourable: in general, what is observed to be favourable in the nervous and putrid malignant fevers, is also favourable in this, and *vice versa*.

Causes. Since the accurate accounts given by Dr Fothergill and Huxham of the epidemics which prevailed about 50 years ago, this disease has frequently been observed at times epidemic in almost every different part of Britain. Like smallpox, measles, and chincough, it seems in every case to be the effect of a peculiar and specific contagion. It has been observed to prevail, equally generally in every situation, and at every season; and on exposure to the contagion, no age, sex, or condition, is exempted from it. But the having once had the disease, seems in this affection to afford the same security against future contagion as in the smallpox: at least instances, where it can be said that the same individual has been twice affected with it, are both very rare and very doubtful, as well as in smallpox.

Cure. Like other febrile contagions, the malignant ulcerous sore throat is terminated only by a natural course; and the chief business of the practitioner is to combat unfavourable occurrences. In this the septic tendency of the disease is chiefly to be kept in view. The debility with which it is attended renders all evacuations by bleeding and purging improper, except in a few instances where the debility is less, and the inflammatory symptoms more considerable. The fauces are to be preserved from the effects of the acrid matter poured out upon them, and are therefore to be frequently washed out by antiseptic gargles or injections; and the putrescent state of the whole system should be guarded against and corrected by internal antiseptics, especially by the Peruvian bark given in the beginning and continued through the course of the disease. Great benefit is also often derived from the liberal use of the mineral acids. Both the sulphuric and muriatic, in a state of proper dilution, have been highly extolled by different medical writers, and are productive of the best effects in actual practice, when they can be introduced to a sufficient extent. In particular, the oxygenated muriatic acid, as recommended by Mr Braithwaite, has been found productive of the greatest advantages. Emetics, both by vomiting and nauseating, prove useful. When any considerable tumor occurs, blisters applied externally will be of service, and in any case may be proper to moderate the inflammation.

Cynanche.

Very lately, the internal use of the capsicum annuum, or Cayenne pepper, as it is commonly called, has been highly celebrated in this affection; and it is particularly said to have been employed with singular success in the West Indies.

But of all the remedies lately proposed, none has been more highly extolled than the external use of cold water. It has even been contended by some that by dashing cold water on the surface of the body, an immediate artificial cure of this disease may be obtained. We are, however, fully persuaded, that cold water will no more destroy the contagion of this disease than of smallpox; and we cannot help thinking that the practice is seldom necessary, and sometimes hurtful.

Angina

Phlegmasiæ. Cynanche.

Angina inflammatoria infantum, *Russel*, Oecon. nat. p. 70.

Angina polyposa sive membranacea *Michealis*. Argentorati 1778, et auctores ab eo allegati.

The best description of this disease we have in Dr Cullen's Practice of Physic. He informs us, that it consists in an inflammation of the glottis, larynx, or upper part of the trachea, whether it affect the membranes of these parts or the muscles adjoining. It may arise first in these parts, and continue to subsist in them alone; or it may come to affect these parts from the cynanche tonsillaris, or maligna, spreading into them.

In either way it has been a rare occurrence, and few instances of it have been marked and recorded by physicians. It is to be known by a peculiar croaking sound of the voice, by difficult respiration, with a sense of straitening about the larynx, and by a pyrexia attending it.

From the nature of these symptoms, and from the dissection of the bodies of persons who died of this disease, there is no doubt of its being of an inflammatory kind. It does not, however, always run the course of inflammatory affections; but frequently produces such an obstruction of the passage of the air, as suffocates, and thereby proves suddenly fatal.

It particularly proves fatal, in consequence of the trachea being obstructed by a membranous substance lining the inside of it, and very nearly approaching in appearance to the inflammatory exudation often discovered on the intestinal canal in those dying of enteritis.

If we judge rightly of the nature of this disease, it will be obvious, that the cure of it requires the most powerful remedies of inflammation to be employed upon the very first appearance of the symptoms. When a suffocation is threatened, whether any remedies can be employed to prevent it, is not yet determined by sufficient experience: but it is evident, that in certain cases the life of the patient can be preserved only by the removal of that matter which obstructs the passage of air through the trachea.

The accounts which books have hitherto given us of inflammations of the larynx, and the parts connected with it, amount to what we have now said; and many instances are recorded of the disease happening in adult persons: but there is a peculiar affection of this kind happening to infants. which has been little taken notice of till lately. Dr Francis Home is the first who has given any distinct account of this disease; but, since he wrote, several other authors have taken notice of it, and have given different opinions concerning it.

This disease seldom attacks infants till after they have been weaned. After this period, the younger they are, the more liable they are to the disease. The frequency of it becomes less as children become more advanced; and there are few instances of children above 12 years of age being affected with it. It attacks children of the midland countries, as well as those who live near the sea; but it occurs much more frequently at certain places than at others. It does not appear to be contagious; and its attacks are frequently repeated in the same child. It is often manifestly the effect of cold applied to the body; and therefore appears most frequently in the winter and spring seasons. It very commonly comes on with the ordinary symptoms of a catarrh; but sometimes the peculiar symptoms of the disease show themselves at the very first.

These peculiar symptoms are the following: A hoarseness, with some shrillness and ringing sound, both in speaking and coughing, as if the noise came from a brazen tube. At the same time, there is a sense of pain about the larynx, some difficulty of respiration, with a whizzing sound in inspiration, as if the passage of the air were straitened. The cough which attends it, is commonly dry; and if any thing be spit up, it is matter of a purulent appearance, and sometimes films resembling portions of a membrane. With all these symptoms, there is a frequency of pulse, a restlessness, and an uneasy sense of heat. When the internal fauces are viewed, they are sometimes without any appearance of inflammation; but frequently a redness, and even swelling, appears; and sometimes there is an appearance of matter like to that rejected by coughing, together with the symptoms now described, and particularly with great difficulty of breathing, and a sense of strangling in the fauces, by which the patient is sometimes suddenly taken off.

Many dissections have been made of infants who had died of this disease, and almost constantly there has appeared a preternatural substance, apparently membranous, lining the whole internal surface of the upper part of the trachea, and extending in the same manner downwards into some of its ramifications. This preternatural membrane may be easily separated, and sometimes has been found separated in part from the subjacent proper membrane of the trachea. This last is commonly found entire, that is, without any appearance of erosion or ulceration; but it frequently shows the vestiges of inflammation, and is covered by a matter resembling pus, like to that rejected by coughing; and very often a matter of the same kind is found in the bronchiæ, sometimes in considerable quantity.

From the remote causes of this disease; from the catarrhal symptoms commonly attending it; from the pyrexia constantly present with it; from the same kind of preternatural membrane being found in the trachea when the cynanche maligna is communicated to it; and from the vestiges of inflammation on the trachea discovered upon dissection; we must conclude, that this disease consists in an inflammatory affection of the mucous membrane of the larynx and trachea, producing an exudation analogous to that found on the surface of inflamed viscera, and appearing partly in a membranous crust, and partly in a fluid form resembling pus.

Though this disease consists in an inflammatory affection, it does not commonly end either in suppuration or gangrene. The most troublesome circumstance of it seems to consist in a spasm of the muscles of the glottis, threatening suffocation.

When this disease terminates in health, it is by resolution of the inflammation, by ceasing of the spasm of the glottis, by an expectoration of the matter exuding from the trachea, and of the crusts formed there,

there, and frequently it ends without any expectoration, or at least with such only as attends an ordinary catarrh. But in some instances, a salutary termination has very speedily taken place, in consequence of the discharge of the membranous substance from the trachea, even under its proper tubular form.

When the disease ends fatally, it is by a suffocation seemingly depending upon a spasm affecting the glottis; but sometimes, probably, depending on a quantity of matter filling the bronchiæ or obstructing the trachea.

As we suppose the disease to be an inflammatory affection, so we attempt the cure of it by the usual remedies of inflammation. Bleeding, both general and topical, has often given immediate relief, and, by being repeated, has entirely cured the disease. Blistering also, near the part affected, has been found useful. Upon the first attack of the disease, vomiting, immediately after bleeding, seems to be of considerable use, and sometimes suddenly removes the disease. But emetics are still more useful in advanced periods. By the employment of these, the matter obstructing the trachea, and inducing spasmodic affections, has often been successfully removed, when the situation of the patient seemed to be almost desperate. And as in the progress of the disease fresh effusions of this matter are very apt to take place, the frequent repetition of emetics becomes necessary. It is often necessary to have recourse to those operating the most expeditiously, such as sulphate of zinc even in large doses. In every stage of the disease, the antiphlogistic regimen is necessary, and particularly the frequent use of laxative glysters. Some practitioners consider mercury, particularly under the form of calomel, as an almost infallible remedy in this disease. It has particularly been extolled by Mr James Anderson, an eminent surgeon in Edinburgh. But we are sorry to say that in some cases at least, after the fairest trial, it has been found to fail. Though we suppose that a spasm affecting the glottis is often fatal in this disease, antispasmodic medicines have not in general been found of great service. Some, however, have strongly recommended the use of asafœtida under the form of injection; others place great confidence in oil or oily mixtures, taken by the mouth; but more immediate benefit is derived from tepid bathing, and the employment of sulphuric ether, both externally and internally.

By these, when the disease is spasmodic, it is often successfully removed. But by much the most dangerous form of the disease is the inflammatory state giving the exudation. And when this inflammatory exudation has even been removed from the upper part of the trachea, yet it has sometimes proved fatal from the inflammation and exudation extending to the branches of the aspera arteria. By such an occurrence the writer of the present article had the misfortune to lose a favourite son; an amiable youth, in the fourteenth year of his age, who was highly admired and sincerely regretted by all to whom he was known.

Cynanche pharyngea, *Sauv.* sp. 6. *Eller* de cogn. et cur. sect. 7.

Anginæ inflammatoriæ, sp. 4. *Boerh.* 804.

This is not materially different from the cynanche tonsillaris; only that the inflammation is said to begin in the pharynx, though Dr Cullen says he never knew an instance of it. The symptoms are almost the same, and the cure is precisely so, with that of the cynanche tonsillaris.

This is a disease well known to the vulgar, but little taken notice of by medical writers. It is often epidemic, and manifestly contagious. It comes on with the usual symptoms of pyrexia, which is soon after attended with a considerable tumour of the external fauces and neck. The swelling appears first as a glandular moveable tumor at the corner of the lower jaw; but it soon becomes uniformly diffused over a great part of the neck, sometimes on one side only, but more commonly on both. The swelling continues to increase till the fourth day; but from that period it declines, and in a few days more goes off entirely. As the swelling of the fauces recedes, it not unfrequently happens that some tumor affects the testicles in the male sex, or the breasts in the female. These tumors are sometimes large, hard, and somewhat painful; but are seldom either very painful or of long continuance. The pyrexia attending this disease is commonly slight, and goes off with the swelling of the fauces; but sometimes, when the swelling of the testicles does not succeed to that of the fauces, or when the one or the other has been suddenly repressed, the pyrexia becomes more considerable, is often attended with delirium, and has sometimes proved fatal.

As this disease commonly runs its course without either dangerous or troublesome symptoms, so it hardly requires any remedies. An antiphlogistic regimen, and avoiding cold, are all that will be commonly necessary. But when, upon the receding of the swellings, the pyrexia comes to be considerable, and threatens an affection of the brain, it will be proper, by warm fomentations, to bring back the swelling; and by vomiting, bleeding, or blistering, to obviate the consequences of its absence.

Under the general head of *Pneumonia*, Dr Cullen comprehends all inflammations of the thoracic viscera, or membrane lining the inside of that cavity; as the symptoms do not always sufficiently distinguish the seat of the affection, nor does a difference in the situation of the affected place make any difference in the cure.

Description. Pneumonic inflammation, however various in the seat, always discovers itself by pyrexia, difficult breathing, cough, and pain in some part of the thorax. It almost always comes on with a cold stage, and is accompanied with the other symptoms of pyrexia; though in some few instances the pulse may not be more frequent, nor the heat of the body increased beyond what is natural. Sometimes the pyrexia is from the beginning accompanied with the other symptoms; but frequently it is formed some hours before them, and particularly before the pain be felt. The pulse for the most part is frequent, full, strong, hard, and quick; but, in a few instances, especially in the advanced state of the disease, it is weak, soft, and at the same time irregular. The difficulty of breathing is most considerable in inspiration, both because the lungs do not easily admit of a full dilatation, and because the dilatation increases the pain attending the disease. The difficulty of breathing is also greater when the patient is in one posture of the body rather than another. It is generally greater when he lies on the side affected; though sometimes the contrary happens. Very often the patient cannot lie upon either side, and can find ease only when lying on the back; and sometimes he cannot breathe readily, except when in somewhat of an erect posture. The cough, in different cases, is more or less urgent or painful. It is sometimes dry, or without any expectoration, especially in the beginning of the disease; but more commonly it is, even from the beginning, moist, and the matter spit up various both in consistence and colour, and frequently it is streaked with blood. The pain is also different in different cases, and felt in different parts of the thorax, but most frequently in one side. It has been said to affect the right side more frequently than the left; but this is uncertain, and we are sure that the left side has been very often affected. Sometimes it is felt as if it was under the sternum; sometimes in the back between the shoulders; and when in the sides, its place has been higher or lower, more forward or backward; but the place of all most frequently affected is about the sixth or seventh rib, near the middle of its length, or a little more forward. The pain is often severe and pungent; but sometimes more dull and obtuse, with a sense of weight rather than of pain. It is most especially severe and pungent when occupying the place last mentioned. For the most part it continues fixed in one part, but sometimes shoots from the side to the scapula on one hand, or to the sternum and clavicle on the other.

Dr Cullen supposes that the disease is always seated, or at least begins, in some part of the pleura, taking that membrane in its greatest extent, as now commonly understood; that is, as covering not only the internal surface of the cavity of the thorax, but also as forming the mediastinum, and as extended over the pericardium, and over the whole surface of the lungs. But as the symptoms never clearly indicate where the seat of the disease is, there is but little foundation for the different names by which it has been distinguished. The term *pleurisy* is improperly limited to that inflammation which begins in and chiefly affects the pleura costalis. This Dr Cullen thinks is a rare occurrence; and that the pneumonia much more frequently begins in the pleura investing the lungs, producing all the symptoms which belong to what hath been called the *pleuritis vera*. The word *peripneumony* has been applied to an inflammation beginning in the parenchyma, or cellular texture of the lungs, and having its seat chiefly there. But to Dr Cullen it seems very doubtful if any acute inflammation of the lungs, or any disease which has been called *peripneumony*, be of that kind. It seems probable, that

Phlegmasiæ.

that every acute inflammation begins in membranous parts; and in every dissection of persons who have died of peripneumony, the external membrane of the lungs, or some part of the pleura, has appeared to have been considerably affected. An inflammation of the pleura covering the upper surface of the diaphragm, has been distinguished by the appellation of *paraphrenitis*, as supposed to be attended with the peculiar symptoms of delirium, *risus sardonicus*, and other convulsive motions: but it is certain, that an inflammation of that portion of the pleura, and affecting also even the muscular substance of the diaphragm, has often taken place without any of the symptoms above mentioned; and neither the dissections which have fallen under Dr Cullen's observation, nor any accounts of dissections, support the opinion that an inflammation of the pleura covering the diaphragm is attended with delirium more commonly than any other pneumonic inflammation.—It is to be observed, however, that though the inflammation may begin in one particular part of the pleura, the morbid affection is commonly communicated to the whole extent of the membrane.

The pneumonic inflammation, like others, may terminate by resolution, suppuration, or gangrene: but it has also a termination peculiar to itself; namely, when it is attended with an effusion of blood into the cellular texture of the lungs, which, soon interrupting the circulation of the blood through the viscus, produces a fatal suffocation. This indeed appears to be the most common termination of pneumonic inflammation when it ends fatally; for upon the dissection of almost every person who has died of this disease, it appears that such an effusion had happened. From the same dissections we learn, that pneumonic inflammation commonly produces an exudation from the internal surface of the pleura, which appears partly as a soft viscid crust, often of a compact membranous form, covering every where the surface of the pleura, and particularly those parts where the lungs adhere to the pleura costalis, or mediastinum; and this crust seems always to be the cement of such adhesion. The same exudation shows itself also by a quantity of a serous fluid commonly found in the cavity of the thorax; and some exudation or effusion is usually found to have been made into the cavity of the pericardium. It seems likewise probable, that an effusion of this kind is sometimes made into the cavity of the bronchiæ; for in some persons who have died after labouring under a pneumonic inflammation for a few days only, the bronchiæ have been found filled with a considerable quantity of serous and thickish fluid, which must be considered rather as the effusion above mentioned, having had its thinner parts taken off by respiration, than as a pus so suddenly formed in the inflamed part. It is, however, not improbable, that this effusion, as well as that made into the cavities of the thorax and pericardium, may be a matter of the same kind with that which in other inflammations is poured into the cellular texture of the parts inflamed, and there converted into pus; but in the thorax and pericardium it does not always put on this appearance, because the crust covering the surface prevents the absorption of the thinner part. This absorption, however, may be compensated in the bronchiæ, by the drying power of the air; and therefore the effusion into them may assume a more purulent appearance. In many cases of pneumonic inflammation, when the expectoration is very copious, it is difficult to suppose that the whole proceeds from the mucous follicles of the bronchiæ; and it seems probable that a great part of it may come from the effused serous fluid just mentioned; and this too will account for the appearance of the expectoration being so often purulent. Perhaps the same thing will account for that purulent matter found in the bronchiæ, which Mr de Haen says he had often observed when there was no ulceration in the lungs, and which he accounts for in a very strange manner, namely, by supposing a pus formed in the circulating blood.

Pneumonia.

Dr Cullen is of opinion, that the effusion into the bronchiæ above mentioned often concurs with the effusion of red blood into the cellular substance of the lungs to occasion the fatal suffocation which frequently terminates peripneumony: that the effusion of serum alone may have this effect: and that the serum poured out in a certain quantity, rather than any debility in the powers of expectoration, is the cause of that cessation of spitting which precedes the fatal event; for in many cases the expectoration has ceased, when no other symptoms of debility have appeared, and when, upon dissection, the bronchiæ have been full of liquid matter. Nay, it is even probable, that in some cases such an effusion may take place without any symptoms of violent inflammation; and in other cases the effusion taking place may seem to remove the symptoms of inflammation which had appeared before, and thus account for those unexpected fatal terminations which have sometimes happened.

Pneumonic inflammation seldom terminates by resolution, without being attended with some evident evacuation. An hæmorrhagy from the nose happening on some of the first days of the disease has sometimes put an end to it; and it is said, that an evacuation from the hæmorrhoidal veins, a bilious evacuation by stool, and an evacuation of urine with a copious sediment, have severally had the same effect; but such occurrences have been rare. The evacuation most frequently attending, and seeming to have the greatest effect in promoting resolution, is an expectoration of a thick, white, or yellowish matter, a little streaked with blood, copious, and brought up without much or violent coughing. Very frequently the resolution of this disease is attended with, and perhaps produced by, a sweat, if it be warm, fluid, copious, over the whole body, and attended with an abatement of the frequency of the pulse, heat of the body, and other febrile symptoms. Although, from the history now given, it appears that pleurisy and peripneumony cannot with propriety be considered as different diseases, yet it is certain that in different cases this affection occurs with an assemblage of symptoms separate and distinct. Thus even Dr Cullen himself, in his Nosology, has defined pleuritis to consist in pyrexia, attended with pungent pain of the side, painful respiration, difficulty of lying down, particularly on the affected side, and distressing cough, in the beginning dry, but afterwards humid, and often with bloody expectoration. While again he has defined peripneumony to consist in pyrexia, attended with a dull pain under the sternum and between the shoulders, anxiety, difficulty of breathing, humid

Phma- Pneumonia.

mid cough, expectoration generally bloody, a soft pulse, and a tumid livid appearance of the countenance. It is highly probable, that the first of these sets of symptoms chiefly arises from a state of active inflammation, and the second from effusion. Thus, in certain cases, the symptoms may appear perfectly separate and distinct; but more frequently both inflammation and effusion are united; and thus the symptoms in both definitions are in general combined in the same patient. But still pleuritis, strictly so called, may be considered as characterized by the acute pungent pain at a particular spot of the chest, and that pain much aggravated on a full inspiration; while proper peripneumonia is distinguished by the dull gravative pain extended over the whole chest, and by the laborious respiration.

Causes of, and persons subject to, this disorder. The remote cause of pneumonic inflammation is commonly cold applied to the body, obstructing perspiration, and determining to the lungs, while at the same time the lungs themselves are exposed to the action of cold. These circumstances operate chiefly when an inflammatory diathesis prevails in the system; and therefore those principally affected with this disease are persons of the greatest vigour, in cold climates, often in the winter season, but particularly in the spring, when vicissitudes of heat and cold are frequent. The disease, however, may arise in any season when such varieties take place. Other remote causes also may have a share in producing this distemper; such as every means of obstructing, straining, or otherwise injuring, the pulmonary organs. The pneumatic inflammation has sometimes been so much an epidemic, that it hath been suspected of depending on a specific contagion; but Dr Cullen never met with an instance of its being contagious.

Prognosis. In pneumatic inflammations, a violent pyrexia is always dangerous. The danger, however, is chiefly denoted by the difficulty of breathing. When the patient can lie on one side only; when he can lie on neither side, but only on his back; when he cannot breathe with tolerable ease, except when the trunk of his body is erect; when even in this posture the breathing is very difficult, and attended with a turgescence and flushing of the face, with partial sweats about the head and neck, and an irregular pulse; these circumstances mark the difficulty of breathing in different degrees; and consequently, in proportion, the danger of the disease. A frequent violent cough, aggravating the pain, is always the symptom of an obstinate disease; and as the disease is seldom or never resolved without some expectoration, so a dry cough must always be an unfavourable symptom.

The proper characteristics of the expectoration have been already laid down; and though an expectoration which has not these marks must indicate a doubtful state of the disease, yet the colour alone can give no certain prognostic. An acute pain, very much interrupting inspiration, is always the mark of a violent disease; but not of a more dangerous disease than an obtuse pain, attended with very difficult respiration, demonstrating effusion into the cells.

When the pains, which had at first affected one side only, shall afterwards spread into the other; or when, leaving the side first affected, they pass entirely into the other; these are always marks of a dangerous disease. A delirium coming on during a pneumonic inflammation is always a symptom denoting much danger.

When pneumonic disorders terminate fatally, it is on one or other of the days of the first week, from the third to the seventh. This is the most common case; but, in a few instances, death has happened at a later period. When the disease is violent, but admitting of resolution, this also happens frequently in the course of the first week; but in a more moderate disease the resolution is often put off to the second week. The disease generally suffers a remission on some of the days; from the third to the seventh: which, however, may be often fallacious, as it sometimes returns again with as much violence as before: and in such a case with great danger. Sometimes it disappears on the third day, while an erysipelas makes its appearance on some external part; and if this continue fixed, the pneumatic inflammation does not recur. If the disease continue beyond the 14th day, it will terminate in a suppuration, or PHTHISIS. The termination by gangrene is much more rare than has been imagined: and when it does occur, it is usually joined with the termination by effusion; the symptoms of the one being hardly distinguishable from those of the other.

Cure. This must proceed upon the general plan mentioned under SYNOCHA; but, on account of the importance of the part affected, the remedies must be employed early, and as fully as possible: and these are chiefly directed with one of three views, viz. for obtaining a resolution of the inflammation in the thorax, for mitigating the urgent symptoms before a resolution can be effected, and for counteracting or obviating the consequences of the disease. Venesection is the remedy chiefly to be depended on; and may be performed in either arm, as the surgeon finds most convenient; and the quantity taken away ought in general to be as large as the patient's strength will allow. The remission of pain, and the relief of respiration, during the flowing of the blood, may limit the quantity to be then drawn: but if these symptoms of relief do not appear, the bleeding should be continued to a considerable extent, unless symptoms of a beginning syncope come on. It is seldom that one bleeding, however large, will cure this disease; and though the pain and difficulty of breathing may be much relieved by the first bleeding, these symptoms commonly and after no long interval recur, often with as much violence as before. In this case the bleeding is to be repeated even on the same day, and perhaps to the same quantity as before. Sometimes the second bleeding may be larger than the first. There are persons, who, by their constitution, are ready to faint even upon a small bleeding; and in such persons this may prevent the drawing so much blood at first as a pneumonic inflammation may require: but as the same persons are found to bear after-bleedings better than the first, this allows the second and subsequent bleedings to be larger, and to such a quantity as the symptoms of the disease may seem to require.

Bleedings are to be repeated according to the state of the symptoms, and they will be more effectual when practised in the course of the first three days than afterwards; but they are not to be omitted though four days of the disease may already have elapsed. If the physician has not been called in time, or the first bleed-

Phlegmasiæ. ings have not been sufficiently large, or even though they should have procured some remission, yet upon the return of the urgent symptoms, bleeding may be repeated at any time within the first fortnight, or even after that period, if a suppuration be not evident, or if after a seeming solution the disease shall have returned.

With respect to the quantity of blood which may be taken away with safety, no general rules can be given; as it must be very different according to the state of the disease, and the constitution of the patient. In an adult male of tolerable strength, a pound of blood is a full bleeding. Any quantity above 20 ounces is a large, and any quantity below 12 is a small, bleeding. An evacuation of four or five pounds, in the course of two or three days, is generally as much as most patients will bear; but if the intervals between the bleedings, and the whole of the time during which the bleedings have been employed, have been long, the quantity taken upon the whole may be greater.

When a large quantity of blood has been taken from the arm, and it is doubtful if more can be taken in that manner with safety, some blood may still be taken by cupping and scarifying. This will especially be proper, when the recurrence of the pain, rather than the difficulty of breathing, becomes the urgent symptom; and then the cupping and scarification should be made as near as possible to the pained part.

An expectoration sometimes takes place very early in this disease; but if the symptoms continue urgent, the bleedings must be repeated notwithstanding the expectoration: but in a more advanced state, and when the symptoms have suffered a considerable remission, we may then trust the cure to the expectoration alone. It is not observed that bleeding, during the first days of the disease, stops expectoration; on the contrary, it has been often found to promote it; and it is only in a more advanced state of the disease, when the patient has been already exhausted by large evacuations and a continuance of his illness, that bleeding seems to put a stop to expectoration; and even then, this stoppage seems not to take place so much from the powers of expectoration being weakened by bleeding, as by its favouring the serous effusion in the bronchiæ, already taken notice of.

Besides bleeding, every part of the antiphlogistic regimen ought here to be carefully employed; the patient must keep out of bed as much as he can bear; must have plenty of warm diluting drinks, impregnated with vegetable acids, accompanied with nitre or some other cooling neutral salt; and the belly also ought to be kept open by emollient clysters or cooling laxative medicines. Vomiting in the beginning is dangerous; but in a somewhat advanced state of the disease emetics have been found the best means of promoting expectoration. Fomentations and poultices to the pained part have been found useful; but blistering is found to be much more effectual. A blister, however, ought not to be applied till at least one bleeding has been premised, as venesection is less effectual when the irritation of a blister is present. If the disease be moderate, a blister may be applied immediately after the first bleeding; but in violent cases, where it may be presumed that a second bleeding may soon be necessary after the first, it will be proper to delay the blister till after the second bleeding, when it may be supposed that the irritation occasioned by the blister will be over before another bleeding becomes necessary. It may frequently be of use in this disease to repeat the blistering; and in that case the plasters should always be applied somewhere on the thorax, for when applied to more distant parts they have less effect. The keeping the blistered parts open, and making what is called a *perpetual blister*, has much less effect than a repeated blistering.

Pneumonia. Many methods have been proposed for promoting expectoration, but none appear to be sufficiently effectual; and some of the expectorants, being acrid stimulant substances, are not very safe. The gums usually employed seem to be too heating; the squills less so; but they are not very powerful, and sometimes inconvenient, by the constant nausea they occasion. The volatile alkali may be of service as an expectorant, but it ought to be reserved for an advanced state of the disease. Mucilaginous and oily demulcents appear to be useful, by allaying that acrimony of the mucus which occasions too frequent coughing; and which coughing prevents the stagnation and thickening of the mucus, and thereby its becoming mild. The receiving into the lungs the steams of warm water, impregnated with vinegar, has often proved useful in promoting expectoration; and, for this purpose, the machine called the INHALER, lately invented by Dr Mudge of Plymouth, promises to be of great service. But of all others, the antimonial emetics, given in nauseating doses, are perhaps the most powerful for promoting expectoration. The kermes mineral has been greatly recommended; but does not seem to be more efficacious than tartrite of antimony or antimonial wine; and the dose of the kermes is much more uncertain than that of the others.

Though this disease often terminates by a spontaneous sweating, this evacuation ought not to be excited by art, unless with much caution. When, after some remission of the symptoms, spontaneous sweats arise, they may be encouraged; but it ought to be without much heat, and without stimulant medicines. If, however, the sweats be partial and clammy only, and a great difficulty of breathing still remain, it will be very dangerous to encourage them.

Physicians have differed much with regard to the use of opiates in pneumonic affections. It appears, however, that in the beginning of the disease, and before bleeding and blistering have produced some remission of the pain, and of the difficulty of breathing, opiates have had a bad tendency, by their increasing the difficulty of breathing and other inflammatory symptoms. But in a more advanced state of the disease, when the difficulty of breathing has abated, and when the urgent symptom is a cough, proving the chief cause of the continuance of pain and want of rest, opiates may be employed with great advantage and safety. The interruption of the expectoration which they seem to occasion, is for a short time only; and they seem often to promote it, as they occasion a stagnation of what was by frequent coughing dissipated insensibly: and therefore give the appearance of what physicians called *concocted matter*.

Opium combined with calomel has of late been highly extolled in this and other inflammatory diseases by Dr Hamilton of Lynn Regis; who has given a full account

Phthisis pulmonalis. count of the success attending his practice with this remedy for the space of 16 years, in the 9th volume of the Edinburgh Medical Commentaries. And since his recommendation, the same remedy has often been employed by others with great benefit.

Vomica, or *Abscess* of the *Lungs*.

5 Vomica, *Boerh*. 835. *Junck*. 35.
Pleurodyne vomica, *Sauv*. sp. 21.

Phthisis sometimes follows pneumonia, though the case is not frequent. The symptoms of it so much resemble ordinary phthisis, that it can most properly be treated of under that head.

Empyema.

7 This is another consequence of a pneumonia terminating unfavourably, and is occasioned by the effusion of a quantity of purulent matter into the cavity of the thorax, producing a lingering and painful disorder, very often incurable.

Description. The first sign of an empyema is a cessation of the pain in the breast, which before was continual: this is followed by a sensation of weight on the diaphragm; and a fluctuation of matter, sometimes making a noise that may be heard by the bystanders: the acute fever is changed into a hectic, with an exacerbation at night: a continual and troublesome dry cough remains. The respiration is exceedingly difficult, because the lungs are prevented by the matter from fully expanding themselves. The patient can lie easily on that side where the matter is effused, but not on the other, because then the weight of the matter on the mediastinum produces uneasiness. The more the hectic heat is augmented, the more is the body emaciated, and its strength decayed. In some there is danger of suffocation when they stoop down, which goes off when they alter that posture of the body; and in some there is a purulent spitting.—These symptoms are accompanied with great anxiety, palpitations of the heart, and faintings. Sometimes the patients have a sensation like a hot vapour ascending from the cavity of the thorax to their mouth. Others, in a more advanced state of the disease, have a putrid taste in the mouth. At the same time, profuse night sweats waste the body, and greatly weaken the patient. The face at first grows red on that side where the matter lies, at last the Hippocratic face comes on, and the eyes become hollow. The pulse is quick, but more frequently intermitting. Sometimes the nails are crooked, and pustules appear on the thorax; and frequently, according to the testimony of Hippocrates, the feet swell, and, on the affected side of the breast, there is an inflation and swelling of the skin.

Causes, &c. An empyema may arise either from the bursting of a vomica of the lungs, or from a suppuration taking place after the inflammatory stage of pneumonia; or sometimes from a suppuration in the case of a quinsy, when the inflammation had extended to the aspera arteria, from whence arises a kind of bloody spittle, and the patients are afflicted with an empyema, unless they die on the 7th day of the disease, according to the observation of Hippocrates. It may arise also from external violence, as wounds of the thorax, &c. blood extravasated, corrupted, or changed into pus. Like the vomica, it is a rare distemper, but may attack all those subject to pneumonia.

Prognosis. Very few recover after an empyema has been once formed, especially if the operation of paracentesis be neglected. After this operation is performed, if a great quantity of bloody fetid pus be discharged, if the fever continue, and if the patient spit up a purulent, pale, frothy, livid, or green matter, with a decay of strength, there is no hope: But when a small quantity of pus, of a white colour, not very fetid, is discharged; when the fever and thirst presently cease, the appetite returns, and fæces of a good consistence are discharged, the strength also returning in some degree; there is then hope of a perfect recovery. If the matter be not dried up in seven weeks time, the disease readily changes to a fistulous ulcer, which is very difficult to cure. An empyema affecting both sides of the thorax is more dangerous than that which affects only one.

Cure. This consists in evacuating the purulent matter contained in the cavity of the thorax, which is best done by the operation of paracentesis of the thorax. See Surgery. Afterwards the ulcer is to be treated with abstergent and consolidating medicines, and the same internal ones are to be given as in a Phthisis.

Genus XIII. CARDITIS. 188

Inflammation of the *Heart*.

Carditis, *Sauv*. gen. 111. *Vog*. 54.
Pericarditis, *Vog*. 53.
Carditis spontanea, *Sauv*. sp. 1. *Senac*. Traité de Cœur, l. iv. c. 7. *Meckel*, Mem. de Berlin, 1756.
Erysipelas pulmonis, *Lomm*. Observ. lib. ii.

Description. This disease is attended with all the symptoms of pneumonia, but in a higher degree; it is besides said to be accompanied with hydrophobic symptoms, fainting, palpitation of the heart, a seeming madness, a sunk and irregular pulse, watery eyes, and a dejected countenance, with a dry and black tongue. On dissection, the heart and pericardium are found very much inflamed, and even ulcerated, with many polypous concretions.

Causes, &c. The same as in the pneumonia.

Prognosis. In the carditis the prognosis is more unfavourable than in the pneumonia; and indeed, unless the disease very quickly terminates, it must prove fatal, on account of the constant and violent motion of the heart, which exasperates the inflammation, and increases all the symptoms.

Cure. Here bleeding is necessary in as great a degree as the patient can possibly bear, together with blistering, and the antiphlogistic regimen likewise carried to a greater height than in the pneumonia; but the general method is the same as in other inflammatory diseases.

Gastritis erysipelatosa, *Sauv.* sp. 4.
Cardialgia inflammatoria, *Sauv.* sp. 13. *Tralles,* de opio, sect. ii. p. 231.

These diseases Dr Cullen has thought proper to consider all under the general head of Gastritis, as there are no certain signs by which they can be distinguished from each other, and the method of cure must be the same in all.

Description. The inflammation of the stomach is attended with great heat and pain in the epigastric region, extreme anxiety, an almost continual and painful hiccough, with a most painful vomiting of every thing taken into the stomach. Sometimes a temporary madness ensues; and there is an instance in the Edinburgh Medical Essays of the disorder being attended with an hydrophobia. The pulse is generally more sunk than in other inflammations, and the fever inclines to the nature of a typhus. The disorder is commonly of the remitting kind, and during the remissions the pulse frequently intermits. During the height of the disease, a mortal phrensy frequently supervenes. The disease terminates on the fourth, seventh, or ninth day, or from the eleventh to the fifteenth; and is more apt to end in a gangrene than pneumonic inflammations, and more frequently in a scirrhus than in an abscess.

Causes, &c. The inflammation of the stomach may arise from any acrid substance taken into it; from a vehement passion, too large draughts of cold liquor, especially when the person is very hot; from a surfeit; a stoppage of perspiration; repulsion of the gout; inflammations of the neighbouring viscera; or from external injuries, such as wounds, contusions, &c.—It affects chiefly those of a plethoric habit and hot bilious constitution.

Prognosis. This disease is always very dangerous, and the prognosis doubtful, which also must always be in proportion to the severity of the symptoms. A cessation of pain, coldness about the præcordia, great debility, with a languid and intermitting pulse, with an abatement of the hiccough, denote a gangrene and speedy death. From the sensibility of the stomach also, and its great connexion with the rest of the system, it must be obvious, that an inflammation of it, by whatever causes produced, may be attended with fatal consequences; particularly, by the great debility it produces, it may prove suddenly fatal, without running through the usual course of inflammations.—Its tendency to admit of resolution may be known by its having arisen from no violent cause, by the moderate state of the symptoms, and by a gradual remission of these symptoms in the course of the first or at most of the second week of the disease. The tendency to gangrene may be suspected from the symptoms continuing with unremitting violence, notwithstanding the use of proper remedies; and a gangrene already begun may be known by the symptoms above mentioned, particularly great debility and sudden cessation of pain. The tendency to suppuration may be known by the symptoms continuing but in a moderate degree for more than one or two weeks, and by a considerable remission of the pain, while a sense of weight and anxiety still remain. When an abscess has been formed, the frequency of the pulse is first abated: but soon after it increases, with frequent cold shivering, and an exacerbation in the afternoon and evening; followed by night sweats, and other symptoms of hectic fever. These at length prove fatal, unless the abscess open into the cavity of the stomach, the pus be evacuated by vomiting, and the ulcer soon healed.

Gastritis.

Cure. It appears from dissections, that the stomach may very often be inflamed when the characteristic marks of it have not appeared; and therefore we are often exposed to much uncertainty in the cure. But when we have sufficient evidence that a state of active inflammation has taken place in the stomach, the principal object to be aimed at is to obtain a resolution. Before, however, this can be accomplished, it will often be necessary to employ measures with the view of obviating urgent symptoms. When the symptoms appear in the manner above described, the cure is to be attempted by large and repeated bleedings employed early in the disease; and from these we are not to be deterred by the weakness of the pulse, for it will commonly become fuller and softer after the operation. A blister ought also to be applied to the region of the stomach; and the cure will be assisted by fomentations of the whole abdomen, and by frequent emollient and laxative clysters. The irritability of the stomach in this disease will admit of no medicines being thrown into it; and if any can be supposed necessary, they must be exhibited in clysters. Diluting drinks may be tried; but they must be of the very mildest kind, and given in very small quantities at a time. Opiates, in whatever manner exhibited, cannot be retained in the stomach during the first days of the disease; but when the violence of the disease shall have abated, and when the pain and vomiting recur at intervals only, opiates given in clysters are frequently employed with advantage; and after bleeding and blisters no remedy is more effectual either in allaying the pain or vomiting. As soon as the stomach will retain any laxative, gentle refrigerant cathartics, taken by the mouth, such as the soda phosphorata, soda tartarisata, or the like, are

are productive of great benefit. A tendency to gangrene in this disease is to be obviated only by the means just now mentioned; but when it does actually supervene, it admits of no remedy. A tendency to suppuration is to be obviated by the same means employed early in the disease. After a certain period it cannot be prevented by any means whatever; and, when actually begun, must be left to nature; the only thing that can be done by art being to avoid all irritation.

B. *Gastritis Erysipelatosa*, or the *Erysipelatous Gastritis.*

Description. This species of inflammation takes place in the stomach much more frequently than the former. From dissections it appears that the stomach has been often affected with inflammation, when neither pain nor fever had given any notice of it; and such is justly looked upon to have been of the erysipelatous kind. This kind of inflammation also is especially to be expected from acrimony of any kind applied to the stomach; and would certainly occur much more frequently, were not the interior surface of this organ commonly defended by mucus exuding in large quantity from the numerous follicles placed immediately under the villous coat. On many occasions, however, the exudation of mucus is prevented, or the liquid poured out is of a less viscid kind, so as to be less fitted to defend the subjacent nerves; and it is in such cases that acrid matters may readily produce an erysipelatous affection of the stomach.

In many cases this kind of inflammation cannot be discovered, as it takes place without pain, pyrexia, or vomiting: but in some it may; namely, when it spreads into the œsophagus, and appears on the pharynx and on the whole internal surface of the mouth. When therefore an erysipelatous inflammation affects the mouth and fauces, and there shall be at the same time in the stomach an unusual sensibility to all acrids, and also a frequent vomiting, there can be little doubt of the stomach's being affected in the same manner. Even when no inflammation appears in the fauces, if some degree of pain be felt in the stomach, if there be a want of appetite, an anxiety and frequent vomiting, an unusual sensibility with regard to acrids, some thirst, and frequency of pulse, there will then be room to suspect an inflammation in the stomach; and such symptoms, after some time, have been known to discover their cause by the inflammation rising to the fauces or mouth. Inflammation of this kind is often disposed to pass from one place to another on the same surface, and, in doing so, to leave the place it had at first occupied. Such an inflammation has been known to spread successively along the whole tract of the alimentary canal; occasioning, when in the intestines, diarrhœa, and in the stomach vomitings; the diarrhœa ceasing when the vomitings came on, and the vomitings on the coming on of the diarrhœa.

Causes, &c. An erysipelatous inflammation may arise from acrid matters taken into the stomach; or from some internal causes not yet well known. It frequently occurs in putrid diseases, and in those recovering from fevers.

Cure. When the disease is occasioned by acrid matters taken internally, and these may be supposed still present in the stomach, they are to be washed out by drinking a large quantity of warm and mild medicines, and exciting gentle vomiting. At the same time, if the nature of the acrimony and its proper corrector be known, this should be thrown in: or if a specific corrector be not known, some general demulcents should be employed.

These measures, however, are more suited to prevent than to cure inflammation after it has taken place. When this last may be supposed to have happened, if it be attended with a sense of heat, with pain and pyrexia, according to the degree of these symptoms, the measures proposed for the cure of the other kind are to be more or less employed. When an erysipelatous inflammation of the stomach has arisen from internal causes, if pain and pyrexia occur, bleeding may be employed in persons not otherwise weakened; but in case of its occurring in putrid diseases, or where the patients are already debilitated, bleeding is inadmissible; all that can be done being to avoid irritation, and only throwing into the stomach what quantity of acids and acescent aliments it shall be found able to bear. In some conditions of the body in which this disease is apt to occur, cinchona and bitters may seem to be indicated; but an erysipelatous state of the stomach will seldom allow them to be used.

Enteritis.

Genus XVI. ENTERITIS. 195

Inflammation of the *Intestines.*

Enteritis, *Sauv.* gen. 105. *Lin.* 29. *Vog.* 57. *Sag.* gen. 307.
Intestinorum inflammatio, *Boerh.* 959.
Febris intestinorum inflammatoria ex mesenterio, *Hoffm.* ii. 170.

Sp. I. *Enteritis Phlegmonodæa*, or the *Acute Enteritis.* 196

Enteritis iliaca, *Sauv.* sp. 1.
Enteritis colica, *Sauv.* sp. 2. *Boerh.* 963.

Description. This disease shows itself by a fixed pain in the abdomen, attended with fever, vomiting, and costiveness. The pain is often felt in different parts of the abdomen, but more frequently spreads over the whole, and is particularly violent about the navel.

Causes, &c. Inflammations of the intestines may arise from the same causes as those of the stomach; though commonly the former will more readily occur from cold applied to the lower extremities, or to the belly itself. It is also found supervening on the spasmodic colic, incarcerated hernia, and volvulus.

Prognosis. Inflammations of the intestines have the same terminations with those of the stomach, and the prognosis in both cases is much the same.

Cure. The cure of enteritis is in general the same with that of gastritis; but in this disease there is commonly more opportunity for the introduction of liquids, of acid, acescent, and other cooling remedies, and even of laxatives; but as a vomiting frequently attends the enteritis, care must be taken not to excite that vomiting by the quantity or quality of any thing thrown into the stomach. With regard to the suppuration

Phlegmasiæ. ration and gangrene of the intestines following the enteritis, the observations made respecting these terminations of gastritis are equally applicable in this disease.

197 Sp. II. *Enteritis Erysipelatosa*, or *Erysipelatous Enteritis.*

Concerning this nothing farther can be said, than what hath been already delivered concerning the gastritis.

198 Genus XVII. HEPATITIS.

Inflammation of the *Liver.*

Hepatitis, *Sauv.* gen. 113. *Lin.* 35. *Vog.* 58. *Sag.* gen. 312. *Boerh.* 914. *Hoffm.* ii. 14. *Junck.* 66.

Description. The inflammation of the liver is thought to be of two kinds, acute and chronic; but the latter very often does not discover itself except by an abscess found in the liver after death, and which is supposed to have been occasioned by some degree of inflammation; for this reason the chronic inflammation often escapes observation, and we shall here only treat of the acute hepatitis.

The acute hepatitis is attended with considerable fever; a frequent, strong, and hard pulse; high coloured urine; an acute pain in the right hypochondrium, increased by pressing upon the part. The pain is very often in such a part of the side as to make it appear like a pleurisy; and frequently, like that, is increased on inspiration. The disease is also commonly attended with a cough, which is generally dry, though sometimes moist; and when the pain thus resembles a pleurisy, the patient cannot lie easily except upon the side affected. The pain is frequently extended to the clavicle, and to the top of the shoulder; and is attended sometimes with hiccough, and sometimes with vomiting. Some have added jaundice, or a yellowness of the eyes, to the symptoms of this distemper; but experience shows that it has often occurred without any such symptom.

When hepatitis is of the chronic kind, depending more on an accumulation and effusion in the liver, than on an increased action of its small vessels, the patient complains rather of a sense of weight than of pain; and the fever is by no means either acute or constant: but it often returns in paroxysms somewhat resembling the attacks of an intermittent. This disease is very slow in its progress, frequently continuing for many months, and at last terminating in a very considerable suppuration. In most cases, however, it may be discovered by careful examination of the region of the liver externally. By this means a considerable enlargement of that viscus may in general be detected.

Causes, &c. The remote causes of hepatitis are not always to be discerned, and many have been assigned on a very uncertain foundation. It is principally a disease of warm climates. It has been supposed that the disease may be an affection either of the extremities of the hepatic artery, or those of the vena portarum; and the supposition is by no means improbable. The opinion, however, most commonly adopted is, that the acute hepatitis is an affection of the external membrane of the liver, and the chronic kind an affection of the parenchyma of that viscus. The acute disease may be seated either on the convex or concave surface of the liver; and in the former case a more pungent pain and hiccough may be produced, and the respiration is more considerably affected. In the latter there occurs less pain; and a vomiting is produced, commonly by some inflammation communicated to the stomach. The inflammation on the concave surface of the liver may be readily communicated to the gall-bladder and biliary ducts: and this, perhaps, is the only case of idiopathic hepatitis attended with jaundice.

Hepatitis.

Prognosis. The inflammation of the liver, like others, may end by resolution, suppuration, or gangrene; and the tendency to the one or to the other of those events may be known from what has been already mentioned concerning the prognosis in gastritis. The resolution of hepatitis is often the consequence of, or is attended with, evacuations of different kinds. A hæmorrhage sometimes from the nose, and sometimes from the hæmorrhoidal vessels, gives a solution of the disease. Sometimes the same thing is accomplished by a bilious diarrhœa; and sometimes the resolution is attended with sweating, and an evacuation of urine depositing a copious sediment. Sometimes it may be cured by an erysipelas appearing in some external part. When the disease has ended in suppuration, the pus collected may be discharged by the biliary ducts; or, if the suppurated part does not adhere anywhere closely to the neighbouring parts, it may be discharged into the cavity of the abdomen; but if, during the first state of inflammation, the affected part of the liver shall have formed a close adhesion to some of the neighbouring parts, the discharge after suppuration may be various, according to the different seat of the abscess. When seated on the convex part of the liver, if the adhesion be to the peritonæum lining the common teguments, the pus may make its way through these, and be discharged outwardly: or if the adhesion shall have been to the diaphragm, the pus may penetrate through this, and into the cells of the lungs; from whence it may be discharged by coughing. When the abscess is seated on the concave part of the liver, in consequence of adhesions, the pus may be discharged into the stomach or intestines; and into these last, either directly, or by the intervention of the biliary ducts. Upon a consideration of all these different circumstances, therefore, together with the general principles of inflammation, must the prognosis of this disease be established.

Cure. For the cure of hepatitis, we must have recourse to the general means of resolving other inflammatory disorders. Bleeding is to be used according to the degree of fever and pain. Blisters are to be applied: fomentations of the external parts, emollient clysters, gentle laxatives, diluents and refrigerants, are also useful. The cure, however, particularly in warm climates, where the disease is much more common than it is in Britain, is chiefly trusted to mercury. Not only in cases of the chronic kind, but in acute hepatitis also, after an attempt has been made to alleviate the urgent symptoms by bleeding and blistering, recourse is immediately had to this powerful mineral. It is employed by different practitioners, and in

Phlegmasiæ. in different cases, under various forms. Some are very fond of the use of calomel. But the preference is in general given, and perhaps with justice, to friction with mercurial ointment over the region of the liver. But under whatever form it may be employed, it is necessary that it should be introduced to such an extent as to keep the patient on the verge of salivation for some length of time; the duration being regulated by the circumstances of the case.

From the liberal use of mercury, there can be no doubt that a successful resolution has been obtained in many cases, which would otherwise have infallibly terminated in suppuration. But notwithstanding the most careful employment of it in some cases, suppuration will ensue; and then it is very doubtful whether any benefit will be derived from the continuance of it. But when a suppuration has been formed, and the abscess points outwardly, the part must be opened, the pus evacuated, and the ulcer healed according to the ordinary methods in use for healing abscesses and ulcers in other parts.

Chronic hepatitis often terminates in scirrhus. Against this, after mercury has failed, nitric acid taken internally has sometimes been employed with success.

Genus XVIII. SPLENITIS.

Inflammation of the Spleen.

Splenitis, *Sauv.* gen. 114. *Lin.* 36. *Vog.* 59. *Junck.* 67. *Sag.* gen. 313.
Lienis inflammatio, *Boerh.* 958. et *Van Swieten*, Comm.
Splenitis phlegmonodæa, *Sauv.* sp. 1. *Forest*, l. xx. obs. 5, 6. *De Haen*, apud *Van Swieten*, p. 958.
Pleuritis splenica, *Sauv.* sp. 3.
Splenalgia suppuratoria, *Sauv.* sp. 3.

Description. This disease, according to *Juncker*, comes on with a remarkable shivering, succeeded by a most intense heat and very great thirst; a pain and tumour are perceived in the left hypochondrium, and the paroxysms for the most part assume a quartan form. When the patients expose themselves for a little to the free air, their extremities immediately grow very cold. If a hæmorrhage happens, the blood flows out of the left nostril. The other symptoms are the same with those of the hepatitis. Like the liver, the spleen is also subject to a chronic inflammation, which often happens after agues; and the tumour which succeeds the inflammation is in many cases very considerable, and is called the *ague cake*, though that name is also frequently given to a scirrhous tumour of the liver succeeding intermittents.

Causes, &c. The causes of this distemper are in general the same with those of other inflammatory disorders; but those which determine the inflammation to that particular part more than another, are very much unknown. It attacks persons of a very plethoric and sanguine habit of body rather than others.

Prognosis. What has been said of the inflammation of the liver applies also to that of the spleen, though the latter is less dangerous than the former. Here also a vomiting of black matter, which in other acute diseases is such a fatal symptom, sometimes proves critical, according to the testimony of Juncker. Sometimes the hæmorrhoids prove critical: but very often the inflammation terminates by scirrhus.

Cure. This is not at all different from what has been already laid down concerning the hepatitis.

Nephritis.

Genus XIX. NEPHRITIS.

Inflammation of the Kidneys.

200

Nephritis, *Sauv.* gen. 115. *Lin.* 37. *Vog.* 65. *Sag.* gen. 314.
Nephritis vera, *Sauv.* sp. 1.

Description. The nephritis has the same symptoms which take place in other inflammations; but its distinguishing mark is the pain in the region of the kidney, which is sometimes obtuse, but more frequently pungent. The pain is not increased by the motion of the trunk of the body so much as a pain of the rheumatic kind affecting the same region. It may also frequently be distinguished by the pain shooting along the course of the ureter, and it is often attended with a drawing up of the testicle, and a numbness of the limb on the side affected; though indeed these symptoms most commonly attend the inflammation arising from a calculus in the kidney or ureter. The disease is also attended with frequent vomiting, and often with costiveness and colic pains. The urine is most commonly of a deep red colour, and is voided frequently and in a small quantity at a time. In more violent cases the urine is commonly colourless.

Causes, &c. The remote causes of this disease may be various; as external contusion, violent or long-continued riding; strains of the muscles of the back incumbent on the kidneys; various acrids in the course of circulation conveyed to the kidneys; and perhaps some other internal causes not yet well known: the most frequent is that of calculous matter obstructing the *tubuli uriniferi*, or calculi formed in the pelvis of the kidneys, and either sticking there or falling into the ureter.

Prognosis. This is not different from that of other inflammatory diseases.

Cure. When any of those causes operating as inducing the inflammation still continue to act, the first object in the cure must be the removal of these; but the principal intention to be had in view, is the resolution of the inflammation which has already taken place. But when, notwithstanding efforts for this purpose, the disease terminates in suppuration, it must be the endeavour of the practitioner to promote the discharge of the purulent matter, and the healing of the ulceration in the kidney.

These different objects are principally accomplished by bleeding, external fomentation, frequent emollient clysters, antiphlogistic purgatives, and by the free use of mild and demulcent liquids. The use of blisters is scarce admissible, or at least will require great care to avoid any considerable absorption of the cantharides.

The other species of nephritis enumerated by authors are only symptomatic.

Genus

Phlegmasiæ.

201 ## Genus XX. CYSTITIS.

Inflammation of the Bladder.

Cystitis, *Sauv.* gen. 108. *Lin.* 31. *Vog.* 66. *Sag.* gen. 309.
Inflammatio vesicæ, *Hoffm.* ii. 157.

202 The Cystitis from *Internal Causes.*

Cystitis spontanea, *Sauv.* sp. 1.

203 The Cystitis from *External Causes.*

Cystitis à cantharidibus, *Sauv.* sp. 2.
Cystitis traumatica, *Sauv.* sp. 3.

The inflammation of the bladder from internal causes is a very rare distemper; and when it does at any time occur, is to be cured in the same manner with other inflammations, avoiding only the use of blisters. When the disease arises from the internal use of these flies, camphor is recommended, besides other cooling medicines, and particularly cooling and emollient clysters.

204 ## Genus XXI. HYSTERITIS.

Inflammation of the Uterus.

Hysteritis, *Lin.* 38. *Vog.* 63.
Metritis, *Sauv.* gen. 107. *Sag.* gen. 315.
Inflammatio et febris uterina, *Hoffm.* II. 156.

Description. This disease is often confounded with that called the *puerperal* or *child-bed fever*; but is essentially distinct from it, as will be shown in its proper place. The inflammation of the uterus is often apt to terminate by gangrene: there is a pain in the head, with delirium; and the uterine region is so exceedingly tender, that it cannot bear the most gentle pressure without intolerable pain. When the *fundus uteri* is inflamed, there is a great heat, throbbing, and pain, above the pubes; if its posterior part, the pain is more confined to the loins and rectum, with a tenesmus; if its anterior part, it shoots from thence towards the neck of the bladder, and is attended with a frequent irritation to make water, which is voided with difficulty; and if its sides or the ovaria are affected, the pains will then dart into the inside of the thighs.

Causes, &c. Inflammations of the uterus, and indeed of the rest of the abdominal viscera, are very apt to take place in child-bed women; the reason of which seems to be the sudden change produced in the habit, and an alteration in the course of the circulating blood by the contraction of the uterus after delivery. The pressure of the gravid uterus being suddenly taken off from the *aorta descendens* after delivery, the resistance to the impulse of the blood passing through all the vessels derived from it, and distributed to the contiguous viscera, will be considerably lessened: it will therefore rush into those vessels with a force superior to their resistance; and, by putting them violently on the stretch, may occasion pain, inflammation, and fever. This contraction of the uterus also renders its vessels impervious to the blood which had freely passed through them for the service of the child during pregnancy; and consequently a much larger quantity will be thrown upon the contiguous parts, which will still add to their distention, and increase their tendency to inflammation.

Rheumatismus.

Prognosis. An inflammation of the uterus may in general be expected to produce an obstruction of the lochia; but the fever produced seldom proves fatal, unless the inflammation be violent, and end in a gangrene.

Cure. This is to be attempted by the same general means already recommended, and the management of this disorder entirely coincides with that of the puerperal fever.

Genus XXII. RHEUMATISMUS. 20

The *Rheumatism.*

Rheumatismus, *Sauv.* gen. 185. *Lin.* 62. *Vog.* 138. *Boerh.* 1400. *Junck.* 19.
Dolores rheumatici et arthritici, *Hoffm.* II. 317.
Myositis, *Sag.* gen. 301.

The *Acute Rheumatism.*

Rheumatismus acutus, *Sauv.* sp. 1.
Rheumatismus vulgaris, *Sauv.* sp. 2.

A. The Lumbago, or *Rheumatism in the Muscles of the Loins.* 20

Lumbago rheumatica, *Sauv.* gen. 212. *Sag.* p. 1.
Nephralgia rheumatica, *Sauv.* sp. 4.

B. The Sciatica, *Ischias,* or *Hip-Gout.* 20

Ischias rheumaticum. *Sauv.* 213. sp. 10.

C. The *Bastard Pleurisy,* or *Rheumatism in the Muscles of the Thorax.* 20

Pleurodyne rheumatica, *Sauv.* gen. 148. sp. 3.
Pleuritis spuria, *Boerh.* 878.

The other species, which are very numerous, are all symptomatic; as,
Lumbago plethorica, *Sauv.* sp. 3.
Ischias sanguineum, *Sauv.* sp. 2.
Pleurodyne plethorica, *Sauv.* sp. 1.
Rheumatismus hystericus, *Sauv.* sp. 7.

Lumbago à saburrâ, *Sauv.* sp. 8.
Pleurodyne à cacochyliâ, *Sauv.* sp. 7.
Rheumatismus saltatorius verminosus, *Sauv.* sp. 8.
Ischias verminosum, *Sauv.* sp. 8.
Pleurodyne verminosa, *Sauv.* sp. 2.
Rheumatismus metallicus, *Sauv.* sp. 10.
Lumbago à hydrothorace, *Sauv.* sp. 14.
Lumbago pseudoischuria, *Sauv.* sp. 16.
Pleurodyne à rupto œsophago, *Sauv.* sp. 20.
Pleurodyne rachitica, *Sauv.* sp. 13.
Ischias à sparganosi, *Sauv.* sp. 5.
Pleurodyna catarrhalis, *Sauv.* sp. 14.

Rheumatismus

Phlegmasiæ.

Rheumatismus necroseos, *Sauv.* sp. 14.
Rheumatismus dorsalis, *Sauv.* sp. 11.
Lumbago à satyriasi, *Sauv.* sp. 15.
Rheumatismus febricosus, *Sauv.* sp. 9.
Lumbago febrilis, *Sauv.* sp. 4.
&c. &c.

Description. The rheumatism is particularly distinguished by pains affecting the joints, and for the most part the joints alone; but sometimes also the muscular parts. Very often they shoot along the course of the muscles from one joint to another, and are always much increased by the action of the muscles belonging to the joint or joints affected. The larger joints are those most frequently affected, such as the hip-joint and knees, of the lower extremities, and the shoulders and elbows of the upper ones. The ancles and wrists are also frequently affected; but the smaller joints, such as those of the toes or fingers, seldom suffer. Sometimes the disease is confined to one part of the body, yet very frequently it affects many parts; and then it begins with a cold stage, which is immediately succeeded by the other symptoms of pyrexia, and particularly by a frequent, full, and hard pulse. Sometimes the pyrexia is formed before any pains are perceived; but more commonly pains are felt in particular parts before any symptoms of fever occur. When no pyrexia is present, the pain may be confined to one joint only; but when any considerable pyrexia takes place, though the pain may chiefly be felt in one joint, yet it seldom happens that it does not affect several joints, often at the very same time, but for the most part shifting their place, and having abated in one joint they become more violent in another. They do not commonly remain long in the same joint, but frequently shift from one to another, and sometimes return to joints formerly affected; and in this manner the disease often continues for a long time. The fever attending these pains has an exacerbation every evening, and is most considerable during the night, when the pains also become more violent; and it is at the same time that the pains shift their place from one joint to another. These seem to be also increased during the night by the body being covered more closely, and kept warmer.

A joint, after having been for some time affected with pain, commonly becomes also affected with some swelling and redness, which is painful to the touch. It seldom happens that a swelling coming on does not take off the pain entirely, but it rarely secures the joint against a return of it. This disease is commonly attended with more or less sweating, which occurs early, but is seldom free or copious, and seldom proves critical, though it may give temporary relief of the pain. The urine is high-coloured, and in the beginning without sediment. This, however, does not prove entirely critical, for the disease often continues long after such a sediment has appeared in the urine. The blood is always sizy. The acute rheumatism differs from all other inflammatory diseases, in not being liable to terminate in suppuration: this almost never happens; but the disease sometimes produces effusions of a transparent gelatinous fluid into the sheaths of the tendons: but if these effusions be frequent, it is certain that the liquor must often be absorbed; for it very seldom happens, that considerable or permanent tumours have been produced, or such as required to be opened and to have the contained fluid evacuated. Such tumours, however, have sometimes occurred, and the opening made in them has produced ulcers very difficult to heal.

Rheumatismus.

Sometimes rheumatism will continue for several weeks; but it seldom proves fatal, and it is rare that the pyrexia continues to be considerable for more than two or three weeks. While the pyrexia abates in its violence, if the pains of the joints continue, they are less violent; more limited in their place, being confined commonly to one or a few joints only; and are less ready to change their place.

It is often a very difficult matter to distinguish rheumatism from gout: but in rheumatism there in general occurs much less affection of the stomach; it affects chiefly the larger joints, and several of these are often affected with severe pain at the same time: it occurs at an earlier period of life than gout; it is not observed to be hereditary; and it can in general be traced to some obvious exciting cause, particularly to the action of cold.

Causes, &c. This disease is frequent in cold, and more uncommon in warm climates. It appears most frequently in autumn and spring; less frequently in winter, while the frost is constant; and very seldom during the heat of summer. It may, however, occur at any season, if vicissitudes of heat and cold be for the time frequent. For the most part, the acute rheumatism arises from the application of cold to the body when unusually warm; or when the cold is applied to one part of the body, whilst the other parts are kept warm; or, lastly, when the application of the cold is long continued, as when moist or wet clothes are applied to any part of the body.—These causes may affect persons of all ages; but the rheumatism seldom appears either in very young or in elderly persons, and most commonly occurs from the age of puberty to that of 35. These causes may also affect persons of any constitution, but they most commonly affect those of a sanguine temperament.

With respect to the proximate cause of rheumatism, there have been various opinions. It has been imputed to a peculiar acrimony; of which, however, there is no evidence; and the consideration of the remote causes, the symptoms, and cure, render it very improbable. A disease of a rheumatic nature, however, may be occasioned by an acrid matter applied to the nerves, as is evident from the toothach, a rheumatic affection generally arising from a carious tooth. Pains arising from deep-seated suppurations may also resemble the rheumatism; and many cases have occurred in which such suppurations occasioned pains resembling the lumbago and ischias; but from what has been already said, it seems improbable that ever any pure rheumatic case should end in suppuration.

The proximate cause of rheumatism has by many been supposed to be a lentor in the fluids obstructing the vessels of the part; but in the observations formerly made, sufficient reasons have been already laid down for rejecting the doctrine of lentor. While we cannot therefore find either evidence or reason for supposing that the rheumatism depends on any change in the state of the fluids, we must conclude that the proximate cause of it is the same with that of other inflammations not depending upon a direct stimulus.

Phlegmasiæ. Rheumatismus.

In the case of rheumatism, it is supposed that the most common remote cause of it, that is, cold applied, operates especially on the vessels of the joints, these being less covered by a cellular texture than those of the intermediate parts of the limbs. It is farther supposed, that the application of cold produces a constriction of the extreme vessels, and at the same time an increase of tone or phlogistic diathesis in the course of them, from which arises an increased impetus of the blood, and at the same time a resistance to the free passage of it, and consequently inflammation and pain. It is also supposed, that the resistance formed excites the *vis medicatrix* to a further increase of the impetus of the blood; and to support this, a cold stage arises, a spasm is formed, and a pyrexia and phlogistic diathesis are produced in the whole system.

Hence the cause of rheumatism appears to be exactly analogous to that of inflammations depending on an increased afflux of blood to a part while it is exposed to the action of cold. But there seems to be further in this disease some peculiar affection of the muscular fibres. These seem to be under some degree of rigidity: and therefore less easily admit of motion, and are pained upon the exertions of it. This also seems to be the affection which gives opportunity to the propagation of pains from one joint to another, and which are most severely felt in the extremities terminating in the joints, because beyond these the oscillations are not propagated. This affection of the muscular fibres explains the manner in which strains and spasms produce rheumatic affections; and, on the whole, shows, that with an inflammatory affection of the sanguiferous system, there is also in rheumatism a peculiar affection of the muscular fibres, which has a considerable share in producing the phenomena of the disease. And it would even appear, that in what has commonly been called *acute rheumatism*, in contradistinction to the chronic, of which we are next to treat, there exists not only a state of active inflammation in the affected parts, but also of peculiar irritability; and that this often remains after the inflammation is very much diminished or has even entirely ceased. Hence a renewal of the inflammation and recurrence of the pain take place from very slight causes; and in the treatment of the disease both the state of inflammation and irritability must be had in view.

Cure. For counteracting the state of active inflammation, the chief aim of the practitioner must be to diminish the general impetus of the circulation, and the impetus at the part particularly affected. For counteracting the state of irritability, he must endeavour to remove the disposition to increased action in the vessels; to prevent the action of causes exciting painful sensations; and to obviate their influence on the part. The cure therefore requires, in the first place, an antiphlogistic regimen, and particularly a total abstinence from animal food, and from all fermented or spirituous liquors; substituting a mild vegetable or milk diet, and the plentiful use of soft diluting liquors. On this principle also, blood-letting is the chief remedy of acute rheumatism. The blood is to be drawn in large quantity; and the bleeding is to be repeated in proportion to the frequency, fulness, and hardness of the pulse, and the violence of the pain. For the most part, large and repeated bleeding during the first days of the disease seem to be necessary, and accordingly have been very much employed; but to this some bounds are to be set; for very profuse bleedings occasion a slow recovery, and are ready to produce a chronic rheumatism.

To avoid that debility of the system which general bleedings are apt to occasion, the urgent symptom of pain may be often relieved by topical bleedings; and when any swelling or redness has come upon a joint, the pain may very certainly be relieved by this evacuation: but as the pain and continuance of the disease seem to depend more upon the phlogistic diathesis of the whole system than upon the affection of particular parts, so topical bleedings will not supply the place of the general bleedings proposed above in most instances.

To take off the phlogistic diathesis prevailing in this disease, purging may be useful, if procured by medicines which do not stimulate the whole system, as neutral salts, and other medicines which have a refrigerant power. Purging, however, is not so useful as bleeding in removing the phlogistic diathesis; and when the disease has become general and violent, frequent stools are inconvenient, and even hurtful, by the motion and pain which they occasion.

Next to blood-letting, nothing is of so much service, both in alleviating the pains in this disease and in removing the phlogistic diathesis, as the use of sudorifies: and of all the medicines belonging to this class, what has commonly been known by the name of Dover's powder, a combination of powder of ipecacuan and opium, is the most convenient and the most effectual. Copious sweating, excited by this medicine, and supported for 10 or 12 hours by tepid diluents, such as decoction of the woods, or the like, will in most instances produce a complete remission of the pain: and by this practice, combined with blood-letting and proper regimen, the disease may often be entirely removed.

If, however, after complete intermissions from pain for some length of time have been obtained by these means, it be found that there is a great tendency to a return of the pains without any obvious cause, recourse may be had with very great benefit to the use of the Peruvian bark. By the early use of this, where a complete intermission from pain is obtained, the necessity of repeated blood-letting and sweating is often superseded; but where a complete remission cannot be obtained, it has been suspected by some to be hurtful: and in these cases, when blood-letting and sudorifics have been pushed as far as may be thought prudent, without being productive of the desired effect, very great benefit is often derived from the use of calomel combined with opium, as recommended in the Edinburgh Medical Commentaries, by Dr Hamilton of Lynn Regis.

In this disease, external applications are of little service. Fomentations in the beginning of the disease rather aggravate than relieve the pains. The rubefacients and camphire are more effectual: but they commonly only move them from one part to another, and do not prove any cure of the general affection. Blistering may also be very effectual in removing the pain

pain from a particular part; but will be of little use, except where the pains are much confined to one place.

ARTHRODYNIA, or *Chronic Rheumatism.*

Rheumatismus chronicus Auctorum.

Description. When the pyrexia attending the acute rheumatism has ceased; when the swelling and redness of the joints are entirely gone, but pains still continue to affect certain joints, which remain stiff, feel uneasy upon motion, changes of weather, or in the night time only, the disease is then called the *chronic rheumatism*, as it often continues for a very long time.

The limits between the acute and chronic rheumatisms are not always exactly marked. When the pains are still ready to shift their place; when they are especially severe in the night time; when, at the same time, they are attended with some degree of pyrexia, and with some swelling, and especially some redness of the joints; the disease is to be considered as partaking of the nature of the acute rheumatism. But when there is no longer any degree of pyrexia remaining; when the pained joints are without redness; when they are cold and stiff; when they cannot easily be made to sweat; or when, while a free and warm sweat is brought out on the rest of the body, it is only clammy and cold on the pained joints; and when, further, the pains of these are increased by cold, and relieved by heat, applied to them; the case is to be considered as that of a purely chronic rheumatism: or, perhaps more properly, the first of the conditions now described may be termed the state of irritability, and the second the state of atony.

The chronic rheumatism, or rather the atonic, may affect different joints; but is especially apt to affect those which are surrounded with many muscles, and those of which the muscles are employed in the most constant and vigorous exertions. Such is the case of the vertebræ of the loins, the affection of which is named *lumbago;* or of the hip joint, when the disease is named *ischias* or *sciatica.*

Violent strains and spasms occurring on sudden and somewhat violent exertions, bring on rheumatic affections, which at first partake of the acute, but very soon change into the nature of the chronic, rheumatism.—Such are frequently the lumbago, and other affections, which seem to be more seated in the muscles than in the joints. The distinction of the rheumatic pains from those resembling them which occur in the siphylis and scurvy must be obvious, either from the seat of the pains, or from the concomitant symptoms peculiar to those diseases. The distinction of the rheumatism from the gout will be more fully understood from what is laid down under the genus Podagra.

Causes, &c. The phenomena of the purely chronic rheumatism lead us to conclude, that its proximate cause is an atony both of the blood-vessels and of the muscular fibres of the part affected, together with such a degree of rigidity and contraction in the latter as frequently attend them in a state of atony: and indeed this atony, carried to a certain extent, gives rise to a state of paralysis, with an almost total loss of motion in the affected limbs. The paralytic state of rheumatism therefore may be pointed out as a fourth condition of the disease, often claiming the attention of the practitioner.

Cure. From the view just now given of the proximate cause of chronic rheumatism, the chief indication of cure must be, to restore the activity and vigour of the part, which is principally to be done by increasing the tone of the moving fibres, but which may sometimes also be aided by giving condensation to the simple solid. When, however, the disease has degenerated into the state of paralysis, the objects to be aimed at are, the restoration of a due condition to the nervous energy in the part affected; the obtaining free circulation of blood through the vessels of the part; and the removal of rigidity in membranes and ligaments.

For answering these purposes, a great variety of remedies, both external and internal, are had recourse to. The chief of the external are, the supporting the heat of the part, by keeping it constantly covered with flannel; the increasing the heat of the part by external heat, applied either in a dry or humid form; the diligent use of the flesh-brush, or other means of friction; the application of electricity in sparks or shocks; the application of cold water by affusion or immersion; the application of essential oils of the most warm and penetrating kind; the application of salt brine; the employment of the warm bath or of the vapour baths, either to the body in general or to particular parts; and, lastly, the employment either of exercise of the part itself as far as it can easily bear, or by riding or other modes of gestation.

The internal remedies are, large doses of essential oils drawn from resinous substances, such as turpentine; substances containing such oils, as guaiac.; volatile alkaline salts, &c. These or other medicines are directed to procure sweat; and calomel, or some other preparation of mercury, in small doses, may be continued for some time. But of all the remedies which have been found useful in atonic rheumatism, perhaps the best is cinchona. It is particularly serviceable in the earlier periods of the disease. It has often been highly efficacious in preventing the degeneracy of the inflammatory into the atonic state of the disease; and by some practitioners, particularly Dr Haygarth of Bath, it has been highly extolled in acute rheumatism. Besides these, there are several other remedies recommended. The cicuta, aconitum, and hyosciamus, have in particular been highly extolled; and an infusion of the rhododendron chrysanthum is said to be employed by the Siberians with very great success. An account of the Siberian mode of practice is given by Dr Matthew Guthrie of Petersburgh, in the fifth volume of the Edinburgh Medical Commentaries, and has been followed with success at other places. Among other internal remedies for rheumatism, the use of arsenic has of late been recommended by Dr Bardsley of Liverpool. It is advised to be given under the form of the mineral solution proposed by Dr Fowler as a remedy in intermittent fever and in periodic headachs. Under this form, it is now ascertained by extensive experience that arsenic may be taken internally with as much safety as any other active medicine; and in some cases of rheumatism in which it has been employed at Edinburgh, there is reason to believe that it has been productive of benefit.

Odontalgia hysterica, *Sauv.* sp. 8.
Odontalgia stomachica, *Sauv.* sp. 9.

Description. This well-known disease makes its attack by a most violent pain in the teeth, most frequently in the *molares*, more rarely in the *incisores*, reaching sometimes up to the eyes, and sometimes backward into the cavity of the ear. At the same time there is a manifest determination to the head; and a remarkable tension and inflation of the vessels takes place, not only in the parts next to that where the pain is seated, but over the whole head.

Causes, &c. The toothach is sometimes merely a rheumatic affection, arising from cold, but more frequently from a carious tooth. It is also a symptom of pregnancy, and takes place in some nervous disorders; it may attack persons at any time of life, though it is most frequent in the young and plethoric.

Cure. Many empirical remedies have been proposed for the cure of the toothach, but none have in any degree answered the purpose. When the affection is purely rheumatic, blistering behind the ear will almost always remove it; but when it proceeds from a carious tooth, the pain is much more obstinate. In this case it has been recommended to touch the pained part with a hot iron, or with sulphuric acid, in order to destroy the aching nerve; to hold strong spirits in the mouth; to put a drop of oil of cloves into the hollow of the tooth, or a pill of equal parts of opium and camphor: but one of the most useful applications of this kind is strong nitrous acid, diluted with three or four times its weight of spirit of wine, and introduced into the hollow of a tooth from which great pain arises, either by means of a hair pencil or a little cotton. Cinchona has also been recommended, and perhaps with more justice, on account of its tonic and antiseptic powers; but very often all these remedies will fail, and the only infallible cure is the extraction of the tooth. See Surgery.

Sp. III. The *Retrocedent* Gout. 214

Sp. IV. The *Misplaced* Gout. 215

Description. What we call a *paroxysm of the gout* is principally constituted by an inflammatory affection of some of the joints. This sometimes comes on suddenly, without any warning, but is generally preceded by several symptoms; such as the ceasing of a sweating which the feet had been commonly before affected with; an unusual coldness of the feet and legs; a frequent numbness, alternating with a sense of prickling along the whole of the lower extremities; frequent cramps of the muscles of the legs; and an unusual turgescence of the veins.

While these symptoms take place in the lower extremities, the body is affected with some degree of torpor and languor, and the functions of the stomach in particular are more or less disturbed. The appetite is diminished; and flatulency, or other symptoms of indigestion, are felt. These symptoms take place for several days, sometimes for a week or two, before a paroxysm comes on; but commonly, upon the day immediately preceding it, the appetite becomes keener than usual.

The circumstances of paroxysms are chiefly the following. They come on most commonly in the spring, and sooner or later according as the vernal heat succeeds sooner or later to the winter's cold, and, perhaps, sooner or later also, according as the body may happen to be more or less exposed to vicissitudes of heat and cold.

The attacks are sometimes felt first in the evening, but more commonly about two or three o'clock in the morning. The paroxysm begins with a pain affecting one foot, most frequently in the ball or first joint of the great toe, but sometimes in other parts of the foot. With the attack of this pain, there is commonly more or less of a cold shivering; which, as the pain increases, gradually ceases; and is succeeded by a hot stage of pyrexia, which continues for the same time with the pain itself. From the first attack, the pain becomes, by degrees, more violent, and continues in this state with great restlessness of the whole body till next midnight, after which it gradually remits; and, after it has continued for twenty-four hours from the commencement of the first attack, it commonly ceases almost entirely; and, with the coming on of a gentle sweat, allows the patient to fall asleep. The patient, upon coming out of this sleep in the morning, finds the pained part affected with some redness and swelling, which, after having continued for some days, gradually abate.

When a paroxysm has thus come on, although the violent pain after 24 hours be considerably abated, the patient is not entirely relieved from it. For some days

days he has every evening a return of more considerable pain and pyrexia, and these continue with more or less violence till morning. After going on, in this manner, for several days, the disease sometimes goes entirely off, not to return till after a long interval.

When the disease, after having thus remained for some time in a joint, ceases entirely, it generally leaves the person in very perfect health, enjoying greater ease and alacrity in the functions of both body and mind than he had for a long time before experienced.

At the beginning of the disease, the returns of it are sometimes only once in three or four years: but as it advances, the intervals become shorter, and at length the attacks are annual; afterwards they come twice each year; and at length recur several times during the course of autumn, winter, and spring; and as, when the fits are frequent, the paroxysms become also longer, so, in the advanced state of the disease, the patient is hardly ever tolerably free from it, except perhaps for two or three months in summer.

The progress of the disease is also marked by the parts which it affects. At first, it commonly affects one foot only; afterwards every paroxysm affects both feet, the one after the other; and as the disease proceeds, it not only affects both feet at once, but, after having ceased in the foot which was last attacked, returns again into the first, and perhaps a second time also into the other. Its changes of places are not only from one foot to another, but from the feet into other joints, especially those of the upper extremities; so that there is hardly a joint of the body which, on one occasion or another, is not affected. It sometimes affects two different joints at the very same time; but more commonly it is at any one time severe in a single joint only, and passes in succession from one joint to another; so that the patient's affliction is often protracted for a long time.

When the disease has often returned, and the paroxysms have become very frequent, the pains are commonly less violent than they were at first; but the patient is more affected with sickness, and the other symptoms of the atonic gout, which shall be hereafter mentioned.

After the first paroxysm of the disease, the joints which have been affected are entirely restored to their former suppleness and strength: but after the disease has recurred very often, the joints affected do neither so suddenly nor entirely recover their former state, but continue weak and stiff; and these effects at length proceed to such a degree, that the joints lose their motion entirely.

In many persons, but not in all, after the disease has frequently recurred, concretions of a chalky nature are formed upon the outside of the joints, and for the most part immediately under the skin. The matter seems to be deposited at first in a fluid form, afterwards becoming dry and firm. In their firm state, these concretions are a hard earthy substance, very entirely soluble in acids. After they have been formed, they contribute, with other circumstances, to destroy the motion of the joints.

In most persons who have laboured under the gout for many years, a nephritic affection comes on, and discovers itself by all the symptoms which usually attend calculous concretions in the kidneys, and which we shall have occasion to describe in another place. All that is necessary to be observed here is, that the nephritic affection alternates with paroxysms of the gout; and that the two affections, the nephritic and the gouty, are hardly ever present at the same time. This also may be observed, that children of gouty or nephritic parents commonly inherit one or other of these diseases; but whether the principal disease of the parent may have been either gout or nephritis alone, some of the children have the one and some the other. In some of them the nephritic affection occurs alone, without any gout supervening; and this happens to be frequently the case with the female children of gouty parents.

In the whole of the history already given, we have described the most common form of the disease, and which therefore, however diversified in the progress of it, may be still called the regular state of the gout.—Upon some occasions, however, the disease assumes different appearances: but as we suppose the disease to depend always upon a certain diathesis, or disposition of the system; so every appearance which we can perceive to depend upon that same disposition, we still consider as symptomatic, and view the disease to be a case of the gout. The principal circumstance, in what we term the *regular gout*, is the inflammatory affection of the joints; and whatever symptoms we can perceive to be connected with, or to depend upon, the disposition which produces that inflammatory affection, but without its taking place or being present at the same time, we name the *irregular gout*.

Of such irregular gout there are three different states, which may be named the *atonic*, the *retrocedent*, and the *misplaced* gout.

The first is, when the gouty diathesis prevails in the system; but, from certain causes, does not produce the inflammatory affection of the joints. In this case, the morbid symptoms which appear, are chiefly affections of the stomach, such as loss of appetite, indigestion, and its various attendants of sickness, nausea, vomiting, flatulency, acid eructations, and pains in the region of the stomach. These symptoms are frequently accompanied with pains and cramps in several parts of the trunk and the upper extremities of the body, which are relieved by the discharge of wind from the stomach. Together with these affections of the stomach, there commonly occurs a costiveness; but sometimes a looseness, with colic pains. These affections of the alimentary canal are often attended with all the symptoms of hypochondriasis, such as dejection of mind, a constant and anxious attention to the slightest feelings, an imaginary aggravation of these, and an apprehension of danger from them.

In the same atonic gout, the viscera of the thorax also are sometimes affected, and palpitations, faintings, and asthma occur.

In the head also occur headachs, giddiness, apoplectic and paralytic affections.

When the several symptoms now mentioned occur in habits having the marks of a gouty disposition, this may be suspected to have laid the foundation for them; and especially when either, in such habits, a manifest tendency to the inflammatory affection has formerly appeared, or when the symptoms mentioned are

Phlegmasiæ. are intermixed with, and are relieved by some degree of the inflammatory gout. In such cases there can be no doubt of considering the whole as a state of the gout.

Another state of the disease we name the *retrocedent* gout. This occurs when an inflammatory state of the joints has, in the usual manner, come on, but without arising to the ordinary degree of pain and inflammation; or at least without these continuing for the usual time, or without their receding gradually in the usual manner; these affections of the joints suddenly and entirely cease, while some internal part becomes affected. The internal part most commonly attacked is the stomach; which then is affected with anxiety, sickness, vomiting, or violent pain: but sometimes the internal part is the heart, which gives occasion to a syncope; sometimes it is the lungs, which are affected with asthma: and sometimes it is the head, giving occasion to apoplexy or palsy. In all these cases there can be no doubt that the symptoms are all a part of the same disease, however different the affection may seem to be in the parts which it attacks.

The third state of irregular gout, which we name the *misplaced*, is when the gouty diathesis, instead of producing the inflammatory affection of the joints, produces an inflammatory affection of some internal part, and which appears from the same symptoms that attend the inflammations of those parts arising from other causes.
