Kant.—Kant's relation to the doctrine of evolution is a many-sided one. In the first place, his peculiar system of subjective idealism, involving the idea that time is but a mental form to which there corresponds nothing in the sphere of noümenal reality, serves to give a peculiar philosophical interpretation to every doctrine of cosmic evolution. Kant, like Leibnitz, seeks to reconcile the mechanical and teleological views of nature, only he assigns to these different spheres. The order of the inorganic world is explained by properly physical causes. In his *Naturgeschichte des Himmels*, in which he anticipated the nebular theory afterwards more fully developed by Laplace, Kant sought to explain the genesis of the cosmos as a product of physical forces and laws. The worlds, or systems of worlds, which fill infinite space are continually being formed and destroyed. Chaos passes by a process of evolution into a cosmos, and this again into chaos. So far as the evolution of the solar system is concerned, Kant held these mechanical causes as adequate. For the world as a whole, however, he postulated a beginning in time (whence his use of the word creation), and further supposed that the impulse of organization which was conveyed to chaotic matter by the Creator issued from a central point in the infinite space spreading gradually outwards.[4] While in his cosmology Kant thus relies on mechanical conceptions, in his treatment of organic life his mind is, on the contrary, dominated by teleological ideas. An organism was to him something controlled by a formative organizing principle. It was natural, therefore, that he rejected the idea of a spontaneous generation of organisms (which was just then being advocated by his friend Forster), not only as unsupported by experience but as an inadequate hypothesis. Experience forbids our excluding organic activity from natural causes, also our excluding intelligence from purposeful (*zweckthätigen*) causes; hence experience forbids our defining the fundamental force or first cause out of which living creatures arose.[5] Just as Kant thus sharply marks off the regions of the inorganic and the organic, so he sets man in strong opposition to the lower animals. His ascription to man of a unique faculty, free-will, forbade his conceiving our species as a link in a graduated series of organic developments. In his doctrine of human development he does indeed recognize an early stage of existence in which our species was dominated by sensuous enjoyment and instinct. He further conceives of this stage as itself a process of (natural) development, namely, of the natural disposition of the species to vary in the greatest possible manner so as to preserve its unity through a process of self-adaptation (*Anarten*) to climate. This, he says, must not be conceived as resulting from the action of external causes, but is due to a natural disposition (*Anlage*). From this

---

[1] Mr Lewes points out that Leibnitz is inconsistent in his account of the intelligence of man in relation to that of lower animals, since when answering Locke he no longer regards these as differing in degree only.

[2] Both Mr Lewes and Prof. Du Bois Reymond have brought out the points of contact between Leibnitz's theory of monads and modern biological speculations (*Hist. of Phil.* ii. 287, and *Leibnitzsche Gedanken in der modernen Naturwissenschaft*, p. 23 *sq.*).

[3] For Herder's position in relation to the modern doctrine of evolution see F. von Bärenbach's *Herder als Vorgänger Darwins*, a work which tends to exaggerate the proximity of the two writers.

[4] Kant held it probable that other planets besides our earth are inhabited, and that their inhabitants form a scale of beings, their perfection increasing with the distance of the planet which they inhabit from the sun.

[5] Kant calls the doctrine of the transmutation of species "a hazardous fancy of the reason." Yet, as Strauss and others have shown, Kant's mind betrayed a decided leaning at times to a more mechanical conception of organic forms as related by descent

capability of natural development (which already involves a teleological idea) Kant distinguishes the power of moral self-development or self-liberation from the dominion of nature, the gradual realization of which constitutes human history or progress. This moral development is regarded as a gradual approach to that rational, social, and political state in which will be realized the greatest possible quantity of liberty. Thus Kant, though he appropriated and gave new form to the idea of human progress, conceived of this as wholly distinct from a natural (mechanical) process. In this particular, as in his view of organic actions, Kant distinctly opposed the idea of evolution as one universal process swaying alike the physical and the moral world.

Schelling.—In the earlier writings of Schelling, containing the philosophy of identity, existence is represented as a becoming, or process of evolution. Nature and mind (which are the two sides, or polar directions, of the one absolute) are each viewed as an activity advancing by an uninterrupted succession of stages. The side of this process which Schelling worked out most completely is the negative side, that is, nature. Nature is essentially a process of organic self-evolution. It can only be understood by subordinating the mechanical conception to the vital, by conceiving the world as one organism animated by a spiritual principle or intelligence (*Weltseele*). From this point of view the processes of nature from the inorganic up to the most complex of the organic become stages in the self-realization of nature. All organic forms are at bottom but one organization, and the inorganic world shows the same formative activity in various degrees or potences. Schelling conceives of the gradual self-evolution of nature in a succession of higher and higher forms as brought about by a limitation of her infinite productivity, showing itself in a series of points of arrest. The detailed exhibition of the organizing activity of nature in the several processes of the organic and inorganic world rests on a number of fanciful and unscientific ideas. Schelling's theory is a bold attempt to revitalize nature in the light of growing physical and physiological science, and by so doing to comprehend the unity of the world under the idea of one principle of organic development. His highly figurative language might leave us in doubt how far he conceived the higher stages of this evolution of nature as following the lower in time. In the introduction to his work *Von der Weltseele*, however, he argues in favour of the possibility of a transmutation of species in periods incommensurable with ours. The evolution of mind (the positive pole) proceeds by way of three stages,—theoretic, practical, and æsthetical activity. Schelling's later theosophic speculations do not specially concern us here.

Followers of Schelling.—Of the followers of Schelling a word or two must be said. Heinrich Steffens, in his *Anthropologie*, seeks to trace out the origin and history of man in connexion with a general theory of the development of the earth, and this again as related to the formation of the solar system. All these processes are regarded as a series of manifestations of a vital principle in higher and higher forms. Oken, again, who carries Schelling's ideas into the region of biological science, seeks to reconstruct the gradual evolution of the material world out of original matter, which is the first immediate appearance of God, or the absolute. This process is an upward one, through the formation of the solar system and of our earth with its inorganic bodies, up to the production of man. The process is essentially a polar linear action, or differentiation from a common centre. By means of this process the bodies of the solar system separate themselves, and the order of cosmic evolution is repeated in that of terrestrial evolution. The organic world (like the world as a whole) arises out of a primitive chaos, namely, the infusorial slime. A somewhat similar working out of Schelling's idea is to be found in Oersted's work entitled *The Soul in Nature* (Eng. trans.). Of later works based on Schelling's doctrine of evolution mention may be made of the volume entitled *Natur und Idee*, by G. F. Carus. According to this writer, existence is nothing but a becoming, and matter is simply the momentary product of the process of becoming, while force is this process constantly revealing itself in these products.

Hegel.—Like Schelling, Hegel conceives the problem of existence as one of becoming. He differs from him with respect to the ultimate motive of that process of gradual evolution which reveals itself alike in nature and in mind. With Hegel the absolute is itself a dialectic process which contains within itself a principle of progress from difference to difference and from unity to unity. "This process (Mr Wallace remarks) knows nothing of the distinctions between past and future, because it implies an eternal present." This conception of an immanent spontaneous evolution is applied alike both to nature and to mind and history. Nature to Hegel is the idea in the form of hetereity; and finding itself here it has to remove this exteriority in a progressive evolution towards an existence for itself in life and mind. Nature (says Zeller) is to Hegel a system of gradations, of which one arises necessarily out of the other, and is the proximate truth of that out of which it results. There are three stadia, or moments, in this process of nature—(1) the mechanical moment, or matter devoid of individuality; (2) the physical moment, or matter which has particularized itself in bodies—the solar system; and (3) the organic moment, or organic beings, beginning with the geological organism—or the mineral kingdom, plants, and animals. Yet this process of development is not to be conceived as if one stage is naturally produced out of the other, and not even as if the one followed the other in time. Only spirit has a history; in nature all forms are contemporaneous.[1] Hegel's interpretation of mind and history as a process of evolution has more scientific interest than his conception of nature. His theory of the development of free-will (the objective spirit), which takes its start from Kant's conception of history, with its three stages of legal right, morality as determined by motive and instinctive goodness (*Sittlichkeit*), might almost as well be expressed in terms of a thoroughly naturalistic doctrine of human development. So, too, some of his conceptions respecting the development of art and religion (the absolute spirit) lend themselves to a similar interpretation. Yet while, in its application to history, Hegel's theory of evolution has points of resemblance with those doctrines which seek to explain the world-process as one unbroken progress occurring in time, it constitutes on the whole a theory apart and *sui generis*. It does not conceive of the organic as succeeding on the inorganic, or of conscious life as conditioned in time by lower forms. In this respect it resembles Leibnitz's idea of the world as a development; the idea of evolution is in each case a metaphysical as distinguished from a scientific one.[2] Hegel gives a place in his metaphysical system to the mechanical and the teleological views; yet in his treatment of the world as an evolution the idea of end or purpose is the predominant one.

Of the followers of Hegel who have worked out his

---

[1] Hegel somewhere says that the question of the eternal duration of the world is unanswerable: time as well as space can be predicated of finitudes only.

[2] Mr Wallace (*Logic of Hegel*, Proleg. pp. 48, 49) speaks of Hegel's system of evolution as having been in a sense the transformation into a philosophic shape of the biological doctrine of evolution as suggested by Treviranus and Lamarck. Yet this relation is by no means obvious.

peculiar idea of evolution it is hardly necessary to speak. A bare reference may be made to Rosenkranz, who in his work *Hegel's Naturphilosophie*, seeks to develop Hegel's idea of an earth-organism in the light of recent science, recognizing in crystallization the morphological element.

Schopenhauer.—Of the other German philosophers immediately following Kant, there is only one who calls for notice here, namely, Arthur Schopenhauer. This writer, by his conception of the world as will which objectifies itself in a series of gradations from the lowest manifestations of matter up to conscious man, gives a slightly new shape to the evolutional view of Schelling, though he deprives this view of its optimistic character by denying any co-operation of intelligence in the world-process. In truth, Schopenhauer's conception of the world as the activity of a blind force is at bottom a materialistic and mechanical rather than a spiritualistic and teleological theory. Moreover, Schopenhauer's subjective idealism, and his view of time as something illusory, hindered him from viewing this process as a sequence of events in time. Thus he ascribes eternity of existence to species under the form of the "Platonic ideas." As Ludwig Noiré observes,[1] Schopenhauer has no feeling for the problem of the origin of organic beings. He says Lamarck's original animal is something metaphysical, not physical, namely, the will to live. "Every species (according to Schopenhauer) has of its own will, and according to the circumstances under which it would live, determined its form and organization,—yet not as something physical in time, but as something metaphysical out of time."

Von Baer.—Before leaving the German speculation of the first half of the century, a word must be said of Von Baer, who not only reached those ideas of individual and serial development which are at the basis of the modern doctrine of organic evolution, but who recognized in the law of this development the law of the universe as a whole. In his *Entwickelungsgeschichte der Thiere* (p. 264) he distinctly tells us that the law of growing individuality is "the fundamental thought which goes through all forms and degrees of animal development and all single relations. It is the same thought which collected in the cosmic space the divided masses into spheres, and combined these to solar systems; the same which caused the weather-beaten dust on the surface of our metallic planet to spring forth into living forms" Von Baer thus prepared the way for Mr Spencer's generalization of the law of organic evolution as the law of all evolution.

Early Half of the Century—English Writers.—We may here conveniently break off our review of German evolutionists, returning to the writers of the latter part of the century presently The thinkers outside Germany who in the first half of the century contributed elements to the growth of the idea of evolution are too unimportant to detain us here In the English philosophy of this period questions of cosmology play a very inconsiderable part. The development of the analytical psychology, especially by the two Mills, may be referred to. Also an allusion may be made to the discussions respecting the nature of cause Among these Sir W. Hamilton's definition of cause (*Lectures on Metaphysics*, ii. 377) is specially interesting as appearing to tell against the production of mind out of matter.

French Writers—Comte.—In France during this period the name of Auguste Comte is the only one that need arrest our attention. Comte's principles of positivism, which restricted all inquiry to phenomena and their laws, are said by his recent disciples to exclude all consideration of the ultimate origin of the universe, as well as of organic life. Yet though Comte did not contribute to a theory of cosmic organic evolution, he helped to lay the foundations of a scientific conception of human history as a natural process of development determined by general laws of human nature together with the accumulating influences of the past. Comte does not recognize that this process is aided by any increase of innate capacity; on the contrary, progress is to him the unfolding of fundamental faculties of human nature which always pre-existed in a latent condition; yet he may perhaps be said to have prepared the way for the new conception of human progress by his inclusion of mental laws under biology.

Italian Writers.—In Italy during this period there meet us one or two thinkers who concern themselves with the interpretation of the world-process. Ant. Rosmini follows Campanella in endowing chemical atoms with sensibility and life, and he bases the hierarchy of beings in the universe on the different degrees of this sensibility. At the same time he follows Bruno in speaking of the totality of the world as an organism endowed with a soul which individualizes itself in the innumerable existences of the universe. Spontaneous generation is to Rosmini a necessary consequence of his theory of a universal life. Other Italian writers adopt Hegel's notion of the world as a self-evolution of the idea. Of these it is enough to mention Terensio Mamiani, who gives an optimistic turn to his conception of evolution by viewing it as a progressive union of the finite with the infinite. Mamiani argues against Darwin, and holds that all specific forms are fixed for all time.

Modern Doctrine of Evolution.—We now approach the period in which the modern doctrine of evolution in its narrow sense has originated. This doctrine is essentially a product of scientific research and speculation. It is a necessary outcome of the rapid advance of the physical sciences. Its final philosophic form cannot yet be said to be fixed. It may be defined as a natural history of the cosmos including organic beings, expressed in physical terms as a mechanical process. In this record the cosmic system appears as a natural product of elementary matter and its laws. The various grades of life on our planet are the natural consequences of certain physical processes involved in the gradual transformations of the earth. Conscious life is viewed as conditioned by physical (organic and more especially nervous) processes, and as evolving itself in close correlation with organic evolution. Finally, human development, as exhibited in historical and prehistorical records, is regarded as the highest and most complex result of organic and physical evolution. This modern doctrine of evolution is but an expansion and completion of those physical theories which opened the history of speculation. It differs from them in being grounded on exact and verified research. As such, moreover, it is a much more limited theory of evolution than the ancient. It does not concern itself (as yet at least) about the question of the infinitude of worlds in space and in time. It is content to explain the origin and course of development of the world, the solar or, at most, the sidereal system which falls under our own observation. It would be difficult to say what branches of science had done most towards the establishment of this doctrine. We must content ourselves by referring to the progress of physical (including chemical) theory, which has led to the great generalization of the conservation of energy; to the discovery of the fundamental chemical identity of the matter of our planet and of other celestial bodies, and of the chemical relations of organic and inorganic bodies; to the advance of astronomical speculation respecting the origin of the solar system, &c.; to the growth of the new science of geology which has necessitated the conception of vast and unimaginable periods of time in the past history of our globe, and to the rapid march of

---

[1] *Der monistische Gedanke*, p. 238 s.

the biological sciences which has made us familiar with the simplest types and elements of organism; finally, to the recent development of the science of anthropology (including comparative psychology, philology, &c.), and to the vast extension and improvement of all branches of historical study.

English Writers—Darwin.—The honour of working out this theory of evolution on a substanial basis of fact belongs to England. Of the writers who have achieved this result Mr Darwin deserves the first notice. Though modestly confining himself to the problem of accounting for the evolution of the higher organic forms out of the lower, Mr Darwin has done much to further the idea of a gradual evolution of the physical world. The philosophic significance of the hypothesis of natural selection, especially associated with Mr Darwin, is due, as Professor Helmholtz points out, to the fact that it introduces a strictly mechanical conception in order to account for those intricate arrangements known as organic adaptations which had before been conceived only in a teleological manner. By viewing adaptations as conditions of self-preservation, Mr Darwin is able to explain how it is that the seemingly purposeful abounds in organic nature. In so doing he has done much to eliminate the teleological method from biology. It is true that, in his conception of seemingly spontaneous variations and of correlations of growth, he leaves room for the old manner of viewing organic development as controlled by some internal organizing principle. Yet his theory, as a whole, is clearly a heavy blow to the teleological method. Again, Mr Darwin has greatly extended the scope of mechanical interpretation, by making intelligible, apart from the co-operation of intelligent purpose, the genesis of the organic world as a harmonious system of distinct groups, a unity in variety, having certain well-marked typical affinities. How greatly this arrangement has helped to support the idea of an ideal plan, we have had occasion to observe. Mr Darwin in his doctrine of the organic world as a survival refers this appearance of systematic plan to perfectly natural causes, and in so doing he gives new meaning to the ancient theory that the harmony of the world arises out of discord. Once more, Mr Darwin's hypothesis is of wide philosophic interest, since it helps to support the idea of a perfect gradation in the progress of things. The variations which he postulates are slight, if not infinitesimal, and only effect a sensible functional or morphological change after they have been frequently repeated and accumulated by heredity.

Mr Darwin's later work, in which he applies his theory of the origin of species to man, is a valuable contribution to a naturalistic conception of human development. The mind of man in its lowest stages of development is here brought into close juxtaposition to the animal mind, and the upward progress of man is viewed as effected by natural causes, chief among which is the action of natural selection. Mr Darwin does not inquire into the exact way in which the mental and the bodily are connected. He simply assumes that, just as the bodily organism is capable of varying in an indefinite number of ways, so may the mental faculties vary indefinitely in correspondence with certain physical changes. In this way he seeks to account for all the higher mental powers, as the use of language and reason, the sentiment of beauty, and conscience.

Finally, Mr Darwin seeks to give a practical and ethical turn to his doctrine. He appears to make the end of evolution the conscious end of man's action, since he defines the general good as "the rearing of the greatest number of individuals in full health and vigour, and with all their faculties perfect under the conditions to which they are subject." Further, in his view of the future of the race, Mr Darwin leans to the idea that the natural process which has effected man's first progress must continue to be an important factor in evolution, and that, consequently, it is not well to check the scope of this process by undue restraints of population, and a charitable preservation of the incompetent.

A. R. Wallace.—Mr A. R. Wallace, who shares with Mr Darwin the honour of establishing the doctrine of natural selection, differs from the latter in setting much narrower limits to the action of this cause in the mental as well as the physical domain. Thus he would mark off the human faculty of making abstractions, such as space and time, as powers which could not have been evolved in this way. Mr Wallace leans to the teleological idea of some superior principle which has guided man in his upward path, as well as controlled the whole process of organic evolution. This law is connected with the absolute origin of life and organization.

Herbert Spencer.—The thinker who has done more than any one else to elaborate a consistent philosophy of evolution on a scientific basis is Mr Herbert Spencer. First of all he seeks to give greater precision to the conception of this universal process. Evolution is a change from the homogeneous to the heterogeneous, from the indefinite or undetermined to the definite or determined, from the incoherent to the coherent. Again, Mr Spencer seeks to show that the causes of evolution are involved in the ultimate laws of matter, force, and motion, among which he gives great prominence to the modern doctrine of the conservation of energy. Thus the rationale of the process shapes itself to Mr Spencer as a distinctly mechanical problem. He sets out with the assumption of a limited mass of homogeneous matter acted upon by incident forces, and seeks to show how, by help of two laws,—namely, the instability of the homogeneous, and the multiplication of the effects of any such incident force,—the process known as evolution is brought about. This process is illustrated in the genesis of the solar system,[1] for the explanation of which Mr Spencer makes use of the nebular hypothesis, in the formation of our planet, as well as the development of organic and mental life. Mr Spencer does not, however, conceive of this process of evolution as unlimited in time. As in the development of the individual organism, so in that of organic beings as a whole, of the earth, and of the solar system, there is a conflict between the forces of which the action is integrating or consolidating and those of which the action is disintegrating. The process of evolution always tends to an equilibration between these conflicting forces and ultimately to a dissolution of the products of evolution. Thus the solar system is a moving equilibrium which is destined to be finally dissipated into the attenuated matter out of which it arose. Mr Spencer thus approaches the earliest theories of cosmic evolution when he tells us (*First Principles*, p. 482) that vast periods in which the forces of attraction prevail over those of repulsion, alternate with other vast periods in which the reverse relation holds. The mechanical theory of evolution thus laid down in the *First Principles* is applied in Mr Spencer's later works to the explanation of organic, mental, and social evolution. The full explanation of the processes of inorganic evolution finds no place in the writer's system: Mr Spencer seeks, in the *Principles of Biology*, to conceive of organic bodies and their actions in mechanical terms. Life is regarded as essentially a correspondence of internal actions in the organism to external actions proceeding from the environment, and the object of Mr Spencer's volumes is to explain on mechanical principles the growth of this correspond-

---

[1] The writer suggests that the whole sidereal system may be the result of a similar process.

ence from the lowest to the highest. He excludes all consideration of the question how life first arose, though it is clear that he regards the lowest forms of life as continuous in their essential nature with sub-vital processes. It is in the later volumes, dealing with mental and social evolution, that Mr Spencer's exposition becomes most interesting to the student of philosophy. In the *Principles of Psychology*, he seeks to deal with mind as an aspect or correlate of life which begins to manifest itself when the process of adjustment to environment, in which all life consists, reaches a certain degree of complexity. Mr Spencer indulges in no hypothesis respecting the universal co-existence of sentience with matter and force. He thinks we must accept the distinctions which common-sense has established, and so limit feeling or consciousness to organic beings endowed with a nervous system. Thus, just as he does not seek to explain the first appearance of life as a whole, so he does not seek to explain the first dawn of mental life. Mr Spencer's unit of consciousness is the blurred undetermined feeling which answers to a single nervous pulsation or shock. Assuming this he seeks to trace the gradual evolution of consciousness. Sensations arise by a number of rapid successions of such elementary feelings variously combined, and all more composite states of mind arise by a similar process of combination of these feelings. Thus mental evolution is a progressive composition of units of feeling in more and more complex forms, and united by more complex relations. Mr Spencer's conception of mind thus excludes all fundamental distinctions of faculty. Instinct, memory, reason, the emotions and volitions, alike develop themselves in divergent directions out of a common elementary process. They are, moreover, all related to one and the same biological process, being incidental accompaniments of the actions by which the organism responds and adjusts itself to the forces of its environment. According as those actions are more complex, and consequently less immediate, the mental actions which accompany them vary in character from reflex action up to deliberate volition, from the most simple presentative feeling or sensation up to the most complex representative and re-representative feeling or emotion. It would be impossible to point to all the applications which Mr Spencer has made of his principle of evolution to the questions of psychology. We may just mention among other points of interest his attempt to explain the innate intuitions of space, moral right, &c, as mental dispositions handed down from progenitors and embodying the uniform experience of many generations, his ingenious endeavour to account for the coincidence between pleasures and pains and actions beneficial and injurious to the organism, and his conception of the æsthetic interest as a growth out of the play-impulse, which is the tendency of activities that have become developed beyond the immediate needs of existence to vent themselves.

Mr Spencer's elaboration of the subject of social evolution has not been carried far enough for us to understand the full bearing of his ideas. Yet the fundamental conceptions are given us. The writer regards society, after the analogy of an individual organism, as possessing a number of various structures or organs and functions, and as tending to evolve itself by a series of adjustments to its environment, physical and social. All ideas and institutions display this process of evolution no less than societies as wholes. History is to our author essentially the record of this social evolution. It is to be observed that Mr Spencer attributes to society a certain spontaneous tendency to evolution apart from natural selection. He looks on progress as a gradual process of self-adaptation of man to the conditions of his environment, and anticipates an age when this adjustment will be complete and human happiness perfect. In this respect Mr Spencer's conception of man's history and destiny wears an optimistic tinge when compared with that very vaguely shadowed forth by Mr Darwin.

To Mr Spencer, as to Mr Darwin, the doctrine of evolution seems to supply the end of conduct. He conceives of morality as essentially an observance of the laws of life, the individual and the collective. At the same time, since Mr Spencer regards the moral sense as a growth out of feelings of pleasure and pain (racial experiences), closely identifies the ends of life and happiness, and distinctly teaches that social evolution or progress makes for an increase of happiness, his ethical doctrine does not materially differ from that of utilitarianism.

So far we have said nothing respecting the metaphysical basis which Mr Spencer seeks to give to his doctrine of evolution. It is generally agreed that this does not really belong to his doctrine of evolution itself. Mr Spencer is a thorough-going realist. From his general scheme of evolution one would be prepared to find him avowing himself a materalist. Yet he seeks to avoid this conclusion by saying that it is one unknowable reality which manifests itself alike in the material and in the mental domain. At the same time, this unknowable is commonly spoken of as force, and in many places seems to be identified with material force. Mr Spencer makes little use of his metaphysical conception in accounting for the evolution of things. He tells us neither why the unknowable should manifest itself in time at all, nor why it should appear as a material world before it appears under the form of mind or consciousness. Indeed Mr Spencer's doctrine of evolution cannot be said to have received from its author an adequate metaphysical interpretation. The idea of the unknowable hardly suffices to give to his system an intelligible monistic basis. In truth, this system seems in its essence to be dualistic rather than monistic.

Metaphysical Interpretation—Professor Clifford.—Of the very few who have dealt with the metaphysical interpretation of the scientific doctrine of evolution, Professor Clifford deserves special notice. In an essay entitled "On things in themselves," published in *Mind* (No. ix.), as well as in other and earlier papers, Mr Clifford, starting from the basis of empirical idealism which asserts that material objects are nothing but states of consciousness, argues that the reality answering to them is in all cases something mental. Thus all existence—including what we call minds as well as bodies—consists in aggregates of elementary "mind stuff," the elements themselves corresponding to Mr Spencer's units of feeling. The writer expressly argues that his idea of a continuity of mental existence throughout the physical (phenomenal) world is the direct consequence of the doctrine of evolution. This theory is curious as providing a monistic and quasi-spiritualistic conception of evolution, which is at the same time a mechanical one.

Problems of Organic Evolution.—G. H. Lewes.—Among the writers who have worked on the lines laid down by our two great evolutionists, a high place must be given to Mr G. H. Lewes, who in his biological and psychological writings, and more especially the *Problems of Life and Mind*, adopts a view of the relations of mind and life or organization closely resembling in its essentials that of Mr Spencer. To Mr Lewes consciousness is but a more complex form of mental life which is correlated with the actions of all the nervous centres, its lowest form being sentience. He appears to look on mind in all its grades as but the other side or face of the bodily processes which it accompanies. Yet he has not so far made use of this monistic conception in explaining the gradual evolution of conscious mental life. Indeed, though Mr Lewes's writings are pervaded with the idea of organic evolution, his discussion of the nature and laws of organism in his last volume, *The Physical Basis of Mind*, might seem ever and again, by its sharp separation of organic and inorganic (mechanical) processes, to tell against the supposition of an evolution of life out of inorganic matter.

J. J. Murphy.—The question of the genesis of life and mind receives a peculiar treatment in Mr J. J. Murphy's *Habit and Intelligence.* In this work the teachings of the evolutionists are largely accepted, while an attempt is made to reconcile these with a teleological view of nature. The process of inorganic and of organic nature is each recognized as one of evolution; but while the former is viewed as the result of mechanical principles, the latter is said to imply an intelligent or formative principle as well. Mechanical principles do indeed operate in organisms; this is the region of habit; but over and above this, vital processes involve a controlling intelligence. The author adopts the hypothesis that the Creator endowed vitalized matter at the first with intelligence under the guidance of which it organizes itself. Evolution is largely the result of this vital intelligent principle, only a small part being attributable to mechanical causes, such as natural selection.

Evolution and Psychology.—The speculations of Mr Darwin and Mr Spencer have had a powerful influence on recent English psychology, which promises to become comparative, not only in the sense of including a comparison of ethnological mental characteristics, but also in the wider sense of bringing human intelligence into relation to that of the lower animals. Among writers who have laboured in this construction of a theory of mental evolution, mention must be made of the late Mr D. Spalding.[1] Again, Mr Chauncey Wright, in his remarkable essay *The Evolution of Self-Consciousness* (printed in a collection of his works), made a brilliant attempt to represent man's highest mental operations as evolved out of simple processes common to man and the lower animals. The influence of evolutional ideas is further traceable in the latest work of Mr A. Bain (*Emotions and Will*, 3d edition), and in the works of Dr Maudsley and other living psychologists. The relation of the doctrine of evolution to psychology is handled in an essay by Mr J. Sully (*Sensation and Intuition*, ch. i.).

Anthropology.—The application of the doctrine of evolution to the question of man's origin and development has engaged the attention of a number of writers. In a sense all recent anthropologists and historians of culture may be said to have worked in this direction. Special attention must, however, be called to those writers who have sought directly to apply the fundamental ideas of evolution to these problems. Mr Bagehot's *Physics and Politics* is remarkable as illustrating the employment of the doctrine of natural selection in order to explain certain aspects of political progress. Still more important is the contribution made by Mr Fiske, in his *Cosmic Philosophy*, to the theory of man's origin and development. Mr Fiske's work is a full exposition of Mr Spencer's doctrine of evolution. In addition to this it contains interesting speculations respecting the steps by which man's distinguishing intelligence and sociality were first acquired and afterwards developed.

Relation to Ethics.—The application of the doctrine of evolution to our ethical and religious ideas has engaged a number of writers. In Mr A. Barratt's *Physical Ethics* the development of man's moral sense out of feelings of pleasure and pain is traced in connexion with his organic and social evolution on which it is said to depend. By conceiving of all matter as endowed with sensibility (pleasure and pain), Mr Barratt is able to connect man's moral evolution with the whole process of organic and of cosmic evolution. The idea of a natural growth of the moral sense out of simpler impulses and instincts may also be frequently found in contemporary English literature. On the other hand, this consequence of the evolution theory has been strenuously opposed in the interests of a thoroughgoing intuitive ethics as, for example, by Mr St George Mivart, in his work, *The Genesis of Species*, and by Mr R. H. Hutton.[2]

Again the question has been discussed whether the doctrine of evolution contributes towards the determination of the end or standard of morals. Mr Sidgwick has shown that it cannot well do this merely by proving how the moral sense has arisen. It is easy, however, to look upon the natural process as a tendency towards an end, and to conceive of our conscious actions as being bound by this tendency, so that the highest end of our existence must be to co-operate with the natural forces. This idea pervades a good deal of contemporary literature. It appears with special distinctness in the writings of Professor Clifford[3] and Mr F. Pollock[4] and in the able work of Miss Simcox on *Natural Law.* On the other hand, Mr H. Sidgwick[5] has made an elaborate study of the bearings of evolution on the ethical end, and reduces these to insignificant proportions. This writer criticises Mr Darwin's definition of the general good, and argues that the idea of a mere quantity of life is inadequate to supply a definite end of conduct. Nevertheless life (ζῆν) is the prime condition of wellbeing (εὖ ζῆν), and so far the evolutionist is right in making life a secondary aim. The differentia of wellbeing, however, requires further interpretation, which can only be supplied by the utilitarian principle. At the same time the doctrine of evolution guides us in the pursuit of this ultimate end, in so far as increase of happiness accompanies organic progress, or elevation in the scale of existence. Mr Sidgwick further points out how little the doctrine of evolution assists the utilitarian in dealing with social and political problems.

Relation to Religion.—The bearing of the doctrine of evolution on religion has formed the theme of a host of minor writings. On the whole, Mr Darwin's doctrine has been said (as it is by the author himself), not only to be compatible with the idea of an original creation of the world, but to supply a higher conception of the divine attributes than the hypothesis of special creations; on the other hand, Mr Spencer's doctrine, distinctly excluding as it does the idea of creative activity, has called forth strong opposition from a number of theological writers, among whom the most powerful is certainly Professor Martineau.[6] In connexion with the subject of the relation of the evolution doctrine to religious ideas, it is worthy of remark that this doctrine appears to be serving as the starting-point for a new quasi-religious conception of nature. The idea of the cosmos and its forces as the author and source of our being easily lends itself to a kind of pantheistic sentiment towards nature. In Mr Spencer's own writings it is the

unknowable force ever sustaining the evolving worlds which is said to excite this emotion. In the work of Miss Simcox already referred to, and the occasional papers of Professor Clifford,[1] it is rather visible nature itself which is thus elevated into a religious object.

Recent French Writers.—The French thought of the latter part of the century offers us but little in the way of a discussion of the problems with which evolution has to do. The activity of biological speculation appears to have influenced but a few philosophic minds. Naturalists have of course discussed the doctrine of evolution, and one of these, E. Quinet, in his work *La Creation*, seeks to apply Mr Darwin's theory to problems of art and morality. Thus the ideal of art should, he thinks, be based on the doctrine of evolution, and be "the presentment of superior forms which slumber still in the bosom of actual things," or the embodiment of "the possible development of the human type in the progress of nature and man." So the ideas of duty and virtue are to be based on this doctrine. Man is the only animal which can retrograde, and evil is retrogression in the path laid down by nature. It is an anachronism, or a revolt of man against himself. Among philosophic writers proper, the first place must be given to M. Th. Ribot, who, in his sympathetic exposition of Mr Spencer's doctrine of evolution in his *Recent English Psychology*, and in his interesting psychological study *On Heredity*, shows himself to be deeply pervaded with the new ideas, more especially in their bearing on mental phenomena. M. Ribot regards mental evolution as depending on material, but adds that the recognition of this connexion between the two domains of phenomena is compatible with idealism no less than with materialism. He would eliminate the conception of progress as a subjective one, and says that the idea of historical progress must be taken up into that of an objective cosmic process. M. Ribot makes many interesting applications of his law of mental heredity, which he rightly regards as a factor in mental evolution; as, for example, when he speaks of free-will as expressing the fixed personal factor in conduct,—namely, the inherited character. Of other philosophic writers who have been affected by the English doctrine of evolution, it is sufficient to name the late Léon Dumont, who was one of the first in France to apply the ideas of Mr Darwin and Mr Spencer to problems of psychology; and Professor A. Espinas, who in his work *Des Sociétés Animales* aims at furthering the theory of man's psychical derivation from lower types of mind. A writer who appears to be in a less distinct manner influenced by the idea of evolution is M. Taine, in whose psychological and historical studies the indirect effect of a study of English evolutionists is traceable. On the other hand, the older and teleological view of the world has not wanted its defenders. The most signal supporter of this direction, in the face of the doctrine of evolution, is M. Paul Janet, who, in his earlier work *Le Materialisme Contemporain*, and still more in his recent publication *Les Causes Finales*, draws a sharp line between the regions of the organic and the inorganic, and maintains that the complex arrangements of the latter are only explicable by means of teleological conceptions.

Recent German Writers—Materialists.—In Germany the recent progress of speculation, since the time of the great systems has exhibited a decided bent towards the problems which group themselves around the doctrine of evolution. First of all the efforts of the materialists directly tended to the formation of a consistent doctrine of cosmic evolution. Their earlier writings appeared just before the epoch-making publication of Mr Darwin, but the ideas of the latter have been incorporated in their later publications. In Moleschott's *Der Kreislauf des Lebens* the whole order of things is conceived as a continual flux and exchange of material elements, which accounts for all psychic life no less than for bodily life, and of which man, equally with the lower animals, is a temporary product. L. Büchner has sought, in his work on *Man* and his *Six Lectures on the Darwinian Theory*, to defend the new doctrine of organic evolution as a necessary factor in the materialistic conception of the world. The latter work connects Darwinism with the whole history of materialism. The former is a somewhat feeble attempt to attach man's ideal aims in the future to the evolutionist's conception of his past history. The writer appears to think that something equivalent to the process of natural selection is to effect man's future progress, but the idea is not presented with any definiteness or precision.

Combination of Mechanical and Teleological View of Evolution.—After the materialists we come to a number of writers, who, under the influence of advancing physical and physiological science, have sought to construct a mechanical conception of the order of the world. Some of these have contented themselves with sketching a natural history of the cosmos, others have connected their mechanical conception with peculiar philosophical ideas.

Czolbe.—A curious combination of the mechanical and teleological conceptions of the world is to be met with in the system of Czolbe. In his first works, *Die neue Darstellung des Sensualismus* and *Die Entstehung des Selbst-Bewusstsein's*, Czolbe regards the world as a product of elementary matter and organic forms both of which are eternal. According to this view, sensation and consciousness are products of particular combinations of movements (circular). To these two original principles he adds, later on, feelings and sensations themselves, which exist in a latent state throughout space, and form a kind of world-soul. Still later, he finds the substantial support of atoms and sensations alike in space, in which feelings are located no less than the material elements. To Czolbe our visible world, together with conscious minds, is thus a mosaic formed out of these elements, which group themselves according to mechanical laws in bodies and conscious minds. He thus adopts a theory of natural evolution which evades the difficulty of explaining the organic as a product of the inorganic, and mind as a product of matter. But he only achieves this by assuming the eternity of all organic forms, and by conceiving of the elementary sensations as themselves spatial or "extensional." Though the mechanical view of the world-order is most prominent in Czolbe, he combines with this a teleological and optimistic view, according to which all things make for the greatest possible perfection of conditioned happiness in every sentient creature.

G. T. Fechner.—Another writer who combines the mechanical view of the world with a curious metaphysical system is G. T. Fechner. Passing by his earlier works, in which he develops his idea of the world as a gradation of souls (including those of plants, an earth-spirit, &c.), we may best turn to his later work *Einige Ideen zur Schöpfungs- und Entwickelungs- Geschichte der Organismen.* Fechner takes a thoroughly mechanical view of the difference between organic and inorganic matter. But by help of this very difference he seeks to prove that the latter is a product of the former, and not conversely. The great law which determines the evolution of the world is the tendency to greater and greater stability, which law at once supplies a mechanical and a teleological conception of the universe. Organic bodies differ from inorganic in that their molecules are in a less stable condition than those of the latter. Hence we must suppose that the original source of the

---

[1] See especially an article on "Cosmic Emotion," in the *Nineteenth Century*, October 1877.

material world is an organism, namely, a primitive "cosmorganic" condition of our earth. This primitive matter has gradually differentiated itself into the regions of the organic and the inorganic, and the former again into the animal and vegetable kingdoms. Consciousness was breathed into the cosmorganic matter by the Creator and so pressed out, as though from the bellows of an organ, into all living creatures. This process of evolution is directed towards an end, namely, the greatest possible degree of mutual adaptation of parts, or the most stable condition; and conscious action is but the subjective side of this tendency.[1]

Lotze.—The mechanical view of the world, as wrought out by modern science, is fully recognized and yet surmounted in the cosmological doctrine put forth by Hermann Lotze in his *Mikrokosmus.* Lotze defends the mechanical method as applicable to all departments of phenomena, and insists on this way of viewing organic processes. At the same time he holds that the mechanical interpretation of nature is limited at every point. The inadequacy of this view may be seen in the attempt to apply it to the question of the genesis of the world and its order. On the one hand, Lotze accepts the teachings of modern speculation respecting the evolution of the solar system, the genesis of the organic out of the inorganic, the continuity of man with the lower animal world; and his exposition and defence of this idea of evolution as the result of mechanical laws is extremely able and interesting. Again, Lotze seeks to bridge over the gulf between material and spiritual evolution by bringing human development into close relation to the processes of nature as a whole. Yet, while thus doing justice to the mechanical conception of the gradual genesis of the world, Lotze strenuously affirms the limitations of this kind of explanation. In the first place, he maintains that the mechanical processes themselves cannot be understood except by help of ideas respecting the real internal nature of the elements concerned. This nature he describes as life, and thus he endows all parts of matter with feeling (though he distinctly rejects Czolbe's idea of a world-soul which includes these feelings). In this internal activity Lotze finds a teleological element, viz., a striving towards self-preservation and development. This idea he seeks to blend with that of mechanical relations among the elements, so as to make the whole upward process of physical evolution the product of purposeful impulses. Thus the first genesis of organisms is represented as a combination of elements (accidentally meeting), through which there is effected a summation of the separate ends of the elements, to a purposeful equilibrium of a composite whole.[2] This may be called the first stage of his teleology. In addition to this, Lotze looks at the world-process as a gradual unfolding of a creative spiritual principle, which he sometimes figuratively describes as the world-soul, more commonly, however, as the infinite substance. This assumption, he says, is necessitated by the very process of cosmic evolution, the absolute beginning and end of which we are wholly unable to conjecture. However far back the evolutionist may go he always has to assume some definite arrangement of parts,—some general laws of action of which he can give no account. The conception of the atomists, that in the beginning of things there was an indefinite number of possibilities, is unthinkable, and the modern doctrine of evolution, by conceiving of the existing world as a survival of certain forms from among many others actually produced, but lacking in the conditions of stability, plainly makes no such absurd supposition. Hence, there must always be a certain order to be accounted for, and science is wholly inadequate to effect this explanation. This conducts to a teleological view of the world-process, as directed by mind towards some end which we cannot distinctly recognize. Lotze's criticisms of previous attempts to formulate the end of the world-process are not the least valuable part of his discussion of the problems of evolution. He shows that neither the notion of a progressive effort towards the highest unfolding of mental life, nor that of an impulse towards the greatest variety of manifestations of one and the same fundamental form, adequately represents the order of organic forms. Here Lotze shows again a due recognition of the mechanical aspect of the world-process, and argues that the evolution of the organic world is no immediate consequence of the self-evolving ideas, but only the form in which the commands of these ideas are capable of being realized on our earth,—that is to say, with our terrestrial conditions. A somewhat similar view of cosmic and organic evolution, as at once a mechanical and a teleological process, is to be found in Ulrici's *Gott und die Natur.*

Mechanical Doctrines of Evolution.—Over against these attempts to carry up a mechanical conception of evolution into a teleological must be set a number of works which content themselves, in the spirit of positive science, with expounding a doctrine of evolution on a strictly mechanical basis. Of these we may first mention C. Radenhausen (Isis), who, in his interesting work *Der Mensch und die Welt,* expounds the idea of a gradual evolution of the solar system, the earth, and organic life. In the growth of the individual man the past evolution of the world is represented. A temperate statement of the doctrine of modern evolution is to be found in Dr Ch. Wiener's volume *Die Grundzüge der Weltordnung.* The problems of the origin of organic life and of the genesis of the nervous system are both said to be as yet insoluble. With this may be compared another interesting presentation of the doctrine of evolution,—namely, H. J. Klein's *Entwickelungsgeschichte des Kosmos.* The mechanical causes of evolution are clearly set forth in a work of the Herbartian C. S. Cornelius, *Ueber die Entstehung der Welt.* Cornelius argues against Czolbe's hypothesis of the past eternity of organic life. Organisms first arose under some quite special physical conditions. A very curious feature in this volume is the criticism of Mr Darwin's doctrine of descent, which is said to involve mystical ideas, &c.

Lange.—Among later works touching on the problems of evolution the *History of Materialism* of Lange deserves mention here. Lange accepts the modern hypothesis of evolution, and justifies the mechanical conception of its various stages. It is true that in his criticism of Mr Darwin's theory he assumes some internal formative principle (as held to by Nageli and Kölliker) as supplementary to the factor of utility emphasized by Mr Darwin. Yet he does not appear to regard this process as other than a mode of mechanical action. Lange's greatest difficulty in view of a consistent materialistic doctrine of evolution is to explain the genesis of conscious life. The difficulty of the atomistic theory, even when we add a rudimentary sensibility to the elements, is to determine "where and how the transition is effected from the manifoldness of the collisions of the atoms to the unity of sensation." Lange supplements his mechanical view of the world by the Kantian conception of the adaptation of the world by reason of its generalities or uniformities to

---

[1] In a new edition of his work Fechner avows himself a convert to Mr Darwin's theory of organic descent.

[2] Lotze does not express himself very clearly with respect to the question of the first genesis of mind. In the *Mikrokosmus* (ii. p. 33) he appears to find the "sparks" of mental life in the atoms which he here conceives of after the manner of Leibnitz's monads. In another place, however (*Medicinische Psychologie,* pp. 164, 165), Lotze tells us that mind is the direct product of the original creative activity, which is stimulated to create by the stimulus involved in the formation of the physical germ.

our intelligence. He argues, with Lotze, that in seeking to frame a theory of physical evolution we must always assume, over and above the eternal atoms, a special initial arrangement of these, without which the order of events would be inconceivable. This modest kind of teleology (he says) is not only not opposed to Mr Darwin's doctrine; it is its necessary pre-supposition. "The formal purposefulness of the world is nothing else than its adaptation to our understanding." Lange seems further disposed to accept Kant's theory of organism as manifesting objective purpose, though he will not allow that this explains anything, all explanations being by way of the principle of mechanical causation.

Noiré.—In Ludwig Noiré we have a writer who accepts all the teaching of scientific evolutionists, and at the same time seeks to give to the doctrine a metaphysical and monistic interpretation. In his two volumes *Die Welt als Entwickelung des Geistes* and *Der Monistische Gedanke*, Noiré assumes the existence of elementary atoms or "monads" endowed with the twofold properties of motion and sensation. Time and space are not simply forms of intuition, but forms of appearance (*Erscheinungsformen*) of these fundamental properties. The process of evolution from the simple to the complex, has its ground in the latter property, sensation, which gives its direction to motion (which latter is unchangeable in amount), and which involves a tendency or impulse to further differentiation. The purposefulness of the process of evolution is due to its being the work of a mental principle (sensation). The formation of inorganic bodies is the preliminary step in the process, and involves an obscure mode of consciousness. The genesis of consciousness is said to be effected by means of a certain mode of collision among the atoms, though this point is not made very clear. Noiré's doctrine of evolution appears to waver somewhat between a mechanical theory (atoms endowed with sensibility, but acting according to strictly mechanical laws) and a distinctly spiritualistic and teleological doctrine, such as that of Schelling and Hartmann.

Hartmann.—The writings of E. von Hartmann have a special interest, as illustrating how Mr Darwin's doctrine of organic development is regarded from the point of view of a thorough-going metaphysical teleology. To Hartmann the world is a manifestation in time—which is real as applying to the activities of this principle—of an ontological principle, styled the unconscious, which is at once will and intelligence. The process of evolution, from the simplest material operations up to conscious human actions, depends on the progressive domination of will, which is the blind force, and answers to the mechanical aspect of the world, by intelligence, which gives to this force form and direction, and answers to the logical and teleological aspect of the world. The end of the process for which this unconscious makes is not, as Hegel says, self-consciousness, but non-existence, to which consciousness is the immediate precondition. Hartmann has devoted a separate volume to Mr Darwin's theory (*Wahrheit und Irrthum im Darwinismus*), in which he shows himself disposed to accept the principle of natural selection as the mechanical means which the unconscious makes use of in order to effect a certain amount of the upward organic progress towards which it strives.

Influence of Darwinism in Germany.—We will close the sketch of the recent German discussion of evolution-problems, and so our historical review as a whole, by a brief reference to the philosophic and quasi-philosophic literature which has sprung up in Germany under the direct influence of Mr Darwin's doctrine. It is not a little curious that, of the two great English evolutionists, the one who has most stimulated German philosophical thought is the writer who has confined himself to questions of natural science, while the writer who has built up the idea of organic descent into a complete cosmological theory is only now beginning to be known in that country.

(*a*) *Darwinism and Methodology.*—First of all, then, a bare allusion must be made to certain criticisms of Mr Darwin's biological hypothesis as legitimate instruments of a sound natural philosophy. It may surprise some English readers to learn that the doctrine of the descent of species by natural selection has been denounced in Germany as partaking of the vices of a spurious and teleological natural philosophy. The writer who has taken most pains to show up the philosophic unsoundness of Mr Darwin's procedure is A. Wigand (*Der Darwinismus und die Naturforschung Newton's und Cuvier's*, see especially vol. ii.)

(*b*) *Darwinism and Cosmology.*—Turning now to the influences of Darwinism on German thought, we may best begin with the more circumscribed branches of speculation. Physical speculation in Germany is being slowly affected by Mr Darwin's theory. A curious example of this is to be met with in a little work by Dr Karl du Prel, entitled *Der Kampf ums Dasein am Himmel.* This work is of real philosophic interest as illustrating how Mr Darwin's way of conceiving self-preservation, as the effect of natural superiority in respect of adaptability to the conditions of existence, may be extended beyond the organic world to the cosmos as a whole. Du Prel regards the cosmic bodies as analogous to competing organisms, space standing for the means of existence for which they struggle, and the force of attraction and the fitness of the body's movement in relation to those of other bodies representing organic efficiency. Those bodies which have these advantages survive, whereas those which lack them are extinguished either by being dissipated or fused with other bodies.

(*c*) *Darwinism and Anthropology.*—Passing by the biological speculations respecting the ultimate origin of living forms to which Darwinism has given rise, we pass to those aspects of anthropology which have a peculiar philosophic interest. In a sense it may be said that Mr Darwin's speculations, especially as carried out by himself in his *Descent of Man*, have powerfully influenced the whole of recent anthropological speculation; for writers like A. Bastian (*Schöpfung und Entstehung* and *Der Mensch in der Geschichte*), who still hold to the doctrine of the fixity of species, and the essential difference between human history and sequences of natural events, are now the exceptions. With anthropology, we must connect that new science of comparative human psychology (*Völkerpsychologie*) which has sprung up of late years.

Origin of Language.—Of the problems which fall under this science of man's genesis and development, none has more of philosophic interest than the question of the origin of language. This question, which lies at the very threshold of a proper understanding of the relation of man's mental nature to that of the lower animals, is touched on by Mr Darwin himself in his *Descent of Man*. In Germany it is being earnestly discussed by a number of writers, on whom the influence of Mr Darwin's theory of human descent is very marked. Among the writers who have explicitly applied the method of evolution, as defined by Mr Darwin, to the explanation of language, may be mentioned A. Schleicher,[1] L. Geiger,[2] Dr G. Jäger,[3] Wilhelm Bleek,[4] and Ernest Haeckel.[5] Jäger, who assumes that man is the immediate descendant of ape-like progenitors,

---

[4] *Ueber den Ursprung der Sprache.*

[5] *The History of Creation*, ii. p. 300 *sq.*

connects the first beginnings of human speech with a superiority in the command of the actions of respiration which is involved in man's erect posture.

(d) Darwinism and Psychology.—From anthropology we pass to psychology. Here the influence of Darwinism meets us too. Among recent psychologists W. Wundt, in his *Grundzüge der physiologischen Psychologie*, makes frequent use of the doctrine of a gradual evolution of mental dispositions by means of heredity. He would, for example, explain the rapidity with which the space-perception is formed in the infant mind by help of such an inherited disposition. Wundt appears to lean to the hypothesis of ultimate sentient elements, by the summation of whose rudimentary feelings arises the unity of consciousness.

The wider consequences of Mr Darwin's theory in the domain of psychology are briefly indicated by Dr Georg von Giz'ycki, in his little work *Die philosophischen Consequenzen der Lamarck-Darwin'schen Entwicklungstheorie.* He argues against attributing sensation to all material things, which supposition (unlike Professor Clifford) he does not regard as a necessary consequence of the evolution hypothesis. He distinctly seizes the bearing of this doctrine on our conception of mind (animal as well as human) as identical in its fundamental laws, and as presenting to the psychologist a single serial development; and he still further follows Mr Spencer in connecting all mental activity with vital functions essential to the preservation of the individual and of the race. Finally, he adopts the view that the mental organism depends on the laws of the external universe. The harmony or adaptation which we see holding between thoughts and things must be interpreted as the effect of the latter acting on and modifying the former in conformity with themselves.

Darwinism and Ethics and Religion.—Passing now to the region of practical philosophy, we find that Darwinism has occasioned in Germany, as in England, a good deal of curious speculation. Among the many writers who have touched on the aspects of Darwinism we can only refer to one or two. Among these we may mention Dr Paul Rée, who, in a recent work, *Der Ursprung der moralischen Empfindungen*, argues that moral dispositions or altruistic impulses have been developed as useful to society, yet rather oddly combines with this idea the pessimistic doctrine that man is not on the whole growing more moral. Again Dr Giz'ycki, in the work just referred to, emphasizes the bearing of the doctrine of human descent on our feeling towards the lower animals as closely linked to ourselves. He goes on to show that this doctrine involves the most definite and stringent form of determinism, and so has a bearing on our ideas of right and wrong, blame, &c. The writer thinks Darwinism by no means excludes a teleological conception of the world as a process striving towards the highest manifestation of mental life, and this idea leading back to that of an absolute first cause of the order of the world, becomes the starting-point for religious and æsthetic aspiration. In Dr G. Jäger's work, *Die Darwin'sche Theorie und ihre Stellung zu Moral und Religion*, we find a practical deduction from Darwinism which curiously contrasts with that of Dr Giz'ycki. Jäger argues that this doctrine teaches us to place ourselves in the greatest possible opposition to the lower animals. The aim of morality, as taught by Darwinism, must be to develop to the utmost those excellences which mark off man from the brute. The author seeks to account for the genesis of social institutions and religious ideas, as utilities which benefited those communities possessing them in the struggle for existence.

A work in which are traced the ethical and religious consequences of the doctrine of evolution is *The Old Faith and the New* of David Strauss. According to Strauss, all morality has its root in the recognition and realization of the idea of kind in ourselves and in others. He argues from the fact that nature has produced man as her last and highest achievement, and the lower forms of creatures but as steps in the progress towards man, that our end and aim must be the furtherance of that which marks us off from the brutes. Religion again begins with the sense of unity with nature, and the new doctrine of the cosmos enables us to regard nature as the source whence our life, as all life, springs.

Interpretation of Modern Scientific Doctrine.—A word or two, in conclusion, respecting what is known as the modern doctrine of evolution. It is important to emphasize the fact that this is a scientific doctrine, which has been built up by help of positive research. As such, of course, it embodies the mechanical, as distinguished from the teleological, view of nature's processes. Yet it still awaits its final philosophic interpretation. We cannot yet say under what head of our historical scheme it is destined to fall.

We think the question of the universal applicability of the doctrine to physical and mental phenomena may be allowed. There are no doubt wide gaps in our knowledge of both orders. Thus it may reasonably be doubted whether physical theory can as yet enable us fully to see the necessity of that universal process from the homogeneous to the heterogeneous in which evolution consists; yet in a rough and vague way the process is being made theoretically intelligible. Again, the transition from the inorganic to the organic is, as Professor Tyndall has lately told us, far from being conceivable in the present state of our knowledge; and this seems to be implied in the remarkable hypothesis by which Professor Helmholtz and Sir W. Thomson seek to account for the first appearance of life on our planet. Yet we may reason from the general tendencies of research that this step may some day be hypothetically explained in physical and mechanical terms. Again, in spite of Mr Spencer's brilliant demonstration of the general continuity of mental life, much remains to be done before all the steps in the process (*e.g.*, from particular to general knowledge, from single feelings to self-consciousness) are made plain. Nevertheless, we may even now dimly see how such mental processes may be knit together in one larger process.

Allowing, then, that the doctrine of evolution as a scientific hypothesis is probably true, the question arises, what is its exact philosophical purport? How far does it help to unify our knowledge, and is it the final explanation of the complex events of our world?

First of all, then, as a unifying generalization, it is clearly limited by the fact of the correlation of mental and physical evolution. These two regions of phenomena may be seen to manifest the same law, yet they cannot be identified. All the laws of physical evolution can never help us to understand the first genesis of mind, and this difficulty is in no way reduced by Mr Spencer's conception of a perfect gradation from purely physical to conscious life. The dawn of the first confused and shapeless feeling is as much a "mystery" as the genesis of a distinct sensation. Our best exponents of evolution, including Professor Du Bois Reymond (*Ueber die Grenzen des Naturerkennens*, p. 25 *sq.*), fully recognize this difficulty. We have here much the same "mystery" which meets us in the conversion of a nerve-stimulus into a sensation in the developed organism. The sequence is unlike any properly physical succession, and so cannot be further explained by being brought under a more general law. Not only so, the doctrine of the conservation of energy, as applied to organic processes, leads to the conclusion that the genesis of mind in general and of every single mental phenomenon is, from a physical point of view, something non-essential.

We may, no doubt, avoid this difficulty, in appearance at least, by assuming that all material processes down to the vibrations of the indivisible atoms are accompanied with a mode of feeling. This may, of course, be proposed as a properly scientific hypothesis, and as involving no metaphysical assumptions respecting the nature of atoms. The great difficulty here would be, how we are to conceive of modes of sensibility that do not enter into a collective consciousness, and which appear to lack all the characteristics of our own conscious life.

Even, however, if this huge difficulty of the genesis of mind is got over, there still remain limits to the explanation effected by the doctrine of evolution. Thus, while it might be able to deduce all the processes of physical evolution from a few assumptions respecting primitive matter and its laws, it would have no such data for resolving all these steps in the mental process which result in a heterogeneous mode of feeling. How, for instance, is it to account on general principles, and by *a priori* reasoning, for the differentiation of a vague tactual sensibility into what we know as sight and hearing—sensibilities which underlie all our ordinary conceptions of the physical world? Here are manifestly set rigid limits to the explanation effected by the doctrine of evolution, the limits which J. S. Mill has laid down as those of all kinds of explanation of phenomena. The doctrine by no means helps us to resolve all laws of succession into one.

The other limits set to the explanatory power of the modern doctrine have already been hinted at. Thus the doctrine sets out from a given point in time, at which it assumes a definite arrangement of material (and mental) elements to have obtained. "Of the beginning of the universe," says Professor Clifford, "we know nothing at all." Again, Professor J. Clerk Maxwell tells us[1] that we must from the first assume an infinite number of molecules exactly alike in their weight and rate of vibration; and he distinctly argues against the supposition that this system of like elements can have been evolved. There is room then for the question, how this particular order of elements arose. And even if we go further back, and make with Mr Spencer the large assumption that these various classes of molecules have been evolved from perfectly homogeneous first elements, one may still ask for an explanation of this original homogeneity. In short, it is plain that every doctrine of evolution must assume some definite initial arrangement, which is supposed to contain the possibilities of the order which we find to be evolved, and no other possibility.

Such being the limits set to the scope of explanation by the idea of evolution, the question arises whether these apparently permanent gaps in our scientific knowledge can be filled up by extra-scientific speculations. One may seek to show the need of such a metaphysical interpretation of evolution by a reference to the very nature of the doctrine. As a scientific truth, it is simply the highest generalization respecting the order of phenomena in time, and as such makes no assumptions with regard to the ultimate nature of that matter, force, and mind, of which it speaks. What, it may be asked, are the realities corresponding to these terms, and how are we to conceive of their mutual relations? Each of the supposed deficiencies in the doctrine of evolution just referred to leads us back to those various metaphysical doctrines in which, as we have seen, the idea of evolution has usually clothed itself. In order to understand what Mr Martineau calls the whence as distinguished from the when, and to provide a substantial support for the thread of phenomenal events, it would seem as if we must fall back on some ultimate philosophic assumption respecting the efficient principle in the process.

With respect to metaphysical dualism, it must be said that it leaves us pretty much where we were. The correlation of two distinct substances and their manifestations in the way required by the doctrine of evolution (whether this correlation be universal or not), needs explanation as much as the correlation of the two sets of phenomena. On the other hand, materialism, spiritualism, and the so-called monism, have each their merits and their drawbacks as helps to the interpretation of evolution. If materialism recommends itself by assuming the fewest possible principles, it is exposed to the objection that it bids us conceive a reality which is wholly distinct from mind. Further, it fails to give any intelligible account of the rise and progress of mental activity. Again, spiritualism assists us in accounting for the genesis of mind, and for the appearance of intelligent order in the world. Yet it is questionable whether this doctrine, assuming as it does some form of unconscious mind (whether as world-soul or as elements of feeling), is not beset with as many difficulties as it resolves. Further, it may be doubted whether the spiritualistic idea, in its common pantheistic form, has yet succeeded in rendering intelligible the fixed mechanical order which marks all stages of evolution. Finally, it may be allowed that the monistic doctrine of one reality with two faces does in appearance lift us over the difficulties which beset the materialistic and the spiritualistic interpretation of evolution. Only is it in truth anything more than a verbal simplification, and does it not rather leave us confined in that dualism where science has to land us?

It would thus seem that the doctrine of evolution has by no means as yet received its final philosophic character. No one of the metaphysical doctrines which are at our command is so plainly and completely adapted to transform it into a final doctrine of existence, that it must of necessity be accepted at once and by all.

To this we must now add that to many minds this resort to a metaphysical principle as the support of the process of evolution will not be held to be necessary. A positivist, who thinks that our knowledge of the universe must for ever be limited to phenomena, is at perfect liberty to accept the doctrine of evolution and to regard it as an ultimate expression for the order of the world. Nay more, the empirical idealist—who may perhaps be defined as a positivist that has fully analysed his "phenomena"—can accept and give a meaning to the doctrine of evolution as formulating the order of sensations, actual and possible, of conscious minds. Mr Spencer somewhere says that, if idealism is true, evolution is a dream. Yet this assertion may be reasonably disputed. It may perhaps seem staggering to be told that evolution postulates vast periods of time in which there existed no mind to experience the sensations into which the world is on the idealistic hypothesis resolved. Yet this difficulty is only apparent, since past physical evolution stands for a projection, so to speak, of now existing minds, and for an order of sensations conceived as possible under other and imaginable circumstances.[2] To the empirical idealist physical evolution stands for an imagined order of perceptions in an indefinite number of minds, mental evolution for actual successions of feeling in many minds, and the transition from the one to the other means the succession of actual states of consciousness on possible or imagined states. The unity of the world-process arises from the ability of the individual mind, which now reflects

[1] *Discourse on Molecules.* See also the very interesting section on the "Nature and Origin of Molecules," which concludes the work on the *Theory of Heat.*

[2] It may be added that the hypothesis of the uniform correlation of the physical and the mental enables us to assign an element of actuality (mental life) to the remote periods here spoken of

on these many successions, to gather them up by a series of acts of imagination into a collective ideal experience for itself.

Thus the doctrine of evolution seems to be susceptible of statement in terms of idealism as easily as in terms of realism. In truth, each mode of viewing the process is at once possible and beset with difficulties. The difficulty of giving an idealistic interpretation arises from the popular distinction of mind or perception and something beyond and independent of this. The difficulties of giving a realistic interpretation have in part been stated already in speaking of the different realistic interpretations (materialism and spiritualism). To these must be now added the fundamental obstacle to all realism, which shows itself, in a specially striking way, in relation to the doctrine of evolution,—namely, the difficulty of conceiving in terms of human consciousness something which is independent of, antecedent to, and creative of, this consciousness.

It may be asked, perhaps, whether the doctrine of evolution, by providing a new conception of the genesis of our cognitions, has anything to say to the question of a real independent object. What the doctrine effects with respect to such cognitions as those of space is to show that the bare fact of intuitiveness or innateness does not establish their non-empirical or transcendental origin. Similarly it may be held that the doctrine opens a way of accounting for the growth of the idea of independent realities, supposing this to be now an innate disposition of the mind—viz., by regarding this idea as arising in a succession of many generations, if not out of, yet by help of, certain elements or aspects of experience. It may, however, be maintained that the idea is not even suggested by experience; if so, it would follow from the evolution theory that its present persistence represents a permanent mental disposition to think in a particular way. Even then, however, the question would remain open whether the permanent disposition were an illusory or trustworthy tendency, and in deciding this point the doctrine of evolution appears to offer us no assistance.[1]

As a scientific doctrine, whatever its ultimate interpretation, evolution has a bearing on our practical, *i.e.*, moral and religious ideas. This has already been shown in part by writers from whom we have quoted. Among other results, this doctrine may be said to give new form to the determinist theory of volition, and to establish the relativity of all moral ideas as connected with particular stages of social development. It cannot, as Mr Sidgwick has shown, provide a standard or end of conduct except to those who are already disposed to accept the law *sequi naturam* as the ultimate rule of life. To such it furnishes an end, though it would still remain to show how the end said to be unconsciously realized by nature, the well-being of individuals and of communities, is to be adjusted to the ends recognized in common-sense morality, including the happiness of all sentient beings. It may be added that the doctrine, by assigning so great an importance to the laws of inheritance as means of raising the degree of organization and life, may be expected to exert an influence on our ideas of the solidarity of the present generation and posterity, and to add a certain solemnity to all the duties of life, prudential morality included.

The bearing of the doctrine of evolution on religious ideas is not so easy to define. Mr Spencer considers the ideas of evolution and of a pre-existing mind incapable of being united in thought (see his rejoinder to Dr Martineau, *Contemporary Review*, vol. xx. p. 141 *sq.*). Yet, according to others, the idea is by no means incompatible with the notion of an original Creator, though it serves undoubtedly to remove the action of such a being further from our ken. At first sight it might appear that the doctrine as applied to the subjective world, by removing the broad distinction between the human and the animal mind, would discourage the hope of a future life for man's soul. Yet it may be found, after all, that it leaves the question very much where it was. It may perhaps be said that it favours the old disposition to attribute immortality to those lower forms of mind with which the human mind is found to be continuous. Yet there is nothing inconsistent in the supposition that a certain stage of mental development qualifies a mind for immortality, even though this stage has been reached by a very gradual process of development. And if, as might be shown, the modern doctrine of evolution is susceptible of being translated into terms of Leibnitz's hypothesis of indestructible monads, which include all grades of souls, then it is clearly not contradictory of the idea of immortality.

Very interesting is the bearing of the doctrine of evolution on that æsthetico-religious sentiment towards the world which has taken the place of older religious emotions in so many minds. First of all by destroying the old anthropocentric view of nature, according to which she is distinct from and subordinated to man, this doctrine favours that pantheistic sentiment which reposes on a sense of ultimate identity between ourselves and the external world. In a sense it may be said that the new doctrine helps to restore the ancient sentiment towards nature as our parent, the source of our life. It is well to add, however, that the theory of evolution, by regarding man as the last and highest product of nature, easily lends support to the idea that all things exist and have existed for the sake of our race. This seems, indeed, to be an essential element in any conception we can form of a rationally evolved universe.

A reference must be made, in closing this article, to the optimistic aspect of the doctrine of evolution. That there is a tone of optimism in much of the more popular exposition of the doctrine of evolution needs not be proved. There is no doubt, too, that both in Mr Darwin's and Mr Spencer's theories there are ideas which tend to support a cheerful and contented view of things. The idea of the survival of the fittest, and of evolution as a gradual process of adaptation to environment, lend themselves to this kind of thought. Indeed, Du Bois-Reymond, in the lecture on Leibnitz already referred to, seriously argues that the doctrine of evolution provides a scientific equivalent to that philosopher's remarkable conception of the best of all possible worlds. On the other hand, as the present writer has elsewhere shown, Mr Darwin's doctrine of evolution contains elements which are fitted to tone down our estimate of the value of the world viewed as the seat of conscious sentient life. The pain involved in the renewed struggle for existence is a large drawback from the gains of human progress and of organic development as a whole. More than this, the principle of natural selection appears almost to favour a pessimist view of the world, in so far as it implies the tendency of organic forms to multiply down to the limits of bare existence.

EVORA, a city of Portugal, capital of the province of Alemtejo, is situated on an eminence in the centre of a fertile plain, 85 miles E. by S. of Lisbon. It is surrounded by ramparts flanked with towers, and has two forts, but all in a ruinous condition, and quite useless as means of defence. The streets are narrow, crooked, and filthy, and the houses old and ill-built. The cathedral is a magnificent Gothic edifice with an altar in the Italian style, extremely rich, and decorated with variously coloured marbles. Evora is the see of an archbishop, and besides the cathedral has several churches, convents, and hospitals, a house of charity, barracks, a diocesan school, and a museum. A university, founded in 1550, was abolished on the expulsion of the Jesuits in the 18th century. An ancient aqueduct and an ancient tower, till a few years ago in pretty good preservation, have been partly demolished to make room for a market. They were long believed to have been of Roman origin, but are now known to have been constructed about 1540 in the reign of Don John III., at the instance of an antiquarian named Resende. The aqueduct was constructed on the site of the old Roman one. The remains of what is said to have been a temple of Diana still exist, but the place is now used as a slaughter-house. Evora, under the name of Ebora, was an important military station in the time of the Romans, and was called *Liberalitas Juliæ* on account of certain municipal privileges bestowed on it by Cæsar. In 712 it was conquered by the Moors and named Jabura, but they were deprived of it in 1162 by an order of Christian knights.

EVREUX (the ancient *Mediolanum*, and afterwards *Eburovices*), a town of France, capital of the department of Eure, is situated on the Iton, an affluent of the Eure, 67 miles W.N.W. of Paris by railway. The town is generally well built, and still contains many antique timber-framed houses. It is the seat of a bishop, and its cathedral is one of the most ancient and curious in France. It dates from the 11th century, and is a very imposing cruciform structure, though not uniform in style. The north transept and the portal are in the flamboyant Gothic, elaborately ornamented; the west front is in the Italian style. The beautiful rose window in the south transept, and the wooden screens of the side chapels round the choir, showing the flamboyant Gothic style modified by the reviving Italian, also merit notice. The lady chapel is of elegant architecture, with painted glass equally remarkable for its fine execution and perfect preservation. At the intersection of the nave and transepts rises an octagonal tower supported on four pillars, and surmounted by a pyramidal spire of open stonework. The church of St Taurin also displays various styles of architecture, and contains the shrine of St Taurin, a work of the 13th century. The episcopal palace, which dates from the 15th century, is a beautiful structure. Among the other objects of interest are the clock-tower built in the 15th century, the abbey of St Saviour, the ancient Séminaire des Eudistes now used as a prison and assize buildings, the museum of antiquities, the town-hall, the prefect's residence, the theatre, the public library, the botanic garden, and the promenades. Evreux is famed for its manufacture of tools, and for stocking making; brewing, distilling, dyeing, tanning, and papermaking are its other principal industries. At Vieil Evreux the remains of a Roman theatre, a palace, baths, and an aqueduct have been discovered, and various relics which are now deposited in the Musée d'Antiquités.

Evreux existed at a very early period. About the end of the 10th century Richard I. of Normandy gave it to his son Robert; and early in the 12th century it came by inheritance into the house of Montfort, from whom it was bought by Philip Augustus of France. Philip II. gave it to his brother Prince Louis, who in 1316 was created Count of Evreux. Count Philip of Evreux acquired by marriage the kingdom of Navarre, and Charles III. of Navarre sold it to Charles VI. of France. Charles VII. gave it in 1426 to John Stuart, earl of Darnley, after whose death it again came into the possession of the crown. Charles IX. bestowed it, along with the title, on his brother the duke of Alençon, but on his death in 1584, it finally returned into the possession of the crown.

EWALD, Heinrich Georg August von (1803–1875), Orientalist, biblicist, and theologian, was born, November 16, 1803, at Göttingen, where his father followed the occupation of a linen-weaver. After receiving the usual preliminary training, he entered the university of his native town in 1820; and there, with Eichhorn as teacher, he at once began to devote himself specially to the study of Hebrew and its cognates. At the close of his academical career in 1823 he was appointed to a mastership in the gymnasium at Wolfenbüttel; but soon afterwards (in the spring of 1824) he was, at the instance of Eichhorn, recalled to Gottingen as repetent, or theological tutor, and in 1827 (the year of Eichhorn's death) he became professor *extraordinarius* in philosophy, and lecturer in Old Testament exegesis. In 1831 he was promoted to the position of professor *ordinarius* in philosophy; and in 1835 he entered the faculty of theology, taking the chair of Oriental languages. Two years later occurred the first important episode in his studious life, which until then had been uninterrupted in its even tenor except by journeys in 1826, 1829, and 1836 to Berlin, Paris, and Italy, for the purpose of consulting rare and important oriental manuscripts. In 1837, on the 18th November, along with six of his colleagues (Dahlmann the historian, Weber the electrician, Gervinus the critic, the brothers Grimm, and W. E. Albrecht) he signed a formal protest against the arbitrary proceeding of King Ernst August (duke of Cumberland) in abolishing the liberal constitution of 1833, which had been granted to the Hanoverians by his predecessor William IV. This bold action of the seven professors made them very popular and famous in the country; but it led to their speedy expulsion from the university (14th December). Early in 1838 Ewald received a call to Tübingen, and there for upwards of ten years he held a chair as professor *ordinarius*, first in philosophy and afterwards, from 1841, in theology. To this period belong some of his most important works, and also the commencement of his bitter feud with F. C. Baur and the Tübingen critical school. In 1848, "the great shipwreck-year in Germany," as he has called it, he was invited back to Göttingen on honourable terms,—the liberal constitution having been restored. He gladly accepted the invitation, for though well treated in Würtemberg (he had been ennobled by the king in 1841), he had never learned to regard his sojourn there as anything else than a period of exile. In 1862–63 he took an active part in a movement for reform within the Hanoverian church, and he was a member of the synod which passed the new constitution. He had an important share also in the formation of the Protestantenverein, or Protestant association, in September 1863. But the chief crisis in his life arose out of the great political events of 1866. His loyalty to King George (son of Ernst August) would not permit him to take the oath of allegiance to the victorious king of Prussia, and in consequence of his refusal to do so he was ultimately placed on the retired list, though with the full amount of his salary as pension. Perhaps even this degree of severity might have been held by the Prussian authorities to be unnecessary, had Ewald been less exasperating in his language. The violent tone of some of his printed manifestoes about this time, especially of his *Lob des Königs u. des Volkes*, led to his being deprived of the *venia legendi* (1868), and also to a criminal process, which, however, resulted in his acquittal (May 1869). Then, and on two subsequent occasions, he was returned by the city of Hanover as a member of the North German and German parliaments. In June 1874 he was found guilty of a libel on Prince Bismarck, whom he had compared to Frederick II. and Napoleon III. —to the former in "his unrighteous war with Austria and his ruination of religion and morality," to the latter in his way of "picking out the best time possible for robbery and plunder." For this offence he was sentenced to undergo three weeks' imprisonment. He died in his 72d year, of heart-disease, May 4, 1875.

From the above brief sketch it will be seen that, even apart from his contributions to philological and biblical science, Ewald was no common man. In the whole course of his public life he displayed in a very high degree many noble characteristics,—perfect simplicity and sincerity, intensest moral earnestness, sturdiest independence, absolute fearlessness. It would be difficult to say whether the intellectual or the emotional side of his nature was most highly developed. He loved with peculiar intensity, loved freedom and truth in every domain, in politics as well as in science and in religion; and just because he loved them with all his great might, he could not help hating all that he believed to be opposed to them. It was impossible for him to be a mere critic; no reader can understand Ewald's position who allows himself to forget that his whole being was possessed with a passionately devoted faith. It was natural that such a man should be frequently engaged in controversy, and equally natural that in these circumstances the "defects of his qualities" should often become painfully apparent. It cannot be denied that in his manner of speaking about his opponents he often overstepped the limits of charity and even of justice. The peculiar character of his intellect, which was rather intuitive than inductive, made him neither a very fair nor a very effective controversialist. No one equalled him in the power of comprehending in a single survey a vast circle of complicated facts, and almost instinctively divining their scientific unity; but the results attained in this way presented themselves to his mind with such intuitive conviction that he was impatient of all objection, and little able to do justice to scholars of a different mental habit. Yet in controversy he probably received injustice more often than he inflicted it; even his extremest views have generally been found to contain much that is true and valuable; and the great Arabist Fleischer is almost the only scholar who gained a conspicuous victory over him on an unambiguous philological issue. As a teacher he had a remarkable power of kindling enthusiasm; and he sent out many distinguished pupils, among whom may be mentioned Hitzig, Schrader, Nöldeke, Diestel, and Dillmann. His disciples have not been all of one school, any more than were those of Socrates; but many eminent moderns who are apparently farthest removed from his influence are only developing some of the fruitful ideas which in the exuberance of his wealth he was wont to fling out by handfuls.

Of no writings more truly than of his could it be said that they are the reservoirs into which, without any waste, the entire energy of a life has been stored. For more than half a century his pen was never idle; from 1823 onwards hardly a year passed which was not marked by the appearance of some highly important contribution to the sciences he loved. By the publication of his *Hebrew Grammar* he inaugurated a new era in biblical philology. All subsequent works in that department have been avowedly based on his. It has already been superseded in parts, especially in its accidence; but the syntax still remains unexcelled for the sagacity with which dry rules are made intelligible and interesting by continued reference to the fundamental laws of language and thought. But even when his *Lehrbuch* shall have become entirely antiquated, to him will always belong the honour of having been, as Hitzig has called him, "the second founder of the science of Hebrew language." As an exegete and biblical critic no less than as a grammarian he has left his abiding mark. It is hardly an exaggeration to say that the publication of his *Geschichte des Volkes Israel* was epoch-making in that branch of research, as much as was the work of Niebuhr in relation to the history of Rome. In its final form, the result of thirty years' labour, it is a noble monument to the genius of its author. No one can fail to be struck with the profundity of insight and patience of research which it displays. While in every line it bears the marks of Ewald's intense individuality, it is at the same time a highly characteristic product of the age, and even decade, in which it first appeared. If it is obviously the outcome of immense learning on the part of its author, it is no less manifestly the result of the speculations and researches of many laborious predecessors in all departments of history, theology, and philosophy. Especially is it indebted to the so-called "destructive" criticism. The Reformation had destroyed that mediæval conception of the Bible which took no account of literary history or doctrinal development at all; and subsequent researches, especially since those of Astruc, had made it abundantly clear that the conditions under which the Old Testament books had come into being were much more complicated than had been at one time supposed. Criticism, however, could not possibly rest satisfied with these purely negative results. If for a time it seemed as if the sacred literature had been reduced to a mere chaos of fragments, which men might well despair of ever being able to reduce to harmony and order, the historical sense had been developing no less remarkably than the spirit of criticism. Taught by some of the more modern schools of philosophy, men had been learning to take larger, and therefore juster, views of the principles that underlie all national histories and the general history of the human race. It was impossible that such a phenomenon as the Jewish people and their literature should be permanently set aside as wholly incomprehensible. The world was only waiting for a bold and vigorous constructive genius like that of Ewald to bring together the scattered fragments, and construe them into an intelligible unity; to show, for example, that, if the Psalter could no longer be regarded as the record of the spiritual experience of the individual to whom it had been traditionally ascribed, it became all the more precious when known to embody all the highest aspirations and purest joys and noblest sorrows of many centuries of national life; and that if the legislation of the Pentateuch was not indeed, as had once been supposed, the work of a few quiet months, it gained in interest and instructiveness when known to be the slow growth of many busy generations. Taking up the idea of a divine education of the human race, which Lessing and Herder had made so familiar to the modern mind, and firmly believing that to each of the leading nations of antiquity a special task had been providentially assigned, Ewald felt no difficulty about Israel's place in universal history, or about the problem which that primitive and highly endowed race had been called upon to solve. The history of Israel, according to him, is simply the history of the manner in which the one true religion really and truly came into the possession of mankind. Other nations, indeed, had attempted the highest problems in religion; but Israel alone had, in the providence of God, succeeded, for Israel alone had been inspired. Such is the supreme meaning of that national history which began with the exodus and culminated (at the same time virtually terminating) in the appearing of Christ, the supremely perfect revelation or self-manifestation of God. The historical interval that separated these two events is treated as naturally dividing itself into three great periods,—those of Moses and the theocracy, of David and the monarchy, of Ezra and the hagiocracy. The periods are externally indicated by the successive names by which the chosen people were called—Hebrews, Israelites, Jews. The events prior to the exodus are relegated by Ewald to a preliminary chapter of primitive history; and the events of the apostolic and post-apostolic age are treated as a kind of appendix. The entire construction of the history is based, as has already been said, on a critical examination and chronological arrangement of the available documents. So far as the results of criticism are still uncertain with regard to the age and authorship of any of these, Ewald's conclusions must of course be regarded as unsatisfactory; and it cannot be denied that later investigations have shown that in many important points his firm faith that finality had been attained was illusory. These admissions, however, hardly affect the permanent value of his work. It will continue to be a storehouse of learning for all subsequent investigators in the field of sacred history, and it will be increasingly recognized as a work of rare genius. It would be impossible to praise too highly the conscientiousness with which the minutest features of the history have been carefully scanned; the marvellous power of combination which, at even the most unlikely points, can draw the most graphic illustrations from contemporary prophets and poets; the vividness with which, not only the politics, but also the religion, the arts, the literature, the domestic life, of each successsive period are depicted; the loving enthusiasm of the student who believes that those only are the enemies of the Bible who fail to investigate it, or who fail to investigate it thoroughly.

In his work on biblical theology, he can hardly be said to have been so successful as in some of his earlier efforts. Though a suggestive and therefore a useful book, its conclusions are vitiated in many cases by a glaring departure from the inductive method, the interpretations being often speculative rather than biblical, and unduly dominated by a preconceived metaphysico-religious system of the universe.

Subjoined is a list of the more important of his works:—*Die Composition der Genesis kritisch untersucht* (1823) [an acute and able attempt to account for the use of the two names of God without recourse to the document-hypothesis; he was not himself, however, permanently convinced by it]; *De metris carminum Arabicorum* (1825); *Das Hohelied Salomo's übersetzt u. erklärt* (1826; 3rd ed. 1866); *Kritische Grammatik der hebr. Sprache* (1827) [this afterwards became the *Ausführliches Lehrbuch der hebr. Sprache* (8th ed. 1870); and it was followed by the *Hebr. Sprachlehre für Anfanger* (4th ed. 1874)]; *Ueber einige ältere Sanskritmetra* (1827), *Liber Vakedii de Mesopotamiæ expugnatæ historia* (1827); *Commentarius in Apocalypsin Johannis* (1828); *Abhandlungen zur biblischen u. orientalischen Literatur* (1832); *Grammatica critica linguæ Arabicæ* (1831–33); *Die poetischen Bücher des alten Bundes* (1835–37, 3rd ed. 1866–67); *Die Propheten des alten Bundes* (1840–41, 2nd ed., 1867–68); *Geschichte des Volkes Israel* (1843–59, 3rd ed. 1864–68); *Alterthümer Israels* (1848); *Die drei ersten Evangelien übersetzt u. erklärt* (1850); *Ueber das äthiopische Buch Henoch* (1854); *Die Sendschreiben des Apostels Paulus übersetzt u. erklärt* (1857); *Die Johanneischen Schriften übersetzt u. erklärt* (1861–62); *Ueber das vierte Esrabuch* (1863); *Sieben Sendschreiben des neuen Bundes* (1870); *Das Sendschreiben an die Hebräer u. Jakobos' Rundschreiben* (1870); *Die Lehre der Bibel von Gott, oder Theologie des alten u. neuen Bundes* (1871–75). The *Jahrbücher der biblischen Wissenschaft* (1849–65) were edited, and for the most part written, by him. He was the chief promoter of the *Zeitschrift für die Kunde des Morgenlandes*, begun in 1837; and he frequently contributed on various subjects to the *Götting. gelehrte Anzeigen.* He was also the author of many pamphlets of an occasional character.

The following have been translated into English:—*Hebrew Grammar*, by Nicholson (from 2nd German edition), Lond. 1836; *Introductory Hebrew Grammar* (from 3rd German edition), Lond. 1870; *History of Israel*, 5 vols. (corresponding to vols. i.–iv. of the German), by Russell Martineau and J. Estlin Carpenter, Lond. 1867–74; *Antiquities of Israel*, by H. S. Solly, Lond. 1876; *Commentary on the Prophets of the Old Testament*, by J. Frederick Smith, 3 vols., Lond. 1876–77; *Isaiah the Prophet*, chaps. i.–xxxiii., by O. Glover, Lond. 1869; *Life of Jesus Christ*, also by O. Glover, Lond. 1865. (J. S. BL.)

EWALD, JOHANNES (1743–1781), the greatest lyrical poet of Denmark, was the son of a melancholy and sickly chaplain at Copenhagen, where he was born on the 18th of November 1743. At the age of eleven he was sent to school at Schleswig, his father's birth-place, and returned to the capital only to enter the university in 1758. His father was by that time dead, and in his mother, a frivolous and foolish woman, he found neither sympathy nor moral support. At fifteen, he fell passionately in love with "the delicate, noble, majestic Arense," a girl whose father, later on, married the poet's mother; and the romantic boy resolved on various modes of making himself admired by the young lady. He began to learn Abyssinian, for the purpose of going out as a missionary to Africa, but this scheme was soon given up, and he persuaded a brother, four years older than himself, to run away that they might enlist as hussars in the Prussian army. They managed to reach Hamburg just when the Seven Years' War was commencing, and were allowed to enter a regiment. But the elder brother soon got tired and ran away, while the poet, after a series of extraordinary adventures, deserted to the Austrian army, where from being drummer he rose to being sergeant, and was only not made an officer because he was a Protestant. In 1760 he was weary of a soldier's life, and deserted again, getting safe back to Denmark. For the next two years he worked with great diligence at the university, but the Arense for whom he had gone through so much hardship and taken so much pains married another man almost immediately after Ewald's final and very successful examination. The disappointment was one from which he never recovered. He plunged into dissipation of every kind, and gave his serious thoughts only to poetry. In 1763 his first work, a perfunctory dissertation *De Pyrologia Sacra*, first saw the light. In 1764 he made a considerable success with a short prose story, *Lykkens Tempel* (The Temple of Fortune), which was translated into German and Icelandic. On the death of Frederick V., however, Ewald first appeared prominently as a poet; he published in 1766 three *Elegies* over the dead king, which were received with universal acclamation, and of which one, at least, is a veritable masterpiece. But his dramatic poem *Adam og Eva* (Adam and Eve), by far the finest imaginative work produced in Denmark up to that time, was rejected by the Society of Arts in 1767, and was not published until 1769. At the latter date, however, its merits were perceived. In 1770 Ewald attained success with *Philet*, a narrative and lyrical poem, and still more with his splendid *Rolf Krage*, the first original Danish tragedy. For the next ten years Ewald was occupied in producing one brilliant poetical work after another, in rapid succession. In 1771 he published *De brutale Klappers* (The Brutal Clappers), a tragi-comedy or parody satirizing the dispute then raging between the critics and the manager of the Royal Theatre; in 1772 he translated from the German the lyrical drama of *Philemon and Baucis*, and brought out his comedy of *Harlequin Patriot*, a satire on the passion for political scribbling created by Struensee's introduction of the liberty of the press. In 1773 he published *Pebersvendene* (Old Bachelors), a comedy. In 1771 he had already collected some of his lyrical poems under the title of *Adskilligt af Johannes Ewald* (Miscellanies). In 1774 appeared the heroic opera of *Balder's Död* (Balder's Death), and in 1779 the finest of his works, the lyrical drama *Fiskerne* (The Fishers), which contains the Danish National Song, "King Christian stood by the high Mast," his most famous lyric. In the two poems last mentioned, however, Ewald passed beyond contemporary taste, and these great works, the pride of Danish literature, were coldly received. But while the new poetry was slowly winning its way into popular esteem, the poet did not lack admirers, and at the head of these he founded in 1775 the Danish Literary Society, a body which became influential, and which made the study of Ewald a cultus. But the poet's health had broken; when he was writing *Rolf Krage* he was already an inmate of the Consumptive Hospital, and when he seemed to be recovering, his health was shattered again by a night spent in the frosty streets. He embittered his existence by the recklessness of his private life, and finally, through a fall from a horse, he ended by becoming a complete invalid. His last ten years were full of acute suffering; his mother treated him with cruelty, his family with neglect, and but few even of his friends showed any manliness or generosity towards him. In 1774 he was placed in the house of an inspector of fisheries at Rungsted, where Anna Hedevig Jacobsen, the daughter of the house, tended the wasted poet with infinite tenderness and skill. He stayed in this house for three years, and wrote there some of his finest later lyrics. Meanwhile he had fallen deeply in love with the charming solace of his sufferings, and won her consent to a marriage. This step, however, was prevented by his family, who roughly removed him to their own keeping near Kronborg. Here he was treated so infamously that he insisted on being taken back to Copenhagen in 1777, where he found an older, but no less tender nurse, in Madame Schouw. Here he wrote *Fiskerne*, with his imagination full of the familiar shore at Hornbæk, near Rungsted. In 1780 he was a little better, and managed to be present at the theatre at the first performance of his poem. But this excitement destroyed him, and after months of extreme agony, he died on the 17th of March 1781, and was carried to the grave by a large assembly of his admirers, since he was now just recognized by the public for the first time as the greatest national poet. Among his papers were found fragments of three dramas, two on old Scandinavian subjects, entitled *Frode* and *Helgo*, and the third a tragedy on the story of *Hamlet*, which he meant to treat in a way wholly distinct from Shakespeare's.

Ewald belongs to the race of poetical reformers who appeared in all countries of Europe at the end of last century; but it is interesting to observe that in point of time he preceded all of them. He was born six years earlier than Goethe and Alfieri, sixteen years before Schiller, nine years before André Chénier, and twenty-seven years earlier than Wordsworth, but he did for Denmark what each of these poets did for his own country. Ewald found Danish literature given over to tasteless rhetoric, and without art or vigour. He introduced vivacity of style, freshness and brevity of form, and an imaginative study of nature which was then unprecedented. But perhaps his greatest claim to notice is the fact that he was the first person to call the attention of the Scandinavian peoples to the treasuries of their ancient history and mythology, and to suggest the use of these in imaginative writing. With a colouring more distinctly modern than that of Collins and Gray, his lyrics yet resemble the odes of these his English contemporaries more closely than those of any Continental poet; from another point of view his ballads remind us of those of Schiller, which they preceded. His dramas, which had an immense influence on the Danish stage, are now chiefly of antiquarian interest, with the exception of "The Fishers," a work that must always live as a great national poem. In personal character and in fate Ewald seems to have been not unlike Heinrich Heine.

The first collected edition of Ewald's works began to appear in his life-time. It is in four volumes, 1780-1784. They have constantly been reprinted, but the standard edition is that by Liebenberg, in 8 vols., 1850-1855. (E. W. G.)

EWING, ALEXANDER (1814-1873), a clergyman of the Scotch Episcopal Church, bishop of Argyll and the Isles, was descended from an old Highland family, and was born in Aberdeen 25th March 1814. After spending two sessions at the university of that city, where he manifested a special bent towards the study of natural history, he studied for a time at a private school in Chelsea, and in 1831 he attended the classes of chemistry, natural philosophy, and natural history in the university of Edinburgh. His uncertain health, however, compelled him for a time to suspend all systematic study. The property inherited from his father rendered it unnecessary for him to adopt a profession from pecuniary considerations, and his delicate health counselled at least delay in taking such a step. Accordingly, for some time after his marriage he occupied himself chiefly in the cultivation of his literary and artistic tastes, residing at first in the north of Scotland, and in October 1838 journeying to Italy where he remained till April 1841. As early as 1836, however, he had begun to look to the church as a profession; and in October 1838 he was admitted to deacon's orders with the object of pledging himself to his future profession before leaving Scotland,—the Episcopalian Church being preferred by him to the Presbyterian, chiefly on account of its comprehensive statements regarding the subject of human redemption. Soon after his return from Italy he was requested to take the charge of the Episcopal congregation at Forres, and on accepting it he was ordained a presbyter in the autumn of 1841. He remained at Forres till 1846, when he was elected first bishop of the newly restored diocese of Argyll and the Isles, the duties of which position he discharged till his death, 22d May 1873. In 1851 he received the degree of D.C.L. from the university of Oxford.

Though the work accomplished by Ewing was necessarily modified and circumscribed by the fact that throughout his whole life he was fettered by a delicate bodily constitution, he yet battled with the vices and religious perplexities and difficulties of his time in a spirit of buoyant cheerfulness. Perhaps his strength lay chiefly in the charm of his personal manner, in his fine tact, and his catholic sympathies; and these gradually secured him, not only the admiration and love of the people and clergy of his diocese, but a prominent position among the ecclesiastics of his own time, both in Scotland and England. In all theological discussions he contended for the exercise of a wide tolerance and charity, shrinking from condemning with ecclesiastical censure even opinions which he feared might be fraught with evil and danger to the church. He did not, indeed, attach much importance to mere ecclesiastical authority and organization, and was more solicitous about the inward than the outward unity of Christianity. His own theological position resembled very closely that of Thomas Erskine of Linlathen, and Frederick Denison Maurice; but his relation to these theologians was rather that of a friendly sympathizer than a disciple, for his opinions were the fruit of his own meditation, and were coloured by his own idiosyncracy, and their perspective was determined by his individual stand-point. Unlike theirs, his teaching was never presented in the form of a complete and elaborate theological treatise, and its purport is only to be gathered from fragmentary publications,—letters to the newspapers, pamphlets, special sermons, essays contributed to the series of *Present Day Papers*, of which he was the editor, and a volume of sermons entitled *Revelation considered as Light*, which he only lived to see through the press. The title of this volume may be taken as indicating the characteristic feature of his theology. He dwelt specially upon the illuminating power of Christianity as revealing the fatherhood of God, and thus "rolling back the clouds of human sin and sorrow," so as even ultimately to "exhaust hell of its darkness." To him each attribute of God was equally light, and therefore he did not believe that any compromise had ever been effected between them. Christ was the supreme manifestation of that light, and the Bible was but the medium of its revelation, the means for enabling it to stream in upon the soul from sources beyond the mere letter of the truths which the written word contained. One of the chief of these external sources of light, specially welcomed by Ewing, was science, to the discoveries of which he looked forward as destined to lead to the manifestation of other and higher aspects of Christianity than were yet fully realized.

Besides his strictly theological writings, Ewing is the author of the *Cathedral or Abbey Church of Iona*, 1865, the first part of which contains drawings and descriptive letterpress of the ruins by Messrs Bucklers, architects, Oxford, and the second a history of the early Celtic church and of the mission of St Columba. See *Memoir of Alexander Ewing, D.C.L.*, by A. J. Ross, B.D., 1877.

EXAMINATIONS. Examinations have lately come very widely into use, and call for consideration at once as educational appliances and as tests of proficiency. Something answering to examinations must enter into all effectual instruction; for in order that the pupil may gain solid advantage it is not enough that what he ought to know should be put before him—as by giving him a book, or by making him listen to lectures—but we must also see that he gets hold of it and understands it aright; this is the function of examinations as appliances for education. They have, however, another use, that of tests or instruments for selection, and this purpose may clash with the educational purpose. But though the examiners may have one purpose primarily in view, and may lay down their scheme with especial reference to it, we must bear in mind that the examination must act in both ways at once. Some sort of advantage must attend on success, or else candidates will not work for it; and, on the other hand, though an examination may only be intended to sift out the ablest, and pains may be taken to avoid giving any advantage to a particular sort of instruction, still it will be found that some particular course is most productive of marks, and this will come into favour.

The few notices which we find of examinations in old times relate to tests of qualification for professions or crafts. We gather from notices of contests between the universities and the medical corporations in London that students had to pass an examination, after going through their apprenticeship, before being allowed to practise. But we never find that an examination was the sole test; it was always attached to a prescribed course of study and service. The foundation deeds of old endowed schools sometimes contain a provision for an examination; the object of this seems to have been rather to ascertain that the teaching was satisfactory than to classify the boys, though sometimes prizes and emoluments were awarded by the examiners.

University examinations are found to take their origin from the "disputations" which appear very early in the history of universities. Dialectical discussion had entered largely into the higher education in classical times, and when the university of Bologna was incorporated as a school of law by the emperor Frederick I. in 1158, disputations soon came into use as exercises for degrees. The university of Paris, which was founded soon after, and which was a school of theology and of arts, adopted the same course; and the forms of these exercises for degrees have survived to the present time in Germany, and did not disappear in England until 1860.

A student who aimed at a degree, which formerly only the more distinguished did, acted three times as opponent to other candidates, and was in time admitted to keep his "Act." This performance began by his reading a Latin thesis, in which he maintained some position in disputation against a doctor in the faculty, as well as the above-named opponents, and, in fact, against all comers. The debate was carried on in syllogistic form; the presiding doctor eventually summed up the controversy, and usually passed a compliment on the disputant, which was the earliest form of university honours.

Academical degrees, in their origin, implied a title to teach, as is seen in the names of Doctor and Master. The notion of a university degree as a criterion of general cultivation is comparatively recent: the B.A. or first degree, which is now so important, was not known in the earliest times, and is not even now granted in the German universities. The disputations took wonderful hold of the popular mind in the Middle Ages. It may be supposed that students looked more to points that gave an opening for attack, or that might be ingeniously defended, than to the truth of the matter; and as the question would be settled by an appeal to the Bible or Aristotle, a habit of looking to authority was engendered. We may catch sight of analogous evils in the examination system; for under this the points that are most likely to yield questions are the most studied. The two plans are only different ways in which the student may make a display of the powers or the knowledge he has acquired. We may observe that disputations bring out "powers," such as ease of expression in Latin, quickness in logical fence, and fertility of resource, more thoroughly than they do actual knowledge; they are better adapted for "Arts" than for sciences.

Each member of the "faculty" had a right of putting questions to the candidate for admission into it in addition to that of formally opposing him in his "Act," and this was freely exercised. This was the germ of the examination, which has since developed itself in England, and displaced the disputation. The transition from disputations to examinations took place in England during the 18th century, and it can be clearly traced at Cambridge, where the competitive system first attracted notice, from the *éclat* attaching to the "tripos list" and the senior wranglership. The name "tripos" has given rise to various strange guesses; the facts are as follows. For the appointment of some university officers, and for settling precedency, a list of those who took their B.A. degree was drawn out in order of priority of admission. This rule of priority was originally determined by favour; it was a piece of patronage belonging to the "moderators," who presided at the acts, and the proctors; afterwards it was settled according to the performances of the candidates at the acts, and eventually by the results of an examination in mathematics and natural philosophy. The day when these bachelors were inaugurated was called the "tripos" day, because on that occasion one of the old bachelors was appointed to take his place on a stool, and to dispute with the new bachelors. It was his business to make sport by a kind of mock disputation, and he was allowed much licence in his remarks. He was called "the bachelor of the stool" or "tripos," and the day was called "the tripos day." The list of names was called the tripos list, and it is probably owing to this need that there was for an order of seniority that the Cambridge tripos list came to be arranged in order of merit.

The subjects of discussion were originally taken chiefly from Aristotle; but soon after the publication of Newton's *Principia* it became usual to take one at least of the three questions which the candidate had to maintain from that work; a second was frequently taken from Newton's *Optics*, and a third from ethical philosophy. The authorities, we find, endeavoured in vain to prevent ethics from being thrust aside, and to maintain something like respectability in the Latin. Interest was concentrated on the mathematical subjects, three-fourths of them belonging to what we should call mathematical physics. These subjects could not be dealt with thoroughly in a disputation, and therefore the moderators adopted the plan of giving out questions which were answered in English. This eventually led to printed papers of questions being given, and in 1838 all vestige of the "Act" for the B.A. degree disappeared, although it was retained for a time in divinity, law, and medicine.

The history of the tripos serves to bring into relief different views as to the end which an examination is meant to serve. Originally it was intended to guide men so that they might learn what was thought best for them, and in the best way; this was the educational view. But colleges had fellowships to dispose of, and the tripos list furnished a ready gauge of merit for the purpose. This made it incumbent on the moderators to exercise rigorous impartiality; and great pains were taken to secure fairness and to judge rightly. A list in order of merit would hardly have approved itself to public opinion in the way the tripos list did, but for the fact that the examination was almost entirely on one subject, and that a subject which admits of questions being set of every shade of difficulty, and for which there is a definite right and wrong. If several subjects had been combined, or if, as was the case at Oxford, the ethical element had been allowed to preponderate, the results could not have been so accurately weighed, there would have been room for difference of opinion, and the only safe course would have been to distribute the names alphabetically in several classes, or in a few classes containing wide brackets, which is nearly the same thing.

The most important change in an educational direction was effected by the influence of Dr Whewell in 1848. He introduced a compulsory examination of adequate length in the elementary subjects, especially elementary natural philosophy; this checked the practice of reading "scraps" of the higher subjects. The old educational party aimed at turning out men in the most effective condition for the ordinary struggles of life, while a later party sought to turn out mathematicians to supply the demands of the scientific world. In the old times the notion was that the senior wrangler would go to the bar, or stay at Cambridge and follow an academical career; now his destination is very commonly a professorship in Scotland or Ireland, or in the colonies. Hence the course at Cambridge has been made to include a technically scientific as well as an educational training; and it has been thereby so much extended that the amount to be carried into the tripos is excessive. As the whole cannot be read in the three years allotted, the tripos no longer affords a fair field for all those who collect together as freshmen, as it did forty years ago. A very high place can hardly be hoped for now unless much ground has been got over before admission to the university. This point has attracted notice, and changes are about to be made (1878).

Before considering other methods, it will be well to take a general view of the action of examinations. First, it may be observed that the employment of examinations rapidly spreads. An examination at a school may at first be confined to a few subjects; it is then found that the rest are neglected, and however ill suited they are for examination, they must be brought in somehow. Again, if certain boys or classes are being prepared for an examination, the others think that they may take their ease, because they are not going to be examined, and the thoughts and interests of the teachers will commonly turn to those who have to prepare for this ordeal. Moreover, if some professions are guarded by an examination, those which are not so will become the resort of the dunces. Hence when examinations are once started they spread in all directions.

It is found that some branches of study are better suited for examination than others; and something more must be said as to the fitness of different classes of subjects for this purpose. Certain studies endow the pupil with the faculty of *doing* something he could not do before, such as that of translating foreign languages, or of solving mathematical problems; and there are others, like history, which though they may add greatly to the wealth of the man's mind, yield no such definite faculty or technical dexterity. We can test the possession of the first sort of acquirement directly, by calling on the student to put in practice the powers he is expected to have acquired. But with respect to the latter we can only ascertain that he recollects some portions of what he has prepared. By choosing these portions judiciously, we can tell whether the student has carefully studied the subject, and linked the various parts of it together, but we cannot make sure of the permanency of this knowledge. Young men used to examination will pick up just the information suited for their examination in a very short time, from an analysis or tutor's note book, and forget much in a few days. This power of "getting up" and "carrying" is not without practical value. It is the power which enables a lawyer to master a mass of details, and we may allow credit for this, for it shows a good analytical memory; but it must be observed that what is thus rewarded is not so much a knowledge of the special branch of study as a power of acquiring, which very probably might be applied to one subject as well as another.

It requires great experience and judgment in an examiner to deal with subjects like history and literature. He must have an eye for the cardinal points, and must know how a student ought to hold things together in his mind. If he yield to the temptation which seems to beset examiners of picking out "things not generally known," and minute details which a wise man is content to leave to be looked up when he wants them, then a kind of artificial knowledge, solely for use in examinations, will be engendered. In this class of subjects the profit obtained by the student is not proportionate to his recollection of what he has learned, and yet it is this recollection only which can be accurately measured. A student may have got good from his reading, and yet be able to do little even in a paper that is well set; because for an examination the subject must not only be read, it must be "got up."

The studies, on the other hand, which enable one to "do" something supply a power that is always at hand. A classical scholar can at any moment translate a passage. This difference is very important. "Information subjects" burden the memory and give rise to "cram" more than the others; besides, a faculty cannot be lost in a few months and information may. The more, therefore, that a competitive examination can be made to turn on "faculty subjects" the better. Information subjects can be dealt with more satisfactorily when competitions, which should be confined to an early age, are over, and the student is fitting himself for the work of life. He will read them most profitably when he feels that he wants the information, not for display, but for practical use.

Examinations, of course, tell us little directly about moral qualities; industry, indeed, they reward, but the work produced may have been done under the strong incentive of eagerness for success, or under compulsion, or in the absence of temptation, and under other circumstances the candidate's zeal may flag. Energy and tastes go far to make a man what he is, and of these examinations tell us nothing. A *course* of examinations tells something more as to steadiness of purpose and growth of mind than a single one, and a person who follows up an unusual kind of study—such as till lately natural science was—has probably a genuine taste for it.

It makes all the difference to the teacher whether the examination is subordinate to the teaching, or the teaching to the examination. In the first case he is really the educator—he lays down the course he thinks best. In the second he carries out a course which may leave him no option; and even if it embrace alternative subjects, these must often be chosen for the marks they will bring in the time allowed rather than for the good they will do the pupil. On the other hand, if a teacher's work is not subject to some external test, he may get careless, and neglect to keep himself abreast of the progress of science and of the art of teaching. Of course no public advantages could be granted to a certificate given to candidates by their own teacher, when his interest lay in getting them through. If he were independent, like an authorized public teacher, he might be trusted, but he would then be a permanent examiner, and his style would soon be understood. There must, however, be some correspondence between the teaching and the examination, especially on subjects which can be treated in different ways. If a professor, for example, occupy himself with the textual criticism of a book, and the examiner ask no question on this, students will neglect the lecture. Hence, the public teacher should be in communication with the examiner, or form one of a body of examiners.

In Germany the difficulty is solved in this way. At the "abiturient" examination the teachers in a gymnasium propose two questions in each subject; of these the Government inspector chooses one, and this the candidates who are leaving for the university answer on paper. The errors in the answers are marked by the masters, and the papers so marked are considered by the inspector, who, along with the school authorities, and with some reference to the pupil's work in school, decides on his fitness for leaving the gymnasium.

The two functions of testing acquirements and of directing and stimulating instruction do not act always along the same lines, and the examiner and teacher may therefore pull different ways. If the examiner wants to pick out the sharpest lad in a school he will give great weight to anything that shows brilliancy. Excellence, too, in any one department is a far better sign of power than mediocrity in many. But the teacher does not want the clever boy to rely on his facility in Latin verses or to give himself up to his favourite study, and will make the examination turn on the general school work. He will set questions in the parts of the subjects which involve drudgery, in order to enforce attention to them. Propositions in Euclid and questions on elementary grammar may have no effect in discriminating between two clever boys; yet these questions must be set if Euclid and grammar are to be learnt.

Again, an examiner may only want to see that the candidate has a certain knowledge, namely, that which is required in the situation in prospect. He may want to see, for instance, that arithmetical questions can be worked correctly; if this can be done he may not care how the knowledge was got,—all he wants being the fact that it is there. But a boy may be taught to do sums by the old mechanical rules, and this kills the reason instead of developing it. The educator is teaching the boy by means of Euclid, arithmetic, and the rest, rather than teaching him Euclid and arithmetic for their value as possessions. He will therefore frame his paper so as to show that the boy has gone through the processes of study which he wants to encourage; his questions will involve principles. His paper may not gauge powers of computation so well as one containing a number of intricate sums to be done in a short time, but it shows whether the boy in learning arithmetic has used his brains.

Examinations are effective in three principal ways as regards education. First, they act as stimulants, partly by holding out the prospect of advantages of some sort, and partly by appealing to the combative spirit in human nature and the desire to excel. Stimulants are valuable in our pharmacopœia, though liable to be used too freely. Youths who might sink into inertness are often roused to vigour by seeing a definite object to work for, or by finding themselves engaged in a contest. On the other hand, if the idea of gain is presented to young people too early, it may over-ride all other motives, such as duty and regard for authority and desire to learn. To those who have been habituated to examinations, it seems useless to work for anything in which they are not going to be examined, and the examinations will not act as a stimulus unless something is to be got by them. Hence competitive examinations should not be often repeated; a single comprehensive one at the end of a long course may do good, but it must not be kept always immediately in view. The pupil should not himself study examination papers, or speculate on the most profitable course, but should trust to his tutor, who will tell him that the best way to get marks is to learn honestly, as if for learning's sake alone. The stimulating effect of examinations leading to gain acts on parents and on schoolmasters. It leads parents to exert themselves to procure, not the best education for their sons they can, but the most direct preparation for competitions. This fosters low notions of education: people overlook the value of developed faculties and good mental habits, and seem to think that if there were no examinations their sons would want no schooling. Often it is of great importance for a youth to pass an examination when there is no time for him to get genuine knowledge; this knowledge must then be simulated by a process called "cram," which means that the "portative memory," or carrying power, must serve as a make-shift for all other faculties. Schoolmasters find a zest given to their work by looking to the places their pupils may gain, but the course which will earn the best place is not always that which will be the best for the youth in the end; and then the master is pulled in the wrong direction by the eagerness of the boy or his parents, and sometimes of his own subordinates, all of whom look first to success. Masters, let it be said, for the most part resist nobly, and aim at doing real good; but the pressure put on them adds to the wear and tear of their work.

Secondly, examinations serve as guides. A youth may seem to be listless only because his energies have not been turned into a definite channel; when he is shown his work, and is started in the way to do it, he becomes quite another being. Besides, a good examination shows what is meant by knowing a subject. The pupil or even a teacher by looking over a thoughtfully drawn up paper of questions gets a higher standard of knowledge; he sees the way of dealing with the subject *secundum artem* as opposed to any slipshod easy-going way of handling it. On the other hand, examination papers which are so meagre that the pupil finds no call on him for intelligence, or in which he can pass by doing a very small portion of the paper, have a most injurious effect. They give the pupil a low view of knowledge, and cripple the teacher, because the pupil is confident of passing with what he thinks he can learn in a week or two before the examination.

Thirdly, examinations oblige a person to be able to produce his knowledge, and encourage him to bring it out in a terse and lucid style. They give no credit to loose or floating knowledge. Notions that are in solution are not available; they must be crystallized in definite form before an examiner will accept them. Great difference is also made between an answer which is perfect and one which is not; and this exerts a good influence, for one of the commonest defects of loosely trained minds is that they are very deficient in exactitude, and do not appreciate the enormous difference between going "somewhere near" the mark and hitting the precise point.

But examinations, even when well conducted, have ill as well as good effects. They destroy spontaneity. Nine young people out of ten may quite rightly be made to move in a good "regulation groove," but the tenth would be better for having room to expatiate. The candidate who is getting up his books is busy about learning, not in thinking. If independent thoughts suggest themselves he puts them aside; his business is with his "books," for his own thoughts cannot be set. This tendency may be obviated by allowing scope in the answers for some discursiveness (but this has its evils also) or by introducing essays, but a man's mind no doubt becomes "examination bound" if he is subjected to repeated definite mechanical examinations. He is kept in a state of pupilage, and only reads to recollect when he is of an age to reflect, to examine, and to judge.

This leads to the question of age. Examinations, though good for boys, are bad for men. Those which deal with general education should not be continued beyond the age of 22. Professional examinations, or examinations in the highest parts of science, intended for those who mean to give their lives to study, must come later, but should be as little competitive as possible. By a "competitive" examination is meant one in which a candidate is depressed or excluded by the superiority of another.

Another point is the strain on the mind produced by competition. This strain is much greater, as has been said above, when many "information subjects" have to be carried in the head at once, than when the pupil has only to exercise in his examination a power which he keeps about him; because, in the former case, he is constantly harassed by the fear that he is dropping something. It is bad for a student when he is interested in his chemistry to feel a panic about his English literature. Nothing wears out the mind so much as being pulled many ways at once, especially if this state of distraction is prolonged. Yearly trials, for instance, for some appointment, a new subject being now and then added to increase the candidates' weight of metal, so habituate the mind to an artificial stimulus that pupils become incapable of studying without it. They can feel no interest in a subject if it is not to be set in an examination; and in time their power of attention is weakened, and their minds become like india-rubber bands which have been too long on the stretch. On the other hand, young people may be expected to be equal to one great effort or perhaps to two. Such occasions may call out some heroism or self-denial, and these qualities are much needed. But for this purpose the teacher should regard the examination with respect, and teach his pupils to respect it,—he must not help them to outwit the examiners. In this view it is well that the teachers should have some influence in framing or altering the examination scheme. They will then regard it as in part their own. Moreover, the pupil should have the examination in view at the end of a long vista of study; the preparation for it should not be hurried. The feeling of being short of time adds to worry, and prevents good work.

There are always some students of an anxious disposition who will over-fag themselves at the approach of an examination. This is more frequently the effect of over-worry than of over-work. It will usually be found on inquiry that the hours of work *per diem* have not been excessive, but the evil is that they have had no rest; when not at their books they are letting their minds run on their work, fancying they are forgetting something,—they are haunted by the idea of the examination, and become physically unfit for it. But we must not throw the blame of the mischief that may thus accrue to them on the examinations. Such cases do not commonly occur among those who are aiming at the highest places, and are most exposed to the strain of competition; very often the sufferers are merely pass men, and they are in fact unequal to any call on their nervous energies. The examination is the first call they encounter, and their weakness is shown in that; but they would probably have been in the same condition the first time they were called on to face any responsibility, such as to make a speech, or preach a sermon, or write an article by a given day. After an examination or two this nervousness is overcome by the stronger sort. No doubt young men have to encounter a severe strain at some examinations, and this should be reduced by lessening the load on the memory at one time. It may be very desirable for young men to learn something of six or eight subjects, but they should not be examined in all at once. It is also desirable that those who are exposed to strain of any kind should be under the eye of one who knows the laws of mental and physical hygiene—who can detect the first symptoms of morbid anxiety, and will have authority enough with the pupil to enforce exercise, proper diet, and mental relaxation. If the mind cannot rest, it must have a change of occupation.

The most important examinations are those which lead to university emoluments, and those by which candidates are selected for the civil service and the army.

A clever youth, destined for the university, is at present subjected to examinations from the age of 14 to 23 or 24. First he is brought on at a preparatory school, to compete for a scholarship at one of the large schools. The credit of his schoolmaster is involved in his success, and great pains are taken with the candidates. Usually the examiners understand boys, and the papers are set with judgment; but a boy at 14 should be extending the roots of his knowledge, not arranging it for display; and if he be trained in order to have something to show, there is a danger that solidity may be sacrificed to the early production of results. An examiner taking a school unawares, and questioning the boys, would probably detect the cleverest without doing any harm; but when boys work up to papers, even if they are carefully set, there is a danger of their developing the fatal facility of remembering words with little care for ideas, which belongs to their age. It is said that those who are elected scholars often seem to fall off at first. They have worked under pressure, and the pressure is removed. They most commonly, however, rally for the next contest, which is that for open scholarships at the university. The examinations for these are now almost always in special branches of knowledge,—classics, or mathematics, and natural science. The colleges too often aim at securing, not the youth who is well-educated all round, but one who is likely to obtain a high degree in a school of university honours. They want men of power; and *special* distinction is held to be the best criterion of this. Schoolmasters often grieve over the necessity of having to put a boy apart to be prepared for the classical or mathematical market, but the public looks in the newspapers for notices of scholarships gained, and a school which may do admirable work with the staple of its boys will yet be carped at if wanting in university success. Boys are hawked from college to college till they find one which will give the price,—that is to say, a scholarship of the value which the parent or master thinks the boy ought to fetch. Of these youths many have little taste for things intellectual, but they have hard heads, and a keen desire to get a scholarship, without which their friends will not send them to the university. By diligent work they may get such a place in a class list as can be won without special ability. Some, of course, are of a higher order, and of a perfectly satisfactory description; and others, on the withdrawal of the pressure that was on them at school, or under their tutors, turn idle and disappoint their purchasers.

At Cambridge, unless the students are at Trinity College, the "tripos" brings their examinations to an end. At Trinity College and at Oxford an examination by the college is held for fellowships. There are thus two systems for awarding these,—that of special examinations, and that of being guided by the university honours obtained. It is in favour of the first that it gives two or three chances, and that, by affording a long period from the first admission to the university, it enables a young man to retrieve himself if his early education has been mismanaged by his friends. In some cases, too, very good work is done in the intervening years, but for this to be the case the candidate must not be anxious about the examinations. Those who profit in this way are those who may reckon pretty certainly on success. Against this special examination it is urged that it retains men in pupilage up to 24 or 25, that with many it is a question whether their chance is worth the investment of the time, and that it gives an advantage to the richer men who can study at leisure, while the poorer must support themselves at schools or by private pupils.

We now come to Government competitive examinations, such as those for the army and civil service. The object of the system was twofold. First of all it was desired to get rid of patronage, with the solicitation and trouble attending it, and, secondly, to secure the ablest men which the situations can command. The first object, no doubt, is attained, and is well worth attaining; with regard to the second, experience seems to show that the system answers quite satisfactorily for the army, and moderately so for the civil service. The reasons of the difference are that the pay in the army is not sufficient to attract those who have no turn for the profession, or who are deficient in the traditional qualities or bearing of the British officer. This examination also is the less distracting of the two, because the number of subjects that may be taken up, both in the case of the ordnance corps and of the line, is limited, and a preponderance is given to those subjects which furnish faculties over those which result in information. If by these examinations we had to pick out 10 men out of 500, the mechanism would be too rough for the purpose; but if we have to take 50, we get down to the great plateau of mediocrity, where we find a batch of candidates nearly on a level; and even if the sixtieth man were to be a trifle better than the fiftieth, either of them would be good enough for the purpose.

The English Government encounters a particular difficulty in such examinations, because there is no uniform national system of education as in Prussia, and advantage must not be given to particular schools. This makes it necessary to allow a wide option of subjects, and the result is that candidates will take, not what is best for them to know, but what will bring most "marks" within a given period of study. The tutor has to invest the pupil's time in that study which promises best for his score. This is not satisfactory to the educationalist, but as a fact, if these youths were not getting up their modicum of zoology or electricity, they would probably be doing nothing better. The money value of an Indian appointment attracts many youths of a different class from those who seek for commissions; these may be wanting in the qualities which are required to command the respect of Hindus, and they may regard their career too narrowly as an investment of brains and labour for which they expect a good return. Physical accomplishments might be allowed to carry some weight, and be required as a qualification.

The next class to be considered are "pass examinations." These are important from the large number of men they affect. By a pass examination we mean one in which the leading object is to ensure a certain standard. It does not follow that some credit may not be obtained by doing well; indeed, for the healthy operation of the examination it is desirable that those who pass should be classified alphabetically in three or four classes. The objects of a pass examination are to sift out incapacity, and to ascertain that the candidates have gone through a certain process of education. The pass examinations of universities, both in England and in France, were until lately framed on a wrong principle. It was thought that the examinations should comprise a specimen of every kind of knowledge that an educated man should possess. If the graduate should prove ignorant of any such branch, the university, it was thought, could absolve itself from responsibility by showing that he had known it at one time. Now, however, we recognize the fact that these scraps of knowledge soon disappear. The portion of chemistry or history which the candidate has passed in is often only so much "book" learnt almost by heart; with those who do really well the case is different. The value of these examinations is only that they show that men can apply their minds, and can express themselves passably well. The subjects should be chosen much less for their value as information than for their requiring the exercise of thought. Pass men are apt to reduce all they can to the action of memory; hence subjects should be taken which require something more than memory. To detect "parrot-work," the examiners should be familiar with the text-books from which the subjects are learnt, and therefore such examinations should be in connexion with set courses of teaching. Translation of unseen passages, in Latin for instance, should be insisted on, but a dictionary might be allowed. Questions in geometry should be set in such a way that they cannot be answered by writing out Euclid by heart.

The difficulty of a pass examination depends both on the number of compulsory subjects it contains, and on the standard maintained in each. Feeble men can get through an examination in one or two subjects at a time, if the standard be moderate. Thus an examination which can be passed piece-meal, like the Cambridge "Little-go," is a poor criterion of brains, while an examination embracing many subjects ensures a certain strength of head, but not lasting knowledge of any one thing. When an examination has to be extemporized in order to ascertain whether candidates have heads on their shoulders, it will be sufficient to read over to them once or twice some short narrative or argument, or a correspondence on business matters, and to call on them to give an account of it on paper. This will test sufficiently well many of the qualities which go to make an efficient subordinate.

It remains to say something as to practical methods of examining. Originally examinations were conducted *viva voce*, and they still are so in part. Examinations in experimental philosophy and natural science are valueless without something of the kind. The student must perform experiments and explain them, and must identify and describe specimens. *Viva voce* examination is not well adapted for discriminating between candidates who are nearly equal, because they have not the same questions put to them, and nervousness is a disturbing element. The value of *viva voce* lies chiefly in detecting shallow knowledge. It convicts an impostor. On paper a candidate may avoid a searching question; in *viva voce* he has no escape. The objection to its employment is its great expense. It requires very skilled examiners, two of whom ought to sit together; and the examination should last a quarter of an hour for each man. When the numbers are large this involves a long period of examination and great cost. The German system of giving only one question in each subject for a pass examination, and allowing plenty of time, but requiring a very full and perfect answer, is well suited for fairly prepared men, who have only to be roughly classified as "excellent," "good," "fair," and "indifferent." This forces the candidate to study the whole subject carefully, while if a dozen questions are given, as in England, candidates will speculate on passing with a knowledge of only half the subject.

Essays may be used in examinations in two ways. Subjects of a general nature, like a maxim or topic of the day, may be proposed, in which case readiness and fertility of ideas are tested, but a kind of superficiality and glibness is engendered; or the student may be required to write on some subject belonging to his course. The classical student, for instance, might write on a point of Greek history. A dissertation written at leisure is an excellent means of judging of qualifications, and may be used for those who are past the proper age for examination.

In marking a paper the examiner distributes his marks to the questions according to the difficulty or the time they take to answer. The aggregate of the marks may not coincide with his impression, and it may be well to keep back one quarter of the marks, to be allotted afterwards, according to the impression obtained when the papers are read over again, not question by question, but as wholes. It may be well sometimes to use *negative* marks, as an answer may reveal such ignorance as to show that some of the correct answers were "parrot-work." When different subjects are compared, a little knowledge should go for nothing, and excellence should count for much It is a good plan to add to the marks got the excess above half the full value assigned to the paper, and then deduct one quarter of the full value, *e.g.*, if the full value be 500 and the candidate obtain 400, his score will stand thus:—

$$400 + 150 - 125 = 425.$$

Candidates for honours may be arranged in order of merit, as is common at Cambridge, or alphabetically classed, as at Oxford. In the first case brackets should be used, so as to class as equal those who fall within certain limits of uncertainty. These limits will be wider where there is room for difference of opinion among the examiners, as in composition or philosophy, than in mathematics. If the candidates whose marks differ by as much as twelve per cent. are bracketed together, we come to something like an alphabetical arrangement in classes. When the alphabetical system is adopted those who are sure of a first class are freed from anxiety. But many are in suspense about their class, and the difference between being in a first or second class alphabetically arranged is greater than that between being last in the first class or first in the second class, where the lists are in order of merit.

Out of 1000 young men who come to a university with a view to taking a degree, we find from experience that, roughly speaking, the following proportions will hold good:—250 will have both good abilities and the requisite power of will, and will take creditable honours; about 200 more will be comparatively weak in one or other of these qualifications, but may still get a place in an honour school or tripos; the next 150 will be the more vigorous pass men, who will show intelligence in subjects of but moderate difficulty, will enter keenly into the life of the place, and will pass their examinations respectably; 200 more will pass without failure; the 100 that follow will meet with failures more or less frequently; and the remaining 100 will never pass any university examination at all. Some of these last instances may almost be regarded as cases of disease, arising from infirmity of will or the want of the power to fix the attention. Neglect of the early acquisition of good mental habits is the cause of many failures. A youth may be rejected once from love of amusement or from underrating the examination, but he does not fail again if he can help it. A second failure shows moral or intellectual incapacity.

On this subject see—"Remarks on State of Education at Cambridge," in Dr John Jebb's works, 1774 (here we find the first plan for examining the pass men); Peacock, *On the Statutes of the University of Cambridge*, 1840; Whewall, *Of a Liberal Education*, 1848; *Reports of her Majesty's Commissioners on Oxford*, 1852, and *on Cambridge*, 1854 (in the latter sea the evidence of Dr Philpott, Prof. Stokes, Dr Merivale, Mr R. Lealie Ellis, and Mr W. Hopkins); *Suggestions on Academical Organization*, Mark Pattison, B.D. (referring to Oxford); L. Wiese, *German Letters on English Education*, translated by L. Schmitz, 1877; *Education in Oxford: its methods, its aids, and its rewards*, James E. Thorold Rogers; *Conflict of Studies*, I. EXARCH (*ἔξαρχος*, a chief person or leader), a title that has been conferred at different periods on certain chief officers or governors, both in secular and ecclesiastical matters. Of these, the most important were the exarchs of Ravenna, the first of whom was appointed by Justinian, emperor of the East, as governor of the middle part of Italy, which was made a province of the Eastern empire after Narses had entirely subdued the Goths and their allies in Italy, 552–554 A.D. Ravenna, with the whole exarchate, was conquered by Astolphus, king of the Lombards, in the year 752; but three years later it was taken by Pepin, king of the Franks, who bestowed it on the pope (Stephen III.), from which time Ravenna and its territory remained united to the papal dominions. The exarch of a diocese was anciently the same as primate. This dignity was intermediate between the patriarchal and the metropolitan, the name patriarch being given only to the heads of the more important dioceses. Metropolitans are also sometimes called exarchs, but apparently not in a technical sense. Exarch is used, in the ecclesiastical antiquities of the Eastern Church, for a general or superior over several monasteries, and is also applied to certain ecclesiastics deputed by the patriarch of Constantinople to collect the tribute payable by the church to the Turkish Government. In the modern Greek Church, an exarch is a deputy, or legate *a latere*, of the patriarch, whose office it is to visit the clergy and churches in the provinces allotted him.

EXCAMBION, or EXCHANGE. Excambion (a word connected with a large class of Low Latin and Romance forms, such as cambium, concambium, scambium, from Latin *cambire*, and Greek *κάμβειν* or *κάμπτειν*, to bend, turn, or fold) means in Scotch law the exchange of one heritable subject for another. Its meaning is extended by Lord Stair (*Inst.*, i. 14, 1) to every case of exchange or barter, the *permutatio* or innominate contract (*Datur res ut vicissim res detur*) of the civil law, about which a fierce controversy raged between the Proculian and Sabinian schools, as to whether it was truly a sale or a separate contract. Both schools used to quote the words of Homer, "And thence, too, wine was got by the long-haired Achæans, some bartering it for bronze, and others the glistening steel, some hides, and some the cows themselves, and some again slaves." This Roman contract was not constituted by consent, but by a formal stipulation; it did not pass the property of movables, if the seller had not a title; and it was liable to be rescinded on proof of great inequality. In each of these features it has been modified by the modern law of most European states. Erskine says (*Inst.*, iii. 3, 13), "This doctrine (of property not passing apart from title) may be equitable if directed only against the party himself and his heir; but there could be little security in the commerce of movables if it were extended against a singular successor who had *bona fide* bought the subject from the party after the exchange." In other points, such as the risk of a subject being destroyed, or the remedies on breach of contract, permutation of movables falls under the same rules as sale. The feudal lawyers amused themselves by discussing what name should be given to a contract in which the consideration consisted partly of money. They called it sale where *major pars in pretio quam in re permutata*. In the more limited sense of the exchange of heritable subjects, this contract received from the feudal law some advantages not given to sale. Thus, the burdensome right of the superior called *protimesis*, or pre-emption, did not apply to excambions. The *decuriones*, or town councils, of the imperial *municipia* were allowed to excamb, although they could not sell, the town-lands; and so with regard to church lands, the *fundus dotalis*, and other subjects partly withdrawn from commerce, excambions, but not sales, were permitted. Sovereigns, too, were allowed to excamb parts of the royal domain, although, as may be seen from the Scotch annexation and dissolution statutes of the 16th century, it required special authority to feu or alienate such subjects. The modern Scotch excambion may consist in the exchange of any heritable subjects whatever, *e.g.*, a patronage or, what often occurs, a portion of a glebe for servitude. The older form of an excambion was in separate dispositions by each "copermutant," as Pothier calls him, in favour of the other, or sometimes mutual charters, each party becoming in turn vassal and superior. And according to the *Leges Burgorum*, c. 55, where lands or houses in burgh were exchanged, the form of delivering sasine consisted in the *apertio* and *clausio* of the door, or the passing out and in of the parties respectively, each of whom gave two pennies (*duo nummi*) to the bailie. But this early form was soon superseded by one contract of excambion (originally drawn by Gilmour and Nisbet, and preserved in the MS. Style Book of Bain of Pitcarly) containing both dispositions, and proceeding generally on the narrative that the parcels of land excambed lie remote from or at least discontiguous to the mansion-house or the principal estate, and, being intersected by the lands of the other party, form a run-rig possession. This contract gives to each party a sufficient narrative of his own title to the lands he is disponing, and it provides, although the law implies this in every express excambion, that on eviction the contract and sasine shall be void and null, and that immediate "recurrency" or regress be given *brevi manu* to the lands which were excambed by the party evicted. Such real warrandice, as it is called, affects excambed land in the hands of singular successors who have purchased *bona fide*, and hence it is often provided that notice of any action of eviction shall be given to the excamber or his heirs. This exceptional severity reminds one of the civil law which distinguished between sale, where delivery of possession with warrandice against eviction was sufficient performance by the seller, and exchange, where an absolute title of property must be given. Writing, however, is not, by the law of Scotland, essential to an excambion. Chiefly in favour of the class of cottars and small feuars, and for convenience in straightening marches, the law will consider the most informal memoranda, and even a verbal agreement, if supported by the subsequent possession. The power to excamb was gradually conferred on entailed proprietors. The Montgomery Act, which was passed in 1770, to facilitate agricultural improvements, permitted 50 acres arable and 100 acres not fit for the plough to be excambed. This was enlarged by the Rosebery Act in 1836, under which one-fourth of an entailed estate, not including the mansion-house, home farm, and policies, might be excambed, provided the heirs took no higher grassum than £200. The power was applied to the whole estate by the Rutherfurd Act of 1848, and the necessary consents of substitute heirs are now regulated by the Entail Amendment Act of 1875.

Exchange, in English law, is defined as the mutual grant of equal interests, the one in consideration of the other. The peculiarities of this very ancient common law conveyance or assurance were—(1) equality of estates, not in value or in subject matter, but in legal right of ownership; (2) the use of the word exchange (*excambium, e.g.*, in Domesday book, *hanc terram cambiavit Hugo*, &c.); (3) that, though formal delivery of seisin was not required, possession or entry was required to complete the transaction by making it notorious; (4) that, in the case of incorporeal hereditaments, and where the lands lay in different counties, a deed was required; (5) an implied condition of re-entry on the lands of him whose title failed (Coke on Littleton, 50 *a*; Blackstone by Sweet, ii. p. 323), the liability to re-entry affecting an alienee, but the right to re-enter being personal to the exchanger and his heirs. This condition, however, did not long survive the statute *Quia emptores*; and exchanges are now generally effected by mutual conveyances with the usual covenants for title, which the Act 8 and 9 Vict. c. 106 declares not to imply any condition, whether the word "exchange" be used in the *testatum* or not. Exchanges are also very frequently made, by order of the inclosure commissioners, under the various Acts of Parliament for the inclosure, exchange, and improvement of lands, from 8 and 9 Vict. c. 118 to 31 and 32 Vict. c. 89 (see Cooke *On Inclosures*). In these cases, the property taken is simply impressed with the title of the property given in exchange. So also statutory exchanges are made under the Acts for the Sale and Exchange of Charity Estates, the Charitable Trust Acts, from 16 and 17 Vict. c. 137 to 32 and 33 Vict. c. 110, which now apply to Roman Catholic charities, formerly under 23 and 24 Vict. c. 134. There are also statutes enabling ecclesiastical corporations to exchange, with the approval of the church estate commissioners. Powers of exchange are generally given to trustees under English settlements, and these are exercised by revocation of the original uses and appointment of new uses, all ancillary powers being given by implication under 23 and 24 Vict. c. 145 (see Davidson's *Precedents in Conveyancing*, vols. ii., iii., and v.).

In what may be called international conveyancing, the exchange of territories is accomplished by treaties, of which there is no fixed style. A well-known example is Art. XII. of the Treaty of Nimeguen, "Les terres enclavées seront exchangees contre d'autres qui se trouveront plus proches et à la bienséance," &c. The Italian duchies and islands have very frequently been exchanged. Thus, in the Quadruple Alliance of 1720, Philip V. exchanged a reversionary title to Sicily for a reversionary title to Sardinia. The exchange of prisoners in war is often regulated by documents called cartels, which specify a certain agreed on value for each rank of prisoners. The transference of prisoners is often carried out by cartel ships, which, though prohibited from carrying cargo or passengers, are entitled to certain privileges. It was in the 17th century that this practice (which seems to have been unknown to Grotius) superseded the older one of ransom at the end of the war.

See Wheaton's *Elements of International Law*, Lawrence's edition, p. 590, and App. A. in Robinson's *Adm. Rep.*, vol. iii. The early law of military exchange will be found discussed by Albericus Gentilis, *De Jure Belli*, cap. xvi., "De permutationibus et liberationibus." (W. C. S.)

EXCHANGE. The system by which commercial nations discharge their debts to each other has been termed "Exchange," or "the Exchanges." It has been subject of much study both by merchants and bankers who have to deal with its phenomena in the course of business, and by economists desirous to discover the causes of the phenomena, and to explain the laws or method of their operation. In rude times the people of neighbouring countries brought their staple or surplus produce to common fairs, where one kind of goods was valued and bartered for another; and the dealers brought a little gold and silver with them to settle the small balances. But this, though a rough type of international trade still, is a wholly different affair from modern commerce, with its transactors multiplied a millionfold, and conducting their transactions far apart in widely distant countries. Money itself does little to obviate the difficulties arising from this multiplicity of crossing and recrossing currents; and whoever, therefore, was the first introducer of the idea of "Exchange" is entitled to a high place in the commercial annals of the world—whether it was the stranger mentioned by Isocrates, who came to Athens with some cargoes of corn, and gave an order on a town on the Euxine where money was owing to him, with recourse on an Athenian merchant in the event of the order being dishonoured; or Cicero, in paying for the studies of his son at Athens by an assignment from a creditor in Rome on his debtor in the Greek city; or the pope, whose lending merchants of Siena and Florence drew upon Henry III., or rather on the prelates and abbots of England, with some English merchants as remitters, for the expenses of deposing Manfred, king of Sicily, in which act of deposition Henry was an interested and obligant party—thus avoiding in these various cases the difficulty and risk of transporting coin. The idea, wherever first exemplified, was too good to be lost. It was early developed into a system in Venice, later in Amsterdam, and is now of world-wide application.

It is well to observe, first, what is exchanged—values of commodities exported and sold from one place or country to another, debts thereby owing, interest, profits of capital invested abroad, foreign loans and subsidies, freights, banking and other commissions, expenses of foreign residence or travel, and, in short, claims of payment of every kind on one part, having their relative obligations of remittance on the other, and originally denominated, as the contract or the occasion may have been, in the money either of the places from which the claims proceed or of those where they are payable. Secondly, the means must be noticed by which the exchange is effected—pieces of paper, bearing express calculation to secure what is exactly due between debtor and creditor. A bill of exchange is an order drawn for a specified and definite sum, in favour of a person who is the buyer and becomes the "remitter" of the order, upon a third person, the "drawee," who is indebted for this sum to the drawer, and on presentation of the order becomes the "acceptor." The person or company in whose favour the order is drawn may pass it into other hands, and these, by writing their names on the back, become "indorsers." On much the same model there are "inland" and "foreign" bills of exchange. The whole system of exchange has its foundation in the drawing of the creditor on the debtor; for, as in every country there are both creditors and debtors of other countries, the debtors find it to their advantage to take up the drafts of the creditors in order to avoid direct remittances in cash.

Inland exchange

Inland exchange is simpler in character and more easily comprehended than foreign exchange, but in reality presents the same phenomena and the same sequence of cause and effect as the other, so far as the circumstances of any country allow these to come into operation.

Mr M'Culloch, in the article on "Exchange" in former editions of the present work, gave a familiar exposition of inland exchange, which it would be difficult to improve:—

> "If the debts reciprocally due by London and Glasgow be equal, whether they amount to £100,000, £500,000, or any other sum, they may be discharged without the intervention of money, and the price of bills of exchange will be 'at Par;' that is, a sum of £100 or £1000 in Glasgow will purchase a bill for £100 or £1000 payable in London, and *vice versa*. But if these cities be not mutually indebted in equal sums, then the price of bills will be

increased in the city which has the greatest number of payments to make, and reduced in that which has the fewest. If Glasgow owe London £100,000, whilst the latter only owes the former £90,000, it is clear, inasmuch as Glasgow has a larger sum to remit to London than London has to remit to Glasgow, that the price of bills on London will rise in Glasgow because of the increased demand, and that the price of bills on Glasgow will fall in London because of the diminished demand. A larger sum would consequently be required to discharge a debt due by Glasgow to London, and a less sum to discharge an equal debt due by the latter to the former; or, which is the same thing, the exchange would be *in favour of* London, and *against* Glasgow. Bills on London would sell in Glasgow at a *premium*, and bills on Glasgow would sell in London at a *discount;* the premium in the one case being equal to the discount in the other.

"On the supposition that the balance of £10,000, due by Glasgow, depresses the exchange on London *one per cent*, it appears, at first sight, that it will cost Glasgow £101,000 to discharge her debt of £100,000 due to London; and that, on the other hand, £89,100 would be sufficient to discharge the debt of London to Glasgow. But a very little consideration will serve to show that this would not be the case. Exchange transactions cannot take place between different cities until debtors and creditors of the one reside in the other. And hence, when the exchange became unfavourable to Glasgow, the premium paid by its merchants for bills on London would not go into the pockets of their creditors in the latter, but into those of their neighbours in Glasgow to whom London was indebted, and from whom the bills were purchased. The loss to Glasgow would, therefore, be limited to the *premium* paid on the balance of £10,000. Thus, supposing that A of Glasgow owes D of London £100,000, and that C of London owes B of Glasgow £90,000, A will pay to B £91,000 for a bill or order on C to pay D £90,000. In this way the £90,000 of London debt at Glasgow would be cleared off,—the premium, which is lost by the debtor to London in Glasgow, being gained by its creditor in the same place. If the business had been transacted in London, C, with £89,100, would have purchased of D a bill for £90,000, payable by A; so that, in this case, the gain would have fallen to the share of the debtor C, and the loss to that of the creditor D, both of London. The complexity of real transactions does not affect the principles on which they are founded. And whatever may be the amount of the debts reciprocally due by different places, the only disadvantage under which any of them could be placed by a fall of the exchange would be the unavoidable one of paying the expense of remitting the *balance* of debt.

"The expense of transmitting money from one place to another limits the fluctuations in the exchange between them. If 20s. sufficed to cover the expense and risk attending the transmission of £100 from Glasgow to London, it would be indifferent to a merchant, in the event of the exchange becoming unfavourable to the former, whether he paid one per cent. *premium* for a bill on London, or remitted money direct to the latter. If the premium were less than one per cent., it would be clearly his interest to make his payments by means of bills rather than by remittances; and that it could not exceed one per cent. is obvious, for every individual would rather directly remit money than incur an unnecessary expense by purchasing bills on London at a greater *premium* than would suffice to cover the expense of a money remittance. If, owing to the badness of roads, disturbances in the country, or any other cause, the expense of remitting money from Glasgow to London were increased, the difference in the rate of exchange between them might also be proportionally increased. But in every case the extent to which this difference could attain would be limited by, and could not for any considerable period exceed, the cost of remitting cash.

"Exchange transactions become more complex when one place, as is often the case, discharges its debts to another by means of bills drawn on a third place. Thus, though London should owe nothing to Glasgow, yet if Glasgow be indebted to London, London to Manchester, and Manchester to Glasgow, the latter may wholly or partially discharge her debt to London by remitting bills on Manchester. She may wholly discharge it, provided the debt due to her by Manchester exceed or is equal to the debt due by her to London. If, however, it be not equal to the latter, Glasgow will either have to remit money to London to pay the balance of debt, or bills on some other place indebted to her.

"Transactions in inland bills of exchange are almost entirely conducted by bankers, who charge a certain rate per cent. for their trouble, and who, by means of their credit and connexions, are able, on all occasions, to supply the demands of their customers. Bills on London drawn in Edinburgh and Glasgow were formerly made payable at forty days' date, which was equivalent to a *premium* of about ½ per cent.; but, owing to the greater facility of communication, this *premium* is now reduced to twenty days' interest, or to about ¼ per cent. Bills for remitting the revenue from Scotland are now drawn at thirty days; previously to 1819 they were drawn at sixty days."

The cost of remittance from Scotland to London has continued to fall during the last thirty years. Bills on revenue account are now drawn at eleven days, free of stamp, and bankers' drafts at seven days, or at a charge of 2s. per £100 up to £300, 6s. for all sums between £300 and £600, and 1s. additional for every £100 above £600. On the other hand, the London bankers remit money, paid over their counters to-day, to Scotland and other parts of the kingdom, payable at par to-morrow. To this extent the rate of exchange is still adverse to Edinburgh and Glasgow, and in favour of London. In like manner the holder of a bill of exchange in Edinburgh or Glasgow upon London finds himself in a somewhat better position than the holder of a bill in London upon either of the two Scotch centres. Yet it would be an error to suppose that the balance of trade is against Scotland and in favour of England. The balance of value of commodities exchanged between the two countries is in favour of Scotland, and might be greatly in her favour, and yet the rate of exchange be adverse; so that we are thus early admonished that the imports and exports of goods, though an important, are not, as was long supposed, a decisive element in the rate of exchange. The transmission of the revenue of Scotland (seven or eight millions annually), the rental of owners of land having their chief domicile in the metropolis, and the amount of obligations of Scotch merchants made payable in London under the increasing concentration of monetary business, would be sufficient to counteract the effect of a large balance of trade on the rate of exchange. Hence London bankers, in taking money even in small sums payable at par next day in Edinburgh or Glasgow, are simply taking beforehand what is already under course of remittance, and reducing *pro tanto* the balances to be remitted from Scotland.

The relations of inland exchange just stated are those of a country where the money is uniform; where the banknotes of Ireland and Scotland are payable on demand in the common imperial standard of value, as the country banknotes of England are similarly exchangeable for gold or for Bank of England notes, which latter are orders for the delivery of so much gold in the issue department; and where, consequently, all inland bills are drawn in precisely the same money. The circumstances are thus highly favourable to an even exchange; and it may be conclusively held that the nearer the monetary system, whether in separate countries within themselves, or in nations closely related by commercial and financial transactions one with another, approaches to these conditions, the difficulties and oscillations of exchange, inland and foreign, will be reduced within narrower limits.

The history of inland exchange in the three kingdoms presents abundant proofs of the immediate effect of money of differing values in disordering the exchanges, or, in other words, the uniform payment of their debts one to another. In the early days of Scotch banking, when the natural limit of a free legal issue of notes was less understood than it soon became, and a structure of bills of exchange was reared upon this basis, it was found that bullion had to be raised by constant re-discounts in London, and that exchange, in short, became impracticable. Even within the same town, given two kinds of money or currency, one of superior value to another, a premium will be immediately established in favour of the money of superior value, and will affect every transaction, however small, by calculations of rate of exchange, as was long illustrated by the *banco* of Hamburg, a strict metallic money of given weight and fineness, in its contact with the worn or degraded coins of various mints in prevailing circulation. In 1689, when, by a proclamation of James II., one penny was added to the nominal value of the Irish shilling, £108, 6s. 8d. Irish money became equal to only £100 of British money in the nominal par of exchange. between Great Britain and Ireland, or a difference of $8\frac{1}{3}$ per cent. against the latter. In the course of another century the monetary system of Ireland and Great Britain had so far become uniform that the bank-notes of both countries were payable on demand in gold, but the dilution of standard proclaimed by James II. was still in force. In the eight years previous to 1797, the date of the Bank Restriction Act suspending specie payments, the rate of exchange between London and Dublin had ranged from $7\frac{1}{2}$ to 9 per cent., being from $\frac{5}{8}$ below to $\frac{2}{3}$ per cent. above the par of exchange, as determined by the actual value of the British and Irish money. The banks of England and Ireland were now alike free to issue notes without legal liability to pay them in gold on demand; and in 1803 the Bank of Ireland had increased its issues from £621,917 to £2,707,956, being in the proportion of 1 to 4 3; while the Bank of England had increased its issues in the same period from £9,181,843 to £16,505,272, or in the proportion only of 1 to 1·8. The rate of exchange was then 17 per cent. against Dublin, being $8\frac{2}{3}$ per cent. more than the normal par. But in the seven subsequent years the issues of the Bank of Ireland increased at the rate of $2\frac{6}{7}$ per cent., and the issues of the Bank of England at the rate of 5 per cent., while the country bank issues of Ireland were much diminished in amount, and those of England were largely increased. During this period the current rates of exchange became more favourable to Dublin. The inconvertible paper currency of Ireland had increased, but it had not increased in nearly the same proportion as the same kind of money in England. The manufacturers of Ulster, at once disaffected against the Government and annoyed at the uncertain value of the bank notes, clung to a gold currency; and while Dublin was under a discount of 8 per cent. in its exchange with London, Belfast was commanding a premium of 3 per cent. against London, and 10 per cent. against Dublin.[1]

Apart, however, from this element of the differing standards and values of money, which comes more fully into view under the head of "foreign exchange," it is impossible to follow closely the description of inland exchange above quoted from Mr M'Culloch without apprehending many of the principal characteristics of the operation, which, as they are sure to arise in exchange transactions under all circumstances, cannot be too soon brought into formal notice; such as (1) that the rate of exchange is ruled by the supply and demand of bills for the time being; (2) when in any market the demand for bills on a given centre is greater than the supply, the deficiency may be supplemented by bills on other centres having a favourable exchange with the given centre—a resource which, though indirect, receives much extension in the wide theatre of the commercial world under the watchful study of experts in bills; (3) the profit of a premium and the loss of a discount on bills fall within the market where the bill is drawn or sold, the drawee or acceptor having the definite sum on the bill to pay in either case; (4) exchange between one country or one centre and another is never a completed or perfectly adjusted process, but a constant series of transactions, reflecting the varying phases of claims and debts as they mature; and (5) the fluctuation of rates of exchange is effectually limited by the expense of transmitting money, that is, coin or bullion,—a principle which, though subject to partial exceptions in foreign exchange, is an underlying and potential law of the whole system.

Foreig e- chang

In the study of foreign exchange some embarrassment arises from the twofold character of the action and its results, and the necessity of realizing in one conception the drawers and buyers of the bills, and the two countries to which their transactions apply. It tends to simplify the matter to remember that what is transacted either in London or Paris expends the whole effect, for purposes of comprehension at least, of the course of exchange between the two cities; and so in other cases. If the debts, the time of settlement of which has come, of London to Paris be greater than the debts of Paris to London, the supply of bills on Paris in London will be less, and the supply of bills on London in Paris will be greater than the demand, which are only different forms of expressing the same relation. There may be a momentary variation in the rate of exchange in the two cities, but as soon as the relation of supply is discovered the variation will disappear. On both fields the same two classes of people, drawers and remitters, are at work, only the party in stronger force on the one is in weaker force on the other, and at both ends there is the same though converse result. In any one market, therefore, there is a complete representation of the action of exchange.

To a circle of exchange four persons, as is explained by Mr Mill, are always necessary: A, say of England, has exported English goods to B, say in France; and in order that B may be saved the expense and risk of sending money to A, A draws a bill on B for the sum due, and sells it to his neighbour D in England, in order that he may send it instead of money to C in France, from whom D has imported French goods of exactly equivalent value, and who, on the expiry of days the bill has to run, takes it to his neighbour B, and gets his payment, while in possession of the bill B has his discharge from A. The debt on both sides is thus paid without the transmission of a single ounce of gold or silver.

This is a genuine circle of foreign exchange; but in the great commerce and diversified creditorship and debtorship of the world the process is frequently of a very complex kind. Not only all the exports and imports, freights, and transit dues round the globe, but nearly all the public and private outlays which one country expends upon another, are paid by means of foreign bills of exchange. Mr Goschen, in a practical treatise which may be said to bring up the science of exchange to the present time,[2] examines the various classes of foreign bills, and specifies some movements of exchange which could hardly be dreamed of save by professional men. For instance, teas shipped from China to New York are generally paid for by a draft of the exporter on a London merchant for account of the American importer. The exporter in China is paid by the price which is given him for his bill on London; and the London acceptor looks for payment to the importer in New York. In the East Indies those who ship produce to America draw on London and not on New York; and the New Orleans cotton exporter to Russia draws on London instead of on St Petersburg. The explanation of this may be partly that Great Britain exports more in manufactures and silver to China, for example, than she imports of Chinese tea and silk, and thus leaves a balance of trade due to her, which the Chinese pay by transferring their claims on New York to their London creditors, and partly from the greater reputation and custom of the London banking houses than

---

[1] The *Bullion Inquiry and Report* of 1819 is full of information and discussion as to the effects on exchange of the long breach in our monetary system during the French Revolutionary wars, which will always be highly instructive, but on which it would here be out of date to dwell. The Scotch banks do not appear, during that trying period, to have departed from the rule of paying their notes in gold on demand. The contrary lesson may have been so well impressed on them by the experience of the previous century, and so well explained by the intermediate instructions of Adam Smith, whom, of course, they were the first to read, as to raise them above temptation.

[2] *The Theory of Foreign Exchanges*, by the Right Hon G. J. Goschen, M.P., ninth edition, London, Effingham Wilson, 1876.

those of New York or St Petersburg, though many of these may be no less wealthy than the others, or simply from the greater convenience of a bill on London. In proportion, however, as direct trade in mutual import and export of goods is established between two countries, direct exchange follows. Formerly the New York houses drew, for their shipments of tobacco and other produce to Bremen, on England for German account. But now since German manufactures and products have been making progress in the New World, bills of exchange are drawn between New York and Bremen, and Rio Janeiro and Hamburg. But the merchants of Bombay and other parts of India, finding few purchasers of bills on Bremen, still draw on London for German account. These indirect exchanges may be regarded as examples of the common expedient of utilizing both debts and credits at various distant points in redressing the inequalities of direct exchange; and, also, of the advantage of London, from the greater extent of British commerce and the greater distribution of British exports than those of any other country, as the centre for ultimate adjustments and clearings of this kind. But Mr Goschen has adduced an extensive class of foreign bills still more remarkable. These are bills "technically said to be drawn in blank," which represent no actual indebtedness at the period of drawing, and by which the acceptor does not pay his debt to the drawer, but on the contrary, the drawer incurs a debt to the acceptor. Mr Goschen admits that they approach nearly to the character of accommodation bills in the home trade, might be even worse abused, and consequently require to be discriminated. In many cases such bills have a function of public utility,—as, for example, where the imports of a country do not fall into the same period of the year as its exports, and the bills in payment of them do not meet each other in the ordinary course. In that case, the importers in seeking to buy bills on foreign countries would not find them, and would have no recourse but to remit specie in payment of their purchases abroad In like manner the exporters of grain, cotton, and other produce might draw bills for their value, but would find the bills were unsaleable, and would have to order the gold, remitted by the importers a few months before, to be sent back again. In this situation banking-houses draw "in blank" on bankers abroad, selling their drafts to importers at one period of the year and buying the bills of the exporters at another, therewith to refund the bankers abroad by whom their drafts have been honoured. The case implies a raising of capital in anticipation of the produce, but there need be nothing fictitious either in its manner or character, and it may well be believed to be the case of many large producing countries and colonies. In the dealings of foreign exchange the small as well as the large bills are embraced. With the piles of single bills for many thousands of pounds sterling, from such countries as China, India, or America, are commingled many bills of small amounts; while from all parts of Europe they are of a still more miscellaneous character—bills of retail as well as wholesale trade, bills of Swedish or Norwegian shipmasters for freights, of Dutch and Belgian farmers for parcels of eggs and butter, of Germans for toys, and French for odd *articles de Paris*, on minor agents, shopkeepers, milliners, and others, who may not have come in the course of their business within the range of inland exchange.

The developments of foreign exchange are always more or less modified in the course of a generation, and so much seems necessary as an introduction to the essential subject itself, and in particular to the explanation of the rate of exchange, how it is determined, and what in a general sense it imports.

Mr M'Culloch, in former editions of this work, treated foreign exchange under three heads:—(1) *nominal exchange*, or the rate of exchange established between two countries on a strict estimate of the respective money, or coins, or currencies, in which the value of their goods are usually denominated and exchanged; (2) *real exchange*, or the effect of the supply and demand of bills in raising the current rate above, or depressing it below, the mean point or equilibrium—nominal, inasmuch as it is an equal value from which there is constant variation by other elements acting on the rate of exchange, but yet of radical fixity and importance; and (3) *computed exchange*, or, in reality, the actual course of exchange as determined day by day from the combined consideration and effects of the other two. While this division was appropriate enough, it may be better here to consider still more in detail the various elements entering into the valuation of foreign bills or, in other words, the rate of foreign exchange. These may be conveniently embraced under the following heads:—(1) par of exchange; (2) supply and demand of bills; (3) rate of interest; (4) cost of specie remittance; to which may be added, what is always implied, (5) correct judgment of the force and duration of the cause or causes affecting the rate of exchange, or its opposite, panic.

Par of exchange.

1. Without some common medium of value in commercial countries, bills of exchange could not be drawn between one and another. The "cash" of China has played no more part in the foreign exchanges than the cowries of Africa; but since a mint has been established in Japan, from which gold pieces are issued under public regulation as to weight and fineness, there may be no difficulty in ascertaining the monetary equivalency, at Yokohama, of any debt due by Japan to England, or *vice versa*. The nations have thus found a medium of exchange in bullion, in gold or silver, or in both. In countries of the double standard, it has been usual to modify the law by liberty of contract for payment in one of the metals, without which liberty, indeed, it would be as well to have only one standard, since it is certain that the debtor will always choose to pay in the metal that has become relatively cheaper. In countries where silver is the sole standard, the par of silver to gold may be 15 to 1, or 16 to 1, as law or custom may have established; but in foreign exchange the par of silver to gold cannot be fixed at any absolute point by the law of any one country, and in the case of a depreciation, say of silver, even though temporary, by which the market price of silver to gold became 17 to 1, a proportionate addition would be made to the figures of the mint or former customary par, and this new sum become practically the par of exchange between the gold currency of England or California and the silver dollars of Mexico or rupees of India. Thus, having gold and silver to deal with, it is always possible, whatever may be the variety and names of the coins of different countries, to estimate the equivalents of the one to the other This is a matter simply of weight and assay; and the ratio thus found is the par of exchange between one country and another.

Mr M'Culloch seems to have thought that the par of exchange should properly include, not only equivalent weight and purity of the precious metals, but their relative cheapness or dearness in given places. "Thus," he says, "if, because of the expense of carriage, the value of bullion in Great Britain be 5 per cent. greater than in San Francisco, 100 ounces of pure gold in the latter would not be worth 100 ounces of pure gold in London, but 5 per cent. less; and the exchange would be at true par when bills for 105 ounces standard bullion, payable in San Francisco, sold in London for 100 ounces." Since this has not been the practice in determining the par of exchange—the 25·30 of Paris, and the old 109 of New York, &c., with London having been based more or less exactly on equal weights of pure gold for pure gold—a question is suggested which the following considerations may help to resolve.

The 5 per cent. claimed from San Francisco is for a relative dearness of gold in London, which can only be overcome by carrying the gold from the one place to the other; but it would be illogical to charge in a bill of exchange for a transport of specie which it is the express object and effect of the bill to supersede. The merchant in London would be entitled to sell a bill on San Francisco for a sum equal to 100 ounces of gold, and to include the costs of exchange, if any; or his debtor in San Francisco might buy a bill on London for a sum sterling equal to 100 ounces of gold; and if the course of exchange were such that this bill cost him only 99 ounces, the merchant in London would yet have no reason to complain. If neither of these modes of settlement were available, the debtor in San Francisco would have to send 100 ounces of gold to London, in which case there would be no rate of exchange in question.

But, apart from the less value of bullion in some countries than in others owing to nearness to the mines or other causes, there is a cheapness of the metallic money, as well as the general currency of a country, which operates directly on the rate of exchange, and requires in one form or other the recognition of a different par from that established under other conditions. The standard may be tampered with; the alloy may be increased; the weight of the coins may be diminished and diminished, till, like the Turkish piastre, they become scarce a shadow of themselves. It is obvious that innovations of this kind compel a rectification of the estimated par of exchange. In other cases coins are legitimately changed; and these variations, in so far as they supersede or modify coins which entered into the par estimate, are bound to have a new rating. A country which allows its coinage to be much worn, defaced, and generally light in weight, is in the same position as one which has deliberately lowered its standard of value; for though its light coins, when sent abroad, which they are not apt to be, count for no more than they weigh, there is the other and more serious effect that they may have been already well weighed at home, and have so raised the prices of the goods of the country as to place all dealings in them under a delusion as to their real value. One may well believe, however, that this is a form of monetary evil which has now passed away. There will always be some more or less worn and light coins in a metallic circulation, and as long as these are limited in number, and circulate in the country of their coinage at the mint price, they do little or no harm. There is a much more convenient process by which to cheapen the money of a country than any form of debasing the coinage, namely, to dispense wholly or almost wholly with metallic money in favour of an inconvertible paper currency.

When a country is impelled to issue paper money not payable on demand in gold or silver, its monetary value slips away from all fixed reckoning. The first effects are so agreeable as naturally to lead to a larger and a still larger issue, and the agreeable effects are prolonged until the real situation begins to be disclosed, and, finally, derangement has spread so widely on all sides that extrication becomes a task of the gravest difficulty. The effects even on the foreign exchanges are for a time somewhat illusive. There being no more need for gold and silver, nearly the whole stock of bullion passes out, and like a new found capital gives ample power of purchase abroad. The importer, finding that there are increasing prices for every commodity in the paper money, goes into his business with new heart and will. The premium, which has early begun to be established on foreign bills, soon becomes so large that the exporter imagines that he can make a fair profit out of the premium on his foreign bill alone, though there may not be a margin of a fraction of one per cent. of profit in the actual trade. Supposing such a result possible to the exporter, it is clear that he makes his profit entirely out of his neighbour the importer, who has to buy his bill, and consequently to pay the premium. Both cannot be right in their views, and in point of fact both are wrong until they begin to realize that the inconvertible paper dollar, rouble, or florin is not so valuable and has not the same purchasing power as the metallic money, or as the paper notes maintained in a constant practical convertibility. This fact is demonstrated within the country itself by the more or less gradual and uniform, but inevitable, rise of prices of all commodities, and of bullion among others, in this new currency. It is discovered very early in the foreign exchanges, not only since there is likely to be an excess of imports over exports when a country is in the act of denuding itself of specie, but because the foreigner has to be careful to get the value of his goods or produce as it is known to him in his own money; and any important change in the money of a country, therefore, obtains a sharp valuation abroad. Both at home and abroad it is soon discovered that the par of exchange, as formerly established, has passed away, and that a new par has come into operation under the pure force of the natural relations of the case. The importer finds no advantage from the advancing prices of what he imports in the domestic markets, since he has to pay more of the domestic money for the foreign bill of exchange by which he discharges the debt for his imports; and the exporter finds no advantage in the premium on his foreign bill which he sells to the importer, since it only replaces what he has already paid in the increased cost of his commodities and other outlays.

This action of exchange is now so familiar as to require little illustration; but a commonplace example may be given, to render more obvious the result on both sides. A, a merchant in London, at a period when the rate of exchange between London and Hamburg is at exact par, can sell a hogshead of sugar worth £50 in London to B in Hamburg for £100, or weight for weight in gold of 100 sovereigns. He exports, draws his bill on B, which he sells for £100, and derives his profit of £50 on the sugar, less expenses of transit. At another period of equal scarcity and dearness of sugar in Hamburg as compared with London, but when the currency of England has been under suspension of specie payment, and has been so much increased in quantity that prices of sugar and other commodities have doubled in the meanwhile, the hogshead of sugar now sells in London for £100. A, however, again exports, draws on B for £100, and, the rate of exchange being now 100 per cent. in favour of Hamburg against the currency of England, sells the bill for £200 in London, and makes a profit in the English currency of £100, equal to £50 in undepreciated money—the same profit as he made before. The results to B, all things being equal as supposed save the depreciation of the English currency, are also the same in both transactions. The case of a British importer, in corresponding circumstances, would not differ from that of A, the exporter; because, however unfavourable the *nominal* exchange might be in the bills by which he paid for his imports from abroad, he would be repaid by the increased nominal prices obtained for them in the home market.

As long as a change in the par of the money of two countries is not recognized or clearly understood, there may be much miscalculation and irregular profit and loss among the merchants on both sides. On the other hand, as soon as noted and brought under generally acknowledged estimate, it does not interfere, *per se*, with the movement of produce or the fair profits of those engaged in foreign trade.

But how is the depreciation of an inconvertible paper currency to be measured? As a convertible paper currency only maintains its par with gold by being always payable on demand in the gold it promises to pay, so an inconvertible paper currency falls just so much below the par of gold as the difference between the amount of gold it professes to be and the amount of gold it exchanges for in its own market. The price of bullion in an inconvertible paper currency rises like that of other commodities—not, indeed, in its general market value, but in its market price within the sphere of the currency; and the amount of this rise marks what may be called either a discount on the paper money or a premium on the gold, and this discount or premium becomes a measure of the depreciation of the currency. It is by no means a satisfactory standard, for it may vary from day to day, and in this respect be as unlike as possible to a par of exchange between the gold and silver moneys alike of small and great states, which may hold good without variation for any number of years. There may also be restrictions on the sale of bullion, prohibition of the export of bullion, and speculative combinations of paper holders and gold-holders to "corner" each other, and the fluctuations may be not only constant but sometimes extreme. But, with all its disadvantages, the relation of gold to the paper money, as it happens to be revealed in the markets, is the only measure of the depreciation to be had, and the premium on gold has consequently to be reckoned as a necessary component part of the rate of exchange with other countries.

The history of the last twenty years, though years of abundant production of gold and silver and great material prosperity, has been marked by an extended resort to inconvertible paper money in many parts of the world; and the exchanges of Russia, Austria, Italy, and many other countries might be referred to for ample proofs of the effect of this monetary expedient on the nominal par, and the extraordinary fluctuations to which it gives rise. The "greenback" money of the United States, a result of the war between North and South, is probably the most familiar, while in some respects also the most instructive example The par of the American dollar to the pound sterling was originally struck in the rough proportion of $40 equal to £9, which made the quotation at New York $4·44 to the pound, or, as stated on the British side, 54d. to the dollar. But on strict inquiry this did not correspond with the gold, weight for weight, in the dollar and the sovereign, and was in fact 9 per cent. too favourable to the dollar. It thus appeared that to correct the scales $9 had to be thrown in with every hundred, and adhering to the old par with the tenacity which has been the general commercial practice in such cases, the exchanges were held to be in equilibrium when bills on London stood at $109 for every hundred of the purchase-money, or 9 per cent. nominal premium in favour of England. The par, as more definitely stated, was then in New York $4·85 equal to the pound, or in London 49½d. equal to the dollar, and this remained the mean specie point from which all other influences acting on the exchange caused the rate either to rise or to fall, until the period of the civil war, and the issue of paper money, guaranteed by Federal security, but inconvertible. The effect of the new currency on the exchanges was neither immediate nor suddenly great in its proportions. The wide territory and large population of the Northern States were a powerful absorbent. Moreover, as the Government increased its issues the banks withdrew their notes, which had the effect *pro tanto* of staying the progress of depreciation. But gold was still absolutely necessary in the ports, and a premium on gold, inevitable from the first, increased month by month with the increased issue and circulation of "greenbacks." What the nominal par of exchange now was became a sort of arithmetical puzzle; for, taking the exchange of New York on London alone. without respect to other countries trading with the United States (the money of some of which was undergoing similar depreciation at the same period), the established premium of 9 per cent. in favour of London was met and supplemented by this new premium on gold, and to add the one premium to the other would not be enough, because the dollar itself was now fallen away from its value when the $9 to the hundred had been strictly ascertained and arranged as a corrective of the original rough par of $40 equal to £9. The Government, issuing the new currency that produced this disturbance in the foreign exchanges, had no theory on the subject, and only made some feeble attempts to regulate the sale of bullion. The adjustment was left in the main to the calculation of bankers and merchants on both sides, in presence of the natural causes in operation, and the solution thus attained may be all the more significant. The premium on gold in its exchange at New York with the paper currency was added to the former premium of 9 per cent. in favour of London, and the 9 per cent. itself, marked of old in $9 of bullion value, was increased *pro rata* by the same premium.[1] This rule has since regulated the nominal par of exchange between New York and London through wide ranges of fluctuation. The exchange was often as high as 180 during the war, so that the quotation must often have been—New York $8·0 = £1, London 30d. = $1·0. It is no less worthy of remark that, without the actual resumption of specie payment, the "greenback" dollar has been quoted of late in New York and other American cities at the metallic par of 4·85—a rare though not unprecedented phenomenon, to be attributed to a severe financial and commercial crisis, followed by four years of lowered prices, steady excess of exports over imports, and accumulation of bullion.

The effect of issues of inconvertible paper money, or the suspension of cash payment of paper currency already in circulation on the par of exchange, is the same as that of a change of the standard of value, a debasement of the coinage, or, where in one of two countries the money is gold, and in the other silver, a depreciation of one metal as compared with the other. When two countries par their gold coins, the object is to arrive at a common term by which value for value will be paid, in equivalent weight and purity of metal, out of the money of each other. When one of them displaces its gold coins by inconvertible paper money, the same object has to be attained, and this is reached, though not so fixedly as in the par of metallic coins, by the premium which gold commands over the paper money in the sphere of its currency. The former par in such cases may be adhered to as a landmark, and this gold premium may be treated as nominal premium on one side and nominal discount on the other, but it is substantially of the nature of par of exchange, and becomes a necessary integer of the rate of exchange. In the case of countries of one of which gold, and of the other silver, is the standard money, the nominal par is subject to variation from changes in the relative market value of the two metals. If, for example, the relation on which the par proceeded was 15 ounces of silver equal to 1 ounce of gold, and the depreciation of silver becomes such that 17 ounces

---

[1] Mr Goschen, in his book on *Foreign Exchanges*, gives the following definition of the process of exchange between New York and London:—"If, before the issue of paper money, the purchaser of a bill on England paid 100 dollars and 9 dollars for it, he would, if the premium on gold had risen to 50 per cent., in the first place pay 150 dollars instead of the 100, and in the second 13½ dollars instead of 9 dollars, or half as much again as what we may call the correcting premium. Thus, if the price of bills when gold stood at 150 was 163½, this price would correspond to the price of 109 at the time when there was no premium on gold. The price might rise to 165, or fall to 161, according as there was supply or demand, but the mean point would be ascertained by the process which has been described."

will buy only 1 ounce of gold, the par of exchange between the two countries will follow the course of that depreciation.

The course of the exchanges of India has been much affected of late years by the depreciation of silver, and so also those of all silver-paying countries. The drawer of a bill sterling on London in Calcutta or Bombay is literally selling gold for silver, and, whatever the more ordinary par may have been, is bound to take into account the market value of silver In 1876, owing to the large quantity of demonetized German silver thrown upon the market, less directly to a pre-existing cause, namely, the large extent to which silver had been cast out even of the fractional currency of countries largely committed to inconvertible paper, and also to exaggerated reports of abundant increase of production in the American mines, silver fell to 47d. an ounce—about the lowest point reached in its relation to gold, and a great reduction from what had long been its par value of 5s. 2d. an ounce. The consequence was that the Indian rate of exchange declined to 1s. 6½d. per rupee in six months' sight bills on London, or, in other words, that the rupee, having an accustomed par value of near 2s., was worth only 1s. 6½d. sterling, *minus* say seven months' interest accruing between the date and the maturity of the bill. It is difficult, or rather impossible, as foreign bills are negotiated, to distinguish the respective force of the various causes operating on the rate of exchange. In the case of India nearly all the constituents of exchange are adverse to the value of the rupee, save that of rate of interest, which is higher in Calcutta or Bombay than in London. The Indian drawer of a six months' bill on London would lose more by holding the bill till its maturity than the buyer of the bill who remits it to London for acceptance and discount; and some middle term must be struck between them, according as the rates of interest in India and England vary. But, on the other hand, India is a country where the imports always exceed the exports, where foreign capital in many forms has been largely invested and has to render its annual tribute, and where the financial relations of the Government of India and the Government of England are such that the latter has to draw periodically a considerable amount of bills on the Indian treasuries; so that, whatever the par of gold and silver might be, the supply of bills on London would always be less than the demand, or, in other words, the Indian creditors have some advantage over the Indian debtors of London in the rate of exchange. Were gold the money of India, the range of the premium thus established on the bill on London would be limited by the cost of remitting gold; but silver being the money of India, the action of the premium itself, or rather of the relative indebtedness of which it is the result, is to extend the range of the specie limit by lessening the demand for silver abroad. The rupee being less valuable than it formerly was, does less work in the Indian circulation and is all the more needed at home; to export it in payment of the adverse balance of trade would be to send it where it is less valuable still. It may thus be concluded that the depreciation of silver has been much the most potent and constant element in the adverse current of Indian exchange. The price of silver having since 1876 risen to 53½d., the rate of six months' bills in London has risen to 1s. 8¾d. The rate of Indian exchange rises in the export seasons when the supply of foreign bills is increased; and it rises with the price of silver at all seasons.

In the silver exchange between Hamburg and London the same rule prevailed. In Hamburg silver was money, but in England and other countries which have a gold standard it is only merchandise, and a rise or fall in the price of silver affected the value of a bill on Hamburg or a bill drawn on Hamburg in English sovereigns. Where a double standard exists, as in France, bills between that country and another are drawn in the standard which is common to both. Thus in the direct exchange between Paris and London, the bills are usually or almost wholly gold bills.

Supply and demand of bills.

2. Were there a common international money, the supply and demand of bills would be the chief determining cause of a rise or fall in the rate of exchange. Hence, in distinction from the nominal par, the relation of supply and demand of bills has been called "real exchange." Mr Goschen speaks of it as "the primary element in the value of bills," which, from so practical an authority, may be regarded as indicating that, notwithstanding all the varieties of money, this continues to hold the chief place in the negotiation of bills of exchange, or that, the nominal par being once determined, or a common principle formed for its rectification when the money of a country has depreciated, it ceases to require the calculation which must always be given to the supply and demand of bills in the market. As the sum of the bills offered, and the sum ready to be bought, never express the whole of the claims upon, or the whole of the debts due to a country, but only such claims as have been drawn for, and debts the time of payment of which has come or is nearly approaching, there is always more or less change of the relation of supply and demand, as well as opportunity of judgment as to the probable course of the market, and means of applying correctives if the balance be swaying too much on the one side or the other. If the price of foreign bills be depressed for want of buyers, drawers may hold back a little; on the other hand, if the demand has raised the price of bills, all who have sums to draw for will be induced to take advantage of the market, and so increase the supply. The buyers are moved in the same way, quickening or delaying their purchase within the limits of their period of remittance, according to their judgment of the probable course of the exchange. But the buyer cannot delay beyond the day when his remittance is due in the foreign country, nor the drawer beyond the ultimate date of drawing, or his own need of realizing the value of his bill; so that, amidst this oscillation, it is always the peremptory business to be done that determines the effect of supply and demand on the rate of exchange. The debtors of a foreign country, finding the supply of bills on that country less than the demand, will be ready to give an addition of price for them, in proportion to the scarcity, within the cost or up to the cost of remitting specie; and the creditors or drawers on a foreign country will submit in the other extremity to discount on their bills within the cost of sending them to their correspondent or banker's correspondent abroad, with orders to take payment and remit the proceeds in specie. When the course of exchange, as thus pursued from week to week, reveals that the claims immediate and maturing upon any country are greater than the debts due to it, and cannot be discharged through the mechanism of direct and indirect bills of exchange, its balance of debt can only be paid by remittances of bullion or an increased export of goods and produce, or other exportable value.

It is unnecessary to dwell further on the law of supply and demand of bills, which differs little from that of other commodities, beyond remarking that an inadequate idea would be formed of the efficacy of bills of exchange in liquidating international debts without taking into account an immense banking organization, aided by bill-brokers and dealers in foreign exchange, who have all the main currents of indebtedness under their eyes, and know with the precision of practice how the debts of one centre can be met by its claims upon others, and a stupendous mass of conflicting operations, ordinary and extraordinary, be most economically effected. Fifty or a hundred millions sterling, as in the case of the French indemnity to Germany, can be transferred from Paris to Berlin at a time without material disturbance of the more ordinary business of exchange. The British chancellor of the exchequer could transfer three millions and a quarter from London to Washington in payment of the Alabama indemnity before the operation was well known in the principal marts of the two countries. When England is lending ten millions to India, fifteen millions to the Australian colonies, or twenty millions to innumerable enterprises in the United States and Canada, or so many millions to Russia, Turkey, or the River Plate republics—or making several of such loans at nearly about the same time, as has sometimes happened—the effect on the foreign exchanges, though considerable, is seldom thought of. A foreign loan is usually taken out—a large part in goods, another part in bills, and the balance most probably in specie. But the effect of a foreign loan on the exchanges is exactly the same as if the borrowing country had exported produce to the lending country equivalent to the amount of the loan, placing it in debt to that amount. The lender has become bound by contract to pay so much to the borrower. The whole weight of a foreign loan, therefore, falls at once to what may be called the adverse exchange of the lending country or the favourable or less unfavourable exchange of the borrowing country. The reverse action comes in half-yearly or yearly bills, when the interest and redemptions of the loan, spread over a series of years, are payable. A foreign loan, if prudently and honourably conceived, may thus, as regards even the rate of exchange, be advantageous on both sides. The lending country gives a great advantage at once to the borrowing country in its exchange, which may be no evil in itself, and which the borrowing country, if the terms of the loan be fulfilled, repays in a period of years, during which its exporting and paying power may be reasonably expected to increase, which may be a common good. It may be added that foreign loans and investments of capital in foreign countries, badly as many may have been conducted, yet in their product of sound and marketable stocks and shares come to play a generally useful part in the rates of exchange. The value of commercial bills might not be so equable between such centres as London and Paris, or London and New York, without the intervention of stock exchange securities.

e of
rest

3. It is obvious that the number of days or months a bill has to run before payable imports the question of interest as an element of valuation in the rate of exchange. The usance of foreign bills is extremely various, from short to long, from payable at sight to payable at six months after sight, and days of grace are allowed by the law or custom of some few countries considerable enough to be taken into count. Where a bill is payable so many days or months after sight the time that must elapse, in the ordinary course of communication, before it can be presented for acceptance, is a further prolongation of the currency of the bill. The buyer takes it with this weight of time upon it, and, whatever the period may be, is entitled to a concession equivalent to the interest of the money which he pays, the converse happening in the case of stocks and shares on which dividend or interest has accrued at the period of sale, and must be accounted for to the seller in the price. But the important question in foreign bills of exchange is what rate of interest is to rule in the transaction. Is it that of the country where the bill is drawn, or the country where it is payable, or a compromise between the two? The drawer, in offering to transfer his bill to a buyer, is wholly in the domain of the rate of interest in his own market. If he sells, he gets the value of the bill in money worth so much interest; and if he holds the bill till its maturity, or to some period nearer its maturity, he deprives himself of money for that period worth the same interest. The buyer who, in the event of an exchange, pays down the value of the bill in money would seem to be under the same condition; but in reality, when closely examined, the relations of the buyer and the seller of a bill of exchange to the rate of interest are different. The buyer has a debt to pay in the country on which the bill is drawn, which debt he is bound to pay *now*, and for his purpose the bill is all the more valuable the less weight of interest it bears, or, in other words, the less discount it is subject to. Supposing, therefore, the bill is drawn in a country where the rate of interest is 7 per cent. on a country where the rate of interest is 3½ per cent., possession of the bill will be more profitable, as regards rate of interest, to the buyer than to the seller. If the seller holds the bill, it bears 100 per cent. more weight of interest than it would bear in the hands of the buyer. If the rates of interest in the two countries be exactly reversed, the bill bears 100 per cent. more of this weight in the hands of the buyer than of the seller. Thus, after the par of the currencies has been established, which, as we have seen, is always practically established, even in the case of an inconvertible paper currency, by the bullion test, and must be regarded as the first condition of all foreign exchange, this question of interest is sufficiently important to modify the action of supply and demand, and of other circumstances operating either to raise the rate of exchange above or depress it below the par of the currencies. It is one of those innumerable commercial relations in which there is an advantage to buyer or seller, but which cannot be realized without mutuality, and which consequently helps them to a transaction. If the advantage of rate of interest be in favour of the buyer of a bill of exchange he will be inclined, other elements of valuation considered, to give a somewhat larger price for it than if this were not in the account; and if the advantage be in favour of the seller he will be less exacting. The whole advantage on either side may not be realized in the actual terms in either case; but it will have had some effect towards a mediation of the prices.

The price of a bill, apart from other elements, is the sum of the bill *minus* the interest it bears at the rate of discount in the country where it is payable. Yet in the practical negotiation this does not hold exact, because the value of the bill to the seller or the buyer is always modified by the relation of the rate of interest where it is payable to the rate of interest where it is drawn.

Rate of interest, though in the aspect it presents to the seller and buyer of a bill thus plain enough, yet comes to play so great a part in the general course of exchange that it is worth while to pursue the subject a little further. Rate of interest regulates the supply and demand of bills, and affects the rate of exchange through that element; where the balance of indebtedness is against a country an advance of the rate of interest tends to restrain imports and to stimulate exports, by which effects the balance of debt is reduced; and where the action of trade is not sufficient to overcome the evil, further rises of the rate of interest may be employed to attract imports of foreign capital and specie. In the case we have supposed of two countries, where the rate of interest is 100 per cent. more in the one than the other, this relation of their rates of interest may be the normal relation from the greater abundance or the greater profits of capital in the one than the other, and their exchange may be supposed to be in equilibrium, so that this normal relation is not disturbed by any changes of rate of interest to correct the supply and demand of bills, or the balance of trade. The effect, as we have seen, of difference of interest was in favour of the price of the bill drawn by the country of high interest on the country of low interest, from the fact that the buyer was moving the bill out of a market where it bore a weight of 7 per cent. to one where it bore a weight of only 3½ per cent. interest. But suppose the balance of indebtedness has become so adverse to the country of low interest that the rate has been increased to 7 per cent. in order to improve the course of exchange, and that the effect has been, as must more or less follow, to render the foreign drawer less eager to sell, and the foreign remitter more eager to buy. The remitter or buyer will find the new influence thus introduced operating in the same direction—viz., in favour of the price of the bill; but, on the other hand, the difference of interest has disappeared. Two effects have thus proceeded from the same cause, which neutralize each other so far as they go; and the remitter, instead of buying a bill, may as well, as regards the rate of interest in the two countries, be drawn upon by his foreign creditor. If the rate of interest be further increased to 10 per cent., the drawer may be induced to hold the bill in order to save the 3 per cent. of discount above the rate of interest in his own market, or an investing buyer may intervene, and give such a price for the bill as will allow the seller 1½ or 1 per cent. of the profit, and leave 1½ or 2 per cent. to himself. In either case the bill would be held till it matured, and relief to that extent be afforded to the exchange of the country raising its rate of interest. But it is clear that not until the rate were raised 3, 4, or 5 per cent. above the rates of the countries drawing upon it could any effect of this kind be produced. It thus appears that the function of rate of interest in controlling the supply and demand of bills is a strictly limited function; and this limitation will probably be found in all the effects expected from it on the state of exchange. It may hasten the course of payments due to a country, but it does not lessen the adverse balance of indebtedness, nor can it much retard the pressure of the foreign claims. It may restrain importation of foreign goods, but it may not at the same time increase exportation of domestic goods; or, if increasing export, it may not diminish import. These are results which will depend on many other causes. It may tend to lower prices, and thus seem to check import, while facilitating export; but, forming in itself an addition to the cost of production and exchange, it may render much outward as well as inward trade less possible. If the rate of interest be carried high enough it may attract much capital from neighbouring countries. Foreign bankers and lenders will buy up bills on the country as the best mode of importing their capital, or may import specie; and admirable as this service may often be, yet it does not lessen the foreign indebtedness of the country. It only transmutes one form of the adverse balance into another more convenient for the time being; and in the meanwhile, if the high rate of interest has crippled the productive and exporting resources of the country, little good or a reverse balance of evil may have been done. Hence bullion reserves are either inadequate in the plan of their formation, or they miss their use and efficacy if, when a heavy balance of indebtedness appears in the exchanges, they cannot be trenched upon without large and excited advances of the rate of interest.

Cost of specie remittance.

4. Nothing is more definite in the system of exchange than what has been more than once stated in the course of these remarks, namely, that the cost of remitting specie forms the limit of variation in the rates of bills. That the buyer of a foreign bill will not give more for it than the cost of remitting specie equal in amount to his foreign debt is an axiom which holds good under all the ordinary conditions. But there are exceptions to the rule where the conditions vary from the ordinary. From the countries of productive gold and silver mines bullion flows abroad as naturally as the corn, cotton, wine, or oil which forms the special merchandise of a country, and it will so flow irrespective of supply and demand of bills, rate of interest, and other causes which have so much sway in rates of exchange. San Francisco will export gold and silver to London in all states of supply and demand of bills, and when its rate of interest may be double that of the Bank of England, and in the common parlance money is there dearer than in London, though it may be only that the average profits of capital are larger in the one place than in the other. If bullion is needed at New York, and commanding a higher premium on the Federal currency, it will be matter of calculation to the bullion exporter at San Francisco whether to send a consignment to New York or to London. If, since the discovery of the Californian mines, a metallic currency had been established throughout the Federal Union, the United States would no doubt have absorbed a proportion of the gold and silver shipped to Europe; but this object accomplished, the export to Europe would have proceeded much as it has been proceeding. In short, from gold and silver producing countries the export of bullion is not a remittance of money, but a transmission of the exportable produce of labour, which but for export would not have been produced. Then, there is the case of exchange between countries of silver standard and countries of gold standard, from either of which remittances of specie cannot be made without exact reference to the market value of the two metals. This will have been already marked in the par of exchange between the gold and the silver country, but it will have introduced a new element into the cost of remittance, since the specie remitted will have to be sold into the specie standard of the country to which it is remitted. Silver from India and China, for example, in the circumstances of recent years, cannot be remitted in payment of an adverse balance of exchange without taking into account a subsequent act of merchandise—namely, what the silver will bring in the gold of England; and this, with silver under a course of depreciation, may be so doubtful that the buyer of a bill on London will rather yield in the rate of exchange, and give some fraction more of a rupee for the pound sterling than run the risk of it. Neither in payment of an adverse balance of debt, nor in transferring capital from one country to another with the view of taking advantage of a higher rate of interest, can specie be remitted between gold and silver standard countries free from this contingency. A Hamburg capitalist wishes to profit by a rate of interest two or three per cent. higher in England than at home. He will therefore buy bills on London up to a certain limit of price; if he has any gold, he will then remit gold rather than exceed this limit for bills; or he will remit the silver specie of Hamburg subject to its market value in London. In this case, indeed, the foreign capitalist has more than one act of merchandise to contemplate, for he has to look to the reverse action when the rate of interest may be higher at home than in England, and when it will be his motive to re-convert his English sovereigns into silver, which in the relative condition of the market value of the two metals may be either favourable or unfavourable. If unfavourable, he will buy bills of England on Hamburg, or some other centre with which the exchange is favourable to Hamburg, rather than re-transmit silver at a higher cost than the rate of the bills. It is obvious that all this does not alter the principle that the cost of specie remittance is the limit of rate of exchange on bills, but only that it gives a larger range to the variation of rate, and to the specie limit, between two countries whose money and standard of value are of different metals than would exist between two countries where they were of the same metal.

In exchange between a gold-paying and a silver-paying country, one of which, say the silver country, has gone largely into an inconvertible paper currency, the case becomes more complicated, and the specie limit to adverse rate on bills recedes, till, if the inconvertibility be so great as to be incapable of valuation, or the Government in its ignorance or alarm has prohibited the export of specie, the limit is wholly lost. A Russian merchant, who has ample silver and paper roubles at command for his purposes, but has a debt to discharge in America, or needs to lift a cargo of cotton at Liverpool or of sugar at Glasgow, and finds that the remittance even of such specie as he may be able to produce is illegal, must buy a foreign bill or a banker's draft on London at any price. At this stage the rate of exchange passes out of the domain of principle, or natural action of principle, into that of purely arbitrary considerations. When, from much less sufficient causes, general discredit passes upon a country, the rate at which its bills or acceptances may be valued is scarcely more reducible to rule. It might even be difficult to define why in the same general circumstances there should be collaterally a higher and lower course of exchange, and the bills drawn or payable by one firm should differ in their rate from those drawn or payable by another firm. It is only by removing abnormal conditions that one arrives at the underlying principle which governs exchange, and determines the success with which it is conducted.

Accordingly it is in countries where bullion, separated from its necessary export from the mines, has become money, and forms the common standard of value in their international trade, that the limitation of the rate of exchange by the cost of specie remittance is most clearly visible. Between all nations trading on a gold basis there is a well-known and definite point above and below the par of exchange where it becomes profitable to move gold from one to the other, and which marks the extreme range of variation in the price of bills. Thus in the exchange of London with Paris, New York, and Berlin respectively, 25·10, 4·81, and 20·30 mark a point in the price of bills below par when it pays to send gold from London to these centres; and, on the other hand, 25·30, 4·87, 20·50, a point above par when it becomes profitable to move gold from Paris, New York, or Berlin to London.

When the rate of exchange, touching, under the supply and demand of bills and other elements of valuation, these extreme points on one side or the other, and tending to exceed them, is the result of an actual over-indebtedness, a transmission of bullion is the best and most satisfactory mode of settlement. It directly reduces the balance of debt, and renders the price of bills again more equitable to the traders. All other modes of fencing it off, save an increased export of goods and produce, are more or less illusory. If, in such a juncture, an amount of foreign capital has been invested in bills on the country with the view of holding them to maturity for sake of profit in rate of interest, and now with the view of realizing the value of the bills in gold they should be pressed on the market before maturity for discount, an advance of one per cent. in the rate of discount may be sufficient to induce the foreign capitalists to hold the bills till they mature. And another advance of one per cent. in the rate of discount may induce them to reinvest in other bills on the country. But the root of the adverse exchange will not have been removed. It will always appear when the foreign capital thus invested in bills on the country is from any cause withdrawn, and until the over-indebtedness is liquidated by remittances of specie, increased export of produce, or transfers of saleable shares and securities.

If, on the other hand, the rate of exchange has been brought to the specie limit by bills, representing no actual debt, but drawn and accepted solely for the purpose of moving bullion, as may probably happen, there is no remedy for what may prove an inordinate demand for specie by irregular means but the detection of the bills, and either refusing them discount or discounting them under exceptionally high rates of interest.

Correct judgment, its opposite, panic.

5. An exposition, however brief, of the causes operating on the rate of exchange would scarce be complete without including the effect of opinion or estimate, correct or erroneous, of the probable course of the market; and therefore it may be observed that a judgment has to be formed in every new phase of the numerous fluctuations. The seller of bills finds that within a few days the market has taken an unfavourable turn. If he judges that this has arisen from merely accidental or temporary causes he will be inclined to hold his bills for what he deems their true value; or if, on the contrary, he judges that the causes operating are more deeply seated, and likely to become stronger for a time, he will sell with the least possible delay. Should his judgment be justified by the event he will have done what is right for him, if otherwise he will have done what is wrong; but in either case, his abstention or action will have affected the supply and demand of bills in the meanwhile. In all the great marts of exchange, and in London probably more than in others, there are frequent wave-currents so to speak, which cannot be rightly interpreted either as the sign of a protracted state of exchange between the points of the compass in which they flow, or of the general foreign indebtedness of the centre upon which they are directed. When New York balances its debts to China and India by bills on London, the bills affect the course of Eastern exchange; but they lose much of the significance they might otherwise bear when it is considered that New York is in course of compensating London in other directions. These operations come to be understood and systematized by dealers and agents in bills with much accuracy; but in addition to the judgment that may be formed by a thorough analysis of the substance of the various currents of exchange, there is the effect of opinion on external events, which, though of almost daily occurrence in one quarter or another, are wholly of future account, and which impress, not only the connoisseurs of exchange, but the whole body of drawers and remitters, from whom the original impulse on the action of exchange in all cases comes. The examples that might be adduced of the great effect of passing events on exchange are innumerable. In the beginning of 1861, when the disastrous rupture between North and South had occurred, and war was imminent, the United States had a most favourable balance of trade with England and Europe. Their exports of wheat and flour and cotton in the previous year had at once reached a maximum in quantity and a rise in value. The drawer of a bill on London was in so good a position that he had only to wait for the buyer to get the value of his bill up to the specie point. But so eager were the drawers, in view of the pending outbreak of civil war, to realize what was owing to them abroad, that they threw their bills on the market in an abundance which reduced their price to the other end of the scale. This, of course, had its converse effect at London, and bills on New York were there selling at such a premium that it seemed as if the United States would have to remit bullion to Europe. The volume of bills, however, told its own tale after a while. England had to remit bullion in large quantity to the United States, and then people began to awake to the perception that, in the exchange transactions, the one element most important of all had been left out—namely, the relative indebtedness. It must have been a time of much profit to those on both sides of the Atlantic who knew the actual state of affairs, and of much loss to those who did not know, of whom there can be little doubt that the latter were much the greater number, but the balance of value between the two countries, as expressed on the face of the bills, had to be rendered all the same.

To take a more recent case. The exchange value of the Russian rouble during the last twelve months of war between Russia and Turkey will amply illustrate what is meant by the prevailing judgment on events in their future aspect, which, while proceeding on a certain amount of reason, yet borders on panic, and may be of the nature of panic. The issue of paper roubles had gone the length of 730 millions before the war, and there was a constantly increased remission during the year, counteracted in some measure by conversions into loans bearing interest. On the mobilization of the troops the value of the rouble was 29d. to 30d.; on war being declared it fell to 27d, when it seemed as if Plevna could not be taken it sank to 22½d., when Plevna fell it rose to 26¾d, and when it followed that the conquest of Turkey and an armistice did not end the difficulties, it fell to the lowest point it had touched, 22⅛d

Favourable and unfavourable exchange

The term "favourable exchange,' as commonly used, not only means a state of the exchanges when the debts due to a country abroad are so much greater than what it owes abroad as to affect potentially the demand and supply of bills, and when the money of the country so situated, as expressed in the price of bills, is equal to more of the money of a foreign country than the nominal par—when its bills on abroad, in short, are dull of sale, while the foreign bills on itself are in much demand; it is also applied to all stages, moderate or extreme, of this relation of the foreign exchanges And so the term "unfavourable," of course, applies to the opposite conditions If these phrases had ever any reference to the prosperity of the foreign trade of a country, they must have arisen under the sway of "the mercantile system' of the last century, the principle of which was that a balance payable in specie is the cardinal condition of prosperous trade with any foreign country, or, if introduced under that erroneous theory, they have been prolonged by the usage of bankers and other dealers in foreign exchange, who, having large liabilities entailing bullion payment, naturally consider a state of exchange which is on the eve of bringing specie more favourable than one on the eve of taking it away This is quite true in the monetary view of the question, and it is true also as to the relative indebtedness for the time being But it is not true to extremes even in a monetary sense The condition of a country to which specie was always flowing in and never going out would be a realization of the fate of Midas The most favourable exchange, therefore, is that where there are only moderate oscillations up or down from the par of exchange

While the terms "favourable" and "unfavourable" are thus somewhat misleading as regards substantial interests, they are involved in a minor technical complexity, which, though well understood by those in the business may here be stated The terms would be strictly applicable in the sense they are used, were the rate of exchange always quoted in the home money. The *certain* properly in exchange transactions is the number of pounds, dollars, francs, or florins a remitter has to pay abroad; the *uncertain* is what amount of his own money is equal to this amount of the foreign money Were the quotation on both sides respectively always made in the home money, the fall or rise of the quotation would always be identifiable with such terms as "favourable" or "unfavourable" Both drawers and remitters would be so familiar with their significance as to know what they meant But this is not the practice, and, with so much variety of currency, could hardly have been the developed practice of exchange. The pound sterling of England is the largest monetary unit, and there is always facility of expressing minute shades of difference in the smaller units, more especially when, as in the case of Paris or New York, they have a decimal character. In London, consequently, the public only hear quotations of rate of exchange with such countries as France and the United States in the foreign money—London thus giving what is called the *certain*, and the smaller moneys the *variable*. On the other hand, not only in the Australian and other British colonies, where the standard of value is the same as in the parent country, but in such large commercial regions as China and India the quotation of rate of exchange on both sides is always expressed in sterling. The Chinese tael of silver is worth so many English pence sterling at Canton, and the rupee is worth so many English pence at Bombay or Calcutta, and in the same terms run the quotations in London. The practice may not alter in any iota the true rate of exchange, but it has the result that when the rate is quoted in sterling money, as in the Indian, Chinese, and Australian exchanges, every drop in the quotation is "more favourable" to England, every rise "less favourable," and this will hold good whether the quotations are made in England or in India, China, or Australia, whereas, on the other hand, when exchanges are quoted in foreign money—French, German, or American, &c—every drop in the rate by the same rule is "less favourable," every rise in the rate "more favourable" to England, whether the quotation be made in England or in the foreign countries.

The states of exchange to which the terms "favourable" and "unfavourable" are thus applied refer wholly to the effect of the demand and supply of bills; so that, since the fluctuations of exchange are due to various causes, it would be an improvement were the quotation always to include the par of exchange, whether between the gold money of one country and the silver money of another, or between either and inconvertible paper, the depreciation of which has to be determined by the gold or silver premium in the country of its currency. The actual rate above or below par would show the effect due to the supply and demand of bills When a sudden alteration takes place in foreign exchange, nothing is more difficult than to discover the relative force of the cause or causes to which it is to be ascribed, and yet nothing is more necessary to know than this, whether in the correctives that may be applied or in the lessons to be conveyed to importers and exporters.

The limited meaning to be given to such terms as "favourable" and "unfavourable" exchange probably applies to other statements that may arise legitimatel in connexion with this subject. The principle, for instance, that the profit and loss of exchange transactions fall, not between the two countries concerned, but between the foreign creditors and debtors in one or other, is exact within its own range; but it leaves as an open question whether in a country where from a depreciated and depreciating currency the rate of foreign exchange is always rising, the general result may not be adverse to its interests in export and import trade. In like manner it would be more than questionable, because "the mercantile theory" was wrong in supposing that a balance of foreign trade in specie, or an excess of export value over import value, was the necessary condition of national prosperity, to posit the opposite doctrine that an excess of imports over exports is the only prosperous condition. The solution of this question must depend on what may be called the permanent indebtedness of some countries to others. A country which is under large tribute to foreign capital is assuredly in the right way for itself and for other countries when the value of its exported exceeds that of its imported produce. And so also it may be observed that "rate of interest," if we are correct in our reasoning on that head, may not have the absolute control over the exchanges which was so strongly emphasized for some years after the passing of the Bank Charter Act of 1844, and has since only been modified in practice without any express recognition of the principle involved.

NEGOTIATION OF BILLS OF EXCHANGE.

Rates of exchange have undergone much variation of late years from changes of standard—in some cases from gold to silver, and in others from silver to gold—and from the circulation of forced paper currency. The tendency, however, is to greater uniformity. The gold standard of value adopted at Berlin extends to the whole German empire, and the rates of exchange are now calculated in imperial marks and pfennige at Hamburg, Frankfort-on-the-Maine, Altona, and other German places, where different moneys formerly were used. The money under the new system is 100 pfennige = 1 mark, 20 marks = 1 twenty-mark gold piece (imperial mark) = 19s. 6·954 sterling mint par. The mark, which is the unit or integer of the system, is a silver coin based on the ratio of 1 to 15½ as the relative value of silver and gold. In like manner the kingdom of Italy has extended a uniform exchange; and the rates at Naples, Palermo, Messina, Milan, Turin, Florence, Leghorn, and other Italian towns are similar to the rates at Genoa.

Bills of exchange may be made payable on demand (as the invariable rule is in the case of cheques), at sight, at a certain specified time *after sight* or *after date*, or at *usance*, which means the customary or usual time for which bills are drawn from a given place, and when the time is doubled it is called *double usance*. No bills are now drawn in London at *usance*, and the practice is being gradually dropped in other countries. The usance of bills drawn from France, Holland, and Germany is 30 days' date; from Spain and Portugal 60 days'; and from Italy 3 months' date; but the currency of bills is regulated more by the classes of business to which they relate than to the usage of any country. The allowance of *days of grace* is also going out of fashion. *Three days* are still given on bills drawn upon or payable in the United Kingdom otherwise than at sight, and a similar practice holds in the United States. St Petersburg gives 3 days on sight bills and 10 days on date bills, Copenhagen 8 days, Christiania 8 days; but in these and other cases the allowance may not mark so distinctly the day when a bill is legally due as an interval within which certain legal proceedings of the respective countries cannot be instituted. The practice, which was at one period extremely various, has now been reduced within such narrow limits that in exchange transactions in London no account is taken of days of grace.

Bills of exchange in London are bought and sold through brokers, who go round the mercantile and banking houses, and discover whether they are buyers or sellers of bills. The negotiations are determined on Tuesdays and Fridays, which correspond with the principal post days in foreign exchange business. In London, as in other great commercial cities, bankers deal largely on the rise and fall of exchanges,—buying bills when they expect a rise, and selling bills when they expect a fall.

Foreign bills are generally drawn in duplicate or triplicate, lest the first should miscarry. When thus drawn in sets, the first is payable only "second and third unpaid," the second "first and third unpaid," and the third "first and second unpaid." Where there is a doubt as to the acceptance, the first may be sent unindorsed to a correspondent of the drawer in the place of payment to have it accepted, and the second sold and put in circulation, bearing the name and address of the party holding the first or accepted bill "in case of need," that is, in case he may not have obtained acceptance, and will protect the drawer from having the bill returned through the indorsers. The indorsed second, and the accepted first of exchange, when wafered together, become one bill and are valid.

Exchange, as regards the abundant arithmetic to which it gives rise in its negotiation, may be divided into—(1) Direct, or exchange between two countries wholly based on their rates of exchange, which is so simple as to need no remark; (2) Cross, or exchange between two countries in which a third country has an interest, as when London, say, has 10,000 francs in Paris which he wishes to move to Hamburg, and has to take account of his own course of exchange to Hamburg as well as the direct between Paris and Hamburg, which is only less simple than direct exchange, inasmuch as it requires two formulæ instead of one; and (3) Indirect or arbitrated, where exchange between two countries is conducted through the medium of a third, or more than one other country, and thus becomes more compound as the sphere of the operation is extended. It is an arbitrated rate because it has no actual form, and is found only in figures out of the current rates of exchange between more than two countries. The object being to discover how a debt in one place may be most economically paid from another, the question carries along with it not only the difference between remitting and drawing which exists in the simplest direct exchange—the debtor in the one country and the creditor in the other having always the option of the one remitting or the other drawing—but such *minutiæ* as whether the rate of exchange given be in the foreign money or in sterling, till it results in the following rules:—

"*For Remittances:*—

"With a foreign rate, any arbitrated rate is better than the direct rate if it is *greater* than the latter;

"With a sterling rate, any arbitrated rate is better than the direct rate, if it is *less* than the latter:

"Because, in either case, a given sum in sterling will produce a greater sum in foreign money, or a given sum in foreign money will cost a less sum in sterling.

"*For Drafts or Returns:*—

"With a foreign rate, any arbitrated rate is better which is *less* than the direct rate;

"With a sterling rate, any arbitrated rate is better which is *greater* than the direct rate:

"Because, in either case, a greater sum in sterling will be obtained from a given sum drawn for in foreign money."[1]

Nor is this all. Arbitrated rates are calculated for present money; the actual rates of exchange on which they are calculated have been affected by time and rate of interest. In the rate of direct exchange particularly, with which the arbitrated rate has to be compared, this effect has to be estimated, long bills reduced to short and the difference of interest on them discounted from the basis of calculation *prima facie*. This, in a superficial view, may be counterpoised by drawing speculative bills of long date on a foreign centre, but there are limits to drawing on a place for purposes external to its ordinary course of exchange, and a large amount of bills thus directed without corresponding remittances might produce an effect on the exchanges which would go far to upset the calculation.

It is obvious that arbitration of exchange, thus burdened at every additional length of the chain by difficulties of estimate, cannot be much extended or become too artificial without the risk of miscarriage. But the mediation of direct exchange through a third place is of such common and useful practice that it may be desirable to give an example broad enough to illustrate the general method of equation.

Take London on Paris at 3 months, quoted f.25·55; Paris on London at 3 months, quoted f.25·10.

The discount for 3 months, in the example to be given, is taken at 1 per cent., or 25 cents., which is deducted from the London rate and added to the Paris rate, to make the two short or cash rates: thus reducing the former to f.25·30, and raising the latter to f.25·35.

If this variable price were in sterling, as for instance with Madrid, the allowance for interest would have to be reversed, that is, added to the London price, and subtracted from the price abroad.

EXAMPLE.

From the following rates of bills in London and Paris it is required to find—

1*st.*—Whether, having money to transmit from London to Paris, it will be better for me to remit direct bills on Paris, or to order-bills in Paris to be drawn upon me in London, at the rate of 4 per cent. per annum.

2*d.*—Whether, having money to draw from Paris, it will be better for my correspondents there to make me remittances, or for me to draw upon them.

3*d.*—If I have to make remittances to Paris, whether any indirect rate will answer better than the rates of direct bills.

4*th.*—If I have to obtain returns from Paris, whether any indirect rate will answer better than either of the direct rates.

RATES OF EXCHANGE.

London, June 17.		Paris, June 14.
25·55	Paris at 3 months.	
12″1¼	Amsterdam	209¼
13″10¼	Hamburg	184
121	Frankfort	210¼
29·47½	Leghorn[2]	15 loss = 100 lire for 85 franc

METHODS OF WORKING THE EQUATIONS.

Amsterdam.

£1?
1 — • 12″1¼ Florins and Stivers.
100 — • 2·09¼ Francs.
Francs 2·09¼ × 12·06¼ = 25·24 Francs.

Hamburg.

£1?
1 — • 13″10¼ Mk. and Sc. = 218¼ Sc.
Sc. 1600 = Mk. 100 — • 184 Francs.
Francs 184 × 218¼ ÷ 1600 = 25·10 Francs.

Frankfort.

£1?
10 — • 121 Florins.
100 — • 210¼ Francs.
Francs 210¼ × 121 ÷ 1000 = 25·42 Francs.

Leghorn.

£1?
1 — • 29·47½ Lire Italiane.
100 — • 85 Francs.
Francs 85 × 29·47½ ÷ 100 = 25·06 Francs.

COMPARISON OF THE ARBITRATED RATES.

Frankfort	121	210¼	25·42
Leghorn	29·47½	85	25·06
Paris, 3 months	...	25·10	25·35 short.

---

[1] These rules of arbitrated exchange, accurately given in Tate's *Modern Cambist*, and the verbal puzzle of which turns chiefly on whether the rate forming the basis of calculation be foreign or sterling, lend force to the observation above that the one rate should never be lost in the other one-sidedly. If distinguished in the practical quotation of exchanges, there seems no reason to take other than one in arbitrated exchange.

[2] The loss at Leghorn is owing to cash premium on forced paper currency [illegible], as it affects London and Paris equally, does not disturb the calculation.

For Direct Paper.

It appears from the direct rates between London and Paris at 25·30 and 25 35 that—

1*st.*—To remit or transfer money from London to Paris, it is better for Paris to draw upon London at 25·35 short, than for London to remit to Paris at 25 30 short, because by the former operation there will be made 5 cents. per pound, or about one-fifth per cent more than by the latter.

2*d.*—To have returns from Paris, it is better, by the same 5 cents, for London to draw upon Paris than for Paris to remit to London, because the bills will cost so much less French money, or produce so much more in sterling.

For Indirect Paper.

1*st.*—For remittances to Paris, it appears from the arbitrated results that bills on Frankfort, bought in London at 121 florins per £10 sterling, and sold in Paris at 212 francs per 100 florins, will produce 12 cents more than direct remittances from London to Paris, or 7 cents. more than is yielded by direct drafts of Paris upon London.

2*d*—For returns from Paris, it appears from the arbitrated results that bills on Leghorn, bought in Paris at 85 centimes per paper lira Italiana, and sold in London at paper lira Italiana 29 47½ per pound sterling, will cost 29 cents. less than direct bills from Paris, and will give 24 cents. more than drafts from London on Paris.

Such is the manner in which the various exchanges are calculated in order to ascertain which will answer best for a speculation in bills through intermediate places. The contingency of a change of rates has to be considered, and the charges of brokerage and commission on the operation have to be deducted from the result, or may be reduced when the operation is done by branches of the same house, or on joint account.

The elasticity of arbitrated rates of exchange is put to the severest strain when a large subsidy, or monster indemnity, like that of France to Germany, has to be paid by one country to another. In these cases it is necessary to employ extensive banking co-operation and at centres on which the drafts are heavy to arrange means for the support of the exchange.

EXCHEQUER, Court of Exchequer, Exchequer Chamber. The name *scaccarium*, from which the word "exchequer" is derived, was used under the Norman kings of England to signify the treasury. Madox, in his learned *History of the Exchequer*, exhausts the possible definitions of the word. According to some, it is connected with *scaccus* or *scaccum*, a chess-board, and the exchequer of England "was in all probability, called scaccarium because a chequered cloth (figured with squares like a chess-board) was anciently wont to be laid on the table in the court or place of that name." "From the Latin," continues Madox, "cometh the French eschequier or exchequier, and the English name from the French. Or if any one thinks more likely that the French word was the ancienter, and the Latin one formed from it, I do not oppose him,—nay, I incline to believe it was so." Another and less probable explanation is, that the original word was statarium, "from its stability, as it was the firm support of the crown or kingdom." But Madox points out that from the early times of the Conquest onwards it was always called scaccarium and never statarium.

At the present day, exchequer means two very different and independent institutions, the historical origin of which is one and the same. It is a court of law—one of the three superior courts at Westminster. It is also the treasury. The connexion between the treasury and the court is still kept up in one or two points. The chancellor of the exchequer still takes his seat in the Exchequer Court on certain formal occasions, and the Exchequer Court (or, as it is now called, the Exchequer Division) is still the appropriate tribunal for cases connected with the revenue.

The Exchequer makes its appearance among English institutions in close connexion with the King's Court (*curia regis*)—the germ from which so large a portion of the English constitution has sprung. In the language of later times it might be called a committee of that court specially charged with the management of the revenue. The King's Exchequer, says Theodore, "was anciently a member of his court, and was wont to be held in his palace. It was a sort of subaltern court, partly resembling in its model that which was properly called the *curia regis*, for in it the king's barons and great men who used to be in his palace near his royal person ordinarily presided, but sometimes the king himself; in it the king's chief-justiciar, his chancellor, his treasurer, his constable, his marshal, and his chamberlain performed some part of their several offices." And just as the *curia regis* was not a pure court of law, so the Exchequer was not merely a financial council but a court of law. Its principal business, says Madox, related to the revenue, and although the justices on circuit had cognizance of revenue matters, such matters, as they arose, were certified or sent into the Exchequer "to which place the affairs of the royal revenue tended as to their centre." Madox divides the business of the Exchequer, during the period between the Conquest and the reign of King John, under the head of revenues, causes, non-litigious business, and matters of public policy.

From the reign of Henry III. the Exchequer was recognized as a separate court, the others being the King's Bench and the Common Pleas (*q.v.*). Mr Stubbs thinks that a separate staff of judges was not assigned to each court until the end of the reign of Henry. The special business of the Exchequer was as before the decision of revenue cases, but from a very early time, and in spite of repeated prohibitions, the lawyers of the Exchequer competed for the ordinary litigious business—the common pleas—of the country. They finally succeeded by means of the well-known fiction which allowed one of the litigants to own that he was indebted to the king, and forbade his opponent to traverse the averment. The organization of the court seems to have been somewhat later in point of time than that of the Common Pleas and the King's Bench. The barons of the Exchequer were not at first recognized as judges. They are not mentioned in the statutes of Nisi Prius (13 Edward I. c. 30, and 14 Edward III. c. 16). In the reign of Elizabeth the Exchequer was definitely recognized a court of co-ordinate jurisdiction with the Common Pleas and the King's Bench.

The Exchequer was further distinguished from the two other courts by possessing an equitable as well as a common law jurisdiction. "The Court of Equity," says Blackstone, "is held before the lord treasurer, the chancellor of the exchequer, the chief baron, and the three *puisne* ones," whereas the common law jurisdiction is exercised by the barons only of the exchequer, and not the treasurer or chancellor. This equity jurisdiction was abolished in 1841, when two additional vice-chancellors were appointed in the Court of Chancery.

By the Judicature Act of 1873 the Court of Exchequer

---

[1] Those marked (*) include premium on gold or silver on account of depreciation of paper currency. The mint par of Vienna is about 10 35. In Genoa and other Italian cities it would be about 25 30. The full metallic par of the Turkish piastre is 111 5 = £1 sterling. Where the quotations in the above table are sterling with silver money, the price of silver has been taken at 5s an ounce, and the par of exchange has to be deduced from lower and higher prices of silver, as compared with that standard.

[2] Foreign merchants trading with China usually keep their accounts in dollars and cents; and the dollar issued from the mint at Hong Kong forms an acceptable basis of exchange from that station.

was abolished as a separate court, and its jurisdiction was transferred to the new High Court of Justice. The Exchequer still survives, however, as one of the divisions of the High Court, and still retains under its new name its old exclusive jurisdiction.

The *Court of Exchequer Chamber* was, until the passing of the Act just referred to, the court of appeal from the three courts of common law. Appeals from any one of these were heard before judges of the other two. It was originally intended (by statute 31 Edward III. c. 12) to determine causes by writs of error from the common law side of the Court of Exchequer, the judges being the lord chancellor, lord treasurer, and the justices of the King's Bench and Common Pleas. A statute of 27 Elizabeth (c. 8) made similar arrangements for writs of error from the King's Bench. The jurisdiction of the Exchequer Chamber is transferred by the Judicature Act to the new Court of Appeal.

The *chancellor of the exchequer* is the second commissioner of the treasury, the first lord being the premier. Occasionally both offices are held by the same person. It is the duty of the chancellor to prepare and lay before the House of Commons the "budget" for the year, and therefore he must be a commoner. The chancellor takes his seat in the Court of Exchequer once a year—at the nomination of persons to serve as sheriffs. (E. R.)

EXCISE, a term of obvious Latin derivation, now well-known in public finance, signifying a duty charged on home goods, either in the process of their manufacture or before their sale to the home consumers. This form of taxation implies a commonwealth somewhat advanced in manufactures, markets, and general riches; and it interferes so directly with the industry and liberty of the subject that it has seldom been introduced save in some supreme financial exigency, and has as seldom been borne, even after long usage, with less than the ordinary impatience of taxation. Yet excise duties can boast a respectable antiquity, having a distinct parallel in the *vectigal rerum venalium* (or toll levied on all commodities sold by auction or in public market) of the Romans. But the Roman excise was mild compared with that of modern nations, having never been more than *centesima*, or one per cent., of the value; and it was much shorter-lived than the modern examples, having been first imposed by Augustus, reduced for a time one-half by Tiberius, and finally abolished by Caligula, 38 A.D., so that the Roman excise cannot have had a duration of much more than half a century. Its remission must have been deemed a great boon in the marts of Rome, since it was commemorated by the issue of small brass coins with the legend *Remissis Centesimis*, specimens of which are still to be found in collections.

The history of this branch of revenue in the United Kingdom dates from the period of the civil wars, when the republican Government, following the example of Holland, established, as a means of defraying the heavy expenditure of the time, various duties of excise, which the Royalists when restored to power found too convenient or necessary to be abandoned, notwithstanding their Roundhead origin and general unpopularity. On the contrary, they were destined to be steadily increased both in number and in amount. It is curious that the first commodities selected for excise were those to which this branch of taxation, after great extension, has again in the age of reform and free trade been in a manner permanently reduced, viz., malt liquors, and such kindred beverages as cider, perry, and spruce beer. The other excise duties remaining are chiefly in the form of licences, such as to kill game and to use and carry guns, to sell gold and silver plate, to pursue the business of appraisers or auctioneers, hawkers or pedlars, pawnbrokers, or patent-medicine vendors, to manufacture tobacco or snuff, to deal in sweets or in foreign wines, to make vinegar, to roast malt, or to use a still in chemistry or otherwise. It may be presumed that the policy of the licence duties is not so much to collect revenue, though in the aggregate they yield a large sum, as to guard the main sources of excise, and to place certain classes of dealers, by registration and an annual payment to the exchequer, under a direct legal responsibility. The excise system of the United Kingdom as now pruned and reformed, however, while still the most prolific of all the sources of revenue, is simple in process, and is contentedly borne as compared with what was the case in the last and the beginning of the present century. The wars with Bonaparte strained the Government resources to the uttermost, and excise duties were multiplied and increased in every practicable form. Bricks, candles, calico prints, glass, hides and skins, leather, paper, salt, soap, and other commodities of home manufacture and consumption were placed, with their respective industries, under excise surveillance and fine. When the duties could no longer be increased in number, they were raised in rate. The duty on British spirits, which had begun at a few pence per gallon in 1660, rose step by step to 11s. 8¼d. per gallon in 1820; and the duty on salt was augmented to three or fourfold its value.

The old unpopularity of excise, though now somewhat out of date, must have had real enough grounds. It breaks out in all our literature, from songs and pasquinades to grave political essays and legal commentaries. Blackstone, in quoting the declaration of parliament in 1649 that "excise is the most easy and indifferent levy that can be laid upon the people," adds on his own authority that "from its first original to the present time its very name has been odious to the people of England" (book i. cap. 8, tenth edition, 1786); while the definition of "excise" gravely inserted by Dr Johnson in the *Dictionary*, at the imminent risk of subjecting the eminent author to a prosecution for libel—viz., "a hateful tax levied upon commodities, and adjudged not by the common judges of property, but wretches hired by those to whom excise is paid"—can hardly be ever forgotten. The levy of excise has more than the disagreeableness of other direct taxation, and though not more inquisitorial than income tax, establishes an espionage and control over premises and processes of manufacture which are much more offensive as well as sometimes injurious. The caustic feeling of last century points directly enough to much rough and arbitrary administration, which it was possible gradually to correct and mitigate.

But what may be deemed the permanent defect of excise is that it is apt to increase the cost of commodities to consumers far more than the amount of duty levied for the revenue. This has been found on the abolition of excise, whether on bricks, calicoes, leather, paper, or other articles of manufacture. The cheapening effect might not be very immediate or apparent, because the duty when abolished might bear only a very fractional proportion to the natural value of the goods; but under the greater freedom of production have arisen more invention, more skilful and varied appliances, and consequently more economy to consumers, and more expansion of the several industries, than could have been attained under the fiscal restrictions. The inexpediency, even for revenue purposes, of fining and fettering a great number of the most useful and necessary home industries by this kind of impost would seem to be abundantly demonstrated by the fact that the excise revenue of the United Kingdom, while being reduced always within narrower compass, has not suffered eventually in its actual produce to the state. The revenue from excise has never been greater, or much greater, than it is at present. The gross receipts from excise in 1820 were £27,955,810;

In the year ended 31st March 1866, when the larger number of the duties had been abolished, the net revenue from excise was £18,332,868; and in the year ended same date 1877, when excise for some years had been almost wholly confined to British spirits and malt liquors, the net revenue was £27,681,523. The following are the general items of the excise revenue in the latter year:—

Chicory	£2,942
Licences	3,548,557
Malt	8,040,378
Railways	728,718
Spirits, home made	14,873,165
Sugar, used in brewing	487,763
Total,	£27,681,523

So large a revenue from so few sources indicates high duties, and the excise on spirits in particular has been maintained during many years at a rate that would have astonished the people of last century, and yet without any of the evils incident to heavy fiscal exaction. There is a check, which has been often exemplified, to the increase of the rate of excise in the encouragement it gives to illicit manufacture, and the consequent defeat of its object, viz., increase of revenue. The high rates of 11s. 8½d. per gallon in England, 6s. 2d. in Scotland, and 5s. 7d. in Ireland, to which the excise on home-made spirits was increased at the close of the great wars, gave rise to so much evasion that "more than one-half of the spirits actually consumed in Scotland and Ireland," as we learn from an official source, "were supplied by the smuggler." The duties were reduced to 7s. per gallon in England, and to 2s. 4¾d. in both the other countries. "The result of these changes was a most surprising increase of legally made spirits. In 1820 the quantity made in the United Kingdom, and retained for home consumption, was 9,600,000 gallons. In 1826"—two years after the change of duties—"it was 18,200,000" (*First Report of Commissioners of Inland Revenue*, 1857). At subsequent periods, when the duties were again moderately increased, it was found that there was a sharp limit to the process, and that the excise on spirits could not be advanced much beyond 3s. 4d. in Scotland and Ireland without a revival of the old evils and a decline of revenue; while in England more than 7s. encouraged adulteration, and much higher prices than were justified by the duty and other trade charges. Later experience shows that this check is elastic. Since 1860 the excise on home-made spirits has been 10s. per gallon uniformly in the three kingdoms, and yet in no previous period have there been fewer complaints of smuggling or illicit distillation. This result is ascribable to various causes. The increase of employment, higher wages for legitimate labour, the opening of all parts of the country by means of communication, the greater sway of the law, and the greater influence of habits of order, must have discouraged the dark though tempting business of smuggling quite as much or more than the enormously high excise encouraged it. The excise service itself has also been much improved, and by simple mechanical provisions in the distilleries much less supervision of officers is requisite, with greater security against fraud than in former times. The exemption from duty of methylated spirit, used extensively in "French polishing" and many other arts, has likewise had a beneficial effect in stamping out illicit distillation. The spirit of wine, or pure alcohol of the druggists, however, is still almost necessarily subject to duty, though it were certainly desirable that in tinctures and other medicaments incapable of being abused as potable liquors, it should be free of tax. But permission to prepare tinctures in bond, in quantities of not less than nine gallons, has not as yet been taken advantage of to any extent. In the export of spirit of wine a rebate of duty is allowed.

The duty on malt, like that on spirits, has also for some years been uniform in the United Kingdom, at the rate of 2s. 7½d. per bushel, with a further duty on brewers of 12s. 6d. for every 12½ quarters mashed, or, what is held equivalent, every 50 barrels of 36 gallons brewed. The duty on each gallon of ale is thus barely one and seven-eighths of a penny—a very lenient excise compared with the 10s. per gallon on spirits. It might be supposed that when the duty on spirits in Scotland and Ireland was made as high as in England, a certain equality should have been established in the incidence of taxation on the liquors most generally used in the several countries. But the legislature has favoured the milder fermented liquors with the view of promoting temperance in all parts of the kingdom, irrespective of taste, habit, or climate. How far this good intention has been realized is a question aside from these explanatory remarks on excise. It has only to be observed that while the consumption of brewed liquors has been increasing in Scotland, the consumption of distilled spirits in England has been increasing in a still greater proportion. The following are the official returns of spirits and malt charged with duty in the three kingdoms in 1867 and 1876:—

	England.		Scotland.		Ireland.	
	1867.	1876.	1867.	1876.	1867.	1876.
Spirits at proof, gallons	9,170,561	13,368,096	7,144,144	9,193,669	6,377,648	8,156,743
Malt, bushels	43,608,570	54,161,929	8,681,501	3,021,891	2,499,366	3,342,868

The abolition of many of the old excise duties, and consequent simplification of the department, prepared the way for an administrative reform, by which the three revenue branches of excise, stamps, and taxes were placed under the superintendence of one board of commissioners, and included in the general description of inland revenue. This was accomplished in 1848, and the board of excise left its old head quarters in Gresham House and was merged in the new body in Somerset House, by which the collection and management of the whole inland revenue has since been directed. The provisions for the consolidation and guidance of the board of inland revenue are embodied in the Act 12 Vict. cap. 1. The numerous statutes of excise, well annotated, have been collected and published under the authority of the commissioners of inland revenue, in one volume (1873). (R. SO.)

EXCOMMUNICATION, the highest ecclesiastical censure, is the judicial exclusion of a baptized person from the fellowship of the visible church of Christ. As part of the discipline of the church it is based on the precept of Christ (Mat. xvi. 19, xviii. 15–18; John xx. 23), and on apostolic example (1 Cor. v. 5; 1 Tim. i. 20, &c.). These and the other texts, however, bearing, or supposed to bear, on the subject of excommunication, have not by any means been uniformly interpreted; and the usages ostensibly based on them have differed accordingly. The praxis of Christian discipline, moreover, has never been wholly independent of Jewish and pagan influences; and its variations cannot be adequately explained unless account be taken of several non-Christian analogues of excommunication. Among other pagan analogues may be mentioned the Greek *χερνίβων εἴργεσθαι* (Demos. 505, 14), with its consequences (Æsch., *Choeph.* 283; *Eum.* 625 f.; Soph., *Œd. Tyr.* 236 ff.); the Roman *exsecratio* and *diris devotio;* the awful power which the Druids claimed of excluding from the sacrifices (Cæs., *B. G.*, vi. 13). But more influential than any of these has been the ancient Jewish practice. The word used in the New Testament to describe an excommunicated person, ἀνάθεμα (1 Cor. xvi. 22; Gal. i. 8, 9; Rom. ix. 3), is the constant LXX. rendering of the Hebrew חֵרֶם (see ANATHEMA). This word (ḥerem), in its primary signification means simply any person or thing separated or set apart, a meaning which is still seen in the familiar Arabic word "harem." The connexion in thought between the notions separation from common use, dedication to God, and devotion to destruction is not very obscure, and it soon established itself in the Hebrew mind. In Lev. xxvii. 21, 28, 29, we read that no "devoted" person or thing was to be sold or redeemed; "none which shall be 'devoted' from among men shall be redeemed, but shall surely be put to death." The Hebrew *moḥoram* (devoted) was precisely in the same position as the Latin *impius* or *sacer* (Mommsen, *Röm. Alt.*, ii. 50 ff.) In Num. xxi. 2, 3, Deut. ii. 34, iii. 6, vii. 2, we find whole cities or nations thus "banned," "excommunicated," or devoted to destruction. We occasionally read of Israelites as well as of aliens falling under this ban (*e.g.*, in Judg. xxi. 5, 11), indeed, the extreme penalty of being "cut off," which is attached to so many sins, appears to have been carried into effect by the congregation only after the חֵרֶם had been duly pronounced by the competent authority (Ex. xxii. 19 [20], Deut. xiii. 7-18 [6-17]; *cf.* Ewald, *Alterth.*, pp. 101, 420). If in this חֵרֶם we already find the analogue of the major excommunication (called anathema) of the mediæval church, we may perhaps look for the analogue of the minor in that temporary separation or seclusion (niddah) which was prescribed for ceremonial uncleanness. Scripture furnishes no distinct trace of the use of the deadly anathema in post-exile times; it is probable, however, that the right of sentencing by a חֵרֶם to capital punishment remained with the Jewish ecclesiastico-civil authorities to a very late period (Ezra vii. 25, 26). In Ezra x. 8, it ought to be observed, we read of an excommunication of a milder kind; its effect was that all the substance of the offender was "forfeited" (*i.e.*, laid under a ḥerem), but he himself merely "separated" from the congregation.

The Talmud recognizes two kinds of excommunication, a minor and a major, called respectively niddui and ḥerem. The niddui (from *niddah*, to drive away) could be pronounced at any time by any competent individual (*cum periculo*, of course); its validity continued for thirty days, during which period the subject of it was expected to go into mourning, absent himself from the synagogue, and separate himself from all his fellows by a distance of not less than four ells. He was not excluded from the temple, but if he visited it he was required to enter by a separate door. If at the end of thirty days he shewed impenitence or contumacy, the niddui might be renewed once and again; and finally, in certain circumstances, the ḥerem might be pronounced. A valid ḥerem, which could only be pronounced by a court of not less than ten judges, had the effect of excluding from the temple as well as from the synagogue, and from all association with the faithful. Some writers have asserted that there was a still more terrible, because irrevocable, sentence called the shammatta; but the preponderance of evidence is against this statement. (See Buxtorf's *Lexicon*, p. 2466, and Selden, *De Jure Nat. et Gen.*, iv. 9.) Among modern instances of expulsion from the Jewish communion, that of Spinoza (16th July 1656) for contempt of the law has became famous. The text of the curse pronounced upon the culprit, which is similar to that given by Selden (as above, iv. 7), may be taken as a fair specimen of the formulæ then in use. The *Exemplar Humanæ Vitæ* of Uriel d'Acosta may also be referred to.

As an authority upon Jewish usages the Talmud does not go nearly so far back as to the beginning of the first Christian century. It is to the New Testament alone that we must look for any little information that can be had on the contemporary practice of the Jewish courts. The sentence of exclusion from the synagogue is plainly indicated in Luke vi. 22, John ix. 22, xii. 42, and the more severe sentence seems to be hinted at in John xvi. 2. The question as to the period at which the Jewish synedrium ceased to have the power of giving full effect to the ḥerem spoken of in Leviticus, has been much disputed. The Talmud itself says that the judgment of capital causes was taken away from Israel forty years before the destruction of the temple. But the point whether the synedrium which tried Jesus Christ could lawfully claim that power is still unsettled.

It has been already said that the use of excommunication as a part of Christian discipline, is based on the precept of Christ and on the apostolic practice. The general principles which ought to be observed can be easily gathered from the New Testament writings; but the church appears to have been left, for most of the practical details, to the guidance of reason and experience. Mat. xviii. 17 leaves unsolved many questions which cannot fail to arise as to the occasion, nature, and effects of excommunication. Tit. iii. 10, which enjoins the "rejection" (comp. 1 Tim. iv. 7) of a "heretic" after two "admonitions," can hardly be called more explicit. The *locus classicus* is 1 Cor. v. taken in connexion with 1 Tim. i. 20. In the former passage, much importance has been attached to the apparent distinction between the *αἴρειν ἐκ μέσου* in vs. 2, 13, and the *παραδοῦναι τῷ Σατανᾷ* in v. 5, the former being (it is alleged) within the competency of the congregation, and the latter a purely apostolic function. The *ἀνάθεμα*, or "delivering over to Satan for the destruction of the flesh," has been the subject of much dispute (see Bingham, *Antiq.*, xvi. 2, 15). The language may safely be assumed to have been borrowed from an older formula. Plainly it was intended as the highest censure, to be pronounced only on grave offenders. It is also manifest that it was not irrevocable, and that it was in every case meant to have a salutary disciplinary effect upon the soul.

The writings of the church fathers give sufficient evidence that two degrees of excommunication, the *ἀφορισμός* and the *ἀφορισμὸς παντελής*, as they were generally called, were in use during, or at least soon after, the apostolic age. The former, which involved exclusion from participation in the eucharistic service and from the eucharist itself, though not from the so-called "service of the catechumens," was the usual punishment of comparatively light offences; the latter, which was the penalty for graver scandals, involved "exclusion from all church privileges,"—a vague expression which has sometimes been interpreted as meaning total exclusion from the very precincts of the church building (*inter hiemantes orare*), and from the favour of God (Bingham, xvi. 2, 16). For some sins, such as adultery, the sentence of excommunication was in the 2d century regarded as *παντελής* in the sense of being irrevocable. Difference of opinion as to the absolutely "irremissible" character of mortal sins led to the important controversy associated with the names of Zephyrinus, Tertullian, Callistus, Hippolytus, Cyprian, and Novatian, in which the stricter and more montanistic party held that for those who had been guilty of such sins as theft, fraud, denial of the faith, there should be no restoration to church fellowship even in the hour of death. On this point the provincial synods of Illiberis (Elvira) in 305 and of Ancyra in 315 subsequently came to conflicting decisions. But the excommunication was on all hands regarded as being "medicinal" in its character. It is noteworthy that the word *ἀνάθεμα* had fallen into disuse about the beginning of the 4th century, and that, throughout the same period, no instance of the judicial use of the phrase *παραδοῦναι τῷ Σατανᾷ* can be found.

A new chapter in the history of church censure may be said to have begun with the publication of those imperial edicts against heresy the first of which, *De summa trinitate et fide* *catholica*, dates from 380. Till then exclusion from church privileges had been a spiritual discipline merely; thenceforward it was to expose a man to serious temporal risks. Excommunication still continued to be occasionally used in the spirit of genuine Christian fidelity, as by Ambrose in the case of Theodosius himself (390); but the temptation to wield it as an instrument of secular tyranny too often proved to be irresistible. In the formula used by Synesius (410), which is to be found in Bingham and in most other works of reference, we already find the attention of magistrates specially called to the censured person. The history of the next thousand years shows that the magistrates were seldom slow to respond to the appeal. Even the hastiest survey of that long and interesting period enables the student to notice a marked development in the theory and practice of excommunication. One or two points may be specially noted. (1.) While it had been held as an undoubted principle by the ancient church that this sentence could only be passed on living individuals, whose fault had been distinctly stated and fully proved, we find the mediæval church on the one hand sanctioning the practice of excommunication of the dead (Morinus, *De Pœnit.*, x., c. 9), and, on the other hand, by means of the papal interdict, excluding whole counties and kingdoms at once from every church privilege. The earliest well-authenticated instance of such an interdict is that which was passed (998) by Pope Gregory V. on France, in consequence of the contumacy of King Robert the Wise. Other instances are those laid respectively on Germany in 1102 by Gregory VII. (Hildebrand), on England in 1208 by Innocent III., on Rome itself in 1155 by Adrian IV. (2.) While in the ancient church the language used in excommunicating had been carefully measured, we find an amazing recklessness in the phraseology employed by the mediæval clergy. The curse of Ernulphus or Arnulphus of Rochester (cir. 1100), which has been made familiar to most students of English literature, is a very fair specimen of that class of composition. With it may be compared the formula transcribed by Dr Burton in his *History of Scotland* (iii. 317 ff.). To the spoken word was added the language of symbol. By means of lighted candles violently dashed to the ground and extinguished the faithful were graphically taught the meaning of the greater excommunication,—though in a somewhat misleading way, for it is a fundamental principle of the canon law that *disciplina est excommunicatio, non eradicatio.* The first instance, however, of excommunication by "bell, book, and candle" is comparatively late (cir. 1190).

At the Reformation the necessity for church discipline did not cease to be recognized; but the administration of it in many Reformed churches passed through a period of some confusion. In some instances the old episcopal power passed more or less into the hands of the civil magistrate (a state of matters which was highly approved by Erastus and his followers), in other cases it was conceded to the presbyterial courts. In the Anglican Church the bishops (subject to appeal to the sovereign) have the right of excommunicating, and their sentence, if sustained, may in certain cases carry with it civil consequences.

In the law of England sentence of excommunication, upon being properly certified by the bishop, was followed by the writ *de excommunicato capiendo* for the arrest of the offender. The statute 5 Eliz. c. 23 provided for the better execution of this writ. By the 53 Geo. III. c. 127 (which does not, however, extend to Ireland) it was enacted that "excommunication, together with all proceedings following thereupon, shall in all cases, save those hereafter to be specified, be discontinued." Disobedience to or contempt of the ecclesiastical courts is to be punished by a new writ *de contumace capiendo*, to follow on the certificate of the judge that the defender is contumacious and in contempt. Sect. 2 provides that nothing shall prevent "any ecclesiastical court from pronouncing or declaring persons to be excommunicate on definite sentences pronounced as spiritual censures for offences of ecclesiastical cognizance." No persons so excommunicated shall incur any civil penalty or incapacity whatever, save such sentence of imprisonment, not exceeding six months, as the court shall direct and certify to the Queen in Chancery.

In Scotland, three degrees of church censure are recognized—admonition, suspension from sealing ordinances (which may be called temporary excommunication), and excommunication properly so called. Intimation of the last-named censure is occasionally (but very rarely) given by authority of a presbytery in a public and solemn manner, according to the following formula:—"Whereas thou N. hast been by sufficient proof convicted of (here mention the sin) and after due admonition and prayer remainest obstinate without any evidence or sign of true repentance: Therefore in the name of the Lord Jesus Christ, and before this congregation, I pronounce and declare thee N. excommunicated, shut out from the communion of the faithful, debar thee from privileges, and deliver thee unto Satan for the destruction of thy flesh, that thy spirit may be saved in the day of the Lord Jesus." This is called the greater excommunication. The congregation are thereafter warned to shun all unnecessary converse with the excommunicate. (See *Form of Process*, c. 8.) Formerly excommunicated persons were deprived of feudal rights in Scotland; but in 1690 all Acts enjoining civil pains upon sentences of excommunication were finally repealed (Burton's *History*, vii. 435). (J. S. BL.)

EXECUTORS AND ADMINISTRATORS, in the law of England, are those on whom the personal property of a deceased person devolves, according as he has or has not left a will. If a man dies and leaves a will, the person or persons named therein to carry out his intentions are his executors, and their title to the personality vests at the moment of the testator's death. If there is no will, the right of administering the personal estate of the deceased is granted, according to certain rules, by the court of probate to persons who are called administrators. When the will contains no nomination of executors, administration is said to be granted "with the will annexed." The title of the administrator vests at the date of the letters of administration. As to the appointment of executors and administrators before the establishment of the Court of Probate, see articles WILL and INTESTACY. The executors or administrators when appointed become the legal personal representatives of the deceased. As to powers and duties administrators stand in the same position as executors.

It is the duty of an executor—(1) to bury the deceased in a manner suitable to the estate he leaves behind him; extravagant expenses will not be allowed, but the payment of legitimate funeral expenses "takes precedence of any debt or duty whatsoever;" (2) to obtain probate of the will (or letters of administration) within six months after the death. (3) He must make an inventory of the personal estate of the deceased, whether in possession or outstanding, and this inventory he is to deliver to the court on oath. He is to collect all the goods so inventoried and to commence actions which may be necessary to recover those which are outstanding. The executor is responsible to creditors for the whole of such estate, whether in possession or in action. (4) He must pay the debts of the deceased according to their several degrees of priority. An executor can, however, pay any debt due to himself by retaining it out of the fund before the other creditors are paid, except in the case of an *executor de son tort.* And a creditor only gains a preference for himself over others of the same class by taking action and obtaining judgment for his debt. If the estate is exhausted by due and proper payments before all the debts are cleared off, the unsatisfied creditors cannot recover. (5) After the debts come the *legacies*, which must be paid as far as the estate will extend. An executor cannot exercise a preference in the payment of his own legacy. (6) The residue of the estate must be paid to the person named in the will as residuary legatee. If there is no will or no residuary legatee named, the residue falls to be distributed among the next of kin, under the statute of distributions (see INTESTACY). It was held at one time that in default of a residuary legatee the residue fell to the executor himself, but now nothing less than the expressed intention of the testator can give it to him.

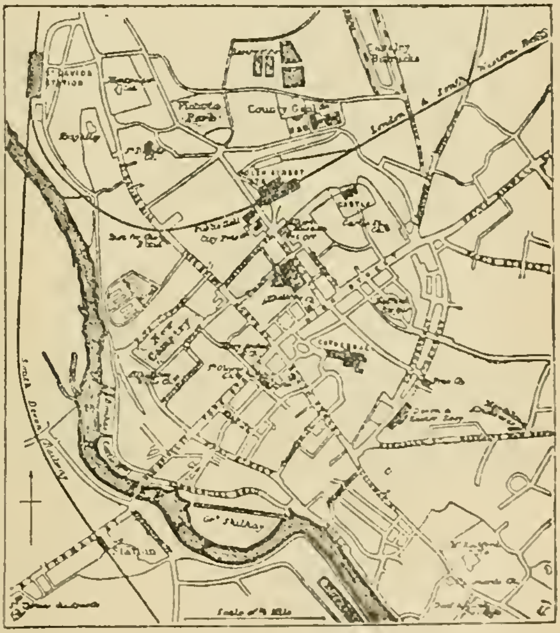
An executor *de son tort* (of his own wrong) is one who intermeddles with the estate of a deceased without authority. He thereby makes himself liable to all the trouble of an executorship without any of its profits.

If an executor is under age or abroad when he is appointed, temporary administration *durante minore ætate*, or *durante absentia*, may be granted to another.

An executor of an executor becomes the executor of the first testator. If, however, an executor dies intestate before completing the administration of the estate, an administrator *de bonis non* must be appointed. This is also the case where an administrator dies before the administration is complete. . R.)

EXELMANS, REMY JOSEPH ISIDORE (1775–1852), a distinguished French general, was born at Bar-le-Duc, November 13, 1775. He volunteered into the 3d battalion of the Meuse in 1791, became lieutenant in 1797, and in 1798 was attached as aide-de-camp to General Eblé. In his first campaign in Italy he greatly distinguished himself; and in April 1799 he was rewarded for his services by the grade of captain in the 16th regiment of dragoons. In the same year he took part with honour in several battles connected with the conquest of Naples, and was promoted to the rank of major; and in 1801 he became aide-de-camp to General Murat. He was named chief of a squadron in 1803, and he accompanied Murat in the Austrian, Prussian, and Polish campaigns of 1805, 1806, and 1807. At the passage of the Danube, and in the battle of Wertingen, he specially distinguished himself; he was made colonel of the 1st regiment of chasseurs for the valour which he displayed at Austerlitz; and after the battle of Eylau in 1807 he obtained the rank of brigadier-general. In 1808 he accompanied Murat to Spain, but was there made prisoner and conveyed to England. On regaining his liberty in 1811 he went to Naples, where King Murat appointed him grand master of horse; but when Murat became estranged from Napoleon, Exelmans left his court and joined the French army. Napoleon was then entering on his Russian campaign, and gave him welcome and immediate employment as a general of division. He was present at the battle of Moscow, and in the famous retreat from that city his steadfast courage was conspicuously manifested on several occasions. In 1813 he received, for services in the campaign of Saxony, the decoration of the Legion of Honour; and in 1814 he reaped additional glory by his intrepidity and skill in the campaign of France. When the Bourbons were restored in 1815 he retained his position in the army, but this did not prevent Napoleon on his return from Elba from intrusting him with the command of the 2d army corps. After the second Restoration he was proscribed, and lived in Belgium, and subsequently in Nassau, till 1819, when he was recalled to France. In the following year he was appointed to an inspector-generalship of cavalry; and after the July revolution of 1830 he received from Louis Philippe the grand cross of the Legion of Honour, and was created a peer of France. In the House of Peers he denounced the execution of Marshal Ney as an "abominable assassination." At the revolution of 1848 Exelmans was one of the adherents of Louis Napoleon; and in 1851 he was, in recognition of his long and brilliant military career, raised to the dignity of a marshal of France. His death, 10th July 1852, was the result of a fall from his horse.

EXETER, the chief town of Devonshire, in England, a city which is a county in itself, and a municipal and parliamentary borough, stands on the Exe, about ten miles north-west of the mouth of the river, where it opens to the English Channel. The distance of Exeter from London is 194 miles. The ancient city (round which suburbs have extended) occupies a broad ridge of land, which rises steeply from the left bank of the Exe. At the head of the ridge is the castle, on the site of a great British earthwork. This was the stronghold of *Caer Isc* (so named from the river Isc or Exe, meaning water); and the British town became the *Isca Damnoniorum* of the Romans, just as Isca Silurum was the Roman name of Caerleon on the *Usk*, in South Wales. Roman coins, tesselated pavements, pottery, and sepulchral urns have been found from time to time, proving that the station was one of importance. It was one of the few cities in Britain which were not deserted at the time of the Saxon Conquest; and when Athelstan came westward about 926, he found *Exanceaster*, the "chester" or fortified town on the Exe, as the Saxons called it, occupied by Britons and Saxons *æquo jure*. The ground plan of the city indicates its Romano-British origin, since the principal streets cross each other nearly in the centre. The main or High Street is, in fact, a portion of the Roman road which extended from the eastern border of the county to the Tamar. Exeter was more than once attacked by the Northmen; but the walls which had been constructed by Athelstan greatly protected the "burgh;" and in 1050 the episcopal see of Devonshire, which had been founded at Crediton about 910, was removed, for greater security, to Exeter.



Plan of Exeter.

The position of Exeter, and its importance as the principal city of the western peninsula, have affected the whole course of its history, and led to its numerous sieges. In 1068 the Conqueror appeared before Exeter, beleaguered it for eighteen days, and then received the submission of its citizens. He afterwards founded the castle, known as "Rougemont," from the red colour of the rock on which it stands. The castle was held for Matilda in 1137 by Baldwin de Redvers, earl of Devon; and King Stephen took it after a siege of three months. Exeter was Lancastrian, and in 1469 held out successfully against Sir William Courtenay and the Yorkists. In 1497 it was besieged by Perkin Warbeck, and in 1549 for thirty-five days by the men of Devon and Cornwall, who rose in defence of the "old religion." The city was taken and retaken during the civil war; and the queen gave birth there to the Princess Henrietta, afterwards duchess of Orleans. After that period the most noticeable event is the entry of the prince of Orange (William III.) in November 1688. His "declaration" was then read by Burnet in the cathedral.

The High Street of Exeter and its continuation, called Fore Street, are narrow, but very picturesque, with many old houses of the 16th and 17th centuries. There is a tangle of lesser streets within the walls, the line of which may be traced. All the gates have been destroyed. The suburbs, which have greatly extended since the beginning of the present century, contain many good streets, terraces, and detached villas. The surrounding country is not only rich and fertile, but is of great beauty. Extensive views are commanded in the direction of Haldon, a stretch of high moorland which may be regarded as an outlier of Dartmoor. The lofty mound of the castle has been laid out as a promenade, with fine trees and broad walks. The city is the centre of the system of western railways. London may be reached either by the Great Western (Bristol and Exeter) line, or by the South-Western, passing by Salisbury and Basingstoke. The distance in both cases is about the same. The North Devon railway runs from Exeter by Crediton to Barnstaple and Ilfracombe; and the South Devon by Teignmouth and Totnes to Plymouth, and thence into Cornwall. There is also a line to Plymouth belonging to the South-Western Company, which passes inland by Lidford and Tavistock.

The population of Exeter in 1871 was 34,650 within the municipal limits. The parliamentary borough contained 44,226 persons. The city, of which the earliest recorded charter was granted by Henry I., has returned two members of parliament since the reign of Edward I. It is situated in the parliamentary division of East Devon. Assizes for the county of Devon are held twice in the year at Exeter, in the assize hall within the castle. The most important buildings in the city are the cathedral, the guildhall, and the Albert Memorial museum; and the remains of the castle are also of interest.

Corporation Seal.

The cathedral, although not one of the largest in England, is inferior to none in the great beauty of its architecture and in the richness of its details. With the exception of the Norman transeptal towers, the general character is Decorated, ranging from about 1280 to 1369. On the exterior the great peculiarities are the towers mentioned above, and the west front, which is of later date than the rest of the church (probably 1369–1394), and is adorned with statues. Transeptal towers occur elsewhere in England only in the collegiate church of Ottery, in Devonshire, where the cathedral served as a model. Within, the points to be specially noted are—the long unbroken roof, extending throughout nave and choir (there is no central tower or lantern); the beautiful sculpture of bosses and corbels; the minstrel's gallery, projecting from the north triforium of the nave; and the remarkable manner in which the several parts of the church are made to correspond. The window tracery is much varied; but each window answers to that on the opposite side of nave or choir; pier answers to pier, aisle to aisle, and chapel to chapel, while the transeptal towers complete the balance of parts. A complete restoration of the cathedral, under Sir G. G. Scott, was began in 1870 and completed in 1877. The new stall work, the reredos, the choir pavement, of tiles, rich marbles, and porphyries, the stained glass, chiefly by Clayton and Bell, and the sculptured pulpits in choir and nave are of the highest merit. The ancient episcopal throne, a sheaf of tabernacle work in wood, erected by Bishop Stapledon about 1320, has been cleaned and renovated; and the organ, of which the pipes are of very nearly pure tin, has been rearranged. The most interesting monuments are those of bishops of the 12th and 13th centuries, in the choir and lady chapel. Some important MSS., including the famous book of Saxon poetry given by Leofric to his cathedral, are preserved in the chapter house. The united sees of Devonshire and Cornwall were fixed at Exeter from the installation there of Leofric (1050) by the Confessor, until the re-erection of the Cornish see in 1876.

Arms of Bishopric.

The Guildhall in the High Street is a picturesque Elizabethan building, which contains some interesting portraits. Among them are a full-length of General Monk, duke of Albemarle, born in Devon (engraved in Lodge), and a full length (given by Charles II.), of the Princess Henrietta. Both are by Sir Peter Lely. The Albert Memorial Museum in Queen Street was designed by Hayward of Exeter (1865). Devonshire materials have been chiefly used in its construction. The building, which is of considerable size, contains a school of art, an excellent free library, a reading room, and a museum of natural history and antiquities. There is a good collection of local birds, and some remarkable pottery and bronze relics extracted from barrows near Honiton or found in various parts of Devonshire. Of the Castle the chief architectural remain is a portion of a gateway tower which may be late Norman. Huge dykes and trenches of the British period exist in an adjoining garden. The parish churches of Exeter are of small importance, but the modern church of St Michael (1860) deserves notice. It is sufficient to mention the Devon and Exeter Institution, founded in 1813, which contains a large and valuable library; the diocesan training college and school; and the grammar school, which dates from the reign of Henry VIII. There are two market houses in the city, many hospitals, and many charitable institutions.

Exeter has few manufactures; and Devonshire or Honiton lace, for which it is celebrated, is made quite as much in the villages of the south coast as in and around Exeter itself, although it is chiefly brought to the city for sale. There is a considerable trade of a miscellaneous description. Hides from South America, wines from Portugal and Spain, fruits and valonia from the Mediterranean, and coal from the northern counties and Wales are imported. Leather, paper, corn, and cider are sent to London and other parts of the country. The woollen trade has quite passed away from Exeter, although it was at one time so considerable that it was only exceeded by that of Leeds, and the value of exported goods in 1768 exceeded half a million annually. The Ship Canal, from Exeter to Topsham, in the estuary of the Exe, greatly assisted this commerce. It was begun in 1564, enlarged in 1675, and again in 1827. Vessels of 300 tons can come up to the quay at Exeter; those of greater burden remain at

Topsham; and those of the largest size lie at Exmouth, at the outfall of the river.

Bibliography.—Of older histories the most important is Izacke's *Antiquities of Exeter*, 1681. The best later authorities are *The History of the City of Exeter*, by the Rev. G. Oliver, 1861; *Lives of the Bishops of Exeter and History of the Cathedral*, by the Rev. G. Oliver, 1861; Archdeacon Freeman's *History of Exeter Cathedral*, 1874; and Murray's *Handbook for the Southern Cathedrals of England* (Exeter),—see edition of 1876. (R. J. K.)

EXHIBITIONS. National and International Exhibitions may be ranked among the most remarkable features in the industrial records of the world, and have taken their place as prominent instruments of civilization, for by their means the diffusion of knowledge has been advanced and extended in the most wonderful manner.

It is to the Society of Arts that the credit is due of having originated national exhibitions. So far back as the year 1761 that body offered prizes for agricultural and other machines, and had an exhibition of these in its apartments. In 1798 France began a series of national expositions under the direction of Napoleon. The exhibitors at first numbered only 110, and a jury of nine was appointed to decide upon their merits. A gold medal was offered to the manufacturer who should deal the heaviest blow to English trade. The second exposition took place in 1801, and was so successful that the third was fixed to take place in 1802. Expositions were subsequently held in 1806, 1819, 1823, 1827, 1834, 1839, 1844, and in 1849, in which year there were 4494 exhibitors. This last was the conclusion of the purely national displays in France before the great London international exhibition of 1851. So exclusive were the French at that time that a proposal made for the representation of foreign products in 1849 was deemed by the minister of commerce to have emanated from the enemies of French industry.

In 1820 a series of exhibitions were opened in various cities of Austria, and national exhibitions were held at Vienna in 1835, 1839, and 1845, which last had 1865 exhibitors. In Germany there were national exhibitions at Berlin in 1822 and 1827, and in 1844 one with 3060 exhibitors. National exhibitions were held in Saxony between 1824 and 1845, in which last year there were 6013 exhibitors. Between 1837 and 1848 exhibitions were held at Lausanne, Berne, St Gall, and Zurich in Switzerland; between 1835 and 1850 at Brussels and Ghent in Belgium; between 1823 and 1844 at Stockholm in Sweden; between 1829 and 1849 at St Petersburg, Moscow, and Warsaw in Russia; between 1844 and 1849 at Lisbon in Portugal; between 1829 and 1855 in the kingdom of Sardinia; between 1827 and 1850 at Madrid; between 1828 and 1844 at New York and Washington in the United States.

In the United Kingdom industrial displays had to fight their way against much apathy and prejudice. In 1828 an exhibition was formed in London under the patronage of George IV., which dragged out an unfortunate existence till 1833, when it was consigned to oblivion as an unsuccessful bazaar. In Ireland exhibitions of native industry were held triennially in the rooms of the Royal Dublin Society, commencing in 1829. In 1845, however, an exhibition of manufactures held in Covent Garden, London, proved a great success; and in 1849 an exposition of industry was held at Birmingham, which was the most complete of any held till that time in the country.

After various proposals made by the Society of Arts between 1846 and 1849, it was held that the great object of an international exhibition of industry was more likely to be carried out than hitherto, and at last a royal commission was issued to take steps for an industrial exhibition to be held in 1851. The commissioners received a site of upwards of 18 acres in Hyde Park, and erected the building known as the "Crystal Palace," from the designs of Mr (afterwards Sir) Joseph Paxton. Its general plan was a parallelogram 1848 feet long by 408 feet wide. There was also a projection on the north side 936 feet long, the whole covering a space of 1,000,000 square feet. The exhibition had four great departments,—raw material, machinery, manufactures, fine arts,—which were subdivided into 30 classes; and this arrangement has been usually followed in the great exhibitions since held. In allocating the space for the display of objects one-half was given to England and the colonies, the other half to foreign countries. The estimated value of the articles exhibited, excluding the famous Koh-i-noor diamond, was £1,781,929. This exhibition was opened on 1st May by Queen Victoria in person, and was closed on 11th October following, and the receipts exceeded the expenditure by a sum of £213,305. The building was afterwards removed to Sydenham, where it forms the main part of the present "Crystal Palace."

The success of the Great Exhibition of 1851 encouraged the repetition of similar displays all over the world, a list of which will be found in the table given below.

In 1855 the great Paris international exhibition was held, which was opened by the emperor of the French on 17th May. The buildings for this exhibition were of various kinds. There were the palais d'industrie, the palais des beaux arts, and the panorama; erections were afterwards added for agricultural implements, carriages, minor articles, &c. The main building, which was of stone, brick, and glass, was only 800 feet long by 350 feet wide. This exposition brought together an assemblage of objects in the industrial and fine arts such as had never been seen before. The distinguishing feature of the palais d'industrie was its collection of the works of living artists, while the London exhibition of 1851 was principally a display of manufactured goods. The exposition was closed on the 15th November, when the distribution of medals to about 12,000 exhibitors took place.

In 1862 the second great English international exhibition was held in London in an immense brick erection adjoining the gardens of the Horticultural Society at South Kensington. The building consisted of two vast domes of glass, 250 feet high and 60 feet in diameter, larger than the dome of St Peter's, connected by a nave 800 feet long, 100 feet high, and 83 feet wide, with a closed roof lighted by a range of windows after the manner of the clerestory of a Gothic cathedral. The domes opened laterally into spacious transepts, and the nave into a wide central avenue and interminable side aisles and galleries roofed with glass. These apartments occupied 16 acres, but in addition there were two *annexes* which covered 7½ acres. The ceremonial with which this exhibition was inaugurated on 1st May was the most imposing public pageant which had been seen in Britain for many years. The number of exhibitors in the industrial division was 26,348, besides 2305 in art making in all 28,653. The fine art collection was very extensive, comprising 901 pieces of sculpture, 1275 engravings, 983 architectural designs, and no less than 3370 paintings. The classification of the objects was based upon that of 1851, and embraced 36 divisions, in addition to those of the fine arts.

In April 1867 a great international *exposition universelle* was opened in Paris in an immense oval building erected in the Champ de Mars. It was arranged in twelve concentric aisles, with a small open central garden. It covered no less than 37 acres, and the total number of exhibitors was 42,000. It was intended to bring into notice all the resources which industry can create for satisfying the requirements of mankind, and it was divided primarily into groups corresponding with the leading wants of the human family. A great feature was the display of actual examples of the styles of domestic and palatial architecture of most countries, even the tents of some of the nomad tribes, such as the Kirghis Tartars, Samoyeds, Bedouin Arabs, &c., being exhibited. In addition, all kinds of civil and military erections of general importance were represented.

In May 1873 an international exhibition was opened in the Imperial Park at Vienna. The building in which it was held was of enormous size, covering about 40 acres. The principal part of the edifice was a grand nave nearly 1000 yards long, in the midst of which rose a vast rotunda or dome of great height. In this part of the building objects of a trophy character were exhibited, and presented a *coup d'œil* of surpassing grandeur. An immense number of prizes and diplomas were distributed, and the awards were shared by almost every nation in the world. This exhibition was closed in November 1873. It was not a success financially, there being a considerable deficit in the receipts. The building has been converted into a national museum.

In 1876, after five years of preparation, the great international exhibition of America, a centennial celebration of the Declaration of Independence, was opened in Fairmount Park, Philadelphia, on the 10th of May. The main building was in the form of a parallelogram extending east and west, 1880 feet in length and 464 feet in width. Its central span, in which was situated the grand avenue, was 1832 feet long by 120 feet wide, being the longest of such a width ever introduced into an exhibition building. The greater portion of the structure was one story high, the interior height being 70 feet. In the centre were four square towers 120 feet high. The frame work was of iron, filled in with glass and wood, it covered 20·02 acres. With the other buildings attached to the exhibition, a total space of 60 acres were covered. Besides the main building there were the machinery hall, the horticultural hall (built in a Moorish style), the agricultural hall, the memorial hall or art gallery, the Government building, covering about 2 acres, in which were illustrated the functions of the Government in time of peace and its resources as a war power Besides these there were the women's pavilion, the judges' hall, and a great many smaller erections, including a Swedish schoolhouse, a timber-framed house somewhat in the style of the 16th century, which formed the head-quarters of the British commission. A structure having the homely designation of "department of public comfort" was used as a place of rest and convenience The total number of buildings within the inclosure was over 160, and their cost was £1,600,000. The number of exhibitors was 60,000, derived from 37 nations. The promenades in the main building were 25 miles in length.

In England, after the great displays of 1851 and 1862 a feeling began to gain ground that as the activity and ingenuity of manufacturers and designers were constantly directed to fresh efforts, universal expositions would attain such gigantic proportions as to become quite unmanageable. A resolution was therefore come to by the British commissioners, as trustees of the fund derived from the proceeds of the great exhibition of 1851, that the objects suitable for exhibition should be divided into groups, and that exhibitions of selections from these groups should be held at more frequent intervals. A plan was then arranged for a series of exhibitions of the fine arts, recent scientific inventions and discoveries, and two or three branches only of manufactures, providing at the same time for the representation of each distinct manufacture once in ten years. Exhibitions were accordingly held in 1871, 1872, 1873, and 1874, but at last it was found that they lost the attractiveness of novelty, and failed to draw the multitude of sight-seers who flocked to the great exhibitions of 1851 and 1862.

Notwithstanding these views of the British commissioners, an *Exposition Universelle* on a great scale was opened in Paris on 1st May 1878 by the President, Marshal MacMahon. It is expected to unite the civilized world, as the sciences are represented as well as the arts. The building, or Industrial Palace, is an enormous erection in the Champ de Mars, consisting of a series of rectangular galleries in which each country has been allotted a division more or less important. Besides the main building, there are about a dozen *annexes* without the *enceinte* of the palace. Immediately across the Seine there is a second palace situated in the Trocadero (so named from a Spanish fort in the harbour of Cadiz, captured in 1823), amidst ornamental gardens with cascades. This is devoted to the fine arts and music, and is to remain a permanent monument of the exhibition. It contains a music gallery even larger than the Albert Hall, London. The space occupied by the exhibition is about 140 English acres; and the total expense has been announced by the minister of commerce as about £1,800,000 sterling.

An international exhibition is proposed to be held in 1879 at Melbourne, a city which in 1851 was a town of but 20,000 inhabitants.

Of the London Great Exhibition of 1851 an official catalogue was published the same year in 4 vols. 8vo, and in 1852 a volume of reports by the juries on the subjects in the 30 classes into which the exhibition was divided, in royal 8vo. A sumptuous edition of this catalogue on large paper was printed, of which copies were presented to distinguished personages and public libraries. Of the exhibition of 1862 an illustrated catalogue was printed by the commissioners the same year in 4 vols. 8vo. Of the Paris exposition held in 1855 there was an official catalogue published the same year; and a *Rapport sur l'Exposition Universelle* (also published) was presented by Prince Napoleon to the emperor in 1857 Of the exposition of 1867 there was published in London the same year a translation from the proof-sheets of the French official catalogue. Of the Vienna exhibition of 1873 there was an official illustrated general catalogue, with a large number of reports of the juries, &c Of the Philadelphia exhibition there was an official catalogue printed in four languages—English, French, German, and Spanish; a series of reports and awards under the different groups into which the exhibition was divided is now being published. Besides the general catalogues of the great international exhibitions, there have been published an immense number of catalogues of the exhibits of the different countries at each, which are to be found available for reference in the South Kensington and other industrial museums. Various beautifully illustrated books, representing the works of art exhibited, have been published both in London and Paris; and one, *Études sur l'Exposition de* 1878, intended to be a complete record of the progress made in all the arts up to the present date, is about to be issued under the direction of E. Lacroix.

The following table shows the statistics of the first six great international exhibitions :—

	Acres.	Exhibitors.	Cost	Days open.	Receipts	Number of Visitors.
London of 1851....	21	17,000	£292,794	144	£506,100	6,039,195
Paris of 1855..	24½	21,779	1,000,000	200	128,099	5,162,330
London of 1862	23¼	28,653	460,000	171	408,530	6,211,103
Paris of 1867.	37	50,226	800,000	217	420,735	10,200,000
Vienna of 1873	40	42,584	2,200,000	186	206,470	7,254,687
Philadelphia of 1876	60	60,000	1,600,000	159	762,744	9,910,966

The following table shows the minor exhibitions which have been held in various parts of the world from 1852 to tho present time (1878):—

1852	Cork	Exhibition of Irish arts and manufactures.
1853	Dublin	Do. do. with those of other countries.
„	New York	Industrial exhibition, which cost £200,000.
„	New Brunswick	Native industry
„	Madras	Do. do
1854	Madrid	Industrial arts.
„	Munich	German industry.
„	Christiania	Norwegian arts and manufacture.
1856	Brussels	Belgian arts.
„	Edinburgh	Exhibition of Art Manufacture Association.
1857	Manchester	Art treasures exhibition.
„	Bern	Swiss arts and manufactures; 2050 exhibitors.
1858	Sardinia	Italian industry.
„	New York	American industry
1859	Hanover	Exhibition, with 296 exhibitors
„	Rouen	Products of 12 northern departments of France.
„	Athens	National exhibition, with 947 exhibitors.
1860	St Petersburg	Russian products.
1861	Florence	Fine art in Tuscany and Italian silk goods.
„	Haarlem	Dutch industries.
„	Brussels	Exhibition of articles of common use.
„	Victoria	Exhibition preliminary to London great exhibition of 1862.
1863	Constantinople	Turkish produce, and foreign machinery
1864	Amsterdam	Dutch produce, art, and industry.
„	Bayonne	Industries connected with corn and wine.
„	Malta	Local art and industry.
„	Calcutta	Principally agriculture
„	Lucknow	Do. do.
„	London	First working men's exhibition.
1865	Dublin	Arts and manufactures, attracted 900,000 visitors.
„	Cologne	Agriculture and horticulture.
„	Boulogne	International fishery exhibition
„	Sierra Leone	Industrial exhibition.
„	Oporto	Arts, manufactures, and agriculture; 3011 exhibitors.
„	Dunedin, New Zealand	Colonial produce.
„	Birmingham	Metals and trades.
„	Vienna	Working men's industrial exhibition.
„	London	Do. do.
„	Stettin	Exhibition of Industry, with 1451 exhibitors.
„	Philadelphia	American produce.
1866	Stockholm	Scandinavian industries.
„	Brazil, Rio de Janeiro	Raw produce, with 2500 exhibitors.
„	Melbourne	Intercolonial exhibition, rich in specimens of minerals.
„	London	Working men's exhibition.
1867	The Hague	Fishery exhibition.
„	Agra	Industries of N.W provinces of India.
1868	Havre	International maritime exhibition.
„	Santiago	Products of Chili.
1869	London	South London industrial classes exhibition.
„	Amsterdam	Netherland Society of Manufacturers; rich in objects of domestic economy.
1870	Berlin	Exhibition of drawing implements.
„	Turin	Italian products.
„	St Petersburg	Russian industrial exhibition.
„	Gujerat	Indian cotton.
„	Sydney	Intercolonial exhibition, with 2914 exhibitors.
„	London	Workmen's international exhibition.
1871	Do	First annual international exhibition at South Kensington.
„	Milan	Exhibition of selected branches of industry.
„	Naples	International maritime exhibition.
1872	London	Second annual international exhibition.
„	Dublin	Irish native produce and fine arts
„	Copenhagen	Scandinavian art and industry; 4000 exhibitors.
„	Lyons	Agriculture, industrial products, and works of art.
„	Moscow	Exhibition on celebration of second centenary of Peter the Great, illustrative of the progress of Russia in manufactures
„	Bogota	Products of South America.
1873	London	Third annual international exhibition.
„	Do.	Fourth and last annual international exhibition
1874	Aberdeen	Exhibition of fungi; 7000 specimens shown.
„	Brussels	Industrial art
1875	Paris	Agricultural machines and implements.
1876	London	Exhibition of needlework in Albert Hall.
„	Do.	Exhibition of bees, their produce, hives, and bee furniture, in Alexandra palace.
„	Paris	Applications of electricity.
„	Thurso	Exhibition of art and industry, and local antiquities.
„	Brussels	Exhibition of life-saving and hygienic apparatus.
„	Kioto, Japan	Exhibition of silks, bronzes, casques, wearing-apparel, &c., being the fifth of a series since 1872.
1877	London	Loan collection of scientific apparatus.
„	Do.	Caxton exhibition, illustrative of the art of printing.
„	Do.	Westminster and Pimlico working classes industrial exhibition.
„	Cape Town	International exhibition of manufactures of all kinds.
„	Hamburg	International dairy exhibition.
„	Ghent	Exhibition of Industrial Art.
1878	Ballarat	International exhibition. (J. SM.)

EXMOUTH, a market-town and watering-place in the county of Devon, England, is situated at the mouth of the Ex, 10 miles E.S.E. of Exeter. It was the first watering-place on the coast of Devon, and is frequented, not only for bathing, but also as a winter residence by those suffering under pulmonary diseases, as it is celebrated for the mildness of its climate, and is well sheltered from the N.E. and S.E. winds by some high hills which rise almost close behind it. The old town, originally only a fishing village, has been altered and improved by new buildings. It lies along the base of the Beacon hill. The new town is built along the slopes of the hill and consists of terraces and detached houses. The sides and walks in the neighbourhood are remarkably beautiful, and the hill commands one of the finest views in the south of England. Exmouth possesses a handsome church, and has assembly rooms, baths, libraries, and other essentials of a fashionable watering-place. Its sea wall, which is 1800 feet long and 22 feet high, affords an admirable promenade. Near the town is a natural harbour, called the Bight. The population of Exmouth in 1871 was 5614.

Exmouth was early a place of importance, and in 1347 contributed 10 vessels to the fleet sent to attack Calais. It at one time possessed a fort or "castelet," designed to command the estuary of the Ex. This fort, which was garrisoned for the king during the civil war, was blockaded and captured by Colonel Shapcoate, in 1646.

EXMOUTH, EDWARD PELLEW, VISCOUNT (1757–1833), an English admiral, was descended from a family which came originally from Normandy, but had for many centuries been settled in the west of Cornwall. He was born at Dover, April 19, 1757. At the age of thirteen he entered the navy, and even then his smartness and activity, his feats of daring, and his spirit of resolute independence awakened remark, and pointed him out as one specially fitted to distinguish himself in his profession. He had, however, no opportunity of active service till 1776, when, at the battle of Lake Champlain, his gallantry, promptitude, and skill, not only saved the "Carleton"—whose command had devolved upon him during the progress of the battle—from imminent danger, but enabled her to take a prominent part in sinking two of the enemy's ships. For his services on this occasion he obtained a lieutenant's commission, and the command of the schooner in which he had so bravely done his duty. The following year, in command of a brigade of seamen, he shared in the hardships and perils of the American campaign of General Burgoyne. In 1782, in command of the "Pelican," he attacked three French privateers inside the Isle of Bass, and compelled them to run themselves on shore—a feat for which he was rewarded by the rank of post-captain. On the outbreak of the French war in 1793, he was appointed to the "Nymphe," a frigate of 36 guns; and, notwithstanding that for the sake of expedition she was manned chiefly by Cornish miners, he captured, after a desperate conflict, the French frigate "La Cléopâtre," a vessel of superior size to his own and better armed. For this act he obtained the honour of knighthood. In 1794 he received the command of the "Arethusa," and in a fight with the French fleet off the Isle of Bass he compelled the "Pomona" to surrender. The same year the western squadron was increased and its command divided, the second squadron being given to Sir Edward Pellew. While in command of this squadron he, on several occasions, performed acts of great personal daring; and for his bravery in boarding the wrecked transport "Dutton," and his promptitude and resolution in adopting measures so as to save the lives of all on board, he was in 1796 created a baronet. In 1798 he joined the channel fleet, and in command of the "Impétueux," took part in several actions with great distinction. In 1802 Sir Edward Pellew was elected member of parliament for Dunstable, and during the time that he sat in the Commons he was a strenuous supporter of Pitt. In

1804 he was made rear-admiral of the blue, and appointed commander-in-chief in India, where, by his vigilance and rapidity of movement, he entirely cleared the seas of French cruisers, and secured complete protection to English commerce. He returned to England in 1809, and in 1810 was appointed commander-in-chief in the North Sea, and in 1811 commander-in-chief in the Mediterranean. In 1814 he was created Baron Exmouth of Canonteign, and in the following year was made K.C.B., and a little later G.C B. When the dey of Algiers, in 1816, violated the treaty for the abolition of slavery, Exmouth was directed to attack the town Accordingly, on the 26th August, he engaged the Algerine battery and fleet, and after a severe action of nine hours' duration, he set on fire the arsenal and every vessel of the enemy's fleet, and shattered her sea defences into ruins. At the close of the action the dey apologized for his conduct, and agreed to a renewal of the treaty, at the same time delivering up 1800 persons of various nations who had been Algerine slaves. For this splendid victory Exmouth was advanced to the dignity of Viscount. Shortly before his death, which took place 23d January 1833, he was made vice-admiral A Life of Exmouth, by Edward Osler, was published in 1835

EXODUS. See PENTATEUCH.

EXORCISM, the act of expelling evil spirits from persons or places by means of certain adjurations and ceremonies, appears in the present custom or past history of almost every nation of the world. Its importance is greatest among barbarous peoples, whose belief in attacks of demons furnishes them with a general theory to account for misfortunes, mysterious events, and especially all diseases of body or mind, so that the exorcists, who are usually priests or sorcerers, become in fact the recognized order of physicians (see article DEMONOLOGY). From among the numerous accounts of modes of exorcism among rude tribes may be instanced that among the Dakota Indians, where the medicine-man summoned to cure a sick person chants "hi-le-li-lah!" to the accompaniment of a gourd rattle, and sucks at the part affected till the possessing spirit is supposed to come out and take flight, when men in waiting at the tent-door fire guns at it (Schoolcraft, *Indian Tribes of North America*, part i. p. 250, part ii. p. 199); and that of the Zulus, among whom the ghosts of the dead who enter men's bodies and cause disease are got rid of by the sacrifice of cattle, with expostulations, such as, "I say, cease, leave off making me ill" (Callaway, *Religious System of the Amazulu*, p. 157). In the most ancient known civilizations we find records of exorcism. An Egyptian tablet records the possession of a princess of the land of Bakhten by a demon, and the exorcism of this spirit by the god Khonsu, who was sent thither in his ark and cured her at once, the spirit saying, "Thou hast come in peace, great god, driver away of possessors. I am thy slave, I will go to the place whence I came" (Birch, in *Records of the Past*, vol. iv p 53). Among the formulas in ancient Babylonian exorcism are such as these:—"May the noxious spirit of the neck, the noxious wind, from the man himself and the clothing of the body be driven forth!" "From the burning spirit of the entrails, which devours the man, may the king of heaven preserve!" (Sayce, in *Records of the Past*, vol i. p. 131). In Greece men of no less distinction than Epicurus and Æschines were the sons of women who lived by the exorcist's art; and both were bitterly reproached, the one by the Stoics, and the other by Demosthenes (*De Cor.*), for having assisted their parents in these practices. This power was in some instances considered as a divine gift; in others it was thought to be acquired by investigations into the nature of demons and the qualities of natural productions, as herbs, stones, &c., and by the use of certain forms of adjurations and ceremonies. The power of expelling demons Josephus places among the endowments of Solomon, and relates that he left behind him the manner of using exorcisms by which they drive away demons. (For the pretended fragments of these books see Fabricius, *Cod. Pseud. Vet. Test.*, p. 1054.) He relates that he had seen a man named Eleazar releasing people that were demoniacal, in the presence of Vespasian, his sons, captains, and soldiers, by means of a certain root set in a ring, on the application of which to the nose of the patient, the devil was expelled through his nostrils. (See *Antiq.* viii. 2, § 5, and *De B ll. Jud.* vii. 6, § 3.) The profession of exorcist was not uncommon among the Jews, and the epithet applied to such persons (*περιερχομένων*; Vulg., *de circumeuntibus Judæis*) perhaps indicates that they were travelling mountebanks. The passages of the New Testament which refer to the exorcism of demons from epileptic, insane, and other diseased persons are too numerous and well known to require particular reference. The prominence of exorcism in the early ages of the Christian church appears from its frequent mention in the writings of the fathers, and by the 3d century there seems to have been an order of exorcists (see Bingham, *Antiquities of the Christian Church*). The ancient rite of exorcism in connexion with baptism is still retained in the Roman ritual, as is also a form of service for the exorcising of possessed persons. The exorcist signs the possessed person with the figure of the cross, desires him to kneel, and sprinkles him with holy water; after which the exorcist asks the devil his name, and abjures him by the holy mysteries of the Christian religion not to afflict the person possessed any more. Then, laying his right hand on the demoniac's head, he repeats the form of exorcism as follows: "I exorcise thee, unclean spirit, in the name of Jesus Christ, tremble, O Satan, thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who has deprived men of life, and hast rebelled against justice, thou seducer of mankind, thou root of evil, thou source of avarice, discord, and envy." Houses and other places supposed to be haunted by unclean spirits are likewise to be exorcised with similar ceremonies.

EXPIATION or ATONEMENT, DAY OF (יוֹם הַכִּפֻּרִים, *ἡμέρα ἐξιλασμοῦ*), called in the Mishna simply "the Day," the only fast enjoined by the Mosaic legislation, occurred annually on the tenth day of the 7th month (Tisri). The laws for its observance are given in Lev. xvi. 1–34, xxiii. 27–32, and Numb. xxix. 7–11 The high priest was to enter the Most Holy Place according to a minutely detailed ritual, and so "make an atonement for" (כִּפֶּר) the sanctuary the tabernacle, the altar, the priests, and all the people. From the one evening to the other the people were enjoined, under the severest penalties, to "afflict their souls," and observe a "perfect sabbath."

EXPLOSIVES. It lies beyond the object of this article to attempt an estimate of the influence, direct or indirect, upon modern civilization of the introduction of explosive agents for the purposes of war. Some eminent authors have gone so far as to consider the invention of gunpowder as next in importance, in its ultimate effects, to those of printing and the application of steam power. However this may be, it is well to remember that explosive substances are now of immense utility in the arts of peace; indeed, it is not too much to say that without their aid many of the great engineering enterprises of the present day would either be impossible, or else have to be carried out at a vast additional expenditure of time and labour.

The germ of all the knowledge of explosive reaction we possess undoubtedly lay in the probably accidental discovery, many ages ago, of the deflagrating properties of the natural substance nitre or saltpetre (KNO_3), when in contact with incandescent charcoal. To trace the consequences of that discovery, very gradual as they have been, and intimately bound up with the progress of chemical and mechanical science, belongs rather to an article on gunpowder; but the fact may be briefly referred to in connexion with the second great epoch in the history of explosive substances. By distilling nitre with oil of vitriol, the alchemists obtained a corrosive fluid which they called *aquafortis*, now known as nitric acid (HNO_3), which parts with its oxygen even more readily than saltpetre; so that if the strongest nitric acid be poured upon finely powdered charcoal, the latter takes fire at the ordinary temperature. Somewhat less than half a century back, it was discovered by some French chemists that upon treating various organic substances, such as starch, the sugars, cotton fabrics, and even paper, with concentrated nitric acid under proper precautions, the chemical constitution of the substances underwent a great change, and they became endowed with violently explosive properties, while remaining for the most part unaltered in external characteristics. To this discovery we owe a distinct class of explosive compounds, the most powerful for practical purposes as yet known; their general formation and properties will be noticed in due course.

We will now proceed to examine into those principles of constitution and action which are more or less common to all explosive substances.

efini-
ions

As the term is often rather loosely employed, "explosion" may for our purpose be defined as the sudden or extremely rapid conversion of a solid or liquid body of small bulk into gas or vapour, occupying very many times the volume of the original substance, and, in addition, highly expanded by the heat generated during the transformation. This sudden or very rapid expansion of volume is attended by an exhibition of force, more or less violent according to the constitution of the original substance and the circumstances of explosion. Any substance capable of undergoing such a change upon the application of heat, or other disturbing cause, is called "explosive."

The explosive substances that are practically the most important essentially contain carbon, oxygen, and nitrogen, the last always existing in a state of feeble combination with the whole or part of the oxygen, and thus creating that condition of unstable chemical equilibrium which is necessary. When explosion takes place, the nitrogen parts with its oxygen to the carbon, for which it has a great affinity, forming carbonic acid (CO_2) and carbonic oxide (CO) gases, the combination being accompanied with great generation of heat, and the nitrogen gas is set free. In most explosives there is also hydrogen accompanying the carbon, and by its combustion producing an extremely high temperature; it combines with part of the oxygen to form water in the form of greatly expanded vapour. Other subordinate elements are often present; in gunpowder, for instance, the potassium binds the nitrogen and oxygen loosely together in the state of saltpetre, and there is sulphur, a second combustible, whose oxidation evolves greater heat than that of carbon. When chlorate of potash is present, the chlorine plays the part of the nitrogen, and is set free in the gaseous state. Two very unstable and practically useless explosive substances, the so-called chloride and iodide of nitrogen, contain neither carbon nor oxygen; but their great violence is equally caused by the feeble affinities of nitrogen for other elements, large volumes of gaseous matter being suddenly disengaged from a very small quantity of a liquid and solid body respectively.

Explosives may be conveniently divided into two distinct classes,—(1) explosive mixtures, and (2) explosive compounds.

The first class consists of those explosive substances which are merely intimate mechanical mixtures of certain ingredients, and which can be again separated more or less completely by mechanical means, not involving chemical action. These ingredients do not, as a rule, possess explosive properties in their separate condition. There are, however, explosives which might almost be classed in both categories; for example, *picric powder* is composed of ammonium picrate and saltpetre, the former of which contains an explosive molecule, but is mixed with the latter to supply additional oxygen, and thus increase the force.

Explosive mixtures.

If a substance that will burn freely in air, combining gradually with the oxygen of the atmosphere, be ignited in pure oxygen gas, the combustion will be much more rapid, and the amount of heat generated greater, at the ordinary atmospheric pressure. If it be possible to burn the substance in a very condensed atmosphere of oxygen, we can readily imagine the combustion being very greatly accelerated, and therefore increased in violence; this is what is ordinarily effected by an explosive "mixture." A combustible body and a supporter of combustion are brought into extremely close contact with one another, by means of intimate mechanical mixture; also, the supporter of combustion, or oxidizing agent, is present in a very concentrated form, constituting what may be termed a magazine of condensed oxygen, solid or liquid. In the case of the explosion of a definite chemical compound, the change may be considered as the resolution of a complex body into simpler forms; this is not, however, always the case when a mechanical mixture is concerned: gunpowder, for example, may be said to contain two elementary substances, carbon and sulphur, not in chemical union.

The chief explosive mixtures may be subdivided into "nitrate mixtures," and "chlorate mixtures."

Nitrate mixtures.

In the nitrates, the oxygen is held in combination with sufficient force to need a powerful disturbing cause to separate it, so that mixtures made from nitrates do not explode very readily, and their action is comparatively gradual; they are not sensitive to friction or percussion, and hence are tolerably safe. Any of the nitrates will form explosive mixtures with combustible substances, but nitrate of potash (KNO_3) is the only one practically employed. The nitrate of soda, called "cubical" or Chili saltpetre, has been used, but absorbs moisture from the air so readily as to give very inferior results. Gunpowder may be taken as the representative of the nitrate explosive mixtures. Picric powder, above referred to, has been proposed by Abel for use as a bursting charge for shells, as being more powerful than a corresponding charge of gunpowder, equally safe as regards friction or percussion, and less hygroscopic; it consists of two parts ammonium picrate, and three parts saltpetre, incorporated, pressed, and finished very much as ordinary gunpowder.

Chlorate mixtures.

The chlorates part with their oxygen far more readily than the nitrates, the strong affinities of chlorine for the metals coming into play, and consequently chlorate mixtures are very sensitive to friction and percussion, and explode with great violence, chlorate of potash ($KClO_3$) is the only one used. Very many chlorate mixtures have been made, some of which are employed in fireworks. "White gunpowder" is a mixture of two parts chlorate of potash, one of yellow prussiate of potash, and one of sugar; it is exploded very easily by friction or percussion. The most important chlorate mixtures are those used for igniting other explosives, such as the composition for friction tubes for firing cannon, percussion cap composition, and percussion fuzes for bursting shells on impact; it is sometimes mixed with sulphur, as a combustible, and sometimes with black sulphide of antimony, which gives a longer flame.

Explosive compounds.

In an explosive "compound," the elements are all in chemical combination, presenting a definite explosive "molecule," which contains, so to speak, both the combustible and the supporter of combustion, in the closest possible union; we can therefore understand its action being much more sudden and violent than that of the most intimate mechanical mixture.

Nitro-substitution products.

The chief explosive compounds are formed from some organic substance containing carbon, hydrogen, and oxygen, by introducing into it, through the action of concentrated nitric acid, a certain portion of nitric peroxide (NO_2), in substitution for an equivalent amount of hydrogen. A new compound, differing outwardly very little, if at all, from the original substance, is thus formed, but in a very unstable state of chemical equilibrium, because of the feeble union of the nitrogen and oxygen in the NO_2 molecule. A slight disturbing cause brings into play the stronger affinity of the carbon and hydrogen for the large store of oxygen contained in the new compound. Gun-cotton and nitro-glycerin are the leading members of this group, being produced in a precisely similar manner, by the substitution of three molecules of NO_2 for three atoms of hydrogen (H). As those explosives will be elsewhere described in detail, we give the formation, as a representative member of the group, of nitro-phenol, or picric acid, by treating phenol, or carbolic acid, with a mixture of nitric and sulphuric acids, the latter being required to absorb the water, and preserve the full strength of the nitric acid:—

Picric acid.

$$\underset{\text{Carbolic acid.}}{C_6H_6O} + \underset{\text{Nitric acid.}}{3HNO_3} = \underset{\text{Picric acid.}}{C_6H_3(NO_2)_3O} + \underset{\text{Water.}}{3H_2O}.$$

The formula of the product may be empirically written $C_6H_3N_3O_7$; it is, like gun-cotton and nitro-glycerin, a *tri-nitro* substitution product. Only the picrates, or salts of picric acid formed with potassium or ammonium, are used in practice, as possessing more force than the uncombined acid. From starch can be obtained, in a strictly analogous manner, an explosive called *xyloidine*, which is a *bi-nitro* product, two molecules of nitric peroxide being substituted for two atoms of hydrogen. In the case of *nitro-mannite*, an explosive made from mannite, one of the sugars, as many as six molecules of the NO_2 are inserted. The number of nitro-substitution products is very great, many of them being more or less violently explosive.

Fulminates.

The fulminates are among the most violent of all explosive compounds, their chemical stability being very small. Sudden in action, their effect is great locally; thus they are well adapted to the purpose, for which alone they are practically used, of igniting, or upsetting the equilibrium of, other explosives.

Fulminate of mercury is produced by adding alcohol (C_2H_6O), under careful precautions, to a solution of mercury in nitric acid; a grey crystalline precipitate is obtained, very heavy (sp. gr. 4·4), and so sensitive to friction or percussion that it is kept in the wet state. The results of analysis show one atom of mercury, and two each of carbon, nitrogen, and oxygen, so that the formula may be empirically written $HgC_2N_2O_2$, or perhaps more correctly $HgO.C_2N_2O$; the chemical factor C_2N_2O is called *fulminic acid*, but has never been produced separately. Opinions differ as to the precise "rational" formulæ of the fulminates, some chemists considering their process of formation to be similar to that of the nitro-substitution products. It will be observed that two atoms of nitrogen take the place of hydrogen, being the ratio of combining proportions of those elements. The products of combustion are carbonic oxide, nitrogen, and metallic mercury, and the violence of action is due to the sudden evolution of a volume of gas and vapour very large in comparison with that of the substance, its density being so great. This fulminate enters into the composition used for percussion caps and electric fuzes; its practical value has of late years been immensely increased by the discovery of its power, even in very small quantities, to produce the almost instantaneous decomposition of several explosive substances.

Fulminate of silver is prepared in a similar manner, but, being far more sensitive, is of little practical value; it is employed, in very minute quantities, in making such toys as detonating crackers.

The difficulties in the way of estimating, with any accuracy, the *force* of explosive substances are very great, especially as no definite standard of comparison can be laid down. However, by means of theoretical considerations, combined with the results of actual experiment, a tolerably fair approximation may be arrived at.

Maximum tension in closed vessel.

When an explosive substance is exploded in a closed vessel sufficiently strong to resist rupture, the tension attains its maximum value in an extremely short space of time and gradually decreases from the heat being conducted away by the metal envelope, and dispersed by radiation. It has, however, been demonstrated that, at the moment of maximum tension, the loss of pressure due to the communication of heat to the vessel, if the latter be filled with the explosive, is less than one per cent. The products of combustion, after cooling down, can easily be determined by analysis, and are then either (*a*) wholly gaseous, as for chloride or iodide of nitrogen; (*b*) gaseous and liquid, in the case of gun-cotton and nitro-glycerin; or (*c*) gaseous and solid, as with gunpowder. It is certain that, at the moment of explosion, the products of the more violent explosive compounds are wholly in a state of gas or vapour, but we should arrive at incorrect results by making the same assumption in the case of a mechanical mixture like gunpowder. The experiments of Noble and Abel on "Fired Gunpowder" (*Phil. Trans. Roy. Soc.*, 1874), which are the most complete ever undertaken, show that the ultimately solid residue is, at the moment of explosion, in a liquid state, and most probably in a very finely divided condition; moreover, that, at that instant, it occupies a space the ratio of which is about ·6 that of the original volume, supposing the substance to fill the vessel in which it is exploded.

Provided the laws concerned can be supposed to hold good at such high temperatures, we may assume for the gaseous products of combustion the well-known equation of the elasticity and dilatibility of permanent gases—

$$pv = Rt \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where R is a constant, and t reckoned from absolute zero (− 273° C). For the sake of convenience, we will consider that a unit of weight of the explosive substance occupies a unit of volume, and, if P be maximum tension developed by the explosion, we have

$$P(1-\rho) = RT \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

where T is the temperature of explosion, and ρ the ratio of the volume of the non-gaseous products, taken as constant; we have also the relation

$$p_0(1-\rho) = R.273, \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

when the vessel is cooled down to 0° C; therefore, eliminating R between (2) and (3), we get

$$P = \frac{p_0 T}{273} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

But permanent gases under the pressure p_0 in atmospheres, at a volume $(1-\rho)$, will occupy a space $p_0(1-\rho)$, if allowed to expand to the normal pressure of 760 mm.; calling this expanded volume V,

$$P = \frac{VT}{273(1-\rho)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

The large amount of aqueous vapour produced by the explosion of some compounds must be added to the value of V, its volume being calculated on the supposition that it can remain uncondensed at the temperature of 0° C.

We have no certain means of directly estimating the temperature of explosion, but if it be assumed, as is usually done, to be the temperature the total products of combustion would attain to if the whole amount of heat generated by the explosion were applied to raise them, under constant volume, from absolute zero, we have the relation

$$H = Tc_v,$$

in which H represents the number of units of heat generated, and c the specific heat under constant volume of the united products, gaseous or otherwise. The quantity of heat can be obtained by experiment, and this divided by the specific heat, will give the temperature. The chief sources of error lie in the assumption that the specific heat remains constant throughout the great range of temperature in question, and in the additional quantities of heat disengaged by secondary reactions. The value of T thus found probably will therefore be higher than the real temperature.

Explosive force

Having regard to the above reasoning, it may be *generally* concluded that the amount of force exerted by an explosive substance depends upon—(1) the *volume of gas or vapour* produced by the transformation, compared with that of the original substance; and (2) the *temperature of explosion*, which determines the extent to which the gases are expanded, or their tension increased; or, in other words, the explosive force is *directly* proportional to the heat of combustion, and the volume of gas and vapour calculated at 0° C. and 7·60 mm. pressure, and *inversely* proportional to the specific heat of the mixed products.

It has been supposed by Berthelot and others that the volume of gas produced may possibly be still further increased by the partial or total "dissociation" of the compound gases, at the high temperatures concerned; for example, that the carbonic acid (CO_2) may be decomposed into carbonic oxide (CO) and oxygen, or the aqueous vapour into oxygen and hydrogen. However, Noble and Abel demonstrate that, in the former instance, the loss of temperature, consequent upon the absorption of heat by the decomposition, would more than compensate for the increase of volume by dissociation. It must also be remembered that, if the temperature be extremely high, so also is the pressure under which dissociation must take place. We may therefore consider that it has no sensible influence upon the explosive force.

Explosive effect.

It is most important to distinguish between explosive force and explosive effect, the latter in great measure depending upon the rapidity with which the metamorphosis takes place, while the same amount of force may be exerted suddenly or gradually. We may, therefore, consider that the explosive effect varies *directly* as the volume of gas produced and the temperature of explosion, and *inversely* as the time required for the transformation. But the time, and, to a certain extent, the products and temperature, will vary with—(*a*.) the physical state of the explosive substance; (*b*.) the external conditions under which it is fired; (*c*.) the mode of firing or exploding.

Physical state of explosives.

The physical or mechanical state of the explosive substance has a most important bearing upon the effect obtained from it. To prove this, it is only necessary to point to the very different results given by gunpowders made with the same proportions of the three ingredients, but varying in density, and in shape and size of grains or pieces. Gun-cotton is even more affected by variations in mechanical condition. In the form of loose wool, it burns so rapidly that gunpowder in contact with it is not inflamed; plaited or twisted tightly, its rate of combustion in air is greatly modified. This is due to the fact that the inflammable carbonic oxide, which is evolved by the decomposition from the want of sufficient stored-up oxygen to oxidize completely all the carbon of the gun-cotton, cannot penetrate between the fibres and accelerate the combustion, but burns with a bright flame away from the surface of the twisted cotton; when the yarn is yet more compressed by any means, the temperature is not kept up to the height necessary for the combustion of the carbonic oxide, so that it escapes unconsumed, abstracting heat, and yet more retarding the rate of burning. For the same reason, pulped and compressed gun-cotton burns comparatively slowly in air, even when dry; in the wet state, it merely smoulders away, as the portions in contact with the fire successively become dried. Yet this same wet compressed gun-cotton can be so used as to constitute one of the most powerful explosives known.

External conditions of explosion.

It is well known that gunpowder behaves differently when fired in the open air and under strong confinement; not only the rate of burning, but even, to a certain extent, the products of combustion are altered. We have discussed the effect of tightly plaiting or compressing gun-cotton; but, when confined in a strong envelope, the whole of the inflamed gas, being unable to escape outwards, is forced into the interstices under immense pressure, and the decomposition greatly accelerated. The amount of confinement or restraint needed by any explosive depends, however, upon the nature of the substance and the mode of exploding it, becoming very much less as the transformation is more rapid, until it may be said to reach the vanishing point. For example, the very violent explosive chloride of nitrogen is usually surrounded, when exploded, with a thin film of water; Abel states that if this film, not exceeding $\frac{1}{1000}$ inch in thickness, be removed, the explosive effect is much lessened. Nitro-glycerin, again, when detonated by a fulminate, is sufficiently confined by the surrounding atmosphere. By the same means, gun-cotton may be exploded unconfined, if compressed, the mechanical cohesion affording sufficient restraint. In the case of wet compressed gun-cotton, which can be detonated with even fuller effect than dry, the mechanical resistance is greater, the air-spaces being filled with incompressible fluid.

Mode of exploding.

The manner in which the explosion is brought about has a most important bearing upon the effect produced. This may be done by the direct application of an ignited or heated body, by the use of an electric current to heat a fine platinum wire, or by means of percussion, concussion, or friction, converting mechanical energy into heat. A small quantity of a subsidiary explosive, such as a composition sensitive to friction or percussion, is often employed, for the sake of convenience, to ignite the main charge, the combustion spreading through the mass with more or less rapidity, according to the nature of the substance.

Detonation.

Although subsidiary or initiatory explosives were at first used merely to generate sufficient heat to ignite the charge, and are often still so employed, they have of late years received an application of far wider importance. Mr Alfred Nobel, a Swedish engineer, while endeavouring to employ nitro-glycerin for practical purposes, found considerable difficulty in exploding it with certainty; he at length, in 1864, by using a large percussion cap, charged with fulminate of mercury, obtained an explosion of great violence. This result led to the discovery that many explosive substances, when exploded by means of a small quantity of a suitable initiatory explosive, produce an effect far exceeding anything that can be attributed to the ordinary combustion, however rapid, of the body in question; in fact, the whole mass of the explosive is converted into gas with such suddenness that it may, practically, be considered instantaneous; this sudden transformation is termed "detonation." Of the substances capable of producing such action, fulminate of mercury is the most important.

Some explosives appear always to detonate, in whatever manner they may be exploded, such as chloride and iodide of nitrogen, the explosive effect is therefore much greater than that of a slower explosive substance, although their explosive force may be less. Again, other substances, such as gun-cotton and nitro-glycerin, are detonated or not according to the mode of explosion. Indeed, Abel has proved that most explosives, including gunpowder, can be detonated, provided the proper initiatory charge be employed.

Two orders of explosives

Roux and Sarrau (*Comptes Rendus*, 1874) have divided explosions into two classes or orders,—"detonations" or explosions of the first order, and "simple explosions" of the second order. They made a series of experiments with the object of determining the comparative values of various explosive substances, detonated, and exploded in the ordinary manner, the method employed was to ascertain the quantity of each just sufficient to produce rupture in small spherical shells of equal strength. The following table gives the comparative results for the three most important explosive substances :—

	Explosive Effect.	
	Second Order	First Order.
Gunpowder	1 00	4 34
Gun-cotton or nitro cellulose ..	3 00	6 46
Nitro-glycerin	4 80	10 13

These experiments, although valuable, cannot be considered as affording a precise method of comparison; the results would be affected, *inter alia*, by the impossibility of ensuring that the shells were all of the same strength, a point of great importance, considering the very small weights of each explosive used; also the rate of combustion, and therefore the explosive effect, of gunpowder is materially affected by its mechanical condition, so that different powders would give a varying standard of comparison. However, they afford fair evidence that, when detonated, gun-cotton has about six times, and pure nitro-glycerin about ten times the local explosive effect of gunpowder simply ignited in the ordinary manner; nitro-glycerin is usually employed in the form of "dynamite," mixed with some inert absorbent substance, so that its power is proportionately reduced.

Theory of detonation.

The rationale of detonation is not yet understood. If the transformation were due merely to the mechanical energy of the particles of gas, liberated from the initiatory charge at a tremendous velocity, being converted into heat by impact against the mass of the explosive substance, then it would follow that the most powerful explosive would be the best detonating agent; this is, however, by no means the case, for a few grains of fulminate of mercury in a metal tube will detonate gun-cotton, whereas nitro-glycerin, although possessed of more explosive force, will not do so unless used in large quantities. The fact of its being possible to detonate wet gun-cotton is also a proof that the action cannot be due to heat alone. It would rather seem to be what Professor Bloxam terms "sympathetic" explosion; the experiments of Abel, as well as those of Champion and Pellet in France, appear to indicate a vibratory action of the detonating agent upon the ultimate particles of the substance to be exploded. An explosive molecule is most unstable, certain very delicately balanced forces preserving the chemical and phys' .' equilibrium of the compound. If these forces be rapidly overthrown in succession, we have explosion; but when, by a blow of a certain kind, they are instantaneously destroyed, the result is detonation. Just as a glass globe may withstand a strong blow, but be shattered by the vibration of a particular note, so it is considered by some authorities that, in the instance cited, the fulminate of mercury communicates a vibration to which the gun-cotton molecule is sensitive, and which overthrows its equilibrium; it is not sensitive to the vibrations caused by the nitro-glycerin, which only tears and scatters it mechanically. Although the action of detonation has been spoken of as instantaneous, and may practically be so considered, yet a certain infinitesimal duration of time is required for the metamorphosis; different substances possess, doubtless, different rates of detonation, for we can scarcely conceive of a mechanical mixture, such as gunpowder, being so sensitive to the action of the detonating impulse as a definite chemical compound, and the rate even varies slightly, for the same explosive, with its physical state. It has been shown, by means of Captain A. Noble's chronoscope, that compressed gun-cotton, when dry, is detonated at a velocity of from 17,000 to 18,000 feet a second, or about 200 miles a minute; by using a small primer of dry gun-cotton, the same substance in the wet state may be detonated at the increased rate of from 18,000 to 21,000 feet a second, or about 240 miles a minute.

The following results are taken from experiments on detonation and its applications, carried out by F. A. Abel, C.B., F.R.S.:—

I. *Illustrating some of the conditions which promote the detonation of an explosive substance—(a) Quality of the initial detonation; (b) Resistance to mechanical dispersion offered by the mass of the substance to be detonated.*

1. A fuze containing rather more than 1 oz. gunpowder, strongly confined, exploded in contact with a mass of compressed gun-cotton, only inflames it, although the explosion of the fuze is apparently a sharp one.
2. Forty-five grains of fulminate of mercury, exploded unconfined on the surface of a piece of compressed gun-cotton, only inflames or disperses it.
3. A fuze containing 9 grains fulminate of mercury, strongly confined, exploded in contact with compressed gun-cotton, or dynamite, detonates it with certainty.
4. An equal quantity of fulminate, similarly confined, does not detonate uncompressed gun-cotton in which it is imbedded, but merely disperses and inflames it.
5. 150 grains compressed gun-cotton, detonated in proximity to dynamite, detonates the latter.
6. 3 oz. of dynamite, and very much larger quantities, detonated in contact with compressed gun-cotton only disperses it

II. *Transmission of Detonation.*

7. Detonation being established at one extremity of a continuous row of distinct masses of compressed gun-cotton, or dynamite, travels the whole length thereof. Stretching insulating wires across the row of discs, at intervals of six feet, their rupture by the detonation gives spark-records on the cylinder of Noble's chronoscope, by means of which the rate of transmission can be calculated.
8. A row of gun-cotton discs, of any length, placed 0·5 inch apart, can all be detonated from one end.
9. Discs of compressed gun-cotton, weighing about 8 oz. each, being placed 6 inches apart, the detonation of the central disc only blows away or breaks up the neighbouring masses.
10. About 2 oz. compressed gun-cotton being inserted into one extremity of a wrought-iron tube 5 feet long, its detonation is transmitted to a disc of compressed gun-cotton inserted into the other extremity of the tube.

III. *Applications of Detonation.*

11. A wrought iron rail can be destroyed by detonating 8 oz. of compressed gun-cotton placed unconfined upon the rail.
12. A piece of wet gun-cotton, quite uninflammable, removed from a fire and detonated upon a block of granite, using a small primer of dry gun-cotton, shatters the block.
13. A stockade can be destroyed by means of a flat charge built up of wet gun-cotton slabs,—detonation being established by means of a small portion of the charge in a dry state.
14. A submerged charge of wet gun-cotton, open on all sides to the water, and merely confined around the dry initiative charge, or primer, by means of a net, can be detonated.

Relat force of explosives.

Many attempts have been made, especially by foreign chemists and physicists, to arrive at an exact determination of the comparative force of explosive substances. The means adopted may be summed up under the two headings of (1) experiment alone, and (2) calculation and experiment combined. In the first category may be placed the experiments of Roux and Sarrau, already noticed. By the second method, Berthelot (*Force de la Poudre et Matières Explosives*, 1872) calculates the volume of gases which would be produced, and having ascertained the quantity of heat generated by the explosion, considers that their product affords a term of comparison according fairly well with the results of experiment. Sarrau (*Effets de la poudre et des substances explosives*, 1874), from a train of reasoning somewhat similar to that here followed, arrives at the conclusion that the explosive force is nearly proportional to the product of the heat of combustion by the weight of permanent gases produced; he obtains both these data by experiments carried out at the Dépôt central des Manufactures de l'État. The following table shows the results of the two methods:—

Explosive Substance.	Relative Force.	
	Sarrau.	Berthelot.
Gunpowder	1·00	1·00
Gun-cotton	3·06	3·42
Nitro-glycerin	4·55	6·80
Picrate of potash	1·98	2·44
Picrate of potash and saltpetre	1·49	2·07
Picrate and chlorate of potash	1·82	3·46
Chloride of nitrogen	1·08	0·85

The plan pursued by Sarrau appears the more reliable of the two, in that he obtains by experiment the quantity of permanent gases evolved; the relative proportions he gives agree fairly well with those experimentally determined by him, in conjunction with Roux, for simple explosion. With reference to Berthelot's figures, it is a well known fact that nitro-glycerin, when not detonated, is very uncertain in its action, so that in all probability it would never give its full theoretic force; Sarrau seems nearer its correct value. On the other hand, chlorine gas, liberated by the explosion of chlorate of potash and chloride of nitrogen, is very heavy, so that considerable variation may arise from estimating it by weight instead of volume. The mean of the results given by five descriptions of gunpowder was adopted by Sarrau as his standard, and he estimates the pressure at about 5290 atmospheres. Noble and Abel have proved these figures to be considerably too low; and we shall, in all probability, be not far wrong if we multiply each of the ratios given in Sarrau's table by 6000, in order roughly to show the pressure, in atmospheres, of equal weights of each of the substances in question exploded in about its own volume, but not detonated.

roducts com- ıstion lowed ex- ınd

We have considered the tension developed in a close vessel of constant volume. Let us now investigate the case of the products of combustion being allowed to expand in a vessel impervious to heat, it having been conclusively proved that with large charges the loss of heat by communication to the metal of a gun is relatively very small, and may practically be neglected. If V, P, and T be respectively the initial volume occupied by the substance, the maximum pressure, and the temperature of explosion, we shall deduce expressions for the pressure and temperature corresponding to any volume v, and the work done by the expansion of the permanent gases in the space $v-V$. It will simplify the calculation if we suppose that the gravimetric density of the substance is unity, that it fills the volume in which it is exploded, and that the charge is burnt before it commences to do work, either upon a projectile or otherwise; even with gunpowder the correction due to this last assumption is not great, and the action of the more violent explosives may practically be considered instantaneous, especially when detonated. It has already been stated that, with most explosives, there is an ultimately solid or liquid residue, the products not being wholly gaseous; with gunpowder this residue is very considerable.

As before, let ρ be the ratio of the volume of the non-gaseous products at the instant of explosion; then the original volume of gas and vapour will be $V(1-\rho)$, and the expanded volume $v-\rho V$; for the sake of brevity these corrections will be made at the end of the calculations. As already stated, for gunpowder the value of ρ is about ·6; it is relatively inconsiderable for the more violent explosive compounds.

Starting with the fundamental relation for permanent gases,

$$pv=Rt. \qquad (1).$$

if we suppose the pressure to remain constant while the volume varies by an infinitesimal amount dv, the temperature will undergo a corresponding variation $\frac{pdv}{R}$, and the gases gain or lose an amount of heat $\frac{c_p.pdv}{R}$, c_p being the specific heat for constant pressure; similarly, if the volume be supposed to remain constant, while the pressure varies by dp, we have a gain or loss of heat $\frac{c_v.vdp}{R}$, c_v being the specific heat for constant volume; consequently, when both pressure and volume vary simultaneously, the gain or loss of heat is

$$\frac{1}{R}(c_p.pdv+c_v.vdp)=dh \qquad (2).$$

and differentiating (1),

$$pdv+vdp=Rdt. \qquad (3).$$

Eliminating vdp between these equations, we get

$$\frac{c_p-c_v}{R}.pdv+c_v\ dt=dh \qquad (4)$$

Again, if c' be the specific heat of the solid residue, assumed to be constant, and σ the ratio of its weight to that of the gas and vapour, it is evident that the residue will part with an amount of heat, $\sigma c'.dt$, during an instant of the expansion while the temperature is lowered by an amount dt; but, by our hypothesis, the heat given off by the residue is acquired by the gases; therefore,

$$dh=-\sigma c'.dt. \qquad (5);$$

and (4) becomes, for the expansion from V to v,

$$-(c_v+\sigma c')\int_T^t dt=\frac{c_p-c_v}{R}\int_V^v pdv \qquad (6).$$

Substituting for p its value derived from (1), dividing both sides by t, and integrating, we have

$$\log_\epsilon\left(\frac{t}{T}\right)^{c_v+\sigma c'}=\log_\epsilon\left(\frac{V}{v}\right)^{c_p-c_v} \qquad (7).$$

whence

$$t=T.\left(\frac{V}{v}\right)^{\frac{c_p-c_v}{c_v+\sigma c'}} \qquad (8);$$

making the correction for the volume of the solid or liquid residue

$$t=T.\left\{\frac{V(1-\rho)}{v-\rho V}\right\}^{\frac{c_p-c_v}{c_v+\sigma c'}}. \qquad (9)$$

In a precisely similar manner, or more briefly by remembering that $PV=RT$, we find

$$p=P\left\{\frac{V(1-\rho)}{v-\sigma V}\right\}^{\frac{c_p+\sigma c'}{c_v+\sigma c'}} \qquad (10)$$

Work done by the expansion.

But the definite integral $\int_V^v pdv$, represents the work done by the expansion of the gas and vapour from the volume V to any volume v, and from equation (6),

$$\int_V^v pdv=-\frac{R(c_v+\sigma c')}{c_p-c_v}\int_T^t dt \qquad (11).$$

Integrating, and remembering that $c_p-c_v=\frac{R}{J}$, where J is Joule's mechanical equivalent of heat, we get

$$W=J(c_v+\sigma c')\{T-t\} \qquad (12);$$

or the work done is directly proportional to the loss of temperature during the expansion.

Substituting the value above found for t, we have

$$W=JT(c_v+\sigma c')\left\{1-\left(\frac{V(1-\rho)}{v-\rho V}\right)^{\frac{c_p-c_v}{c_v+\sigma c'}}\right\}; \qquad (13);$$

but $T(c_v+\sigma c')=H$, the whole amount of heat generated by the explosion, so that we have the expression,

$$W = JH\left\{1 - \left(\frac{V(1-\rho)}{v-\rho V}\right)^{\frac{c_p - c_v}{c_v + \sigma c'}}\right\} . \quad . \quad . \quad . \quad (14)$$

This expression for the work done is of considerable practical value in the case of gunpowder, or any explosive which can be used as a propelling agent with heavy guns. Knowing the length and diameter of the bore, we can calculate the total maximum work due to a given weight of charge in expanding to that volume. This maximum is of course not attained in practice, and it is therefore necessary to multiply it by a ratio, or factor, dependent on the nature of the gun and projectile, the powder used, mode of ignition, &c. However, by making use of the results of actual experiment, this "factor of effect," or percentage of work realized, can be determined with much accuracy. Its value is greatest for very large guns, being 93 per cent. for the 38-ton gun, and becoming as low as about 50 per cent. in the case of the little 7-pr. mountain gun of 150 lb. weight; the difference is chiefly due to the loss of heat by communication to the metal of the gun. (See Noble and Abel on "Fired Gunpowder.")

Initial velocity.

We can approximate to the "muzzle velocity," or the velocity at which the projectile leaves the bore, by substituting the value of W, found for the particular gun, in the ordinary equation of work, $W = \frac{wV^2}{2g}$, where V is the velocity, and w the weight of the projectile; we thence obtain

$$V = \sqrt{\frac{2g}{w} . Wf} .$$

If W, the maximum work due to the expansion of the gaseous products in the volume of the bore, be multiplied by the factor of effect f, for the nature of gun and powder used, the result will be very nearly the mean observed velocity.

Graphical representation of work.

The mathematical expression for the work done by an explosive substance in expanding from V to v, or $\int_V^v pdv$, evidently denotes the area of a plane curve; the work may therefore be graphically represented by the area enclosed by a curve, having for its ordinates the pressures in foot-tons, or atmospheres, and for abscissæ the corresponding volumes or spaces occupied by the gases.

Total theoretic work.

If, in equation (14), we take the limits between V and infinity, we arrive at a very simple expression for the total theoretic work due to the indefinite expansion of a given weight of any explosive substance, v becoming indefinitely great compared to the original volume V, and we have

$$= JH, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15),$$

which may be called the "potential energy" of the explosive, being the product of the total quantity of heat generated by the explosion and the mechanical equivalent of heat. This conclusion, within the assumptions made, is in strict accordance with the principle of the mutual convertibility of energy and heat.

The following table shows the potential energy, in foot-tons, calculated from the heat of combustion for each explosive, determined by Roux and Sarrau, in the experiments already referred to; that for gunpowder is the mean given by five kinds.

Explosive Substance.	Potential Energy per lb. Foot-tons.
Gunpowder	480
Gun-cotton	716
Nitro-glycerin	1139
Picrate of potash	536
Picrate of potash and saltpetre	615
Picrate and chlorate of potash	781
Chloride of nitrogen	216

The above figures naturally direct our attention to the small amount of work stored up in even the most violent explosive substance, compared with the potential energy of 1 lb. of coal, which is about 4980 foot-tons. Noble and Abel point out that this great difference is not alone due to the fact that the coal draws its oxygen from the air, but also because the explosive has to expend a considerable amount of work in converting its condensed magazine of oxygen into gas, before it can combine with the carbon; further, with reference to the economic value of the work done, that the oxygen used by the coal costs nothing, whereas much expense is incurred in condensing the oxygen into the explosive substance.

Practical value of an explosive.

The practical value of any explosive must depend greatly upon the object to be attained. It is essential to distinguish between explosive force and effect; the more sudden the action the more local will be the effect produced, and hence the very violent explosive substances are useless as propelling agents for heavy guns or small arms, since they would destroy the weapon before overcoming the inertia of the projectile. It is true that gun-cotton, prepared in various forms, and mixed with other substances to moderate its action, as well as a similar compound made from saw-dust, an inferior form of cellulose, are sometimes used with small arms; but, in addition to a want of uniformity in action, the strain caused by such substances would be far too great in the large charges needed for heavy guns. Again, there are cases, even in mining or blasting operations, for instance, when it is desired to displace large masses of earth or soft rock, in which a comparatively slow explosive, such as gunpowder, would give better results than gun-cotton or dynamite. However, speaking generally, gunpowder in some one of its forms is far the most valuable as a propelling agent, while, for destructive purposes, the last-named substances are much more effective, especially when detonated.

Law relating to explosives.

Law.—In 1860 an Act was passed "to amend the law concerning the making, keeping, and carriage of gunpowder and compositions of an explosive nature, and concerning the manufacture and use of fireworks" (23 and 24 Vict. c. 139), whereby previous Acts on the same subject were repealed, and minute and stringent regulations introduced. Gunpowder may only be manufactured in mills, lawfully used at the commencement of the Act, or duly licensed as in this Act provided; other explosive compositions require a licence, and the precautionary rules as to quantity, distance from dwelling houses, &c., are set forth in minute detail. No person may sell fireworks without a licence, or to persons apparently under 16 years of age; and throwing fireworks on the streets was made punishable by a penalty not exceeding £5. Other regulations deal with carriage by land and sea, search-warrants, inspections of mills, &c. Amending Acts were passed in 1861 and 1862.

In 1875 was passed the "Explosives Act" (38 Vict. c. 17), which repeals the former Acts, and deals with the whole subject in a more comprehensive manner. "Explosives" are thus defined:—(1) Gunpowder, nitro-glycerin, dynamite, gun-cotton, blasting powders, fulminate of mercury or of other metals, coloured fires, and every other substance, whether similar to those above mentioned or not, used or manufactured with a view to produce a practical effect by explosion or a pyrotechnic effect, and including (2) fog-signals, fireworks, fuzes, rockets, percussion caps, detonators cartridges, ammunition of all descriptions, and every adaptation or preparation of an explosive as above defined. Part i. deals with gunpowder; part ii. with nitro-glycerin and other explosives; part iii. with inspection, accidents, search, &c., part iv. with various supplementary provisions. In addition to the licence required for manufacturing gunpowder, it is provided that gunpowder shall not be kept in any place except (1) a licensed factory, (2) a licensed magazine or store, or (3) premises registered for keeping gunpowder. Private persons may keep gunpowder for their own use to the amount of thirty pounds. Rules for the proper keeping of gunpowder on such registered premises are prescribed. The Act contains 122 sections, and applies to Scotland and Ireland as well as England. It was based on the report of a Committee of the House of Commons. Public opinion had been greatly excited on the subject by the terrible explosion on the Regent's Canal in 1874.

Petroleum is governed by the Petroleum Act 1871—an annual Act, which has been included every year in the Expiring Acts Continuance Bill.

In 1877 the "Fisheries (Dynamite) Act" was passed, whereby any person who uses dynamite or other explosive substance to catch or destroy fish in a public fishery, shall be liable, on summary conviction, to a fine not exceeding £20, or imprisonment for a term of not more than two months.

Bibliography.—See, on the general subject, the following works:—Count de St Robert, *Traité de Thermodynamique*, Turin, 1865; Berthelot, "Recherches de Thermochimie," *Annales de Physique et de Chimie*, tome vi.; Berthelot, *Sur la Force de la Poudre et les Matières Explosives*, 1872, Roux and Sarrau, "Experiments on Explosives," *Comptes Rendus*, tome lxxvii. 1871; Bunsen and Schiskoff's "Researches on Fired Gunpowder," *Poggendorff's Annalen*, vol. cii.; Sarrau, *Recherches théoriques sur les effets de la poudre, et des substances explosives*, 1874; Noble and Abel, *Researches on Explosives—Fired Gunpowder*, 1875; *Recent investigations and applications of explosive agents*, F. A. Abel, F.R.S., 1871, "Contributions to the history of Explosive Agents," F. A. Abel, F.R.S. (*Proc. Roy. Soc.*, No. 150, 1874), *Chemistry Inorganic and Organic*, C. L. Bloxam (articles on Gunpowder, Gun-Cotton, &c.), London, 1875; "Vibratory motions produced by Detonants," Champion and Pellet (*Comptes Rendus*, vol. lxxv.); *Notes on certain Explosive Agents*, Walter N. Hill, S.B. Chemist, U.S. Torpedo Service, Boston, 1875. The bibliography of explosives is chiefly contained in memoirs scattered throughout proceedings of various learned societies. (W. H. W.)

EXTRADITION. When a person who has committed an offence in one country escapes to another, what is the duty of the latter with regard to him? Should the country of refuge try him in its own courts according to its own laws, or deliver him up to the country whose laws he has broken? To the general question international law gives no certain answer. Some jurists, Grotius among them, incline to hold that a state is bound to give up fugitive criminals, but the majority appear to deny the obligation as a matter of right, and prefer to put it on the ground of comity. And the universal practice of nations is to surrender criminals only in consequence of some special treaty with the country which demands them.

There are two practical difficulties about extradition which have probably prevented the growth of any uniform rule on the subject. One is the variation in the definitions of crime adopted by different countries. The second is the possibility of the process of extradition being employed to get hold of a person who is wanted by his country, not really for a criminal, but for a political offence. In modern states, and more particularly in England, offences of a political character have always been carefully excluded from the operation of the law of extradition.

Extradition, as stated above, has for the most part been regulated by special treaties. A full list of the extradition treaties between the principal civilized countries will be found in Phillimore's *International Law*, vol. i. c. 21. Just before the passing of the Extradition Act of 1870, England had only two treaties subsisting—one with France, another with the United States. Both were confirmed by Acts of Parliament. The "Extradition Act 1870" enacts that "where an arrangement has been made with any foreign state, with respect to the surrender to such state of any fugitive criminals, Her Majesty may, by Order in Council, direct that this Act shall apply in the case of such foreign state," subject to any limitations, conditions, or restrictions that may be thought expedient. It is expressly provided—

1. That a fugitive criminal shall not be surrendered for a political offence, or if he prove that his surrender has in fact been required with a view of trying him for a political offence.
2. Provision must be made that a surrendered criminal shall not be tried for any but the extradition crime.
3. Criminals accused or convicted of offences in England shall not be surrendered in extradition until they are discharged.
4. There must be an interval of 15 days between the committal to prison and the surrender.

An Order in Council under the Act must be in conformity with its provisions, and must provide for the determination of the arrangement after not more than a year's notice.

When the Act applies, a fugitive criminal of a foreign state is liable to surrender. A requisition for that purpose must be addressed to a secretary of state by some person recognized as a diplomatic representative of the foreign state. The secretary of state, unless he thinks the offence is one of a political character, may inform a police magistrate of the requisition, and require him to issue his warrant for the apprehension of the criminal. The police magistrate, when the criminal is brought before him, shall receive any evidence tending to show that the offence is political, or is not an extradition crime. If the evidence is such as would justify a committal for trial in England, or would prove that the prisoner has been convicted, the magistrate commits him to prison, and after fifteen days' interval, or if a *habeas corpus* is issued after the decision of the court, the secretary of state may by his warrant deliver him over to the representatives of the foreign country. If the prisoner is not removed within two months he must be discharged. The Act applies, with certain modifications, to all British possessions.

"Fugitive criminal" means any person accused or convicted of an extradition crime committed within the jurisdiction of any foreign state, who is in, or is suspected of being in, any portion of Her Majesty's dominions. The following is a list of extradition crimes, to be construed according to the law existing in England:—

Murder and attempt and conspiring to murder; manslaughter; counterfeiting or altering money, and uttering; forgery, counterfeiting, and altering what is forged, &c.; embezzlement and larceny, obtaining money and goods by false pretences; bankruptcy crime, fraud by bailee, banker, agent, &c.; rape; abduction; child-stealing; burglary and housebreaking; arson; robbery with violence; threats by letter or otherwise, with intent to extort; piracy by law of nations; sinking or destroying a vessel at sea, or attempting or conspiring to do so; assaults on board ship on the high seas, with intent to destroy life or to do grievous bodily harm; revolt or conspiracy to revolt by two or more persons on board a ship on the high seas against the authority of the master. The Extradition Act of 1873 adds the following:—Kidnapping and false imprisonment; perjury and subornation of perjury; and indictable offences, not previously named, under the Larceny and other Criminal Acts of 1861 (24 and 25 Vict. c. 96, 97, 98, 99, 100, 101).

The countries with which England has entered into extradition treaties are the following:—Austria, 3d December 1873; Belgium, 30th May 1876; Brazil, 13th November 1872; Denmark, 31st March 1873; France, 13th February 1843; Germany, 14th May 1872; Hayti, 7th December 1874; Honduras, 6th January 1874; Italy, 5th February and 7th May 1873; Netherlands, 10th June 1874; Sweden and Norway, 26th June 1873; Switzerland, 31st March 1874; United States, 9th August 1842 (Abdy's edition of Kent's *International Law*, Cambridge, 1878). The treaties with France and the United States, it will be noticed, are those which were in force before the English Extradition Acts. Difficulties have arisen between this country and the United States as to the effect of the Extradition Act on the subsisting treaty. In 1875 the English Government protested against the trial for a second offence of a criminal who had been surrendered to the United States. The United States Government maintained that the principle of the English Extradition Act (that the surrendered criminal shall not be tried for any offence committed prior to his surrender other than the extradition crime) did not apply to the treaty of 1842, that this treaty could not be newly construed at the will of one of the parties, and that the claim of the English Government made it impossible for the United States to ask or grant extradition under it. The English Government have in the meantime surrendered three fugitive criminals without insisting on their claim. A royal commission on the Extradition Acts is now sitting (1878).

See *A Treatise on the Law of Extradition*, by Edward Clark, barrister-at-law, 2d edition, London, 1874. (E. R.)

EXTREME UNCTION, one of the seven sacraments of the Romish Church, now to be administered only after those of penance and the Eucharist to persons who are supposed to be at the point of death. Among the Orientals oil has long been employed as a cure for various disorders, as well as for the purpose of promoting the general health of the body. According to the narrative of Mark, it was employed by the disciples of Jesus apparently for the purpose of effecting miraculous cures (Mark vi. 13). The apostle James also exhorts Christians to make use of it, accompanied with prayer, in the case of sick persons. "Is any sick among you, let him call for the elders of the church; and let them pray over him, anointing him with oil in the name of the Lord; and the prayer of faith shall save the sick, and the Lord shall raise him up; and if he have committed sins, they shall be forgiven him" (James v. 14, 15). Unction is not referred to by any of the fathers as a sacrament, but Origen, in his second homily on Lev. iv., implies that in his time it was conjoined with the imposition of hands in the restoration of the lapsed; and Irenæus (i. 21, 5) states that among some of the Gnostics it was common to anoint the dying with a mixture of oil or opobalsam and water, to render their souls invisible to their spiritual enemies in the other world, and proof against their machinations. There is evidence that among the Christians of the 4th century a superstitious efficacy was ascribed to the use of oil in cases of sickness, and instances are recorded in which the oil used in the lamps of the churches was stolen in order to be applied in sickness, or to ward off attacks of disease. The first proof of the use of the rite in the Roman Church is contained in a letter of Innocent I. to Decentius, bishop of Eugubium (Gubbio), in the year 416, in which he speaks of it as "a kind of sacrament;" but he adds that after the oil has been blessed by the bishop, it may be used, not merely by the bishops and priests, but by Christians generally. From the 8th century the rite is often mentioned in the acts of the councils, and has been the occasion of a considerable amount of discussion and difference of opinion, at least in regard to details. In 850 it was declared by the synod of Regiaticinum (Pavia) to be a sacrament by which sins were forgiven, and consequently bodily health restored, but its chief purpose was represented to be the restoration of the sick person. In the 12th century the question whether the rite could be repeated was raised, and began to be answered in the negative; and an attempt was made by some to obtain a decision that the person to whom it had been administered should not afterwards touch the earth with his bare feet, nor indulge in any of the pleasures of the flesh; and although these proposals were not carried, the general result of the discussions was to deepen the impression that it was a rite of unusual solemnity, to which recourse should not be had except in cases of great necessity. About this time the rite came to be known as *sacramentum exeuntium* or *extrema unctio*. By Peter the Lombard it was placed fifth in the list of the seven sacraments, and its spiritual significance was further developed by the scholastic theologians, especially by Thomas Aquinas. According to him, its principal end was the removal of the spiritual weakness resulting from the sins of the past life, and the healing of the body was only its secondary end; but among other theologians of his time discussions as to the purpose of the rite were the cause of considerable difference of opinion. It was, however, regarded by most as having only a relative necessity, its omission not entailing any positive spiritual evil. According to the decrees of the Council of Trent, it confers the pardon of any faults that may previously have been unexpiated, and it removes the remains of sin; it relieves and strengthens the soul, and enables it better to bear up under pain, and more successfully to withstand the assaults of the devil—bodily ease and health following so far as these are advantageous to the soul's welfare. As to its repetition the council contented itself with declaring that it might be repeated in cases of similar peril. According to the Romish catechism, two ends are obtained by its observance,—1st, the pardon of venial sins, it not possessing the highest efficacy in regard to mortal sins; 2d, the removal of the spiritual infirmity resulting from sin, and of all the other remains of sin. For the observance of the rite the Romish Church appeals to the authority of Christ, as implied in Mark vi. 13, and to the authority of the apostles, as implied in James v. 14, 15. The Council of Trent has decreed extreme unction to be a sacrament, and declares that "whosoever shall affirm that extreme unction is not truly and properly a sacrament, instituted by Christ our Lord, and published by the blessed apostle James, but only a ceremony received from the fathers, or a human invention, is to be accursed." And it denounces a similar anathema against all who "shall affirm that the sacred unction of the sick does not confer grace, nor forgive sin, nor relieve the sick, but that its power has ceased, as if the gift of healing existed only in past ages." The ceremony is performed in the following way. When a person's recovery is despaired of, his eyes, ears, nostrils, mouth, hands, feet, and reins are successively anointed with the sacred oil by the priest. At each anointing the priest says, "By this holy unction, and through His great mercy, Almighty God forgive thee whatever sins thou hast committed by sight" (or smell, hearing, touch, &c.). The oil used in extreme unction is supposed to represent the grace of God poured down into the soul, and conferring pardon and spiritual strength. It is blessed by the bishop on Maundy Thursday, and delivered to the parochial clergy to be used by them throughout the year. If any oil is left after the expiry of the year it is burned, and if the supply threatens to become exhausted, other oil may be added to that which has been consecrated, but only a small proportion of new oil is permitted. In the Greek church the rite is called ’Ευχέλαιον, or ῞Αγιον ἔλαιον. The oil is not consecrated by the bishop, but is taken out of the sanctuary lamps as required and blessed by seven priests, or, if that number cannot be gathered together, by not less than three. The rite is administered in diseases of all kinds; and such sick persons as are able are expected to visit the church, especially on Maundy Thursday, to experience its bodily and spiritual blessings. Only in extreme cases does the anointing take place in the sick chamber.

EYCK, Van, the name of a family of painters in whose works the rise and mature development of art in western Flanders are represented. Though bred in the valley of the Meuse, they finally established their professional domicile in Ghent and in Bruges; and there, by skill and inventive genius, they changed the traditional habits of the earlier schools, remodelled the primitive forms of Flemish design, and introduced a complete revolution into the technical methods of execution familiar to their countrymen.

1. **Hubert Van Eyck** was the oldest and most remarkable of this race of artists. The date of his birth and the records of his progress are lost amidst the ruins of the earlier civilization of the valley of the Meuse. He was born about 1366, at Maeseyck, under the shelter or protection of a Benedictine convent, in which art and letters had been cultivated from the beginning of the 8th century. But after a long series of wars,—when the country became insecure, and the schools which had flourished in the towns decayed,—he wandered to Flanders, and there for the first time gained a name. As court painter to the hereditary prince of Burgundy, and as client to one of the richest of the Ghent patricians, Hubert is celebrated. Here, in middle age, between 1410 and 1420, he signalized himself as the inventor of a new method of painting. Here he lived in the pay of Philip of Charolais till 1421. Here he painted pictures for the corporation, whose chief magistrates honoured him with a state visit in 1424. His principal masterpiece, and the only picture that can be traced to his

hand, the Worship of the Lamb, commissioned by Jodocus Vijdts, lord of Pamele, is the noblest creation of the Flemish school, a piece of which we possess all the parts dispersed from St Bavon in Ghent to the galleries of Brussels and Berlin,—one upon which Hubert laboured till he died, leaving it to be completed by his brother. Almost unique as an illustration of contemporary feeling for Christian art, this great composition can only be matched by the Fount of Salvation, in the museum of Madrid. It represents, on numerous panels, Christ on the judgment seat, with the Virgin and St John the Baptist at His sides, hearing the songs of angels, and contemplated by Adam and Eve, and, beneath him, the Lamb shedding His blood in the presence of angels, apostles, prophets, martyrs, knights, and hermits. On the outer sides of the panels are the Virgin and the angel annunciate, the sibyls and prophets who foretold the coming of the Lord, and the donors in prayer at the feet of the Baptist and Evangelist. After this great work was finished it was placed, in 1432, on an altar in St Bavon of Ghent, with an inscription on the framework describing Hubert as "*maior quo nemo repertus*," and setting forth, in colours as imperishable as the picture itself, that Hubert began and John afterwards brought it to perfection. John Van Eyck certainly wished to guard against an error which ill-informed posterity showed itself but too prone to foster, the error that he alone had composed and carried out an altarpiece executed jointly by Hubert and himself. His contemporaries may be credited with full knowledge of the truth in this respect, and the facts were equally well known to the duke of Burgundy or the chiefs of the corporation of Bruges, who visited the painter's house in state in 1432, and the members of the chamber of rhetoric at Ghent, who reproduced the Agnus Dei as a *tableau vivant* in 1456. Yet a later generation of Flemings forgot the claims of Hubert, and gave the honours that were his due to his brother John exclusively.

The solemn grandeur of church art in the 15th century never found, out of Italy, a nobler exponent than Hubert Van Eyck. His representation of Christ as the judge, between the Virgin and St John, affords a fine display of realistic truth, combined with pure drawing and gorgeous colour, and a happy union of earnestness and simplicity with the deepest religious feeling. In contrast with earlier productions of the Flemish school, it shows a singular depth of tone and great richness of detail. Finished with surprising skill, it is executed with the new oil medium, of which Hubert shared the invention with his brother, but of which no rival artists at the time possessed the secret,—a medium which consists of subtle mixtures of oil and varnish applied to the moistening of pigments after a fashion, only kept secret for a time from guildsmen of neighbouring cities, but unrevealed to the Italians till near the close of the 15th century. When Hubert died on the 18th September 1426, he was buried in the chapel on the altar of which his masterpiece was placed. According to a tradition as old as the 16th century, his arm was preserved as a relic in a casket above the portal of St Bavon of Ghent. During a life of much apparent activity and surprising successes, he taught the elements of his art to his brother John, who survived him.

2. John Van Eyck. The date of his birth is not more accurately known than that of his elder brother, but he was born much later than Hubert, who took charge of him and made him his "disciple." Under this tuition John learnt to draw and paint, and mastered the properties of colours from Pliny. Later on, Hubert admitted him into partnership, and both were made court painters to Philip of Charolais. After the breaking up of the prince's household in 1421, John became his own master, left the workshop of Hubert, and took an engagement as painter to John of Bavaria, at that time resident at the Hague as count of Holland. From the Hague he returned in 1424 to take service with Philip, now duke of Burgundy, at a salary of 100 livres per annum, and from that time till his death John Van Eyck remained the faithful servant of his prince, who never treated him otherwise than graciously. He was frequently employed in missions of trust; and following the fortunes of a chief who was always in the saddle, he appears for a time to have been in ceaseless motion, receiving extra pay for secret services at Leyden, drawing his salary at Bruges, yet settled in a fixed abode at Lille. In 1428 he joined the embassy sent by Philip the Good to Lisbon to beg the hand of Isabella of Portugal. His portrait of the bride fixed the duke's choice. After his return he settled finally at Bruges, where he married, and his wife bore him a daughter, known in after years as a nun in the convent of Maeseyck. At the christening of this child the duke was sponsor, and this was but one of many distinctions by which Philip the Good rewarded his painter's merits. Numerous altarpieces and portraits now give proof of Van Eyck's extensive practice. As finished works of art and models of conscientious labour they are all worthy of the name they bear, though not of equal excellence, none being better than those which were completed about 1432. Of an earlier period, a Consecration of Thomas à Becket has been preserved, and may now be seen at Chatsworth, bearing the date of 1421; no doubt this picture would give a fair representation of Van Eyck's talents at the moment when he started as an independent master, but that time and accidents of omission and commission have altered its state to such an extent that no conclusive opinion can be formed respecting it. The panels of the Worship of the Lamb were completed nine years later They show that John Van Eyck was quite able to work in the spirit of his brother. He had not only the lines of Hubert's compositions to guide him, he had also those parts to look at and to study which Hubert had finished. He continued the work with almost as much vigour as his master. His own experience had been increased by travel, and he had seen the finest varieties of landscape in Portugal and the Spanish provinces. This enabled him to transfer to his pictures the charming scenery of lands more sunny than those of Flanders, and this he did with accuracy and not without poetic feeling. We may ascribe much of the success which attended his efforts to complete the altarpiece of Ghent to the cleverness with which he reproduced the varied aspect of changing scenery, reminiscent here of the orange groves of Cintra, there of the bluffs and crags of his native valley. In all these backgrounds, though we miss the scientific rules of perspective with which the Van Eycks were not familiar, we find such delicate perceptions of gradations in tone, such atmosphere, yet such minuteness and perfection of finish, that our admiration never flags. Nor is the colour less brilliant or the touch less firm than in Hubert's panels. John only differs from his brother in being less masculine and less sternly religious. He excels in two splendid likenesses of Jodocus Vijdts and his wife Catherine Burluuts. The same vigorous style and coloured key of harmony characterizes the small Virgin and Child of 1432 at Ince, and the Madonna, probably of the same date, at the Louvre, executed for Rollin, chancellor of Burgundy. Contemporary with these, the male portraits in the National Gallery, and the Man with the Pinks, in the Berlin Museum (1432–4), show no relaxation of power; but later creations display no further progress, unless we accept as progress a more searching delicacy of finish, counterbalanced by an excessive softness of rounding in flesh contours. An unfaltering minuteness of hand and great tenderness of treatment may be

found, combined with angularity of drapery, and some awkwardness of attitude, in a full length portrait couple at the National Gallery (1434), in which a rare insight into the detail of animal nature is revealed in a study of a terrier dog. A Madonna with Saints, at Dresden, equally soft and minute, charms us by the mastery with which an architectural background is put in. The bold and energetic striving of earlier days, the strong bright tone, are not equalled by the soft blending and tender tints of the later ones. Sometimes a crude ruddiness in flesh strikes us as a growing defect, an instance of which is the picture in the museum of Bruges, in which Canon Van der Paelen is represented kneeling before the Virgin under the protection of St George (1434). From first to last Van Eyck retains his ability in portrait. Fine specimens are the two male likenesses in the gallery of Vienna (1436), and a female, the master's wife, in the gallery of Bruges (1439). His death in 1440-41 at Bruges is authentically recorded. He was buried in St Donat. Like many great artists he formed but few pupils. Hubert's disciple, Jodocus of Ghent, hardly does honour to his master's teaching, and only acquires importance after he has thrown off some of the peculiarities of Flemish teaching. Petrus Cristus, who was taught by John, remains immeasurably behind him in every thing that relates to art. But if the personal influence of the Van Eycks was small, that of their works was immense, and it is not too much to say that their example, taken in conjunction with that of Van der Weyden, determined the current and practice of painting throughout the whole of Europe north of the Alps for nearly a century. (J. A. C.)

EYE

THE sense of vision is excited by the influence of light on the retina, the special terminal organ connected with the optic nerve. By excitation of the retina, a change is induced in the optic nerve fibres, and is conveyed by these to the brain, the result being a luminous perception, or what we call a sensation of light or colour. If light were to act uniformly over the retina, there would be no image of the source of the light formed on that structure, and consequently there would be only a general consciousness of light, without reference to any particular object. One of the first conditions, therefore, of vision for useful purposes is the formation of an image on the retina. To effect this, just as in a photographic camera, refractive structures must be placed in front of the retina which will so bend luminous rays as to bring them to a focus on the retina, and thus produce an image. Throughout the animal kingdom, various arrangements are found for this purpose; but they may be all referred to three types, namely—(1) eye-specks or eye-dots, met with in Medusæ, Annelidæ, &c.; (2) the compound eye, as found in insects and crustaceans; and (3) the simple eye, common to all vertebrates. The *eye-specks* may be regarded simply as expansions of optic nerve filaments, covered by a transparent membrane, but having no refractive media, so that the creature would have the consciousness of light only, or a simple luminous impression, by which it might distinguish light from darkness. The *compound eye* (an account of which, as met with in the common lobster, will be found under CRUSTACEA, vol. vi. p. 637) consists essentially of a series of transparent cone-like bodies, arranged in a radiate manner against the inner surface of the cornea, with which their bases are united, while their apices are connected with the ends of the optic filaments. As each cone is separated from its neighbours, it admits only a ray of light parallel with its axis, and its apex represents only a portion of the image, which must be made up, like a mosaic-work, of as many parts as there are cones in the eye. When the cones are of considerable length, it is evident, from their form and direction, their apices being directed inwards, that the oblique rays emanating from a luminous surface will be cut off, and that only those rays proceeding along the axis of the cone will produce an effect. Thus distinctness or sharpness of definition will be secured. The size of the visual field will depend on the form of the eye, the outermost cones marking its limits. Consequently the size of the visual field will depend on the size of the segment of the sphere forming its surface. The eyes of many insects have a field of about half a sphere, so that the creature will see objects before and behind it as well as those at the side. On the other hand, in many the eyes have scarcely any convexity, so that they must have a narrow field of vision.

A description of the simple eye will be found in the article ANATOMY, vol. i. p. 885 *sq.* Optically, it consists of a series of refractive media placed in front of the retina by which rays emanating from an external object are brought to a focus on that structure. In this article, we shall consider (1) the physical causes of vision; (2) the optical arrangements of the eye; (3) the specific influence of light on the retina; (4) sensations of colour; (5) the movements of the eyes in vision; and (6) the psychical relations of luminous impressions.

1. PHYSICAL CAUSES OF VISION.

A luminous sensation may be excited by various modes of irritation of the retina or of the optic nerve. Pressure, cutting, or electrical shocks may act as stimuli, but the normal excitation is the influence of light on the retina. From a physical point of view, light is a mode of movement occurring in a medium, termed the ether, which pervades all space; but the physiologist studies the operation of these movements on the sentient organism as resulting in consciousness of the particular kind which we term a luminous impression. Outside of the body, such movements have been studied with great accuracy; but the physiological effects depend upon such complex conditions as to make it impossible to state them in the same precise way. Thus, when we look at the spectrum, we are conscious of the sensations of red and violet, referable to its two extremities: the physicist states that red is produced by 392 billions of impulses on the retina per second, and that violet corresponds to 757 billions per second; but he has arrived at this information by inductive reasoning from many facts which have not at present any physiological explanation. We cannot at present trace any connexion, as cause and effect, between 392 billions of impulses on the retina per second and a sensation of red. Below the red and above the violet ends of the spectrum there are vibrations which do not excite luminous sensations. In the first case, below the red, the effect as a sensation is heat; and above the violet the result is that of chemical activity. Thus the method of dispersion of light, as is followed in passing a ray through a prism, enables us to recognize these general facts:—(1) rays below the red excite thermal impressions; (2) from the lower red up to the middle of the violet, the thermal rays become gradually weaker until they have no effect; (3) from the lower red to the extreme violet, they cause luminous impressions, which reach their greatest intensity in the yellow; and (4) from about the end of the yellow to far beyond the extreme violet, the rays have gradually a less and less luminous effect, but they have the power of exciting such chemical changes as are produced in photography. In general terms, therefore, the lower end of the spectrum may be called thermal, the middle luminous, and the upper actinic or chemical; but the three merge into and overlap one another. It may be observed that the number of vibrations in the extreme violet is not double that of the low red, so that the sensibility of the eye to vibrations of light does not range through an octave. The ultra violet rays may act on the retina in certain conditions, as when they are reflected by a solution of sulphate of quinine, constituting the phenomenon of fluorescence.

2. Optical Arrangements of the Eye.

(1) *General* —When light traverses any homogeneous transparent medium, such as the air, it passes on in a straight course with a certain velocity; but if it meet with any other transparent body of a different density, part of it is reflected or returned to the first medium, whilst the remainder is propagated through the second medium in a different direction and with a different velocity. Thus we may account for the phenomena of reflection and of refraction, for which see the article Light. Let *a b*, in fig. 1, be a plane surface of some transparent substance, say a sheet of glass; a ray, *c d*, perpendicular to the surface, will pass through without refraction; but an oblique ray, *e f*, will be sent in the direction *e h*. If the ray *e h* had passed from a dense into a rarer medium, then the direction would have been *e g*. It might also be shown that the *sine* of the angle of incidence always bears a certain ratio to the *sine* of the angle of refraction; this ratio is termed the *index of refraction*. Thus, if a ray pass from air into water, the sine of the angle of incidence will have to the sine of the angle of the refraction the ratio of 4 · 3, or $\frac{4}{3}$.

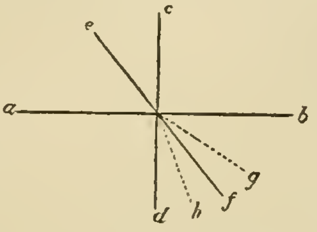


Fig. 1.—Refraction of Light.

Before a ray of light can reach the retina, it must pass through a number of transparent and refractive surfaces. The eye is a nearly spherical organ, formed of transparent parts situated behind each other, and surrounded by various membranous structures, the anterior part of which is also transparent. The transparent parts are—(1) the *cornea*; (2) the *aqueous humour*, found in the anterior chamber of the eye; (3) the *crystalline lens*, formed by a transparent convex body, the anterior surface of which is less convex than the posterior; and (4) the *vitreous humour*, filling the posterior chamber of the eye. The ray must therefore traverse the cornea, aqueous humour, lens, and vitreous humour. As the two surfaces of the cornea are parallel, the rays practically suffer no deviation in passing through that structure, but they are bent or refracted during their transmission through the other media.

From the optical point of view, the eye may be regarded as a *dioptric system* consisting of various refractive media. In such a system, as shown by Gauss, there are six cardinal points, which have a certain relation to each other. These are—

Two focal points · every ray passing through the *first* focal point becomes, after its refraction, parallel to the axis, and every ray which before refraction is parallel to the axis passes after its refraction to the *second* focal point; (2) *Two principal points:* every ray which passes through the first point before refraction passes after refraction through the second, and every ray which passes through any point of a plane elevated on a perpendicular axis from the first principal point (the *first principal plane*) passes through the corresponding point of on analogous plane raised upon the axis at the second principal point (the *second principal plane*); and (3) *Two nodal points*, which correspond to the optical centres of the two principal planes just alluded to. The distance of the first principal point from the first focal point is called the *anterior focal length*, and the term *posterior focal length* is applied to the distance of the posterior focal point from the second principal point. Listing has given the following measurements in millimetres from the centre of the cornea for the cardinal points in an ideal eye.—

Anterior focal point......	12 8326.	First nodal point.....	7 2420.
Posterior focal point......	22 6470.	Second nodal point	7 6398.
First principal point......	2 1746	Anterior focal length.....	15 0072.
Second principal point...	2 5724.	Posterior focal length....	20 0746.

A view of such an ideal eye is shown in fig. 2.

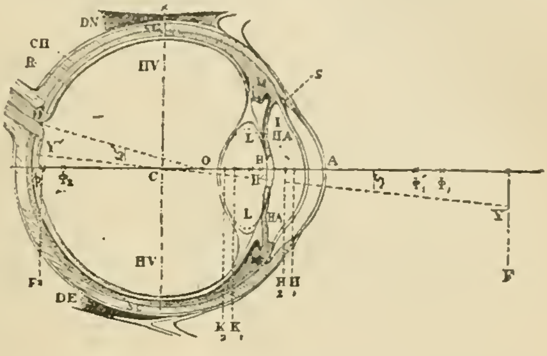

Fig. 2.—Transverse section of an Ideal or Schematique Eye.

A, Summit of cornea. SC, Sclerotic: S, Schlemm's canal; CH, Choroid; I, Iris; M, Ciliary muscle; R, Retina; N, Optic nerve; HA, Aqueous humour; L, Crystaline lens, the anterior of the double lines on its face showing its form during accommodation; HV, Vitreous humour; DN, Internal rectus muscle; DE, External rectus; YY', Principal optical axis; ΦΦ, Visual axis, making an angle of 5° with the optical axis, C, Centre of the ocular globe. *The cardinal points of Listing*—H_1H_2, principal points; K_1K_2, nodal points; F_1F_2, principal focal points. *The dioptric constants according to Giraud-Teulon*:—H, Principal points united, $\phi_1\phi_2$ principal foci during the repose of accommodation; $\phi'_1\phi'_2$, principal foci during the maximum of accommodation; O, fused nodal points.

The remaining measurements of such an eye are as follows —

Radii of curvature.

Of *anterior* face of cornea = 8 millimetres.
Of *anterior* face of lens = 10 ,,
Of *posterior* face of lens = 6 ,,

Indices of Refraction.

Aqueous humour	$\frac{103}{77}$	= 1 ·3379
Crystalline lens	$\frac{16}{11}$	= 1 4545
Vitreous humour.	$\frac{103}{77}$	= 1 3379

The optical constants of the human eye may be still further simplified by assuming that the two principal points and the two nodal points respectively are identical. Thus we may construct a *reduced eye*, in which the principal point is 2·3448 mm. behind the cornea, and the nodal point is 7·4969 mm., having an anterior focal length of 15 mm. and a posterior focal length of 20 mm. The refracting surface, or lens, has a radius of 5 mm., and is 3 mm. behind the cornea; and the index of refraction is that of the aqueous humour, or $\frac{103}{77}$.

(2.) *The Formation of an Image on the Retina.*—This may be well illustrated with the aid of an ordinary photographic camera. If properly focussed, an inverted image will be seen on the glass plate at the back of the camera. It may also be observed by bringing the eye-ball of a rabbit near a candle flame. The action of a lens in forming an inverted image is illustrated by fig. 3, where the pencil of rays proceeding from *a* is brought to a focus at *a'*, and those from *b* at *b'*, consequently the image of *a b* is inverted as at *b'a'*. The three characteristic features of the retinal image

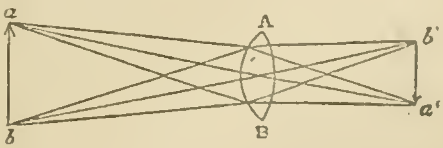

Fig. 3.—Inversion by action of a Lens.

are—(1) it is reversed ; (2) it is sharp and well defined if it be accurately focussed on the retina ; and (3) its size depends on the visual angle. If we look at a distant object, say a star, the rays reaching the eye are parallel, and in passing through the refractive media, they are focussed at the posterior focal point,—that is, on the retina. A line from the luminous point on the retina passing through the nodal point is called the *line of direction.* If the luminous object be not nearer than, say, 60 yards, the image is still brought to a focus on the retina without any effort on the part of the eye. Within this distance, supposing the condition of the eye to be the same as in looking at a star, the image would be formed somewhat behind the posterior focal point, and the effect would be an indistinct impression on the retina. To obviate this, for near distances, accommodation, so as to adapt the eye, is effected by a mechanism to be afterwards described.

When rays, reflected from an object or coming from a luminous point, are not brought to an accurate focus on the retina, the image is not distinct in consequence of the formation of what are called *circles of diffusion,* the production of which will be rendered evident by fig. 4. From the point A luminous rays enter the eye in the form of a cone, the kind of which will depend on the pupil. Thus it may be circular, or oval, or even triangular. If the pencil is focussed in front of the retina, as at *d*, or behind it as at *f*, or, in other words, if the retina, in place of being at F, be in the positions G or H, there will be a luminous circle or a luminous triangular space, and many elements of the retina will be affected. The size of these diffusion circles depends on the distance from the retina of the point where the rays are focussed : the greater the distance, the more extended will be the diffusion circle. Its size will also be affected by the greater or less diameter of the pupil. Circles of diffusion may be readily studied by the following experiment, usually called the experiment of Scheiner :—

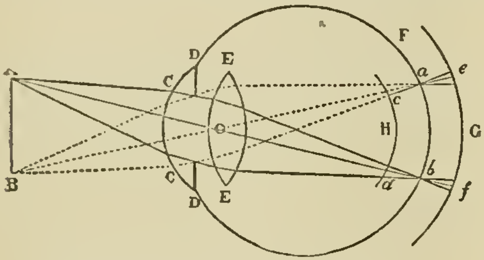

FIG. 4.—Formation of Circles of Diffusion.

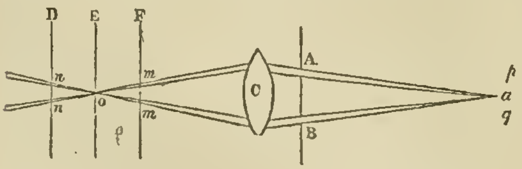

FIG. 5.—Diagram illustrating the experiment of Scheiner.

Let C be a lens, and D E F be screens placed behind it ; hold in front of the lens a card perforated by two holes A and B, and allow rays from a luminous point *a* to pass through these holes; the point *o* on the screen E will be exact focus of the rays emanating from *a* ; if *a* were removed farther from the lens, the focus would be on F, and if it were brought near to C, the focus would then be on D. The screens F and D show two images of the point *a*. If, then, we close the upper opening in A B, the *upper* image *m* on F, and the *lower* image *n* on D, disappear. Suppose now that the retina be substituted for the screens D and F, the contrary will take place, in consequence of the reversal of the retinal image. If the eye be placed at *o*, only one image will be seen; but if it be placed either in the plane of F or D, then two images will be seen, as at *m m*, or *n n*; consequently in either of these planes there will be circles of diffusion and indistinctness, and only in the plane E will there be sharp definition of the image

To understand the formation of an image on the retina, suppose a line drawn from each of its two extremities to the nodal point and continued onwards to the retina, as in fig. 6, where the visual angle is *x*. It is evident that its size will depend on the size of the object and the distance of the object from the eye. Thus, also, objects of different sizes, *c*, *d*, *e*, in fig. 6, may be included in the same visual angle, as they are at different distances from the eye. The size of the retinal image may obviously be calculated if we know the size of the object, its distance from the nodal point *o*, and the distance of the nodal point from the posterior focus. Let A be the size of the object, B its distance from the nodal point, and C the distance of *o* from the retina, or 15 mm. ; then the size of the retinal image $x=\frac{A+15}{B}$. The smallest visual angle in which two distinct points may be observed is 60 seconds ; below this, the two sensations fuse into one ; and the size of the retinal image corresponding to this angle is ·004 mm., nearly the diameter of a single retinal rod or cone. Two objects, therefore, included in a visual angle of less than 60 seconds, appear as one point. A small visual angle is in most eyes a condition of sharpness of definition. With a large angle, objects appear less sharply marked. Acuteness is determined by a few retinal elements, or even only one, being affected. A very minute image, if thrown on a single retinal element, is apparently sufficient to excite it. Thus it is possible to see a brilliant point in an angle even so small as $\frac{1}{4}$ of a second, and a sharp eye can see a body the $\frac{1}{50}$th of a line in diameter, that is, about the $\frac{1}{600}$th part of an inch.

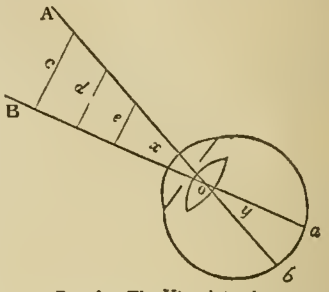

FIG. 6.—The Visual Angle.

(3.) *The Optical Defects of the Eye.*—As an optical instrument, the eye is defective ; but from habit, and want of attention, its defects are not appreciated, and consequently they have little or no influence on our sensations. These defects are chiefly of two kinds—(1) those due to the curvature of the refractive surfaces, and (2) those due to the dispersion of light by the refractive media.

(*a*) *Aberration of Sphericity.*—Suppose, as in fig. 7, M A K to be a refractive surface on which parallel rays from L to S impinge, it will be seen that those rays passing near the circumference are brought to a focus at F^1, and those passing near the centre at F^2,—intermediate rays being focussed at N. Thus on the portion of the axis between F^1 and F^2 there will be a series of focal points, and the effect will be a blurred and bent image. In the eye this defect is to a large extent corrected by the following arrangements :—(1) the iris cuts off the outer and more strongly refracted rays ; (2) the curvature of the cornea is more ellipsoidal than spherical, and consequently those farthest from the axis are least deviated ; (3) the anterior and pos-

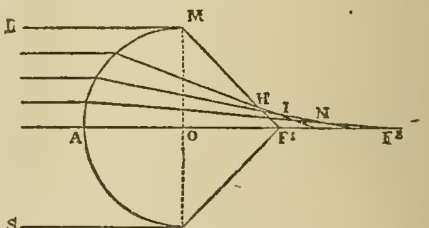

FIG. 7.—Spherical Aberration.

to a certain extent, the action of the other; and (4) the structure of the lens is such that its power of refraction diminishes from the centre to the circumference, and consequently the rays farthest from the axis are less refracted.

(*b*) *Astigmatism.*—Another defect of the eye is due to different meridians having different degrees of curvature. This defect is known as *astigmatism.* It may be thus detected. Draw on a sheet of white paper a vertical and a horizontal line with ink, crossing at a right angle; at the point of distinct vision, it will be found impossible to see the lines with equal distinctness at the same time: to see the horizontal line distinctly the paper must be brought near the eye, and removed from it to see the vertical. In the cornea the vertical meridian has a shorter radius of curvature, and is consequently more refractive than the horizontal. The meridians of the lens may also vary; but, as a rule, the asymmetry of the cornea is greater than that of the lens. The optical explanation of the defect will be understood with the aid of fig. 8.

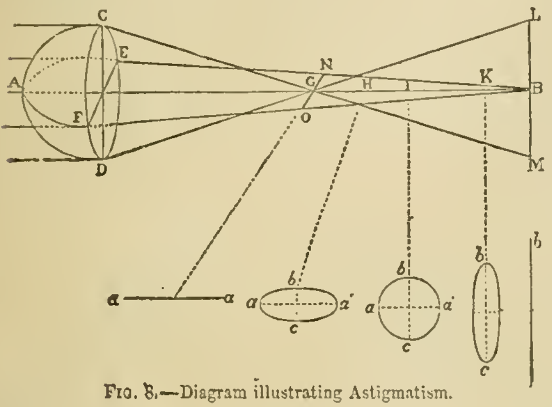

FIG. 8.—Diagram illustrating Astigmatism.

Thus, suppose the vertical meridian C A D to be more strongly curved than the horizontal F A E, the rays which fall on C A D will be brought to a focus G, and those falling on F A E at B. If we divide the pencil of rays at successive points, G, H, I, K, B, by a section perpendicular to A B, the various forms it would present at these points are seen in the figures underneath, so that if the eye were placed at G, it would see a horizontal line *a a'*; if at H, an ellipse with the long axis *a a'* parallel to A B; if at I, a circle; if at K, an ellipse, with the long axis, *b c*, at right angles to A B; and if at B, a vertical line *b c*. The degree of astigmatism is ascertained by measuring the difference of refraction in the two chief meridians; and the defect is corrected by the use of cylindrical glasses, the curvature of which, added to that of the minimum meridian, makes its focal length equal to that of the maximum meridian.

(*c*) *Aberration of Refrangibility.*—When a ray of white light traverses on a lens, the different rays composing it, being unequally refrangible, are dispersed: the violet rays (see fig. 9), the most refrangible, are brought to a focus at *e*, and the red rays, less refrangible, at *d*. If a screen were placed at *e*, a series of concentric coloured circles would be formed, the central being of a violet, and the circumference of a red colour. The reverse effect would be produced if the screen were placed at *d*. Imagine the retina in place of the screen in the two positions, the sensational effects would be those just mentioned. Under ordinary circumstances, the error of refrangibility due to the optical construction of the eye is not observed, as for vision at near distances the interval between the focal point of the red and violet rays is very small. If, however, we look at a candle flame through a bit of cobalt blue glass, which transmits only the red and blue rays, the flame may appear violet surrounded by blue, or blue surrounded by violet, according as we have accommodated the eye for different distances. Red surfaces always appear nearer than violet surfaces situated in the same plane, because the eye has to be accommodated more for the red than for the violet, and consequently we imagine them to be nearer. Again, if we contemplate red letters or designs on a violet ground the eye soon becomes fatigued, and the designs may appear to move.

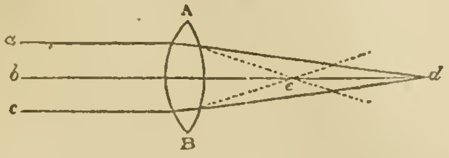

FIG. 9.—Diagram illustrating the Dispersion of Light by a Lens.

(*d*) *Defects due to Opacities, &c., in the Transparent Media.*—When small opaque particles exist in the transparent media, they may cast their shadow on the retina so as to give rise to images which are projected outwards by the mind into space, and thus appear to exist outside of the body. Such phenomena are termed entoptic. They may be of two kinds:—(1) *extra-retinal*, that is, due to opaque or semi-transparent bodies in any of the refractive structures anterior to the retina, and presenting the appearance of drops, striæ, lines, twisted bodies, forms of grotesque shape, or minute black dots dancing before the eye; and (2) *intra-retinal*, due to opacities, &c., in the layers of the retina, in front of Jacob's membrane. The intra-retinal may be produced in a normal eye in various ways. (1) Throw a strong beam of light on the edge of the sclerotic, and a curious branched figure will be seen, which is an image of the retinal vessels. The construction of these images, usually called *Purkinje's figures,* will be understood from fig. 10. Thus, in the figure to the left, the rays passing through the sclerotic at *b,"* in the direction *b"c*, will throw a shadow of a vessel at *c* on the retina at *b'*, and this will appear as a dark line at B. If the light move from *b"* to *a"*, the retinal shadow will move from *b'* to *a'*, and the line in the field of vision will pass from B to A. It may be shown that the distance *c b'* corresponds to the distance of the retinal vessels from the layer of rods and cones (see ANATOMY, vol. i. p. 888). If the light enter the cornea, as in the figure to the right, and if the light be moved, the image will be displaced in the same direction as the light, if the movement does not extend beyond the middle of the cornea, but in the opposite direction to the light when the latter is moved up and down. Thus, if *a* be moved to *a'*, *d* will be moved to *d'*, the shadow on the retina from *c* to *c'*, and the image *b* to *b'*. If, on the other hand, *a* be

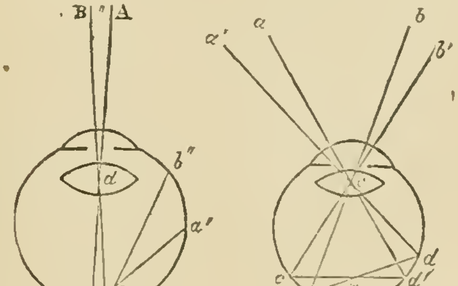

FIG. 10.—Purkinje's Figures.

In the eye to the right the illumination is through the sclerotic, and in the one to the left through the cornea.

moved above the plane of the paper, *d* will move below, consequently *c* will move above, and *b′* will appear to sink (2) The retinal vessels may also be seen by looking at a strong light through a minute aperture, in front of which a rapid to and fro movement is made. Such experiments prove that the sensitive part of the retina is its deepest and most external layer (Jacob's membrane).

(4.) *Accommodation, or the Mechanism of Adjustment for Different Distances.*—When a camera is placed in front of an object, it is necessary to focus accurately in order to obtain a clear and distinct image on the sensitive plate. This may be done by moving either the lens or the sensitive plate backwards or forwards so as to have the posterior focal point of the lens corresponding with the sensitive plate For similar reasons, a mechanism of adjustment, or accommodation for different distances, is necessary in the human eye. In the normal eye, any number of parallel rays, coming from a great distance, are focussed on the retina. Such an eye is termed *emmetropic* (fig. 11, A). Another form of eye (B) may be such that parallel rays are brought to a focus *in front of* the retina This form of eye is *myopic* or short-sighted, inasmuch as, for distinct vision, the object must be brought near the eye, so as to catch the divergent rays, which are then focussed on the retina. A third form is seen in C, where the focal point, for ordinary distances, is *behind* the retina, and consequently the object must be held far off, so as to allow only the less divergent or parallel rays to reach the eye. This kind of eye is called *hypermetropic*, or far-sighted. For ordinary distances, at which objects must be seen distinctly in every-day life, the fault of the myopic eye may be corrected by the use of concave and of the hypermetropic by convex glasses. In the first case, the concave glass will remove the posterior focal point a little farther back, and in the second the convex glass will bring it farther forwards; in both cases, however, the glasses may be so adjusted, both as regards refractive index and radius of curvature, as to bring the rays to a focus on the retina, and consequently secure distinct vision.

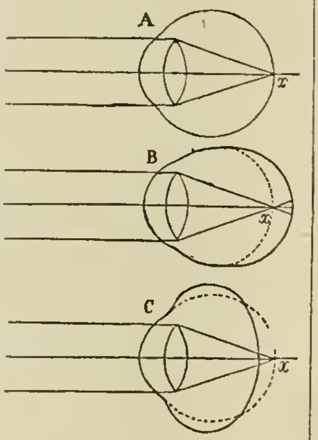

Fig. 11.

A. Emmetropic or normal eye. B, Myopic or short-sighted eye; C. Hypermetropic or long-sighted eye

From any point 65 metres distant, rays may be regarded as almost parallel, and the point will be seen without any effort of accommodation This point, either at this distance or in infinity, is called the *punctum remotum*, or the most distant point seen without accommodation. In the myopic eye it is much nearer, and for the hypermetropic there is really no such point, and accommodation is always necessary, If an object were brought too close to the eye for the refractive media to focus it on the retina, circles of diffusion would be formed, with the result of causing indistinctness of vision, unless the eye possessed some power of adapting itself to different distances. That the eye has some such power of accommodation is proved by the fact that, if we attempt to look through the meshes of a net at a distant object, we cannot see both the meshes and the object with equal distinctness at the same time. Again, if we look continuously at very near objects, the eye speedily becomes fatigued. Beyond a distance of 65 metres, no accommodation is necessary; but within it, the condition of the eye must be adapted to the diminished distance until we reach a point near the eye which may be regarded as the limit of visibility for near objects. This point, called the *punctum proximum*, is usually 12 centimetres (or about 4 inches) from the eye. The range of accommodation is thus from the *punctum remotum* to the *punctum proximum*.

The mechanism of accommodation has been much disputed, but there can be no doubt it is chiefly effected by a change in the curvature of the anterior surface of the crystalline lens. If we hold a lighted candle in front and a little to the side of an eye to be examined, three reflections may be seen in the eye, as represented in fig 12. The first, *a*, is erect, large, and bright, from the anterior surface of the cornea, the second, *b*, also erect, but dim, from the anterior surface of the crystalline lens, and the third, *c*, inverted, and very dim, from the posterior surface of the lens, or perhaps the concave surface of the vitreous humour to which the convex surface of the lens is adapted. Suppose the three images to be in the position shown in the figure for distant vision, it will be found that the middle image *b* moves towards *a*, on looking at a *near* object The change is due to an alteration of the curvature of the lens, as shown in fig. 13. The changes occurring during accommodation are:—(1) the curvature of the anterior surface of the crystalline lens increases, and may pass from 10 to 6 mm.; (2) the pupil contracts, and (3) the intraocular pressure increases in the posterior part of the eye. An explanation of the increased curvature of the anterior surface of the lens during accommodation has been thus given by Helmholtz In the normal condition, that is, for the emmetropic eye, the crystalline lens is flattened anteriorly by the pressure of the anterior layer of the capsule, during accommodation, the radiating fibres of the ciliary muscle pull the ciliary processes forward, thus relieving the tension of the anterior layer of the capsule, and the lens at once bulges forward by its elasticity The exact mechanism of the ciliary muscle is still not clearly understood.

Fig 12.—Reflected images in the Eye

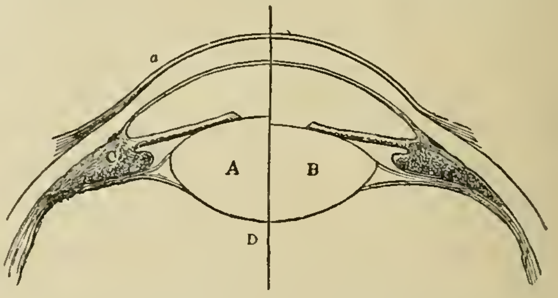

Fig 13 —Mechanism of Accommodation.

A. The lens during accommodation, showing its anterior surface advanced B. The lens as for distant vision; C. Position of the ciliary muscle

Helmholtz has succeeded in measuring with great accuracy the sizes of these reflected images by means of an instrument termed an ophthalmometer, the construction of which is based on the following optical principles. When a luminous ray traverses a plate of glass having parallel sides, if it fall perpendicular to the plane of the plate, it will pass through without deviation; but if it fall obliquely on the plate (as shown in the left hand diagram in fig. 14) it undergoes a lateral deviation, but in a direction parallel to that of the incident ray, so that to an eye placed behind the glass plate, at the lower A, the luminous point, upper A, would be in the direction of the prolonged emergent ray, and thus there would be an apparent lateral displacement of the point, the amount of which would increase with the obliquity of the incident ray. If, instead of one plate, we take two plates of equal thickness, one placed above the other two images will be seen, and by turning the one plate with reference to the other, each image may be displaced a little to one side. The instrument consists of a small telescope (fig. 14) T, the axis of which coincides with the plane separating the two glass plates C C and B B. When we look at an object X Y, and turn the plates till we see two objects *xy*, *xy* touching each other, the size of the image X Y will be equal to the distance the one object is displaced to the one side and the other object to the other side Having thus measured the size of the reflection, it is not difficult, if we know the size of the object reflecting the light and its distance from the eye, to calculate the radius of the curved surface (See Woinow's *Ophthalmometrie*, St Petersburg, 1871, and an account given in Appendix to M'Kendrick's *Outlines of Physiology*, 1878.) The general result is that, in accommodation for near objects, the middle reflected image becomes smaller, and the radius of curvature of the anterior surface of the lens becomes shorter.

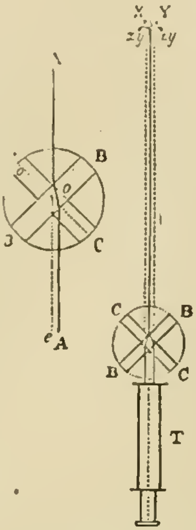

FIG. 14. — Diagrammatic view of the Ophthalmometer of Helmholtz.

(5.) *Absorption and Reflection of Luminous Rays from the Eye.*—When light enters the eye, it is partly absorbed by the black pigment of the choroid and partly reflected. The reflected rays are returned through the pupil, not only following the same direction as the rays entering the eye, but uniting to form an image at the same point in space as the luminous object. The pupil of an eye appears black to an observer, because the eye of the observer does not receive any of those reflected rays. If, however, we strongly illuminate the retina, and hold a lens in front of the eye, so as to bring the reflected rays to a focus nearer the eye, then a virtual and erect, or a real and reversed, image of the retina will be seen. Such is the principle of the ophthalmoscope, invented by Helmholtz in 1851 Eyes deficient in pigment, as in albinos, appear luminous, reflecting light of a red or pink colour; but if we place in front of such an eye a card perforated by a round hole of the diameter of the pupil, the hole will appear quite dark, like the pupil of an ordinary eye. In many animals a portion of the fundus of the eyeball has no pigment, and presents an iridescent appearance. This is called a *tapetum*. It probably renders the eye more sensitive to light of feeble intensity.

(6.) *Functions of the Iris.*—The iris constitutes a diaphragm which regulates the amount of light entering the eyeball. The aperture in the centre, the *pupil*, may be dilated by contraction of a system of radiating fibres of involuntary muscle, or contracted by the action of another system of fibres, forming a sphincter, at the margin of the pupil. The radiating fibres are controlled by the sympathetic, while those of the circular set are excited by the third cranial nerve. The variations in diameter of the pupil are determined by the greater or less intensity of the light acting on the retina. A strong light causes contraction of the pupil; with light of less intensity, the pupil will dilate. In the human being, a strong light acting on one eye will often cause contraction of the pupil, not only in the eye affected, but in the other eye. These facts indicate that the phenomenon is of the nature of a reflex action, in which the fibres of the optic nerve act as sensory conductors to a centre in the encephalon, whence influences emanate which affect the pupil. It has been ascertained that if the fibres of the optic nerve be affected in any way, contraction of the pupil follows. The centre is probably in the anterior pair of the corpora quadrigemina, as destruction of these bodies causes immobility of the pupil. On the other hand, the dilating fibres are derived from the sympathetic; and it has been shown that they come from the lower part of the cervical, and upper part of the dorsal, region of the cord. But the iris seems to be directly susceptible to the action of light. Thus, as was first pointed out by Brown Séquard, the pupil of the eye of a dead animal will contract if exposed to light for several hours, whereas, if the eye on the opposite side be covered, its pupil will remain widely dilated, as at the moment of death.

The pupil *contracts* under the influence—(1) of an increased intensity of light, (2) of the effort of accommodation for near objects, (3) of a strong convergence of the two eyes; and (4) of such active substances as nicotine, morphia, and physostigmine; and it *dilates* under the influence—(1) of a diminished intensity of light, (2) of vision of distant objects; (3) of a strong excitation of any sensory nerve; (4) of dyspnœa, and (5). of such substances as atropine and hyoscyamine. The chief function of the iris is to so moderate the amount of light entering the eye as to secure sharpness of definition of the retinal image. This it accomplishes by (1) diminishing the amount of light reflected from near objects, by cutting off the more divergent rays and admitting only those approaching a parallel direction, which, in a normal eye, are focussed on the retina; and (2) preventing the error of spherical aberration by cutting off divergent rays which would otherwise impinge near the margins of the lens, and would thus be brought to a focus in front of the retina.

3. SPECIFIC INFLUENCE OF LIGHT ON THE RETINA.

The retina is the terminal organ of vision, and all the parts in front of it are merely optical arrangements for securing that an image will be accurately focussed upon it. The natural stimulus of the retina is light. It is often said that it may be excited by mechanical and electrical stimuli; but such an observation really applies to the stimulation of the fibres of the optic nerve. It is well known that such stimuli applied to the optic nerve behind the eye produce always a luminous impression; but there is no proof that the retina, strictly speaking, is similarly affected. Pressure or electrical currents may act on the eyeball, but in doing so they not only affect the retina, consisting of its various layers and of Jacob's membrane, but also the fibres of the optic nerve. It is probable that the retina, by which is meant all the layers except those on its surface formed by the fibres of the optic nerve, is affected only by its *specific* kind of stimulus, light. This stimulus so affects the terminal apparatus as to set up actions which in turn stimulate the optic fibres. The next question naturally is,—What is the specific action of light on the retina? Professors Holmgren of Upsala individually, and Dewar and M'Kendrick conjointly, have shown that when light falls on the retina it excites a variation of the natural electrical current obtained from the eye by placing it on the cushions of a sensitive galvanometer. The general effect was that the *impact* of light caused an increase in the natural electrical current,—during the *continuance* of light, the current diminished slowly, and fell in amount even below what it was before the impact,—and that the *withdrawal* of light was followed by a rebound, or second increase, after which the current fell in strength, as if the eye suffered from fatigue.

It was also observed in this research that the amount of electrical variation produced by light of various intensities corresponded pretty closely to the results expressed by Fechner's law, which regulates the relation between the stimulus and the sensational effect in sensory impressions. This law is, that the sensational effect does not increase proportionally to the stimulus, but as the logarithm of the stimulus. Thus, supposing the stimulus to be 10, 100, or 1000 times increased, the sensational effect will not be 10, 100, or 1000 times, but only 1, 2, and 3 times greater. This law, then, applies to the phenomena happening in the terminal organ, and not, as generally supposed, exclusively to those occurring in the brain.

Such electrical phenomena probably result either from thermal or chemical changes in the retina. Recent researches of Boll and Kühne have shown that light produces chemical changes in the retina. If an animal be killed in the dark, and if its retina be exposed only to *yellow* rays, the retina has a peculiar purple colour, which is at once destroyed by exposure to ordinary light. The purple matter apparently is decomposed by light. Kühne has also shown that an image may actually be *fixed* on the retina by plunging it into a solution of alum immediately after death. Thus it would appear that light affects the purple-matter of the retina, and the result of this chemical change is to stimulate the optic filaments; if the action be arrested, we may have a picture on the retina, but if it be not arrested, the picture is evanescent; the purple-matter is used up, and new matter of a similar kind is formed to take its place. The retina might, therefore, be compared to a sensitive plate having the sensitive matter quickly removed and replaced by chemical changes; and it is probable that the electrical expression of these changes is what has been above described.

(*a*) *Phosgenes.*—Luminous impressions may also be produced by pressure on the eyeball. Such impressions, termed *phosgenes*, usually appear as a luminous centre surrounded by coloured or dark rings. Sometimes they seem to be small bright scintillations of various forms. Similar appearances may be observed at the moments of opening or of closing a strong electrical current transmitted through the eyeball.

(*b*) *The Retina's Proper Light.*—The visual field, even when the eyelids are closed in a dark room, is not absolutely dark. There is a sensation of faint luminosity which may at one moment be brighter than at another. This is often termed the *proper light of the retina*, and it indicates a certain condition of molecular activity, even in darkness.

(*c*) *The Excitability of the Retina.*—The retina is not equally excitable in all its parts. At the entrance of the optic nerve, as was shown by Mariotte in 1668, there is no sensibility to light. Hence, this part of the retina is called the *blind spot*. If we shut the left eye, fix the right eye on the cross seen in fig. 15, and move the book towards and away from the eye, a position will be found when the round spot disappears, that is when its image falls on the entrance of the optic nerve. There is also complete insensibility to colours at that spot. The diameter of the optic papilla is about 1·8 mm., giving an angle of 6 degrees; this angle determines the apparent size of the blind spot in the visual field, and it is sufficiently large to cause a human figure to disappear at a distance of two metres (Beaunis).

FIG. 15.—Diagram for the study of the *Blind Spot.*

The *yellow spot* in the centre of the retina is the most sensitive to light, and it is chiefly employed in direct vision. Thus, if we fix the eye on a word in the centre of this line, it is distinctly and sharply seen, but the words towards each end of the line are vague. If we wish to see each word distinctly, we "run the eye" along the line,—that is, we bring each successive word on the yellow spot. This spot has a horizontal diameter of 2 mm., and a vertical diameter of ·8 mm.; and it corresponds in the visual field to an angle of from 2 to 4 degrees. It is believed that the fossa in the spot, where there are almost no retinal elements except Jacob's membrane, consisting here entirely of cones (2000 in number), is the area of most acute sensibility. This fossa has a diameter of only ·2 mm., which makes the angle ten times smaller. Thus the field of distinct vision is extremely limited, and at the same moment we see only a very small portion of the visual field. Images of external objects are brought successively on this minute sensitive area, and the different sensations seem to be fused together, so that we are conscious of the object as a whole.

Towards the anterior margin of the retina sensitiveness to light becomes diminished; but the diminution is not uniform, and it varies in different persons.

(*d*) *Duration and Persistence of Retinal Impressions.*—To excite the retina, a feeble stimulus must act for a certain time; when the retina is excited, the impression lasts after the cessation of the stimulus; but if the stimulus be strong, it may be of very short duration. Thus the duration of an electrical spark is extremely short, but the impression on the retina is so powerful, and remains so long, as to make the spark visible. If we rotate a disc having white and black sectors we see continuous dark bands. Even if we paint on the face of the disc a single large round red *spot*, and rotate rapidly, a continuous red *band* may be observed. Here the impressions of red on the same area of retina succeed each other so rapidly that before one disappears another is superadded, the result being a fusion of the successive impressions into one continuous sensation. This phenomenon is called the *persistence of retinal impressions*. It has been ascertained that an impression lasts on the retina from $\frac{1}{50}$ to $\frac{1}{30}$ of a second. If we look steadily at a bright light for a few seconds and then quickly close the eyes or gaze into a dark room, a luminous image of the light will be visible for a short time. Such an appearance is called a *positive accidental image*, or a consecutive image. It may also be observed in this experiment that the intensity of the retinal excitation is not uniform. It increases quickly at its commencement, and after it has reached a maximum it slowly declines. Many familiar toys, such as the thaumatrope, or wheel of life, stroboscopic discs, and the phenakistoscope, produce curious effects due to persistence of retinal impressions.

(*e*) *The Phenomena of Irradiation.*—If we look at fig. 16, the white square in the black field appears to be larger than the black square in the white field, although both are of precisely the same size. This is due to *irradiation*, a phenomenon explained by Helmholtz, by stating that the borders of clear surfaces advance in the visual field and encroach on obscure surfaces. Probably, even with the most exact accommodation, diffusion images form round the image of a white surface on a black ground, forming a kind of penumbra, thus causing it to appear larger than it really is.

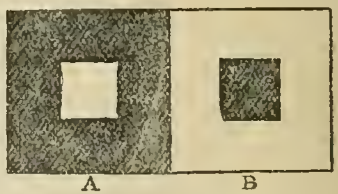

FIG. 16.—Illustrating the effect of irradiation.

(*f*) *Intensity of Light required to excite the Retina.*—Light must have a certain intensity to produce a luminous impression. It is impossible to fix the minimum intensity necessary, as the effect will depend, not only on the intensity of the stimulus, but on the degree of retinal excitability at the time. Thus, after the retina has been for some time in the dark, its excitability is increased; on the other hand, it is much diminished by fatigue. Aubert has stated that the minimum intensity is about 300 times less than that of the full moon. The sensibility of the eye to light is measured by *photometers*, instruments which will be described under the article LIGHT.

(*g*) *Consecutive Retinal Images.*—Images which persist on the retina are either positive or negative. They are termed *positive* when the bright and obscure parts of the image are the same as the bright and obscure parts of the object; and *negative*, when the bright parts of the object are dark in the image, and *vice versa*. Positive images are strong and sharply marked when an intense light has acted for not less than ⅓ of a second. If the excitation be continued much longer, a negative and not a positive image will be seen. If, when the positive image is still visible, we look on a very brilliantly illuminated surface, a negative image appears. Negative images are seen with greatest intensity after a strong light has acted for a considerable time. These phenomena may be best studied when the retina is very excitable, as in the morning after a sound sleep. On awakening, if we look steadily *for an instant* at the window and then close the eyes, a *positive* image of the window will appear; if we then gaze fixedly at the window for one or two minutes, close the eyes two or three times, and then look at a dark part of the room, a *negative* image will be seen floating before us. The positive image is due to excitation of the retina, and the negative to fatigue. If we fatigue a small area of the retina with white light, and then allow a less intense light to fall on it, the fatigued area responds feebly, and consequently the object, such as the window pane, appears to be dark. Many curious experiments may be made to illustrate the laws of consecutive images. Thus, if we look at a black figure on a white ground for, say, one minute, and then gaze into a dark part of the room, a gigantic *white* figure, of corresponding shape, may make its appearance. A white figure on a black ground will produce a black image, a green figure will produce a red, and a red a green,—the reproduced colour being always complementary to that of the figure.

4. SENSATIONS OF COLOUR.

(1.) *General Statement.*—Colour is a special sensation excited by the action on the retina of rays of light of a definite wave length. Thus we have a sensation of red when a certain number of waves of light impinge on the retina in a unit of time, and with about twice the number of waves in the same time the sensation will not be of red but of violet. When we examine a spectrum, we see a series of colours merging by insensible gradations the one into the other, thus:—red, orange, yellow, green, blue, and violet. These are termed *simple* colours. If two or more coloured rays of the spectrum act simultaneously on the same spot of the retina, they may give rise to sensations of *mixed colours*. These mixed colours are of two kinds:—(1) those which do not correspond to any colour in the spectrum, such as purple and white, and (2) those which do exist in the spectrum. White may be produced by a mixture of two simple colours, which are then said to be *complementary*. Thus, red and greenish-blue, orange and cyanic-blue, yellow and indigo-blue, and greenish-yellow and violet all produce white. Purple is produced by a mixture of red and violet, or red and bluish-violet. When white light falls on a surface, the surface may absorb all the rays except the red. If the red rays are alone reflected, then the object will be red; if the green rays are reflected, then the object will appear to be green. Again, if we look through red glass, all the rays are absorbed except red, and consequently the world beyond appears to be red. So with regard to the other transparent coloured media. The following table by Helmholtz shows the compound colours produced by mixing other colours:—

	Violet	Indigo-blue	Cyanic-blue	Greenish-blue	Green	Yellowish-green	Yellow
Red	Purple	Deep-rose	White-rose	*White*	Whitish yellow	Golden yellow	Orange
Orange	Deep-rose	White rose	*White*	Whitish-yellow	Yellow	Yellow	
Yellow	White rose	*White*	Whitish-green	Whitish-green	Yellowish-green		
Yellowish-green	*White*	Green	Green	Green			
Green	Blue	Water-blue	Greenish-blue				
Greenish-blue	Water-blue	Water-blue					
Cyanic blue	Indigo-blue						

This table shows that if we mix two simple colours, not so far separated in the spectrum as the complementary colours, the mixed colour contains more white as the interval between the colours employed is greater, and that if we mix two colours further distant in the spectrum than the complementary colours, the mixture is whiter as the interval is smaller. By mixing more than two simple colours, no new colours are produced, but only different *shades* of colour.

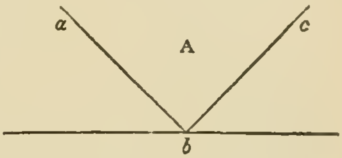

FIG. 17.—Form of double slit for the partial superposition of two spectra.

(2.) *Modes of Mixing Colour-Sensations.*—Various methods have been adopted for studying the effect of mixing colours.

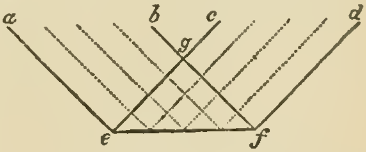

FIG. 18.—Diagram of double spectrum partially superposed.

(*a*) *By Superposing two Spectra* (Helmholtz and Clerk Maxwell).—This may be done in a simple way by having a slit in the form of the letter V (see fig. 17), of which the two portions *a b* and *b c* form a right angle; behind this slit is placed a vertical prism, and two spectra are obtained, as seen in fig. 18, in which *b f e a* is the spectrum of the slit *a b*, and *c e f d* that of the slit *b c*, the coloured spectra are contained in the triangle *g e f*, and, by arrangement, the effects of mixture of any two simple colours may be observed.

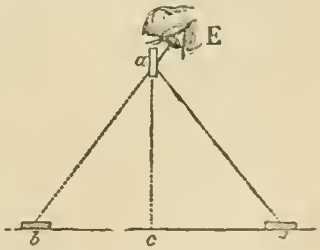

FIG. 19.—Diagram showing Lambert's method of mixing sensations of colour.

(*b*) *By Lambert's Method of Reflection.*—Place a red wafer on *b*, in fig. 19, and a blue wafer on *d*, and so angle a small glass plate *a* as to transmit to the eye a reflection of the blue wafer on *d* in the same line as the rays transmitted from the red wafer on *b*. The sensation will be that of purple; and by using wafers of different colours, many experiments may thus be performed.

(*c*) *By the Use of Rotating Discs which quickly superpose on the same Area of Retina different Impressions of Colour.*—Such discs may be constructed of cardboard, on which coloured sectors are painted, as shown in fig. 20, representing diagrammatically the arrangement of Sir Isaac

Newton. The angles of the sectors were thus given by him :—

Red	60° 45·5′	Green	60° 45·5′
Orange	34° 10·5′	Blue	54° 41′
Yellow	54° 41′	Indigo	34° 10·5′
Violet	60° 45·5′		

With sectors of such a size, *white* will be produced on rotating the disc rapidly. This method has been carried out with great efficiency by the colour-top of Clerk Maxwell. It is simply a flat top, on the surface of which discs of various colours may be placed. Dancer has added to it a method by which, even while the top is rotating rapidly, and the sensation of a mixed colour is strongly perceived, the eye may be able to see the *simple* colours of which it is composed. This is done by placing on the handle of the top, a short distance above the coloured surface, a thin black disc, perforated by holes of various size and pattern, and weighted a little on one side. This disc vibrates to and fro rapidly, and breaks the continuity of the colour-impression; and thus the constituent colours are readily seen.

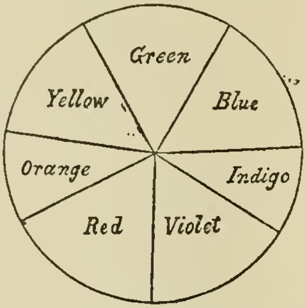

Fig. 20.—Diagram of the Colour Disc of Sir Isaac Newton.

(3.) *Physiological Characters of Colours.*—All colours have three special characters :—(1) *Tone*, depending on the number of vibrations per second ; (2) *Intensity*, depending on the extent or amplitude of the vibrations, and passing from the most sombre to the most brilliant shades; and (3) *Saturation*, which depends on the amount of *white* the colour contains; thus, it is saturated when there is no white, as in the pure colours of the spectrum, and there may be an infinite number of degrees of saturation from the pure colour to white.

(4.) *The Geometric Representation of Colours.*—Colours may be arranged in a linear series, as in the solar spectrum. Each point of the line corresponds to a determinate impression of colour ; the line is not a straight line, as regards luminous effect, but is better represented by a curve, passing from the red to the violet. This curve might be represented as a circle in the circumference of which the various colours might be placed, in which case the complementary colours would be at the extremities of the same diameter. Newton arranged the colours in the form of a triangle, as shown in fig. 21. If we place three of the spectral colours at three angles, thus,—green, violet, and red,—the sides of the triangle include the intermediate colours of the spectrum, except purple.

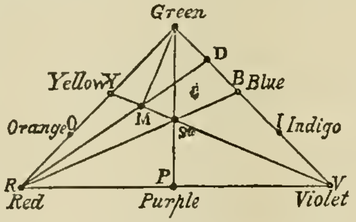

Fig. 21.—Geometrical representation of the relations of colours as shown by Newton.

The point S corresponds to white, consequently, from the intersection of the lines which join the complementary colours, the straight lines from green to S, R S, and V S, represent the amount of green, red, and violet necessary to form white ; the same holds good for the complementary colours ; for example, for blue and red, the line S B = the amount of blue, and the line S R = the amount of red required to form white. Again, any point, say M, on the surface of the triangle, will represent a mixed colour, the composition of which may be obtained by mixing the three fundamental colours in the proportions represented by the length of the lines M to green, M V, and M R. But the line V M passes on to the yellow Y; we may then replace the red and green by the yellow, in the proportion of the length of the line M Y, and mix it with violet in the proportion of S V. The same colour would also be formed by mixing the amount M Y of yellow with M S of white, or by the amount R M of red with the amount M D of greenish blue.

(5.) *The Theory of Colour-Perception.*—The theory generally accepted was first proposed by Thomas Young and afterwards revived by Helmholtz. It is based on the assumption that three kinds of nerve fibres exist in the retina, the excitation of which give respectively sensations of red, green, and violet. These may be regarded as fundamental sensations. Homogeneous light excites all three, but with different intensities according to the length of the wave. Thus long waves will excite most strongly fibres sensitive to red, medium waves those sensitive to green, and short waves those sensitive to violet. Fig. 22 shows graphically the irritability of the three sets of fibres. Helmholtz thus applies the theory :—

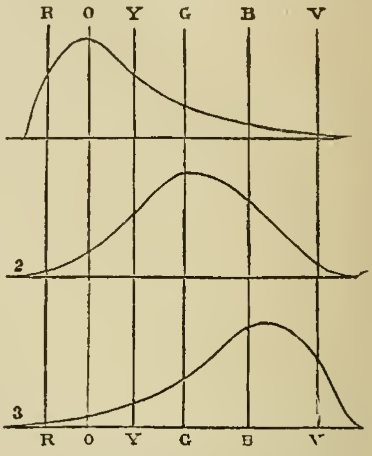

Fig. 22.—Diagram showing the irritability of the three kinds of retinal elements. 1 Red; 2 Green; 3 Violet. R, O, Y, G, B, V, initial letters of colours

"1. Red excites strongly the fibres sensitive to red and feebly the other two—sensation : *Red.*
2. Yellow excites moderately the fibres sensitive to red and green, feebly the violet—sensation : *Yellow.*
3. Green excites strongly the green, feebly the other two—sensation : *Green.*
4. Blue excites moderately the fibres sensitive to green and violet, and feebly the red—sensation : *Blue.*
5. Violet excites strongly the fibres sensitive to violet, and feebly the other two—sensation : *Violet.*
6. When the excitation is nearly equal for the three kinds of fibres, then the sensation is *White.*"

This theory explains some of the phenomena of what is called *colour blindness* or *Daltonism.* All individuals appear to have some kind of colour-sensation ; in some, however, there may be no sensation for particular colours. The most common defect is insensibility to *red* (Daltonism properly so called). The spectrum to such an eye is deficient in red, and the sensation corresponding to all compound colours containing red is that of the complementary colour only. Thus, white is bluish-green, and intense red appears green, so that red poppies in a green cornfield do not appear of a different hue from the green by which they are surrounded. If we suppose in such cases an absence or paralysis of the red-fibres, the phenomena are accounted for. Blindness to green and violet is rare.

Young's theory also explains the appearance of the consecutive coloured images already referred to.

Suppose, for example, that we look at a red object for a considerable time ; the retinal elements sensitive to red become fatigued. Then (1) if the eye be kept in *darkness*, the fibres affected by red being fatigued do not act so as to give a sensation of red ; those of green and of violet have been less excited, and this excitation is sufficient to give the sensation of pale greenish blue ; (2) if the eye be fixed on a *white* surface, the red fibres, being fatigued, are not excited by the red rays contained in the white light ; on the contrary. the green and violet fibres are strongly excited, and the consequence is that we have an intense complementary image ; (3) if we look at a *bluish-green* surface, the complementary of red, the effect will be to excite still more strongly the green and violet fibres, and consequently to have a still more intense complementary image; (4) if we regard a *red* surface, the primitive colour the red fibres are little affected in consequence of being fatigued, the green and violet fibres will be only feebly excited, and therefore only a very feeble complementary image will be seen; and, (5) if we look at a surface of a *different* colour altogether, this colour may combine with that of the consecutive image, and produce a mixed colour; thus, on a yellow surface, we will see an image of an orange colour.

(6.) *The Contrast of Colours.*—If we look at a small white, grey, or black object on a coloured ground, the object appears to have the colour complementary to the ground. Thus a circle of grey paper on a *red* ground appears to be of a greenish-blue colour, whilst on a blue ground it will appear pink. This effect is heightened if we place over the paper a thin sheet of tissue paper; but it disappears at once if we place a black ring or border round the grey paper. Again, if we place two complementary colours side by side, both appear to be increased in intensity. Various theories have been advanced to explain these facts. Helmholtz is of opinion that the phenomena consist more in modifications in judgment than in modifications of sensation; Plateau, on the other hand, attempts to explain them by the theory of consecutive images.

5. The Movements of the Eye.

(1.) *General Statement.*—The globe of the eye has a *centre of rotation*, which is not exactly in the centre of the optic axis, but a little behind it. On this centre it may move round *axes of rotation*, of which there are three,—an antero-posterior, a vertical, and a transverse. In normal vision, the two eyes are always placed in such a manner as to be fixed on one point, called the *fixed point* or the *point of regard.* A line passing from the centre of rotation to the point of regard is called the *line of regard.* The two lines of regard form an angle at the point of regard, and the base is formed by a line passing from the one centre of rotation to the other. A plane passing through both lines of regard is called the *plane of regard.* With these definitions, we can now describe the movements of the eyeball, which are of three kinds. (1) *First position.*—The head is erect, and the line of regard is directed towards the distant horizon. (2) *Second position.*—This indicates all the movements round the transverse and horizontal axes. When the eye rotates round the first, the line of regard is displaced above or below, and makes with a line indicating its former position an angle termed by Helmholtz the angle of vertical displacement, or the *ascensional angle*; and when it rotates round the vertical axis, the line of regard is displaced from side to side, forming with the median plane of the eye an angle called the *angle of lateral displacement.* (3) *Third order of positions.*—This includes all those which the globe may assume in performing a rotatory movement along with lateral or vertical displacements. This movement of rotation is measured by the angle which the plane of regard makes with the transverse plane, an angle termed the *angle of rotation* or of *torsion.*

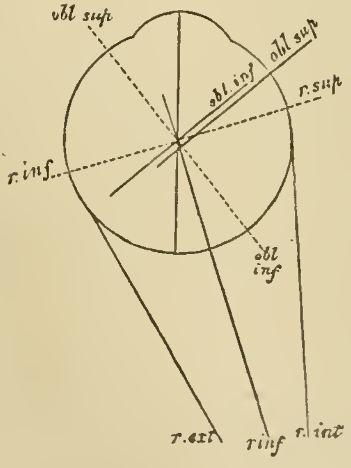

Fig. 23.—Diagram of the attachments of the muscles of the eye and of their axes of rotation, the latter being shown by dotted lines. (Fick.)

The axis of rotation of the rectus internus and externus being vertical, that is, perpendicular to the plane of the paper, cannot be shown.

The two eyes move together as a system, so that we direct the two lines of regard to the same point in space.

The eyeball is moved by six muscles, which are described in the article Anatomy, vol. i., p. 891. The relative attachments and the axes of rotation are shown in fig. 23. The following table, given by Beaunis, summarizes their action :—

Number of Muscles in activity.	Direction of Line of Regard.	Muscles acting.
One	Inwards	Internal rectus.
	Outwards	External rectus.
Two	Upwards	Superior rectus. Inferior oblique.
	Downwards	Inferior rectus. Superior oblique.
Three	Inwards and upwards	Internal rectus. Superior rectus. Inferior oblique.
	Inwards and downwards	Internal rectus. Inferior rectus. Superior oblique.
	Outwards and upwards	External rectus. Superior rectus. Inferior oblique.
	Outwards and downwards	External rectus. Inferior rectus. Superior oblique.

The term *visual field* is given to the area intercepted by the extreme visual lines which pass through the centre of the pupil, the amount of dilatation of which determines its size. It follows the movements of the eye, and is displaced with it. Each point in the visual field has a corresponding point on the retina, but the portion, as already explained, which secures our attention is that falling on the yellow spot.

(2.) *Simple Vision with Two Eyes.*—When we look at an object with both eyes, having the optic axes parallel, its image falls upon the two yellow spots, and it is seen as one object. If, however, we displace one eyeball by pressing it with the finger, then the image in the displaced eye does not fall on the yellow spot, and we see two objects, one of them being less distinct than the other. It is not necessary, however, in order to see a single object with two eyes that the two images fall on the two yellow spots; an object is always single if its image fall on *corresponding points* in the two eyes. Thus, in the experiment above described, after having seen two images by displacing one eyeball, we may be able again to see only one image by pressing on the other eyeball. There are then corresponding points in the two retinæ, so that if they were superposed the two yellow spots would coincide; the upper and lower parts of the left retina would touch the upper and lower parts of the right retina; the nasal side of the left retina would correspond to the temporal side of the right retina, and the reverse would also hold good. The relation of the two retinæ to each other in the field of vision may be illustrated by the diagram in fig. 24. When an image falls on non-corresponding points of the retina, it is seen double.

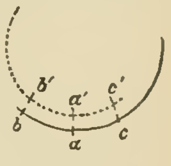

Fig. 24.—Diagram to illustrate the physiological relations of the two retinæ.

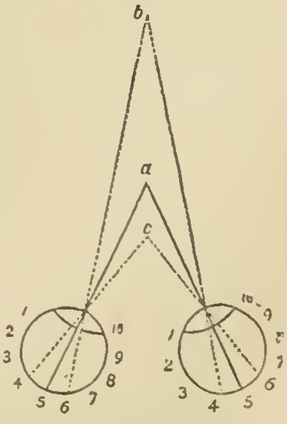

Fig. 25.—Diagram to illustrate phenomena of double vision. (Muller.)

Thus as in fig 25, suppose two eyes looking at a single object, placed at *a* *b* or *c* If the image of the point *b* fall in one eye on 6 and in the other on 7, the point 6 of the one retina being correspondent with the point 6 of the other retina, the distance of the two images seen will be equal to the distance between 6 and 7 Again, if images of *a* fall on 5 and 5, it will be seen single. Further, if the image of *b* fall on the left eye at 6 and on the right at 4, as these two points do not correspond, it will appear double. And so with regard to the other retinal points indicated by the numbers.

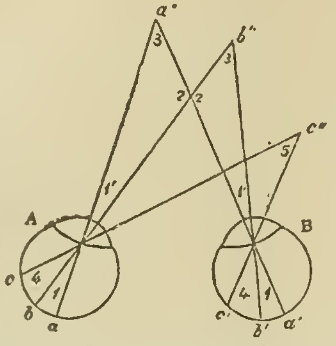

Fig. 26.—Diagram to illustrate the theory of corresponding retinal points. (Müller.)

The phenomena may also be studied with the aid of fig. 26. Any object at a'', or at b'', or at c'', will be seen simply by the two eyes A and B, as the images fall on corresponding points in the retinæ, namely, *aa'*, *bb'*, and *cc'*. It will be readily seen that, if the eye B were displaced, the images would not fall on corresponding points, and consequently two would be seen.

The name *horopter* has been given to a line connecting those points in the visual field which form their image on corresponding points of the retina The older physiologists first gave this name to "a straight line or plane, passing through the point of convergence of the axes of the eyes or the point to which the eyes are directed;" but Vieth and Müller showed that it cannot be a straight line or plane, but must have a circular form.

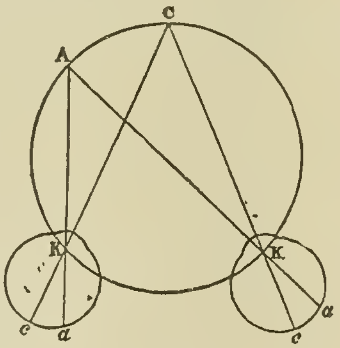

Fig. 27.—Diagram to illustrate the simple horopter.

Thus if the points *a*, *b*, *c* in fig. 26 correspond to the points *a'*, *b'*, *c'*, the angles 4 and 1 in the one eye must correspond to the angles 4 and 1 in the other. Then *a b* being equal to *a' b'* the angle 1 in eye A equal to angle 1 in eye B, the angles 1' and 1' will be equal. Since the angles 2 and 2 are equal, the angles 3 and 3 must also be equal. In the same way, the angle 5 is equal to angle 3. For *b c* = *b' c'*, and angle 4 = angle 4. Thus the angles 3, 3, and 5 are equal, and a'' b'' c'' cannot lie in a straight line, for it is the property of a circle only that angles erected on the same chord, and reaching the periphery have at the periphery equal angles (Müller's *Physiology*, vol. ii. p. 1195.)

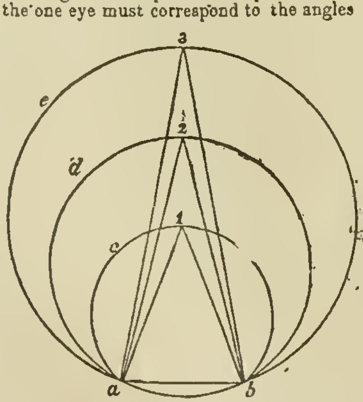

Fig. 28.—Diagram illustrating the simple horopter of objects at different distances from the eyes.

A line joining a'', b'', and c'' is therefore the simple horopter, and its form is illustrated by fig. 27. It is a circle, of which the chord is formed by the distance between the points of decussation of the rays of light in the eye (K A C K in fig 27). Its size is determined by the position of the two eyes, and the point toward which their axes converge. This is illustrated by fig. 28. Thus if *a b* be the distance of the eyes from each other, the circle *c* is the horopter for the object marked 1, the circle *d* for 2, and the circle *e* for 3.

An object which is not found in the horopter, or, in other words, does not form an image on corresponding points of the retinæ, is seen double. When the eyeballs are so acted upon by their muscles as to secure images on non-corresponding points, and consequently double vision, the condition is termed *strabismus*, or squinting, of which there are several varieties treated of in works on ophthalmic surgery It is important to observe that in the fusion of double images we must assume, not only the correctness of the theory of corresponding points of the retina, but also that there are corresponding points in the brain, at the central ends of the optic fibres. Such fusion of images may occur without consciousness,—at all events it is possible to imagine that the cerebral effect (except as regards consciousness) would be the same when a single object was placed before the two eyes, in the proper position, whether the individual were conscious or not. On the other hand, as we are habitually conscious of a single image, there is a psychical tendency to fuse double images when they are not too dissimilar.

(3.) *Binocular Perception of Colour.*—This may be studied as follows. Take two No 3 eye-pieces of a Hartnack's microscope, or two eye pieces of the same optical value from any microscope, placee on in front of each eye, direct them to a clear window in daylight, keep them parallel, and two luminous fields will be seen, one corresponding to each eye. Then converge the two eye-pieces, until the two luminous circles cross, and the central part, like a bi-convex lens, will appear clear and bright, while the outer segments will be much less intense, and may appear even of a dim grey colour. Here, evidently, the sensation is due to a fusion of impressions in the brain. With a similar arrangement, blue light may be admitted by the one eye-piece and red by the other, and on the convergence of the two, a resultant colour, purple, will be observed. This may be termed the binocular vision of colours. It is remarkable that by a mental effort this sensation of a compound colour may be decomposed into its constituents, so that one eye will again see blue and the other red.

6. THE PSYCHICAL RELATIONS OF VISUAL PERCEPTIONS.

(1.) *General Characters of Visual Perceptions.*—All visual perceptions, if they last for a sufficient length of time, appear to be external to ourselves, erect, localized in a position in space, and more or less continuous.

(*a*) *Visual Sensations are referred to the Exterior.*—This appears to be due, to a large extent, to habit. Those who have been born blind, on obtaining eye-sight by an operation, have imagined objects to be in close proximity to the eye, and have not had the distinct sense of exteriority which most individuals possess. Slowly, and by a process of education, in which the sense of touch played an important part, they gained the knowledge of the external relations of objects. Again, phosgenes, when first produced, appear to be in the eye, but when conscious of them, by an effort of imagination, we may transport them into space, although they never appear very far off.

(*b*) *Visual Sensations are referred to Erect Objects.*—Although the images of objects are *inverted* on the retina we see them erect. The explanation of the effect is that we are conscious not of the image on the retina, but of the luminous object from which the rays proceed, and we refer the sensation in the *direction* of these rays. Again, in running the eye over the object, say a tall pole, from base to apex, we are not conscious of the different images on the retina, but of the muscular movements necessary to bring the parts successively on the yellow spot.

(*c*) *Visual Sensations are referred to a Position in Space.*—The localization of a luminous point in space can only be determined by observing its relations to other luminous points with a given position of the head and of the eye. For example, in a perfectly dark room, if we look at a single luminous point, we cannot fix its exact position in space, but we may get some information of a vague character by moving the head or the eye. If, however, a second luminous point appears in the darkness, we can tell whether it is nearer or farther distant, above or below the first. So with regard to other luminous points we observe their reciprocal relations, and thus we localize a number of visual impressions. There are three principal directions in space—(1) the *transverse* (breadth), the *vertical* (height), and the *sagittal* (depth). Luminous points may be localized either in the transverse or vertical directions. Here we have to do simply with localization on a surface. A number of points may be observed simultaneously (as when the eye is fixed) or successively (as when the eye moves). If the movement of the eye be made rapidly, the series of impressions from different points may be fused together, and we are conscious of a *line*, the direction of which is indicated chiefly by the muscular sensations felt in following it. The case is different as regards points in the sagittal direction. We see only a single point of this line at a time; it may be a transverse series of retinal elements A, B, and each of these formed by a number of smaller elements 1, 2, 3, 4 situated in the axis of each principal element; it may be, on the other hand, the transverse line *a b* situated in space and formed by a series of points in juxtaposition. Each of these points will impress a retinal element, and the result will be the perception of a transverse line; but this will not be the same for the points *c, d, e, f, g*, situated in space in a linear series, in the sagittal direction; only one of those points *c* will impress the corresponding retinal element, and we can see only *one* point at a time in the line *c g*. By accommodating successively, however, for the various points at different and considerable distances along the line *c g*, we may excite retinal elements in rapid succession. Thus, partly by the fusion of the successive impressions on the retina, and partly from the muscular sensations caused by repeated accommodations and possibly of ocular movements, we obtain a notion of *depth* in space, even with the use of only one eye. It is, however, one of the chief effects of binocular vision to give precision to the notion of space in the sagittal direction

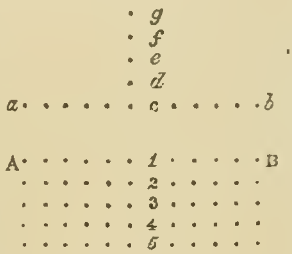

Fig. 29.—Diagram illustrating the localization of visual perceptions.

(*d*) *Visual Sensations are continuous.*—Suppose the image of a luminous line falls on the retina, it will appear as a line although it is placed on perhaps 200 cones or rods, each of which may be separately excited, so as to cause a *distinct* sensation. Again, on the same principle, the impression of a superficial surface may be regarded as a kind of *mosaic*, made up of individual portions corresponding to the rods or cones on which the image of the surface falls. But in both cases, the sensation is continuous, so that we see a line or a surface. The individual images are fused together.

(2.) *Notions derived from Visual Perceptions.*—When we look at any object, we judge of its size, the direction of its surfaces (unless it be a point), its distance from the eye, its apparent movement or fixedness, and its appearance of solidity.

(*a*) *Apparent Size.*—This, so far as regards a comparatively small object, depends on the size of the retinal image, as determined by the visual angle. With a very large object, there is an appreciation of size from the muscular sensations derived from the movements of the eyeball, as we "range" the eye over it. It is difficult to appreciate the distance separating two points between which there are other points, as contrasted with an apparently similar distance without intermediate points. For example, the distance A to B appears to be greater than from B to C, in fig. 30.

Fig. 30.—Diagram to illustrate illusions of size and distance.

(*b*) *Direction.*—As the retina is a curved surface, a long straight line, especially when seen from a distance, appears curved. In fig. 31 a curious illusion of direction, first shown by Zoellner, is depicted. If these lines be looked at somewhat obliquely, say from one corner, they will appear to converge or diverge, and the oblique lines, on each side of the vertical lines, will appear not to be exactly opposite each other. But the vertical lines are parallel, and the oblique lines are continuous across them. The effect is evidently due to an error of judgment, as it may be controlled by an intense effort, when the lines will be seen as they really are.

Fig. 31.—Zoellner's figure showing an illusion of direction.

(*c*) *Apparent Distance.*—We judge of distance, as regards large objects at a great distance from the eye—(1) from their apparent size, which depends on the dimensions of the visual angle, and (2) from the interposition of other objects between the eye and the distant object. Thus, at sea, we cannot form, without great experience, an accurate estimate of how many miles we are off the coast, and all know how difficult it is to estimate accurately the width of a river. But if objects be interposed between the eye and the distant object, say a few vessels at different distances at sea, or a boat in the river, then we have certain materials on which to form a judgment, the accuracy of which, however, even with these aids, will depend on experience. When we look at a near object, we judge of its distance chiefly by the sense of effort put forth in bringing the two lines of regard to converge upon it.

(*d*) *The Movement of a Body.*—If the eye be fixed, we judge of movement by successive portions of the retina being affected, and possibly also, by a feeling of an *absence* of muscular contractions necessary to move the eye-balls. When the eye moves, so as to "follow" the object, there is a sense of muscular effort, which is increased when, in addition we require to move the head.

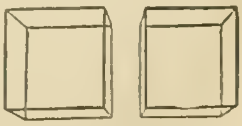

Fig. 32.—Illustrating stereoscopic vision.

(*e*) *The Apparent Solidity of an Object.*—If we look at an object, say a cube, first with the right eye and then with the left, it will be found that the two images of the object are somewhat different, as in fig. 32. If, then, by means of a stereoscope, or by holding a card between the two eyes, and causing a slight convergence of the eyes, the two images are brought upon corresponding points of the two retinæ, the image will at once be seen in relief.

Consult regarding the physiology of the eye, as the most complete treatise on the subject, Helmholtz's *Optique Physiologique*, 1867; one of the best of the older treatises is Mackenzie *On the Eye and Vision*, 1841; in the first-mentioned treatise, a full list is given at the end of each section of all the more important works and monographs bearing on the physiology and optical arrangements of the eye, up to 1867. A very valuable bibliographical account is one recently published by J. Plateau, entitled *Bibliographie analytique des principaux phénomènes subjective de la Vision depuis les temps anciens jusqu'à la fin du XVIIIe siècle, suivie d'une bibliographie simple pour la partie écoulée du siècle actuel extrait du tome xlii. des Mémoires de l'Académie royale des sciences, des lettres, et des beaux-arts de Belgique*, 1877 (J. G. M.)

EZEKIEL (יְחֶזְקֵאל *i.e.*, יְחַזֵּק אֵל, God will strengthen, or יֶחֱזַק אֵל, God will prevail, Ἰεζεκιήλ; *Ezechiel*) was the son of Buzi a priest, probably of the line of Zadok, who appears to have lived in Jerusalem, and to have held a position of some prominence there. According to an ancient and not impossible interpretation of his own words (chap. i. 1), Ezekiel was born in 624 B.C. This interpretation is at least preferable to that which reckons "the thirtieth year" from a hypothetical era of Nabopolassar, but it is not free from all objection, and if it fail us we have no data for precisely determining the prophet's age. Notwithstanding the expression made use of by Josephus (παῖς ὤν, *Ant.*, x. 7, 3) we may reasonably assume, however, that he had at least attained to early manhood, and already had read and observed much, when, along with King Jehoiachin and many other prisoners of the better class (2 Kings xxiv 12–16, Jer xxix. 1) he was carried into exile by Nebuchadnezzar in 599 B C With others of his compatriots he was settled at a place called Tel-Abib ("Cornhill"), on the banks of the river Chebar, by which most probably the Nahr-Malcha or "Grand" Canal of Nebuchadnezzar is meant, though some still think of the Chaboras (modern Khabur), an affluent of the Euphrates more to the north.[1] We are left almost wholly to precarious inference and conjecture for all further details of his history. We learn incidentally, indeed, from his writings that he was a married man living in a house of his own, and that his wife died in the ninth year of his exile. But of the nature of his ordinary employments, if he had any, we are not informed. His life, as a priest whose heart was thoroughly absorbed in priestly work, could hardly fail to be tinged with sadness. condemned as it was to be spent in an "unclean land" far away from "the inheritance of the Lord." He seems to have been of a brooding temperament, and to have passed much of his time in silence and solitude. A recent writer (in the *Studien u. Kritiken* for 1877) has ingeniously suggested and endeavoured to show that he was an invalid, suffering much from some chronic nervous malady. In the fifth year of his exile (594 B.C.) he had a remarkable vision, of which he has given a very full description in the opening chapters of his book. On this occasion he was divinely called to the prophetic office. Thenceforward, for a period of at least 22 years, both orally and in writing, he continued to discharge prophetic functions at frequent if somewhat irregular intervals; and whatever may have been the force and bitterness of the opposition he originally had to face, he ultimately, as a "watchman" and acknowledged leader of public opinion, came to exercise an incalculably powerful influence in keeping alive the Jewish national feeling, and also in quickening and purifying the religious hopes and aspirations of his time. The last date mentioned in his writings is the 27th year of his exile (572 B.C.). It is not probable that he lived long after that time. Nothing authentic, however, has been handed down to us as to the time, place, or manner of his death. Several unimportant traditions may be found in the work of the Pseudo-Epiphanius, *De vit. et mort. proph.*, in the *Itinerary* of Benjamin of Tudela, and elsewhere.

In the present Massoretic canon the book of Ezekiel stands third in order among those of the so-called Nebi'im Aharônim (latter prophets), being preceded by those of Isaiah and Jeremiah, and followed by that of the twelve minor prophets. In the list of canonical books given in the Talmud (*Baba bathra*, 14, 2) it is the second of the four, being followed by "Isaiah" and "the twelve." Its arrangement is unusually simple, the chronological corresponding for the most part with the natural order. Its three divisions date respectively from before, during, and after the siege of Jerusalem

1. The first 24 chapters carry the reader from the time of the prophet's consecration down to the beginning of the siege of Jerusalem, *i.e.*, from 594 to 590 B.C. They are made up of some 29 distinct oracles, all of which, with the trifling exception of xxi. 33–37 [28–32], have direct reference to the religious and political condition of Ezekiel's compatriots in Babylonia and in Palestine. First in order stands the famous "chariot" (comp. 1 Ch. xxviii. 18) vision, which has been so variously estimated, both from the æsthetic and from the theological point of view, by different critics. Rightly interpreted, as a mere description, it cannot justly be called vague or obscure, and it is hard to account for the strange stories told of the difficulties felt by the Jews in expounding it. The prophet sees in a storm-cloud coming out of the north a group of four living creatures (cherubs), each with four wings and four different faces. Together they are borne upon four wheels which are full of eyes. Resting upon their heads is a firmament, supporting a sapphire throne, whereon is seated a man-like figure, which is almost hidden in a blaze of light. Hereupon Ezekiel receives and eats the bitter-sweet roll in which are written "lamentations and mourning and woe;" he is now ready to go forth to his fellow-countrymen fearlessly declaring the truth as it is revealed to him, however unwelcome it may be. The recorded oracles that follow belong to the fifth, sixth, seventh, and ninth years of his exile. They can be understood only when viewed in connexion with the general history of that period. Soon after his accession to the throne, Zedekiah, the uncle and successor of Jehoiachin, had begun to intrigue against his suzerain the king of Babylon, and had entered into secret relations with the king of Egypt. Ezekiel, like his older contemporary Jeremiah, had insight and sagacity enough to see the unwisdom of such a policy. By various symbolical actions (iv. 1–8; iv. 9–17, v. 1–4; vi. 11; xii. 1–16; xxi. 11 [6]), and also by unequivocal words, he repeatedly declared the certainty of the doom that was impending over Jerusalem, Judah, and all the mountains of Israel; he insisted on the uselessness of any struggle against Babylon, and distinctly predicted Zedekiah's captivity, blindness, and death. In language of the severest invective he rebuked the sins and idolatries, worse than those of Sodom, which had brought this inevitable ruin upon the land and people of the Lord; at the same time he held forth the hope of ultimate restoration and final happiness for both Judah and Ephraim at the end of "forty years," under the guidance of the coming prince

---

[1] Bleek (*Einl.* § 221, note) is probably wrong in identifying both כְּבָר and Chaboras with the חָבוֹר of 2 Kings xvii. 6, which is most probably the Khabur. a tributary of the Tigris (Delitzsch, *Jesaja*, p 16, note).

whose right it is (chaps. xi. 14-21, xvii. 22-24, xx. 40-44, xxi. 32 [27]).

2. The eight chapters which follow (xxv.-xxxii.) belong to the period which elapsed between the beginning of the siege and the announcement of the capture of Jerusalem, xxix 17-21 is an exception, belonging to the 27th year of the prophet's exile, and perhaps also chap. xxv., which has no date. During this period the prophet had no word to speak concerning Judah and Israel.[1] In these chapters the divine woe is pronounced against the seven neighbouring nations which had shown most hostility to Judah and Israel, namely, Ammon, Moab, Edom, Philistia, Tyre, Sidon, and Egypt. The oracles relating to Tyre and Egypt are of great length. The others are comparatively brief. With regard to Tyre its capture and ruin by Nebuchadnezzar are foretold, and it is predicted that within a very short time Egypt shall be desolate forty years. The addition (xxix 17-21) made seventeen years afterwards is apparently due to the fact that the earlier prediction regarding Tyre (xxvi. 7-14) had not been literally fulfilled. This section contains several passages that are specially interesting from a literary point of view. The description of the great merchant city in chap. xxvii. is noticeable for the richness of its details, and also for the vigour with which the comparison to a ship is carried out in ver. 5-9, 26-36. Striking also is the dirge (chap. xxviii. 12-19) upon the king. "Thou deftly made signet-ring, full of wisdom, and perfect in beauty—thou hast been in Eden, the garden of God; every precious stone was thy covering, the sardius, the topaz, and the diamond. Beside the overshadowing cherub did I place thee, thou wast upon the holy mountain of God; thou walkedst up and down in the midst of stones of fire. Thou wast perfect in thy ways from the day that thou wast created, till iniquity was found in thee. By the multitude of thy merchandise they have filled the midst of thee with violence, and thou hast sinned; therefore I will cast thee as profane out of the mountain of God, and the overshadowing cherub shall destroy thee from the midst of the stones of fire." As Tyre had been likened to a ship, so is Egypt with great minuteness of detail likened to a cedar in chap. xxxi. In chap. xxxii. follows a corresponding dirge, in which the assembled nations are represented as mourning women singing their lament over Egypt's grave.

3 The remainder of the book (xxxiii.-xlviii.) dates from after the fall of Jerusalem In chap. xxxiii. we read how the prophet's dumbness was taken away in the twelfth (more probably the eleventh[2]) year of his exile, on the day when tidings were brought of the ruin of the city. Thereupon chap. xxxiv. opens with a brief retrospect, in which the former avarice, idleness, and cruelty of Israel's shepherds which have led to such disaster are exposed and rebuked. But the future—the immediate and the distant—chiefly occupies the prophet's mind. He tells of a coming shepherd, "David," under whose rule great and uninterrupted prosperity is to be secured. Edom is to be finally destroyed, but the twelve tribes are to be resuscitated and gathered together in their own land once more. A final battle has yet to be fought with Gog from the land of Magog, who shall come up against the chosen people with a great army, but only to be utterly destroyed, that Israel may thenceforward dwell in safety, wholly secure from any possible repetition of former calamities. Then follow in detail the final arrangements of the reorganized theocracy. The new temple, its dimensions, construction, furniture, are described; new laws as to sacrifice and festival are given for the priests, prince, and people of the new commonwealth. Directions are given for the equitable partition of the Holy Land among the twelve tribes, and for the building of the new city, which is to be called by the new name Jahveh Shammah, "the Lord is there." In all these regulations a general formal resemblance to the Pentateuchal legislation is abundantly manifest; but the differences of detail are no less striking. The following may be mentioned among others. Ezekiel's temple is larger, but simpler, than that of Solomon. The distinction between the Holy and the Most Holy Place is much less marked Both ark and high-priest are passed over in silence. The priesthood is specifically Zadokite. The "prince" has priestly functions assigned him The morning burnt-offering is brought into special prominence; of the great festivals, the passover and the feast of tabernacles alone are noticed. The feast of pentecost is omitted, nor is any mention made of the great day of atonement, but an observance unknown in the Pentateuch, on the 1st and 7th of the first month, is proposed instead.

The genuineness of the book of Ezekiel has seldom been questioned Some perplexity has been caused by the statement in the Talmud (*Baba bathra* 15, 1) that the men of the great synagogue "wrote" Ezekiel. This obscure expression, by which most probably mere editing was meant, has been deprived of some of its importance by Kuenen's demonstration of the unhistorical character of the entire tradition regarding the great synagogue. Towards the close of last century some doubts were expressed by Oeder, Vogel, and an anonymous English writer in the *Monthly Magazine* (1798), with regard to the genuineness of the last nine chapters, which were supposed rather to be of a Samaritan origin, and by Corodi with respect also to chaps. xxxviii. and xxxix., but these doubts were unanimously set aside by the not too conservative critics of that period. Zunz (*Gottesdienstliche Vorträge*, 1832, also *Gesammelte Schriften*, i. 217 *f.*, 1875) was the first to impugn the genuineness of the entire work, his thesis, in its most recent form, being that no such prophet as Ezekiel ever existed, and that the present work bearing that fictitious name was written somewhere between the years 440 and 400 B.C. His arguments are partly of the *a priori* kind, such as that the special predictions contained in it (xvii. 16, xxiv. 2, 16, &c.) are inconsistent with the genuineness of the book, and that it is inconceivable that in 570 B.C. any prophet could ever have thought of suggesting a new division of the Holy Land, or of drafting a new law-book, or of sketching the plans of a new temple and city. He argues further from the silence of other scriptures, particularly of Jeremiah and of the book of Ezra, with regard to Ezekiel, from certain allusions in the book itself, such as those to Daniel, to the wine of Halybon, &c., also from its grammatical and linguistic peculiarities. There is still practical unanimity, nevertheless, among critics of all schools in the opinion that the stamp of Ezekiel's individuality is unmistakably and even obtrusively visible in every page of the book that bears his name. Keil and Kuenen agree in holding him to have been its author, and its editor as well. He is believed indeed not to have reduced it to its present form till near the close of his life; and many have embraced the opinion of Ewald, that the earlier dates have in some cases been incorrectly given by him. The text, it ought to be remembered, however, has reached us in a somewhat impure state.

The question principally discussed in recent years, and likely to be discussed for some time to come, in connexion with Ezekiel's name is not whether he wrote less than tradition has assigned to him, but rather whether he may

---

[1] The language of xxiv 27, taken along with that of xxxiii. 22, has led many to the conclusion that Ezekiel was literally dumb during this period, and that the oracles belonging to it must necessarily have been written, not spoken. But xxix. 21, dating from a much later period, requires to be also considered in this connexion He may possibly have been speechless on certain subjects only.

[2] So the Peshito and a few of the MSS. See Ewald, Hitzig, Bleek.

not possibly have written more. In connexion with his theory of the late origin of the priestly legislation in the Pentateuch, Graf, in 1866, arguing from admitted similarities of style, gave it out as his belief that Ezekiel was the author of certain chapters of Leviticus (xviii.–xxiii., xxv., xxvi.). This view, which in substance has subsequently been adopted by Colenso and a few others, is manifestly one which does not admit of anything like demonstration. On the other hand, the larger and more interesting inquiry as to the relative priority of the Levitical and Deuteronomic legislations does not fall to be discussed in this place (see PENTATEUCH).

It remains that something should be said of Ezekiel's place as an author and as a religious teacher. His work may be judged from the purely literary point of view more fairly perhaps than that of any of the earlier prophets,—for, unlike them, he was a writer much more than he was a preacher. His oracles were sometimes written before they were spoken; sometimes he wrote what he had no intention of speaking at all. He may be called one of the first sopherîm or scribes, if we use that word in its higher sense as denoting "bookmen," and not mere readers or copyists. As a leader of public opinion, he handled a variety of subjects in a corresponding variety of styles, but always with a manner entirely his own. His prose is invariably simple and unaffected; if there be any obscurity at all, it is really caused by his excessive desire to make it impossible for his reader to misunderstand him. His poetry has suffered much at the hands of translators, and the student who is wholly dependent on our Authorized Version will be often at a loss to understand the comparisons to Æschylus, Dante, or Milton which have occasionally been suggested. More than that of any other prophet, it has been subjected to the extremes of exaggerated praise and undue depreciation by its critics. The sympathetic modern reader, however, will be able to find in it a sublimity, a tenderness, a beauty, a melody, wholly peculiar to itself. Chapter xix., which even Schrader pronounces "masterly," may be specially referred to; also chapters xxviii. and xxxii.

As a religious teacher, it is natural to compare Ezekiel with Jeremiah, his older contemporary, on the one hand, and with his immediate successor, the author of Isa. xl.–lxvi., on the other. It has frequently been said (most strongly perhaps by Duhm) that the contrast is very great, and very much to the disadvantage of Ezekiel. The three men, nevertheless, have much that is common to them all. If Ezekiel sometimes (and especially in his closing chapters) shows a preponderating externalism, a tendency to delight in the fulness and minuteness of his ceremonial details, it must not be forgotten that Jeremiah too looked forward to a restored sanctuary and a reorganized priesthood as essential elements in the perfected theocracy of the future. And if the "Great Unnamed" be justly regarded as one of the loftiest and purest exponents of the spiritual religion of coming days, we must at the same time remember that Ezekiel too had bidden men seek above all things that city, open only to the pure in heart, of which the glory is that "the Lord is there."

Ezekiel is nowhere mentioned by name in the New Testament, and the direct traces of his writings there, apart from those in the Apocalypse, are comparatively few: Matt. vii. 24–27 compared with Ezek. xiii. 10–13, and John x. 16 compared with Ezek. xxxiv. 22, 23, may be referred to Both directly, however, and also through the writer of the Apocalypse, his influence upon Christian thought, and especially upon Christian eschatology, has been considerable.

Literature.—For the ancient, mediæval, and earlier modern commentaries, see Carpzow and other works of introduction. The most important works of recent date are those of Ewald, *Die Propheten des alten Bundes*, vol. ii. 2nd. ed., 1868, Engl. tr. 1877; Hävernick, *Commentar ü. d. Proph. Ezechiel*, 1843; Hitzig, *D. BL.)

EZRA (עֶזְרָא *i.e.*, help; Ἔσδρας; *Esdras*), the famous scribe, was a priest of the line of Zadok. According to the genealogy given in Ezra vii. 1–5, his father's name was Seraiah. If we identify this Seraiah with the person mentioned in Ezra ii. 2, Neh. xii. 1, then the Ezra who is the subject of the present article may well be identified, as has been done by Michaelis and others, with the Ezra named in the last-quoted texts; and in this case he must have been a very old man even at the beginning of that public work with which his name is chiefly associated. But a careful comparison of the genealogy in 1 Ch. vi. 4–15 with that in Ezra vii. leads rather to the conclusion that the latter has most probably been abridged, so far as the more immediate and less eminent ancestors of our Ezra are concerned. They are omitted probably because, though closely connected with Joshua, the son of Josadak, they did not avail themselves of the permission, granted by Cyrus, to return to Jerusalem in 536. They do not seem on that account, however, to have lost much, if any, of the social influence to which their high rank in the priesthood entitled them. Josephus tells us, somewhat mysteriously, that Ezra himself was high-priest of the Jews who were left in Babylon. Be this as it may, we know that when he first appears in history, in the seventh year of Artaxerxes Longimanus (458 B.C.), he is already a man of great learning, zeal, and authority, enjoying the confidence, not only of his own compatriots, but also of the Persian king. It is to be regretted that we should so imperfectly know what was the true condition of the Jews in Babylon during the years that immediately followed the close of the "exile." We have various indications, however, that many of them devoted themselves to the study of the written law, kept up friendly intercourse with their compatriots in Jerusalem, regularly sent free-will offerings to the temple there (Philo, *Ad Caium*, 1013), and made occasional pilgrimages thither (Zech. vi. 9). In Judea, on the other hand, the fifty-eight years between 516 and 458, which are passed over in silence in the history, do not seem to have been more prosperous than the twenty preceding years of which the record has been preserved. Whether influenced by unfavourable reports of the condition of affairs at Jerusalem, or proceeding upon knowledge personally obtained in some previous visit, Ezra, who had "been directing his heart to seek the law of the Lord, and to do it, and to teach in Israel statutes and judgments," asked and received in the above-mentioned year the royal authority to make an official visit to Judea. From the terms of his commission, which are given in Ezra vii. 12–26, we learn that very considerable powers and privileges were at that time conferred upon him. On the first day of the first month of the Jewish year he set out on his westward journey, carrying with him many valuable offerings, and accompanied by some 1500 of his fellow-countrymen. The first considerable halt was made at "the river of Ahava," a locality which has not been identified as yet (it is called Theras in 1 Esdras

viii. 41)[1], and here it was found that no Levites had joined the expedition. A message was accordingly sent to a place (now unknown) called Casiphia, where a large colony of them had settled, inviting their assistance. A considerable number of Levites were thus induced to join the party. A fast was thereafter appointed, the sacred treasures were solemnly entrusted to the keeping of twelve priests and twelve Levites (see Bertheau on Ezra viii. 24), and, deliberately dispensing with the usual military escort, the caravan set out on the twelfth day of the first month, arriving in Jerusalem on the first of the fifth. Here, in the course of the investigation which he had been commissioned to make, Ezra very soon found a field for his reforming activities. He learned that the population generally, priests, Levites, and rulers not excepted, had been intermarrying with the surrounding peoples to an extent which seemed to threaten the subversion of the true religion, and the obliteration of the Jewish nationality. The unexpected discovery filled him with amazement and shame. Soon a large number of the inhabitants came to him, and, with Shechaniah for spokesman, assured him that the people at large were willing to dismiss their foreign wives with their children, if only he would take in hand the direction of the matter. With all convenient speed a solemn assembly of all Judah and Jerusalem was then convened, at which, after Ezra had pointed out to the people their transgressions, it was agreed, with only a few dissentient voices (Ezra x. 15, where for "were employed in" read "stood up against"), to appoint a committee to inquire into and decide on all the cases of mixed marriage. This committee had finished its work by the beginning of the following year, when a complete list was drawn up of those who had "taken strange wives" and now pledged themselves to put them away. Thus far the Scripture narrative has carried us; but at this point, after detailing the events of precisely one year of Ezra's public life, it abruptly breaks off; nor do we read of him again for the next thirteen years. Modern writers are by no means at one in the conjectures they make as to what occurred during the interval. Ewald thinks that he remained in Jerusalem during all the intervening time; others (such as Kuenen) are of the opinion that he very soon left the city, and that during his absence occurred those relapses and disasters which were the occasion of his subsequent activities, and also of those of Nehemiah Hitzig thinks that he never reappeared at all, and corrects Nehemiah accordingly. According to the existing tex , in the twentieth (twenty-first ?) year of Artaxerxes, on the first day of the seventh month, we find him "in the open space that was before the water-gate," solemnly reading, by public request, in the hearing of all the people, the "book of the law of Moses." One of the immediate effects of this fresh publication of the Mosaic law was that straightway the feast of tabernacles was observed as it had not been "since the days of Joshua the son of Nun;" and very soon afterwards a solemn fast was proclaimed, during which a written covenant was drawn up and confirmed by all the people, with Nehemiah at their head, by which they became bound "to walk in God's law which was given by Moses the servant of God," special prominence being given to the following points,—separation from the people of the land, strict observance of the Sabbath day and the sabbatic year, punctual payment of the third part of a shekel for the service of the temple, of the first fruits for the priests, and of the tithes for the Levites. And now, once more, after a second period of public activity, which in this case seems to have lasted for little more than a month, the name of Ezra abruptly disappears from the Scripture narrative. We have no authentic information from any source as to the events of his subsequent life, or as to the time, place, and manner of his death. According to Josephus, "he died an old man, and was buried in a magnificent manner at Jerusalem;" but several palpable blunders with reference to Ezra in other parts of this historian's narrative warn us to be cautious in receiving this statement. Other traditions relate that he died in Babylon, or at Zamzumu on the Tigris, while on a journey from Jerusalem to Susa. According to the best texts of the Apocryphal work known to English readers as 2 Esdras, he did not die at all, but was translated (xiv. 49).

Tradition is somewhat inconsistent with itself also in the account it gives of Ezra's relation to the Pentateuch. At one time it speaks of him as a mere copyist or transcriber; at another time it speaks of him as a voluminous author, a prophet, an independent legislator. Modern criticism in like manner has not as yet reached a unanimous finding on the position occupied by him with reference to previous oral and written enactments While Ewald, on the one hand, maintains that the last editor of the Pentateuch lived when the kingdom of Judah was still standing, Graf and Kuenen, on the other hand, assign to Ezra a very large share in the production of that law-book as we now have it. Between the two extremes there is room for an intermediate view, akin to that of ecclesiastical tradition, which, without determining the extent of Ezra's work, admits that, having before him an earlier work, he added and perhaps also altered some things in an editorial capacity.

It cannot be doubted that Ezra was successful in at least giving to the law as written a prominence and an influence which it had never before possessed. Under him it became the exclusive rule of public and private life in a way that had never before been known. The rise of the order of "scribes," that is, of those whose business it was to know the law, to interpret it, and "make a hedge" round it, can be traced directly to him. If he thus was in a sense the founder of that pharisaism which in later ages degenerated into the well-known forms which were so abhorrent to Christ and to the spirit of Christianity, it ought to be remembered, on the other hand, that the synagogue services,—those assemblies throughout the towns and villages of the land in which the written word was weekly read and expounded with praise and prayer,—are most probably to be traced to his influence. The synagogue worship passed directly over from Judaism into the Christian church; and in this way Ezra, so far as he originated it, has exercised an incalculable influence on the religious culture of the race.

For much valuable information on the life and times of Ezra, and also for references to the older authorities, the histories of Israel by Ewald, Hitzig, Jost, Herzfeld, Graetz, and Kuenen may be consulted. See also Stanley's *Lectures on the History of the Jewish Church*, vol. iii. (J. S. Bl.)

EZRA AND NEHEMIAH, BOOKS OF. The two canonical books entitled Ezra and Nehemiah in our English Bibles correspond to the 1 and 2 Esdras of the Vulgate, to the 2 Esdras and Nehemiah of the LXX., and to the Ezra and Nehemiah of the Massoretic text. Though for many centuries they have thus been treated as separate compositions, we have abundant evidence that they were anciently regarded as forming but one book. Thus, Origen (Euseb., *H. E.*, vi. 25), expressly enumerating the twenty-two books of the old covenant as acknowledged by the Jews and accepted by the Christian church, gives as one of them *Ἔσδρας πρῶτος καὶ δεύτερος ἐν ἑνὶ Ἐζρᾶ*. Melito of Sardis (Euseb., *H. E.*, iv. 26) in like manner mentions the book of Esdras only. So also the Talmud (in *Baba bathra*, 14, 2), nor can it be supposed that Josephus in his enumera-

---

[1] Hit, anciently called Ihi or Ihi-da-Kira, "the well-known spot where caravans make their plunge into the desert," has been suggested. Stanley, *Lectures on Jewish Church*, iii. 116. See p. 670 of the present volume (art. EUPHRATES).

tion (*C. Ap.* i. 8) reckoned Nehemiah as apart from Ezra. Some of the oldest copies of the LXX. make no division between 2 Esdras and Nehemiah; and that the Massoretes themselves recognized no real separation is shown by their epicrisis on Nehemiah.

If the external evidence for the unity of the book of Ezra-Nehemiah is strong, the internal evidence is decisive. As the result of long-continued careful examination, modern criticism, with practical unanimity (Havernick and Keil are hardly exceptions), has reached the conclusion that Ezra and Nehemiah, so far from being separate compositions, together constitute but a section of a larger historical work, the origin, authorship, and plan of which have already been discussed in the article CHRONICLES, to which the reader is referred. Comparatively little remains to be said here on the special questions that arise in connexion with the Ezra-Nehemiah portion of the work.

Contents.—Resuming the abruptly broken off narrative of Chronicles, the first six chapters of Ezra relate how, in the first year of Cyrus king of Persia (537–6), Zerubbabel (called Sheshbazzar in chap. i.), along with Joshua and some 50,000 others who are enumerated according to their families, returned to Jerusalem, set up the altar of burnt-offering there, and in face of many difficulties and discouragements succeeded in rebuilding the temple, which was finally dedicated in the sixth year of Darius Hystaspis (516). An interval of fifty-eight years is then passed over in silence. The next chapters (Ezra vii.–x.) tell of Ezra's mission to Jerusalem in 458, and the dissolution of the heathen marriages there the one result of a period of eight months' activity. Another blank of thirteen years occurs in the history. Then we read (Neh. i. 1–vii. 73*a*) of Nehemiah's expedition to Jerusalem, of the difficulties he encountered on his arrival there (445–4), and how, notwithstanding all the opposition of the Samaritans, the building of the walls was successfully completed in fifty-two days. The list of those who had returned under Zerubbabel is given as in Ezra, chap. ii. The narrative then goes on to relate (Neh. vii. 73*b*–x. 39) how in the same year the law of Moses was anew promulgated by Ezra, being solemnly read by him in the presence of a national assembly; how the feast of the tabernacles was then observed with a strictness that had been unknown since the days of Joshua the son of Nun; and how a written covenant was drawn up and signed by which the people pledged themselves to observe the whole law. After some genealogies and other lists have been given (Neh. xi.–xii. 26), we next have an account of the ceremonial which took place at the dedication of the walls (440); also further particulars of arrangements for due support of the temple-worship, and of steps taken for the exclusion of aliens from the congregation of Israel. Finally, after an interval of not less than twelve years, we read of a second visit of Nehemiah to Jerusalem (probably in 432). This visit was the occasion of renewed efforts towards religious and social reformation. Special mention is made of a collision with Eliashib the high-priest, and also with Joiada his son, which resulted in the expulsion of the latter.

Authorship.—The abstract given above shows very clearly that Ezra-Nehemiah cannot claim to be a continuous chronicle of all the important events of the 110 years of Jewish history over which it extends. Indeed, of the 110 years only some twenty are referred to at all. This want of continuity cannot be attributed to lack of materials; but rather to the specific purpose by which the author was guided in the selection of his facts. That purpose manifestly was to give an account of the progress of the restored theocracy in Judah and Jerusalem, particularly in what related to the temple, and to the share of the priests and Levites in the temple-worship. The striking literary peculiarities which are here displayed in all that is not merely copied from earlier documents, and even in the manner in which these documents themselves are handled, all indicate one and the same author for Chronicles and for Ezra-Nehemiah.

Sources.—It lies open to the most superficial observation that the work of the Chronicler is a compilation derived from many sources. The authorities for this portion of it may be classified as follows: (1) Statistics derived from official records. The list contained in Ezra ii., and repeated with some variations in Neh. vii., may be taken as a specimen. It was already old in Nehemiah's day (Neh. vii. 5). The author mentions also a book of chronicles (*dibrê hajjâmîm*, Neh. xii. 23), from which the information in Neh. xii. 1–26 was derived. Neh. xi. 3–36 and 1 Ch. ix. 3–33 are also probably drawn from a common source of an official character. (2) A history of the building of the temple and of the obstacles that had to be overcome, written in Chaldee. This history seems to have furnished the section Ezra v. 1–vi. 18, and also to have been the source of the document given in Ezra iv. 8–23 (3) Ezra's personal memoirs. These have been directly transcribed in Ezra vii. 27–ix. 15; and they have been drawn upon for Ezra vii. 1–11, for chap. x., and also for Neh. vii. 73*b*–x. (4) Nehemiah's personal memoirs. These have been extracted from in Neh. i. 1–vii. 5, xi. 1, 2, xii. 31–42, xiii. 4–30, and they have been combined with those of Ezra in Neh. vii. 73*b*–x.

Date.—In the article CHRONICLES it has been shown that the genealogies there given (1 Ch. iii. 19 *sq.*), when fairly interpreted, must be taken as reckoning the descendants of Zerubbabel to six generations, thus bringing the history down to near the close of the Persian monarchy. In Ezra-Nehemiah all the indications of date which are given go to support the same conclusion. Neh. xii. 11, 22 brings the list of high-priests down to Jaddua, the contemporary of Alexander the Great. In verse 22 there is a reference, moreover, to Darius Codomannus, the opponent of Alexander. The kings of Persia are throughout alluded to in a manner which is fitted to suggest that the Persian empire had already passed away. Ezra and Nehemiah themselves are occasionally spoken of, not as contemporaries, but as vanished heroes of the venerable past (see, for example, Neh. xii. 26, 47). But the same data which forbid us to fix a date for Ezra-Nehemiah earlier than 350 B.C., manifestly also forbid the conclusion of Spinoza (*Tract. Theol. Polit.*, x. 28) who placed the work later than the Maccabees.

Credibility.—The doubts raised by Graf and others with reference to the historical value of the earlier portion of the work of the Chronicler do not extend to the Ezra-Nehemiah section. There is general concurrence in the conviction that the sources he had access to fully guarantee the trustworthiness of his narrative. A question has, indeed, been raised as to the measure of sagacity he has shown in his employment of some of the materials he had at his disposal, Bertheau and others believing (in opposition to Ewald) that he has inappropriately introduced into the narrative of Ezra iv. certain documents which really refer to the later period of Nehemiah.

The text of Ezra-Nehemiah has reached us in a somewhat impure state. Great caution requires to be exercised, especially as regards the numerals and proper names. Some help may be got from the LXX. translator, who has been faithfully literal "almost to unintelligibility."

Literature.—In addition to the works referred to under CHRONICLES, the following may be consulted:—Zunz, *Gottesdienstliche Vorträge* (1832) p. 18 *sq.*; Bertheau's admirable commentary in the *Exegetisches Handbuch* (1862); his article "Chronik" in Schenkel's *Bibel-Lexicon*; Dillmann on "Chronik" in Herzog's *Real-Encyclopädie*; Nagelsbach on "Ezra" in the same work; Keil, *Commentar* (Engl. tr. 1873); Schultz, in Lange's *Bibelwerk* (1876; Eng. tr 1877); Rawlinson in the *Speaker's Commentary*, vol. iii. (J. S. BL.)

F was the sixth letter of the primitive Greek alphabet. It represented the sound of our W, *i.e.*, a soft labial. But that sound was unpleasant to the Greek ear, and it began to fall out of use at an early time in all parts of Hellas; it disappeared most completely in the Ionic and in the cognate Attic dialect; it survived longer in the Æolic and the Doric, and it is not improbable that the symbol F may have been written in these dialects after the sound it represented had perished. The grammarians in dealing with this extinct letter gave it the name "digamma" from the shape of the symbol, *i.e.*, a gamma (Γ) with a second horizontal stroke, and they added the name "Æolic" from a mistaken impression that it lingered longer in that dialect than in the Doric. It was from the Doric of Cumæ, as has been already said (see ALPHABET), that the Latins derived the symbols of their alphabet, and F with the others. But though the Latin language contained the sound *w*, it did not seem necessary to have a special symbol to distinguish it from the vowel *u*: and F was used to express quite a different sound, one which the Greek did not possess. This was probably the same sound which the letter still denotes with us—the hard labio-dental (to which V is the corresponding soft sound) produced by pressing the upper teeth on the lower lip, and then letting the breath escape laterally or through the interstices of the teeth—very much, as Quintilian says in his amusing description of the Latin sound (xii. 10, 29), which "pæne non humana voce, vel omnino non voce, potius inter discrimina dentium efflanda est." It was quite distinct from *ph*—a distinction which we have sacrificed; *ph* was a *p* followed by a slight breath, not quite so strong as in "upheave," but very similar; and it expressed in Latin the sound of the Greek *ϕ*. The Greeks found the Latin *f* a difficult sound—much as the Germans find the English *th*—and we find Cicero laughing at a Greek witness because he could not pronounce the first letter of "Fundanius," which he doubtless called "P-hundanius." The emperor Claudius has the credit of endeavouring to improve the Roman system of spelling by filling up of some of the defects of the alphabet. Thus, he proposed to use an inverted F (Ⅎ) to denote the corresponding soft consonant (*v*) which, as we have said above, had no special symbol in the Roman alphabet. Thus in inscriptions of his reign we find ℲOℲIMUS, IOℲI, &c. But this improvement did not long survive its author.

FABER, BASIL (1520–1576), a German schoolmaster and theologian, was born at Sorau in Lower Lusatia in 1520. After studying at the university of Wittenberg, which at that time was under the direction of Melanchthon, he chose the profession of a schoolmaster, and became rector of the school at Nordhausen, whence he went successively to Tennstädt, Magdeburg, and Quedlinburg. His religious opinions led to his being removed from his office in the last-named place in 1570, but a short time afterwards he received and accepted an invitation to become master of the Raths-gymnasium at Erfurt, where he continued till his death in 1576. Faber was a strong Lutheran, and translated the first 25 chapters of Luther's commentary on Genesis, and in various other ways zealously endeavoured to promote the spread of Lutheran opinions. He was a contributor to the first four of the *Magdeburg Centuries*. He is, however, best known by his *Thesaurus Eruditionis Scholasticæ*, a work which for many years retained a high place in Germany as a scholastic manual. It was originally published in 1571, and the last edition, edited and improved by Leich, appeared in 1749.

FABER, CECILIA BÖHL VON (1797–1877), the great woman-novelist of Spain, better known by her masculine pseudonym of Fernan Caballero, was born at Morges, Canton de Vaud, in 1797, her parents being then on a tour through Switzerland. Her father, Johann Nikolas Böhl von Faber, the son of a Hamburg merchant, had removed early in life to Cadiz, prospered in business, professed the Catholic faith, and married Doña Francisca de Larrea, a member of the Spanish aristocracy. Cecilia received a considerable part of her education in Germany at Gorslow near Schwerin, where her father had an estate; and here, besides other accomplishments, including a complete mastery of German and Spanish, she acquired a competent knowledge of Latin, English, French, and Italian. In 1813 she returned to Cadiz, and in the following year became the wife of Captain Planells, whom she accompanied to America, where she seems to have spent some years of married life. Not long after the death of her first husband, she was married to the Marques de Arco Hermoso, and in virtue of her exalted station frequently attended the court of Madrid, where she was much admired for her beauty, vivacity, and wit. In 1837, having, by the death of the marquis (1835), been again left a widow, she gave her hand to Señor de Arrom, a member of the bar. This union appears to have been productive of little happiness, and when her husband accepted an appointment as Spanish consul abroad, she decided to remain alone in Seville. It is to the trials and disappointments that came upon her in the later years of her life that the world is indebted for the fascinating works of this distinguished writer, who seems to have been driven to authorship less by any imperious literary instinct than by the necessity she felt for some anodyne against sorrow. Rarely does it happen that literary genius such as she possessed lies dormant for so long a time, unguessed by the world, hardly suspected even by its owner. As early as 1828, indeed, if not earlier, she had committed to writing, in the form of a novel, a tale of peasant life, which she had heard prosaically told under the olive trees at the village of Dos Hermanas, in the neighbourhood of Seville, but singularly enough, she had preferred to make use of the German language, and does not appear to have contemplated publication. Although Washington Irving, in the course of one of his visits to Spain, had seen and praised the manuscript, and had encouraged the writer to cultivate literature, and especially Spanish literature, as a serious pursuit, it was not till many years afterwards that this first effort, *La Familia de Alvareda*, was presented to the public; nor was it till after her fiftieth year had been passed that she appeared as an author at all, and even then only under an assumed name. Her first, and in some respects her best, publication, *La Gaviota* (The Sea-Gull), was originally printed in short daily instalments in the pages of a Madrid newspaper in 1849. It met with high appreciation in the capital, and was accordingly followed at brief intervals by *Elia*, *Clemencia*, *La Familia de Alvareda*, *Una en Otra*, *Simon Verde*, and other *Cuadros de costumbres populares* (pictures of popular life). Slowly but surely the works of the new writer found their way all over the peninsula, and gradually were translated into French and German, until within ten years she had achieved a European reputation. A collected edition of her works in 13 volumes was issued from the royal printing press at Madrid in 1859, and about the same time she received an appointment as governess to the royal children. From 1863 to 1868 she occupied rooms in the palace of the Alcazar,—

the Hampton Court of Seville. At the revolution of 1868 she removed to private apartments in the Calle de Burgos; and though with advancing years her pen became less busy, she continued with unimpaired faculties to take a keen and kindly, if somewhat needlessly anxious, interest in the important events that were revolutionizing the institutions of her country. Among the numerous schemes of beneficence that busied her, especially in later life, was the promotion of a society for the prevention of cruelty to animals. She was engaged in correcting for the press the last sheets of a compilation of stories, nursery-rhymes, &c., for the use of children (*Cuentos, Oraciones, Adivinas, y Refranes populares é infantiles*) when she died in her eightieth year, on April 7, 1877.

Her works, though numbering about fifty in all, are none of them very large, and she cannot be called a voluminous writer. They all belong to one comparatively brief period of her long and chequered life; and, if classified at all, can be so only by the application of some comparatively artificial criterion. Some deal principally with the features of Andalusian life as it exists among the labourers and peasants; some delineate the higher phases of society; and in others "the interest lies, not in the characters of the persons and the description of scenery and manners, but in the selection of incidents which are intended to point a moral or adorn a proverb." While all are marked by deep and tender sympathy with nature, by subtle and unerring delineation of character, by a quaint humour that is never far removed from pathos, and by an exquisite power of expression, it may safely be said that, as "George Sand" is most delightful when she lovingly depicts the quiet scenes of Berri, the home of her youth, so Fernan Caballero excels in her descriptions of the peasant life of Andalucia. Foreign critics complain not unnaturally of the bitter ultramontane prejudice and the exaggerated *Españolismo* which are so needlessly paraded in almost all her works; yet even this peculiarity, as imparting to these productions of undoubted genius a unique *couleur locale*, may fairly enough be held to enhance rather than diminish their value in the eyes of the dispassionate student of the infinitely varied phases of human thought and feeling.

Besides those already noted, the following stories may be mentioned:—*Cuentos y Poesias populares Andaluces*, *Un Verano en Bornos*, *Cosa cumplida solo en la otra vida*, *La Estrella de Vandalia*, *Pobre Dolores*, &c. Her principal works may be found in the *Coleccion de Autores Españoles*, published by Brockhaus, Leipsic. Most of them have been translated into French. *La Gaviota* and *Elia* have been translated into English,—the former by the Honourable Augusta Bethell (1867); *La Familia de Alvareda*, under the title of *The Castle and the Cottage in Spain*, by Lady Wallace, appeared in 1861, and a second translation, by the Viscount Pollington, was published in 1872. An appreciative and able estimate of Fernan Caballero, with a full analysis of several of her best known works, appeared in the *Edinburgh Review*, July 1861.

FABER, Frederick William (1814–1863), a famous hymn writer and theologian, the son of Thomas Henry Faber, secretary to Dr Barrington, bishop of Durham, was born on the 28th of June 1814, at Calverley, Yorkshire, of which place his grandfather, Thomas Faber, was vicar. He attended the grammar school of Bishop Auckland for a short time, but a large portion of his boyhood was spent in Westmoreland; and the lake scenery left an indelible impression on his imagination. He afterwards went to Harrow, where he remained until he became a student of Balliol College, Oxford, in 1833. About the beginning of 1835 he began to reside at University College, in consequence of obtaining a scholarship there; and in 1836 he gained the Newdigate prize for a poem on the "The Knights of St John," which elicited special praise from Keble. Among his college friends were Dean Stanley and Sir Roundell Palmer. In January 1837 he was elected fellow of University College. Meanwhile he had given up the Calvinistic views of his youth, and had become an enthusiastic admirer and follower of John Henry Newman. In 1841 a travelling tutorship took him to the Continent; and, on his return, a book appeared called *Sights and Thoughts in Foreign Churches and among Foreign Peoples*, which he dedicated to his dear friend the poet Wordsworth. The journal of his travels is beautifully written, and reveals an intense love of nature, and an almost southern susceptibility to her charms. There is none of the interjectional piety which so often disfigures books of travel written by religious men. He accepted the rectory of Elton in Huntingdonshire, but soon after proceeded again to the Continent, with the intention of studying the methods followed by the Roman Catholic Church. Returning to Elton, he devoted himself, with great earnestness, to the work of his parish, although the two years he spent there were marked by severe mental struggles, which issued in his conversion to the Roman faith in November 1845. On leaving Elton his parishioners sobbed out—"God bless you, Mr Faber, wherever you go" (*Life*, p. 238). He founded a religious community at Birmingham, called Wilfridians, after the name Wilfred, which Faber assumed. The community was ultimately merged in the oratory of St Philip Neri, of which Father Newman was the head; and in 1849 a branch of the oratory—subsequently considered independent—was established in London, first in King William Street, and afterwards at Brompton over which Father Faber presided till his death on the 26th of September 1863. In spite of his weak health, an almost incredible amount of work was crowded into those years. He published a number of theological works, and edited the *Oratorian Lives of the Saints*. He was an eloquent preacher, a brilliant talker, and had an unsurpassed power of gaining the love of all with whom he came in contact. It is mainly as a hymn writer, however, that he will be known in the future. There is a sweet saintliness, and at the same time a grandeur of thought and a simplicity of poetical expression in Faber's hymns, which we fail to find in much of the Protestant hymnology. Among the finest are—"The Greatness of God," "The Will of God," "The Eternal Father," "The God of my Childhood," "Jesus is God," "The Pilgrims of the Night," "The Land beyond the Sea," "Sweet Saviour! bless us ere we go," "I was wandering and weary," and "The Shadow of the Rock." The hymns are largely used in Protestant collections.

The only complete edition of Faber's *Hymns* is the one published by Richardson and Son in 1861, of which a second issue appeared in 1871. In addition to hymns, pamphlets, letters, and translations, he published the following works:—*Sights and Thoughts in Foreign Churches and among Foreign Peoples*, *All for Jesus*, *The Precious Blood*, *Bethlehem*, *The Blessed Sacrament*, *The Creator and the Creature*, *Growth in Holiness*, *Spiritual Conferences*, *The Foot of the Cross*, *Ethel's Book*, *Sir Lancelot*, *Poems*, *An Essay on Canonization and Beatification*, *Characteristics of the Lives of the Saints*, and *Catholic Home Missions*. *Notes on Doctrinal and Spiritual Subjects* were edited by Father Bowden, and issued after Faber's death. See his *Life and Letters*, by Father Bowden, and *A Brief Sketch of the Early Life of the late F. W. Faber, D.D.*, by his only surviving brother.

FABER, George Stanley (1773–1854), an English clergyman, son of Thomas Faber, vicar of Calverley, Yorkshire, was born October 25, 1773. He entered University College, Oxford, in 1789, graduated B.A. in 1792, and in 1794 was elected fellow and tutor of Lincoln College. He received his M.A. degree in 1796, and his B.D. degree in 1803. In 1801 he was appointed to the office of proctor and the same year he delivered the Bampton lecture, which he afterwards published under the title of *Horæ Mosaicæ*. He was at this time one of the foremost preachers of the university, and his earnestness and eloquence secured for his discourses an interested and eager audience. In his preaching he gave considerable prominence to the doctrines usually known as evangelical, but he endeavoured to avoid as much as possible the technicalities of a system, and to give all that he spoke a directly practical bearing. Marrying in 1803, he lost his fellowship, and for two years he acted as curate to his father. In 1805 he became vicar of Stockton-on-Tees, and three years later of Redmarshall, both in the county of Durham. In 1811 he obtained the rectory of Long Newton, in 1831 was made a prebendary of Salisbury Cathedral, and the following year received the mastership of Sherborn Hospital, where he died in the master's residence on 27th January 1854. Faber wrote over forty volumes treating more or less directly of theological subjects, and chiefly of those which are of a polemical nature. They manifest great and varied erudition, and considerable acuteness within a certain limited sphere, but his abilities are frequently misapplied in vain endeavours to establish baseless theories, and in minute discussions regarding subjects of no general or lasting importance.

Among his principal works are *Mysteries of the Cabiri, or the Great Gods of Phœnicia*, 2 vols., 1803; *Origin of Pagan Idolatry*, 3 vols., 1816; *Difficulties of Romanism*, 1826; *Apostolicity of Trinitarianism*, 2 vols., 1832; *Election*, 1842; *Papal Infallibility*, 1851; and the *Sacred Calendar of Prophecy*, 3 vols., 1828. The last is his most popular work, and has passed through several editions.

FABER, or LEFÈVRE, JACOBUS (*c.* 1450–1536), surnamed Stapulensis, an eminent pioneer of the Protestant movement in France, was born of humble parentage at Étaples in Picardy about 1450, and received his higher education at the university of Paris. After having graduated, and for some time made use of the privilege of teaching which the degree of magister at that time actually conferred, he went to Italy for the prosecution of his favourite classical studies. On his return to Paris he became professor in the college of Cardinal Lemoine, and at the same time he began the publication, with introductions, commentaries, or translations, of various famous works, including the *Physics*, *Metaphysics*, and *Ethics* of Aristotle. In 1507 he commenced residence within the Benedictine Abbey of St Germain des Près near Paris, of which his friend Briçonnet had become superior; and here he began to give himself to biblical studies. The first fruit of his labours was the *Quintuplex Psalterium; Gallicum, Romanum, Hebraicum, Vetus, Conciliatum* (Parisiis, Hen. Stephani, 1509). This was followed in 1512 by *S. Pauli Epistolæ XIV. ex vulgata Editione, adjecta intelligentia ex Græco cum commentariis*, a work characterized by great intelligence and independence of judgment. His *De Maria Magdalena et triduo Christi disceptatio*, published in 1517, provoked a violent controversy, and was ultimately condemned by the Sorbonne in 1521. In 1523 he removed to Meaux as vicar to his friend Briçonnet, who had recently been advanced to that bishopric; and in the same year he published his new French translation of the New Testament, also *Les Épistres et Évangiles pour les LII. dimanches de l'an à l'usage du diocèse de Meaux*. In his prefaces and notes to both these works he had expressly declared his conviction that the Bible is the only rule by which doctrines are to be tried, and also that justification is by faith alone. These utterances excited much hostility, but the powerful protection of the king (Francis I.) and of the Princess Margaret shielded him from any serious consequences. After the battle of Pavia (25th February 1525), Francis being at the time in captivity, Faber was formally condemned, and his works were vigorously suppressed by a commission of the parliament; these proceedings, however, were at once quashed on the return of the king some months afterwards. In 1526 Faber became librarian in the royal palace at Blois; and two years afterwards his translation of the Pentateuch appeared. In 1530 he completed his translation of the Bible, which at once took a high place, has often been reprinted, and has indeed been the basis of all subsequent French versions, both Roman Catholic and Protestant. In 1531 he was induced by Margaret (who had become queen of Navarre) to take refuge at Nérac from the storm of persecution which had broken out with fresh violence; and here he spent the closing years of his life in comparative quietude. His death took place in 1536.

See Graf in *Zeitschr. f. histor. Theol.*, 1852, and in Herzog's *Real-Encyclopadie*. A full list of Faber's very numerous writings is given in the *Biographie Generale* (*s. v.* Lefevre d'Étaples).

FABER, or LEFÈVRE, JOHANN (1478–1541), surnamed from the title of one of his works Malleus Hæreticorum, was the son of a smith named Heigerlin, and was born at Leutkirch in Swabia in 1478. At an early age he joined the Dominicans, and he afterwards studied theology at Freiburg in Breisgau, where he received the degrees of M.A. and doctor of canon law. His reputation for ability and learning soon led to his being appointed vicar of Lindau and Leutkirch, and shortly afterwards canon in the cathedral church of Basel. In 1518 the bishop of Constance named him one of his vicar generals, and Pope Leo X. appointed him to be papal protonotary. At this time Faber was on a friendly footing with the principal German Reformers, and sympathized generally with their opinions. Of the many evil customs with which the church had become infected he was well aware, and he was so energetic in opposing the practice of indulgences in his diocese that he was looked upon with suspicion at Rome. He also defended Luther against the attacks of his opponent Eck, although he admitted that many of Luther's views were too far in advance of the times. In 1521, however, Faber made a journey to Rome, which seems to have wrought almost an immediate and complete change in his manner of regarding the efforts of the Reformers, for as soon as he returned he began strenuously to oppose them both by speech and writing. In 1523 he appeared as an opponent of Zwingli in a disputation at Zurich, and the same year he published his tractate against Luther entitled *Malleus Hæreticorum*. From this time his chief efforts were devoted either to win back the Reformers to the church of Rome, or to get that church to adopt such measures as would best tend to nullify their influence with the people. Among other means employed by him was the establishment of a boarding-house for poor theologians, in order to train a class of preachers fitted by their peculiar qualifications to rival the Reformed preachers in popular esteem. In 1526 Faber became court preacher to the emperor Ferdinand, and in 1527 and 1528 was sent by him as ambassador to Spain and England. He was chosen bishop of Vienna in 1531, and died there 12th June 1541. Most of his works were directed against the doctrines of Protestantism. They were collected and published in 3 vols., Cologne, 1537, 1539, and 1541.

FABIAN GENS, THE, was said by the genealogists to have been descended from Hercules and a daughter of the Arcadian Evander. Niebuhr's supposition of the Sabine origin of the clan has been held to be inconsistent with the tradition regarding the pre-Sabine institution of the *Lupercalia*, the yearly festival inaugurated at the sacrifice which Romulus and Remus offered in the Lupercal after the death of Amulius, and at which, according to the legend, they agreed to distinguish their respective adherents by the names Quinctilii and Fabii. The two colleges of the Luperci retained these designations long after the members of the two clans ceased to exercise exclusive control over the *sacra*. The chief family names of the Fabian gens or clan, during the commonwealth, were Vibulanus, Ambustus, Maximus, Buteo, Pictor, Dorso, Labeo; and Verrucosus, Rullianus, Gurges, Eburnus, Æmilianus, Allobrogicus, may be enumerated among their *agnomina*. Vibulanus and the two following names belonged, however, to the same family at different epochs, Q. Fabius Vibulanus, who was consul in 412 B.C., having been the first to assume the cognomen of Ambustus; while Rullianus, according to some accounts, changed the latter into Maximus, in 312 B.C.—his full name thus being Q. Fabius Maximus Rullianus. Of the Vibulani, first noticed about the year 486 B.C., the most distinguished were the three brothers, Quintus, Kæso, and Marcus, one or other of whom filled one of the two consulships from that date to 479. In that year the Fabii—to the number, it is said, of 306 patricians, exclusive of their numerous dependents—emigrated from Rome under the leadership of Kæso, who had just been consul for the third time, and settled on the banks of the Cremera, a few miles above Rome. Some accounts have attributed that secession to the opposition which the Fabian support of the plebs had aroused among the old patrician families. For two years the exiles or seceders continued to be the city's chief defence against the Veientes, until at last they were surprised by the latter, and cut off to a man. The only survivor of the gens was the son of Marcus, who had been left behind at Rome, and who thus became the ancestor of the succeeding Fabii. He was consul in 467 B.C., and a member of the second decemvirate in 450. When the Gauls captured Rome in 390 the pontifex maximus was a Fabius Ambustus. The most famous of this line—*i.e.*, supposing Rullianus to have been the first Maximus—was the father of Rullianus. He was thrice consul, and was dictator in 351 B.C. His son, Rullianus, called by Arnold the "Talbot of the 5th century of Rome," was master of the horse in 365 B.C. to Papirius Cursor, by whom he was degraded for having fought and beaten the Samnites contrary to orders. In 296, when consul for the sixth time, he defeated, at the great battle of Sentinum, the combined forces of the Etrurians, Umbrians, Samnites, and Gauls. But the greatest Roman who bore the name of Fabius—one of the most illustrious Romans of the republic—was Q. Fabius Maximus Verrucosus (see below). Of the later Fabii, Q. Fabius Maximus Æmilianus and Q. Fabius Maximus Allobrogicus were among the most distinguished The former, a Fabius only by adoption, served in the last Macedonian war, 168 B.C., and was consul in Spain 145 B.C., when he conquered Viriathus. He was the pupil and the patron of the historian Polybius. The Fabius named Allobrogicus (after his victory over the Allobroges and their ally Bituitus, king of the Arverni) was consul in 121 B.C. The Fabian name is occasionally met with as late as the 2d century A.D.

Perhaps the most complete work on this family is the *Disputatio de Gente Fabia*, by G N Du Rieu, Leyden, 1856, where may also be found a list of previous writers on the same subject.

FABIUS MAXIMUS VERRUCOSUS, Quintus, also named *Cunctator* and *Ovicula*, was one of the most distinguished Romans of the republic,—the incarnation of all that a Roman meant by patriotism. It appears that he served his first consulship in Liguria, 233 B.C., that he was censor in 230, and consul for the second time in 228. In 218 he was sent to Carthage to inquire whether that state approved of Hannibal's conduct in attacking Saguntum. The answer proved unsatisfactory; and Fabius, assuming the haughty dignity of a Roman senator, and folding up his cloak so as to form a cavity, thus addressed the nobles of Carthage: "Hic vobis bellum et pacem portamus; utrum placet sumite." Being answered that he might give which he pleased, he indignantly exclaimed, "Then I give you war;" and the deputies returned to Rome to state the result of their mission. The disastrous campaign on the Trebia, and the defeat on the banks of the Thrasymene Lake, warned the Romans that their successful resistance to Hannibal, and even their existence, depended on the wisdom of the general to whom they entrusted their troops. So Fabius was named dictator in 271, and began his tactics of "masterly inactivity." Manœuvring among the hills, where Hannibal's horse were useless, he cut off his supplies, harassed him incessantly, did everything except fight. His steady adherence to this plan, in spite of all the misconceptions which his caution had aroused at Rome, evinced the moral strength of the man. He was suspected of an ambition for the prolongation of his command. Hannibal was one of the few men in Italy who understood him. Even Minucius, the master of the horse, ridiculed the proceedings of Fabius; and he seized the opportunity of the latter's absence at Rome to attack the enemy, and win a victory. This tended only more strongly to confirm the opponents of Fabius in their opinion, and the command was divided between Minucius and Fabius. The result was exactly such as might have been anticipated. Minucius engaged in battle with Hannibal, and his army was on the verge of ruin when the opportune arrival of Fabius changed the aspect of affairs. Minucius seems to have had the moral courage to confess his folly, and cheerfully to submit to the orders of Fabius. Fabius having retired at the end of the legal time of six months, the conduct of the war was entrusted to Æmilius, who followed the ex-dictator's plan, and Varro, who did not. "You must beware of Varro, as well as of Hannibal," said Fabius, and the warning was followed by the disaster of Cannæ. Fabius might have accused him; but it is narrated that the magnanimous Roman thanked his rival "because he had not despaired of the republic." After the defeat at Cannæ (216 B.C.) he was appointed to the command of the armies with Marcellus, "the sword," as Fabius himself was "the shield," of the republic. He laid siege to the important city of Capua; and when Hannibal marched towards Rome, threatening the city itself, Fabius remained firmly at his post. In 214 B.C. when consul for the fourth time, he captured Casilinum in Samnium. In his fifth consulship, 209, he took the city of Tarentum, and when it was proposed, towards the conclusion of the war, that Scipio should pass into Africa, Fabius was decidedly opposed to the scheme. He did not live to witness the final success of Scipio, having died at an advanced age, 203 B.C. In the previously named year he became *princeps senatus*, a dignity almost hereditary in the family of the Fabii Maximi.

FABIUS PICTOR, Quintus, the father of Roman history, was the grandson of the Fabius who, surnamed Pictor for his artistic skill, bequeathed that name to a family of the Fabian gens. In the interval between the first and second Punic wars we find him taking an active part in the subjugation of the Gauls in the north of Italy (225 B.C.); and after the battle of Cannæ (216), he was employed by the Romans to proceed to Delphi in order to consult the oracle of Apollo. The rude muse of Nævius had already celebrated in verse the glory acquired by the Roman arms in the first Punic war, and Ennius had clothed the annals of his adopted country in the language of poetry. But till the time of Fabius Pictor, no one had appeared to chronicle in simple prose the *res gestæ* of Rome and the Romans. The historian's materials consisted of the *Annales Maximi*, *Commentarii Consulares*, and similar records (see Fasti) of names, feasts, battles, prodigies, and the like, together with such chronicles as every great Roman family preserved of its own deeds; as also—what furnished the most valuable part of his work—his own experiences in the second Punic war. His *Annals*, as they were called, existed in the time of Pliny the Elder, but are now known only from a few fragments and allusions. According to Livy, they contained a description of the battle of Thrasymene, and Niebuhr even conjectures that Dion Cassius derived his knowledge of Roman constitutional history from Pictor's work It seems certain, however, that Fabius wrote his *Annals* in Greek. Dionysius expressly asserts this to be the fact; and Cicero's allusion to the Latin prose writer who lived between the time of Cato and that of Piso probably refers to Servius Fabius Pictor.

See C. T. Cruttwell's *History of Roman Literature*, London, 1877, Du Rieu's *Disputatio*, and especially Wagner's *History of Roman Literature*, 1873, translated from Teuffel's *Geschichte*, 1870.

FABLE. With certain restrictions, the necessity of which will be shown in the course of the article, we may accept the definition which Dr Johnson proposes in his life of Gay:—"A *fable* or *apologue* seems to be, in its genuine state, a narrative in which beings irrational, and sometimes inanimate (*arbores loquuntur, non tantum feræ*), are, for the purpose of moral instruction, feigned to act and speak with human interests and passions." Before tracing the history of the fable we may compare it with its nearest congeners in literature, the myth, the allegory, and the parable. The myth, whether, as is most commonly the case, it has its origin in some physical phenomenon, or can be traced to mistaken metaphor or distorted history, or is merely a play of the imagination, is always the unconscious product of the race, never like the fable invented expressly for a moral or didactic purpose. A closer analogy to the fable is to be found in the literary myth, the artificial product of a later age, such, for instance, as the Λιταί of the *Iliad*, the Hesiodic legend of Pandora, or the story of Er in the *Republic* of Plato. Yet these allegorical myths are clearly distinguished from the fable, inasmuch as the story and the moral are intermingled throughout. Between the parable and the fable there is no clear line of distinction. Archbishop Trench insists on two essential differences,—first, that the parable teaches spiritual truths, whereas the fable never lifts itself above the earth, and secondly, that the parable never transgresses the actual order of nature. But, though the parables of the New Testament may well be set in a class by themselves, a comparative study of religious writings will show that the parable is one of the commonest forms of religious teaching, and that no hard or fast line can be drawn between moral and spiritual truths. The second difference we should regard as accidental, and it is not altogether borne out by facts.

Most writers on the history of the fable are content to trace its origin to Æsop or the *Pañca Tantra* of the mythical Vishnu Sarman, and these are doubtless the oldest collections which have been preserved in writing; but though we possess no earlier record, we may, from its wide diffusion, regard it as a natural growth of the imagination, and one of the most primitive forms of literature. It springs from the universal need of men to express their thoughts by concrete images and emblems, and thus is strictly parallel to the use of metaphor in language. Even now fables are made every day, and a quick-witted race like the Arabs will invent fables at every turn as the readiest form of argument. To take a familiar illustration, the wise saws and modern instances of Sam Weller would only need a slight expansion to form a very respectable book of fables. Our most familiar proverbs are often fables in miniature.

With the fable, as we know it, the moral is indispensable. As La Fontaine puts it, an apologue is composed of two parts, one of which may be called the body, the other the soul. The body is the fable, the soul the morality. But if we revert to the earliest type we shall find that is no longer the case. In the primitive beast-fable, which is the direct progenitor of the Æsopian fable, the story is told simply for its own sake, and is as innocent of any moral as our fairy tales of Little Red Ridinghood and Jack and the Beanstalk. Thus, in a legend of the Flathead Indians, the Little Wolf found in cloud land his grandsires the Spiders with their grizzled hair and long crooked nails, and they spun balls of thread to let him down to earth; when he came down and found his wife the Speckled Duck, whom the Old Wolf had taken from him, she fled in confusion, and this is why she lives and dives alone to this very day. Such animal myths are as common in the New World as in the Old, and abound from Finland and Kamtchatka to the Hottentots and Australasians. From the story invented, as the one above quoted, to account for some peculiarity of the animal world, or told as a pure exercise of the imagination, just as a sailor spins a yarn about the sea-serpent, to the moral apologue the transition is easy; and that it has been effected by savages unaided by the example of higher races seems sufficiently proved by the tales quoted by E. B. Tylor (*Primitive Culture*, vol. i. p. 411). From the beast-fables of savages we come next to the Oriental apologues which are still extant in their original form. The East, the land of myth and legend, is the natural home of the fable, and Hindustan was the birth-place, if not of the original, of these tales, at least of the oldest shape in which they still exist. The *Panca Tantra*, or fables of the Brahma Vishnu Sarman, have been translated into almost every language and adapted by most modern fabulists. The *Kalila wa Damna* (names of two jackals), or fables of Bidpai, is an Arab version made about 760 A.D. From the Hebrew version of Rabbi Joel, John of Capua produced a Latin translation about the end of the 15th century, whence all later imitations are derived. (See Monier Williams, *Indian Wisdom*, p. 508.) The *Hitopadesa*, or "friendly instruction," is a modernized form of the same work, and of it there are three translations into English by Dr Charles Wilkins, Sir William Jones, and Professor F. Johnson. The *Hitopadesa* is a complete chaplet of fables loosely strung together, but connected so as to form something of a continuous story, with moral reflections freely interspersed, purporting to be written for the instruction of some dissolute young princes. Thus, in the first fable a flock of pigeons see the grains of rice which a fowler has scattered, and are about to descend on them, when the king of the pigeons warns them by telling the fable of a traveller who being greedy of a bracelet was devoured by a tiger. They neglect his warning and are caught in the net, but are afterwards delivered by the king of the mice, who tells the story of the Deer, the Jackal, and the Crow, to show that no real friendship can exist between the strong and the weak, the beast of prey and his quarry, and so on to the end of the volume. Another book of Eastern fables is well worthy of notice, *Buddhaghosha's Parables*, a commentary on the *Dhammapada, or Buddha's Paths of Virtue*. The original is in Pali, but an English translation of the Burmese version has been made by Captain T. Rogers, R.E. As the work is little known we may venture to extract a single gem. A young mother, disconsolate for the death of her first-born son, carries the dead body of her child from house to house seeking medicine to restore it. At last she is sent to Para Takem, the lord and master of the Buddhists, who promises to help her, but she must herself fetch the medicine, which is some mustard seed taken from a house where no son, husband, parent, or slave has died. Gladly the girl speeds on her errand, carrying the dead body of her son on her hip. By degrees she is taught that she is not the only mourner. In the whole of the Savetthi country everywhere children are dying, parents are dying. She leaves her dead son and returns to Para Takem, having learnt the first and last commandment of the Buddhist creed.

From Hindustan the Sanskrit fables passed to China, Thibet, and Persia; and they must have reached Greece at an early age, for many of the fables which passed under the name of Æsop are identical with those of the East. Æsop to us is little more than a name, though, if we may trust a passing notice in Herodotus (ii. 134), he must have lived in the 6th century B.C. Probably his fables were never written down, though several are ascribed to him by Xenophon, Aristotle, Plutarch, and other Greek writers, and Plato represents Socrates as beguiling his last days by versifying such as he remembered. Aristophanes alludes to them as merry tales, and Plato, while excluding the poets from his ideal republic, admits Æsop as a moral teacher. Of the various versions of *Æsop's Fables*, by far the most trustworthy is that of Babrius or Babrias, a Greek of the 1st century A.D., who rendered them in choliambic verse. These, which were long known in fragments only, were recovered in a MS. found by M. Minas in a monastery on Mount Athos in 1842, and have been edited by Sir G. C. Lewis.[1] An inferior version of the same in Latin iambics was made by Phædrus, a slave of Thracian origin, brought to Rome in the time of Augustus, and manumitted by him, who tells us that he published in senarian verse the rude materials produced by Æsop; but the numerous allusions to contemporary events, as, for example, that to Sejanus in the Frogs and the Sun, which brought upon the author disgrace and imprisonment, show that many of them are original or free adaptations. For some time scholars doubted as to the genuineness of Phædrus's fables, but their doubts have been lately dispelled by a closer examination of the MSS. and by the discovery of two verses of a fable on a tomb at Apulum in Dacia. Phædrus's style is simple, clear, and brief, but dry and unpoetical; and, as Lessing has pointed out, he often falls into absurdities when he deserts his original. For instance, in Æsop the dog with the meat in his mouth sees his reflexion in the water as he passes over a bridge; Phædrus makes him see it as he swims across the river.

To sum up the characteristics of the Æsopian fable, it is artless, simple, and transparent. It affects no graces of style, and we hardly need the moral with which each concludes, ὁ μῦθος δηλοῖ ὅτι, κ. τ. λ. The moral inculcated is that of wordly wisdom and reasonable self-interest. Æsop is no maker of phrases, but an orator who wishes to gain some point or induce some course of action. It is the Æsopian type that Aristotle has in view when he treats of the fable as a branch of rhetoric, not of poetry.

If we consider their striking gift of narrative and their love of moralizing, it is strange that the Romans should have produced no body of national fables. But, with the doubtful exception of Phædrus, we possess nothing but solitary fables, such as the famous apologue of Menenius Agrippa to the Plebs, and the exquisite Town Mouse and Country Mouse of Horace's *Satires*.

The fables of the rhetorician Aphthonius in Greek prose, and those in Latin elegiac verse attributed to Avianus or Avienus, make, in the history of the apologue, a sort of link between the classical and the dark ages. In that overflowing chaos which constitutes the literature of the Middle Ages, the fable reappears in several aspects. In a Latin dress, sometimes in prose, sometimes in regular verse, and sometimes in rhymed stanzas, it contributed, with other kinds of narratives, to make up the huge mass of stories which has been bequeathed to us by the monastic libraries. These served more uses than one. They were always easier reading, and were often held to be safer and more instructive reading also, than the difficult and slippery classics, for those monks who cared for reading at all, and were not learned enough for any pursuit deserving the name of study. For those who were a little more active-minded, they aided the *Gesta Romanorum* and other collections of fabliaux or short novels, in suggesting illustrations available for popular preaching. Among those mediæval fables in Latin, very little of originality is to be detected. The writers contented themselves with working up the old fables into new shapes, with rendering from prose into verse, or from verse into prose,—a species of attempts which had its merits in such hands as those of Babrius or Phædrus, but from which no fruit could be expected to be gathered in the convents. The few monks who could have performed such a task well aimed wisely at something higher. It might be enough to name, among the monkish fabulists, Vincent of Beauvais, a Dominican of the 12th century, in whose *Speculum Doctrinale* are a good many prose fables, more than half of them from Phædrus. About the end of the same century, too, a considerable number of fables, some of which have been printed, were compiled by an English Cistercian monk, Odo de Cerinton. Nor was this the only collection that arose in England.

As the modern languages became by degrees applicable to literary use, fables began to appear in them. A good many still exist in Norman-French, of which may be noted the fables called those of Ysopet, and those composed by Marie de France, the authoress of the well-known fabliaux. Later, also, they were not wanting, though not numerous, in our own tongue. Chaucer has given us one, in his Nonne Preste's Tale, which is an expansion of the fable "Don Coc et don Werpil" of Marie of France; another is Lidgate's tale of The Churl and the Bird. But the course of the short and isolated fables through the Middle Ages is not here worth prosecuting.

Several of Odo's tales, like Chaucer's story, can be ultimately traced to a work, or series of works, for the sake of which chiefly the mediæval history of the apologue is interesting—the History of Reynard the Fox. This great beast-epic has been referred by Grimm as far back as the 10th century, and is known to us in three forms, each having independent episodes, but all woven upon a common basis. The Latin form is probably the earliest, and the poem *Reinardus et Ysengrinus* dates from the 10th or 11th century. Next come the German versions. The most ancient, that of a minnesinger Heinrich der Glichesaere (probably a Swabian), was analysed and edited by Grimm in 1840. In 1498 appeared *Reynke de Voss*, almost a literal version in Low Saxon of the Flemish poem of the 12th century, *Reinaert de Vos*. Hence the well-known version of Goethe into modern German hexameters was taken. It was written in 1793, during the siege of Mainz, and the philosophic poet sought, in the study of animal nature and passions, to divert his thoughts from the bloody scenes of the Reign of Terror. The poem has been well named "an unholy world bible." In it the Æsopian fable received a development which was in several respects quite original. We have here no short and unconnected stories. Materials, partly borrowed from older apologues, but in a much greater proportion new, are worked up into one long and systematic tale, so as to form what has been quaintly called an animal-romance. The moral, so prominent in the fable proper, shrinks so far into the background, that the work might be considered as a mere allegory. Indeed, while the suspicion of its having contained personal satires has been convincingly set aside, some writers deny even the design to represent human conduct at all; and we can scarcely get nearer to its signification than by regarding it as being, in a general way, what Carlyle has called "a parody of human life." It represents a contest maintained successfully, by selfish craft and audacity, against enemies of all sorts, in a half-barbarous and ill-organized society. With his weakest foes, like Chaunteclere the Cock, Reynard uses brute-force; over the weak who are protected, like Kiward the Hare and

---

[1] M. Minas professed to have discovered under the same circumstances another collection of ninety-four fables by Babrius. This second part was accepted by Sir G. C. Lewis, but J. Conington has conclusively proved that it is spurious, and probably a forgery. See article BABRIUS.

Belin the Ram, he is victorious by uniting violence with cunning; Bruin, the dull, strong, formidable Bear, is humbled by having greater power than his own enlisted against him; and the most dangerous of all the fox's enemies, Isengrim, the obstinate, greedy, and implacable Wolf, after being baffled by repeated strokes of malicious ingenuity, forces Reynard to a single combat, but even thus is not a match for his dexterous adversary. The knavish fox has allies worthy of him in Grimbart the watchful badger, and in his own aunt Dame Rukenawe, the learned She-ape; and he plays at his pleasure on the simple credulity of the Lion-King, the image of an impotent feudal sovereign. The characters of these and other brutes are kept up with a rude kind of consistency, which gives them great liveliness; many of the incidents are devised with much force of humour; and the sly hits at the weak points of mediæval polity and manners and religion are incessant and palpable.

It is needless, as has already been said, to attempt tracing the appearance which fables, or incidents borrowed from them, make so frequently as incidental ornaments in the older literature of our own country and others. Nor is there here fit occasion for dwelling minutely on the cultivation of the apologue in modern times, as a special form of poetical composition. It has appeared in every modern nation of Europe, but has nowhere become very important, and has hardly ever exhibited much originality either of spirit or of manner. In our own language, Prior indicated the possession of much aptitude for it; but neither the fables of Moore, nor even the much more lively ones of Gay, possess any distinguished merit. To Dryden's spirited remodellings of old poems, romances, and fabliaux, the name of fables, which he was pleased to give them, is quite inapplicable. In German, Hagedorn and Gellert are quite forgotten; and even Lessing's fables are read by few but schoolboys. In Spanish, Yriarte's fables on literary subjects are sprightly and graceful. A spirited version of the best appeared in *Blackwood's Magazine*, 1839. Among Italians Pignotti is famous for versatility and command of rhythm, as amongst Russians is Kriloff for his keen satire on Russian society. He has been translated into English by Mr Ralston.

France alone in modern times has attained any pre-eminence in the fable, and this distinction is almost entirely owing to one author. Marie de France in the 13th century, Gilles Corrozet, Guillaume Haudent, and Guillaume Gueroult in the 16th, are now studied only as the precursors of La Fontaine, from whom he may have borrowed a stray hint or the outline of a story. The unique character of his work has given a new word to the French language: other writers of fables are called *fabulistes*, La Fontaine is named *le fablier*. Referring for fuller details to the article La Fontaine, we must content ourselves here with briefly indicating his chief characteristics. He is a true poet; his verse is exquisitely modulated; his love of nature often reminds us of Virgil, as does his tenderness and pathos (see, for instance, The Two Pigeons and Death and the Woodcutter). He is full of sly fun and delicate humour, like Horace he satirizes without wounding, and "plays around the heart." Lastly, he is a keen observer of men. The whole society of the 17th century, its greatness and its foibles, its luxury and its squalor, from *Le grand monarque* to the poor *manant*, from his majesty the lion to the courtier of an ape, is painted to the life. To borrow his own phrase, La Fontaine's fables are "une ample comédie à cent actes divers."

The fables of Lessing represent the reaction against the French school of fabulists. "With La Fontaine himself," says Lessing, "I have no quarrel, but against the imitators of La Fontaine I enter my protest." His attention was first called to the fable by Gellert's popular work published in 1746. Gellert's fables were closely modelled after La Fontaine's, and were a vehicle for lively railings against the fair sex, and hits at contemporary follies. Lessing's early essays were in the same style, but his subsequent study of the history and theory of the fable led him to discard his former model as a perversion of later times, and the "Fabeln," published in 1759, are the outcome of his riper views. Lessing's fables, like all that he wrote, display his vigorous common sense. He has, it is true, little of La Fontaine's *curiosa felicitas*, his sly humour and lightness of touch; and Frenchmen would say that his criticism of La Fontaine is an illustration of the fable of the sour grapes. On the other hand he has the rare power of looking at both sides of a moral problem; he holds a brief for the stupid and the feeble, the ass and the lamb; and in spite of his formal protest against poetical ornament, there is in not a few of his fables a vein of true poetry, as in the Sheep (ii. 13) and Jupiter and the Sheep (ii. 18). But the value of the work is infinitely enhanced by the monograph on the essence of the fable which appeared at the same time, and as an illustration of which the fables were written. Much of the essay is taken up with the refutation of the theories of contemporary fabulists, De la Motte, Richer, Breittinger, Batteux, who only survive in Lessing's pages like the fly in amber. Passing over this negative criticism we may briefly state the results of Lessing's investigation. According to Lessing the ideal fable is that of Æsop. All the elaborations and refinements of later authors, from Phædrus to La Fontaine, are perversions of this original. The fable is essentially a moral precept illustrated by a single example, and it is the lesson thus enforced which gives to the fable its unity and makes it a work of art. The illustration must be either an actual occurrence or represented as such, because a fictitious case invented *ad hoc* can appeal but feebly to the reader's judgment. Lastly, the fable requires a story or connected chain of events. A single fact will not make a fable, but is only an emblem. We thus arrive at the following definition:—"A fable is a relation of a series of changes which together form a whole. The unity of the fable consists herein, that all the parts lead up to an end, the end for which the fable was invented being the moral precept."

We may notice in passing a problem in connexion with the fable which had long been debated, but never satisfactorily resolved till Lessing took it in hand,—Why should animals have been almost universally chosen as the chief *dramatis personæ?* The reason, according to Lessing, is that animals have distinct characters which are known and recognized by all. The fabulist who writes of Britannicus and Nero appeals to the few who know Roman history. The Wolf and the Lamb comes home to every one whether learned or simple. But, besides this, human sympathies obscure the moral judgment; hence it follows that the fable, unlike the drama and the epos, should abstain from all that is likely to arouse our prejudices or our passions. In this respect the Wolf and the Lamb of Æsop is a more perfect fable than the Rich Man and the Poor Man's Ewe Lamb of Nathan.

Lessing's analysis and definition of the fable, though he seems himself unconscious of the scope of his argument, is in truth its death-warrant. The beast-fable arose in a primitive age when men firmly believed that beasts could talk and reason, that any wolf they met might be a were-wolf, that a peacock might be a Pythagoras in disguise, and an ox or even a cat a being worthy of their worship. To this succeeded the second age of the fable, which belongs to the same stage of culture as the Hebrew proverbs and the gnomic poets of Greece. That honesty is the best policy, that death is common to all, seemed to the men of that day profound truths worthy to be embalmed in verse or set off by the aid of story or anecdote. Last comes an age of high literary culture which tolerates the trite morals and hackneyed tales for the sake of the exquisite setting, and is amused at the wit which introduces topics and characters of the day under the transparent veil of animal life. Such an artificial product can be nothing more than the fashion of a day, and must, like pastoral poetry, die a natural death. A serious moralist would hardly choose that form to inculcate, like Mandeville in his *Fable of the Bees*, a new doctrine in morals, for the moral of the fable must be such that he who runs may read. A true poet will not care to masquerade as a moral teacher, or show his wit by refurbishing some old-world maxim. (F. S.)

FABRE D'ÉGLANTINE, PHILIPPE FRANÇOIS NAZAIRE (1755–1794), a French dramatist and revolutionist, was born at Carcassonne, December 28, 1755. His real name was simple Fabre, the "d'Églantine" being an addition which he adopted in commemoration of his receiving the golden eglantine of Clemence Isaure from the academy of the floral games at Toulouse. After travelling through the provinces as an actor, he came to Paris when about thirty years of age with the intention of continuing the same career, but being ignored by the critics he ventured to take his revenge by a comedy entitled *Les gens des Lettres ou le Provincial à Paris*, and in spite of its failure continued to bring piece after piece on the boards. Shortly after the outbreak of the revolutionary movement he entered the political arena, was chosen by Danton as his private secretary, and obtained from the electors of Paris a place in the National Convention. He distinguished himself by the extravagance of his speeches and measures, voting for the king's death, supporting the *maximum* and the law of the suspected, and giving distorted evidence against the Girondins. On the abolition of the Gregorian calendar he was one of the most active members of the committee entrusted with the formation of the republican substitute, and to him was due a large part of the new nomenclature, with its poetic *Prairial* and *Floreal*, its prosaic *Primidi* and *Duodi*, and its absurd substitution of the names of trees and beasts and implements for those of saints and heroes. The report which he made on the subject on 24th October is not without scientific value. On January 12, 1794 he was arrested by order of the committee of public safety on a charge of malversation and forgery in connexion with the affairs of the Compagnie des Indes. During his trial he displayed the greatest apparent nonchalance, sitting in an arm chair, looking out dreamily at the rain, and singing his own well-known song of *Il pleut, il pleut, bergère, rentre tes blancs moutons.* On his way to the scaffold he distributed his manuscript poems to the people.

Fabre d'Églantine left behind him seventeen plays and a number of miscellaneous productions. One only of the plays, *Le Philinthe de Molière*, still preserves its reputation as a good specimen of the second class. It professes to be a continuation of Molière's *Le Misanthrope*, but the hero of the piece is of a different character from the nominal prototype—an impersonation, indeed, of pure and simple egotism. On its publication the play was introduced by a preface, in which the author mercilessly satirizes the *Optimiste* of his rival Collin d'Harleville, whose *Chateaux en Espagne* had gained the applause which D'Églantine's *Présomptueux* had failed to win. A posthumous play, *Les Précepteurs*, steeped with the doctrines of Rousseau's *Émile*, was performed on 17th September 1794, and met with an enthusiastic reception. The author's *Œuvres mêlées et posthumes* were published at Paris 1802, 2 vols.

See Albert Maurin, *Galerie hist. de la Révolution française*, tome ii.; Jules Janin, *Hist. de la Litt. dram.*, Chénier, *Tableau de la Litt. française.*

FABRETTI, RAPHAEL (1618–1700), a celebrated Italian antiquary, was born in 1618, at Urbino in Umbria. A younger son, and destined to the pursuit of the law, he studied first at Cagli, and afterwards in his native city, where he took the degree of doctor at the age of eighteen years. While in Rome, preparing for practice at the bar, he early attracted the notice of Cardinal Lorenzo Imperiali, who employed him on important and difficult political affairs in Spain. He was named successively treasurer and auditor of the papal legation in that country, where he remained thirteen years. During all this time, however, his favourite classical and antiquarian studies were not neglected; and returning to Rome with the legate, Bonelli, who had been made cardinal, he was able on the journey to make important observations of the relics and monuments of Spain, France, and Italy, and to converse with the many eminent scholars of those countries who afterwards corresponded with him. At Rome he was appointed judge of appellation of the Capitol, which post he left to be, under the legate, Cardinal Cerri, auditor of the legation at his native city, Urbino. After three years he returned to Rome, on the invitation of Cardinal Carpegna, vicar of Innocent XI., a great lover of antiquities and learning, and now found that fulness of leisure which enabled him to carry on those studies and produce those works which have made him famous. He examined with minute care the monuments and inscriptions of the Campagna. In his solitary expeditions he always rode a horse which his friends nicknamed Marco Polo, after the celebrated Venetian traveller, saying that it could discover half-hidden monuments by smelling only, and thus frequently led its master to notice what he would otherwise have passed by. Fabretti was delighted with the name, and used it himself in a letter on the study of antiquity, still in manuscript. By Innocent XII. Fabretti was made keeper of the archives of the castle St Angelo, a charge of great responsibility and trust, which he retained till his death.

His work *De Aquis et Aquæ-ductibus veteris Romæ*, 1680, three dissertations which cleared up a number of obscurities as to the topography of ancient Latium, is inserted in Grævius's *Thesaurus*, iv. 1677. His interpretation in this work of certain passages in Livy and other classical authors involved him in a dispute with Gronovius, which bore a strong resemblance to that between Milton and Salmasius, Gronovius addressing Fabretti as *Faber Rusticus*, and the latter, in reply, speaking of *Grunnovius* and his *titivilitia*. In this controversy Fabretti used the pseudonym Iasitheus, which he afterwards took as his pastoral name in the Academy of the Arcadians. His other works, *De Columna Trajani Syntagma*, Rome, 1683, and *Inscriptionum Antiquarum Explicatio*, Rome, 1699, throw much light on Roman antiquity, especially with the aid of the principle which he himself employed of making one monument interpret another. In the former of these works is also to be found his explication of a bas-relief, with inscriptions, now in the Capitol at Rome, representing the war and taking of Troy, known as the Iliac table. Letters and other shorter works of Fabretti are to be found in some miscellaneous publications of the time, as the *Journal des Savants*. He died at Rome, January 1700. His collection of inscriptions and monuments was purchased from his relatives by Cardinal Stoppani, and placed in the ducal palace at Urbino, where they may still be seen.

Crescimbeni, *Le Vite degli Arcadi illustri;* Fabroni, *Vitæ Italorum*, vi. 174; Niceron, iv. 372.

FABRIANO, a town of central Italy, province of Ancona, is situated at the foot of the Apennines, and on the railway from Ancona to Rome, 35 miles S.W. of Ancona. It has paper and parchment works, tanneries, and powder mills. Among its principal buildings are the cathedral, several churches with pictures by the Fabriano school of artists, the town hall, which contains ancient inscriptions, and the museum of the Count of Ressenti, where may be seen a very fine collection of objects in ivory. Fabriano is the birth-place of the painter Gentile da Fabriano. The population of the town proper in 1870 was 6071, or including the outskirts, 7612.

FABRIANO, Gentile da, an Italian painter, was born at Fabriano about 1370. He is said to have been a pupil of Allegretto di Nuzio, but there is every probability that he received most of his early instruction from Fra Giovanni, surnamed Angelico, to whose manner his bears in some respects a close similarity. About 1411 he went to Venice, where by order of the doge and senate he was engaged to adorn the great hall of the ducal palace with frescoes from the life of Barbarossa. He executed this work so entirely to the satisfaction of his employers that they granted him a pension for life, and accorded him the privilege of wearing the habit of a Venetian noble. About 1422 he went to Florence, where in 1423 he painted an Adoration of the Kings for the church of Santa Trinita, which is preserved in the Florence gallery of paintings, and is considered his best work now extant. To the same period belongs a Madonna and Child which is now in the Berlin Museum. Fabriano had by this time attained a wide reputation, and was engaged to paint pictures for various churches, more particularly Siena, Perugia, Gubbio, and Fabriano. About 1426 he was called to Rome by Martin V. to adorn the church of St John Lateran with frescoes from the life of John the Baptist. He also executed a portrait of the pope attended by ten cardinals, and in the church of St Francesco Romano a painting of the Virgin and Child attended by St Benedict and St Joseph, which was much esteemed by Michelangelo, but is no longer in existence. Fabriano died about 1450. Michelangelo said of him that his works resembled his surname Gentile, noble or refined. They are full of a quiet and serene joyousness, and he has a naïve and innocent delight in splendour and in gold ornaments, with which, however, his pictures are not overloaded.

FABRICIUS, Caius Luscinus, a Roman general and consul, was perhaps the first member of the Fabricia gens who settled in Rome. He makes his earliest appearance in history as one of the ambassadors sent to the Tarentines to dissuade them from making war on the Romans. Elected consul in 282 B.C., he in the same year defeated the Boii and the Etruscans. When in the following year the Romans were defeated by Pyrrhus, Fabricius was sent to treat for the ransom and exchange of the prisoners, and Pyrrhus endeavoured unsuccessfully to bribe him with large offers to enter his service. In 278 Fabricius was elected consul for the second time, and was successful in negotiating terms of peace with Pyrrhus, who sailed away to Italy. Fabricius afterwards gained a series of victories over the Samnites, the Lucanians, and the Bruttii, and on his return to Rome received the honour of a triumph. Notwithstanding the offices he had filled he died poor, and provision had to be made for his daughter out of the funds of the state. In honour of his military achievements and his incorruptible integrity, the senate also decreed that he and his descendants should have a burial place inside the city.

FABRICIUS, George (1516–1571), poet, historian, and archæologist, was born at Chemnitz in Upper Saxony, on the 24th April 1516. He completed his studies at Freiberg and Leipsic. Travelling into Italy with one of his pupils, he made an exhaustive study of the antiquities of Rome. The result was the second work named below, in which the correspondence between every discoverable relic of the old city and the references and descriptions which lay scattered throughout ancient literature was traced with the minutest detail. Even learned Germans suspected that the work was in reality an ancient performance. Having returned to Germany in 1553, he was appointed director of the college of Meissen, where he died on the 13th July 1571. In his sacred poems, which obtained for him considerable distinction, he affected to avoid every word with the slightest savour of paganism; and he blamed the poets for their allusions to pagan divinities.

The following list includes the principal works which he published, either as author or as editor:—(1) *Terentii Afri Comœdiæ sex cum castigatione duplici Joannis Rivii et G. Fabricii*, Strasburg, 1518, 8vo; (2) *Roma, sive Liber utilissimus de veteris Romæ situ, regionibus, viis, templis, aliisque ædificiis*, Basel, 1550, 8vo; (3) *Virgilii Opera cum commentariis Servii et T. C. Donati*, Basel, 1551, fol.; (4) *Virgilii Opera a Fabricio castigata*, Leipsic, 1551, 1591, 8vo; (5) *Poematum sacrorum libri quindecim*, Basel, 1560, 16mo; (6) *Poëmatum veterum ecclesiasticorum opera Christiana et operum reliquiæ ac fragmenta*, 1562, 4to; (7) *De Re Poetica libri septem*, 1566, 8vo; (8) *Rerum Misnicarum libri septem*, 1569, 4to; (9) *Originum illustrissimæ stirpis Saxonicæ libri septem*, 1597, fol.; (10) *Rerum Germaniæ magnæ et Saxonicæ universæ memorabilium volumina duo*, Leipsic, 1609, fol. A life of George Fabricius was published in 1839, at Leipsic, by Professor C. G. Baumgarten Crusius. In 1845 the same biographer issued an edition of Fabricius's *Epistolæ ad Wolf. Meurerum et alios æquales*, prefixed to which there is also a short sketch *De Vita Ge. Fabricii et de gente Fabriciorum*.

FABRICIUS, Hieronymus (1537–1619), a celebrated Italian anatomist and surgeon, was surnamed Acquapendente from the episcopal city of that name, where he was born in 1537. At Padua, after a course of philosophy, he studied medicine under Fallopius, whose successor as teacher of anatomy and surgery he became in 1562. From the senators of Venice he received numerous honours, and an anatomical theatre was built by them for his accommodation. He died May 21, 1619.

The collective works of Fabricius were printed by Bohn under the title of *Opera omnia Anatomica et Physiologica*, Leipsic, 1687. The Leyden edition, published by Albinus in 1738, folio, is preferred to that of Bohn, as containing a life of the author and the prefaces of his treatises. See ANATOMY, vol. i., p. 809, and SURGERY.

FABRICIUS, Joannes Albertus (1668–1736), one of the most learned, laborious, and useful of bibliographers, was born at Leipsic, November 11, 1668. His father, Werner Fabricius, director of music in the church of St Paul at Leipsic, was the author of several works, particularly *Deliciæ Harmonicæ*, published in 1657. Joannes Albertus himself commenced his studies under his father, who on his deathbed recommended him to the care of Valentine Alberti. He studied under Wenceslas Buhl and J. S. Herrichen, and afterwards at Quedlinburg under Samuel Schmidt. It was in Schmidt's library, as he afterwards said, that he found the two works, Barthuiss's *Adversaria* and Morhoff's *Polyhistor*, which suggested to him the idea of his Bibliothecæ, the kind of work for which he stands pre-eminent among scholars. Having returned to Leipsic in 1686, he was the same year admitted bachelor in philosophy; and in the beginning of 1688 he took the degree of master in the same faculty, shortly after which he published his first work, *Scriptorum recentium decas*, an attack on ten writers of the day, Thomasius among them. His *Decas Decadum, sive plagiarorum et pseudonymorum centuria*, published in the following year, is the only one of his works to which he signs the name Faber. He then applied himself to the study of medicine, which, however, he relinquished for that of theology; and having gone to Hamburg in 1693, he proposed to travel abroad, when the unexpected tidings that the expense of his education had absorbed his whole patrimony, and even left him in debt to his trustee, forced him to abandon his project. He therefore remained at Hamburg, where J. F. Mayer employed him in the capacity of librarian. In 1696 he accompanied his patron to Sweden;

and, on his return to Hamburg, not long afterwards, he competed for the chair of logic and philosophy. The suffrages being equally divided between Fabricius and Sebastian Edzardi, one of his opponents, the appointment was decided by lot in favour of Edzardi ; but in 1699 Fabricius succeeded Vincent Placcius in the chair of rhetoric and ethics, after which he took the degree of doctor in theology at Kiel. In 1701 J. F. Mayer, who had established himself at Greifswald, caused the chair of theology in that city to be offered to Fabricius; but he refused it on account of his health. But in 1708 he accepted the professorship of theology, logic, and metaphysics, and was preparing to entér on his new office, when the senate of Hamburg induced him to remain, by adding to his professorship the office of rector of the school of St John, then held by his father-in-law Schuitz. Schultz died in 1709, but Fabricius retained the rectorship two years longer. In 1719 the landgrave of Hesse-Cassel made him so advantageous an offer that he was on the point of accepting it; but this time also the magistrates, by a seasonable increase of salary, prevailed on him to remain with them. An attempt was subsequently made to draw him to Wittenberg; but he refused to listen to the proposals made to him, and remained at Hamburg, where he died April 30, 1736.

Niceron and Reimar give a list of 128 books by Fabricius, but very many of them were only works which he had edited. One of the most famed and laborious of his works is the *Bibliotheca Latina, sive notitia auctorum veterum Latinorum quorumcunque scripta ad nos pervenerunt*, Hamburg, 1697, 8vo, a work which was republished in an improved and amended form by J. A. Ernesti, Leipsic, 1773, in three vols. 8vo. The divisions of the compilation are—the writers to the age of Tiberius ; thence to that of the Antonines ; and thirdly, to the decay of the language ; while a fourth gives fragments from old authors, and chapters on early Christian literature. His *chef d'œuvre* is the *Bibliotheca Græca, sive notitia scriptorum veterum Græcorum quorumcunque monumenta integra aut fragmenta edita extant, tum plerorumque e manuscript. ac deperditis*, Hamburg, 1705-1728, in 14 vols. 4to, a work which has justly been denominated *maximus antiquæ eruditionis thesaurus*. It was rearranged by Harles, at Hamburg, in 1790. Its divisions are marked off by Homer, Plato, Christ, Constantine, and the capture of Constantinople in 1453, while a sixth section is devoted to canon law, jurisprudence, and medicine. Of his remaining works we may mention—*Bibliotheca Antiquaria, sive introductio in notitiam scriptorum qui antiquitates Hebraicas, Græcas, Romanas, et Christianas scriptis illustrarunt*, 1713 and 1726, 4to; *Centifolium Lutheranum, sive notitia literaria scriptorum omnis generis de B. D. Luthero*, 1728 and 1730, 8vo ; as also *Salutaris lux evangelii toti orbi per divinam gratiam exoriens, sive notitia historico-chronologica, litteraria, ac geographica propagatorum per orbem totum Christianorum sacrorum*, 1731, 4to ; and *Hydro-theology*, in German, 1734, 4to. Among the principal works edited by Fabricius may be named *Joannis Mabillonii iter Germanicum, et Joannis Launoii de Scholis celebribus a Carolo Magno et post Carolum Magnum in occidente instauratis liber*, 1717, 8vo.

The details of the life of Fabricius are to be found in *De Vita et Scriptis J. A. Fabricii Commentarius*, by his son-in-law, H. S. Reimar, published at Hamburg, 1757. This is the work whence Niceron, Chauffepié, and other writers on the subject have borrowed their materials. Niceron's work is entitled *Memoires pour servir a l'histoire des hommes illustres dans la republique des lettres, avec un catalogue raisonné de leurs ouvrages*, Paris, 1729-1745.

FABRICIUS, Johann Christian (1745-1808), one of the chief founders of scientific entomology, was born at Tondern in Schleswig, January 7, 1745. His father was a physician of enlightened views, who encouraged his son's inclination to study the natural sciences, and, after educating him at Altona and Copenhagen, sent him to Upsala, where, attending the lectures of the great Linnæus, his future destiny, as he himself says, appears to have been laid. Of his career, apart from entomology, it may be briefly recorded that he devoted his attention professionally to political economy, and, after lecturing on that subject in 1769, was appointed a few years later professor of natural history, economy, and finance at Kiel, in which capacity he wrote various works, chiefly referring to Denmark, and of no special interest. He also published a few other works on general and natural history, botany, and travel (of which the *Reise nach Norwegen*, 1779, deserves separate mention),—for, although his professional stipend was small, he extended his personal researches into every town in northern and central Europe where a natural history museum was to be found. In 1771 he married the daughter of Counsellor Ambrosius of Flensborg, by whom he had two sons and one daughter ; and he died on 3d March 1808.

It is, however, purely as an entomologist that the memory of Fabricius survives, aided perhaps in this country by the fact that he visited Great Britain many times after 1767, exhibiting a marked partiality for English naturalists, amongst whom were Solander, Sir Joseph Banks, Drury, Hunter, Francillon, Pennant, and Greville. Sir Joseph Banks's specimens, indeed, formerly in the collection of the Linnean Society, and now separately treasured in the British Museum, still retain the labels written by Fabricius, and are often consulted by entomologists as evidence of his views. For many years his great scientific reputation rested upon the system of classification, which (it can scarcely be said in opposition to that of his revered master Linnæus) he founded upon the structure of the mouth-organs, instead of the wings. No scheme, however, based upon solitary characters suffices any longer for the comprehension of the vast number of forms now known to science; and, although the value of the cibarian organs is still fully recognized, the system exclusively founded on them has long since passed into disuse. But the name of Fabricius is indelibly stamped upon the science, as he had a keen eye for specific differences, and possessed the art of describing in a marvellously terse and accurate manner ; and, from his being recognized as a master, added to the opportunities afforded during his many journeys to European capitals, great numbers of insects passed through his hands for description and arrangement according to his system, at a time when almost everything was new, owing to paucity of workers.

A complete list of his entomological publications (31) will be found in Hagen's *Bibliotheca Entomologiæ;* the following are the chief:—*Systema Entomologiæ*, 1775 ; *Genera Insectorum*, 1776 ; *Philosophia Entomologica*, 1778 ; *Species insectorum*, 1781 ; *Mantissa Insectorum*, 1787 ; *Entomologia Systematica*, 1792-1794, *with a supplement*, 1798 ; *Systema Eleutheratorum* (1801), *Rhyngotorum* (1803), *Piezatorum* (1804), and *Antliatorum* (1805). Full particulars of his life will be found, with a portrait, in the *Transactions of the Entomological Society of London*, vol. iv. (1845), pp. i.-xvi., where his autobiography is translated from the Danish by the Rev. F. W. Hope, then president of the society. There is also a good account by Professor Westwood, in the article "Insecta," *British Cyclopædia*, p. 881. Baron Walckenaer's verbose life in the *Biographie Universelle*, like Latreille's "Notice Biographique" in the *Annales du Muséum d'Histoire Naturelle*, ii. 393 (1808), contains important errors.

FABRONI, Angelo (1732-1803), a celebrated Italian biographer, was born at Morradi, Tuscany, 25th September 1732. After studying at Faenza under the grammarian Girolamo Ferri, he entered the Roman college founded for the education of young Tuscans. On the conclusion of his three years' curriculum, he resolved, being determined to attain to literary distinction, to continue his stay in Rome, and having been introduced to the celebrated Jansenist Bottari, received from him the canonry of S. Teresa in Trastevere. Some time after this he was chosen to preach a discourse in the pontifical chapel before Benedict XIV., and made such a favourable impression that the pontiff settled on him an annuity left by the Countess Rospigliosi to young men who had taken a degree in law. With the possession of this annuity Fabroni was able to devote his whole time to study. Besides his other literary labours, he commenced at Pisa in 1771 a literary journal, which he continued till 1796. About 1772 he made a journey to Paris, where he formed the acquaintance of Condorcet, Diderot, D'Alembert

Rousseau, and most of the other eminent Frenchmen of that age. He also spent four months in London. He died at Pisa 22d September 1803.

The following are his principal works:—*Vitæ Italorum doctrina excellentium qui sæculis XVII. et XVIII. floruerunt*, Pisa, 1778–1799, 1804–1805, 20 vols. 8vo (the last two vols. were published posthumously, and contain a life of the author); *Laurentii Medicei Magnifici Vita*, Pisa, 1784, 2 vols. 8vo; *Leonis X. pontificis maximi Vita*, Pisa, 1797; and *Elogi di Dante Alighieri, di Angelo Poliziano, di Lodovico Ariosto, e di Torq. Tasso*, Parma, 1800.

FABROT, Charles Annibal (1580–1659), a French jurisconsult, was born at Aix in Provence, 15th September 1580. At an early age he made great progress in the ancient languages and in the civil and the canon law; and in 1602 he received the degree of doctor of law, and was made avocat to the parlement of Aix. In 1609 he obtained a professorship in the university of his native town. He is best known by his translation of the *Basilica*, which may be said to have formed the code of the Eastern empire till its destruction. This work was published at Paris in 1647 in 7 vols. fol., and obtained for its author a considerable pension from the chancellor Seguier, to whom it was dedicated. Fabrot likewise rendered great service to the science of jurisprudence by his edition of Cujas, which comprised several treatises of that great jurist previously unpublished. He also edited the works of several Byzantine historians, and is besides the author of various antiquarian and legal treatises. He died at Paris 16th January 1659.

FABYAN, Robert, an English chronicler, sprung from an Essex family, is said by Bishop Tanner to have been born in London about the middle of the 15th century. Even the date of his death, 1512, is an inference from that upon which his will was proved, namely, 12th July 1513. The records of the Draper's Company, of which he was a member, might have settled these and other chronological doubts; but in consequence of the destruction of the company's hall by fire, there are no memoranda of a date earlier than 1602. All the ascertained details of his life are given in the biographical preface to Sir Henry Ellis's admirable edition of Fabyan's *Chronicles*. From this source we learn that Fabyan was alderman for the ward of Farringdon-Without, and that in 1493 he was appointed to the office of sheriff. In 1502, though he is believed on good grounds to have been very rich, he resigned the former office on the plea of poverty, not wishing probably to be elected to the expensive position of Lord Mayor, as he had a very numerous family. Fabyan's *Chronicle* extends from the time when "Brute entryd firste the Ile of Albion" to the year 1485. In subsequent editions it was continued by unknown authors to the year 1559. There have been five editions of the work,—the first printed in 1516 by Pynson, the second by Rastell in 1533, the third by Reynes in 1542, the fourth by Kyngeston in 1559. The fifth, in the preparation of which all the previous editions were compared, was published by Sir Henry Ellis in 1811. For its exposure of ecclesiastical abuses, Wolsey, it is said, ordered many copies of the first edition to be burnt,—hence its scarcity. The second edition was not published until after the cardinal's death. A great merit of the work consists in its details of city government and ceremonial. Wharton, indeed, observes that, in the eyes of the chronicler, a lord mayor of London seemed to be as august a personage as a king of England, and a city company's dinner as important an event as an English victory in France or a constitutional struggle at home. Ellis, it may be added, suggests that the part of the history which may have excited the hostility of Wolsey was an abstract of the Commons Bill, 11th year of Henry IV., for the resumption of ecclesiastical property. But the story of the suppression of the first edition appears to rest on the uncorroborated assertion of Bayle. In col. 256, vol. i. of Anthony à Wood's *Athenæ Oxonienses* (Bliss's edition, 4 vols., 1813–1820) there is an entry to the effect that Fabyan was "born in London, bred in grammaticals and something in logicalls in this university." In this account it is stated that Fabyan died in February 1511.

FACCIOLATI, Jacopo (1682–1769), was born at Torreglia, in the province of Padua, in 1682. He owed his admission to the seminary of Padua to Cardinal Barberigo, who had formed a high opinion of the boy's talents. As professor of logic, and regent of the schools, Facciolati was the ornament of the Paduan university during a period of forty-five years. He published improved editions of several philological works, such as the *Thesaurus Ciceronianus* of Nizolius, and the polyglot vocabulary known under the name of Calepino. The latter work, in which he was assisted by his pupil Forcellini, he completed in four years —1715 to 1719. It was written in seven languages, and suggested to the editor the idea of his *opus magnum*, the *Totius Latinitatis Lexicon*, 4 vols. fol., Padua, 1771. In the compilation of this work the chief burden seems to have been borne by Facciolati's pupil Forcellini, to whom, however, the lexicographer allows a very scanty measure of justice, though the work occupied thirty years of his life. Perhaps the best testimony to the learning and industry of the compiler is the well-known observation that the whole body of Latinity, if it were to perish, might be restored from this lexicon. Facciolati's mastery of Latin style, as displayed in his epistles, has been very much admired for its purity and grace. In or about 1739 Facciolati undertook the continuation of Papadopoli's history of the university of Padua, carrying it on to his own day. Facciolati was known over all Europe as one of the most enlightened and zealous teachers of the time; and among the many flattering invitations which he received, but always declined, was one from the king of Portugal, to accept the directorship of a college at Lisbon for the young nobility. He died in 1769. His history of the university was published in 1757, under the name *Fasti Gymnasii Patavini*. In 1808 a volume containing nine of his *Epistles*, never before published, was issued at Padua.

FACTORS, in mercantile law, are agents entrusted with goods for the purpose of sale. The general rule as to sales at common law is that no person but the true owner can give a title to a purchaser. If, therefore, a factor or any similar kind of agent, being in possession of goods belonging to his principal, dealt with them in any unauthorized way, the persons dealing with him acquired no right as against the real owner. The inconvenience and injustice of this rule are apparent. A merchant *bona fide* buying goods from a person who was in possession of them, and had what among mercantile men are called the documents of title, was liable to have his rights defeated by the appearance of the real owner, who repudiated the transaction and recovered the goods. Or an agent might pledge the goods entrusted to him for advances made to him in good faith on that security, and the unfortunate lender might find that the goods belonged to a principal, and that he had no security for his loan. It thus became necessary in such cases to inquire into the real ownership of the goods and the nature of the agent's authority,—an intolerable necessity in trade. Accordingly the Factors Acts were passed for the protection of such transactions.

The 4 Geo. IV. c. 83 was an Act for the "better protection of the property of merchants and others who may hereafter enter into contracts or agreements in relation to goods, wares, and merchandise entrusted to factors or agents." It was followed by the 6 Geo. IV. c. 94, the principal Factors Act, the second section of which enacts that "persons entrusted with, and in possession of, any bill of lading, Indian warrant, dock warrant, warehouse keeper's certificate, warrant or order for the delivery of goods, shall be deemed and taken to be the true owner of the goods, so far as to give validity to sales made by them to buyers," without notice of the fact that they are not the real owners. When a factor pledges goods deposited with him as security for an antecedent debt, the pledger shall acquire no further interest in the goods than was possessed by the factor himself. By section 4, contracts made with agents for the purchase of goods consigned to them shall be held binding upon the owners notwithstanding that the purchaser had notice that the vendors were only agents: *provided* such contracts be made in the usual course of business, and that the purchaser had not notice that the agent had no authority to sell.

By the Amendment Act, 5 and 6 Vict. c. 39 (which recites that much litigation had arisen on the construction of the former statute, and that it is necessary to explain and extend the provisions thereof), it is enacted "that any agent who shall thereafter be entrusted with the possession of goods, or of the documents of title to goods, shall be deemed and taken to be owner of such goods and documents, so far as to give validity to any contract or agreement by way of pledge, lien, or security *bona fide* made to any person with such agent, as well for any original loan, advance, or payment, made on the security of such goods or documents, as also for any further or continuing advance." And such contracts shall be binding on the owner notwithstanding notice of the agency. *Bona fide* deposits in exchange are protected, *i.e.*, where an agent pledges goods consigned to him in exchange for other goods on which the person delivering them up had at the time a valid lien. In all cases the transaction must be *bona fide*, and without notice that the agent is acting beyond his authority or in bad faith as regards his principal.

"These Acts," says Mr Benjamin in his treatise on *The Sale of Personal Property*, "apply solely to persons entrusted as factors or commission merchants, not to persons to whose employment a power of sale is not ordinarily added, as a wharfinger, who receives goods usually without a power to sell. The statute is limited in its scope to mercantile transactions, to dealings in goods and merchandise, and does not embrace sales of furniture or goods in possession of a tenant or bailee for him." And the courts of law have unfortunately felt themselves constrained to put a very narrow interpretation on the scope of the Acts. The most remarkable case was that of Fuentes *v.* Montes (*Law Reports*, 3 Common Pleas, 268). Here the plaintiffs, wine merchants in Spain, had consigned some casks of sherry to a London factor for sale, but afterwards revoked his authority. He, while in possession of the wine, but after the revocation, pledged it as security for advances made by the defendant, who acted in good faith, and in entire ignorance of the revocation. The court held that the words "entrusted with and in possession of" referred to the time of the pledge only, and that the factor was not so entrusted at the time of the pledge. This decision, which unsettled the confidence of merchants in dealing with apparent owners of goods, and a general uncertainty as to the true construction of the enactments, led to the passing of the last Factors Act (40 and 41 Vict. c. 39). The second section overrules the decision in Fuentes *v.* Montes, by providing that a revocation of authority shall not affect the right of persons purchasing from factors without notice of such revocation. Then the Act goes on to provide for other cases of apparent ownership in which the same hardships had arisen which the Factors Acts were intended to meet. Thus, where goods have been sold, and the vendor has been permitted to retain possession of the documents of title, any sale by him or his agent will be as valid and effectual as if he or his agent were a person entrusted with, or in possession of, the goods under the Factors Acts. A case recently decided (Johnson *v.* the Credit Lyonnais Company) will illustrate the purpose of this enactment. A, a tobacco broker, had 50 hogsheads of tobacco lying in dock for which warrants were issued to him. He sold it to B, who paid for it, but left the warrants in A's hands, and took no steps to have any change made in the books of the dock company as to the ownership. In the meantime A obtained advances on the tobacco from C and D, handing over to them the dock warrants. It was held that these transactions were not protected as against B; under the new Act such transactions are protected. The fourth section deals with cases in which goods have been sold, and the vendee has got possession of the documents of title, although some lien or other right remains to the vendor. Dealings with the vendee in respect of the goods, and in ignorance of the vendor's right, are protected. The fifth section protects *bona fide* transfers of documents of title for a previous vendor's lien or right of stoppage *in transitu*. (E. R.)

FACTORY ACTS. The long series of Factory Acts, culminating in the home secretary's bill of the present session (1878), constitutes one of the most important chapters in the history of modern English legislation. The Acts assert the right of the state to control the industrial organizations which depend upon the labour of women and children. As yet the freedom of the adult male labourer has been held sacred from the interference of the legislature, but it is necessarily involved, to some extent, in the protection exercised over persons whose co-operation is necessary to his work. The gradual rise of the important principle that, in the interests of the moral and physical well-being of the community, the labour of women and children should be restricted by law within reasonable limits may be seen by a glance at the Factory Bills introduced in parliament since the beginning of the century.

In 1802 an Act was passed "for the Preservation of the Health and Morals of Apprentices and others employed in Cotton and other Mills, and Cotton and other Factories." The immediate cause of passing this bill was the fearful spread throughout the factory district of Manchester of epidemic disease, which made dreadful havoc among the youthful labouring population on account of their scanty mode of living and peculiar way of working.[1] Pauper children from the agricultural districts of the south were sent to the northern counties to work in the factories which sprang up there in consequence of their superior supply of water-power. Their long hours of labour, the wretched accommodation provided for them, and the over-crowding of workmen in mills and factories, caused the alarming epidemic fevers of those times and districts. The Act of 1802 subjected all mills employing three or more apprentices, or twenty other persons, to the rules and regulations of the Act. The walls were to be washed with quicklime and water; a sufficient number of windows was to be provided; the apprentices were always to have two suits of clothing, one to be new every year. The most important regulation, however, was that which fixed the hours of work at twelve per day, and prohibited work altogether from 9 o'clock at night to 6 in the morning. This Act, being intended to meet the evils of the apprentice system, did not extend to factories where children residing in the neighbourhood were employed. The use of steam-power had meanwhile caused the growth of factories in populous town districts. In 1819 an Act was passed for the regulation of cotton mills: children were not to be admitted before the age of nine, and between that age and sixteen were restricted to twelve hours a day, exclusive of an hour and a half for meal-time.

---

[1] Von Plener, *Factory Legislation*, p. 1.

In 1825 Sir John Cam Hobhouse's Bill was passed, which established a partial holiday on Saturday, and provided penalties for offences against the Act. An amending Act was passed (10 Geo. IV. c. 51), and in 1831 (by the 1 and 2 Will. IV. c. 39) night work in the cotton factories was prohibited for persons between nine and twenty-one years of age; the working day for persons under eighteen was to be twelve hours, and on Saturdays nine. This was the time of the great political movement which brought about the Reform Act of 1832, and the factory question entered into and to some extent complicated the purely political issues. In the wool districts the unions of the working men clamoured for a restriction of non-adult labour in factories to ten hours a day, and their demand was supported by the Conservative and country party, out of opposition to the manufacturers, who were for the most part keen supporters of the Reform Bill. The wool factories had not been touched by the recent legislation, and the sufferings of the over-worked children appealed powerfully to the imagination of the public. After much discussion in committees and commissions, the Act of 1833 (3 and 4 Will. IV. c. 103) was passed. Night work (between 8.30 p.m. and 5.30 a.m.) was prohibited to persons under eighteen in cotton, wool, worsted, hemp, flax, tow, and linen spinneries and weaving mills; children from nine to thirteen were not allowed to work more than 48 hours a week; and young persons from thirteen to eighteen were restricted to 68 hours a week. In silk factories children might be admitted under nine, and children under thirteen were to be allowed ten hours a day. Provision was also made for school attendance and for the appointment of factory inspectors to watch over the working of the law. The manufacturers, dreading the economical results of the loss of children's labour, subsequently induced the Government to propose that children over eleven should be allowed to work the full time of 69 hours a week, but in the face of the agitation for greater restrictions this amendment was not persisted in.[1]

The extension of the Factory Acts to unprotected industries now engaged the attention of philanthropists. A Mining Act (5 and 6 Vict. c. 99) was passed, which prohibited under-ground work to children under ten and women. In 1844 the Factory Act, 7 Vict. c. 15, was passed. Children from eight to thirteen might be employed in textile industries for not more than six hours and a half per day, but in factories where "young persons" restricted to ten hours a day were employed, children might also be employed for ten hours a day on alternate days. Children so employed had to attend school during the "half time." Adult women were brought under the same rules as "young persons." Lord Ashley's[2] Printworks Act followed in 1845. A Ten Hours Bill was at last carried in 1847 (10 Vict. c. 29). Women and young persons were restricted to ten hours a day, and the legal working day was fixed from 5.30 a.m. to 8.30 p.m. By employing protected persons in relays, manufacturers were enabled to keep their works going during the whole of the legal day; and to meet this evasion, as it was deemed to be, of the factory legislation a uniform working day was fixed, 13 and 14 Vict. c. 54. Young persons and women were allowed to work only between 6 a.m. and 6 p.m.—an hour and a half being allowed for meal-time. No protected person was to work on Saturday after 2 p.m. By the 16 and 17 Vict. c. 104, children were limited to a legal day beginning at 6 a.m. and ending at 6 p.m. Bleaching and dyeing works were subjected to similar restrictions by Acts passed in 1860 and 1862, calendering and finishing works in 1863 and 1864. Lace factories were placed under the regulations of the Factories Acts by 24 and 25 Vict. c. 117. Night work in bakehouses was prohibited to young persons under eighteen, by 26 and 27 Vict. c. 40. After the report of a commission, a new Factory Acts Extension Act was passed (27 and 28 Vict. c. 48), which brought manufactories of earthenware, percussion caps, lucifer matches, and cartridges, paper-staining, and fustian-cutting within the scope of the factory legislation. In 1867 a distinction was drawn in legislation between factories and workshops. The Factory Acts Extension Act of that year applied to all furnaces, iron and copper works, machine manufactories, metal and gutta-percha factories, paper-mills, glass-works, printing offices, and bookbinders' shops, and to all establishments in which over 50 persons are employed for a period of a hundred days. Special modifications, however, were introduced to suit the requirements of the different trades. In the same year the Workshop Regulation Act was passed, for small trades and handicrafts, fixing the working day for children at 6 a.m. to 8 p.m., and for young persons and women from 5 a.m. to 9 p.m. Printing, bleaching, and dyeing works were brought under the general law by the Factory and Workshop Act 1870. In 1871 another Act with the same title was passed, which, *inter alia*, subjected Government factories to the general law. The Factory Act of 1874, the last of the series, raised the minimum of age in children to ten.

By these various enactments the state has emphatically taken under its protection the whole class of children and young persons employed in manufacturing industries. It has done this in the name of the moral and physical health of the community. The slow but steady advance of the principle of interference may be traced in the titles of the successive statutes. It is needless here to discuss the wisdom of the policy, which has now received *en bloc* the stamp of legislative approval. The substantive law of the Factories Acts has been re-enacted in a measure laid before parliament in the present session, which has already (May 1878) passed both Houses. In the debates in the Commons the only question of principle seriously raised was whether the freedom of adult women ought to be curtailed by legislative interference. Mr Fawcett's motion in the negative was rejected by a large majority.

The following outline will give some idea of the scope of the law relating to factories and workshops consolidated by the new measure:—

Part I. contains the general law relating to factories and workshops, under the following heads—(1) Sanitary Provisions; (2) Safety; (3) Employment and meal hours; (4) Holidays; (5) Education; (6) Certificates of fitness for employment; (7) Accidents.

(1.) Under the first head, the buildings must be kept in a clean state, and free from effluvia arising from any drain, privy, or other nuisance.

(2.) The second contains provisions for the fencing of dangerous machinery, and restrictions on the employment of children and young persons in cleaning, &c., machinery in motion.

(3.) A child, young person, or woman shall not be employed except during the period of employment fixed as follows:—

(*a*.) In textile factories.—*For young persons and women*, the period shall be from 6 a.m. to 6 p.m. or 7 a.m. to 7 p.m.; on Saturday, from 6 a.m. till 1 p.m. for manufacturing processes, and 1.30 for all employment, if one hour is allowed for meals; otherwise at 12.30 and 1. Or if the work begins at 7 a.m., it shall end on Saturdays at 1.30 and 2 p.m. respectively. For meal times two hours at least on week days, and on Saturdays half an hour, must be allowed. Continuous employment without a meal time of at least half an hour not to exceed four hours and a half.

For children. Employment to be for half time only (in morning or afternoon sets, or alternate days). The work-day is the same as

---

[1] One of the consequences of the restrictions imposed on the employment of children was the increased use of machinery as a substitute. In 1835 (before the Factory Act), there were 56,455 children employed in 3164 factories; in 1838 (under the Factory Act), 29,283 children were employed in 4217 factories.—Von Plener's *English Factory Legislation*, p. 22.

[2] Afterwards earl of Shaftesbury, whose name, more than any other, is entitled to be associated for ever with the English factory legislation.

above. A child must not be employed for two successive periods of seven days in the same set, whether morning or afternoon, nor on two successive Saturdays, nor on Saturday in any week if he has already on one day been employed more than five hours and a half. Nor shall a child be employed on two successive days, nor on the same day in two successive weeks.

(*b.*) In non-textile factories.—*For young persons and women.* Period of employment same as before, ending at 2 p.m. on Saturdays; meal times not less than an hour and a half, on Saturday half an hour; continuous employment without a meal not to exceed 5 hours; these regulations also apply to *young persons in workshops.*

For children. Half time arrangements generally the same as before, continuous employment without a meal not to exceed 5 hours.

Women in workshops are subject to the same regulations as young persons, if young persons or children are employed; if not, the period of employment for a woman in a workshop shall be from 6 a.m. to 9 p.m. (on Saturday 4 p.m.). Absent time for meals, &c., must be allowed to the extent of four hours and a half (Saturdays two hours and a half).

The employment of young persons or children at home, when the work is the same as in a factory or workshop, but no machine power is used, is also regulated,—the day being fixed at 6 a.m. to 9 p.m.; for children, 6 a.m. to 1 p.m., or 1 p.m. to 8. Meal times in factories or workshops must be simultaneous, and employment during such meal times is forbidden. The occupier of a factory or workshop must issue a notice of the times of employment, &c. No children under 10 shall be employed.

(4.) The following holidays shall be allowed to all protected persons:—Christmas day, Good Friday (or the next public holiday), and eight half-holidays, two of which may be commuted for one entire holiday.

(5.) Occupiers must obtain a weekly certificate of school attendance for every child in their employment.

(6.) Medical certificates of fitness for employment are required in the case of children and young persons under 16. When a child becomes a young person a fresh certificate is necessary.

(7.) Notice of accidents, causing loss of life or bodily injury, must be sent to the inspector and certifying surgeon of the district.

Part II. contains special provisions for particular classes of factories and workshops, such as bake-houses, print-works, bleaching and dyeing works. The third schedule to the Act contains a list of special exceptions too numerous to be given in detail.

Part III. provides for the administration of the law. Two classes of officers are to be appointed by the secretary of state, viz., (1) inspectors, charged with the duty of inspecting and examining factories and workshops at all reasonable times, and of exercising such other powers as may be necessary to the carrying out of the Act; and (2) certifying surgeons to grant certificates of fitness under the Act. Numerous other sections relate to penalties and legal proceedings.

Part IV. defines the principal terms used in the Act. Child means a person under fourteen years of age; a "young person" is between fourteen and eighteen; "a woman" means a woman over eighteen. Other sections apply the Act to Scotland and Ireland, with a temporary saving for the employment of children under 10 and children over thirteen (lawfully employed at the time of the passing of the Act). Previous enactments are repealed. (E. R.)

FACULTY, in law, is a dispensation or licence to do that which is not permitted by the common law. The word in this sense is used only in ecclesiastical law. Thus, any alteration or enlargement of a church requires a licence or faculty from the ordinary. The faculty court belonging to the archbishopric of Canterbury is presided over by the Master of the Faculties, who has power "to grant dispensations, as to marry, to eat flesh on days prohibited, to hold two or more benefices incompatible," &c. (Burn's *Ecclesiastical Law*).

In universities and other learned bodies faculty means the association of professors or practitioners of some special branch of learning or skill. Thus, in the Scotch universities we have the usual faculties of arts, medicine, divinity, and law. Again, the society of advocates of the court of session, and local bodies of legal practitioners, are described as faculties. The word, in this sense, has fallen into disuse in England.

FAENZA, a city of Italy, at the head of a circondario in the province of Ravenna, situated in a fertile plain about 20 miles S.W. of Ravenna, at the junction of the Zanelli canal with the Lamone (the ancient Anemo), and on the railway between Bologna and Ancona. It is regularly built, surrounded by walls, and defended by a citadel. Around the market-place (a spacious square in the centre of the town with a fine marble fountain) are arranged the cathedral St Constantius), the town-hall, the theatre, and many handsome residences. The town-hall or *palazzo communale* was formerly the palace of the Manfredi family, and is famous as the scene of the assassination of Galeotto Manfredi by his wife, which has been dramatized by Monti. Several of the churches in the town possess valuable paintings, among which are a few by Girolamo da Treviso. A college, a school of painting, a hospital, and two orphan asylums are among the public buildings of importance. The majolica ware, which takes its French name of "fayence" from the town, still continues to be manufactured, though not to such an extent as formerly; and there are also paper-mills and factories for spinning and weaving silk. A considerable trade is carried on by the canal which was opened in 1782 by Signor Zanelli, to unite the Lamone with the Po di Primaro at Sant' Alberto. About 2½ miles from the town there are thermal and saline springs, from the latter of which salt is extensively manufactured. The same product is also obtained from the cinericious tufa on the banks of the Lamone, and between the Lamone and Sentria runs an abundant vein of sulphur. The population of the town in 1871 was 36,299.

Faenza is identified with the Faventia which is noted in history as the place where Carbo and Norbanus were defeated with great loss by Metellus, the general of Sulla, in 82 B.C. In the time of Pliny it was celebrated for the whiteness of its linen. It was greatly favoured by the emperor Constantine, and during the Middle Ages it continued to be a place of some importance. Dante mentions it as the seat of the powerful family of the Pagani. In 1241 it was captured by Frederick II. after a protracted siege, and not long after the Bolognese obtained temporary possession. A period of independence followed, till the Manfreds, who settled in the city about 1286, established their supremacy. In 1376 the town was pillaged by the notorious Sir John Hawkwood of Essex (the Giovanni Acuto of the Italian chronicles), who served under Gregory XI. The Manfredi power came to an end in 1500, and in 1509 Pope Julius II. secured Faenza against the Venetians by the battle of Ghiara d'Adda. It continued subject to the church till the unification of Italy. At a little distance is the scene of the first battle between the pontifical forces and the French in 1797. The town claims the honour of being the birth place of Torricelli, and has erected a statue to his memory.

FÆSULÆ. See FIESOLE.

FAHLCRANTZ, CHRISTIAN ERIK (1790–1866), a Swedish author, was born at Stora Tuna in Sweden on the 30th of August 1790. The family to which he belonged was a gifted one, and of his brothers, two, Carl Johan the landscape-painter, and Axel Magnus the sculptor, became hardly less distinguished than himself. In 1804 he entered on his career as a student; in 1821 he became tutor in Arabic, and in 1825 professor of the Oriental languages at the university of Upsala. In 1828 he entered the church, but earlier than this, in 1825, he published his polemical and satirical poem of *Noah's Ark*, which enjoyed an immense success. In 1826 appeared a second part of *Noah's Ark*, together with various pieces, original and translated. In 1835 Fahlcrantz brought out his epic of *Ansgarius*, which grew as time went on, and finally consisted, in 1846, of 14 books. In 1842 he was made a member of the Swedish Academy, and in 1843 entered into a furious controversy with the famous novelist, Almqvist, against whose writings he published a thick volume in 1845–46. In 1849 he was made bishop of Vesterås, and his next literary work was an archæological study on the beautiful ancient cathedral of his diocese. In the course of the years 1858–61 appeared the six volumes of his *Rome as it was and is*, a theological polemic, mainly directed against the Jesuits. In 1863 he began to collect and issue his complete works, a task which was still unfinished when he died on the 6th of August

1866, a few hours after conducting service in Vesterås Cathedral.

Of the writings of no Swedish author so much as of those of Fahlcrantz can it be said *facit indignatio versus.* He writes ill, except at a white heat of scorn or anger. His early humoristic poem, *Noah's Ark*, was once extremely popular; it was a satire upon the literary life of 1820, under the form of a parody of the world before the flood. It is still readable, which is more than can be said of *Ansgarius*, a very tedious production. Fahlcrantz will live, if he live at all, by the point and venom of his wit.

FAHRENHEIT, GABRIEL DANIEL (1686–1736), well known for the improvements made by him in the construction of the thermometer and barometer, was born at Dantzic, May 14, 1686. He early relinquished trade for the study of natural philosophy; and, after having travelled in Germany and England, he settled in Holland, where Gravesande and other men of science were his teachers and friends. In 1714 he conceived the idea of substituting mercury for spirits of wine in the construction of thermometers. He took as the zero of his thermometric scale the lowest temperature observed by him at Dantzic during the winter of 1709, which he found was that produced by mixing equal quantities of snow and sal-ammoniac. The space between this point and that to which the mercury rose at the temperature of boiling water he divided into 212 parts. At the time of his death, which took place on September 16, 1736, Fahrenheit was engaged in the contrivance of a machine for draining inundated land. See THERMOMETER and METEOROLOGY.

FAIR. A fair is defined as a "greater species of market recurring at more distant intervals;" both have been distinguished by Lord Coke from "mart," which he considers as a greater species of fair; and all three may comprehensively be described as customary or legalized public places for the sale of commodities (including labour). Thus, in England, no fair can be held without a grant from the sovereign, or prescription which presupposes such grant. In France, the establishment and abolition of fairs—with the exception of cattle markets and the markets of the metropolis—are generally left to the discretion of the departmental prefects. The most commonly accepted derivation of the word fair is from *feriæ*, a name which the church borrowed from Roman custom and applied to her own festivals. A fair was generally held during the period of a saint's feast, and in the precincts of his church or abbey—the time and the place of the chief popular assemblages; but in England this desecration of church and churchyard was first forbidden by the statutes of Henry III. and Edward II. Most of the famous fairs of mediæval England and Europe, with their tolls or other revenues, and, within certain limits of time and place, their monopoly of trade, were grants from the sovereign to abbots, bishops, and other ecclesiastical dignitaries. Their "holy day" associations are preserved in the German word for fairs, *messen;* as also in the *kirmiss*, "church mass," of the people of Brittany. So very intimate was the connexion between the fair and the feast of the saint that the former has very commonly been regarded as an off-shoot or development of the latter. Nevertheless, there are grounds for the supposition that fairs were already existing national institutions, long before the church turned or was privileged to turn them to her own profit. The first charter of the great fair of Stourbridge, near Cambridge, was granted by King John, for the maintenance of a leper hospital; but the origin of the fair itself is ascribed to Carausius, the rebel emperor of Britain, 207 A.D. At all events, it may be seen from the *data* given in Mr Herbert Spencer's *Descriptive Sociology* that the country had then arrived at the stage of development where fairs might have been recognized as a necessity. The Romans also appear to have elaborated a market-law similar to that in force throughout mediæval Europe—though it must be observed that the Roman *nundinæ*, which some have regarded as fairs, were weekly markets. It has also been supposed that the ancient fairs of Lyons were a special privilege granted by the Roman conquerors; and Sidonius Apollinaris, 427 A.D., alludes to the fairs of the district afterwards known as the county of Champagne, as if they were then familiarly known institutions. Fairs, in a word, would not only have arisen naturally, wherever the means of communication between individual centres of production and consumption were felt to be inadequate to the demand for an interchange of commodities; but, from their very nature, they might be expected to show some essential resemblances, even in points of legislation, and where no international transmission of custom could have been possible. Thus, the fair courts of pre-Spanish Mexico corresponded very closely to those under whose supervision the Beaucaire fair is conducted in the present day. They resembled our own courts of piepowder. The Spaniards, when first they saw the Mexican fairs, were reminded of the like institutions in Salamanca and Granada. The great fair or market at the city of Mexico is said to have been attended by about 40,000 or 50,000 persons, and is thus described by Prescott:—

> "Officers patrolled the square, whose business it was to keep the peace, to collect the dues imposed on the various kinds of merchandise, to see that no false measures or fraud of any kind were used, and to bring offenders at once to justice. A court of twelve judges sat in one part of the *tianguez* clothed with those ample and summary powers which, in despotic countries, are often delegated even to petty tribunals. The extreme severity with which they exercised those powers, in more than one instance, proves that they were not a dead letter."

But notwithstanding the great antiquity of fairs, their charters are comparatively modern—the oldest known being that of St Denys, Paris, which Dagobert, king of the Franks, granted (642 A.D.) to the monks of the place "for the glory of God, and the honour of St Denys at his festival." The first recorded grant in England appears to be that of William the Conqueror to the bishop of Winchester, for leave to hold an annual "free fair" at St Giles's hill. The monk who had been the king's jester received his charter of Bartholomew fair, Smithfield, in the year 1133. And in 1248 Henry III. granted a like privilege to the abbot of Westminster, in honour of the "translation" of Edward the Confessor. Sometimes fairs were granted to towns as a means for enabling them to recover from the effects of war and other disasters. Thus, Edward III. granted a "free fair" to the town of Burnley in Rutland, just as, in subsequent times, Charles VII. favoured Bordeaux, after the English wars, and Louis XIV gave fair charters to the towns of Dieppe and Toulon The importance attached to these old fairs may be understood from the inducements which, in the 14th century, Charles IV held out to traders visiting the great fair of Frankfort-on-the-Maine. The charter declared that both during the continuance of the fair, and for eighteen days before and after it, merchants would be exempt from imperial taxation, from arrest for debt, or civil process of any sort, except such as might arise from the transactions of the market itself and within its precincts. Philip of Valois's regulations for the fairs of Troyes in Champagne might not only be accepted as a fair type of all subsequent fair-legislation of the kingdom, but even of the English and German laws on the subject. The fair had its staff of notaries for the attestation of bargains, its court of justice, its police officers, its sergeants for the execution of the market judges' decrees, and its visitors—of whom we may mention the *prud' hommes,*—whose duty it was to examine the quality of goods exposed for sale, and to confiscate those found unfit for consumption. The confiscation required the consent of five or six representatives of the merchant community at the fair. The effect of these great "free fairs" of England and the Continent on the development of society was indeed great. They helped to familiarize the western and northern countries with the banking and financial systems of the Lombards and Florentines, who resorted to them under the protection of the sovereign's "firm peace," and the ghostly terrors of the pope. They usually became the seat of foreign agencies. In the names of her streets Provins preserved the memory of her 12th century intercourse with the agents and merchants of Germany and the Low Countries, and long before that time the Syrian traders at St Denys had established their powerful association in Paris. Like the church on the religious side, the free fairs on the commercial side evoked and cherished the international spirit. And during long ages, when commercial "protection" was regarded as indispensable to a nation's wealth, and the merchant was compelled to "fight his way through a wilderness of taxes," they were the sole and, so far as they went, the complete substitute for our modern free trade.

Their privileges, however, were, from their very nature, destined to grow more oppressive and intolerable the more the towns were multiplied and the means of communication increased. The people of London were compelled to close their shops during the days when the abbot of Westminster's fair was open. But a more curious and complete instance of such an ecclesiastical monopoly was that of the St Giles's fair, at first granted for the customary three days, which were increased by Henry III. to sixteen. The bishop of Winchester was, as we have seen, the lord of this fair. On the eve of St Giles's feast the magistrates of Winchester surrendered the keys of the city gates to the bishop, who then appointed his own mayor, bailiff, and coroner, to hold office until the close of the fair. During the same period, Winchester and Southampton also—though it was then a thriving trading town—were forbidden to transact their ordinary commercial business, except within the bishop's fair, or with his special permission. The bishop's officers were posted along the highways, with power to forfeit to his lordship all goods bought and sold within seven miles of the fair—in whose centre stood "the pavilion," or bishop's court. It is clear, from the curious record of the *Establishment and Expenses of the Household* of Percy, fifth earl of Northumberland, that fairs were the chief centres of country traffic even as late as the 16th century. They began to decline rapidly after 1759, when good roads had been constructed and canal communication established between Liverpool and the towns of Yorkshire, Cheshire, and Lancashire. In the great towns their extinction was hastened in consequence of their evil effects on public morals. All the London fairs were abolished as public nuisances before 1855,—the last year of the ever famous fair of St Bartholomew; and the fairs of Paris were swept away in the storm of the Revolution.

English Fairs and Markets.—For the general reasons apparent from the preceding sketch, fairs in England, as in France and Germany, have very largely given way to markets for specialities. Even the live-stock market of the metropolis is being superseded by the dead-meat market, a change which has been encouraged by recent legislation on cattle disease, the movements of home stock, and the importation of foreign animals. Agricultural markets are also disappearing before the "agencies" and the corn exchanges in the principal towns. Still there are some considerable fairs yet remaining. Of the English fairs for live stock, those of Weyhill in Hampshire (October 10), St Faith's, near Norwich (October 17), as also several held at Devizes, Wiltshire, are among the largest in the kingdom. The first named stands next to none for its display of sheep; whilst the second is the principal resort of the Scotch drovers and cattle-dealers, and supplies a large proportion of the fat stock required for the London market. Horncastle, Lincolnshire, is the largest horse fair in the kingdom, and is regularly visited by American and Continental dealers. The other leading horse fairs in England are Howden in Yorkshire (well known for its hunters), and Woolbridge (on Lady Day) for Suffolk horses. Exeter December fair has a large display of cattle, horses, and most kinds of commodities. Large numbers of Scotch cattle are also brought to the fairs of Market Harborough, Carlisle, and Ormskirk. Ipswich has a fair for lambs on 1st of August, and for butter and cheese on 1st of September. Gloucester fair is also famous for the last-named commodity. The guild or jubilee held at Preston, Lancashire, every twentieth year, occurred last in 1862. Falkirk fair, or tryst, for cattle and sheep, is one of the largest in Scotland; and Ballinasloe, Galway, holds a like position among Irish fairs. The Ballinasloe cattle are usually fed for a year in Leinster before they are considered fit for the Dublin or Liverpool markets. In 1790 there were 61,931 sheep and 8632 horned cattle exhibited at the fair, and for 1867 the returns, in the foregoing order, were 73,364 and 23,734.

French Fairs.—The most important is that of Beaucaire, once among the first in Europe. Its position on the Rhone (14 miles east of Nismes), and its connexion with the canals, still enable it to maintain a high rank among the Continental markets. It lasts from the 22d to the 28th July, and is visited by about 60,000 persons, from all parts of the Continent between Spain and the Levant; articles of all descriptions are sold at it. It is a rule that all bills due at this fair must be presented on the 27th and protested, if necessary, on the 28th.

German Fairs.—First, though no longer of world-wide importance, are those of Frankfort-on-the-Maine, Frankfort-on-the-Oder, and Leipsic. Those of Frankfort-on-the-Maine begin on Easter Tuesday and on the nearest Monday to September 8 respectively, and their legal duration is three weeks, though the limit is regularly extended. The fairs of the second-named city are *Reminiscere*, February or March; *St Margaret*, July; *St Martin*, November. Ordinarily they last fifteen days, which is double the legal term. The greatest of the German fairs are those of Leipsic, whose display of books is famous all over the world. Its three fairs are dated January 1, Easter, Michaelmas. The Easter one is the book fair, which is attended by all the principal booksellers of Germany, and by many more from the adjoining countries. Most German publishers have agents at Leipsic. As many as 5000 new publications have been entered in a single Leipsic catalogue. As in the other instances given, the Leipsic fairs last for three weeks, or nearly thrice their allotted duration. Here no days of grace are allowed, and the holder of a bill must demand payment when due, and protest, if necessary, on the same day, otherwise he cannot proceed against either drawer or endorser.

Russian Fairs.—These are very numerous, the chief being those of Nijni Novgorod, of Irbit in Perm, Kharkoff (January and August), Poltava (August and February), Koreunais in Koursk, Ourloupinsknia in the Don Cossack country, Krolevetz in Tchernigoff, and a third fair held at Poltava on the feast of the Ascension. It is calculated that in 1851 the aggregate value of goods sold at the above named fairs amounted to nearly 120,000,000 silver roubles. The chief fair of Novgorod is attended by 100,000 to 150,000 persons from all parts of Asia and of eastern Europe. Thirty years ago the fair of Kiatcha, on the Russo-Chinese frontier, yielded one million sterling in revenue, but in 1867, according to Mr Lumley, secretary to the

English embassy at St Petersburg, the sum had fallen by one half. This was in consequence of the opening of new communications, and the abolition of the Kiatcha monopoly.

Turkish Fairs.—Of these there are a very considerable number, and the vast bulk of the internal commerce of the country is transacted at them. Among the most noteworthy are the fairs of Usundji, in Roumelia, on a tributary of the Maritza, 40 miles from Adrianople; Janina in Albania; Strouga, on the lake of Orida; Novi-Bazaar in Upper Mœsia; Islioui in Thrace; Nicopoli and Prelip in Macedonia; Eski-djouma in Bulgaria; and Zeitoun and Pharsalia in Thessaly. There is a large show of western manufactures at the Usundji fair.

Indian Fairs.—The largest of these, and perhaps the largest in Asia, is that of Hurdwar, on the upper course of the Ganges. The visitors to this holy fair number from 200,000 to 300,000; but every twelfth year there occurs a special pilgrimage to the sacred river, when the numbers may amount to a million or upwards. Those who go solely for purposes of trade are Nepaulese, Mongolians, Thibetans, Central Asiatics, and Mahometan pedlars from the Punjab, Scinde, and the border states. Persian shawls and carpets, Indian silks, Cashmere shawls, cottons (Indian and English), preserved fruits, spices, drugs, &c., together with immense numbers of cattle, horses, sheep, and camels, are brought to this famous fair.

American Fairs.—The word fair, as now used in the United States, appears to have completely lost its Old World meaning. It seems to be exclusively applied to industrial exhibitions, and to what we in England would call fancy bazaars. Thus, during the civil war, large sums were collected at the "sanitary fairs," for the benefit of the sick and wounded. To the first-named class belong the State and county fairs, as they are called. Among the first and best known of these was the "New York World's Fair," opened in 1853 by a company formed in 1851. Since 1829 the "American Institute" held annual "fairs" for the encouragement of the agricultural and manufacturing arts. The chief centres of these "fairs," or exhibitions, appear to be Cincinnati, Baltimore, Boston, San Francisco, and Buffalo.

Law of Fairs.—As no market or fair can be held in England without a royal charter, or right of prescription, so any person establishing a fair without such sanction is liable to be sued, under a writ of *Quo warranto*, by any one to whose property the said market may be injurious. Nor can a fair or market be legally held beyond the time specified in the grant; and by 5 Edward III. c. 5 a merchant selling goods after the legal expiry of the fair forfeited double their value. To be valid, a sale must take place in "market-overt" (open market); "it will not be binding if it carries with it a presumption of fraudulence." These regulations satisfied, the sale "transfers a complete property in the thing sold to the vendee; so that however injurious or illegal the title of the vendor may be, yet the vendee's is good against all men except the king." (In Scotch law, the claims of the real owner would still remain valid.) However, by 21 Henry VIII. c. 2 it was enacted that, "if any felon rob or take away money, goods, or chattels, and be indicted and found guilty, or otherwise attainted upon evidence given by the owner or party robbed, or by any other by their procurement, the owner or party robbed shall be restored to his money, goods, or chattels," but only those goods were restored which were specified in the indictment, nor could the owner recover from a *bona fide* purchaser in market-overt, who had sold the goods before conviction. For obvious reasons the rules of market overt were made particularly stringent in the case of horses. Thus, by 2 Philip and Mary c. 7 and 31 Eliz. c. 12, no sale of a horse was legal which had not satisfied the following conditions:—Public exposure of the animal for at least an hour between sunrise and sunset; identification of the vendor by the market officer, or guarantee for his honesty by "one sufficient and credible person;" entry of these particulars, together with a description of the animal, and a statement of the price paid for it, in the market officer's book. Even if his rights should have been violated in spite of all these precautions, the lawful owner could recover, if he claimed within six months, produced witnesses, and tendered the price paid to the vendor. Tolls were not a "necessary incident" of a fair—*i.e.*, they were illegal unless specially granted in the patent, or recognized by custom. As a rule, they were paid only by the vendee, and to the market clerk, whose record of the payment was an attestation to the genuineness of the purchase. By 2 and 3 Philip and Mary c. 7 every lord of a fair entitled to exact tolls was bound to appoint a clerk to collect and enter them. It was also this functionary's business to test measures and weights. Tolls, again, are sometimes held to include "stallage" and "picage," which mean respectively the price for permission to erect stalls and to dig holes for posts in the market grounds. But toll proper belongs to the lord of the market, whereas the other two are usually regarded as the property of the lord of the soil. The law also provided that stallage might be levied on any house situated in the vicinity of a market, and kept open for business during the legal term of the said market. Among recent statutes, one of the chief is the Markets and Fairs Clauses Act (10 Vict. c. 14), the chief purpose of which is to consolidate previous measures. By the Act no proprietors of a new market are permitted to let stallages, take tolls, or in any way open their grounds for business, until two justices of the peace have certified to the completion of the fair or market. After the opening of the place for public use, no person other than a licensed hawker shall sell anywhere within the borough, his own house or shop excepted, any articles in respect of which tolls are legally exigible in the market. A breach of this provision entails a penalty of forty shillings. Vendors of unwholesome meat are liable to a penalty of £5 for each offence; and the "inspectors of provisions" have full liberty to seize the goods and institute proceedings against the owners. They may also enter "at all times of the day, with or without assistance," the slaughter-house which the undertaker of the market may, by the special Act, have been empowered to construct. For general sanitary reasons, persons are prohibited from killing animals anywhere except in these slaughter-houses. Again, by 36 and 37 Vict. c. 37, times of holding fairs are determined by the secretary of state; while 34 Vict. c. 12 empowers him to abolish any fair on the representation of the magistrate and with the consent of the owner. The preamble of the Act states that many fairs held in England and Wales are both unnecessary and productive of "grievous immorality."

The Fair Courts.—The Piepowder Courts, the lowest but most expeditious courts of justice in the kingdom, as Chitty calls them, were very ancient. The Conqueror's law *De Emporiis* shows their pre-existence in Normandy. Their name was derived from *pied puldreux*, Norman for pedlar.[1] The lord of the fair or his representative was the presiding judge, and usually he was assisted by a jury of traders chosen on the spot. Their jurisdiction was limited by the legal time and precincts of the fair, and to disputes about contracts, "slander of wares," attestations, the preservation of order, &c.

Authorities.—See Herbert Spencer's *Descriptive Sociology*, 1873, especially the columns and paragraphs on "Distribution;" Prescott's *History of Mexico*, for descriptions of fairs under the Aztecs; Giles Jacob's *Law Dictionary*, London, 1809; Joseph Chitty's *Treatise on the Law of Commerce and Manufactures* (vol. ii. chap. 9), London, 1824; Holinshed's and Grafton's *Chronicles*, for lists, &c., of English fairs; Meyer's *Das Grosse Conversations Lexicon*, 1852, under "Messen;" article "Foire" in Larousse's *Dictionnaire Universelle du XIXe. Siècle*, Paris, 1866–1874, and its references to past authorities; and especially, the second volume, commercial series, of the *Encyclopédie Méthodique*, Paris, 1783; M'Culloch's *Dictionary of Commerce*, 1869-1871; Wharton's *History of English Poetry*, pp. 185, 186, of edition of 1870, London, Murray & Son, for a description of the Winchester Fair, &c.; a note by Professor Henry Morley in p. 498, vol. vii. *Notes and Queries*, second series; the same author's unique *History of the Fair of St Bartholomew*, London, 1859; Wharton's *Law Lexicon*, Will's edition, London, 1876; and also, for some effects of recent legislation, as regards meat and fat stock markets, the debates in the House of Lords Feb. 12 and March 5, 1878.

(J. MA.)

FAIRBAIRN, Sir William, Baronet (1789–1874), a distinguished mechanical engineer, was born at Kelso, Roxburghshire, February 19, 1789. His father, who occupied the humble position of farm bailiff, possessed a large measure of the untiring energy and practical skill which were so conspicuously manifested in the son, but on account of adverse circumstances the family were often reduced to very hard straits; and as they frequently required to change their place of residence, the education which the children received was somewhat fragmentary. At the age of ten, however, young Fairbairn had "mastered the rules of arithmetic as far as practice and the rule of three," and had acquired a taste for reading by a perusal of the selections from English authors in Scott and Barrow's col-

---

[1] Skene has shown the identity in Scotch borough law between "marchand travelland" and "pied puldreux," or "dusty fute."

sections. He afterwards received additional instruction in reading, writing, and accounts, and obtained from his uncle, who was a parish schoolmaster, some knowledge of mensuration; but "the want of a good grammatical course, and a slight knowledge of the classics," was a frequent subject of regret to him in his subsequent life. Other circumstances worthy of notice connected with his earlier years were his fondness for athletic exercises, which often tempted him to the performance of daring feats in climbing, and the early development of his mechanical genius, which first displayed itself in the construction of a waggon to save himself the trouble and fatigue of carrying his infant brother on his back. It is somewhat remarkable that the other efforts of his mechanical genius in boyhood had reference chiefly to ships and mills, with the construction of both of which his name was subsequently so largely associated. In 1803 it was found necessary that Fairbairn should contribute something to the very straitened family income, and he obtained work at three shillings a week as a mason's labourer on the Rennie bridge at Kelso; but a serious accident which happened to him a few days after beginning this employment not only deprived the family of the small help of his earnings, but, by the expense it entailed, contributed to bring them almost to the brink of starvation. His father having, however, shortly after this obtained the situation of steward on a farm connected with Percy Main Colliery near North Shields, William obtained employment as a carter in connexion with the colliery. Here, on account of his "Scotch accent and different manner, he became the mark of every species of annoyance," and had to take part in no less than seventeen pugilistic encounters before he was "able to attain a position calculated to ensure respect." In March 1804 an immense change for the better occurred in his surroundings and prospects, by his being bound an apprentice to a millwright at Percy Mains. He now commenced a systematic course of self-improvement, assigning each day of the week to a particular subject of study, and devoting also a fixed amount of his time to recreation and amusement. Besides obtaining by unaided application a pretty complete knowledge of practical mathematics he contrived to go through an extensive course of general reading; and an attachment he formed to a young girl, whom he afterwards married, by leading him to begin letter writing, was his first stimulus to the practice of literary composition. It was at Percy Mains also that he made the acquaintance of George Stephenson, who then had charge of an engine at a neighbouring colliery, and the friendship thus begun lasted through life.

For some years subsequent to the expiry of his term of apprenticeship, Fairbairn, who, with all his forethought and persevering diligence, had still in his composition a strong love of adventure and a spice of recklessness, lived a somewhat roving life, seldom remaining long in one place and often reduced to very hard straits before he got a job. But soon after his marriage he began seriously to set himself to the attainment of the object he had long contemplated, his emancipation from daily labour; and in November 1817 he entered into partnership with a shopmate of the name of Lillie, with whose aid he hired an old shed in High Street, Manchester, where he set up a lathe, and began business. His first order was to renew the shaftwork of an extensive cotton mill, which with great diligence he accomplished within the specified time, and not only satisfactorily, but with the substitution of improvements which virtually amounted to a revolution of the whole system of mill construction. Such a successful performance of their first contract immediately secured to the new firm a great reputation, and orders pressed in much faster than they were able with their limited capital to execute them. Their fame soon extended beyond Manchester, and in 1824 Fairbairn was engaged to plan and execute a new arrangement of the water-power of Catrine cotton works, Ayrshire, where, and at Deanston, Perthshire, he introduced a system of water-wheel construction whose hydraulic power has never been surpassed. In the summer of 1824 he also effected similar improvements in a mill at Zurich, Switzerland. In 1832 Fairbairn dissolved partnership with Lillie, retaining the works in Canal Street to which they had previously removed. In 1830 he had been employed by the Forth and Clyde Canal Company to make experiments with the view of determining whether it were possible to construct steamers capable of traversing the canal at a speed which would enable the canal interest to compete successfully with that of the railway; and the results of his investigation were published by him in 1831, under the title *Remarks on Canal Navigation.* His plan of using iron boats proved inadequate to overcome the difficulties of his problem, but it first suggested the construction of iron vessels; and in the development of the use of this material both in the case of merchant vessels and men-of-war the chief merit must be assigned to Fairbairn. In this way also he was led to pursue those experiments in regard to the strength of iron, according to its combination with other substances, and to various methods of preparation and construction, which have given him a place in this branch of mechanical engineering altogether pre-eminent. In 1835 Fairbairn established, in connexion with his Manchester business, a ship-building yard at Millwall, London, where he constructed several hundred vessels, including many for the royal navy; but he ultimately found it impossible with his other engagements to superintend the work in such a satisfactory manner as to make it pay, and at the end of 14 years he disposed of the concern at a great loss. In 1837 he was employed by the sultan of Turkey with the view of assisting in the introduction of the mechanical arts into that country, and after his return home his services were rewarded by a decoration. For several years Fairbairn was engaged, in conjunction with Eaton Hodgkinson, in making experiments on the strength and other properties of iron, and in 1845 he was consulted by Robert Stephenson in reference to the best method of constructing the tubular bridge which the latter designed for carrying the railway across the Conway and Menai Straits. Although the share Fairbairn had in the undertaking has been the subject of some dispute, there can be no doubt that he was guided in his experiments chiefly by his own independent judgment, and that he was the inventor of the rectangular self-supporting tube which was the essential feature of the construction. For this invention he, with the concurrence of Stephenson, took out a patent, and he afterwards constructed more than a thousand bridges on the same principle. In reference to his connexion with the invention, he published a volume entitled *An Account of the Construction of the Britannia and Conway Tubular Bridges*, &c., 1849. In 1849 he was invited by the king of Prussia to submit designs for the construction of a bridge across the Rhine, but after various negotiations, another design, by a Prussian engineer, which was a modification of Fairbairn's, was adopted. Another matter which engaged much of Fairbairn's attention was steam boilers, in the construction of which he effected many improvements. He is also the inventor of the tubular crane, and took out several patents for the construction and arrangement of steam machines. In 1851 he greatly aided, by his fertility and readiness of invention, in an investigation carried on at his works by Mr Joule and Sir William Thomson in reference to the properties of the materials of the earth's surface; and from 1861 to 1865 he was employed to guide the experiments of the Government committee appointed to inquire into the "application of iron to defensive purposes." The results of his experiments were published in the proceedings of the committee. Fairbairn was a member of many learned societies, both British and foreign. In 1860 he received the degree of LL.D. from the university of Edinburgh, and in 1862 that of D.C.L. from the university of Cambridge. He declined the honour of knighthood in 1861, but accepted a baronetcy in 1869. He died at Moor Park, Surrey, August 18, 1874. Perhaps no one ever made more use than Fairbairn of the time at his disposal, for amid all the cares of business he not only found leisure for varied scientific investigation, but managed to obtain a wide acquaintance with general literature, to conduct an extensive correspondence on a great variety of subjects, and also to participate largely in the delights of social intercourse. In private his unassuming but dignified simplicity, his thorough honour, and his geniality and kindness secured him general esteem. The results he achieved in mechanical science were due chiefly to minute, patient, and sagacious observation and experiment. It was his habit to aid himself in his investigations by committing his ideas to writing, and, when his opinions on any subject were matured, to communicate them to the world either in a published volume, or by a paper read before some learned institution. By his extensive acquaintance with English authors, and his early and patient practice of composition, he acquired the possession of a clear, simple, and nervous style, and his writings are in this respect worthy to be regarded as models in their own species of literature.

Among his principal writings, besides those already mentioned, may be named *On the Application of Cast and Wrought Iron to Building Purposes*, 1856; *Iron, its History, Properties, and Processes of Manufacture* (reprinted from the eighth edition of the *Encyclopædia Britannica*), 1861; *Treatises on Mills and Millwork*, part i., 1861, part ii., 1863; *Treatise on Iron Shipbuilding*, 1865; and *An Experimental Enquiry into the Strength, Elasticity, Ductility, and other Properties of Steel*, 1869. These have all passed through several editions. His papers read before learned societies are too numerous to be mentioned. The *Life of Sir William Fairbairn*, partly written by himself, and edited and completed by William Pole, F.R.S., was published in 1877, and a popular edition of this work appeared in 1878.

FAIRFAX, EDWARD (? 1580–1632), the most poetical of all the translators of Tasso, was a native of Yorkshire, second son of Sir Thomas Fairfax of Denton. As Roger Dodsworth, the antiquary—a contemporary of Fairfax—styles him the "natural" son of Sir Thomas, it has been assumed that the poet was illegitimate, but it is certain that in the time of Queen Elizabeth the term "natural" was often used to signify *true* or *legitimate*, *i.e.*, the father's *own* son. We may therefore conclude with Douglas in his *Peerage* that Edward was the lawful son of Sir Thomas Fairfax, by Dorothy his wife, daughter of George Gale of Ascham Grange. The date of his birth has not been ascertained. He is said to have been only about twenty years of age when he published his translation of the *Gerusalemme Liberata*. This is very doubtful, but it would place his birth about the year 1580. He seems early to have preferred a life of study and retirement to the military service in which his brothers were distinguished. Having married, he lived at Fuystone, a place situated between the paternal seat of Denton and the forest of Knaresborough, and there his time was spent in his literary pursuits, and in the education of his children and those of his elder brother, Sir Thomas Fairfax, afterwards baron of Cameron. His famous translation appeared in 1600,—*Godfrey of Bulloigne, or the Recoverie of Ierusalem, done into English heroicall Verse by Edw. Fairefax, Gent.* Never did any mere translation receive such enthusiastic and continued approbation as this work by Fairfax. In the same year in which it was published extracts from it were printed in *England's Parnassus*. Edward Phillips, the nephew of Milton, in his *Theatrum Poetarum*, a work in which, as Warton says, may be discovered many traces of Milton's hand, warmly eulogized the translation. Waller said he was indebted to it for the harmony of his numbers. Dryden places the translator almost on a parity with Spenser (whom undoubtedly Fairfax imitated), and Collins has beautifully associated him with his great original, Tasso:—

> "How have I sat, when piped the pensive wind,
> To hear his harp by British Fairfax strung!
> Prevailing poet, whose undoubting mind
> Believed the magic wonders which he sung!"[1]

In more recent times we find Campbell pronouncing Fairfax's work one of the glories of the reign of Elizabeth, to whom it was dedicated. Hallam, more critical, said the translation did not represent the grace of its original, and deviated too much from its sense, yet was by no means deficient in spirit or vigour. The poetical spirit of the work is indeed its life blood and preservation. Hoole and Hunt may give a more literal version, but Fairfax alone seizes upon the poetical and chivalrous character of the poem. As Denham says of Fanshawe's rendering of the *Pastor Fido*:—

> 'They but preserve the ashes, he the flame
> True to its sense, but truer to its fame."

And in this way he carries along with him the interest and admiration of the reader. The sweetness and melody of many passages are scarcely excelled even by Spenser. Fairfax made no other appeal to the public. He wrote however, a series of eclogues, ten in number, one of which, the fourth, was published by permission of the family, in Mrs Cooper's *Muses' Library* (1737). He wrote also a *Discourse on Witchcraft, as it was acted in the Family of Mr Edward Fairfax of Fuystone in the county of York in* 1621, which was edited from the original copy by Mr Monckton Milnes (now Lord Houghton) in the *Miscellanies of the Philobiblon Society*, 1858–9. Fairfax was a firm believer in witchcraft. He fancied that some of his children had been bewitched, and he had the poor wretches whom he accused brought to trial, but without obtaining a conviction. Such "follies of the wise" are painful to contemplate. Fairfax, however, only shared in the common superstition of the age, and it is at once a memorable and melancholy fact that Sir Matthew Hale, the most upright and able of lawyers, condemned two women to the stake on a charge of witchcraft. Fairfax described himself as "neither a fantastic Puritan nor superstitious Papist; but so settled in conscience as to have the sure ground of God's word to warrant all he believed, and the commendable ordinances of the English Church to approve all he practised." And he adds, "I live a faithful Christian and an obedient subject, and so teach my family." His descendants have not deemed it necessary to publish his writings on theological subjects and the keen controversies of the times. His fame is secure, grafted on the stem of Tasso, and flourishing in perennial beauty and vigour. Fairfax was living in 1631, and is supposed to have died soon afterwards, about 1632.

FAIRFAX, THOMAS, THIRD LORD, better known as Sir Thomas Fairfax, the eminent Parliamentary general and commander-in-chief during the civil wars, was the eldest son of Sir Ferdinando (afterwards Lord) Fairfax by Mary, daughter of Lord Sheffield, president of the North, and was born at Denton, on the banks of the Wharfe, near Otley, Yorkshire, on the 17th of January 1611–12. He studied

---

[1] *Ode on Popular Superstitions.* Sir Walter Scott conceived that the lines applied to Fairfax (*Demonology*, Letter viii.), and Thomas Campbell seems to have entertained the same opinion (*Specimens of the Poets*),—also Charles Knight and others. A careful perusal of the stanza, however, will show that Collins intended the honour for Tasso, not for his translator. Both, indeed, may be said to have "believed the magic wonders which they sung."

at St John's College, Cambridge, about four years (1626–30), and then proceeded to Holland to serve as a volunteer with the English army in the Low Countries under Lord Vere of Tilbury. This connexion led to one still closer; in the summer of 1637 Fairfax married Anne, daughter of Lord Vere, a lady of spirit, whom Mr Carlyle characterizes as "a Vere of the fighting Veres and given to Presbyterianism." The Fairfaxes, though serving at first under Charles I., were opposed to the arbitrary prerogative of the crown, and Sir Thomas (he had been knighted by Charles in 1640) declared that "his judgment was for the parliament as the king and kingdom's great and safest council." When Charles endeavoured to raise a guard for his own person at York, intending it, as the event afterwards proved, to form the nucleus of an army, Fairfax was employed to present a petition to his sovereign, entreating him to hearken to the voice of his parliament, and to discontinue the raising of troops. This was at a great meeting of the freeholders and farmers of Yorkshire convened by the king on Heyworth Moor near York. Charles evaded receiving the petition, pressing his horse forward, but Fairfax followed him and placed the petition on the pommel of the king's saddle. The incident is typical of the times and of the actors in the scene. War broke out, Lord Fairfax was appointed general of the Parliamentary forces in the north, and his son Sir Thomas, was made general of the horse under him. Both father and son distinguished themselves in the campaigns in Yorkshire. At first the Parliamentary troops were not successful. The Cavalier spirit of honour and high-bred loyalty was too much, as Cromwell said, for poor tapsters and town-apprentice people. There was little hope of success until men of strong religious feelings could be brought into the field against them, and this was effected by Oliver and his Ironsides, his invulnerable troop of disciplined horsemen. In the beginning of 1644 the Scottish army under the command of the earl of Leven joined the Parliamentary forces, and after some minor engagements, commenced the siege of York, then invested by the marquis of Newcastle. York was considered the second town of England, and upon its preservation Charles believed that the safety of his crown mainly depended. There were several assaults and sallies, but news having arrived that Prince Rupert was marching to raise the siege with 20,000 men, the besieging generals, Leven, Fairfax, and Manchester, resolved to draw off their troops, and encamp on the moor seven miles west of York. On the 2nd of July 1644, was fought the important battle of Marston Moor, which virtually decided the fate of the war. The gallantry of the troopers led by the old earl of Leven, Manchester, and Fairfax was conspicuous.[1] Fairfax was severely wounded, and he lost a brother in the action. The victory was so decisive that the marquis of Newcastle fled the kingdom, and the Royalists abandoned all hope of retrieving their affairs. The city of York was taken, and nearly the whole north submitted to the parliament.

In the south and west of England, however, the Royalist cause was still active. The war had lasted two years, and the nation began to complain of the contributions that were exacted and the excesses that were committed by the military. Dissatisfaction was expressed with the military commanders, Essex and Manchester, and as a preliminary step to reform, the self-denying ordinance was passed. This Act took from all members of parliament their commands in the army or their civil employments. The earl of Essex was removed from the supreme command, and Sir Thomas Fairfax appointed his successor. Cromwell, as a member of the House of Commons, was excluded by the ordinance, but he was too important to be dispensed with; he was made lieutenant-general under Fairfax. The army was new modelled, incompetent officers were dismissed, and the regiments completed by more select levies. The hostile armies met on the 14th of June 1645, at Naseby in Northamptonshire, and a decisive battle took place, which ended in the total discomfiture of the Royalists. The king himself was in the field. "At Naseby," says Carlyle, "Charles fought his last battle—dashed fiercely against the new model army which he had despised till then—and saw himself shivered utterly to ruin"—partly through the fiery rashness of Prince Rupert, but mainly through the able generalship of Fairfax and Cromwell. The king fled to Wales. Fairfax besieged Leicester, and was successful at Taunton, Bridgewater, and Bristol. The whole west was soon reduced to obedience. The king had returned from Wales and established himself at Oxford, where there was a strong garrison, but danger was too apparent; the vacillating monarch withdrew secretly, and proceeded to Newark to throw himself into the arms of the Scots. Oxford capitulated; and by the end of September Charles had neither army nor garrison in England.

Fairfax arrived in London on the 12th of November 1645. In his progress towards the capital he was accompanied by applauding crowds. Complimentary speeches and thanks were presented to him by both houses of parliament, along with a jewel of great value set with diamonds, and a sum of money. Charles was delivered up to the commissioners of parliament by the Scots in January 1646. He had voluntarily surrendered himself to the Scots army, and they negotiated with the parliamentary leaders in his favour. There was a debt of £600,000, arrears of pay, owing to the Scots, but they agreed to take £400,000, one half of which was to be paid before the army left England. The bargain was concluded some months before there was any stipulation to deliver up the king, but probably, as Hallam remarks, the parliament would never have actually paid the money on any other consideration than the delivering of the king's person.[2] The transaction was naturally seized upon by the Royalists and the Cavalier wits, and poets, as a subject of obloquy and reproach to the Scots commissioners, and, by implication, to the whole Scottish nation. It is not yet forgotten. Such political libels are not of that class which the poet says are "born to die." They become the shibboleths of a party, and descend from generation to generation.

Charles was delivered up to the commissioners of parliament on the 30th January 1646–7. Fairfax, who preceded the king, having met him beyond Nottingham, dismounted from his horse, kissed the royal hand, and having resumed his seat, discoursed with the unfortunate prince during the journey to Holdenby. "The general," said Charles, "is a man of honour, and keeps his word which he had pledged to me." His chivalrous courtesy is of a piece with his whole character.

The agitation in the army now became formidable, and threatened anarchy. The Independents were too powerful for both parliament and Presbyterians. Fairfax resolved to

---

[1] Cromwell, in the letter to his brother-in-law, assumes the whole credit of the defeat of the Royalist right, certainly at the expense both of truth and honour. He says: "The left wing which I commanded, being our own horse, saving a few Scots in our rear, beat all the Prince's horse. God made them as stubble to our swords." Now the few Scots consisted of 1920 men out of 4200, and Cromwell's assertion that they were in the rear is contradicted by every other eye-witness who mentions them. Principal Bailie, who received a long account of the battle from his namesake, and had other sources of information now lost, says that David Leslie (Leven) in all places that day was Cromwell's leader.—Markham's *Life of Fairfax*. Mr Carlyle does not take up this disputed point.

[2] Major-General Skippon carried up the cash, £200,000, to Newcastle successfully in a proper number of waggons; got it all counted there, bags of £100, chests of £1000 (5–19th January 1646-7) after which the Scots marched peaceably away.—*Carlyle*.

resign his commission as commander-in-chief, but he was persuaded to retain it, and was passive, if not co-operating, in all the proceedings of the army which had for their object to destroy the power of parliament. Lord Ferdinando Fairfax died in the spring of 1647, and Sir Thomas succeeded to his title and to his office as governor of Hull. A second civil war broke out in the summer of 1648; a Scots army of 40,000 was raised to deliver the king from the "sectaries;" there were tumults in England and in Wales. Fairfax displayed the greatest activity in putting down these insurrections, and took Colchester, whither the royalist army had betaken themselves. It was at this time, when the commander-in-chief was besieging Colchester, that Milton addressed to him the sonnet:—

> "Fairfax, whose name in arms through Europe rings,
> Filling each mouth with envy or with praise."

The poet eulogizes the brave soldier for "firm unshaken virtue," but he hesitated to go along with the army and Independents in the trial of the king. He was placed at the head of the judges before whom Charles was arraigned, but he refused to act. In calling over the court, when the crier pronounced the name of Fairfax, a lady in the gallery called out "that the Lord Fairfax was not there in person, that he would never sit among them, and that they did him wrong to name him as a commissioner." This was Lady Fairfax, who could not forbear, as Whitelock says, to exclaim aloud against the proceedings of the High Court of Justice. The decision of the court was a grievous error. "When living, Charles was a baffled tyrant," as Lord John Russell has remarked; "when dead he became a royal martyr." In June 1650, after the Scots had declared for Charles II., the council of state resolved to send an army to Scotland in order to prevent an invasion of England. Fairfax declined to act against the Presbyterian Scots, and resigned his commission. Cromwell was appointed his successor, "captain-general and commander-in-chief of all the forces raised or to be raised by authority of parliament within the commonwealth of England." Fairfax received a pension of £5000 a year, and is no more heard of till after the death of the triumphant Protector.

When Monk invited him to assist in the operations about to be undertaken against Lambert's army he promptly obeyed the call, and in December 1659 appeared at the head of a body of Yorkshire gentlemen; and such was the influence of Fairfax's name and reputation that the Irish brigade, consisting of 1200 horse, quitted Lambert's colours and joined him. This was speedily followed by the breaking up of all Lambert's forces, and that day secured the restoration of the monarchy. A "free" parliament was called; Fairfax was elected member for Yorkshire, and was put at the head of the commission appointed by the House of Commons to wait upon Charles II. at the Hague and urge his speedy return. Of course the "merry monarch, scandalous and poor," was glad to obey the summons, and Fairfax provided the horse on which Charles rode at his coronation. The remaining eleven years of the life of Lord Fairfax were spent in retirement at his seat in Yorkshire. He must, like Milton, have been sorely grieved and shocked by the scenes that followed—the brutal indignities offered to the remains of his companions in arms, Cromwell and Ireton, the sacrifice of Sir Harry Vane, the neglect or desecration of all that was great, noble, or graceful in England, and the flood of immorality which, flowing from Whitehall, sapped the foundations of the national strength and honour. Lord Fairfax died at Nunappleton on the 12th of November 1671. The integrity of Fairfax has never been doubted. No one has ever attempted to charge meanness or corruption on the Parliamentary general. But he was great only in the field, and had apparently none of the qualities of a statesman. He is placed at great disadvantage, however, by being both in war and in peace overshadowed by his associate Cromwell:

> "And under him
> His genius was rebuked, as, it is said,
> Mark Antony's was by Cæsar."

Lord Fairfax had a taste for literature. He translated some of the Psalms, and wrote poems on solitude, the Christian warfare, the shortness of life, &c., none of which are above mediocrity. During the last year or two of his life he wrote two *Memorials* which have been published—one on the northern actions in which he was engaged in 1642–44, and the other on some points during his command in the army. At York and at Oxford he endeavoured to save the libraries from pillage, and he enriched the Bodleian with some valuable MSS. His correspondence was published in 1848–9 in four volumes, and a life of him by Clements R. Markham in 1870. (R. CA.)

FAIRFIELD, a town and port of entry of Fairfield co., Connecticut, is situated near Long Island Sound, and on the New York and New Haven railroad, 22 miles S.W. of New Haven. It consists chiefly of one spacious street of new and handsome buildings. The beautiful scenery and fine sea air of the neighbourhood attract to the town a considerable number of summer visitors, but its prosperity depends chiefly on its shipping trade. About one and a half miles south-east from the town is Black Rock, one of the finest harbours of the state. Fairfield was settled in 1659. In 1779 it was burned by the British under Governor Tryon. The population in 1870 numbered 5645, but since then a portion of the town, containing more than a fourth of the inhabitants, has been annexed to Bridgeport.

FAIRHOLT, FREDERICK WILLIAM (1813–1866), a most industrious antiquary, draughtsman, and editor of our older literature, was born in London in the year 1813. His father, who was of a German family (the name was originally Fahrholz), was a tobacco manufacturer, and for some years Fairholt himself was employed in the business. He had, however, other aims. For a time he was a drawing-master, afterwards a scene-painter. Some pen and ink copies made by him of figures from Hogarth's plates led to his being employed by Charles Knight on several of that gentleman's illustrated publications. His first published literary work was a contribution to Hone's *Year-Book* in 1831. His life seems to have been one of almost uninterrupted quiet labour, carried on until within a few days of death. Several works on civic pageantry and some collections of ancient unpublished songs and dialogues were edited by him for the Percy Society in 1842. In 1844 he was elected fellow of the Society of Antiquaries. An edition of the dramatic works of Lilly was published by him in 1853. His principal independent works are *Tobacco, its History and Association*, 1859; *Up the Nile and Home Again*, 1862; many articles and serials contributed to the *Art Journal*, some of which were afterwards separately published, as *Costume in England*, 1846; *Dictionary of Terms in Art*, 1854. These works are illustrated by numerous cuts, drawn on the wood by his own hand. His pencil was also employed in illustrating Evan's *Coins of the Ancient Britons*, Madden's *Jewish Coinage*, Halliwell's folio *Shakespeare*, Roach Smith's *Richborough*, the *Miscellanea Graphica* of Lord Londesborough, and many other works. Mr Fairholt was entirely a Londoner; born in London, and never out of sight of St Paul's for the first twenty-two years of his life, he ever loved a paved street better than a green lane. His later years were much troubled by disease which, though temporarily alleviated by a voyage to Egypt and Nubia with the present Lord Londesborough, terminated in consumption. He died April 3, 1866. His books relating to Shakespeare were bequeathed to the library at Stratford-on-Avon; those on civic pageantry (between 200 and 300 volumes) to the Society of Antiquaries; his old prints and works on costume to the British Museum.

FAIRIES (Fr., *fée, faerie;* Prov., *fada;* Sp., *hada;* Ital., *fata;* Med. Lat., *fatare*, to enchant, from Latin *fatum*, fate, destiny). In early times, when so much of the energy of man was not, as now, applied to practice, it seems to have found a natural outlet in the imagination. Of all the minor creations of mythology, the fairies are the most beautiful, the most numerous, the most memorable in literature. Like all organic growths, whether of nature or of the fancy, they are not the immediate product of one country or of one time; they have a pedigree, and the question of their ancestry and affiliation is one of wide bearing and weighty side-issues. But mixture and connexion of races have in this, as in many other cases, so changed the original folk-product that it is difficult to disengage and separate the different strains that have gone to the making or moulding of the result as we have it. Certain points, however, in the course and development of the superstition can be definitely placed.

The character of the religion of the people of Gaul was undoubtedly much changed by the Roman occupation, but, in inscriptions and legends, traces are to be found of what the primitive belief was, which faintly shadow out that primitive belief, and it is here that we first find traces of one of the various classes of beings which have in later times received the general name of fairies. Votive inscriptions to supernatural beings, corresponding to the nymphs and fauns of classic mythology, have been found on Gaulish and German soil repeatedly. A passage in Pomponius Mela (*De Situ Orbis*, bk. iii. c. 6) points distinctly to a belief of the Bretons in certain beings having many characteristics of the fairies.

> "Sena being situate in the British sea against the country of the Osismyes is renowned with the oracle of the god of the Galles, whose vowesses in number nine, are hallowed to continual virginitie. They call them Galliceus, and are of opinion that, through the singular wisdom wherewith they are indued, they raise the seas and winds with their charms, and transform themselves into what beastes they will, and heale such diseases as to others are incurable, and knowe things to come and prophesy of them, but not unto any other than such as sayle thither for the nonce, and come of set purpose to demaund counsell of them."—Golding's translation, p. 78.

The similarity of these beings to the fays that play so important a part in mediæval romances is remarkable. A passage in the romance of Lancelot du Lac is so directly descriptive that it may be quoted:—

> "En cellui temps estoient appellees fées toutes celles qui sentermettoient den-chantements et de charmes, et moult en estoit pour lors principallement en la Grande Bretagne, et scavoient la force et la vertue des parolles, des pierres, et des herbes, parquoy elles estoient tenue en jeunesse et en beaulte et en grandes richesses comment elles divisoient. Et ce fut estably au temps de Merlin le prophete.—Ed. 1533, p. v.

These fays preside at the birth and influence the destiny of men, taking individuals under their special protection. They take lovers from among men, and are often described as of delicate, unearthly, ravishing beauty. The enjoyment of their charms is, however, generally qualified by some restriction or compact, the breaking of which is the cause of calamity to the lover and all his race, as in the notable tale of Melusine. This fay by enchantment built the castle of Lusignan for her husband. It was her nature to take, every week, the form of a serpent from the waist below. The hebdomadal transformation being once, contrary to compact, witnessed by her husband, she left him with much wailing, and was said to return and give warning by her appearance and great shrieks whenever one of the race of Lusignan was about to die. At the birth of Ogier le Dannois six fairies attend, five of whom give good gifts, which the sixth overrides with a restriction. Gervaise of Tilbury, writing early in the 13th century, has, in his *Otia Imperialia*, a chapter ***De lamiis et nocturnis larvis***, where he gives it out, as proved by individuals beyond all exception, that men have been lovers of beings of this kind whom they call *Fadas*, and who did, in case of infidelity or infringement of secrecy, inflict terrible punishment—the loss of goods and even of life. There seems little in the characteristics of these fairies of romance to distinguish them from human beings, except their supernatural knowledge and power. They are not often represented as diminutive in stature, and seem to be subject to such human passions as love, jealousy, envy, and revenge. To this class belong the fairies of Boiardo, Ariosto, and Spenser

The etymology traced at the beginning of this article is that generally given, but it is by no means universally accepted. Some fanciful theories that prevailed at the beginning of the century, as, for instance, that adopted by Sir W. Scott in his *Essay on the Fairy Superstition*, which connects the word fairy with the Persian *peri*, are now generally rejected. M. Walckenaer believed the word to be purely Celtic (see his *Letters sur les Contes des Fées*, Paris, 1836). Apart, however, from the question of the origin and varying intention of the term, the kind of beings first signified by it can be fairly connected with creatures of the Greek and Roman mythology.

The Gauls had no doubt a populous pantheon. The peasants seem to have offered worship to, and peopled the old hills, trees, rocks, streams, and springs with, beings similar to the nymphs and fauns of antiquity. And each little locality seems to have had its protecting deities, female, and generally three in number. The coming of Christianity only changed slightly the way of regarding these creatures—did not by any means overcome the superstition. It is most likely to the similarity in character and function of these local deities to the Parcæ or Fates of antiquity that we owe the name generally given to all the different beings, a great part of whose functions it was to preside at the birth and rule the destiny of man. It seems probable that among the people generation after generation of nurses changed these topical divinities into those fairies, the tales of which Perrault and his successors made so popular. The fairy tales in the *Piacevoli Notte* of Straparola (1550–54) and the *Pentamerone* of Basile (1672) are also, no doubt, the results of genuine tradition. By this time, however, the influence of Eastern stories had been brought by travellers and crusaders to bear upon the traditions of the West, as well as that of the superstition next to be mentioned. To the elves and duergar of the northern mythology we must go for the origin of those little creatures that dance in the woods and meadows. The elves are divided into two classes, the light and the dark. It is related in the prose Edda that the gods reflected how the duergar animated the clay below the earth like maggots in flesh; and certainly, under different names, as brownie, cluricaune, kobbold, nisse, lutin, hobgoblin, beings of this kind, whether of the hill or wood, of the rock or stream, or of the household, have played a great part in the life of the peasantry of many countries. They are represented as of very various characteristics and propensities. Their appearance and power are sometimes propitious, at other times baleful. "He that looks on them shall die," says Falstaff, and hides his face accordingly. Perhaps the leading features of their character with relation to man is a desire for fair human children, which, substituting abortive creatures, they practise many tricks to obtain. They are often represented as animated by a spirit of malicious mockery towards men, which is not, however, altogether malignant. In connexion with their fabled abode underground, it is to be noted that Chaucer makes Pluto and Proserpina king and queen of faery.

Besides scattered allusions, we owe to this superstition many fair products of our poetry. Works of Drayton, Ben Jonson, Fletcher, Randolph, and Herrick will at once suggest themselves. Its influence is of course very marked in the youthful works of Milton. Of the *Midsummer Night's Dream*, that perfect rose among all these flowers of fancy, it is unnecessary to speak, even were it possible to do so adequately.

For an elaborate account of fairies in general, see Keightley's *Fairy Mythology*, where the legends of different countries are collected.

FAITHORNE, William, a painter and engraver, was born in London, at what date is uncertain, but most probably either in 1626 or 1627. He was apprenticed to Robert Peake, a painter and printseller, who received the honour of knighthood from Charles I. On the outbreak of the civil war he accompanied his master into the king's service, and being made prisoner at Basinghouse, he was confined for some time to Aldersgate, where, however, he was permitted to follow his profession of engraver, and among other portraits did a small one of the first Villiers, duke of Buckingham. At the earnest solicitation of his friends he very soon regained his liberty, but only on condition of retiring to France. There he was so fortunate as to receive instructions from Robert Nanteuil, by which his style was greatly benefited. He was permitted to return to England about 1650, and took up a shop near Temple Bar, where, besides his work as an engraver, he carried on a large business as a printseller. In 1680 he gave up his shop and retired to a house in Blackfriars, occupying himself chiefly in painting portraits from the life in crayons, although still occasionally engaged in engraving. He died of a lingering consumption, May 13, 1691; and it is said that his life was shortened by the misfortunes, dissipation, and early death of his son William. Faithorne is especially famous as a portrait engraver, and among those on whom he exercised his art were a large number of eminent persons, including Sir Henry Spelman, Oliver Cromwell, Henry Somerset, the marquis of Worcester, John Milton, Queen Catherine, Prince Rupert, Cardinal Richelieu, Sir Thomas Fairfax, Thomas Hobbes, Richard Hooker, Robert second earl of Essex, and Charles I. All his works are remarkable for their combination of freedom and strength with softness and delicacy, and his crayon paintings unite to these the additional quality of clear and brilliant colouring. Faithorne is the author of a work on engraving, which was published in 1622.

FAITHORNE, William (1656–1686), a mezzotinto engraver, son of the former, was born in 1656. He had the advantage of his father's instructions, and devoting his attention chiefly to mezzotinto, at an early age gave promise of attaining great excellence, but became idle and dissipated, and it is said involved his father in money difficulties. Among persons of note whose portraits he engraved are Charles II., Mary princess of Orange, Queen Anne when princess of Denmark, and Charles XII. of Sweden. He died in 1686.

The best account of the Faithornes is that contained in Walpole's *Anecdotes of Painting*. A life of Faithorne the elder is preserved in the British Museum among the papers of Mr Bayford, librarian to Lord Oxford, and an intimate friend of Faithorne.

FAIZÁBÁD, a division or commissionership of Oudh in British India, now under the jurisdiction of the lieutenant-governor of the North-Western Provinces. It lies in 26°–28° 30′ N. lat. and 81° 5′–83° 15′ E. long., and comprises the three districts of Faizábád, Gondá, and Bharaich. It is bounded on the N. by the independent state of Nepál, on the E. by Gorakhpur district, on the S. by Azimgarh and Sultánpur, and on the W. by Bára Banki, Sitápur, and Kheri. Population, according to the census of 1868—Hindus, 3,028,502, Mahometans and others, 350,760; total, 3,379,262, of whom 1,747,411 were males and 1,631,851 females. Number of villages or townships, 8452. Area 7671 square miles.

Faizábád, a district of British India in Oudh, under the lieutenant-governor of the North-Western Provinces, in 26°–27° N. lat. and 81°–82° E. long., is bounded on the N. and E. by the Gogra river, on the S. by Azimgarh district, and on the W. by the Gumti river. The area, according to the latest estimate in 1877, is 1649 square miles, and the population 1,024,092 souls. Faizábád forms a very historical district, lying between the two great rivers of Oudh, and is interesting alike for its calamities and its ruins. Ajodhyá, the capital of the ancient kingdom of Oudh, which plays so conspicuous a part in the Sanskrit epics, lies in its northern angle, close to the present city of Faizábád. In more modern times the district was the centre of the nawáb vizier's influence, and contained his capital until the removal of his court to Lucknow in 1775. In 1857 it became the scene of the disaster described below. Since the mutiny, the district has settled down into a peaceful part of the British empire, with an increasing population. It is penetrated throughout its length from north to south by the Oudh and Rohilkhand railway, and does an important trade with the great cities of the north-west. The growth of its population has been the more marked, owing to the previous desertion and decay in the last century on the transfer of the nawáb's court to Lucknow. The population, classified according to religion, is—Hindus, 922,360, Mahometans, 100,410, Christians, 1322, of whom 1267 represent the European soldiers; total, 1,024,092; the density of population averaging 621 per square mile. The five largest towns, containing upwards of 5000 inhabitants, are—Faizábád, population, 37,804; Tánda, 13,543; Ajodhyá, 9949; Jalálpur, 6275; and Sajauli, 5614. The railway stations are the following:—Málipur, Akbarpur, Kánurpur, Gosáinganj, Tandauli, Belarghát, Darsinagar, Ajodhyá, Faizábád, and Sajauli. The estimated cultivated area in 1875 was 628,690 acres, of which rice was returned as occupying 162,562; wheat, 162,895; other food grains, 248,837; oil-seeds, 6888; sugar, 27,800; cotton, 492; opium, 4982; indigo, 6900; fibres, 202; tobacco, 3957; and vegetables, 3522. The total value of the trade of Faizábád in 1874–75 was exports £425,115, and imports £122,511, the chief articles of export being food grains, oil-seeds, country cloth, and silk, and cotton; and of imports, sugar, spices, European piece goods, &c. The revenue of the district in 1874–75 was £151,856, of which £133,243, or 85 per cent., was derived from the land-tax. The machinery for protecting person and property consisted of 15 magisterial and 15 civil and revenue courts. The regular police force consisted of 552 officers and men, maintained at a cost of £8363 out of the imperial revenue; a town and cantonment police numbering 237, and costing £1402 from local sources; and a village police numbering 2277 men, maintained by the villagers or landholders at a cost of £5524. The average daily number of prisoners in jail in 1875 was 791, or one to every 1294 of the population. The schools in the same year numbered 98, attended by 4461 pupils. Four charitable dispensaries afforded medical aid to 13,463 patients; and a poorhouse furnished assistance to 6752 paupers in the shape of food, clothing, and shelter.

Faizábád, the chief town and administrative head-quarters of the district of the same name, situated on the right or south bank of the Gogra, in 26° 47′ N. lat. and 82° 15′ E. long. Adjacent to Faizábád on the E., and now forming a suburb of the town, is Ajodhyá, the ancient capital of King Daswratha, the father of Ráma, the hero of the Rámáyaná. Of this ancient city, said to have covered an area of 48 *kos*, now hardly a trace remains. The modern Ajodhyá contains several Jain and Hindu temples. The city of Faizábád was founded about 1730 by Sa'adat Ali Khán the first nawáb vizier of Oudh, who made it his capital. The place rapidly grew in importance until 1775, when the court of Oudh was removed to Lucknow. It then rapidly decayed, all the leading merchants, bankers, &c., abandoning the place. In 1839, Butter estimated its population at 100,000 but fast diminishing, owing to the exactions and oppressions by the native officials of the nawáb's Government. At the time of the census in 1869 Faizábád contained only 37,804 inhabitants; but it is now again advancing in prosperity, and is rapidly becoming an emporium of trade. At the time of the annexation of Oudh in 1856 Faizábád was made, and still continues to be, a large military station. On the outbreak of the mutiny in 1857, the cantonment contained two regiments of infantry, a squadron of cavalry, and a light field battery of artillery —all natives. Owing to their threatening demeanour after the Meerut massacre, many of the European ladies and children were sheltered by one of the great landholders of Oudh, and others were sent forward to less disturbed parts of the country. The troops rose, as was anticipated, and although they at first permitted their officers to take boats and proceed towards Dinapur, a message was afterwards sent to a rebel force lower down the river to intercept the fugitives. Of four boats, one succeeded in reaching Dinapur safely, having passed the rebels unnoticed. Of the occupants of the other three boats, one person alone escaped. Faizábád is now a station for European as well as for native troops.

CHICAGO
R. S. PEALE COMPANY
1892

ory of Prince Potemkin, who founded the town in 1777.

EKOWE, the capital of the territory of Zululand.

ELÆAGNUS, a genus of *Elæagnaceæ*, the oleaster family, of which there are about thirty-five species, all natives of north temperate countries. *Elæagnus angustifolia*, the oleaster, sometimes called wild olive, is a small spiny tree of the Mediterranean region, hoary with stellate hairs, and is frequently planted for its silvery white foliage and fragrant flowers.

ELÆOCARPACEÆ, a sub-order of *Tiliaceæ*, mostly East Indian trees. The fruits of some are eaten and the deeply-wrinkled stones, often called olive nuts, are made into beads for necklaces and bracelets in India.

ELÆOCOCCA, a genus of *Euphorbiaceæ*, the seeds of some of which yield useful oils. The oil obtained from *Elæococca verrucosa* is used for food in Japan, notwithstanding considerable acridity. The tree is cultivated in the Mauritius, and the oil is there used only for burning. That obtained from *Elæococca vernicia* of China is used in painting.

ELÆODENDRON, a genus of trees of the natural order *Celastraceæ*, having a 5-partite calyx, 5 petals, a 5-angle disc, 5 stamens, the ovary immersed in the disc, and a drupaceous fruit. *Elæodendron glaucum*, a native of Ceylon and the South of India, is sometimes called the *Ceylon Tea-tree*, from the resemblance of its leaves to those of the tea-shrub. The timber of *Elæodendron croceum*, called *saffronwood* at the Cape of Good Hope, is much used there in building and cabinet-making; it is fine-grained, hard and tough. The fruit of *Elæodendron Kubu*, another South African species, is eaten by the colonists. That of *Elæodendron argan* yields an oil similar to olive oil, much used by the Moors.

ELANET (*Elanus*), a genus of *Falconidæ*, allied to the kites (see Britannica, Vol. XIV, p. 104), which they resemble in many of their characters; but from which they differ in having the short tarsi half covered with feathers, and the claws, except that of the middle toe, rounded beneath. The tail is very little forked. One species (*Elanet melanopterus*) is common in Africa, from Egypt to the Cape of Good Hope, and is found also in India. Another species is the black-shouldered hawk (*Elanet dispar*) of America, the northern limit of which appears to be South Carolina. Both of these feed chiefly on insects, which they catch on the wing, but they also prey on small birds and reptiles.

ELASTIC TISSUE, known also as yellow fibrous tissue, derives its name from the remarkable physical property which it possesses of permitting its fibers to be drawn out to double their length, and again returning to their original length. It occurs in various ligamentous and other structures of the animal body in which elasticity is required—as, for example, in the vocal chords, the membranes connecting the cartilaginous rings of the trachea, the middle coat of the arteries, the skin, etc.

ELATER, a Linnæan genus of coleopterous insects, now divided into many genera, and forming the tribe or family *Elateridæ*. They have a narrow elongated body; the head is in almost all cases inserted deeply into the thorax; a strong spine on the under part of the thorax at its base fits into a groove; the legs are short and rather slender. They are generally found upon the flowers and leaves of plants, which are their food. See Britannica, Vol. VI, p. 132.

EL BASSAN, a town of Turkey, in central Albania, 75 miles south-southeast of Scutari, with manufactories of copper and iron-wares. It is the seat of a Greek bishop. Population, 8,000.

ELBOW-PIECES: in armor, or *coudières*, the metal plates used to cover the junction of the rere-brace and vant-brace, by which the upper and lower half of the arm were covered. An *Elbow Gauntlet* was a gauntlet of plate reaching to the elbow, adopted from the Asiatics in the 16th century.

ELCHINGEN, a village of Bavaria on the left bank of the Danube, about eight miles northeast of Ulm.

EL DORADO, city and county-seat of Butler county, Kan., situated on Walnut River. It has waterworks, gas, and electric lights, woolen and flour-mills, machine shop, iron foundry, and extensive quarries of magnesian limestone.

ELDORADO SPRINGS, a popular health resort of Missouri, located in the northwestern part of Vernon county. It is a rapidly growing town, its popularity being due to the presence of several springs, whose waters are chalybeate.

ELDRED, a railroad junction of McKean county, Pa., 24 miles east of Bradford.

ELECTION, in theological language, denotes the divine act by which certain individuals are chosen to salvation in Christ. It is defined in the seventeenth of the thirty-nine articles.

ELECTION LAWS OF THE UNITED STATES. Under the Federal Constitution the jurisdiction of the election laws of the United States extends only to the elective officers of the Federal Government. These are the President, Vice-President, and members of the House of Representatives. The State legislatures determine severally the qualifications for voting in those States.

All the States except Wyoming restrict the right to vote at general elections to males of 21 years of age and upwards. In Wyoming women have voted on the same terms with men since 1870. They requested the constitutional convention to guarantee suffrage to them in 1889. This was done with practical unanimity in convention and at the polls. As Congress declared that it "accepted, ratified and confirmed" this constitution, women have the full right of suffrage in Wyoming. In Kansas women have suffrage on the same terms with men in all municipal elections; and in Delaware municipal suffrage is accorded them in many places, school suffrage being universal throughout the State. In Montana women have the right to vote on questions of local taxation. In Washington Territory women voted generally for five years, and then were excluded by decision of the Territorial Supreme Court. In adopting a State Constitution the women were not permitted to vote, and the woman suffrage clause was defeated. The women assert that they were illegally prevented from voting, and have appealed to the United States Supreme Court. In Utah women voted until excluded by the Edmunds law. In Pennsylvania women can vote on local improvements, by signing or refusing to sign petitions therefor. In New York women can vote at school elections, at water-works elections, and on questions of paving, grading, drainage, street lighting, and other local improvements. The right to vote at school elections is also accorded to women, on various terms, in Arizona, Colorado, Idaho, Indiana, Kansas, Kentucky, Massachusetts, Michigan, Minnesota, Nebraska, New Hampshire, New Jersey, North Dakota, Oregon, South Dakota, Texas, Vermont, Washington and Wisconsin. In Arkansas and Missouri women vote (by signing or refusing to sign petitions) on granting liquor licenses.

QUALIFICATIONS OF VOTERS IN THE SEVERAL STATES.

States.	Requirements as to Citizenship.	Previous Residence Required.				Persons Excluded from Suffrage.
		In State.	In County.	In Town.	In Precinct.	
Alabama	Citizen of United States or alien who has declared intention.	1 year.	3 mos..	30 days	30 days	Convicted of treason or other crime punishable by imprisonment, idiots, or insane.
Arkansas	Citizen of United States or alien who has declared intention.	1 year.	6 mos..	....	1 mo...	Idiots, insane, convicted of felony, until pardoned.
California	Citizen by nativity, naturalization, or treaty of Queretaro.	1 year.	90 days	....	30 days	Chinese, insane, embezzlers of public moneys, convicted of infamous crime.
Colorado	Citizen or alien who has declared intention 4 months previous to offering to vote.	6 mos..	90 days	....	10 days	Convicted of felony and unrestored to citizenship.
Connecticut†	Citizen of United States who can read constitution or statutes.	1 year.	....	6 mos..	....	Convicted of any offense for which infamous punishment is inflicted.
Delaware	Citizen, and paying county tax after age 22.	1 year	1 mo...	....	15 days	Idiots, insane, paupers, felons.
Florida	Citizen of United States or alien who has declared intention, who has paid capitation tax 2 years.	1 year.	6 mos..	....	(*a*)	Insane, under guardianship, convicted of felony, or any infamous crime.
Georgia	Citizen of the United States..	1 year.	6 mos..	....	....	Idiots, insane, convicted of crime punishable by imprisonment.
Idaho	Citizen of the United States..	6 mos..	30 days	....	....	Chinese, Indians, Mormons, felons, insane, convicted of bribery.
Illinois	Citizen of the United States..	1 year.	90 days	30 days	30 days	Convicted of crime punishable in penitentiary until pardoned and restored to rights.
Indiana†	Citizen of United States or alien who has declared intention and resided one year in United States and 6 months in State.	6 mos..	....	60 days	30 days	Convicted of crime and disfranchised by judgment of the court.
Iowa	Citizen of the United States..	6 mos..	60 days	....	(*a*)	Idiots, insane, convicted of infamous crime, United States soldiers and marines not *bona fide* residents.
Kansas	Citizen of United States or alien who has declared intention.	6 mos..	....	....	30 days	Idiots, insane, convicts, rebels, public embezzlers, bribed.
Kentucky	Citizen..........................	2 yrs*..	1 year.	....	60 days	Convicted of robbery, forgery, counterfeiting or like crime.
Louisiana	Citizen of United States or alien who has declared intention.	1 year.	6 mos..	....	30 days	Idiots, insane, convicted of treason, embezzlement of public funds, all crime punishable by imprisonment in penitentiary.
Maine	Citizen of the United States..	3 mos..	3 mos..	3 mos..	....	Paupers, persons under guardianship, Indians not taxed.
Maryland†	Citizen of the United States..	1 year.	6 mos..	....	1 day..	A person over 21 years convicted of larceny or other infamous crime, unless pardoned, persons under guardianship, as lunatics or *non compos mentis*.
Massachusetts†	Citizen who can read Constitution in English, write, and has paid tax within 2 years.	1 year.	....	6 mos..	30 days	Paupers (except honorably discharged U. S. soldiers and sailors) and persons under guardianship.
Michigan†	Citizen or inhabitant who has declared intention under U. S. laws 6 months before election.	3 mos..	....	10 days	10 days	Aliens who have not declared intention 6 months previous to election, Indians, duelists and accessories.
Minnesota†	Citizen of United States or alien who has declared intention, and civilized Indians.	4 mos‡.	10 days	....	10 days	Convicted of treason or felony, unless pardoned, persons under guardianship or insane.
Mississippi	Citizen of the United States who can read or understand Constitution after January 1, 1892.	2 yrs...	1 year.	....	1 year.	Insane, Indians not taxed, felons, persons who have not paid taxes.
Missouri†	Citizen of United States or alien who has declared intention not less than one year or more than five before offering to vote.	1 year.	60 days	60 days	... .	U.S. soldiers and marines, paupers, criminals convicted once until pardoned, felons and violators of suffrage laws convicted a second time.

*Unless there has been one year's previous residence in the county. †Australian Ballot Law or a modification of it in force. ‡And one year's residence in United States prior to voting. (*a*) Actual residence in the precinct or district required.

QUALIFICATIONS OF VOTERS IN THE SEVERAL STATES—*Continued.*

States.	Requirements as to Citizenship.	Previous Residence Required.				Persons Excluded from Suffrage
		In State.	In County.	In Town.	In Precinct.	
Montana†	Citizen of the United States..	1 year.	30 days	30 days	30 days	Indians, felons not pardoned.
Nebraska	Citizen of United States or alien who has declared intention thirty days prior to election.	6 mos..	40 days	....	10 days	Idiots, insane, convicted of treason or felony, unless pardoned.
Nevada	Citizen of the United States..	6 mos..	30 days	....	....	Idiots, insane, convicted of treason or felony, unamnestied Confederates who bore arms against the United States.
New Hampshire	Inhabitant, native or naturalized.	6 mos..	....	6 mos..	....	Paupers (except honorably discharged U. S. soldiers and sailors), persons excused from paying taxes at their own request.
New Jersey†	Citizen of the United States..	1 year.	5 mos..	....	....	Idiots, insane, persons convicted of crimes (unless pardoned), which exclude them from being witnesses, which crimes include blasphemy, treason, murder, rape, sodomy, arson, perjury, etc.
New York†	Citizen who shall have been a citizen for ten days.	1 year.	4 mos..	....	30 days	Convicted of bribery or any infamous crime, unless pardoned, bettors on result of any election at which they offer to vote, bribers for votes and the bribed.
North Carolina	Citizen of the United States..	1 year.	90 days	....	....	Convicted of felony or other infamous crime.
North Dakota	Citizen of the United States, alien who has declared intention and civilized Indian*	1 year.	6 mos..	....	90 days	United States soldiers and sailors, persons *non compos mentis*, and felons.
Ohio	Citizen of the United States..	1 year.	30 days	....	20 days	Felony until pardoned and restored to citizenship, idiots, insane.
Oregon	Citizen of United States or alien who has declared intention one year preceding election.	6 mos..	....	....	....	Idiots, insane, convicted of felony, United States soldiers and sailors, Chinese.
Pennsylvania	Citizen of the United States at least one month, and if 22 years old or more must have paid tax within two years.	1 year‡.	....	....	2 mos..	Convicted of some offense whereby right of suffrage is forfeited, non-taxpayers.
Rhode Island	Citizen of the United States..	2 years	....	6 mos..	....	Paupers, lunatics, persons *non compos mentis*, convicted of bribery or infamous crime until restored to right to vote, under guardianship.
South Carolina	Citizen of the United States..	1 year.	60 days	....	....	Convicted of treason, murder, or other infamous crime, or of dueling, paupers, insane.
South Dakota	Citizen of the United States or alien who has declared intention.	6 mos.§	6 mos..	....	30 days	Under guardianship, idiots, insane, convicted of treason or felony, unless pardoned.
Tennessee†	Citizen of the United States..	1 year.	6 mos..	....	(*a*)	Convicted of bribery or other infamous offense.
Texas	Citizen of the United States or alien who has declared intention.	1 year.	6 mos..	....	(*a*)	Idiots, lunatics, paupers, supported by county, convicted of felony, United States soldiers and seamen in service.
Vermont†	Citizen of the United States..	1 year.	....	6 mos..	....	Unpardoned convicts and deserters from United States military or naval service during civil war, ex-Confederates.
Virginia	Citizen of the United States..	1 year.	3 mos..	3 mos..	30 days	Idiots, lunatics, convicted of bribery at election, embezzlement of public funds, treason, felony and petty larceny, duelists and abettors, unless pardoned by legislature.
Washington†	Citizen of the United States..	1 year.	90 days	....	30 days	Indians not taxed.
West Virginia	Citizen of the State..........	1 year.	60 days	....	(*a*)	Paupers, persons of unsound mind, convicted of treason, felony or bribery at elections.
Wisconsin†	Citizen of the United States or alien who has declared intention.	1 year.	....	....	10 days	Insane, under guardianship, convicted of treason or felony, unless pardoned.
Wyoming	Citizen of the United States or alien who has declared intention.	6 mos..	30 days	....	....	Under guardianship, idiots, insane, unpardoned felon, bettors on elections.

---

*Indian must have severed tribal relations two years next preceding the election. †Australian ballot law or a modification of it in force. ‡Or if, having previously been a qualified elector or native, he shall have removed and returned, then months. §One year's residence in the United States prior to election required. (*a*) Actual residence in the precinct or trict required.

REGISTRATION.

Voters are required to register in Alabama, California, Colorado, Connecticut, Florida, Louisiana, Maine, Maryland, Massachusetts, Mississippi, Nevada, New Hampshire, North Carolina, Pennsylvania, South Carolina, Vermont and Virginia. In Georgia registration is required in a few counties; in Iowa, Kansas and Nebraska, in all cities. In Illinois registration is required, but, except in a few cities, a legal voter not registered may vote upon filing an affidavit by himself and another known legal voter that he is a qualified voter and has not already voted. In Minnesota registration is required in all cities of 1,200 inhabitants or over; in Missouri, in cities of 100,000 inhabitants and over; in New Jersey, in cities of over 10,000 inhabitants; in Wisconsin, in cities of 20,000 inhabitants or over; in Ohio, registration is generally required. Registration is not required in Arkansas, Delaware, Indiana, Kentucky, Oregon, Tennessee, Texas and West Virginia. It is prohibited in Arkansas, Texas and West Virginia by the constitution. In New York, voters in cities must register personally; in all other places within the State they may register on the first two registration days by proxy.

ELECTORAL COMMISSION, a special commission appointed by act of the United States Congress approved Jan. 29, 1877, for the purpose of determining the electoral votes of the States of Florida, Louisiana, and South Carolina and of one vote of the State of Oregon, in the Presidential election of November, 1876. The commission consisted of United States Supreme Court Justices Clifford, Strong, Miller, Field and Bradley; United States Senators Edmunds, Morton, Frelinghuysen, Thurman and Bayard, and United States Representatives Payne, Hunton, Abbott, Garfield, and Hoar.

The question before the commission was of the gravest national interest. Its answer would practically decide the choice of the nation with regard to the ensuing Presidential administration. The appointment of the commission was the result of prolonged discussion in both houses of Congress, and this plan of averting an impending evil was reported by a joint committee, representing not only both the Senate and House of Representatives, but also most equably the two great political parties. This joint committee was composed of Senators Geo. F. Edmunds, of Vermont; Frederick T. Frelinghuysen, of New Jersey; Roscoe Conkling, of New York; Allen G. Thurman, of Ohio; Thomas F. Bayard, of Delaware, and Oliver P. Morton, of Indiana. Also of Representatives Henry B. Payne, of Ohio; Eppa Hunton, of Virginia; Abram S. Hewitt, of New York; William Springer, of Illinois; Geo. W. McCrary, of Iowa; Geo. F. Hoar, of Massachusetts, and Geo. Willard, of Michigan. Of this committee seven were Republicans and seven were Democrats. The committee reported the bill Jan. 18, 1877, and, with the exception of a single dissentient (Senator Morton), by a unanimous recommendation. The bill provided for the creation of the Electoral Commission, to be composed of five Senators, five Representatives, and five Associate Justices of the United States Supreme Court, four of the latter being designated by their districts in the bill itself, the fifth to be chosen subsequently by those four. All certificates and other documents from the contesting parties, and all questions relating to the powers of Congress in the premises (with the authority to exercise the same powers in ascertaining the legal vote of each State) were to be referred to this commission as a tribunal; and the decision in each case to stand as final, *unless rejected by the concurrent vote of both houses of Congress.* The bill also provided that objections that might be made to any electoral votes from States not presenting double certificates should be considered not by the commission but by the houses separately, and unless sustained by both should be of no effect.

The bill thus reported with such remarkable unanimity was submitted to extended discussion in both houses, resulting in its adoption by the Senate, Jan. 25, by a vote of 47 yeas to 17 nays (the Republicans 24 yeas to 16 nays, and the Democrats 23 yeas to one nay); absent or not voting, nine Republicans and one Democrat. The vote was taken in the House, Jan. 26, resulting in the adoption of the bill by a vote of 191 yeas to 86 nays (the Democrats 158 yeas to 18 nays, and the Republicans 33 yeas to 68 nays); absent or not voting, seven Republicans and seven Democrats.

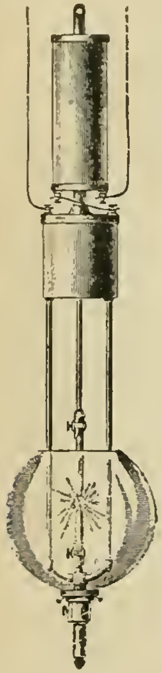
As a majority of the Senate was Republican, and a majority of the House Democratic, it was agreed that three Republicans and two Democrats should be selected from the Senate and three Democrats and two Republicans from the House. Of the United States Supreme Court Justices the four, as stated above, were designated in the report of the joint committee, namely: Justice Clifford, of Maine; Justice Miller, of Iowa; Justice Field, of California, and Justice Strong, of Pennsylvania. These four appointed, as the fifth, Justice Joseph P. Bradley, of New Jersey.

The commission perfected its organization Feb. 1, 1877, and closed its work Feb. 27, and its decision was reported at the joint electoral convention of the two houses of Congress held March 1, resulting in the announcement early the next morning that Rutherford B. Hayes, of Ohio, and William A. Wheeler, of New York, had been elected, respectively, President and Vice-President of the United States.

ELECTORAL CROWN, or, more properly, CAP, was a scarlet cap, turned up with ermine, which was worn by the electors of the German Empire. It was closed with a demi-circle of gold, covered with pearls, and on the top was a globe with a cross on it, also of gold.

ELECTRICITY

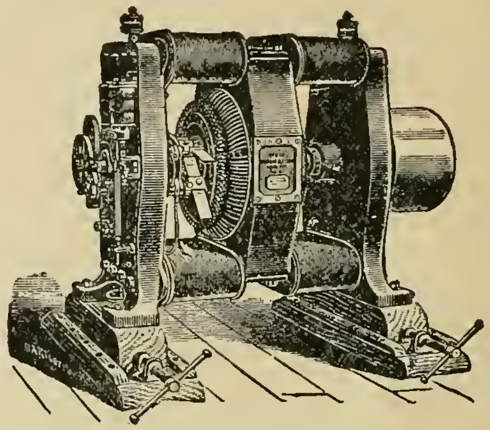
FOR the general subject of electricity, and an elaborate and exhaustive discussion of the methods of applied electricity, brought down to the year 1878, see Britannica, Vol. VIII, pp. 3–105; also see TELEGRAPH, Vol. XXIII, pp. 112–126. It is only required in these Revisions and Additions that a record should be outlined of the later discoveries and progress in electrical science, and especially in applied electricity.



ARC LIGHT.

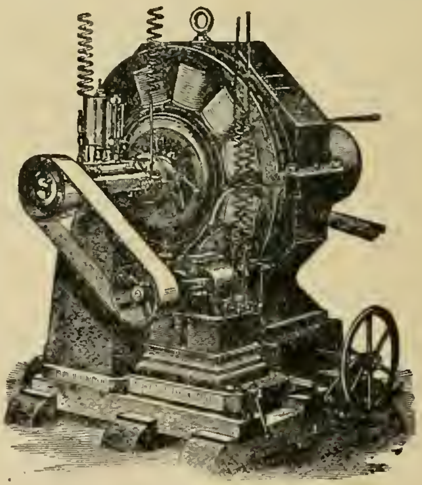
ELECTRIC LIGHTING.—The principal uses to which electricity is put to-day, outside the all-important classes of electric signaling and electro-chemical work, are for furnishing light, heat, and power; and of these three applications that of electric lighting is perhaps the most important. There are two kinds of lamps in use, entirely dissimilar in principle and construction, and used for entirely different purposes. In one, known as the "arc" light, the light is obtained by causing a heavy current of electricity to cross a small space, taking a slightly curved path, called the electric arc, from which its name is derived. This is the intensely brilliant light used for street lighting. In the other, known as the "incandescent," the light is produced by passing a small current through a fine wire or filament, which it heats to a dazzling brilliancy or incandescence.

The arc light, which is much older than the incandescent, is now produced practically by passing a powerful current between the points of two large carbon rods, which are kept close together by an automatic mechanism known as the regulator of the lamp. The space allowed between the tips of the rods, across which the current jumps, is about one-sixteenth of an inch, and the duty of the regulator is to move one of the rods toward the other as fast as the tips are burned off by the intense heat, keeping the space to be jumped by the current as nearly uniform as possible. The carbon rods are placed perpendicularly, one above the other. The electric current, after reaching the upper carbon, passes across the tips and through the lower carbon, thence through a wire which is wound around a magnet, thence to the continuation of the line, and on to the next lamp. This magnet attracts a lever which, when raised, grasps the upper carbon through the agency of a washer which allows the carbon to slide downward through it except when it is tilted by the action of the magnet and lever. The upper carbon is arranged in suitable guides to slide straight up and down, and the lower carbon is held stationary. When at rest the washer lies flat, and the upper carbon slides down until in contact with the lower one. When the current is turned on it passes across the tips of the carbons, which at first are in contact, and around the magnet, causing it to raise the lever, tilt the washer till it grasps the carbon, and thus elevates the movable carbon until the increased length of the space between the tips weakens the current and checks the lifting action of the magnet. The light then burns steadily until enough of the tip is burned off to further weaken the current by increasing the space, when the magnet, being no longer able to support the carbon, lowers it enough to readjust the space.



WOOD DYNAMO.

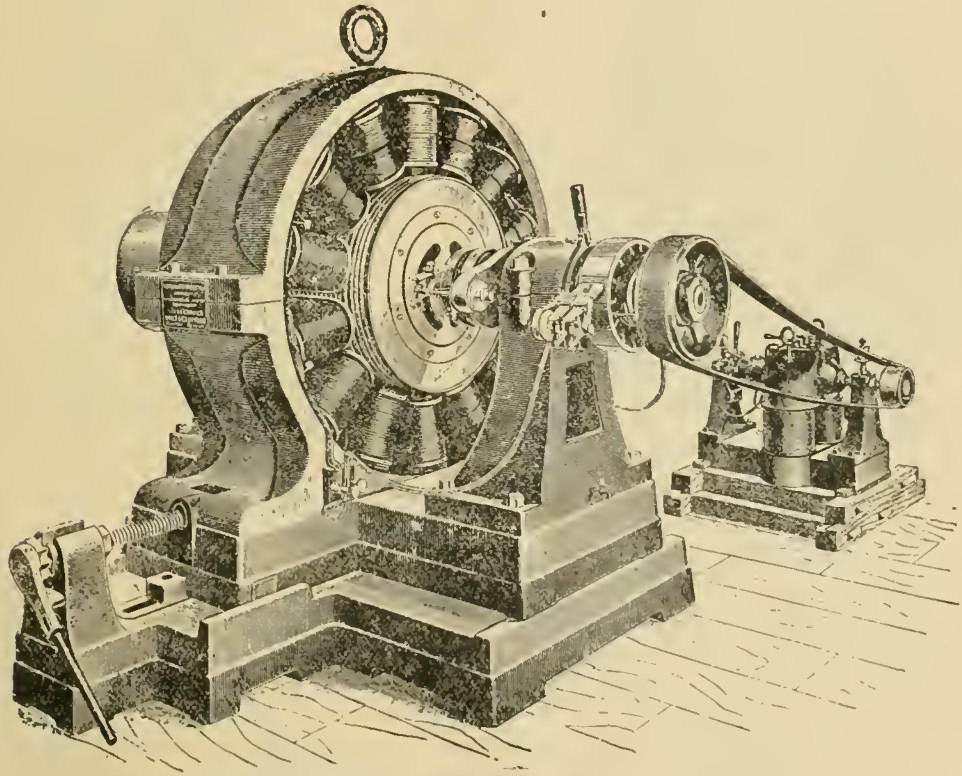
So long as the source of power for producing the electricity was the galvanic battery, experience of this promising illuminator only served to lay bare its practical defects. It was found to be unsteady, flickering, and unreliable, and although great ingenuity was displayed in producing electric lamps but little real progress was made. The first magneto-electric machine, the forerunner of the dynamos of the present day, was exhibited at the French Académie des Sciences in 1832. With this machine sparks and strong shocks were obtained, water decomposed, etc. In 1841 Wheatstone patented a plan by which more powerful effects could be obtained by combining several machines together. The next important advance was made in 1866, when H. Wilde, of Manchester, Eng., announced the somewhat paradoxical principle that a current or magnet indefinitely weak could be made to pro-



SLATTERY INCANDESCENT DYNAMO.

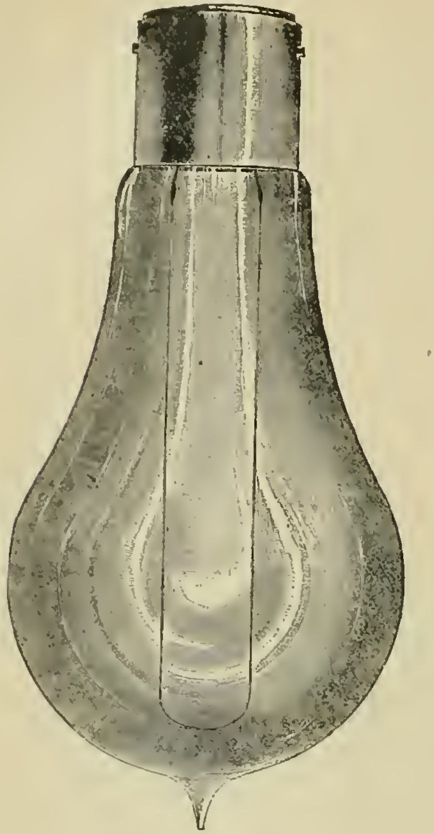
duce a current or a magnet of indefinitely great strength. Carrying out this principle, Wilde constructed a very powerful machine, which, turned by a steam engine, produced such a powerful electric current that an iron rod 15 inches long and a quarter of an inch thick was melted, and an electric light produced between carbon points of an intensity sufficient to cast shadows from the flames of ordinary gas burners a quarter of a mile distant from the source of light. The "reaction" principle in magneto-electric machines was discovered the same year (1866). In the machine of Wilde, the starting point of the source of power was a permanent steel magnet, but in the reaction principle the residual magnetism which is always found more or less in soft iron was made use of to originate the electric current. This principle has been far-reaching in its results, and upon it all the numerous "dynamos" of the present day are worked.

In 1870 another important advance in "dynamo-electric" machines was made by Z. T. Gramme, of Paris. Gramme's machine involved the new principle of forming the movable part of the machine of an endless ring of soft iron round which was coiled a series of bobbins of wire, all connected together. By this invention a nearer approximation to a continuous electric current was obtained than by any previous form of machine. After this, invention followed invention, step by step, each one perfecting the dynamo machine more and more, so that not only were these machines made more compact and better generally in design, but the electric power obtained from them for a given amount of horse power used to drive them continually, also approached nearer the theoretical limit, until but little further improvement seems possible except in small matters of detail.



IMPROVED DYNAMO.

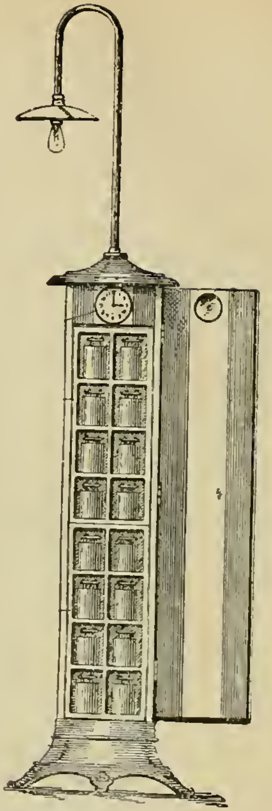
While the dynamo was thus being gradually developed towards theoretical perfection, regard was also had to the bettering of the carbon points or luminous electrodes of the light. The wasting of the carbon points necessitated a contrivance for regulating the distance between the points so as to keep the arc of sensibly constant width. In 1876, P. Jablochkoff, a Russian, introduced a modification of the arc lamp by which all regulating mechanism was dispensed with. The invention was called an electric "candle," and promised very great things. In spite, however, of the progress made in "arc" electric lighting, the general results were not completely satisfactory except for special purposes, and it is difficult to say what the fate of such lighting would have been; but in September, 1878, Thomas E. Edison, of New York, announced his discovery of a method of dividing the electric light, so as to obtain from a given current many lights of moderate power in the place of one of excessive brightness. He constructed an incandescent electric lamp, or glow lamp, in which the current is made to pass through a strip of some substance, which, because of its high resistance, becomes highly heated, and hence brilliantly incandescent. He employed for this substance carbon in the form of a thin strip or wire, carefully prepared for the purpose and bent in a loop, inclosed in a bulb of glass from which the air had been exhausted. The vacuum prevented the consumption of the carbon at the high temperature to which it was raised. These lamps are readily applied to the existing gas fixtures at moderate cost, and mark an important era in the progress of electric lighting. The demand for incandescent lamps has been enormous, so that at the present time there are over 3,000,000 in use in the United States.



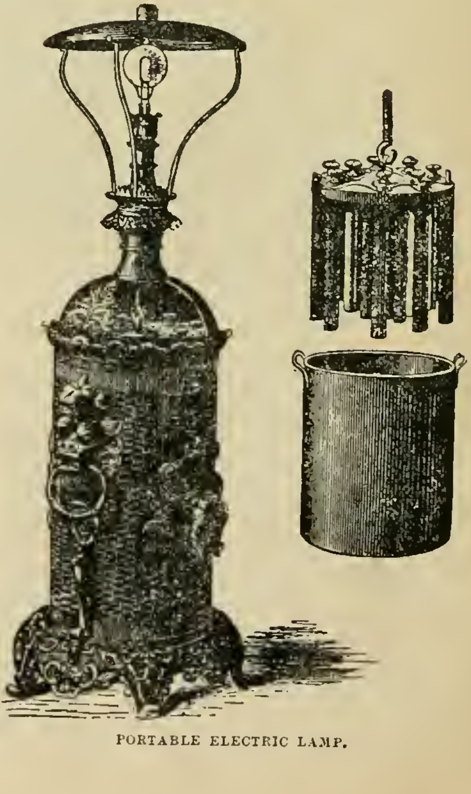
INCANDESCENT LAMP.

Portable Electric Lamp.—A device intended for street or lawn lighting at points where an electric lighting current is not accessible, is among the recent inventions in electrical apparatus. The device comprises, as will be understood from an inspection of the illustration, a case or stand provided with shelves, upon which a series of secondary battery cells may be mounted, and carries a bracket, to which is secured an incandescent lamp. The device is controlled by a time switch so that the circuit may be closed and the lamp lighted at any desired hour. The case is provided with a door in which is arranged a bull's-eye, through which the clock may be seen when the door is closed. The apparatus when completed weighs about 200 pounds, which gives it sufficient stability for the purposes for which it is designated.

Another form of portable electric lamp, illustrated in the accompanying cut, was exhibited at a recent electrical exhibition in Paris by M. Larochelle. The battery is inclosed in the lower part, and consists of an ebonite vessel divided into eight compartments by partitions, furnishing eight cells, or elements, in a very compact form. The vessel will hold about three liters of liquid, capable of acting for about eight hours without exhaustion. Each element is made up of a rod of zinc and two rods of carbon fixed to a disk which can be lowered into the liquid, or lifted out of it, by turning a key



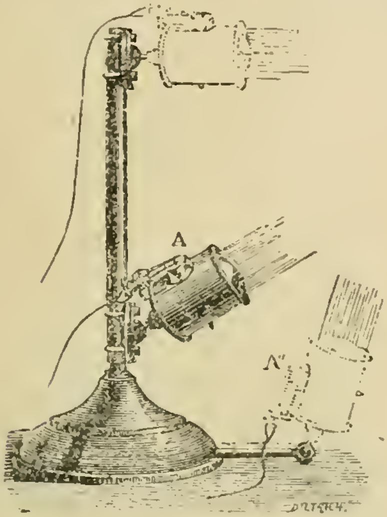
PORTABLE ELECTRIC LAMP.



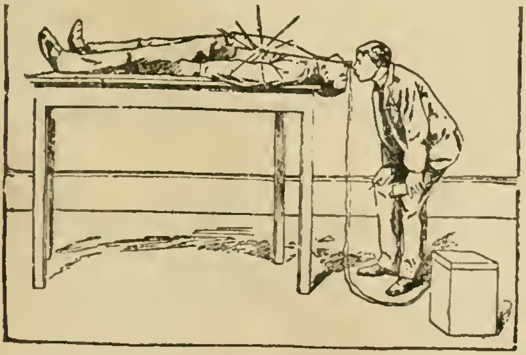
PORTABLE ELECTRIC LAMP.

like that used in a Carcel oil-lamp. The power of the lamp is regulated by the depth to which the zincs and carbons are immersed. The zincs are screwed into the disk so as easily to be removed for renewal.

The Electric Light in Microscopy.—The incandescent electric light is very highly recommended as a substitute for the usual lamps used in microscopy, or even for the direct daylight. A small lamp, which only requires one cell of a bichromate battery to operate it, and which can be adjusted to any position, is now made for this purpose. Among the advantages of the electric light are its intensity, which allows the use of very oblique rays in illuminating the object; the larger proportion of white and blue rays in the light, which bring out the finer details more clearly; the small amount of heat given out, which enables the lamp to be placed as close to the condenser of the microscope as may be desired; and the doing away with the necessity of a mirror to reflect the light upon the object, since the lamp can be placed in any desired position in reference to it. It is also claimed that the light is less fatiguing to the eye than even ordinary daylight; while, for purposes of micro-photography, the large proportion of actinic rays in the electric light and the ease with which it can be regulated render it far superior to any other illuminant.



ELECTRIC LIGHT IN MICROSCOPY.



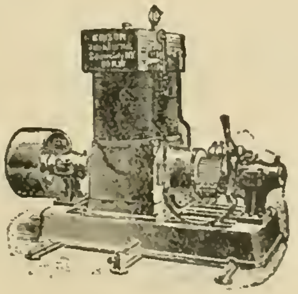
EXAMINING THE STOMACH BY ELECTRIC LIGHT.

Illuminating the Stomach by Electric Light.—Medical electricians have recently devised a plan by which the interior of the human stomach may be illuminated for examination. The patient is laid upon the operating table, and a slender tube carrying a glass bead upon its end is introduced into the stomach. A small light inside the bead is supplied by fine wires running out through the tube and connected to a small battery. The interior of the stomach is plainly lighted, and all its parts are brought into view by a small movable mirror at the end of the tube.

CAUTERY WIRE HEATED BY ELECTRICITY.

Cautery Wire Heated by Electricity.—Another application of electricity for physicians is the electro-cautery shown in the accompanying illustration, by which the principle of electric heating is applied to surgical operations. The instrument consists of a loop of fine platinum wire mounted in a rubber handle, through which connecting wires pass. These wires are led to a battery, the current from which follows the wires, and keeps the platinum loop white-hot. The heat is inside the wire, as it were, and can be regulated to any intensity, and kept there during an operation without withdrawing the instrument for reheating.

Electric Lights for Carriages.—In Paris numerous private carriages are now fitted up with incandescent electric lamps, instead of the old-fashioned candles or oil lamps. Not only are the regular side-lights thus arranged, but the interior of the vehicle is also illuminated by a lamp sufficiently powerful to read by; and a similar lamp is sometimes placed on the head of the horse, producing a very brilliant and "stylish" effect. These lamps are connected by wires with small accumulators placed under the driver's seat. These accumulators are only about eight inches square and four inches high, and each one will supply a lamp of 5-candle power for six hours. During the day they are removed, charged with electricity from a dynamo-machine or otherwise, and at night they are ready for service.



EDISON GENERATOR.

Electric Light and Plants.—At the Winter Palace, St. Petersburg, Russia, there is a noted collection of ornamental plants, especially of fine palms, grown for decoration of the banqueting halls of the palace. Since the introduction of the electric light these plants have been greatly injured. The illumination of a room for a single night will cause the leaves to turn yellow, dry up, and finally fall off. The days in winter at St. Petersburg are almost sunless, and the sudden change from this dim light to the blinding glare of the electric lights is more than the plants can bear. Plants that are partly shaded escape injury to their foliage.

Submarine Telegraphy.—The first submarine cable was laid across the English Channel, from Dover, England, to Calais, France in 1850. Being unprotected it lasted but a few hours. The connecting wires (27 miles long) were placed on the government pier in Dover harbor, and in the *Goliath* steamer were coiled about 30 miles in length of telegraphic wire, inclosed in a covering of gutta-percha, half an inch in diameter. The *Goliath* started from Dover, unrolling the telegraphic wire as it proceeded, and allowing it to drop to the bed of the sea. In the evening the steamer arrived on the French coast, and the wire was run up the cliff at Cape Grisnez to its terminal station, and messages were sent to and fro between England and France. But the wire, in settling into the sea bottom, crossed a rocky ridge, and snapped in two, and thus the enterprise for that time failed. A stronger cable was prepared, the type of which is used at the present day almost entirely unmodified, and in November, 1851, was laid between Dover and Calais, and successfully operated.

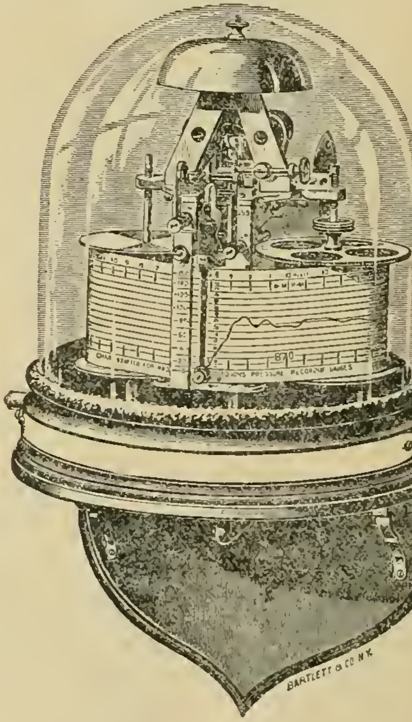
The practicability of submarine telegraphy being thus established, lines rapidly multiplied. In May, 1853, a cable was successfully laid and operated between Dover and Ostend, and in the following year connection was established between Holyhead and Howth, and between Paris and Bastia.

As early as 1845 a plan to unite Europe and America by telegraph was entered at the government registration office in England, and proposals for carrying out the plan were submitted to the government, but were not accepted. In 1857 the plan was attempted to be carried out by a company, with the concurrence of the British and American governments. The cable, 2,500 miles in length, having been constructed, and thoroughly tested, the work of laying it down commenced at Valentia, in Ireland, Aug. 5, 1857. Four vessels were employed; two American, the *Niagara* and *Susquehanna*, and two British, the *Leopard* and *Agamemnon*. After sailing a few miles the cable snapped. This was soon repaired, but on August 11, after 300 miles of the cable had been laid, it snapped again, and the vessels returned to Plymouth. A second attempt to lay the cable, made in June of the following year, was defeated by a violent storm. Later in the year a third attempt was made, which was entirely successful. The junction between the two continents was completed by the laying down of 2,050 miles of cable, from Valentia, Ireland, to Newfoundland. The first two messages were sent Aug. 5, 1858, and were: one from the Queen of England to the President of the United States, and the other his reply. This event caused great rejoicing in both countries; but, unfortunately, the insulation of the wire being faulty, the power of transmitting intelligence ceased a month later.

A new company was formed in 1860, but it was not till 1865 that the work of laying down a new cable was undertaken. The *Great Eastern* steamer, engaged to lay down 2,300 miles of cable, with 25,000 tons' burden, sailed for Valentia, July 15, 1865. After connecting the cable with the land, the *Great Eastern* sailed from Valentia, July 23. Telegraphic communication with the vessel (interrupted by two faults, due to defective insulation, caused by pieces of metal pressed into the gutta percha coating, which were immediately repaired) finally ceased Aug. 2. The apparatus for raising the wire proving insufficient, the vessel returned to England.

During the winter the Atlantic Telegraph Company was reconstituted as the Anglo-American Telegraph Company, and in June, 1866, the *Great Eastern*, with a new cable on board, again sailed for Valentia. The shore end was spliced with the main cable, and July 13, 1866, the *Great Eastern* sailed for America, reaching Heart's Content, Newfoundland, and completing the laying of the cable July 27, 1866. During the same year the lost cable of 1865 was recovered, and its laying completed at Newfoundland.

Prior to this cables had been laid connecting London with Constantinople, Cromer with Enden, Aden with Suez, Malta with Alexandria, England with Bombay, and Marsala with La Calle.



RECORDING AND ALARM GAUGE.

In 1868 the French government granted a concession for 20 years to Julius Reuter and Baron Emile d'Erlangen, for a French Atlantic telegraph line; and the European end of the cable was laid at Brest, June 17, 1869, and the American end at Duxbury, Mass., July 23, 1869.

In 1870 a cable was laid between Bombay and Suez, and in 1873 the fourth Atlantic cable was laid by the *Great Eastern* from Valentia, Ireland, to Heart's Content, Newfoundland. The Brazil telegraph cable was also opened in September, 1873.

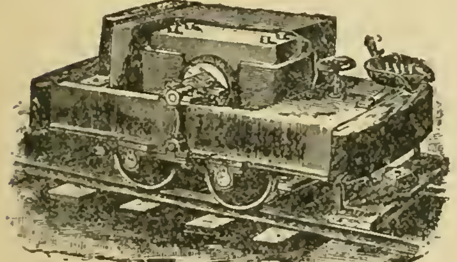
In 1874 a great electric cable ship, the *Faraday*, was constructed, and sailed to lay the "Direct United States Company's cable," May 16. The shore end was laid in Nova Scotia, May 31, in New Hampshire, June 8, and connected with Newfoundland in July. The sixth Anglo-American telegraph was laid by the *Great Eastern* in August and September of the same year.

In December, 1879, the South African cable line between Mozambique and Natal was opened to the public, and June 1, 1880, a new French Transatlantic cable from Brest to New York was completed. The following year a new Atlantic cable was laid by the *Faraday*, and in September, 1882, a line was completed from England to Panama.

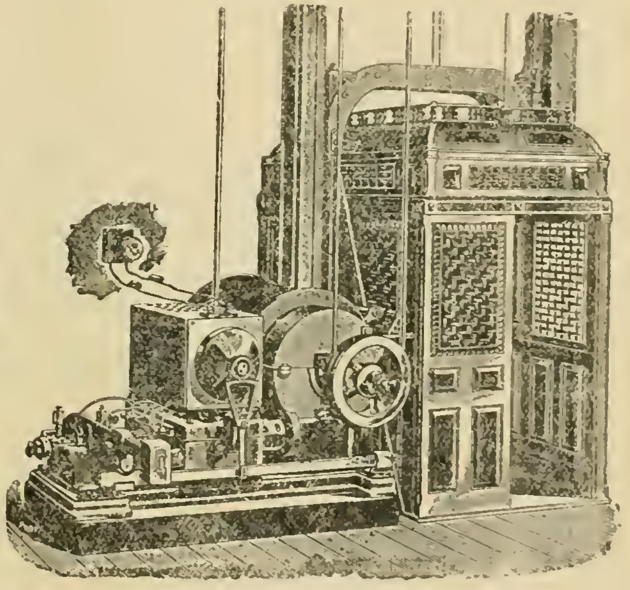
During the last decade lines have multiplied until there are now (1891) 942 submarine cables, exclusive of the seven working Atlantic cables, with an aggregate length of 112,740 nautical miles. For laying and maintaining this huge network of cables, a fleet of nearly 40 vessels is constantly occupied.

THE PHONOPORE.—The phonopore is a telegraphing device invented by Mr. Langdon-Davies, of London. Some two or three years ago, he first developed the system of transmitting signals through circuits which in the ordinary sense are not closed. Recent experiments in his laboratory were made through an artificial line of 4,000 ohms' resistance, and comprised the sending of phonopore messages alone, and of phonopore and telegraph messages simultaneously, in the same wire, and in the same or opposite directions. In one experiment the same wire transmitted a telegraph message and two phonopore messages simultaneously, and the working of the phonopores was perfect, even after the resistance of the line had been increased to 23,000 ohms, when the telegraph messages, which were received by needle instruments, could no more be read. A further experiment was made with a line wire open at both ends, and containing a resistance of 100,000 ohms. In this case the ordinary telegraph could, of course, not be worked at all, but duplex working of the phonopore was perfectly feasible.

At St. Pancras, messages were being sent by phonopore between London and Leicester in both directions, on one of the company's wires which all the time transmitted ordinary telegraph messages. The London phonopore was joined to the line between two Morse relays about half a mile apart, one at the passenger and the other at the goods station, while the Leicester phonopore tapped the line thirty miles from the nearest telegraph instrument, which is at Derby. Between Leicester and London there are on this wire about six telegraph instruments, and as during operation the continuity of the line is constantly being broken by the working, each instrument is shunted by a phonopore, so that the phonopore messages are translated some six times.



ELECTRIC LOCOMOTIVE.



ELECTRIC ELEVATOR.

This method of bridging the telegraph instruments does not in any way diminish the clearness of signals as compared with a continuous wire. The messages were printed on a Morse receiver, which was actuated by a phonopore relay. The phonopore transmitter has a vibrating reed, and the distant phonopore receiver is also provided with a reed in the shape of a stretched steel band, which can be tuned to the same note.

TELEGRAPHING FROM A TRAIN IN MOTION.—One of the latest inventions in the art of telegraphing is a device by means of which messages may be sent to and from a railroad train when traveling at any speed. The surprising feature of this invention is that there is no connection between the train and the telegraph wire beside the track, over which the messages travel to the station, after jumping from the car to the wire. The message is telegraphed from inside to the tin roof of the car, and reaches the regular telegraph wire along the track by means of lines of force which each signal throws through the air as soon as it reaches the roof. The signals created in the main line in this way are much fainter than the ordinary telegraph signals, but this difficulty is easily overcome by using more sensitive receiving instruments. The operation of telegraphing to the car is carried on in the same way. The message is sent along the line, and imparts a slight electrical effect to the metallic car roof at each signal. The weak signals thus produced in the car roof are listened to with a delicate receiving instrument in the hands of the operator. As the main-line wire is parallel with the track, it makes no difference where the car is; and as the action of electricity is almost immeasurably quick, it makes no difference how rapidly the car is moving. The only special construction required to adapt a line for use with this system is that the wire be strung on rather short poles, so as to bring it near the roofs of the cars. The instruments for the operator on the train are portable, and are arranged to be held in the lap like a writing tablet.

Extension of Electric Telegraphing.—The overland telegraph has assumed mammoth proportions. There is in the United States alone a total of 807,589 miles of wire, enough of the attenuated metal to go around the equatorial belt of the globe 32 times. France has 241,800 miles of wire; Germany 186,733; Great Britain and Ireland 183,502; and Russia 172,360. In number of messages transmitted the United States leads with 80,000,000, followed by Great Britain with 57,765,347; France 22,341,000; Germany 17,782,323; Austria-Hungary, 13,240,642. and Russia 10,477,049. The following table exhibits the number of miles of lines, of wire, and number of messages transmitted in each country of the globe for the year indicated:

Countries.	Year.	Miles of Lines.	Miles of Wires.	Number of Messages.
Algeria	1888	7,000	16,000	....
Argentine Republic	1889	14,700	28,550	3,511,420

The Western Union Telegraph Company reports the average toll per message in 1868 was 104.7; in 1889 was 31.2; in 1890 was 32.4. The average cost per message to the company in 1868 was 63.4; in 1889 was 22.4; in 1890 was 22.7. The number of messages annually transmitted throughout the world may be estimated at 300,000,000.

Progress in Rapid Telegraphing.—In 1837 the first telegraph of Cook and Wheatstone transmitted messages at the rate of four words per minute, five wires being required; now six messages are conveyed by one wire on the Delaney multiplex apparatus at ten times that speed; and on the Wheatstone fast-speed apparatus 600 words per minute are transmitted on one wire.

Telephone.—The history of the telephone is quite modern, although as early as 1850 the probability of speech being telegraphically transmitted was foreshadowed; and again in 1860, Reis succeeded in transmitting musical sounds and imperfect speech. It was reserved for Graham Bell, in 1876, completely to solve the problem, and for Edison a little later to perfect the same by the invention of the "carbon transmitter" (see Britannica, Vol. XXIII, pp. 127–135). An important advance has been made in telephony by the discovery that the use of copper, instead of iron wire, enabled the telephone to work to a practically unlimited distance, and long-distance telephone lines are being rapidly extended throughout the country.

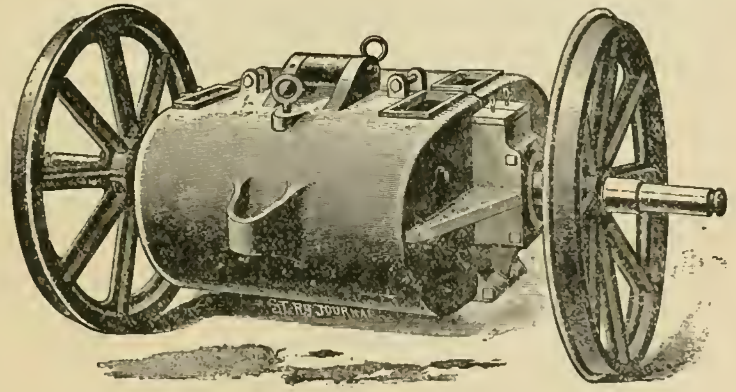
According to the latest statistics made public by the American Bell Telephone Company, which practically monopolizes the telephone business in the United States, there were in 1890 in this country 757 exchanges, 471 branch offices, 192,610 miles of land wire, 603 miles of submarine cables, 156,780 circuits, and 185,003 subscribers. The number of instruments in the hands of licensees under rental at the beginning of 1890 was 444,861. The number of exchange connections daily in the United States is 1,240,147, or a total per year of over 400,000,000. The average number of daily calls per subscriber is 6.13. The company received in rental of telephones in 1889 $2,657,361. It paid its stockholders in dividends during the same year, $1,838,913. The Bell Company and its subsidiary companies represent about $80,000,000 of capital; the Long-Distance Telephone Company about $5,000,000.

Electric Motors.—Electric traction was first practically worked in 1879 by Dr. Werner Siemens, who constructed and started an electric tramway in the grounds of the Industrial Exhibition at Berlin. A train of three cars was placed upon the railway, which was 900 yards long. On the first car an electro-dynamic machine was so fixed as to cause one pair of wheels to rotate when the current passed through its coils. A middle rail, supported on insulating blocks of wood, ran between the working rails, and by this the current was led from the generating apparatus to the car. After passing through the electric motor, it passed by the wheels to the outer rails, and so back to the generating dynamo. Between twenty and thirty persons at a time could be accommodated on the train; and during the summer of that year 100,000 were carried over the line at a speed of from 15 to 20 miles an hour. The locomotive could exert 5-horse power, and was started and stopped by a commutator for closing and opening the circuit. Since then the progress of electric traction has been very rapid, and in the United States alone there were in 1891 over 200 electric railways, having a collective length of 1,750 miles, with 2,400 motor-cars traveling thereon.

In the present state of electrical science, however, electric motors cannot take the place of the steam engine for originating power. Given a supply of electricity, the motor can be used for all sorts of purposes, and can be applied to almost as many uses as a steam engine. But to obtain the electricity cheaply we must have power of some kind. There must be a waterfall, or a steam engine, a tide-mill or a wind-mill to produce the power in the first place. By this power a dynamo can be driven, and this gives the electricity for driving motors. Electricity is the driving power of the electric motor as steam is of the steam engine. As a consequence the motor's usefulness is limited to such places as are within the reach of an electric supply. By means of wires the electricity can be conveyed to motors over a distance of some miles from the generating station. The use of the electric motor cannot be considered applicable to all purposes until some means have been discovered whereby electricity may be produced from coal as directly as we now produce steam by burning coal beneath a boiler. At present we have first to produce power in order to generate electricity, then transmit it by wires to the motor which transforms the electricity again into power, and so does our work. The economy or the reason for this double transformation is found in the ease with which the transformation is accomplished. Instead of costly and cumbersome shafting, belting or ropes, only moderate-sized wires are required. Instead of being limited to short distances and to fixed locations, the wires give great freedom for the change of location, and the distance covered may be several miles.

Electric Street Railways.—In an able paper on this subject, read before the Society of Arts in Boston in 1889, Capt. Eugene Griffin, well known as an electrical expert of high authority, presented a mass of statistics showing the great progress already made in the use of electricity on street railways, accompanied by a great amount of information of practical interest and value, portions of which we condense as follows:

The dynamo or generator and the motor are theoretically the same. If a steam engine be belted to an armature pulley and the armature pulley be made to revolve, a current of electricity is passed through the machine, the armature is made to revolve, and by belting to the armature pulley, mechanical power is available. In this way one dynamo will convert the mechanical power of the steam engine into electrical power, and the electrical power may be carried through the wires to the second dynamo, perhaps five miles away, where it is reconverted into mechanical power, and so made available for any desired purpose. The second dynamo is called the motor, and differs from the first, not in principle, but only in details, which make it better suited for its special work. In this way we do away with the zinc fuel and come back to coal, except in those places where we are fortunate enough to have water power.



WESTINGHOUSE IRONCLAD GEARLESS MOTOR.

A brief description of the dynamo or generator and the motor is essential to a proper understanding of this subject.

The modern dynamo electric machine is simply an application on a larger scale of Professor Faraday's discovery that if a wire be moved through the magnetic field of a permanent electro-magnet, a current of electricity is produced in that wire. A dynamo machine consists of a pair of field magnets, between whose poles or extremities revolves a soft iron rotating support, wound about with a series of coils of wire in which the current is developed. The revolving body is called the armature. It is generally made to revolve by belting a steam engine to a pulley on the armature shaft. As each wire moves through the magnetic field of one pole of the magnet, the induced or generated current in the wire is in one direction; as the wire moves through the field of the other magnet pole, the current is in the opposite direction. The current taken from the poles of the machine or generator, as it is usually called, would therefore be alternating, were it not for the device called a commutator.

This consists of a copper cylinder on the armature shaft, divided into as many segments as there are separate coils of wire in the armature, each segment insulated electrically from the others and connected with its own armature coil. This commutator revolves with the armature, and against it are pressed two copper brushes, as they are called, which do not revolve.

These brushes are the current collectors, and when they are connected by a metallic wire five inches or ten miles long, so as to close the circuit, a direct current flows through this wire as long as the armature is made to revolve. Without going into details, it is sufficient to say that the brushes are so placed that as each segment of the commutator comes in contact with the brush, the induced current in the corresponding wire is flowing in a constant direction, so we have a direct instead of an alternating current. As a matter of fact the armature is not made up of separate coils; but the connections are so made with the commutator segments that we may theoretically regard the coils as separate.

The motor is practically the same as the generator, except that the power applied is electrical energy and the power obtained is mechanical. The current coming from the generator goes to the brushes on the motor, thence to a segment of the commutator and so to the armature coils. The wire with a current flowing through it in a given direction is repelled by one pole and attracted by the other. The powers of attraction and repulsion compel the armature to move, it revolves and we have mechanical energy. We gear the armature to the car axle and we have motion.

There are two general methods of using electricity for the propulsion of street cars:

1. The direct method by conductors extending from the dynamo along the track.

2. The indirect method, by the use of storage batteries, secondary batteries, or accumulators.

In the direct method the conductors may be overhead, underground, or on the surface.

In the conduit system the conductors are placed in a conduit between the rails or between the tracks. The wires must be bare and yet must be thoroughly insulated from the ground, a condition very difficult to obtain under such circumstances. A slot about five-eighths of an inch wide gives access to the conductors by means of a contact plow, but unfortunately also permits the flow of water, slush, mud, etc., into the conduit.

The overhead-wire is suspended from poles by brackets or from cross-wires which span the street between poles on either side. When the street is of sufficient width, poles are placed in the center of the street between the two tracks, with bracket arms carrying the conducting wires. These poles are placed about 125 feet apart, and from actual experience are found to present little or no obstruction to traffic. The wires may be single or double. When single wire is used, the rails are utilized for the return current. When two wires are used, one wire carries the outgoing and one the return current. Contact is obtained with the wire by an over-running or an under-running trolley. The over-running trolley is a light carriage with one or more wheels resting on the wire.

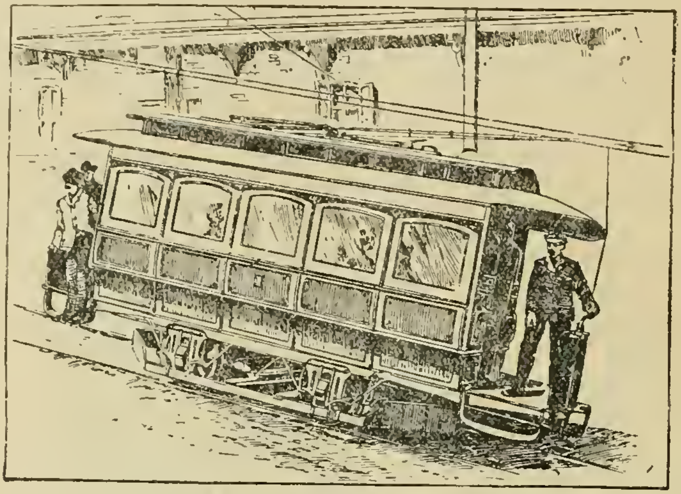
A flexible conductor carries the current down to the car. The trolley is pulled along by the flexible conductor. The objections to the over-running trolley are that it is difficult to keep the trolley on the wire, it is difficult to replace the trolley when it comes off, and any automatic system of switching on to a turnout, branch, or Y is impossible. The latter is such a serious objection that except in special cases the over-running trolley will never be used. In the under-running trolley a light arm of the requisite length is mounted on the top of the car, reaching up to the wire. A wheel on the end of the arm is pressed up against the wire by means of springs at the other end, and the current is carried from the wheel down through the arm itself if made of metal or through wires if the arm is made of wood. This arm is usually called the contact bar. The under-running trolley is automatic in its action at curves, turnouts, etc., and follows the direction of the car. It turns on a swivel through the entire circle, and moves through an arc of 90° in a vertical direction.

In the storage system, a battery of about 120 cells is carried on the car, and the motors are driven by the current from this battery. The advantages of this system are:

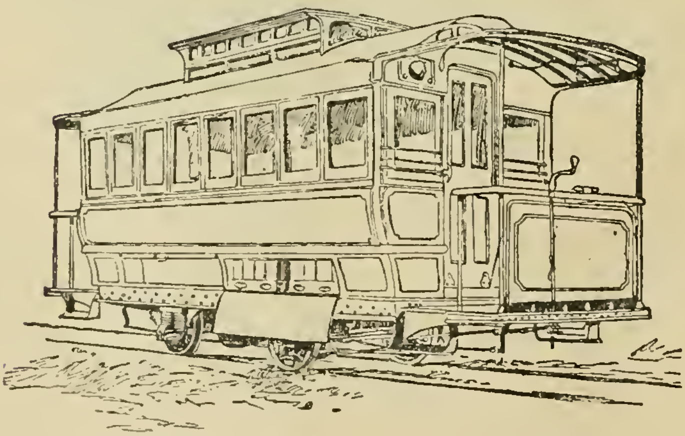
1. The cars can run on any track.
2. No wires, either overhead or underground, are required.
3. Each car is more independent than is the case in other systems.

The disadvantages are:

1. The extra weight of about two tons on each car. The power required to carry this dead weight in addition to that required to drive cars required by the other methods.



ELECTRIC CAR ON A 10 PER CENT. GRADE.



JULIEN CAR PROPELLED BY STORAGE BATTERIES.

2. The lack of efficiency in the batteries. The highest efficiency claimed is 82 per cent. The actual practical efficiency is stated by many authorities as about 70 per cent.

3. Storage cars cannot be regularly operated on grades exceeding 5 per cent. or 6 per cent. The power required on grades makes too great a demand on the batteries.

4. The expense. The cost of two sets of batteries per car is about $3,000.

5. The cost of maintenance. Batteries have not yet been made of sufficient durability to be operated economically.

There are four qualities which the electric motor must be shown to possess before it will be generally adopted for street-car work. These are efficiency, economy, durability, and reliability.

1. As to efficiency: The steam engine is not an efficient machine. If we can utilize 15 per cent. of the units of energy stored in the coal, we are fortunate. In other words, we must expect a loss of 85 per cent. of the heat units in converting the other 15 per cent. into mechanical power.

The dynamo electric machine, on the other hand, possesses a high degree of efficiency. No good generator runs below 92 per cent. efficiency. The loss in the line depends upon the amount of copper used in proportion to the current to be carried. The size of the conductor is generally calculated for a loss of 10 per cent. The efficiency of the motor under favorable circumstances has been shown to be but little below the generator; in actual tests running as high as 91½ per cent.

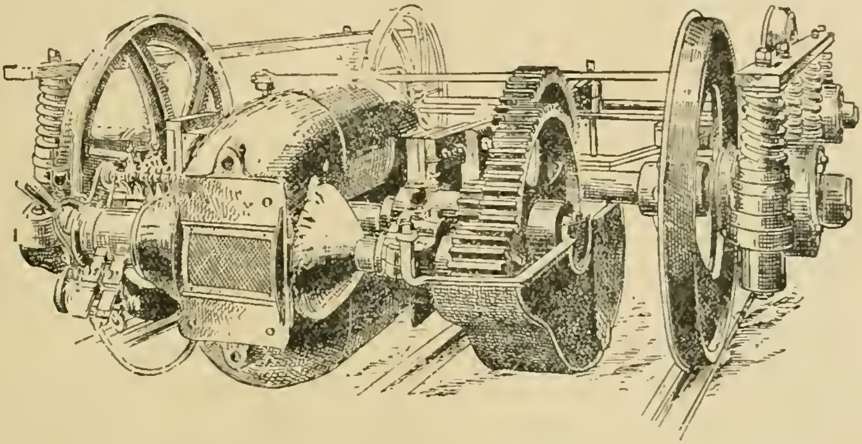
In practice it would not probably be taken higher than 35 per cent. Starting, then, with 100 horse-power in the steam-engine, we lose 8 per cent. in the dynamo in converting the mechanical into electrical energy. The output of the generator is then 92 horse-power. In the line we lose 10 per cent. and deliver 82.8 horse-power to the motor. Here we lose 15 per cent., and on the final reconversion into mechanical energy on the car we have 70.4 horse-power out of the original 100 horse-power. By no other known method could this power be transported to such a distance with so little loss.

2. Economy: This is perhaps a quality which appeals more directly to the railway official than any other. What will it cost? An electric railway connects Omaha with Council Bluffs across the new bridge. I am credibly informed that to run 20 cars per day they consume five tons of slack, for which they pay \$1.14 per ton. This is 28½cents per day for fuel. These cars are scheduled at 15 miles per hour, and the average daily mileage per car is over 100 miles. Where natural gas or water is available, fuel may be even cheaper. On many different roads from numerous measurements it has been found that where the grades are slight the power required averages from five to eight horse-power per car. The consumption of fuel varies from three to six pounds of coal per horse-power, according to the style of engine and its more or less economical operation. Of course a road operating only one or two cars would show abnormal results in every way, and these averages are only true of roads operating a number of cars—10 or more. The wear and tear on the generating plant does not exceed three per cent. The depreciation on line work does not exceed or even equal 10 per cent. The depreciation on car equipment has been variously estimated at from 10 to 20 per cent.

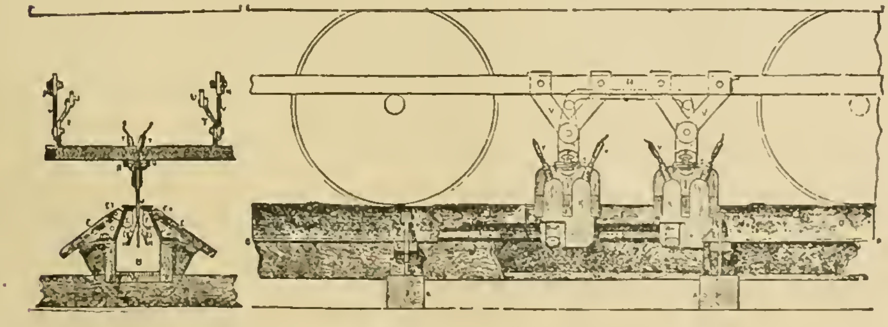
On some roads, under very favorable conditions, the cost of renewals and repairs to electrical apparatus has been but little below one dollar per day per car in actual operation. On other roads, under very favorable conditions, the cost of maintenance has been less than 25 cents per day per car.

A mean of the reports obtained from 11 roads in actual operation under different conditions shows a daily cost of operation of less than \$2.50 per car, not including drivers and conductors. Experience has shown that it is well within limits to put the saving of electric over horse power at 25 per cent. In some cases a saving of 50 per cent. has been shown. The secretary of the Des Moines Broad Gauge Railway Company, under date of January 8, 1889, writes as follows: "The receipts from four cars electrically are four times more than five cars by horses."

3. Durability: The Washington road has been in operation for over six months. They now have seven motor cars and seven tow cars. The latter are double-deck cars, on which 160 fares have been collected on one trip. These cars are hauled around sharp curves and up a five per cent. grade by two 10-horse-power motors. While the track was new it settled. A car left the track, and while it was being pried back one of the motors was injured mechanically. With this exception not a single armature or field has been burned, and the gears show but trifling signs of wear. The road has operated without any repair shop, and practically without any repairs up to the present time.



THE BENTLEY-KNIGHT TRUCK AND CONDUIT.



PLOUGH, CONTACT SHOES, AND CONDUIT.

At Lynn, Mass., a single car has been in daily operation since November 9 of last year. It runs 93 miles per day, and the 1.7 miles of track contains 11 curves and numerous grades ranging up to a maximum of 12 per cent. The durability of the electrical apparatus under such unusual conditions has been remarkable.

4. Reliability: On the Lynn road, above referred to, the single car has made its daily trips with but very few departures from the schedule. On one occasion the car axle broke, due to a flaw in the metal. On another occasion the belt slipped from the engine at the power station. Since the middle of February not a scheduled trip has been lost from any cause whatever, nor has the car failed to run on time. No one can look at the daily record of this car under conditions which would prevent horse-car work, and doubt the reliability of electrical apparatus. On the Cambridge line of the West End road the conditions are unusually bad. During the month ending April 19, the schedule called for 5,912 round car trips. Of these the electrical cars failed to make just four trips.

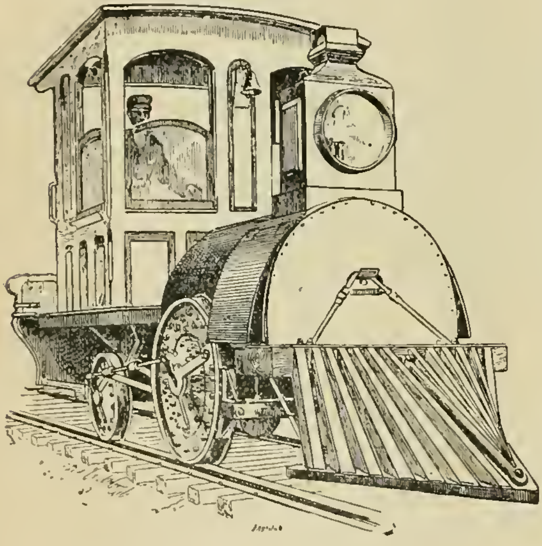
As the railway employes become more familiar with electrical apparatus and learn more of the details of handling the cars, accidents, mishaps, and lost trips will grow fewer and fewer; but the records above referred to suffice to prove the reliability of the electric motor.

Storage battery cars are in operation on one road in the United States—the Fourth Avenue line in New York city. Conduits have been built in several places, In San José, Cal., and in Denver, Col., they were complete failures. In Allegheny City, Pa., the conduit has operated with considerable success. In Boston it has not been a marked success. There are at the present time over 100 roads in operation or under contract where the overhead wire system is to be employed. From this we may infer that the storage battery and conduit are yet in an experimental stage, while the overhead wire is a pronounced and demonstrated success. What the future of storage batteries and conduits may be no one can tell; but we all hope that the difficulties encountered may be overcome, as the storage system is unquestionably the ideal system.

The objections usually urged against the overhead wires are:

1. They are dangerous, as they carry death-dealing currents.
2. They are eyesores.
3. The poles obstruct the street.
4. They are in the way in case of fires.

Now, the railway wire should not be confounded with other electric wires. Arc and incandescent wires, telegraph and telephone wires, have simply to carry the current from the point where it is generated to the point where it is to be used, and so far as this purpose is concerned they may be above ground or under ground. The railway wire, on the other hand, must have current taken from it every differential of an inch from one end to the other. The wire must be bare that the trolley wheel may be in constant contact. To put this wire underground and to keep it properly insulated is a very different problem from burying the other wires. The railway wire cannot be considered in the same category with other electric wires. Now, as to danger. For railway work we use a constant potential generator, and the cars and motors are placed between the two conductors on the multiple-arc system. One conductor, the overhead wire, runs out from one pole of the generator; the other conductor, the rail, runs out from the other pole of the generator. An electrical connection between these two conductors completes the circuit, and the current flows through the connecting material, whatever it may be. If it be the motors on a car, then the cars move; if it be a man, he receives a shock.



THE IMPROVED EDISON LOCOMOTIVE.

Each connecting material, be it car, man, wire or whatsoever, receives a current of electricity which is absolutely and always determined by Ohm's law that the current is equal to the electro-motive force or pressure divided by the resistance. The electro-motive force is always 500 volts. With several cars in operation, the amperes of current in the overhead system near the generator may run as high as 180, but each car takes its own proportion according to its resistance. The average resistance of a man is 4,000 ohms. If he places himself in the circuit, he will receive a current which is measured in amperes by dividing 500 by 4,000, or, in other words, a 500-volt current can only drive ⅛ of an ampere through the average human body. It would not make a particle of difference to the man whether the overhead wire he touched was carrying a current of 1 ampere, or 180 amperes, or 180,000 amperes. The effect in his case would be the same; he would receive ⅛ of an ampere. Were this not true, then the whole multiple arc theory would be false, and electric railways, as at present operated, would be impossibilities. It would then make no difference as to danger whether one or a million cars were in operation on the line.

To make this matter plain to those unfamiliar with electrical terms, we may suppose the overhead wire to be a large pipe or main through which a pump (the generator) is forcing water; the rails, electrically connected, as another large pipe through which the water is to be forced back to the station. Suppose the diameter of these mains is 12 inches. If they are closed at the outer ends, we may fill the overhead main, but after that no water can flow until we connect the two pipes. Now we will put in a one-inch pipe connecting the upper main with the lower main, say 1,000 feet from the pump or generator. A certain amount of water will flow through the connecting pipe, which amount depends upon its size—one inch—and upon the pressure of the water in the upper main. From the generator to the one-inch connecting-pipe the same amount of water flows in the upper main as flows down through the connection, no more and no less. Beyond the connecting-pipe, no water is flowing in the upper main.

Now we will put in a second connecting pipe 1,000 feet beyond the first. For the first 1,000 feet we have twice as much water flowing as before. Half of it goes down through the first pipe. It is the same with every additional connecting pipe we put in until we reach the capacity of the upper main or the capacity of the generator to force water through it. By increasing the pressure, we know that we could force more water through the one inch connecting pipe; but so long as the pressure remains the same, the quantity flowing through the inch pipe will be the same, whether the upper main be 12 inches, 12 feet, or 1,000 feet in diameter.

The analogy to electric railway work is close. Electricity takes the place of the water and the connecting pipes are electric cars, or it may be some unfortunate man placed where he had not ought to be. He is only an inch pipe, however, and the pressure (500 volts) can only drive so much electricity through him.

The current for railway work has been fixed at 500 volts, as this is well within the safe limits. A shock from 500 volts is unpleasant, but not dangerous. No man, woman or child has ever been killed or even seriously injured by a 500-volt current. The United States Senate had this question before them last summer. After a thorough investigation the District committee unanimously reported that a 500-volt current is not dangerous. If there were any real question of its being dangerous, we should use 400 volts or 300 volts. The objection to this, however, is that by reducing the voltage we must correspondingly increase the quantity in order to retain the same horse power, and an increase in quantity (amperes) means an increase in the size of the overhead wires, which is objectionable. The danger limit with the electric current is probably about 1,000 to 1,200 volts.

The poles cannot obstruct the street, as they are inside the curb. They are just as much of an obstruction to the sidewalk as lamp posts and awning posts are—no more and no less. If the sidewalks be narrow and permission can be obtained from the property owners, hooks or eyebolts may be placed on the buildings, the cross-wires fastened to these, and the poles done away with entirely.

Every overhead wire is objectionable to the fire commissioners; the railway wire is less objectionable than any other, because there is but one wire, and this wire is in the middle of the street, away from the buildings.

If the single overhead working conductor is insufficient to carry the current necessary to operate the cars, it must be reënforced by feeder wires. These feeder wires may be insulated and may be placed underground. The overhead wire may be divided into sections of three, four, six, or 1,000 feet in length. At the ends of each section a cut-out or switch may be placed on the pole like a fire-alarm box, so that in case of fire the current may be cut out of the section or sections in the vicinity of the fire. The firemen would then have no difficulty in handling the wires, which in any event are easily cut by pliers with insulated handle. As ladders are usually raised parallel to the face of the building, rather than across the street, and as the cross-wires are 125 feet apart, it would be a very rare thing that the railway wires would be found to interfere at all with the operations of the fire department. As Prof. Thomson pertinently remarked to the insurance representative: "It will not be long before you will be taking power from these wires to put out your fires. It will not be long before we have electric motor fire engines."

Charles J. Van Depoele and Leo Daft were the pioneers in the modern electric railway work in this country.

The first roads were built in 1884–85. The new motive power was, however, viewed with suspicion, and progress was slow until the Richmond road was built by the Sprague Company in 1887–88. This road did much to popularize electric motors. The rapidity with which the horse is now going is shown by the growth of the railway business of the Thomson-Houston Electric Company, one of the several companies working in this field. In the spring of 1888 this company purchased the patents of the Van Depoele Electric Company, of Chicago. At that time there were some 14 roads operating under the Van Depoele electric system. The first Thomson-Houston car was started at Crescent Beach, Mass., July 4, 1888. On the 1st of April, 1889, in less than nine months, there were 18 roads with 104 motor cars in operation, and 33 roads with 210 motor cars under contract. The Americans are essentially a fast people. We live fast, and, unfortunately, we die fast. But as long as we do live, we go. Any time-saving device is gladly welcomed, and at once becomes popular. The limit of speed with horse cars is about eight miles per hour. With electricity the only limit is what we may fix as a safe speed. If horse cars are delayed, there is little or no chance of making up lost time. The reverse is true of electricity. With electricity we have rapid transit, and we can obtain it in a very simple and not too expensive way. Electric motor cars do not smoke or give off noxious gases or make disagreeable noises. It is not necessary to run them in the air or under the ground, though they would run well in either position. They are safe, clean, fast, and reliable. They do not keep the street in an unclean and unhealthy condition. They do not take up as much of the street as do horse cars, for they have no horses. They are brilliantly lighted at night.

All of these qualities appeal to the public, and the verdict everywhere is favorable to electricity. The United States

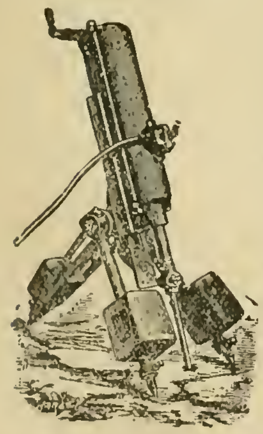
Senate and House of Representatives in reporting on a proposed extension of the Washington road, said: "It is undoubtedly the best electric railway in the United States, and beyond comparison superior to any horse railway."

To obtain these advantages the public must aid the railways. The rails must be of sufficient weight and of such form as to best carry the increased weight and stand the increased speed Some form of girder rail weighing not less than 45 pounds to the yard is best suited to this work. The rail must be so placed as to be easily kept clean, and for this purpose should be slightly elevated above the surface of the street.

On the part of the railway companies, while the first cost is great, they can look forward to reduced operating expenses, a greater car mileage per day, and a great increase of traffic. Electricity has undoubtedly come to stay.

Telpherage—Is a special application of electric energy to traction for the conveyance of minerals and goods over a rough district, where the cost of railways is too great for practical use. A telpher line crosses rivers, roads, bridges, and valleys; and even when the whole of the line is erected over a territory continually rising, the telpher locomotive can easily be made to draw loads up gradients which cannot be done on an ordinary railway. Ingenious means have been invented and practically applied to cause a telpher train to travel automatically, without any driver to control it. When properly equipped a telpher train proceeds along the level and ascends or descends gradients at about the same speed. It is the great point in telpherage that the loads should be small, and that the trains should follow each other rapidly. Among the more recent telpher lines which have been made for the carriage of minerals is one at the Eastpool tin mine in Cornwall, England, over a mile and a quarter in length, for the transport of 1,000 tons of tin ore per week.

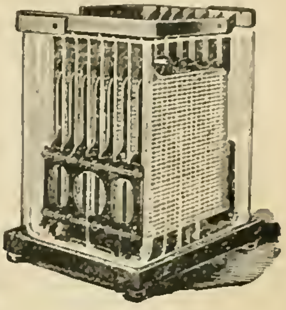
Electrical Transmission of Power.—One of the most important applications of electricity to industrial purposes which the modern development of the electric light has led to is the electrical transmission of power. Siemans a few years ago pointed out that no further loss of power was involved in the transformation of electrical into mechanical energy than is due to friction and to the heating of the conducting wires by the resistance they oppose. This loss, careful researches have demonstrated, need not be more than 13 per cent., provided there is no loss in the connecting leads. The Paris Electrical Exposition of 1881 afforded interesting illustrations of the performance of a variety of work by power electrically transmitted, including a short line of railway constructed by the firm of Siemans, which was a further development of the successful result already attained in Berlin by Werner Siemans in the same direction, and was in turn surpassed by the considerably longer line worked by Messrs. Siemans at the Vienna Exhibition two years later.



ELECTRIC PERCUSSION DRILL.

A further development of the electrical transmission of energy is to take place in the utilization of the power of Niagara, and a large tract of land about a mile distant from the falls has been acquired for the purpose, with the view of erecting mills for utilizing the power, which it is proposed to transmit to distant towns. An International Commission has been formed, which will carefully consider the problems involved in the execution of this grand scheme.

Storage Batteries, or Accumulators.—The problem how to save and store up the enormous amount of natural energy which is daily dissipated in producing natural phenomena has long occupied the attention of scientists. During the last few years this attention has been especially directed toward electricity as an agent, and the result of experiments has been the development of the electrical storage batteries, or accumulators, as they are sometimes called. In an interesting article on this subject, published in the "Popular Science Monthly" for January, 1891, Prof. Samuel Sheldon states that the employment of these names for the apparatus is very unfortunate. They are the cause of the popular idea that electricity, which is considered as a subtle, indefinite, and intangible something, is stored up in them, as valuables are stored in a vault. The commercial current electricity cannot, in large quantities, be stored and still preserve its character. It has but a flitting existence, and is no sooner produced than it dissipates itself, and is converted into some other form of energy. The energy which a current may at any instant be said to possess is immediately transformed into heat in the circuit, which will under certain conditions produce light; into chemical energy; into motion, which may or may not produce sound; or into magnetic and electrotonic conditions. The last may either be permanent or have the same evanescent existence as the original current.



ELECTRICAL ACCUMULATOR.

When electricity is employed to charge a storage battery, only that part which is transformed into chemical energy is used. The rest is dissipated. The battery, then, instead of being a place where electricity is laid away, is a place where chemicals are left by the current, with the expectation that they will in turn produce a current when called upon. This may seem a fine distinction, but it is only apparently so. For instance, the current might be produced by a dynamo turned by Niagara water-power. The chemical left by it might be zinc deposited from a solution of zinc sulphate. This might be transported, preserved, bought and sold, and finally be employed by some physicist to produce another current. To understand this transformation more clearly, and to obtain a clear idea of what goes on in a storage battery, one must first become acquainted with that part of electricity which treats of the phenomena resulting when a current of electricity passes through a liquid. This is called electrolysis, and the liquid through which a current can be made to pass is called an electrolyte. If a current of electricity flows into a liquid solution of any metallic salt by means of a wire, and if, after traversing it, it flows out through another wire, then it will, by its passage, separate the salt into two parts and deposit the metal upon the latter wire. If, for instance, the solution be one of silver cyanide, then silver will be deposited on the second wire. If a brass fork be connected with this wire and dipped in the solution, it will receive a coating of silver by the process and will be silver-plated. Substitute a solution of nickel nitrate, and the article would become nickel-plated. By using copper sulphate, the faces of types and cuts are coated with copper, which increases their hardness, and consequently their endurance.

The simplest storage battery, then, would seem to be one constructed of two copper plates suspended in a solution of some zinc salt. A current of electricity passed into this would deposit zinc upon one of the plates. After disconnecting the charging current, the battery of itself would give off a current until the zinc was redissolved.

PRIMARY BATTERY.

It might be well, right here, to define a primary battery. If any two different metals be dipped in an acidulated liquid, and if their external extremities be connected by wire a current of electricity will flow through the wire. Such a combination is called a primary battery. Under the same conditions the amount of electricity obtained depends upon the character of the metals. If nickel and iron were employed, a small amount of electricity would result. If, however, zinc be used in connection with either silver, gold, platinum, carbon, or copper, a large amount is obtained. The first three of the group are very expensive; hence, in most primary batteries, we find zinc combined with either carbon or copper, the differences between the various forms arising from difference in the liquids employed, or in the shape of construction. Furthermore, pieces of the same metal under different physical conditions, when combined with each other, will give a current. For instance, a piece of polished iron opposed to a rusty piece gives a current; and a plate of very rusty lead, if we may use the expression, combined with a piece of bright lead, yields even more current than zinc or carbon. Unfortunately, lead does not rust sufficiently well to suit electricians, and other physical reasons prevent its being used in primary batteries. It will thus be seen that a storage battery, when once charged, becomes nothing more or less than a primary battery. In the case before described, after charging, we have zinc and copper in a solution of zinc sulphate.

In describing the effects of electricity in passing through an electrolyte, we have assumed that the liquid contained a metal in solution. Suppose, now, that we take water, which has no metal in it, and subject it to the action of the current. The electricity can get no metal to deposit on the wire, where it passes out, and in consequence does the next best thing, and leaves one of the components of the water—namely, hydrogen gas. The other component, oxygen, collects around the entrance wire. The English physicist, Grove, showed that if these two wires, around which the gases had collected, were connected together, a current of electricity would flow the same as if there were two metals instead of two gases. Now, water is cheap, and if there were not some serious difficulties as regards efficiency, Grove's battery would be universally employed. It was reserved, however, for M. Gaston Planté to construct the first practical secondary battery. He considered the following points in its construction: Water is cheap; water, when subjected to the electric current, gives off oxygen and hydrogen; rusty lead, when combined with bright lead, has a high electro-motive force; oxygen makes lead rusty, and hydrogen makes it bright. His battery consisted, then, of two lead plates suspended in water, which contained a little sulphuric acid to assist in the conduction. When a current of electricity was passed through, hydrogen was thrown off at one plate, making it bright, and oxygen at the other plate, peroxidizing its surface. When the charging source was removed, the altered plates would send off a current which was in a direction opposite to the one which had charged them, and this would keep until the plates had assumed their original condition. Planté's choice of materials was most wise, and all practical storage batteries of to-day are but modifications of this style. In order that his battery might give a strong current, and one that would last a long time, it was found necessary that his two lead plates should be as near to each other, and that they should be as large as possible. He accomplished both of these ends with economy of space by winding large plates into a spiral form, they being separated from each other by strips of rubber.

In charging this battery, care must be exercised that the current be not too strong; otherwise the gases would be sent off too rapidly for the lead to take them up, and they would then rise to the top of the liquid and escape into the air. The electrical energy which separated them would thus be lost. It accordingly takes a long time to charge a new Planté battery to its full capacity. After being subjected to the current for a day or two, it will be found that the plate which received the oxygen has changed its physical character; instead of having a smooth surface, it presents a spongy appearance, having little holes and cavities in it, and thus exposes a larger superficial area. If the battery be now discharged, and be again subjected to the charging current, it will be found that a much stronger current may be used than at first, without any gas escaping. This is owing to the much larger surface exposed and to its spongy character. This original charging of a new battery, to change the character of the lead surfaces, has been termed *formation*, and, inasmuch as only one plate is altered by a charge in one direction, a complete formation consists in a charging in two directions.

From what has been said it will be seen that the electricity which is used for charging an accumulator is apparently used in the production of oxygen and hydrogen gases. These are made to oxidize one plate and clean up the other. Now, an interesting question arises, whether it would not be more economical to employ gases, which can be more cheaply produced through chemical means. Difficulties, however, arise here; for the oxygen of electrolysis is generated in the form of nascent oxygen, which is far more active than ordinary oxygen. A molecule of the ordinary gas contains two elementary atoms, which work upon each other; with the electrolytic generation, however, a single atom is sent off, and this is chemically very active. It is sometimes called ozone; but chemists say that a molecule of ozone contains three atoms. Now, there is no known method of chemically manufacturing ozone in large quantities, and ordinary oxygen does not produce the desired effect. Again, Planté's supposition that the charging current produced these two gases only, is incorrect. The sulphuric acid in the water, which he supposed only assisted in the conduction, really acts upon the lead in forming lead sulphate. This has its use in preventing the charged battery from running down when not in use, and from too rapidly expending itself when put to use.

The storage battery is susceptible of many improvements, chiefly in respect of increasing its durability. A more perfect system is much to be desired. The advance made in the past few years in this direction has been encouraging, and to prophesy that a practicable system will be produced before the world is many years older (in fact, in dealing with electricity, whose development is so rapid, we might say months instead of years), is to make a very safe prophesy indeed, as the entire history of electrical and mechanical invention points to such a conclusion.

Police and Fire Alarm Systems.—In the police and fire alarm signaling system in use in Boston, Mass., and several other cities, numbered signal boxes, containing telephones and automatic signaling instruments, are placed on every patrolman's beat, and are electrically connected with the police station. From them the patrolman can either telephone or automatically transmit messages to the station, or the station house can signal the patrolman. Citizens can also summon police assistance from any signal box. The signaling system consists of three distinct and non-interfering methods of communications: namely, automatic and manual signaling from the street stations to the station house, automatic and manual signaling from the station house to the street stations, and telephonic communication between the street stations and the station house and *vice versa*. These are arranged to operate over a single metallic circuit. The signaling from the street stations to the station house is further divided into two classes: alarm signals, comprising signals directing the station house to send a patrol wagon or ambulance, or to use the telephone; and "patrol" or "on duty" signals, which indicate at the station house the movement of the patrolmen over the territory under their charge. The signaling from the station house to the street station is accomplished by the use of currents of electricity of a different character from those employed to signal from the street station to the station house, and they sound a bell in the street station to indicate the reception by the station house of an alarm signal, or to announce to the patrolman that the station house desires to speak to him by telephone. The telephones are inductively connected with the circuit, and they are so arranged, with relation to the signaling part of the system, that conversation may be carried on between two or more points, signals may be sent from a street station to the station house, and from the latter to the former, all simultaneously over a single wire without interference or confusion.

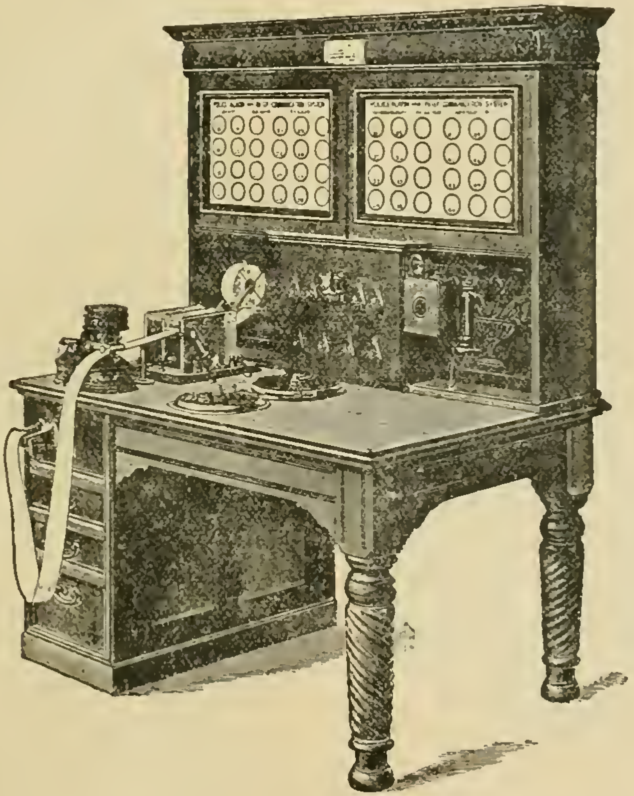


Fig. 1.—POLICE AND SIGNAL SYSTEM.—STATION HOUSE DESK, SHOWING REGISTER, TIME-STAMP, ETC.

Figure 1 illustrates the station house desk, showing register, electric time-stamp, etc. Figure 2 shows a signal box in position to be operated with a citizen's key. Figure 4 shows a signal box with the door open, while Figure 3 shows the stable apparatus for patrol-wagon service. When the door of the signal box is open (Fig. 4), a large dial and pointer, the automatic signal pull coöperating therewith, a telephonic receiver and transmitter, are exposed to view. Upon the dial are inscribed the alarm signals as desired. Upon the inside of the dial is mounted the signaling mechanism, including a gong to receive and sound the signal sent from the station house. By turning the pointer to the service required and operating it by the pull, any one of the inscribed signals may be automatically transmitted. A push button is also provided to communicate with the station when a connecting wire is broken. A call for the patrol-wagon may be sent from the outside with the door closed, by simply inserting a key, termed the "citizen's key," into a key-hole at the front of the box and turning it as far as it will go. This key cannot be withdrawn until the door is opened. A master-key is carried by each patrolman. The boxes are made of iron, very strong and substantial. The pointer may be turned to the right or left, and the act of closing the door always sets it back to the zero or starting-point. The receiving cabinet to be used at the station house (Fig. 1) is carefully constructed and wired, and serves as a very convenient operating table. The signals received from the street stations are recorded in ink automatically upon a paper tape, which also receives the impression of an automatic time and date stamp, so as to mark upon the tape the exact time at which each signal is received.

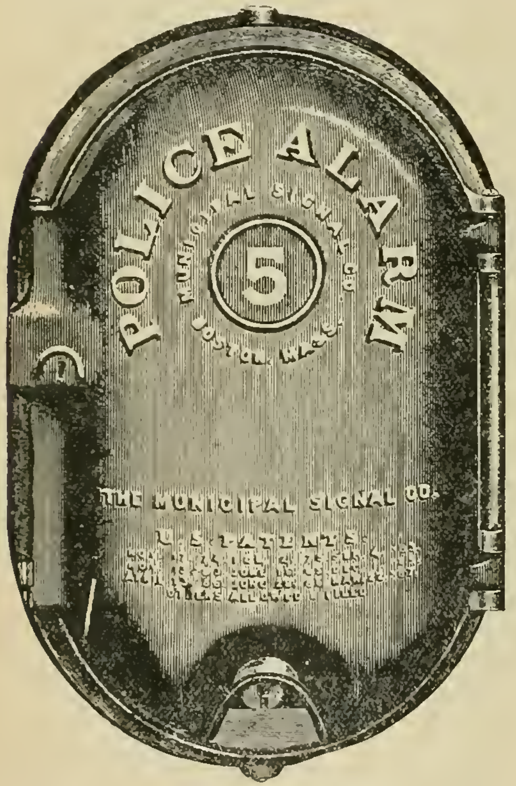

Fig. 2.—SIGNAL BOX.—IN POSITION TO BE OPERATED WITH "CITIZEN'S" KEY.

Capital Punishment by Electricity.—Of all the potent forces capable of producing death, there is none known to science more nearly instantaneous than electricity. In the ordinary occurrence in nature, where a person struck by lightning falls dead, nothing can be more sudden or rapid. And where electricity is generated artificially for illuminating purposes, the interruption of the alternating current by the intervention of or contact with any portion of the human body is invariably followed by the most serious consequences to the latter. Numerous cases of accidental death by such contacts have been recorded during the past few years, and in every case the action of the current was so instantaneous as to leave not the shadow of a doubt that death was literally quicker than thought. The body was not mutilated; there were no indications of any death-struggle; none of physical pain. Respiration and heart-action instantly ceased, and electricity, with a velocity equaling that of light, destroyed life before nerve-sensation, at a speed of only one hundred and eighty feet per second, could reach the brain.

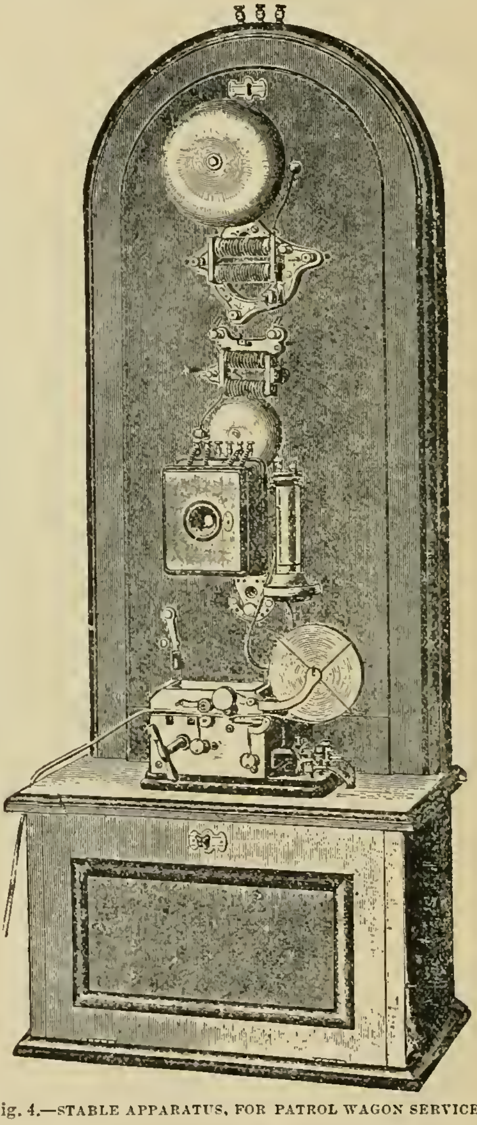

Fig. 4.—STABLE APPARATUS, FOR PATROL WAGON SERVICE.

Recognizing the advantages of electricity as a death-dealing agent, the legislature of the State of New York in 1888 amended its Code of Criminal Procedure by substituting for the death penalty by hanging the "causing to pass through the body of the convict a current of electricity of sufficient intensity to cause death; and the application of such current must be continued until such convict is dead." The first "electrocution" under this provision of the law took place in the State-prison at Auburn, N. Y., Aug. 6, 1890. After a few preliminaries the victim, William Kemmler, was seated in a large oak chair, and securely confined with straps. An electrode, formed of a rubber cup containing a sponge wet with sodium chloride, was pressed down upon a spot upon the murderer's head, from which the hair had been closely cropped. The other electrode was similar in construction, but was attached to a stiff spring, which projected upward from the seat of the chair. This was placed in contact with the bared skin at the base of the spine. The warden gave a pre-arranged signal to an assistant stationed at the switchboard in an adjoining room, who turned the switch and closed the circuit. There was a sudden momentary convulsion of the victim, and apparently all was over. Death appeared to be instantaneous and painless. In 17 seconds the current was turned off, and the body at once collapsed. A moment later, however, Kemmler gave signs of life, and the current was turned on a second time, the circuit remaining closed for a period of about four minutes, and until smoke was noticed curling upward from the two points of contact, and the pungent and sickening odor of burning hair and flesh pervaded the room. When the current was finally shut off, and the straps removed, the body collapsed and sunk in a heap on the chair.

The facts regarding this first execution were so surrounded with secresy, prejudice and interest, that it is difficult to arrive at a true understanding of the actual condition of affairs. The physicians in attendance disagree as to whether Kemmler was killed by the first or second shock. They agree only that he was unconscious from the instant the fatal current first touched him, and hence that his death was painless, if not instantaneous.

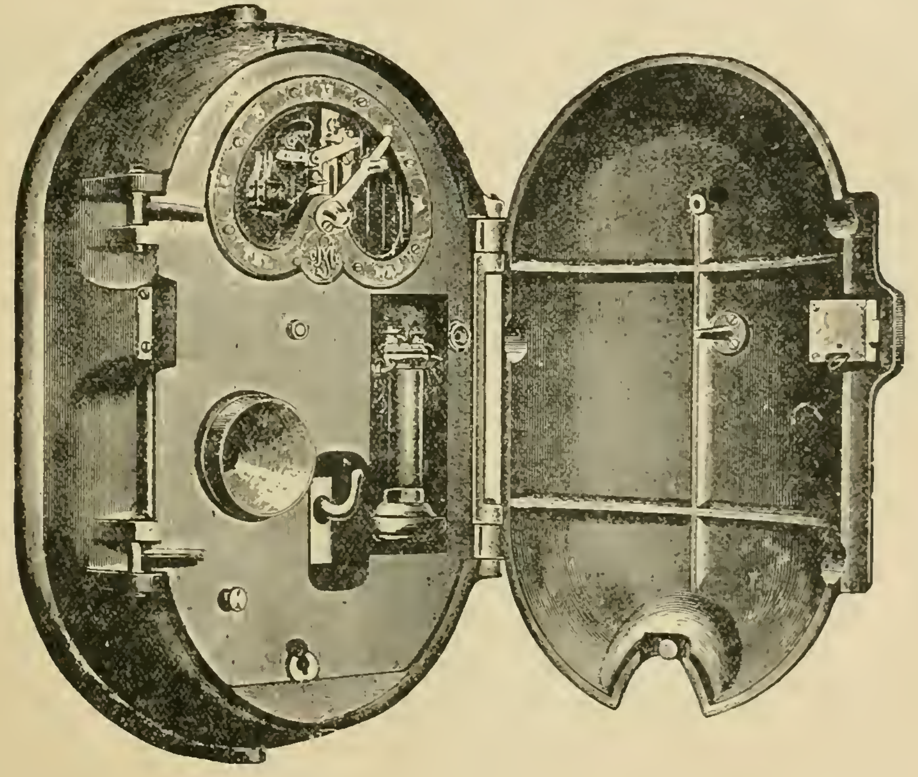

Fig. 4.—SIGNAL BOX.—DOOR OPEN READY FOR OPERATION.

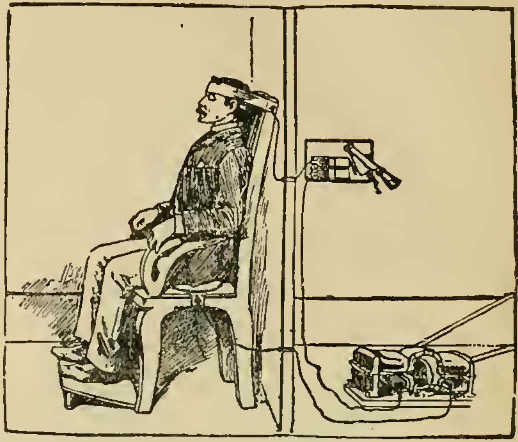
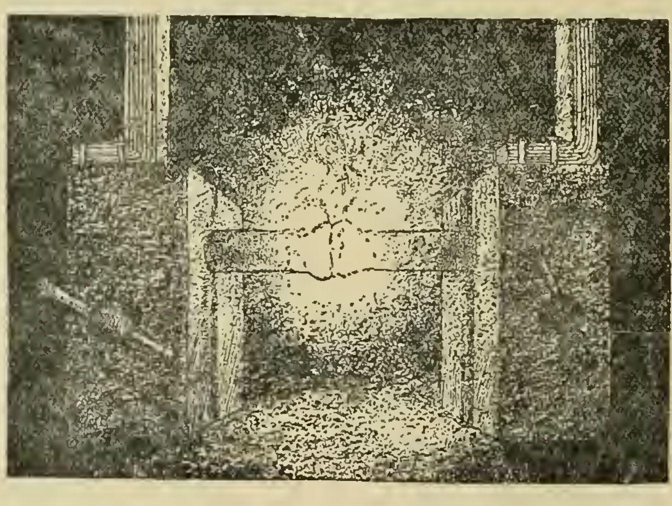
Tempering Steel with Electricity.—An interesting application of electricity to the arts consists of tempering watch-springs by means of the electric current. A one-light dynamo is connected with an ordinary oil-tempering bath. One of the conductors connects with a point within the oil-bath, and the other with a point without. The piece of flat, soft steel wire that is to be tempered to the blue color is fed under the contact-point on the outside of the bath first, and then under the one on the inside. When it reaches the latter the circuit is complete, and the steel ribbon immediately and uniformly becomes heated. No means have been devised to measure the current exactly for the purpose of doing the work mechanically. The variation in the percentage of carbon in different pieces of steel forbids the delicate process of tempering from becoming a purely mechanical piece of work. Therefore, with the electric current as with a fire, the color of the steel determines the length of time that it shall be heated. This process of tempering has several advantages. The chief one is, that the steel does not have time to oxidize, after it has been heated to the proper color, before it is under cover of the oil, and consequently that the steel ribbon is of the same thickness as it was before it entered the process. The heating is uniform throughout the length of the spring, and there is less liability of defective spots. The process is a rapid one, the springs being heated and passing into the bath at the rate of four inches per second.

Reduction of Ores.—One of the most important of the recent industrial applications of electricity is the reduction of refractory metallic ores by a method based upon the resistance of a mass of carbon to the electric current. The furnace is built of fire-bricks, and is rectangular in shape. Two carbon electrodes similar to those used in arc lights, are passed through opposite walls of the furnace. The ore of the metal intended for reduction is mixed with coarsely pulverized gas carbon, and formed into a sort of long core, the ends of which are connected with the electrodes referred to above. The furnace is filled with finely powdered charcoal, forming a bed in which the core of gas carbon and metallic ore rests. The charcoal possessing greater resistance to the electric current than the gas carbon, nearly all the current passes through the core; and the walls of the furnace, which would otherwise be destroyed by the intense heat, are protected from injury. When the poles of a powerful dynamo-machine are connected with the electrodes, and the current sent through the central core, owing to its great resistance, an intense heat is developed, far surpassing that of the most powerful blast-furnaces. The most refractory oxides are unable to withstand the temperatures attained in this furnace. Aluminium, boron, silicon, manganese, sodium, and potassium, are all quickly reduced to the metallic state, and the charcoal itself is changed to graphite in considerable quantities. Valuable results are expected from this process, not only in the cheapening of the cost of certain metals and alloys, but also in an increased knowledge of the behavior of different elements at temperatures hitherto unattainable, and the consequent aid to investigations in theoretical chemistry.



THE DEATH PENALTY BY ELECTRICITY.



WELDING A BAR BY ELECTRICITY.

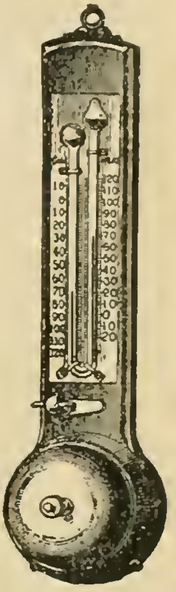
Welding Metals by Electricity.—Another important application of electric heating is the electric welding process. The parts to be welded are clamped in vises and pressed against each other at the point where it is intended to unite them. A current of great heating power is then passed through the joint by suitable cables fastened to the vises, and the joint is brought to a melting heat and cooled off again before the heat has had time to spread any distance through either piece. The scaling or defacing of the work by the action of the coals when buried in a blacksmith's fire is thus avoided, and the risks of a bad joint from the presence of ashes or dirt are entirely disposed of. For the same reason very little flux is required. The nature of the joint produced is a little different from an ordinary weld. Instead of being hammered into a union at a red heat, the parts are actually melted together and frozen in an instant.

Range-finding at Sea by Electricity.—The latest advance in the art of finding distances at sea has been made in the United States, and results have been obtained which show that the problem of making accurate and quick range measurements by automatic means has finally been solved. People discovered long ago that marine wars could not be ended by paving the bottom of the ocean with cannon balls, and sea captains were instructed not to engage an enemy until he came within point-blank range, which is the distance over which the shot will fly before striking the water when the gun is fired at level from its port on board ship. This distance was then about 500 yards. The greater accuracy of modern weapons has increased this fighting distance, but still no naval conflict has been fought with a greater distance between the contending vessels than that of 1,100 yards. At any greater distance the firing was very inaccurate, not only because it is harder to hit a target at 1,500 yards than at 1,000 yards, but principally because it was difficult to ascertain the exact distance, and hence to determine the exact elevation required for the gun. To insure effectiveness. therefore, beyond point-blank range the exact distance must be ascertained, and as the target (an enemy's ship) is usually in rapid motion, this measurement must be made instantaneously and automatically, and without calculation. This is now accomplished by the invention of Lieutenant Bradley A. Fiske, of the U. S. Navy. The apparatus is by no means complicated, and involves nothing but simple elementary principles in mathematics and electricity. It is based on the familiar mathematical proposition that if two angles and one side of a triangle are known, the other two sides of the triangle can easily be found. The Fiske range-finder, however, eliminates all calculations, and finds the range automatically. A base-line fixed once for all on the ship is the known side of the imaginary triangle. The distance of the object is represented by either of the other two sides. The target, therefore, is at one angle of the imaginary triangle; and at the other angles, at the extremities of the fixed base-line, are placed two spy-glasses, which can be directed upon it. As these spy-glasses are turned into the proper position they move over and touch wires which are bent in the form of arcs. The difference in length of the wires passed over corresponds mathematically to the distance of the object. As this length of wire increases or diminishes, it will offer more or less resistance to an electrical current sent through it. A very simple electrical contrivance, amounting practically to a balance, allows this resistance to be measured and read, not in units of resistance, but in yards. The two spy-glasses being pointed at the target, the observer at each spy-glass has nothing to do but to keep it thus pointed. Elsewhere in the ship another observer may stand at a telephone listening to a buzzing sound produced by an electrical device known as a circuit breaker, and simultaneously moving with one hand a pointer over a graduated scale. The instant the buzzing in the telephone stops he reads the range denoted by the pointer from the scale, and conveys the information by a simple form of telegraph to the men at the guns.

While Lieutenant Fiske's invention finds its most immediate use for military purposes, it is not without peaceful adaptations. Many a ship has gone ashore, even in sight of land, through an error of judgment on the part of her navigator as to her distance from the coast. The range-finder will not only prevent such misjudgment, but even at night, when the friendly beacon seems to stand out like an isolated star in the midst of the black chaos of sky and water, the mariner may learn with certainty his distance from the perilous shoal or reef.

An Electric Pinnace.—A wooden pinnace called the "Electric," built for the Royal Engineers, to be propelled by electricity, has recently been launched in England. She is 38 feet 6 inches long over all, by 8 feet 9 inches beam. Her mean draught is 2 feet 3 inches, with all machinery in position and 40 persons on board. The hull is built of mahogany and is unpainted. The motive power is electrical, there being 70 accumulators, having 19 plates each. They have a discharging current of 1 to 40 amperes and 120 ampere hours. The power is transmitted from the accumulators to a motor discharging 32 amperes at full power, the propeller rotating at 800 revolutions. The propeller is 22 inches in diameter, and is of delta metal. The maximum break-horse power is 5¼, which is said to give a mean speed through the water of 8¼ miles per hour. The motor is a single magnet machine, designed especially for marine propulsion. The boat will run from 8 to 12 hours with one charge of the accumulators. The total weight of all machinery is 2½ tons, the displacement being 4½ tons. There are two masts, each carrying a balance lug-sail, there being also a stay-sail forward. The sail spread is about 350 square feet. With the effective lead ballast, given by the accumulators, the boat should perform well under canvass, especially in view of the small propeller that is characteristic of electrical vessels.

Electric Alarm Thermometer.—A recent invention is the application of an electric alarm to a thermometer, causing the thermometer to sound an alarm whenever the temperature rises above or falls below any required point. It is designed for use in offices, schools, hospitals, breweries, and all places where the maintenance of an equable temperature is desired. Its construction will be readily understood by reference to the accompanying illustration. The electrical alarm can be arranged to sound at any distance from the thermometer, and the device can thus be used to sound an alarm in case of fire.



ELECTRIC ALARM THERMOMETER.

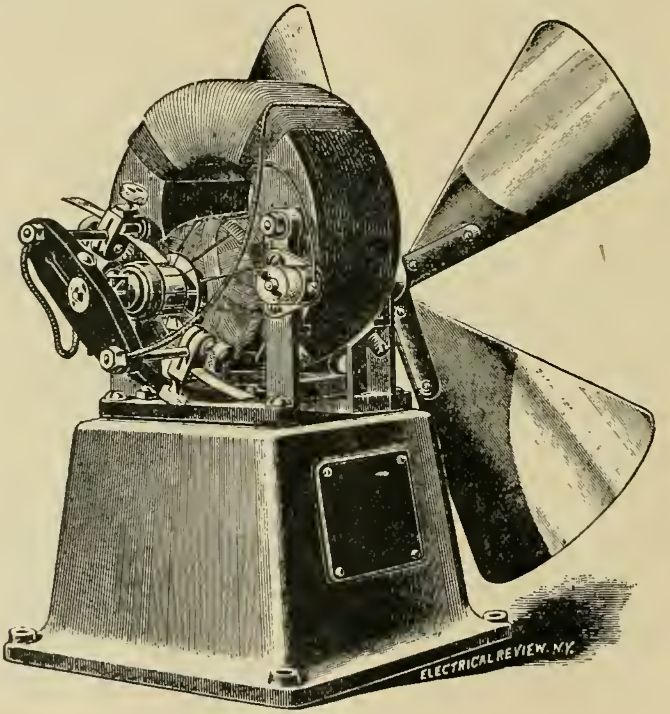
Alternating Current Fan Motor.—Another interesting device is a fan motor for use with alternating currents. The motor is simple in design and light in weight, and will drive a 12-inch fan at 1,000 revolutions per minute with a current of about one ampere. The whole apparatus, motor and pedestal, as illustrated, weighs only about 15 pounds, thus rendering it very portable. The motor comprises an arc-shaped laminated field magnet and a continuously wound drum armature, having a finely laminated core and a commutator, the field magnet and armature windings being connected in series relation. The motor is used on a 50-volt transformer circuit, and exhibits almost no sparking. The simplicity of the device is one of its chief recommendations, presenting many analogous points of construction to a direct current motor, except its fine lamination, which adapts it for alternating currents. There is very little heating of the iron when the motor is in operation. It is adapted to a number of commercial and domestic uses, in which but little power is required, such as the operating of fans, and the driving of sewing-machines.

An Electric Awakener.—One of the latest electrical novelties consists of an ordinary alarm clock with an electrical attachment, which includes in circuit one of the rollers at the bottom of the legs of the bed. When the hour arrives at which the sleeper has set the alarm, his weight closes the circuit and the bell rings, and continues to ring until the sleeper gets off the bed. A spring is adjustable to the weight of the person.

Electricity in Machine Belting.—In a dry atmosphere and between shafting practically insulated by wooden blocks, or other non-conducting means of support for the bearings, a troublesome development of electricity sometimes takes place with machine belts driven at a high velocity. The pulleys become veritable frictional electric machines, excited by the rubbing of the belting. Herr Bacher, inspector of lighting at the Dresden Theater, declares that very powerful effects may be produced by this means. A Leyden jar has been charged in a few seconds, giving sparks 4 millimeters long when discharged. It is probable that to this cause may be attributed many disastrous fires, which are generally classified as spontaneous. Flour mills, factories in which the air is heavily charged with floating organic fibers of all kinds, are peculiarly subject to these mysterious conflagrations. All lines of shafting, therefore, should be metallically connected, through their bearings, with other masses of metal or the earth.

Electro-Therapeutics.—The medical and surgical relationships of electricity are so extensive that it is impracticable to give more than the briefest mention in a work of this character. In the "International Medical Annual" for 1890, A. D. Rockwell, M. D., of New York, an acknowledged authority on this subject, asserts that electricity is a tonic of a very high order. It possesses varied influences of this kind, according to the method of its application, and therefore may be indicated in a multitude of symptoms, and for conditions apparently most diverse in their origin and character. Electricity may be said to be indicated whenever a constitutional tonic influence is called for. For the long period of convalescence following typhoid or typho-malarial fever, there is no remedy that is comparable with it; and in almost any condition where a constitutional tonic influence is indicated, electricity, in some one of its methods of applications, is likely to be of more or less service. It gives passive exercise to the muscles; it promotes and renders more natural the processes of excretion and secretion; it corrects circulatory disturbances—in a word, it imparts tone and strength to both nerve and muscle.

While the consensus of opinion among those who have had any adequate experience in the use of electricity is that it is occupying a position of growing importance, there are yet differences of opinion in regard to its efficacy. Dr. M. Allen Starr, in a paper on the "Physics and Physical Action of Electricity," read at a meeting of the New York Academy of Medicine, March 21, 1889, stated: (1.) "Static electricity offered nothing more than the interrupted galvanic current, and failed to furnish those effects which were most desirable in the treatment of disease. (2.) The constant galvanic current could produce chemical changes which aided nutrition or destroyed tissue according to the strength employed. (3.) The constant galvanic current could transfer medicines into the body from without. (4.) The interrupted galvanic current or Faradic current could excite various organs to functional activity. (5.) It was questionable whether the pathological state causing organic diseases could be in any way influenced by electricity. (6.) If functional diseases were benefited, it was in an uncertain manner, and the physiological indications for the agent were as yet uncertain.



ALTERNATING CURRENT FAN MOTOR.

Dr. L. C. Gray, in a paper on the effects of "Electricity on Central Nervous Diseases," claimed it to be an efficient remedy in relieving sub-acute mania, melancholia, the insanity of doubt, and functional insanities, but only in the period of convalescence, not in the acute stage. Of the gross cerebral diseases it might be said that it was useless to administer electricity in brain tumors, meningitis of traumatic, epidemic, or aural origin, or in facial hemiatrophy. It was a useful adjuvant in intracranial syphilis, in the early stages of headache and insomnia, and sometimes in the later stages following hemiplegia.

Dr. W. R. Birdsall, in a paper on the "Effects of Electricity on Spinal-cord Diseases," while admitting that he had never seen a case of organic disease of the spinal cord cured by electricity, stated that he had never seen such a case cured by any single therapeutic agent whatever. But for the relief of symptoms he had seen electricity serve a more useful purpose than any other. Electricity was essentially a stimulant, an exciter of living tissues. He believed, however, that the main benefit obtained from electricity in spinal-cord diseases was due to the peripheral impression.

Dr. E. D. Fisher, in a paper on the "Effects of Electricity in Functional Nerve Affections," considered galvanism more important as a remedial agent in functional nervous diseases than was static or Faradic electricity; yet, in neurasthenic cases, static electricity had a stimulating and pleasing effect. It was in functional diseases, however, with error in nutrition, and not organic troubles, that static electricity found its field of usefulness.

Dr. A. D. Rockwell, in a paper on "Electricity in Peripheral Nerve Lesions," declared that electricity sensibly hastened recovery in curable cases. While admitting that electricity possesses only a limited range of usefulness in severe lesions of either the central or peripheral nervous system, he thought it was one of the most efficient remedies we possess for the relief of the various symptoms associated with these lesions, while, for the removal of the finer nutritive disturbances that underlie many persistent neuralgias, the galvanic current was certainly a remedy of the greatest value.

Curative Effects of Electricity.—An interesting illustration of the curative effects of electricity is reported from Bangor, Me. A lady who, as it was supposed, had become a crippled paralytic for life, and had been advised by her physicians that she could not live more than three months, while waiting for death to set her free from her sufferings, was taken out for a ride on an electric street car. Although very exhaustive, the ride appeared to do her good, and each pleasant day thereafter the trip was repeated, the invalid clearly improving day by day. In about a week her appetite showed a marked improvement, and her paralyzed limbs became more sensitive. In about two weeks a strange pricking sensation was felt in the hand and foot that were paralyzed, as if they were asleep. As both limbs had been without sensation for 12 years, this was deemed remarkable, and the rides were continued with increased frequency. In five weeks she exchanged her crutch for a cane, and in an other week discarded the cane. All this time she had been taking no medicine, yet her strength steadily increased; and a few weeks later she was apparently entirely cured. One of Bangor's leading physicians, who had been in attendance upon the lady, stated that her recovery was entirely due to the currents of electricity passing through the car. She was naturally sensitive, and what to most persons would have been too weak a current to have been felt, acted as a tonic to her, and coming when it did led to her recovery.

Electricity and Hygiene.—Not only is electricity a useful slave to the industrial world, doing the mechanical work and annihilating time and space—it also is an ally and helper of sanitary science, and is rapidly becoming one of the most beneficent of sanitary agents known. The use of electric lights in churches, public halls, theaters, and other places of public assembly has been of immense advantage to the purity of the air, hitherto vitiated by the combustion of gas, oil, and kindred agents that depend on atmospheric oxygen for their illuminating power.

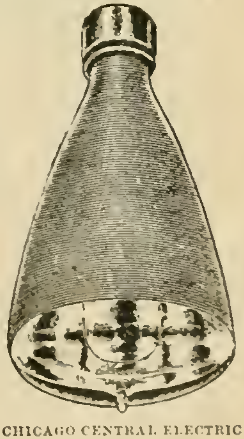
Within a very few years it has been discovered that a discharge of electric sparks through an atmosphere laden with dust, has the effect of causing the dust to settle; and this discovery has been utilized in lead furnaces to free the air of the deleterious fumes of volatilized lead. In flour mills, also, electricity is used to free the air from the impalpable dust which otherwise permeates the atmosphere, and which is injurious to the health of the workmen, as well as greatly increasing the risk of fire, owing to its extreme inflammability.

In the manufacture of alcohol from beet-sugar refuse as formerly carried on, the alcohol was liable to be contaminated with the higher alcohols which rendered it both unpalatable and dangerous to health. An electrical apparatus has been devised by means of which a certain number of molecules of hydrogen are added to these noxious alcohols, so that the distilled product is completely freed from their presence. Beverages prepared from the alcohol thus obtained are thus preserved from at least one deleterious admixture, and public health is so far the gainer.

Many lives in mines have been saved by the use of electricity, not only as an illuminant, but also as a substitute for the fuse formerly employed in blasting. Scores of miners met their death because the fuse burned too quickly, not giving them time to reach a place of safety before the explosion; or, if it burned too slowly, they often supposed it had become extinguished, and on approaching to place another fuse in its place, were surprised by the delayed discharge. Electricity induces the explosion at the precise moment desired, and if it fails the locality can be approached with perfect safety, as no discharge is possible until the electrical connection has been repaired.

In electrotyping, the battery process has been substituted in place of the old gilding and silvering by the aid of mercury, which was highly injurious to the health of the workmen.

Although it has been frequently asserted that the electric light affects the eyesight injuriously, no doubt much of the evil would be avoided if greater care were exercised in locating the lights. The fact that an incandescent lamp does not give out much heat and will not singe the hair or whiskers, is no reason why the lamp should be placed close to, or on a level with the eyes, where the light can shine directly in them. Incandescent lamps should be properly placed and shaded so as not to cast their rays directly on the eyes, and if these very simple precautions are carried out, there will be no complaint of the injurious effect of the electric light upon the eyesight.



CHICAGO CENTRAL ELECTRIC CO.'S DESK LAMP.

Electrical Injuries.—The rapid introduction of electricity as a method of lighting, heating, motor power and locomotion, to say nothing of its use in the telegraph and telephone, has developed a new class of diseases and injuries, which must be taken into account in a general treatment of the subject of electricity. The means by which the electrical current does harm varies, naturally, with the form in which it is used. The telegraph and telephone produce peculiar neuroses, due to the peculiar demand made upon the nervous system of the operator, and not to the electrical current directly, and results in telegraphers' cramp, aural and mental disorders, etc. Most of the observed cases of electrical injury come from the apparatus carrying electrical currents for lighting and power. Such injuries were formerly produced only by lightning, and were consequently rare.

Electrical currents produce three kinds of severe accidents: (1) They kill at once; (2) they burn severely; or (3) they cause traumatic neuroses through mental and physical shock. Usually, if they burn severely they do not kill; hence, practically the rule is, if contact with electrical wires does not kill, the victim gets only a burn or a harmless shock. In very rare cases the current seems to affect the nerves or nerve-centers, causing paralysis. The minimum current safe to receive is not definitely known. Probably 800 to 1,000 volts of continuous current, and a third less of alternating current, would not be fatal. The wires for lighting and for power carry the more dangerous currents.

Photograph of a Lightning Flash—The accompanying illustration is an exact copy of a photograph of a flash of lightning made by Joseph Gray, at Brixton, England, during a recent thunder storm. The flash presents a most striking and eccentric appearance, gradually dying away at the right-hand side, apparently in the distance, until it becomes too faint to affect the sensitized plate. The zigzag and irregular form of most lightning flashes is a very peculiar circumstance, and is usually explained by supposing that the air in the direct path of the electric current becomes compressed and condensed by its passage, thus increasing its resistance to the current, which is obliged to change its direction, and pass through air of less density, according to the well-known law that an electric current always follows the path of least resistance. This is one of the most perfect and satisfactory photographs of a lightning flash yet obtained.

Amusing Electrical Experiment.—Bodies charged with unlike electricities attract each other, while similar electricities repel. This principle may be illustrated by a simple experiment, which, if successfully performed, is very amusing. Take two large books and place between their leaves a pane of glass so that it will form a bridge between the two books about an inch and a quarter above the surface of the table. Then cut from tissue paper a number of small figures of men or animals, about three-fourths of an inch in height. Place them under the glass, and rub it briskly with a silk handkerchief. The figures will be attracted by the electrified plate; but, as soon as they reach the glass, they are repelled again to the table, thus performing a regular dance, which continues for some time after the rubbing of the glass is discontinued, and may be continued as long as desired by occasionally passing the handkerchief over the glass. To insure the success of the experiment, both glass and handkerchief must be dry and warm.

ELECTRO-CHEMICAL ORDER OF THE ELEMENTS. In the action of gases, liquids and solids upon each other, as in the construction of galvanic batteries, it has been observed that certain elements are readily acted upon, and give rise to electric currents, whilst others are, under the same circumstances, comparatively passive. This has led to the tabulation of the simple substances into a group, where the more readily acted upon, or electro positive element, is placed at the one end of the series, and the less active, or electronegative element, at the opposite end. The following table will show the electric order of the majority of the elements:

Electro-positive.
Potassium.
Sodium.
Lithium.
Barium.
Strontium,
Calcium.
Magnesium.
Aluminium.
Uranium.
Manganese.
Nickel.
Cobalt.
Cadmium.
Lead.
Tin.
Bismuth.
Copper.
Silver.
Mercury.
Palladium.
Platinum.
Gold.
Hydrogen.
Silicon.
Titanium.
Tellurium.
Antimony.
Carbon.
Boron.
Tungsten.
Molybdenum.
Vanadium.
Chromium.
Arsenic.
Phosphorus.
Iodine.
Bromine.
Chlorine.
Fluorine.
Nitrogen.
Selenium.
Sulphur.
Oxygen.
Electro-negative.

ELECTROTYPING. See Britannica, Vol. XXIII, p. 703.

ELECTUARY, a form of medicinal preparation in which the remedy is enveloped or suspended in honey or syrup, so as to make a mixture of thick semi-fluid consistence.

ELEGIT, Estate by, the right in lands which is enjoyed by one who has acquired the land under writ of elegit.

ELEGIT, Writ of, a writ whereby a creditor in England can seize the lands of his debtor in satisfaction of his claim. A creditor who has seized the lands is not entitled to take the person of his debtor.

ELEGY: in music, is a composition depicting feeling of mourning, sadness, longing, or ardent desire, and love.

ELEMENTAL SPIRITS beings who, according to the popular belief of the Middle Ages, presided over the four "elements," living in and ruling them. The elemental spirits of fire were called Salamanders; those of water, Undines; those of the air, Sylphs; and those of the earth, Gnomes.

ELEMENTS, in astronomy, are those numerical quantities, and those principles deduced from astronomical observations and calculations, which are employed in the construction of tables exhibiting the planetary motions. They include the greatest, least, and mean distances of the planets from the sun, the eccentricities of their orbits; their mean motions, daily and annual, with the motions of their aphelia; and the inclinations of their orbits to the ecliptic; their masses and densities, etc.

ELEPHANT, a geographical term of obvious origin, indicating various localities in Asia and Africa. (1.) Elephant Point, a promontory of Pegu, in Further India. It marks the west extremity of the mouth of the Rangoon, the most easterly arm of the Irrawaddy. It is in latitude, 16° 28′ N., and longitude 96° 25′ E. (2.) Elephant Bay, an inlet of the Atlantic, on the coast of Benguela, Southwest Africa, in latitude 13° 14′ S., and longitude 12° 33′ E. (3.) Elephant Island, in Senegambia, about 100 miles up the Gambia. (4.) Elephant River, in the Cape Colony of South Africa. It enters the Atlantic after a course of 140 miles, about latitude 30½° S., and longitude 18° E.

ELEPHANTINE, a small island of the Nile, lying opposite Assouan, the ancient Syene, on the confines of Egypt and Nubia, in 24° 5′ N. lat., and 32° 54′ E. long. The island was anciently called Abu, or the "ivory island," from its having been the entrepot of the trade in that precious material.

ELEPHANT-SEAL (*Macrorhinus leoninus* or *proposcideus*), also known as the sea elephant, the largest of the seal family (*Phocidæ*), and an inhabitant of the seas of the Southern hemisphere (see

Britannica, Vol. XV, p. 444). It is sometimes 20 feet in length, with a circumference of about 18 feet at the thickest part, which is at the chest, immediately behind the fore-flippers or swimming-paws, the body tapering towards the tail. The color is grayish, bluish-gray, or more rarely blackish-brown. The whole body is covered with very short hair, distributed in patches, giving it a spotted appearance somewhat like watered silk. The swimming-paws are large and powerful, and have five nails, the thumb-nail easily distinguishable from the others; the hind-paws have not even the rudiments of nails, but are beautifully constructed, like the webbed foot of a bird, so as to expand, and increase the power of swimming. The true tail is very short, not more than six inches long. The head is larger in proportion than in many seals; the eyes are very large and prominent, with eyebrows of coarse hair; the whiskers are composed of very long and coarse spirally twisted hairs; there are no external ears; the canine teeth are remarkably large and massive, somewhat assuming the character of tusks. The nose of the males is prolonged into a kind of proboscis.

This animal becomes so fat that when crawling the whole body trembles as if it were a bag of jelly. The tongue is reckoned savory food; the skin is used extensively for carriage and horse harness. The oil yielded by this animal is clear, inodorous, and not liable to become rancid; one individual produces as much as from 1,400 to 1,500 lbs. It is employed chiefly in the manufacture of cloth.

ELEPHANT'S FOOT, or Hottentot's Bread (*Testudinaria elephantipes*), a plant of the natural order *Dioscoreaceæ*, of which the root-stock forms a large fleshy mass, curiously truncate, or abruptly cut off at the end, so as somewhat to resemble an elephant's foot, and covered with a soft, corky, rough and cracked bark. From this springs a climbing stem, which bears leaves and flowers. The root-stock is used as food by the Hottentots.

ELEPHANT-SHREW, a name applied to a number of long-nosed, long-legged insectivora, forming the family *Macroscelidæ*. They are natives of Africa, and are notable for their agile jumping over loose sand. They use their hind-legs somewhat like the kangaroo. There are two genera, *Macroscelides* and *Rhynchocyon*, with fourteen species. See Britannica, Vol. XV, p. 402.

ELEUSINE, a genus of grasses, chiefly natives of India and other warm climates, several of which are cultivated as grains. This is especially the case with *E. corocana*, an Indian species called Natchnee and Nagla Ragee, also Mand and Murwa, which has aggregated digitate spikes finally incurved. The Thibetans make from this grain a weak sort of beer, much in use among them. *E. stricta* is cultivated as a grain crop in the same parts of the world, and is, like the former, extremely productive. The grain called tocusso (*E. tocusso*) in Abyssinia is also a species of this genus. A decoction of *E. Ægyptiaca* is used in Egypt for cleansing ulcers, and a drink made from the seeds is regarded as useful in diseases of the kidneys and bladder. *E. Indica*, which has been naturalized in the Northern United States, is the common crab grass, also known as dog's tail and wire grass.

ELEUTHERIA BARK, a name not infrequently given to the bark of the *Croton Eleutheria*, also known as Cascarilla Bark. It is called Eleutheria (or Eleuthera) Bark, because it is chiefly gathered on the island of Eleuthera.

ELEVATED: wings turned upward are described in heraldry as elevated.

ELEVATION: in architectural drawing, a representation of the flat side of a building, drawn with mathematical accuracy, but without the slightest attention to effect.

ELEVATION: in astronomy and geography, generally the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intersected between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator, and is always equal to the latitude of the place. The elevation of a star, or any other point, is similarly its height above the horizon, and is a maximum when the star is on the meridian.

ELEVATOR. See Britannica, Vol. XIV, p. 573.

ELEVENTH, in music, is the interval of the octave above the fourth.

ELF ARROW-HEADS, ELFIN ARROWS, ELF BOLTS, ELF DARTS, ELF SHOT AND ELF STONES, names popularly given in the British Islands to the arrow-heads of flint which were in use at an early period among the barbarous tribes of Europe, as they are still in use among the American Indians, the Esquimaux of the Arctic regions and the inhabitants of some of the islands in the Pacific Ocean. It was believed that elves or fairies, hovering in the air, shot these barbs of flint at cattle, and occasionally even at men.

ELGIN, a city of Illinois, located in Kane county, on the Fox River, 36 miles northwest of Chicago. It is the center of a large dairy business, and has important manufactures, especially of watches, carriages, washing-machines, shoes, farming implements, etc. The Elgin National Watch Works employ 3,000 skilled hands, and manufacture 1,800 watches daily. In addition to twelve public schools there is an academy, a Catholic seminary, a school of manual training, and a public library. The Northern Illinois Hospital for the Insane is located at Elgin. The growth of the city has been very rapid during the last decade. Population in 1880, 8,787; in 1890, 17,429.

ELIAS, Mount St., a mountain on the north west coast of America, in latitude 60° 18′ and in longitude 140° 30′ W. It rises about 17,860 feet, or almost 3½ miles above the sea, being visible to mariners at a distance of 50 leagues.

ELIE, or Ely, a pretty little watering-place of Scotland, County of Fife, 23 miles northeast of Edinburgh (34 by rail). Population, 917.

ELIOT, Charles William, an American educator, born in 1834. In 1854 he was appointed tutor in mathematics at Harvard; in 1858 became assistant professor in mathematics and chemistry; in 1861 taught chemistry in Lawrence Scientific School; from 1863 to 1865 studied chemistry in Europe; in 1865 became professor of analytical chemistry in the Massachusetts Institute of Technology, and in 1869 was elected president of Harvard University. He is a member of many scientific and literary bodies, and is a popular public speaker. He has written various works on chemistry.

ELIOT, George. See Cross, Marian, in these Revisions and Additions.

ELIOT, John (1754–1813), an American clergyman. He began to preach in 1776; was for a time chaplain of a Boston regiment, and from 1779 till his death was pastor of the New North Church of Boston. He published a *Biographical Dictionary of Eminent Characters in New England.*

ELIOT, Samuel, an American author, born in 1821. From 1839 to 1841 he was in a Boston counting-house; spent four years in foreign travel; on his return taught private school; was professor of political science and history in Trinity College, Hartford, Conn., in 1856–64; its president, 1860–64; lecturer on constitutional law and political science, 1864–74; lectured at Harvard in 1870–73; was master of the Boston Girls' High School in 1872–76; superintendent of the Boston public schools in 1878–80; was an overseer of Harvard in 1866–72; and in 1868–72 was president of the American Social Science Association. He has published many works on historical and other subjects.

ELIXIR, a term in pharmacy which has come down from the days of alchemy, and is applied to various preparations, consisting mostly of solutions of aromatic and bitter vegetable substances in spirits of wine. The term tincture is now more common.

ELIZABETH, Madame (1764–94), a French princess, sister of Louis XVI.

ELIZABETH, a city of New Jersey, and county-seat of Union county (see Britannica, Vol. VIII, pp. 145–46). Although largely a place of residence for New York business men, Elizabeth has numerous manufactories, some of them of national importance. The Singer Manufacturing Company occupies 32 acres, and employs 3,000 men in the manufacture of the Singer sewing-machines. The manufacture of cordage is another industry which has grown to large proportions. The city is supplied with excellent water, obtained from the Elizabeth River at its source at the base of the mountains 20 miles distant. The high school building, presented to the city by one of its citizens, Mr. Joseph Battin, is one of the finest school buildings in the State. The city has a general hospital and dispensary, a home for aged women, and an orphan asylum. Library Hall has recently been completed at a cost of $50,000, and contains a large library. The public school system is divided into five branches of instruction: normal training for teachers, manual training, high school, grammar schools, and primary schools. In addition to these there are numerous private boarding and day schools, including a business college, with a preparatory college course. Population in 1880, 28,229; in 1890, 37,683.

ELIZABETHAN ARCHITECTURE, a term applied to the mixed style which sprang up on the decline of Gothic architecture. By some it is called the Tudor style, but that name belongs more correctly to the Perpendicular, or latest kind of Gothic.

ELIZABETH CITY, the county-seat of Pasquotank county, N. C., on Pasquotank River. It has a deep, safe harbor, which can be entered by large vessels; has a park, State normal school, planing-mill, shingle factories, and cotton factories. It is 46 miles south of Norfolk, Va., with which it is connected by rail, and by the Dismal Swamp canal.

ELIZABETH ISLANDS, the name given to 16 small islands off the coast of Massachusetts between Buzzard's bay and Vineyard sound.

ELIZABETHTOWN, the county-seat of Essex county, N. Y., on Bouquet River, 125 miles north of Albany, situated in the vicinity of iron mines.

ELIZABETHTOWN, a village and county-seat of Hardin county, Ill., on the Ohio River, situated in a lead-bearing region.

ELIZABETHTOWN, a railroad junction and county-seat of Hardin county, Ky., 42 miles southwest of Louisville.

ELIZABETHTOWN, a village of Lancaster county, Pa., 18 miles northwest of Lancaster city. It manufactures farming implements.

EL-KHARGEH, capital of the Great Oasis, Upper Egypt, situated in latitude 25° 28′ N., longitude 30° 40′ E. In the vicinity of the town are numerous ruins, among which are those of a temple; there is also a remarkable necropolis. Population, 6,000.

ELKHART, a city of Indiana, situated at the confluence of the St. Joseph and Elkhart Rivers, in Elkhart county, in the northern part of the State. The town was settled in 1832, and incorporated as a city in 1875. The streets are well paved and lighted with gas and electricity. The principal manufactures are musical instruments, flour, starch, paper, carriages; it has iron foundries and planing mills. The locomotive shops of the Lake Shore railroad are located here. Population in 1880, 6,953; in 1890, 11,370.

ELKHORN, a railroad junction and county-seat of Walworth county, Wis. It is situated in a rich farming district.

ELKHORN RIVER rises in the north-eastern part of Nebraska, flows southeast, and enters the Platte River. It is about 250 miles long.

ELK POINT, a railroad junction and county-seat of Union county, South Dakota, on the Missouri river, 21 miles northwest of Sioux City.

ELK RIVER, the county-seat of Sherburne county, Minn., situated 38 miles northwest of St. Paul, and on the Elk and Mississippi Rivers. It has many manufactories, and its principal business is lumber, stock and grain.

ELK RIVER rises in Rich Mountains in West Virginia, flows westward for 150 miles and enters the Great Kanawha River at Charleston.

ELKTON, the county-seat of Cecil county, Md., at the head of navigation on Elk River, 52 miles northeast of Baltimore. Flour, iron and paper are here manufactured. The place was settled by Swedes in 1694.

ELL, a measure of length now little used. It was originally taken in some vague way from the arm, and hence has been used to denote very different lengths. The English ell, as a measure of cloth, is equal to five-quarters of a yard.

ELLAND, a town of England, in the West Riding of Yorkshire, on the river Calder, three miles southeast of Halifax by rail. It has cloth-mills and there are valuable stone-quarries in the vicinity. Population, 8,278.

ELLENRIEDER, Marie, a female painter of very high excellence, born at Constance in 1791, studied in Munich, and in 1820 went to Rome to perfect her knowledge of art. On her return to Germany she painted a *Martyrdom of St. Stephen* as an altar-piece for the Roman Catholic Church at Karlsruhe. She was afterwards appointed court-painter at Munich, but subsequently fixed her residence at Constance, and devoted herself exclusively to her profession. Among her principal pieces are the *Transfiguration of St. Bartholemy*, *Christ Blessing Little Children*, *Mary and the Infant Jesus*, *Joseph and the Infant Jesus*, *St. Cecilia*, *Faith, Hope and Charity*, and a *Madonna*.

ELLENVILLE, a thriving village of Ulster county, N. Y., 30 miles west of the Hudson River, situated at the foot of Shawangunk Mountains. It has fine public and private buildings, is a favorite summer resort, and the seat of Ulster Seminary. Glass, cutlery, leather, stoneware pottery, and boats are here manufactured.

ELLERY, William (1727–1820), a Signer of the Declaration of Independence. He began the practice of law in 1770; became a member of the Continental Congress in 1776, continuing in office till 1786, with the exception of the years 1780 and 1782; was commissioner of the Continental loan office for Rhode Island in 1786; for a time was chief justice of the Rhode Island superior court; and from 1790 till his death was collector of Newport.

ELLET, Charles (1810–62), an American civil engineer. After spending some time in engineering pursuits in the United States he completed his education in Europe. He was connected for a time with various railroads in America, and was chief engineer of the James and Kanawha canal. In 1842 he built the wire suspension bridge across the Schuylkill River at Philadelphia, the first of its kind on the continent. In 1847 he planned and built the suspension bridge over the Niagara River, and later built a suspension bridge at Wheeling, Va. He afterwards engaged in numerous important engineering works, and in 1861 was commissioned colonel of engineers in the army. While on duty on the Mississippi River, off Memphis, he received a musket-ball wound above the knee, from the effects of which he died.

ELLICOTT, Charles John, bishop of Gloucester and Bristol, born at Whitwell, near Stamford, April 25, 1819. He graduated from Cambridge University in 1841, and was elected fellow of St. John's College. In 1848 he became rector of Pilton, Rutlandshire, and professor of divinity at King's College, London, in 1858; Hulsean lecturer at Cambridge in 1859, and Hulsean professor of divinity the year after. He was nominated dean of Exeter in 1861, and raised to the episcopal bench in 1863. Dr. Ellicott was chairman for eleven years of the New Testament Revision Committee, and he is well known as a commentator on the Epistles of the New Testament.

ELLICOTT CITY, the county-seat of Howard county, Md., on the Patapsco River, 10 miles southwest of Baltimore. It has two cotton factories, a large flouring mill, a barrel factory, machine shop, a foundry, and three colleges.

ELLICOTTVILLE, a village of Cattaraugus county, N. Y., on Great Valley Creek, 44 miles southeast of Buffalo, on the Rochester and State line railroad.

ELLIOT, Jean (1727–1805), the author of *The Flowers of the Forest*, a touching lyric on the disaster of Flodden. The greater part of her life was spent in Edinburgh.

ELLIOTT, Robert Woodward Barnwell (1840–87), an American P. E. bishop. He entered the Confederate army at the beginning of the civil war, and attained the rank of major. In 1868 he took deacon's orders; was ordained priest in 1871, and the same year became pastor of St. Philip's church in Savannah, Ga. In 1874 he was consecrated missionary bishop of western Texas.

ELLIOTT, Stephen (1[illegible]), an American naturalist. In 1793 he became a member of the legislature of South Carolina, and continued in office until 1812, when he became president of the bank of the State. He was one of the founders of the Literary and Philosophical Society of South Carolina; in 1825 was instrumental in the establishment of the State Medical College, and was its professor of natural history and botany. He published a work on *The Botany of South Carolina and Georgia.*

ELLIOTT, Stephen, Jr. (1806–66), an American P. E. bishop, son of the naturalist. He practiced law from 1827 to 1833; was ordained deacon in 1835; was professor of sacred literature in South Carolina College; took priest's orders in 1836; became first bishop of the diocese of Georgia in 1840; in 1841 was made rector of St. John's church, Savannah, and in 1844 became provisional bishop of Florida. Subsequently he was rector of Christ's church, Savannah, until his death.

ELLIOTT, William, a lawyer, born in Beaufort, S. C., Sept. 3, 1838. He was educated at Beaufort College, Harvard University, and the University of Virginia; entered the profession of law in Charleston, S. C., in 1861, and served as an officer in the Confederate army during the war of the Rebellion. In politics he is a Democrat, and was elected a member of the State legislature and intendant of Beaufort in 1866; was a delegate to the Democratic National Convention in 1876 and 1888, and a Democratic Presidential elector for the State at large in 1880. He was elected a Representative from the Seventh Congressional District of South Carolina to the 50th Congress; was declared elected to the 51st Congress, but was unseated by the House of Representatives. He was elected from the same district to the 52d Congress in 1890.

ELLIPSIS, a term used in grammar and rhetoric to signify the omission of a word necessary to complete the expression or sentence in its usual form. The object of ellipsis is shortness and impressiveness.

ELLIS, Alexander John (formerly Sharpe, the name having been changed in 1825), F. R. S., English philologist, born at Hoxton, near London, June 14, 1814; studied at Shrewsbury and Eton, graduated with high honors at Trinity College, Cambridge, in 1837, and studied law in the Middle Temple. He has published *The Alphabet of Nature* (1845); *Essentials of Phonetics* (1848); *Early English Pronunciation* (1869); *Speech in Song* (1878); *Basis of Music;* and has translated Ohm's *Spirit of Mathematical Analysis* and *Helmholtz's Sensations of Tone as a Physiological Basis for the Theory of Music.*

ELLIS, George Edward, an American clergyman, born in 1814. He was ordained in 1840 as pastor of the Harvard Unitarian church, Charlestown, Mass., remaining there until 1869; was professor of systematic theology in Harvard Divinity School in 1857–63; was at one time editor of the "Christian Register," and later of the "Christian Examiner." In 1887 he became president of the Massachusetts Historical Society. He is the author of many works, principally of a biographical or historical nature.

ELLIS, Robinson, an English classical scholar, born at Barming, Kent, Sept. 5, 1834, and educated at Walthamstow, at Rugby, and at Oxford. He was elected a fellow of Trinity College, Oxford, and there remained till 1870, when he became professor of Latin in University College, London. Six years later he returned to Oxford. He has contributed a number of philological articles to English and American periodicals, and has published critical editions of the *Ibis* of Ovid and of the text of Catullus.

ELLISTON, Robert William (1774–1831), an English actor, born in London in 1774, and educated at Cambridge. In 1791 he ran away from home, and made his first appearance on the stage at Bath, where his *Romeo* lifted him to public favor. In 1819 he became lessee and manager of Drury Lane Theater, but in 1826 he retired bankrupt. Elliston was an actor of wonderful versatility, the first comedian, and one of the first tragedians of his day; but dissipation shattered his health, and apoplexy caused his death, July 8 1831.

ELLORE, a town in the Godavari district, Madras, India, on the Jammaler River, 225 miles north of Madras, with manufactories of woolen carpets and saltpeter. The heat is very oppressive, reaching 110° F. in the shade. Population, 25,092.

ELLSWORTH, a town of Kansas, and county-seat of Ellsworth county. It has good water works parks, schools, churches, and mills. Rock salt has recently been here discovered 730 feet below the surface of the ground.

ELLSWORTH, the county-seat of Pierce county Wis., 40 miles southeast of St. Paul, Minn. It has a stave-mill and steam saw-mill.

ELLSWORTH, Oliver (1745–1807), an American jurist. He was admitted to the Connecticut bar in 1771; at the outbreak of the Revolution was chosen to represent Windsor in the general assembly; in 1778 took his seat as a delegate to the Continental Congress, and from 1780 to 1784 was a member of the governor's council. In 1783 he was reëlected to Congress, but declined to serve. He became judge of the Connecticut superior court in 1784, and in May, 1787, was made a member of the Federal convention at Philadelphia. In 1789 he was made a United States Senator; from 1796 to 1800 was chief justice of the United States Supreme Court; 1800–01 was at the head of a commission to negotiate with France; and in 1802 was again elected a member of the governor's council. In 1807 he again became chief justice of the Connecticut Supreme Court.

ELLWANGEN, a town of Würtemberg on the Jagst River, 55 miles north of Ulm by rail. The old castle of Hohen-Ellwangen has been used as an agricultural school since 1843. Population, 4,793.

ELM, a village of Switzerland, at the head of a valley in the canton of Glarus. In 1881 the whole of the northern side of Tshingel Peak (10,230 feet) crashed down upon it, destroying a large part, and filling the valley with débris.

ELMALU, a town of Asia Minor, in the province of Konieh, on the Lycian tableland, 45 miles west of Adalia. It has manufactories of red leather and dye-works. Population, 25,000, chiefly Greeks and Armenians.

ELMENDORF, John James, an American educator, born in 1827. In 1848 he became instructor of mathematics at Columbia College, and in 1868 professor of philosophy in Racine College, Wis. Among his works are: *Manual of Rites and Ritual; History of Philosophy;* and *Outlines of Logic.*

ELMIRA, a city of New York, and county-seat of Chemung county (see Britannica, Vol. VIII, p. 153). Six railroads center here: viz., New York, Lake Erie and Western; the Delaware, Lackawanna and Western; Northern Central; Lehigh Valley; Elmira, Cortland and Northern; and the Tioga. The city contains 90 miles of streets, most of which are paved, lined with handsome shade trees, and well lighted with gas and electricity. The area of the city is 3,000 acres. A board of trade was organized in 1879. Manufacturing interests are numerous and extensive, giving employment to about 4,000 persons. The educational advantages of Elmira are excellent. The city has over $3,000,000 invested in school property. There are 9 public schools, 4 private select schools, 3 commercial colleges, and the Elmira Female College (Presbyterian), with an endowment of $100,000. Among the charitable institutions are the Arnot-Ogden Memorial Hospital, Home for the Aged, Orphan's Home, Industrial School, and the Anchorage. The city contains six parks, among them Eldridge Park, with an area of 89 acres; Riverside Park, 40 acres; and Grove Park, 10 acres. Population in 1880, 20,541; in 1890, 28,070.

ELMORE, a village of Ottawa county, Ohio, on Portage River, 16 miles from Toledo and 20 miles from Lake Erie.

ELMO'S FIRE, St., the name of an electric display sometimes seen, during thunder storms, of a brush or star of light at the tops of masts, spires, or other pointed objects. See Britannica, Vol. XIV, p. 633.

ELMSHORN, a town of Denmark, in the duchy of Holstein, 20 miles northwest of Hamburg, situated on both banks of the Kruckau, a navigable stream, and feeder of the Elbe. It is well built, has considerable manufactures, and an active trade in grain; it has a boat-building yard and tanneries.

ELMSLEY, Peter, classical scholar, born in 1773, educated at Oxford, where he graduated B. A. in 1794, and in 1823 was appointed principal of St. Albans Hall, and Camden professor of ancient history. He contributed to the *Edinburgh* and *Quarterly* reviews, but is now remembered only by his valuable critical work on Sophocles and Euripides.

ELMWOOD, a village of Peoria county, Ill., 163 miles southwest of Chicago.

ELOCUTION (*Lat.*, for speaking out), the art of effective speaking, more especially of public speaking. It regards solely the utterance or delivery; while the wider art of oratory, of which elocution is a branch, takes account also of the matter spoken.

ÉLOGE. When a member of the French Academy dies, it is customary for his successor to deliver an oration setting forth his merits and services. This is called an *éloge*, and a considerable branch of French literature goes by the name.

ELOHIM (Hebr., plural of *Eloăh;* Arab., *Ilâh;* Chald., *Elâh;* Syr., *Alôh*), might, power; in plur., intensified, collective, highest power—great beings, kings, angels, gods, *Deity*. As a *pluralis excellentiæ* or *majestatis*, and joined to the singular verb, it denotes, with very rare exceptions, *the One* true God. Joined to a plural verb, however, it usually means gods in general, whether including the One or not.

EL PASO, a city of Woodford county, Ill., containing mills, grain elevators, agricultural implement works, and a carriage manufactory.

EL PASO, a city of Texas, and county-seat of El Paso county, situated on the left bank of the Rio Grande River, at one of the great gateways of travel between the United States and Mexico. In 1881 the first railroad reached the city; ten years later five great trunk lines centered here, having their main connections with the Pacific coast, the Mexican capital, and the great grazing and mining regions of the Rocky Mountains. The public schools are excellent. El Paso contains a court house costing $100,000, a jail costing $35,000, a handsome city hall, custom house, and a federal building costing $200,000. There is no city debt. The United States Government has established a military post in the vicinity, the citizens having donated 1,000 acres of land for that purpose. Population in 1880, 730; in 1890, 10,836.

ELPHIN, a bishop's see in Roscommon, Ireland, united to Kilmore in 1833.

ELSSLER, Fanny (1811–84), one of two celebrated dancers, sisters, natives of Vienna. Their first great triumph was at Berlin in 1830. In 1841 they visited America, where they excited unwonted enthusiasm. In 1851 they retired. Theresa became the wife of Prince Adelbert of Prussia, and was ennobled by the king of Prussia as Frau von Barnim.

ELSTER, the name of two rivers of Germany, the White and the Black Elster. The White Elster rises at the foot of the Elster Mountains, on the northwestern boundary of Bohemia, flows in a northerly direction, and falls into the Saale three miles south of the town of Halle, in Prussia. Its chief affluent is the Pleisse from the right. Total length, 110 miles. The Black Elster rises in the kingdom of Saxony, within two miles of Elstra, flows northwest, enters Prussia, and joins the Elbe eight miles southeast of Wittenberg. Length, 105 miles.

ELSTER, Kristian, a Norwegian novelist, born March 4, 1841, died April 11, 1881. He was author of *Tora Trondal* and *Farlige Folk*, both works of great merit. The latter had not yet appeared in print at the time of the author's death. Some short sketches of his were collected and published by Alexander Kjilland in a volume entitled *Solskyer* (1882).

ELSTRACKE, Renold, a noted English engraver, born probably in Belgium in the 16th century. His engravings, including portraits of the kings of England, of Mary Queen of Scots, and other notabilities, are much sought after, chiefly from their rarity.

ELSWICK, a township on the outskirts of Newcastle, England. The works of Sir W. G. Armstrong, Mitchell & Co., are located here. The engineering section of these works dates from 1847, the ordnance works from 1857. The frontage on the river is about one mile, the entire area about 125 acres, and 14,000 people are employed. Population, 34,642.

ELTON, a shallow, oval-shaped salt lake of Russia, with an area of 62 square miles, in the government of Astrakhan, the center of it being in lat. 48° 56′ N., and long. 46° 40′ E. In spring the lake has a layer of almost pure salt crystals, from 2 to 4½ inches thick. The annual yield is about 96,000 tons, or about one-seventh of the total production of Russia.

ELTON, Charles Isaac, an eminent jurist and ethnologist, of Whitestaunton, Somerset, England, born in 1839. He was educated at Cheltenham and Balliol College, Oxford, became fellow of Queen's College in 1862. Was called to the bar at Lincoln's Inn in 1865, and afterwards became Q. C. He was returned to Parliament as a Conservative in 1884, was defeated in 1885, but again returned the year after. His books had already gained him reputation as a jurist, when he placed himself in the front rank of English ethnologists by his *Origins of English History* (1882).

ELUTRIATION is the term applied to the process of separating, by means of water, the finer particles of earths and pigments from the heavier portions. This process is much employed in the manufacture of the materials used in pottery and in the preparation of pigments.

ELWES, John, M. P. (1714–89), a famous English miser. He would walk miles in the rain to save the hire of a conveyance, or risk his life to save paying a penny at a turnpike. He died at Marcham, Berkshire, leaving property worth two and a half millions of dollars.

ELYRIA, the county-seat of Lorain county, Ohio, finely situated at the junction of the east and west branches of the Black River, 7 miles south of Lake Erie. It contains a telegraph college, gas factory, has excellent water power, and manufactures cheese, building-stone, grindstones, tobacco, screws, and confectionery.

ELZE, Frederick Karl, Shakespearian scholar, born at Dessau, May 22, 1821, died at Halle, Jan. 21, 1889. He studied at Leipzig and Berlin, devoting especial attention to English literature. In 1875 he was appointed to the newly established chair of English language and literature at Halle.

EMANCIPATION, Chronological Outline of. For general article on the subject of Slavery, the Slave-trade, and Emancipation, see Britannica, Vol. XXII, pp. 129–144. The following chronological historic outline furnishes a convenient summary of facts, classified by countries, relating to the prevalence of slavery at different periods, and indicating the progress and success of the vigorous efforts put forth in behalf of universal emancipation:

The custom of selling men and women into bondage was introduced into Egypt, Arabia, and other countries of the East, from Chaldea.

The Jews were permitted to make bondsmen of the captives taken in war, and also to make slaves of insolvent debtors—the service to continue until the debt was paid, with the provision that all slaves should be given their pardon in the fiftieth, or "Jubilee" year, and that those whose slavery was the result of debt should all be free at the close of a period of 7 years.

In Greece, in the days of Homer, all prisoners were regarded as slaves (1000 B. C.). In Attica alone there were 400,000 slaves (317 B. C.). When Alexander razed Thebes he sold the whole people for slaves (335 B. C.).

In Rome many thousand prisoners were held as slaves, and in many cases were chained at the galley oars in perpetual servitude. It was a common habit to find slaves chained to the gate of a rich man's house to admit the invited guests (266 B. C.–250 A. D.).

C. Polio, the Roman, was accustomed to throw any offending slaves into his ponds to fatten his lampreys (42 B. C.).

The first Janissaries (an order of Turkish infantry) were selected from among the Christian slaves seized in battle (1339).

In England, under Saxon and Norman rule, the peasantry were commonly sold for slaves. Children were sold in the Bristol market the same as cattle, for home use or for exportation to Ireland, Scotland, and other countries, and slaves were entailed by bequest the same as other property.

The English slave-trade was begun by Sir John Hawkins and other Englishmen. First expedition took place in 1562.

England employed 130 ships in the slave-trade, and carried 42,000 slaves in 1786.

In the time of the Stuarts several English slave-trading companies were chartered by the English government, and Charles II and James II were members of some of them, while James II was at the head of one (1660–80).

The privilege of supplying slaves to the American Colonies was conferred by special grant to certain English companies, with which many persons of royal blood were connected (1681–1750).

So great were the evils of slavery in England that severe laws relating to it were enacted in 1371–1381.*

THE MODERN SLAVE-TRADE.

The slave-trade as a department of commerce began in this wise: In 1441 two officers of an exploring party, under the leadership of Prince John (third son of King John I), of Portugal, seized some Moors and conveyed them to Portugal. A year later these Moors were allowed to ransom themselves, and among the goods given by them were 10 black slaves. The value of such persons in commerce was thus suggested, and three years later a large company was organized to engage in the business. The claim of the managers was that the traders did not enslave the Africans, but merely transferred them from one condition of servitude to another, which they regarded as less wretched. The first 4 slaves captured by the Portuguese were in 1444.

A large number of slave factories were opened in Africa, about 1445–1495.

Generally prevalent in a belt of African country, extending about 900 miles on each side of the Equator, for 250 years (1485–1795).

Accredited authorities estimated that the slave-trade carried on by Europeans had involved a total of 90,000,000 of Africans up to 1784.

The slaves taken from Africa in a single year numbered 104,000—namely, in 1768.

---

* A statute was enacted, by Edward VI, that a runaway, or any one who lived idly for three days, should be brought before two justices of the peace, and marked V with a hot iron on the breast, and adjudged the slave of him who bought him for two years. He was to take the slave and give him bread, water, or small drink, and refuse meat, and cause him to work by beating, chaining, or otherwise; and if, within that space, he absented himself fourteen days, he was to be marked on the forehead or cheek by a hot iron with an S, and be his master's slave forever; second desertion was made felony. It was lawful to put a ring of iron round his neck, arm, or leg. A child might be put apprentice, and, on running away, become a slave to his master (1547).

Queen Elizabeth ordered her bondsmen in the western counties to be made free at easy rates (1574).

Serfdom was finally extinguished in 1660, when tenures *in capite*, knight's service, etc., were abolished.

When the Spaniards conquered Mexico they found in operation a well-defined "Aztec code" relating to slavery. This code recognized several classes of slaves: prisoners of war, which were generally reserved for sacrifice; criminals, public debtors, and those who, in poverty or extreme peril, had voluntarily resigned their freedom; and children who were sold by their parents. Slavery in Mexico, however, was so regulated by the Aztec laws as to be much less severe than in most countries, except in case of prisoners taken in battle, or of those slaves who were refractory or vicious—these being held for sacrifice. Such was slavery in Mexico in 1521–91.

Documents presented to the British government showed that since 1792, 3,500,000 native Africans had been taken from their homes, and had either perished on shipboard, or had been sold in the West Indies, during the period ending with 1807.

The slaves in the United States in 1800 numbered 697,897; in 1810, 1,191,364; in 1820, 2,009,831; in 1850, 3,204,313; 1860, 4,002,996.

SUPPRESSION OF THE SLAVE-TRADE BY GREAT BRITAIN.

The Society for the Suppression of the Slave-trade," founded in England by Clarkson, Wilberforce, and Dillwyn, 1787.

Slave-trade question debated in British Parliament (1787).

The debate for its abolition continued two days, April, 1791.

Mr. Wilberforce's motion lost by a majority of 88 to 83, April 3, 1798.

The trade abolished by British Parliament, March 25, 1807.

It is said that about 40,000 slaves were landed at Cuba in 1860.

A treaty between Great Britain and the United States, for the abolition of the slave-trade, was signed April 7; ratified May 20, 1862.

The Spanish government denounced the slave-trade as piracy, November, 1865.

Sir Samuel Baker headed an English expedition to put down slave-trading on the Nile, January, 1870; reported to be partially successful, June 30, 1873. He published *Ismailia*, a history of the expedition, 1874.

The species of slave-trade arose about 1870 in the South Seas; the natives being enticed on board certain British vessels and shipped to Queensland, Australia, and the Fiji Isles; the subject was brought before the British Parliament, 1871–72.

The ship *Carl* (owner, Dr. James P. Murray; master, Joseph Armstrong) left Melbourne for South Sea Isles; it anchored off Malokolo, Solomon's, and Bougainville Isles, and kidnapped many natives as laborers for the Fiji Isles; while about twenty miles from land the prisoners arose and attempted to set fire to the ship; were fired on; about 50 killed and 20 wounded were cast into the sea. At Melbourne Murray gave evidence, and Armstrong was committed for trial, Aug. 16; master and mate sentenced to death, November, 1872.

Sir Bartle Frere went to Zanzibar on a mission to suppress the East African slave-trade (1872–73).

An act of Parliament, for consolidating with amendment the acts for carrying into effect treaties for the more effectual suppression of the slave-trade, passed Aug. 5, 1873.

Several African kings and chiefs, at Cape Coast Castle, agreed to give up slave-trade, at an interview with Governor Strahan, Nov 3, 1874.

Slave-trade on the Gold Coast abolished by proclamation of Governor Strahan, Dec. 17, 1874.

Convention with Egypt forbidding the slave-traffic, Aug. 4, 1877.

Col. Gordon's efforts to suppress it in the Soudan reported successful (1879).

Slave-traffic prohibited at West African Conference, Jan. 7, 1885.

Slave-trade in East Africa checked by British cruisers in 1886.

England and Germany proclaim the blockade of East coast of Africa, from Suakin to Zanzibar, for the suppression of the slave-trade, Dec. 2, 1888.

Slave-trade reported nearly extinct in Egypt (only a few slaves remaining), May, 1889.

ABOLITION OF SLAVERY BY GREAT BRITAIN.

Act for the abolition of slavery throughout the British Colonies, and for compensation to the persons hitherto entitled to the services of such slaves by the grant from Parliament of £20,000,000 sterling, passed Aug. 28, 1833.

Slavery terminated in the British possessions; 770,280 slaves became free, Aug. 1, 1834.

Slavery was abolished in the East Indies, Aug. 1, 1838.

In 1853 John Anderson, a runaway slave, killed Septimus Digges, a planter of Missouri, who attempted to arrest him, and escaped to Canada. The American government claimed him as a murderer. The Canadian judges deciding that the law required his surrender, Mr. Edwin James, Q. C. (Jan. 15), obtained a writ of *habeas corpus* for his appearance before the Queen's Bench, and Anderson was discharged on technical grounds, February, 1861.

English Government Commission, consisting of Chief Justice Cockburn and others, reported against permitting the return of slaves to their owners, June 13, 1876.

New Admiralty instruction orders issued by English government, directing that fugitive slaves be received, but not given up; that sea captains use their discretion, so that breach of international faith shall be avoided, Aug. 10, 1876.

SUPPRESSION OF SLAVE-TRADE BY OTHER FOREIGN COUNTRIES.

Slave-trade abolished by Austria in 1782.

French convention declared against all slave-traffic (1794).

The allies at Vienna declared against it, February, 1815.

Napoleon, in the Hundred Days, abolished the trade, March 29, 1815.

English treaty for its suppression with Spain, 1817; with the Netherlands, May, 1818; with Brazil, November, 1826.

In June, 1857, the French government gave permission to M. Regis to convey free negroes from Africa to Guadaloupe and Martinique, French colonies. This having led to abuses and consequent troubles, was eventually given up in January, 1859.

EMANCIPATION OF SLAVES IN THE UNITED STATES.

The Massachusetts Supreme Court decided that the "Bill of Rights," declaring that "All men are born free and equal," is a bar to slaveholding in that State (1783).

Congress unanimously passed an ordinance "for the government of the territory to the northwest of the Ohio," containing an "unalterable" provision forbidding slavery or involuntary servitude in the said territory, July 13, 1787.

Louisiana, in which slavery existed, was purchased in 1803.

The *Missouri Compromise* (drawn by Henry Clay, of Kentucky), was passed by Congress, permitting slavery in Missouri, but prohibiting it in all States thereafter to be created west of the Mississippi River and north of 36° 30′ north latitude, March 3, 1820.

California admitted as a State, but the "Fugitive Slave Act" passed, 1850.

The "Kansas-Nebraska Bill" passed, leaving the people of these Territories to decide whether they should be organized as slave States (1854).

The judgment in the Dred Scott case rendered by the U. S. Supreme Court. Dred Scott was claimed as a slave in a free State; four judges declared for his freedom, five against it, causing great dissatisfaction throughout the Free States, March, 1857.

John Brown's failure (at Harper's Ferry) to destroy slavery by creating a slave revolution, Oct. 16, 1859.

Abraham Lincoln elected President of United States, Nov. 4, 1860.

South Carolina passed the ordinance of secession, 1860.

Slavery abolished in District of Columbia, April 13, 1862.

President Lincoln issued his proclamation declaring the abolition of slavery in the Southern States, to take effect Jan. 1, 1863, provided that those States have not returned to the Union, Sept. 22, 1862.

President Lincoln proclaims the freedom of all slaves in the Southern States, except in parts held by the U. S. Army, Jan. 1, 1863. Congressional action needed to give it effect, in the latter part of the year.

Fugitive Slave act repealed by Congress, June 13, 1864.

The Confederate Congress decreed the arming of the slaves, Feb. 22, 1865.

Surrender of the Confederate Army under Gen. Lee, April 9, 1865.

Union flag replaced on Fort Sumter, April 14, 1865.

President Lincoln assassinated, April 15, 1865.

Several Southern States pass an ordinance annulling secession and abolishing slavery, September, October, and November. 1865.

President Johnson vetoed the Freedman's Bureau Bill, Feb. 1, 1866, and also the bill for securing to the colored people civil rights equal in all respects to those of the whites, March 27, 1866.

Congress passed the "Equal Rights Bill" over the President's veto, April 9, 1866.

Bill giving to colored persons in the District of Columbia the full right of suffrage, passed Dec. 13, 1866.

ABOLITION OF SLAVERY IN OTHER COUNTRIES.

Serfdom in Prussia abolished by Frederick I, in 1702.

Serfdom in Denmark abolished by Christian VII, 1766.

Serfdom in Germany abolished by Joseph II, 1789.

Slave-trade abolished in Jamaica, May 1, 1807.

All slaves in Jamaica emancipated, Aug. 1, 1834.

Slavery abolished in Dutch West Indies, July 1, 1861.

Decree issued in Brazil declaring that all children born hereafter to slaves shall be free, and that all slaves shall be free 20 years later, Sept. 27, 1871.

Decree issued in Brazil declaring all slaves to be free by enlisting in the army, from November, 1871.

Porto Rico issued decree abolishing slavery, March 23, 1873.

Portugal issued decree suppressing slavery in the colonies of St. Thomas, etc., February, 1876.

Spanish Senate voted gradual emancipation, Dec. 24, 1879; same bill passed by Deputies, Jan. 21, and act promulgated, Feb. 18, 1880.

Egypt issued decree abolishing slavery, July 31, 1881.

Russian decree abolishing serfdom in the imperial domains issued by Nicholas I, in 1842.

Imperial edict providing for the entire abolition of serfdom in the whole Russian empire, proclaimed by Alexander II, March 3, 1861. The following numbers are from Marshall's tables:

RUSSIAN SERFS EMANCIPATED IN 1861.

	Male.	Female.	Total.
Crown serfs	11,168,000	11,683,000	22,851,000
Appanage	1,624,000	1,702,000	3,326,000
Held by nobles	10,674,000	11,081,000	21,755,000
Total	23,466,000	21,466,000	47,932,000

NOBLEMEN'S SERFS IN 1861.

Nobles.	Serfs.	Average.
23,100	18,575,000	802
36,150	2,520,000	70
43,800	660,000	15
103,050	21,755,000	211

COST OF REDEMPTION.

Mortgages remitted	$152,000,000
Government scrip	101,150,000
Paid by serfs	52,350,000
Balance due	19,500,000
Indemnity award	$325,000,000

The indemnity to the nobles was about $15 per serf. The lands were mortgaged to the state until 1912. The lands ceded to crown serfs were mortgaged only till 1901. The above item of "mortgages remitted" is the amount due by nobles to the Imperial Bank and canceled.

LANDS HELD BY FREED SERFS IN 1879.

Title.	Holders.	Acres.	Average Acres.
Crown-gift	6,117,000	84,200,000	14
Appange	1,625,000	30,200,000	18
Purchase	10,137,000	65,500,000	6¼
Beggar-lots	1,810,000	6,440,000	3½
Total	19,719,000	186,340,000	9

In return for crown-gift the holders have to pay 50 per cent. extra poll-tax till 1902. Beggar-lots are lands given gratis by the nobles to the peasants, rather than sell farm-lots at $5 per acre to them.

AUSTRIAN SERVITUDE (1840).

	Value.
Labor (two days a week)	£35,000,000
Tithe of crops, etc	12,000,000
Male tribute	1,400,000
Female tribute, spun wool	1,800,000
Fowl, eggs, butter	1,000,000
Total	£51,200,000

There were 7,000,000 serfs, whose tribute averaged more than $35 per head, which was, in fact, the rent of their farms. Some Bohemian nobles had as many as 10,000 serfs. The redemption was effected by giving the nobles 5 per cent. government scrip, and land then rose 50 per cent. in value.

GERMAN SERFS.

In 1848 the state took 60,000,000 acres from the nobles, leaving them still 25,000,000 acres, and gave the former among the serfs. Indemnity as follows:

1. Government scrip, $900 for each serf family, to nobleman.
2. Land-tax, $15 per annum, transferred to peasant.
3. Interest, $35 per annum for 47 years, to be paid by peasant to the state, being 4 per cent. on cost of redemption.

EMANCIPATION IN BRITISH COLONIES IN 1834.

Colonies	Number.	Indemnity.	Per Head.
Jamaica	311,700	£6,152,000	$100
Barbadoes	83,000	1,721,000	105
Trinidad	22,300	1,039,000	250
Antigua, etc	172,083	3,421,000	100
Guiana	84,900	4,297,000	265
Mauritius	68,600	2,113,000	155
Cape of Good Hope	38,400	1,247,000	165
Total	780,893	£20,000,000	$130

SLAVERY IN BRAZIL.

Provinces.	Slaves.	Population.	Slave Ratio, per cent.
Minas	370,400	2,039,000	18
Rio Janeiro	341,600	1,057,700	32
Bahia	167,800	4,380,000	12
San Paulo	156,600	837,400	19
Pernambuco	89,100	841,500	11
Maranham	74,900	359,100	21
Rio Grande-do-Sul	67,800	434,800	16
Various	242,600	1,890,900	8
Total	1,510,800	9,930,400	15

There were 805,000 male and 706,000 female slaves held by 41,000 owners, averaging 37 to each owner. In 1882 the total number of slaves was 1,300,000, representing a market value of $520,000,000. It is probable there will be no slaves remaining in 1900.

EMANUEL, or IMMANUEL, the symbolical name of the child announced by Isaiah to Ahaz and the nation, and applied by St. Matthew to the Messiah born of the Virgin.

EMBA, a river of the Asiatic Russian government of Orenberg, in the Kirghiz territory, rising at the western base of the Mugadshar Mountains, flowing southwest, and entering the Caspian Sea after a course of about 450 miles.

EMBATERION, a war song of the Spartans, which was accompanied by flutes, and which they sang marching in time, and rushing on the enemy. The origin of the embaterion is lost in antiquity.

EMBATTLED, or IMBATTLED, one of the partition lines in heraldry, traced in the form of the battlements of a castle or tower.

EMBLEM, a representation of an object intended to signify or indicate to the understanding something else than that which it directly represents to the eye. The meaning of the emblem rests upon its secondary, not its primary signification. Emblem is often used in a sense synonymous with symbol.

EMBLEMATA (GR.), the works of art with which gold and silver vessels were decorated by the ancients. These sculptured figures were generally executed either in the precious metals or in amber. They were called crustæ by the Romans, though the Greek word was also used.

EMBLICA, a genus of plants of the natural order *Euphorbiaceæ*, having a fleshy fruit. *E. officinalis* is a tree found in most parts of India, with a crooked stem, thinly scattered spreading branches, long narrow leaves, minute greenish flowers, and a globular fruit, about the size of a gall-nut, which is a source of tannin.

EMBOUCHURE (FR.), that part of a wind instrument to which the lips are applied to produce the sound. The term embouchure is also applied to the mouth of a river.

EMBOWED, the heraldic term for anything bent like a bow—as, for example, the arm of a man.

EMBRACERY: in the law of England, the offense of influencing jurors by corrupt means to deliver a partial verdict. Not only persons attempting to influence the jury, but also jurors themselves attempting unduly to bias the minds of their fellows, are guilty of embracery. The using of indirect means in order to be sworn as a juror is also embracery.

EMBROCATION (Gr. *en*, into, and *brecho*, I wet), the same as liniment.

EMBRYOTOMY, a division of the fœtus into fragments; to extract it by piecemeal; when the narrowness of the pelvis or other faulty conformation opposes delivery.

EMBURY, PHILIP (1729–75), an Irish American preacher. He became a local preacher in 1758; in 1766 began to hold services in New York city, and he probably presided over the first Methodist congregations formed in the United States. The first Methodist church was built under his charge in 1768, and he afterwards preached there gratuitously. He went to Salem, N. Y., in 1769, where he preached on Sunday, and worked as a carpenter during the week. He organized the first Methodist society within the bounds of what is now Troy conference.

EMERITUS, a term applied originally to a Roman soldier who had served out his time, and been discharged on something equivalent to our half-pay. It is now employed to designate certain functionaries, such as professors, who have been honorably relieved from the duties of their office, on account of infirmity or long service, and who are usually granted a retiring allowance.

EMERSION, the reappearance of one heavenly body from behind another, after an eclipse or occultation. Minutes or scruples of emersion are the arc of the moon's orbit passed over by her center, from the time she begins to emerge from the earth's shadow to the end of the eclipse.

EMERSON, Ralph Waldo, an American author, born in Boston, Mass., in 1803, died in Concord in 1882. In 1826 he was approbated to preach, and in 1829 was ordained as colleague of Rev. Henry Ware, Jr., in the pastorate of the 2nd church, Boston, and succeeded Ware within eighteen months. He resigned his pastorate in 1832, and went to Europe the following year for his health. While on this journey he met several eminent writers, and formed with Thomas Carlyle one of the most interesting friendships in literary annals. He returned to the United States in 1834, and for the succeeding three years lectured in Boston. In 1835 he moved into a house on the old Lexington road, along which the British had retreated from Concord sixty years before; and this house he made his home for the remainder of his life. For several years he had been writing poetry, but he published little until after he settled on the Lexington road, when his career became distinctively that of a literary man. For a time he edited "The Dial," a literary journal published from 1840 to 1844, and through its columns gave to the public more than forty of his own pieces, both prose and verse. From 1847 to 1849 he traveled in Europe, and delivered many lectures on topics of the day. During the civil war he took sides with the North, and delivered several forcible lectures favoring abolition. Besides contributing to numerous periodicals he published *Nature* (1836); a volume of essays (1841); another volume (1844); volume of poems (1846); *Representative Men* (1850); *English Traits* (1856); *Conduct of Life*, a volume of essays (1860); volume of essays, entitled *Society and Solitude* (1870); and *Letters and Social Aims* (1875).

EMINENCE, a title given to cardinals by Urban VIII. Up to the period of his pontificate they had been called Most Illustrious, and Most Reverend.

EMINENCE, a town in Henry county, Ky., 26 miles west of Frankfort, in a fine blue-grass region, where farming and stock-raising are carried on. There is a valuable mineral spring here, two colleges, and also woolen and flour-mills.

EMINENT DOMAIN denotes the universal right in the public over property, by virtue of which the supreme authority in a state may compel a proprietor to part with what is his own for the public use.

EMIN PASHA, whose native name is Eduard Schnitzer, was born in 1840 at Oppeln, Silesia, educated at Neisse, and studied medicine at Breslau and Berlin. In 1864 he went to Turkey, where he quickly established a reputation as a physician. He accompanied Hakki Pasha on his official journeys through Armenia, Syria, and Arabia. He went with Ismail, governor of Scutari, in his exile to Trebizond. He knew the Turkish and Arabic languages well, and had so completely adopted the habits and customs of the people that he readily passed for one of them. He adopted the name Emin, "the Faithful One," and, upon the death of Ismail (who had been restored to royal favor) he married his widow. In 1876 he joined the Egyptian service and was ordered to Khartum, and thence as chief medical officer to the Equatorial Province, of which in 1878 he was appointed governor by General Gordon. Here he was isolated and shut off from the world, and harassed by the troops of the Mahdi and by revolts instigated in the interest of the slave-trade. In 1886 news was received in England that he was still holding his post in Central Africa, and an expedition under Stanley was sent to his relief. The expedition reached Emin in May, 1888. In August, while the expedition was looking for its rear-guard, he was imprisoned by the natives, but escaped in December, and in February, 1889, rejoined Stanley, with whom he reached Zanzibar in December. The patron's medal of the Royal Geographical Society was awarded to him in 1890; in which year, also, he entered the German service and is now 1891 again in the center of Africa.

EMLY, an ancient Irish sea, united to Cashel in 1568.

EMMENAGOGUES, medicines intended to restore, or bring on for the first time, the menstrual excretion in women. The emmenagogues chiefly in use are the preparations of aloes, iron, myrrh, and other stimulants, in connection with purgatives; and also the local use of the warm bath, leeches, fomentation, etc.

EMMETTSBURG, a railroad junction and county-seat of Palo Alto county, Iowa, on the Des Moines River, 55 miles northwest of Fort Dodge. Flour and lumber are produced here.

EMMITTSBURG, a village of Frederick county, Md., one mile from Mason and Dixon's line. It was laid out by William Emmett in 1773, and contains Mount St. Mary's College (Catholic), St. Joseph's Academy, and the mother-house of the Sisters of Charity in the United States. Its educational buildings are among the largest in Maryland.

EMMONS, Nathanael (1745–1840), an American theologian, licensed to preach in 1769. From 1773 to 1827 he was pastor at Franklin, Mass., and during this long pastorate prepared fifty-seven young men for the ministry. He was a founder and the first president of the Massachusetts missionary society. He published many essays, sermons, and dissertations.

EMOLLIENTS (from Lat. *mollis*, soft), substances used to soften the textures to which they are applied, as poultices, fermentations, etc., externally, and demulcents internally.

EMORY, a village of Washington county, Va., 10 miles east of Abingdon. It is the seat of Emory and Henry College.

EMORY, John (1789–1835), an American M. E. bishop. In 1805 he began the practice of law, but in 1810 entered the Methodist Episcopal ministry. He was a delegate to the general conferences, with one exception, from 1816 to 1832. In 1820 he was sent to the British Wesleyan conference, and in 1832 was ordained a bishop. For a long time he managed the affairs of the Book Concern, and edited the "New York Christian Advocate." He founded the "Methodist Quarterly Review," and was active in the establishment of the University of New York, Wesleyan University and Dickinson

College. Among his works are *The Divinity of Christ Vindicated*, and *Defense of Our Fathers.*

EMORY COLLEGE. See COLLEGES, in these Revisions and Additions.

EMPANEL, to write in a schedule or roll the names of such jurors as the sheriff returns to pass upon any trial.

EMPECINADO, DON JUAN MARTIN DIAZ, EL (1775–1825), one of the leaders of the Spanish revolution of 1820. He entered the Spanish army in 1792. At the head of about 6,000 men he carried on a guerilla warfare against the French during the Peninsular struggle, and acquired great distinction. In 1814 he was appointed colonel in the regular army, and the king himself created him field-marshal; but in consequence of petitioning Ferdinand, in 1815, to reinstitute the Cortes he was imprisoned and afterwards banished to Valladolid. On the outbreak of the insurrection in 1820 he took a prominent part on the side of the Constitutionalists, and on several occasions exhibited great courage and circumspection. After the triumph of the Absolutists in 1825, he was arrested and finally executed.

EMPEROR MOTH, a moth of the same family (*Bombycidæ*) with the silk-worm moth, and of a genus to which the largest of lepidopterous insects belong. Its expanse of wings is about three and a half inches. Each wing is ornamented with a large, eye-like, glassy and transparent spot, and such spots are exhibited by many of the genus.

EMPIRE CITY, the county-seat of Coos county, Oregon, on Coos bay, 130 miles southwest of Salem. It exports excellent lignitic coal.

EMPIRIC, originally meaning an experimentalist or searcher after facts in Nature, came to be synonymous with vulgar ignorance. The empirics were a regular sect of ancient physicians in the time of Celsus and Galen, who give us some insight into their modes of thought and practice. They laid great stress on the unprejudiced observation of Nature, and thought that, by a careful collection of observed facts forming a history, the coincidence of many observations would lead to unalterable prescriptions for certain cases. By an empiric in medicine is now understood a man who, for want of theoretic knowledge, prescribes remedies by guess according to the name of the disease or to individual symptoms, without thinking of the constitution of the patient or other modifying circumstances.

EMPIRICAL FORMULA: in chemistry, a mode of expressing the results by elementary symbols. There are numerous compound substances, such as acetic acid, lactic acid, glucose, etc., which would all give the same result on analysis, and would be represented by the empirical formula CH_2O, or one equivalent of carbon, two equivalents of hydrogen, and one equivalent of oxygen. The very different properties of these bodies, all composed of the same elements, must be due to a different order of combination, which, to a great extent, may be represented by *rational* formula as distinguished from empirical. Acetic acid is the hydrated oxide of acetyl, or may be regarded as a molecule of water (H_2O), in which half the hydrogen is replaced by acetyl, C_2H_3O; and this expressed by the *rational* formula $\left.\begin{matrix}C_2H_3O\\H\end{matrix}\right\}O$, but could not be implied by the empirical mode, either in the form of CH_2O, or $C_2H_4O_2$.

EMPIRICAL LAWS are such as express relationships, which may be merely accidental, observed to subsist among phenomena, or cause of the production of phenomena. They are usually tentative, and form stages in the progress of discovery of causal laws.

EMPIRICISM, the dependence for knowledge or skill on experience or experiment rather than on theory. Professor Ward, in *Dynamic Sociology*, defines empiricism as the application of superficial truths, recognized in a loose, unsystematic way, to immediate and special needs. In medicine the term is used of the dependence upon mere experience in the trial of remedies, without knowledge of the medical sciences or of the clinical observations and opinions of others. In metaphysics the theory which attributes the origin of all our ideas to sensuous experience, denying the existence of innate or *à priori* conceptions, is called empiricism. Mr. Lewes, in *Problems of Life and Mind*, says that this term, although commonly employed by metaphysicians with contempt, may be accepted, since even the flavor of contempt only serves to emphasize the distinction.

EMPORIA, a flourishing city and county-seat of Lyon county, Kan., situated in a fine agricultural region. It has a State normal school, the College of Emporia, a business college, conservatory of music, gas and electric lights, opera houses, water works, and produces various manufactures, among which are canned goods.

EMPORIUM, a railroad junction and county-seat of Cameron county, Pa., situated 99 miles northwest of Williamsport. It has a good lumber trade, and valuable salt wells are found in the vicinity.

EMPORIUM: in Homer's time, a person who sailed in a ship belonging to another, but later a wholesale merchant as opposed to a retailer. An emporium thus came to be applied to the receptacle in which wholesale merchants stowed their goods in seaports and elsewhere, and thus corresponded to our warehouses.

EMPSON, SIR RICHARD, the unpopular agent of Henry VII. In 1491 he became Speaker of the House of Commons, and in 1504, now a knight, high steward of Cambridge University, and chancellor of the duchy of Lancaster. Throughout Henry's reign he was employed in exacting taxes and penalties due to the crown. His conduct was by the people regarded as infamous, and in the second year of Henry VIII's reign he was convicted of treason, attainted, and beheaded on Tower Hill, Aug. 17, 1510.

EMPYREAN, a word used by the old metaphysical natural philosophers to designate the highest region of light, where the purest and most rarefied elements of fire existed; and by mediæval and modern poets to indicate heaven, the source of light and the home of the blessed.

EMPYREUMA, the burned smell and acrid taste which result when vegetable or animal substances are decomposed by a strong heat. The cause of the smell and taste resides in an oil called *empyreumatic*, which does not exist naturally in the substance, but is formed by its decomposition.

EMS, a river in the northwestern part of Germany. It rises in Westphalia, at the southern base of the Teutoburger Wald, and flowing first in a northwestern, and then, through the Hanoverian territories, in a northern direction, empties itself into Dollart bay. In 1818 it was connected by a canal with the Lippe, and thus with the Rhine.

EMULSION, the term applied to those preparations in pharmacy where the product is a milky white opaque mixture, composed more or less of oily particles floating in mechanical suspension in mucilaginous liquid.

ENAREA, a country of Africa south of Abyssinia, situated within lat. 7°–9° N., and long. 36°–38° E., but its limits have not yet been definitely ascertained. It is inhabited by a portion of the Gallas tribes, who, owing to the continued communication which they keep up with Abyssinia, and also to the residence of many Mohammedan merchants among them, are much more civilized than the Gallas usually are. Their government is an hereditary and absolute monarchy. The principal rivers of Enarea are the Gibbe and the Dodesa. Its coffee plantations are extensive. It is remarkable for its manufactures of ornamented arms, and of cloths with embroidered borders. Besides these it exports slaves, gold, ivory, civet, and skins into Abyssinia. The king and a small portion of the population are Mohammedans, and it is said that native Christians have been found in Enarea. The capital is Saka, near the river Gibbe.

ENARTHROSIS, the term used by anatomical writers to express the kind of joint which admits of the most extensive range of motion. It occurs in the hip and shoulder joints, and is commonly called the ball-and-socket joint.

ENCALADA, Manuel Blanco, born in Buenos Ayres in 1790, died at Santiago, Sept. 5, 1876. He studied at Madrid and in the naval academy at Leon, deserted the Spanish ranks and joined the Chilian party. In 1819 he became rear-admiral, and in 1820 major-general of infantry, and in 1825 he was appointed head of the Army of Chili. He was for two months president of the Republic in 1826, governor of Valparaiso from 1847 to 1852, and minister to France from 1853 to 1858.

ENCAMPMENT (Lat. *campus*, a plain), a lodgment or home for soldiers in the field. There are now four different kinds of these lodgments in use: namely, *intrenched* camps, where an army is intended to be kept some time, protected against the enemy; *flying* camps, for brief occupation; camps of *position*, bearing relation to the strategy of the commander; and camps of *instruction*, to habituate the troops to the duties and fatigues of war.

ENCEINTE, in fortification, denotes generally the whole area of a fortified place. Properly, however, it means a cincture or girdle, and in this sense the *enceinte* signifies the principal wall or rampart encircling the place.

ENCEPHALOCELE, the term applied to a tumor projecting through the skull in one of the parts where the bones are incomplete in infancy, and consisting of a protrusion of the membranes of the brain, containing a portion of the brain itself. The most common situation of such tumors is in the middle line and at the back of the head.

ENCORE ("again"), a French expression, generally used in England by the audience of a theater or concert-room, when requesting the repetition of the performance of a piece of music. It is not used by the French themselves, who, in similar circumstances, exclaim *bis* (twice).

ENCRINAL, or Encrinital Limestone, a name given to some carboniferous limestones from the great abundance in them of the calcareous skeletons of encrinites.

ENCRINITES, fossil crinoids, often known as stone-lilies.

ENCYCLICAL, a letter addressed by the Pope to all his bishops, condemning current errors, or advising the Christian people how to act in regard to great public questions. It differs from a bull in that the latter is usually more special in its destination.

END, a familiar word concerned in some important discussions, and especially in ethics. It is generally used in the sense of the thing aimed at, the object, purpose, or goal of human action; but not infrequently to mean the close, or death.

ENDEMIC, a term applied to diseases which affect numbers of persons simultaneously, but so as to show a connection with localities as well as with their inhabitants. Endemic diseases are usually spoken of as contrasted with epidemic and sporadic; the first term indicating that a disease infects habitually the population within certain geographical limits, and also that it is incapable of being transferred or communicated beyond those limits; while, on the other hand, a disease is termed epidemic if it is transmitted without reference to locality; and sporadic if it occurs in isolated instances only. The most marked type of an endemic disease is ague, which has the habits mentioned above, and is to so marked a degree a denizen of particular tracts of country as to lead to their being in some instances almost depopulated.

ENDICOTT, John (1588–1665), a colonial governor of Massachusetts. In 1628 he took charge of the plantation at Naumkeag, now Salem, and continued to exercise the chief authority until the arrival of John Winthrop, who took charge in 1630. In 1641–44 he was deputy-governor of Massachusetts, again in 1650 and in 1654, and was governor in 1644, 1649, 1650–53, and in 1655–65. In 1645 he became sergeant major-general of the colony, and in 1685 president of the colonial commissioners.

ENDLICHLER, Stephen Ladislas (1804–49), a systematic botanist, born in Hungary, June 24, 1804. He was designed for the priesthood, but in 1827 commenced botanical and linguistic studies, and in 1840 became professor of botany in Vienna. In 1848 he fell into melancholy, and in 1849 put an end to his life.

ENDOGENOUS PLANTS, or Endogens, a name applied by Lindley to monocotyledons to express an erroneous view of the difference in their usual mode of stem-thickening from that of dicotyledons, and now wholly unused by botanists.

ENDOMORPH, the name given to a mineral which is inclosed within another mineral, the latter being termed a *perimorph*.

ENDORSE: in heraldry, an ordinary containing the fourth part of a pale. *Endorsed*, again, or *indorsed*, signifies that objects are placed on the shield back to back.

ENDOSMOSE and EXOSMOSE, terms applied to the transfusion that takes place when two liquids or two gases of different densities are separated by an animal or a vegetable membrane. This action performs a very important part in living organisms, and explains many phenomena of the circulation of sap and the processes of nutrition, which were previously referred only to the wonderful action of vital energy. The term *osmose*, or *osmotic action*, is now preferred.

ENEMA, a medicine or fluid substance, conveyed into the body by injection, usually through the rectum or lower bowel.

ENERGICO, an Italian term in music, meaning with energy and force; with strong articulation and accentuation, and a marked powerful delivery of the single notes, without losing in distinctness of execution.

ENFIELD, a village of Grafton county, N. H., 42 miles northwest of Concord. The place is a summer resort and a portion of the inhabitants are members of the United Society of Shakers; they manufacture pails, tubs, and brooms, and raise garden-seeds. There are also manufactories of furniture, leather, knit-goods, and carriages.

ENFIELD, a village of Halifax county, N. C., 144 miles from Wilmington. It exports large quantities of cotton, lumber, staves, peaches, wine, shingles, and brick. There is a gold mine in the vicinity.

ENFRANCHISE, ENFRANCHISEMENT, to make free; the admission to certain liberties or privileges. Thus, a person made a denizen of the country, or receiving the freedom of a city or burgh, is said to be enfranchised.

ENGELBERG, a village of Switzerland in the canton of Unterwalden, at the foot of Mount Titlis. It has a famous school library, valuable paintings, and an extensive cheese-cellar.

ENGELHARDT, Johann Georg Veit, a learned German theologian, born at Nenstadt, on the Alsch, Nov. 12, 1791, died Sept. 13, 1853. He studied at Erlangen, where in 1820 he was appointed extraordinary professor, and in 1822 ordinary professor in theology. In the course of his life he wrote many learned dissertations in the *Journal of Historical Theology.*

ENGELMANN, George (1809–84), an American botanist. He studied in Germany and in France, and in 1832 emigrated to the United States. He settled in St. Louis, and soon became prominent as a physician. In 1836 he started "Das Westland," a German newspaper, which gained high reputation in the United States and in Europe. About this time he became distinguished as a botanist, and contributed many articles to the American Academy of Arts and Sciences, and to the Government reports. He was a member of several scientific societies.

ENGLEWOOD, a railroad junction of Cook county, Ill., 7 miles south of Chicago. It contains a school for the training of school teachers.

ENGLEWOOD, a village in Bergen county, N. J., 14 miles north of New York city, and near the palisades of the Hudson River.

ENGLAND. See Great Britain, in these Revisions and Additions.

ENGLISH, Thomas Dunn, a lawyer, born in Philadelphia, Pa., June 29, 1819. He was educated at the University of Pennsylvania, graduating with the degree of M. D. in 1839. He entered the profession of law in Philadelphia in 1842, and received the degree of LL.D. from William and Mary College in 1876. In politics he is a Democrat. He was elected member of the New Jersey State legislature in 1863 and 1864. In 1890 he was elected a Representative from the Sixth Congressional district of New Jersey to the 52d Congress.

ENGLISH RIVER, (1) an estuary in southeast Africa, on the west side of Delagoa bay; (2) another name for the Churchill River of Canada.

ENGLISHRY. The Danish conquerors of England drew a legal distinction between the Danes and the English; and in this point the Normans followed their example. "The Englishry," like the "Jewry," was a term of contempt. In cases of murder the hundred was punished unless it could make a " presentment of Englishry," showing that the person slain belonged to the conquered race. There are recorded cases in which the hundred incurred an additional penalty for declaring that a murdered " Frenchman " was an Englishman.

ENGRAILED: in heraldry, a line composed of a series of little semi-circular indents, with the points turned outwards and upwards.

ENGROSSING A DEED, writing it out in full and regular form on parchment or paper for signature.

ENGUICHÉ, a hunting horn, the rim around the mouth of which, being of different color from the horn itself, is said in heraldry to be enguiché, of the color in question.

ENNEMOSER, Joseph, a medico-philosophic writer, born at Hintersee, in the Tyrol, Nov. 15, 1787, died in 1854. He commenced his academic studies at Innsbruck in 1806. On the rising of the Tyrolese against the French in 1809 Ennemoser honorably distinguished himself in battle on several occasions. In 1816 he took the degree of Doctor of Medicine, and in 1819 was made professor of medicine at the new University of Bonn. In 1841 he went to Munich, where he obtained a great reputation by the application of magnetism as a curative power.

ENOCHS, William H., a lawyer, born in Noble county, Ohio, March 29, 1842. He received a common-school education; entered the Union army as a private at the outbreak of the war of the Rebellion, and was mustered out a brigadier-general He was three times severely wounded. He studied law and entered the profession in 1867 at Ironton. In politics he is a Republican, and has served as prosecuting attorney of Lawrence county, and as a member of the Ohio State legislature. In 1890 he was elected a Representative from the Twelfth Congressional District of Ohio to the 52nd Congress.

ENSEMBLE (Fr.), the general effect produced by the whole figures or objects in a picture, the persons and plot of a drama, or the various parts of a musical performance.

ENSILAGE. See Silo, Britannica, Vol. XXII, p. 67.

ENTADA, a genus of leguminous climbing shrubs (sub-order *Mimoseæ*) having pinnate or bipinnate leaves, and being remarkable for their great pods, in which the egg-sized seeds lie amid a gelatinous substance. These pods are sometimes fully five feet long, and six inches broad.

ENTELLUS MONKEY, or Honuman (*Semopithecus entellus*), an East Indian species of monkey, with yellowish fur, face of violet tinge, surrounded with projecting hairs, long limbs, and very long muscular and powerful—though not prehensile—tail. It is held in superstitious reverence by the Hindoos.

ENTENTE CORDIALE, a term which originated, according to Littré, in the French chamber of deputies in 1840–41, and which has been used especially to denote the friendly relations and disposition existing between France and Great Britain.

ENTERITIS, inflammation of the bowels, and especially of their muscular and serous coat, leading to constipation and pain, with colic, and sometimes ileus. Enteritis is distinguished from these last affections, indeed, only by the presence of inflammatory symptoms—that is, pain, tenderness, fever, etc., from a very early stage of the disease, and in so decided a form as to require special attention. The disease is one of great danger, and should never be incautiously treated with domestic remedies. It is closely allied to peritonitis, and often depends upon internal mechanical causes, or on external injury.

ENTEROPNEÜSTA, a class of worm-like animals, including Balanoglossus and Cephalodiscus. It is of great zoölogical importance, because of the characters in which the members resemble vertebrates.

ENTERPRISE, a winter resort, and county-seat of Volusia county, Fla., situated at the head of steamboat navigation on St. John's River, 80 miles south of St. Augustine. "Green Spring," a noted sulphur spring, 80 feet in diameter and 100 feet deep, is located here.

ENTOMOSTRACA, a general name for the lower orders of Crustacea, including Phyllopods, Ostracods, Copepods, and Cirripedes.

ENTOPHYTES, a term employed to denote those parasitic plants which grow on living animals.

ENTR'ACTE: in music, an instrumental piece, composed in the form of a little symphony or overture, to be performed between the acts of a play.

ENTRÉ DOURO e MINHO, a province in the extreme northwest of Portugal, consisting of three districts—Braga, Vianne, and Porto, with the town of Braga for the capital.

ENTRE RIOS (*Sp.*, between rivers), an Argentine State, which takes its name from its occupying the space between the Parana and the Uruguay, immediately above the point where they unite to form the Rio de la Plata. The area is estimated at 32,000 square miles. Population, about 160,000. The capital is Entre Rios, with a population of 16,000.

ENTRESOL, a low story between two main stories of a building, generally above the first story. *Mezzanine* is another name for the entresol.

ENTROPIUM, or Entropion, inversion of the eyelashes, or even eyelid, consequent either on loss of substance, or on inflammatory swelling of the lid.

ENTRY: in law, taking possession of lands or tenements by entering or setting foot upon them; also, the entering into a building unlawfully, as in housebreaking or burglary.

ENTRY, Right of. A person is said in law to have a right of entry who has been wrongfully dispossessed or ousted of land and tenements by abatement, intrusion, or disseizin. See the several articles under these heads.

EPACRIDACEÆ, a natural order of exogenous plants, consisting of shrubs and small trees, which, both in appearance and in botanical character, much resemble the *Ericaceæ*, or heath family. The most important distinguishing structural character is found in the simplicity of the anthers, which are one-celled, open longitudinally, and are destitute of appendages. The flowers of the *Epacridaceæ* have generally a tubular corolla dividing into five segments, which sometimes become separate petals. The calyx is persistent, often colored, has the same number of segments with the corolla, and is surrounded with small bracts. The stamens are fewer than in the *Ericaceæ*, usually equal in number to the segments of the corolla, and alternate with them. The fruit is sometimes a capsule, sometimes a berry, sometimes a drupe. The leaves are simple, generally alternate, often crowded; the flowers in spikes, in terminal racemes, or axillary and solitary. About 400 species of the *Epacridaceæ* are known, all natives of the Indian archipelago, the South Sea Islands, and Australia.

EPAULETTE, a shoulder-knot worn by commissioned officers in the naval profession, both as an ornament and a distinction.

EPEIRA, a genus of spiders, the type of a family called *Epeiridæ*. They are of those spiders which have only a pair of pulmonary sacs and spiracles; construct webs with regular meshes, formed by concentric circles and straight radii; and are furnished with a pair of almost contiguous eyes on each side, other four eyes forming a quadrangle in the center.

EPES, James F., a lawyer, born in Nottoway county, Va., May 23, 1842. He was educated in the common schools and at the University of Virginia; was a cavalryman in the Confederate army during the war of the Rebellion; studied law in the Washington and Lee University, and entered the profession of law in 1867. In politics he is a Democrat, and was attorney for the Commonwealth from 1870 to 1882. In 1890 he was elected a Representative from the Fourth Congressional District of Virginia to the 52d Congress.

EPHEMERA, a fever which lasts only a day, or part of a day, and is generally dependent on some slight local irritation.

EPHEMERES, a name applied to almanacs from their containing notices of each day. It is mostly confined to astronomical tables giving the daily places of the sun, moon, and planets, and other phenomena of the heavens.

EPHOD, a vestment worn by the Jewish high-priest. It consisted of two shoulder-pieces, one covering the back, the other the breast and upper part of the body. Two onyx stones set in gold fastened it on the shoulders, and on each of the stones were engraved the names of six tribes, according to their order. A girdle or band, of one piece with the ephod, fastened it around the body. Just above this girdle, in the middle of the ephod, and joined to it by little gold chains, rings, and strings, rested the square oracular breastplate with the mysterious *Urim* and *Thummim*.

EPI, or Girouette, a species of light, ornamental finial of ironwork or terra-cotta with which pointed roofs or the tops of spires are sometimes surmounted.

EPIDEMIC, a disease which attacks numbers of persons in one place, simultaneously or in succession, and which in addition is observed to travel from place to place, often in the direction of the most frequented line of communication.

EPICYCLOID, the name of a peculiar curve. When a circle moves upon a straight line, any point in its circumference describes a cycloid; but if the circle moves on the convex circumference of another circle, every point in the plane of the first circle describes an epicycloid, and if on the concave circumference a hypocycloid. The circle that moves is the generating circle; the other, the base.

EPIGASTRIUM, the part of the abdomen which chiefly corresponds to the situation of the stomach, extending from the sternum towards the navel or umbilicus, and bounded on each side by the hypochondria. It is called, in popular language, the pit of the stomach.

EPIGENE, a term applied to those geological agents of change which affect chiefly the superficial portions of the earth's crust, as the *atmosphere*, *water*, *plants*, and *animals*.

EPIGLOTTIS, a cartilaginous valve, which partly closes the aperture of the larynx.

EPILOBIUM, a genus of plants of the natural order *Onagraceæ*, having four deciduous calycine segments; four petals; a much elongated, four-sided, four-celled, four-valved, many-seeded capsule; and seeds tufted with hairs at one end. The species are herbaceous perennials, natives of temperate and cold countries, and very widely diffused both in the Northern and in the Southern hemispheres.

EPISCOPAL CHURCH, Protestant. See Britannica, Vol. VIII, p. 943. See also Religious Denominations, in these Revisions and Additions.

EPISTLE. The lesson in the church service called the Epistle derives its name from being most frequently taken from the Apostolic Epistles, although it is sometimes also taken from other parts of Scripture.

EPISTLE SIDE OF THE ALTAR, the left side of the altar or communion table, looking from it, at which in the church service the epistle of the day is read. It is of lesser distinction than the right or Gospel side, and is occupied by the clergyman of lower ecclesiastical rank.

EPISTOLÆ OBSCURORUM VIRORUM, the title of a collection of satirical letters which appeared at the commencement of the 16th century, and professed to be the composition of certain ecclesiastics and professors in Cologne and other places in Rhenish Germany. They were directed against the scholastics and monks, and lashed with merciless severity their doctrines, writings, morals, modes of speech, manner of life, follies and extravagances, and thus helped in no small degree to bring about the Reformation.

EPIZOA, animals that live on the bodies of other organism in various degrees of parasitism.

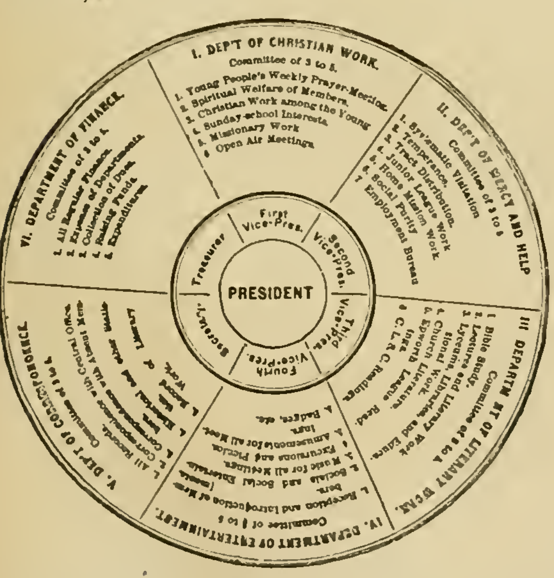
EPIZOÖTIC, or Epizoöty, any disease temporarily prevalent among the lower animals; especially the influenza when thus prevalent among horses or other domestic animals. Many of the epidemics of influenza, nearly one hundred of which have occurred since the beginning of the 16th century, have been accompanied by similar disorders among horses, cows and dogs. About 16,000 horses were attacked by it in New York during the prevalence of the pestilence in 1872. See Britannica, Vol. XIII, p. 73.

EPODE, the last part of the chorus of the ancient Greeks, which they sung after the strophe and antistrophe, when the singers had returned to their original place. The epode had its peculiar measure of syllables and number of verses.

EPONYM, a mythical personage created to account for the name of a tribe or people.

EPROUVETTE, a machine for testing the strength of gunpowder. The ordinary eprouvette is an instrument shaped like a small pistol without a barrel, and having its breach chamber closed by a flat plate connected with a strong spring. On the explosion of the powder against the plate, it is drawn back to a distance indexed according to the strength of the powder, and is retained at its extreme state of propulsion by a ratchet-wheel.

EPWORTH, a town in the northwest of Lincolnshire, England, 30 miles north-northwest of Lincoln, distinguished as the birthplace of John Wesley, the founder of Methodism, as also of Kilham, founder of the Methodist New Connection. Population, about ?.300.



EPWORTH LEAGUE, a young people's society connected with the Methodist Episcopal church. In April, 1891, it was the strongest denominational young people's society in existence, and its growth had been phenomenal. In May, 1889, a conference of all the general young people's societies of the M. E. church assembled in Cleveland, Ohio. Accredited delegates were present from the Young People's Methodist Alliance, the Oxford League, the Young People's Christian League, the Young People's Methodist Union, and the Young People's Methodist Alliance of the North Ohio Conference. The result of this meeting was the merging of these societies into one new organization, to be called the Epworth League, whose object is "to promote an earnest, intelligent, practical, and loyal spiritual life in the young people of the church, to aid them in constant growth in grace and in the attainment of purity of heart." The success attending the organization has been extraordinary. In less than two years 5,000 local chapters have been enrolled, with a total membership of about 300,000. The general organization includes District, Annual Conference, and General Conference District Leagues. The management rests with a board of control, five of whom are chosen by the bishops, five by the managers of the Tract Society, five by the managers of the Sunday-school Union, and two are elected by each General Conference district. The plan of local organization is clearly represented by the accompanying diagram, known as the Epworth wheel.

In this wheel is shown the president surrounded by his cabinet, each member of which is the chairman or head of a department. Each cabinet officer has associated with him in the conduct of his department a committee of three or five, nominated by himself and confirmed by the League. The president must be a member of the M. E. church, and the remaining officers are to be of good moral character, but all must be approved by the Quarterly Conference. A pledge is provided, but its adoption by local chapters is made altogether voluntary. The general headquarters of the League are at 150 Fifth Avenue, New York.

EQUABLE MOTION, that by which equal spaces are passed over in equal time.

EQUATOR, Terrestrial, the great circle on the earth's surface dividing the earth into the Northern and Southern hemispheres, and being half way between the poles.

EQUERRY: in the household of British sovereigns, an official in the department of the Master of the Horse, whose duty it is to accompany the sovereign when riding in state. The royal princes have also equerries.

EQUESTRIAN ORDER, or Equites, a body which originally formed the cavalry of the Roman army, and is said to have been instituted by Romulus, who selected from the three principal Roman tribes 300 equites.

EQUESTRIAN STATUE, the representation of a man on horseback. Equestrian statues were awarded as a high honor to military commanders and persons of distinction in Rome, and latterly were chiefly restricted to the emperors, the most famous in existence; the only ancient equestrian statue in bronze being that of the Emperor Marcus Aurelius, which now stands in the piazza of the capitol at Rome.

EQUIANGULAR, having equal angles. A figure is said to be equiangular whose angles are all equal to one another, as a square or any regular polygon. Also triangles and other figures are said to be equiangular one with another whose corresponding angles are equal.

EQUILATERAL, having equal sides. A square is equilateral. The equilateral hyperbola is that whose axes and conjugate diameters are equal.

EQUINOCTIAL, the same as the celestial Equator. The equinoctial and the ecliptic intersect. Equinoctial time is time reckoned from the moment in each year when the sun passes the vernal equinox. This instant is selected as a convenient starting-point of a uniform reckoning of time for the purposes of astronomical observers.

EQUINOCTIAL GALE, or STORM, a gale or storm that happens at or near the time of the equinox, in any part of the world. It is a wide-spread belief that gales and storms are more frequent about the time of the spring and autumn equinoxes, but this belief is unsupported by the records of careful observations.

EQUIPMENT, Equipage: in military matters, names given to certain of the necessaries for officers and soldiers.

ERASED and ERADICATED, in heraldry, signifies that an object is plucked or torn off, and showing a ragged edge.

ERASURE, or Razure, the scraping or shaving of a deed or other formal writing.

ERCKMANN-CHATRIAN, the compound name of two French romancists, whose stories of Alsatian peasant life are known the whole world over. Émile Erckmann was born May 20, 1822, and Alexandre Chatrian Dec. 2, 1826. Their literary partnership dates from 1848.

ERDMAN, Axel Joachim, a Swedish geologist, born Aug. 12, 1814, died Dec. 1, 1869. He published *Lärebok, Mineralogien* (1853), *Vägledning till bergarternos Kännedom* (1855), and *Bidrag till Kännedom om Sveriges quartära bildningar* (1868).

ERDMANN, Johann Eduard, a German philosopher, born at Wolmar in Livonia, Russia, in 1805, died in 1887. He studied at Dorpat and Berlin, and became professor of philosophy at Halle in 1839. He wrote several works on philosophy, psychology, logic and metaphysics.

EREBUS, Mount, an active volcano on Victoria Land, in 78° 10' south latitude, rising 12,367 feet above the sea. It was discovered in 1841 by Ross, in command of the *Erebus* and *Terror*, who named it after one of his vessels.

ERGASTERIA, a mining town in the Greek monarchy of Attica and Bœotia, near Cape Colonna, with ancient lead and silver works, reopened in 1864. Population, 6,500.

ERICACEÆ, or Heaths, a large, widely distributed order of corallifloral dicotyledons, chiefly small shrubs, frequently evergreen and social in growth, covering large areas, especially in mountainous regions and on tablelands.

ERICSSON, John (1803–89), a Swedish-American engineer. At the age of 12 he became a leveler at the grand Swedish ship canal, and two years later was engaged in setting out the work of a section employing 600 soldier operatives. In 1820 he became an officer of engineers in the Swedish army, and soon after received the appointment on the survey of Northern Sweden. In 1827 he resigned from the army, and spent the remainder of his life in experimenting and inventing. In 1839 he came to the United States. He made numerous valuable inventions in machinery; but he is best known to the public world as the designer and builder of the partially submerged war vessel, the *Monitor*, which defeated the Confederate ironclad *Merrimac*, March 9, 1862. In 1883 he erected in New York a "sun motor," having made many early experiments for developing power direct from the sun. Captain Ericsson died in New York city on March 5, 1889, and in compliance with his expressed wish his remains were carried to Sweden, a United States war vessel, the *Baltimore*, being detailed by the Government for the purpose, and interred at his birth-place, in Filipstad, Wermland. The burial took place Sept. 15, 1890.

ERICSSON, Nils, a Swedish engineer, brother of John Ericsson, was born Jan. 31, 1802, died at Stockholm, Sept. 8, 1870. In 1832 he became major in the engineering corps of the Swedish army; was afterwards head of the mechanical corps in the navy; and from 1855 to 1863 had charge of the construction of Swedish railroads. He was also engineer of the Saima canal in Finland, and of the locks near Stockholm and at Trollhättan. In recognition of his services he was knighted in 1854, and in 1860 was made a baron.

ERIE, a city and county-seat of Neosho county, Kansas.

ERIE, a city of Pennsylvania, and county-seat of Erie county (see Britannica, Vol. VIII, p. 522). The city has an area of six square miles, with 150 miles of streets, wide, well paved and lighted. Many of the streets are paved with Medina stone and asphalt, and lined with elegant mansions, surrounded by beautiful gardens and shrubbery. On State street are handsome fountains, and a soldiers' monument, costing $10,000. An elaborate system of water works supplies the city with an abundance of pure water. The stand-pipe at the pumps is 251 feet high, said to be the highest water pipe in the world. The Government building, completed in 1889, is a notable structure, 114x72 feet, built of stone and granite. The city hall is 64x124 feet, 88 feet in height, and cost $300,000. The court-house is 61x132 feet, and cost $60,000. An addition is now (1891) being constructed, at a cost of $50,000. Charitable institutions are: Soldiers' and Sailors' Home, Home for the Friendless, Hamot Hospital, and St. Vincent's Hospital. An excellent system of public schools is maintained. The Central High School building is 270x120 feet, seats 1,500 pupils, and cost $100,000. Other educational institutions are: Clark's Business College, the Erie Academy, the Erie Art School, and St. Benedictine (Roman Catholic) Academy. Erie is an important manufacturing center, and the market for a rich farming country. Population in 1880, 27,757; in 1890, 39,699.

ERIE, Canal. See Clinton, DeWitt, Britannica, Vol. VI, p. 7.

ERIE, Lake. See Britannica, Vol. XIV, pp. 216–22; Vol. XVII, p. 451; Vol. XXI, pp. 179, 182.

ERIES. See Indians, American, in these Revisions and Additions.

ERIGERON, a genus of plants of the natural order *Compositæ*, sub-order *Corymbiferæ*, having heads (flowers) of many florets, the florets of the ray numerous, in several rows, of a different color, from those of the disc. *Erigeron Philadelphicum*, a native of North America, with pale purple ray, and a fœtid smell, is valued in the United States as a diuretic.

ERIOCAULACEÆ, a natural order of endogenous plants, nearly allied to *Restiaceæ*, and containing about 200 known species, many of which are aquatic or marsh plants. The *Eriocaulaceæ* are chiefly natives of the tropical parts of America and Australia.

ERIODENDRON, a genus of trees of the natural order *Sterculiaceæ*, natives of tropical countries. Their thick woody capsules contain a kind of wool surrounding the seeds. They are sometimes called Wool-Trees, or silk-cotton trees.

ERITH, a town of Kent, on the banks of the Thames, 15½ miles by rail east of Charing Cross. It is a summer resort for Londoners, and the headquarters of several yacht clubs. It has a much restored church, rich in brasses. At Erith the *Grace de Dieu* was built in 1515. Population of parish, about 10,000.

ERMELAND, or Ermland, one of the eleven districts of the old province of Prussia, extending inland from the Frisches Haff. In 1250 it was created one of the four bishoprics of the country of the Teutonic Knights. In 1354 the bishop of Ermeland, who had been subject to the archbishop of Riga, was made directly dependent upon the Pope, and elevated to the position of a prince of the empire. In 1466 West Prussia was transferred to Poland, and the bishop of Ermeland became a member of the

Polish senate. Since 1722 Ermeland and its bishop have again been Prussian.

ERMENONVILLE, a village in the southeast of the department of Oise, in France. It is celebrated for its beautiful and extensive parks, and as being the resting-place of Rousseau. It was also the residence of Gabrielle d'Estrées, the mistress of Henry IV, who inhabited a hunting-tower, part of which is still standing, and bears her name. Ermenonville was purchased by Stanislaus de Girardin, and is preserved for the lovers of art, of Nature, and of historical monuments.

ERNST, the name of several German princes.

EROSION, the influence of a stream or river in hollowing out its channel.

EROTIC POETRY, poetical pieces of which love is the predominating subject.

EROTOMANIA, a species of mental alienation caused by love.

ERRATA, the list of errors, with their corrections, placed at the end of a book.

ERRATICS, the name given to the water-worn blocks of stone that have been washed out of the bowlder-clay, or are still inclosed in it, because they have generally been derived from rocks at a distance.

ERRETT, ISAAC (1820–88), an American clergyman. He was a follower of Alexander Campbell, and in 1840 became a preacher. He was pastor in Pittsburgh, Pa., in New Lisbon, Warren, and North Bloomfield, Ohio, in Detroit, Muir and Ionia, Mich., and in Chicago. In 1866 he began the publication of "The Christian Standard," in Cleveland, and in 1868 became the president of Alliance College, but soon resigned to establish the "Christian Standard" in Cincinnati. He was corresponding secretary of the Ohio Christian Missionary Society in 1853–56, and its president in 1867–70; was corresponding secretary of the General Christian Missionary Society in 1857–60, and president in 1874–76, and was president of the foreign society in 1875–86. His principal literary works are: *A Commentary on First and Second Corinthians; Walks About Zion*, and *A Search After the Landmarks of Ancient Christianity.*

ERRHINES, medicines administered locally to produce sneezing and discharge from the nostrils, in catarrh, and in various disorders of the head and eyes. Common snuff, and various other vegetable irritants in powder, have been used for this purpose.

ERYNGO, a genus of plants of the natural order *Umbelliferæ*, having simple umbels, which resemble the heads of composite flowers, a leafy involucre and leafy calyx, and obovate, scaly fruit destitute both of ridges and vittæ. The species are numerous, mostly natives of the warmer temperate parts of the world, with alternate, simple or divided leaves, which have marginal spines.

ERYSIMUM, a genus of plants of the natural order *Cruciferæ*, tribe *Sisymbrieæ*. The pod is four-sided. *Erysimum cheiranthoides*, a branching annual about 18 inches high, with lanceolate, scarcely toothed leaves, and small yellow flowers, is found in North America and many parts of Europe. Some of the plants formerly referred to as Erysimum are now included in other genera, as *Sisymbrium* and *Alliaria*.

ERYTHRONIUM, a genus of bulbous-rooted plants of the natural order *Liliaceæ*, with drooping flowers and the segments of the perianth reflexed. *Erythronium dens canis*, the DOG-TOOTH VIOLET, so called from the resemblance of its little white bulbs to dog's teeth, is well known.

ERYTHROPHLÆUM, a genus of leguminous trees, sub-order *Mimoseæ*. One species, a native of Guinea, contains a red juice used for poisoning arrows, and also in ordeals. The tree sometimes attains a height of 100 feet.

ERYTHROXYLACEÆ, a natural order of exogenous trees or shrubs, allied to *Malpighiaceæ*. Nearly 100 species are known, natives of warm countries, chiefly of tropical America.

ESBJERG, a port of Denmark, 56 miles west of Fredricia by rail, with a large export trade in cattle, mostly to England. Its harbor, the only one of importance on the west coast of Jutland, was constructed by the state at great expense in 1868–74.

ESCALADE: in siege operations, a mode of gaining admission within the enemy's works. It consists in advancing over the glacis and covert-way; descending, if necessary, into the ditch by the means of ladders, and ascending to the parapet of the curtain and bastions by the same ladders differently placed. The leaders of an escalade constitute a "forlorn hope."

ESCANABA, or ESCANAWBA, a city, the county-seat of Delta county, Mich. It is at the north end of Green Bay, has a good harbor, and does a large shipping business, sending out annually 500,000 tons of Lake Superior iron ores.

ESCAPE: in law, the evasion of legal restraint; departure from the custody of a sheriff or other officer, or transcending the limits of confinement without due process of law. The term is used also of the liability of a sheriff for suffering a prisoner to escape.

ESCARP: in fortification, the side or slope of the ditch next the rampart, and of the parapet itself. When the ditch of a fortress is dry the escarp is usually faced with mason-work to render it difficult of ascent, and behind this facing there are often passages or casemates for defense. The escarp is always made at as large an angle as the nature of the soil will allow.

ESCARPMENT, a long line of cliff formed by the outcrop, of a relatively hard stratum of rock imbedded among more yielding strata, the inclination of which is generally gentle. This structure is the result of denudation; the hard rock projects because it has yielded less readily to the agents of erosion.

ESCARS, large heaps of gravel, consisting chiefly of carboniferous limestone, that were accumulated during the Pleistocene period. They occur in central Ireland, but are identical with the *ösar* of Sweden, and are known also under the name of *kames* in Scotland. The gravel is often heaped into narrow ridges, 40 to 80 feet high and from 1 to 20 miles long.

ESCHAR, a slough or portion of dead or disorganized tissue. The name is commonly applied to artificial sloughs produced by the application of caustics.

ESCHELLES, LES, a village in Savoy, situated on the Guier, 12 miles southwest of Chambéry. The valley beyond this village, on the road to Chambéry, is blocked up by a huge limestone rock 800 feet high, over which travelers formerly used to climb by means of ladders—hence the name of the village. Through this mass of limestone a tunnel now extends, which is 25 feet high, 25 feet wide, and 1,000 feet long. The tunnel was projected and commenced by Napoleon I, and finished in 1817 by the king of Sardinia.

ESCHOLTZ BAY, a portion of the Arctic Ocean in Alaska, forming the innermost part of Kotzebue Sound, the first great inlet to the northeast of Bering Strait. It is about long. 161° W., being barely on the outside of the Polar Circle. It is worthy of notice on account of its fossil remains, which, though common on the northern coast of Siberia, are rare on that of the new continent.

ESCHSCHOLTZIA, a genus of plants of the natural order *Papaveraceæ*, of which *E. Californica* and other species, natives of California, have now become very common in our flower-gardens, making a very showy appearance with large, deep yellow flowers. The genus is remarkable for the calyx which separates from the dilated apex of the flower-stock, being thrown off by the expanding flower, and resembling in its form the extinguisher of a candle.

ESCUDO DE VERAGUA, a river and an island on the Atlantic side of Central America—the island being at the mouth of the river. They are situated a little to the east of the boundary between New Granada and Costa Rica. The island is in lat. 9° N., and long. 81° 30′ W.

ESENBECKIA, a genus of trees of the natural order *Diosmaceæ*. The bark of *E. febrifuga* is said to be equal in its effects to Peruvian Bark. It is a tree 40 feet high, a native of the south of Brazil.

ESERIN, the alkaloid of the Calabar Bean.

ESLA, a river of Spain, and an important affluent to the Douro. It rises in the province of Palencia, Old Castile, from the southern base of the Asturias Mountains, 10 miles northwest of the town of Valleburon. It flows southwest and joins the Douro 15 miles below the town of Zamora. It is 125 miles in length. Its waters are well stocked with fish.

ESMARCH, Johannes Friedrich August, a German surgeon, born at Tonning, in Schleswig-Holstein, Jan. 9, 1823. He was educated in the gymnasia at Rendsburg and Flensburg, and studied medicine at Kiel and Göttingen. During the Danish war of 1848 he served as assistant surgeon, later as adjutant of Stromeyer, and in 1850 was promoted to be chief surgeon. He was appointed professor and director of the hospital at Kiel in 1857; became a member of the hospital commission at Berlin in 1866, and during the Franco-German war of 1870 was surgeon-general and consulting surgeon of the army. The latter position he resigned in 1871, and since his return to Kiel he has been constantly engaged in his work as professor and surgeon. He is known to the medical profession throughout the world by his great invention in surgery, the bloodless method of operating on the extremities. Dr. Esmarch has published many valuable professional works.

ESOCIDÆ, a family of malacopterous fishes, which is now regarded as including only the pikes, but in which the flying fishes and others now constituting the family *Scomberasocidæ*, of the order *Pharyngognaths*, were until recently included.

ESPALIER, a term borrowed from the French, and signifying a railing on which fruit trees are trained, as on a wall.

ESPARTERO, Baldomero (1793–1879), a Spanish soldier. He entered the army in 1809. In 1816 he was ordered to Peru, and promoted captain. He served with marked bravery in numerous important battles, and in 1825 was appointed chief of the general staff of the Army of Peru. In 1833 he became commander-in-chief of the province of Biscay, and later lieutenant-general. Subsequently he was appointed general-in-chief of the Army of the North, viceroy of Navarre, and captain-general of the Basque Provinces, and in 1839 was created a grandee of the first class, with the title of Duke of Victoria and Morella. In 1840 he was placed at the head of the ministry, and the following year was appointed regent by the Cortes. He retired to England in 1843, but in 1854 returned to Spain and was placed at the head of the ministry. He resigned, however, in 1856. In 1870 he was offered the crown of Spain by several members of the Cortes, but declined it on the ground of great age.

ESPLANADE, the open space intentionally left between the houses of a city and the glacis of its citadel. It requires to be at least 800 paces broad, that the enemy, in case of getting possession of the town, may not be able to assail the citadel under cover of the nearest houses. In old works on fortification the term is often applied to the glacis of the counter-scarp, or the slope of the parapet of the covered way towards the country.

ESPRINGAL, or Springal, in the military engineering of the days before the introduction of gunpowder into European warfare, was a machine for throwing missiles. These missiles were either large darts called *muchettes*, or arrows winged with brass and called *viretons*, from their whirling motion when shot forth.

ESPRIT DIVA, an aromatic liquor made in Switzerland, from a plant called *Genipi*. Like the *Swiss tea*, made from the same plant, it possesses sudorific properties.

ESPY, James Pollard (1785–1860), an American meteorologist. In 1808 he became principal of the classical Academy in Cumberland, and later was admitted to the Ohio bar. In 1817 he became a professor in the classical department of the Franklin Institute, Philadelphia. Later he advanced the theory that every great atmospheric disturbance begins with the uprising of air that has been rarefied by heat. In 1840 he visited Europe and presented his views to foreign scientists for examination. They reported favorably on them, but subsequent researches have led to important modifications of his views. In 1843 he received an appointment under the war department, and instituted a service of daily bulletins on the condition of the weather in different localities, which has since developed into an important branch of the war department. He published several volumes of weather reports, besides *Philosophy of Storms*.

ESSAYS AND REVIEWS, the title of a remarkable volume published in 1860, containing the following seven papers: (1) *The Education of the World*, by Dr. Temple; (2) *Bunsen's Biblical Researches*, by Dr. Rowland Williams; (3) *On the Study of the Evidences of Christianity*, by Professor Baden Powell; (4) *The National Church*, by H. B. Wilson; (5) *The Mosaic Cosmogony*, by C. W. Goodwin; (6) *Tendencies of Religious Thought in England, 1688–1750*, by Mark Pattison; (7) *The Interpretation of Scripture*, by Professor B. Jowett. All the writers, except Mr. Goodwin, were clergymen of the Church of England; and their work, which was censured for its heterodox views by nearly all the bishops, and formally condemned by convocation in 1864, caused much excitement and controversy. Dr. Williams and Mr. Wilson were sentenced by the ecclesiastical courts to suspension for a year, but on appeal the sentence was reversed by the Privy Council; and Dr. Temple's election to the see of Exeter in 1869 was also ineffectually opposed.

ESSENCE DE PETIT GRAIN is obtained by distillation from small unripe oranges, about the size of a cherry, and is used as a perfume in the same manner as *orange-flower water*.

ESSEX, a manufacturing town of Middlesex county, Conn., on the Connecticut River. It produces soap and carriages.

ESTHERVILLE, the county-seat of Emmett county, Iowa, situated on the east branch of the Des Moines River. It has excellent educational advantages, grist and saw mills, and a machine shop. The business of the locality is farming and stock-raising.

ESTOILE, or Star, in heraldry, differs from the mullet by having six waved points; the mullet consisting of five plain points.

ESTRAY: in law, a horse, sheep or other domestic animal found wandering, and the owner of which is supposed to be unknown. By the common law of England estrays belonged to the sovereign. By statute law an estray becomes the property of the person in whose inclosure it is found, if not claimed by the owner within a year and a day. In the United States the law of estrays varies in the different States.

ESTREAT: in English law, a true extract copy, or note of some original writing or record, and specially of fines or amercements, as entered in the rolls of a court, to be levied by bailiffs or other officers.

ESTRÉES, Gabrielle de (*c.* 1571–99), mistress of Henry IV of France, with whom she became acquainted in 1590. She was married to a gentleman of Picardy, named Liancourt, from whom she soon separated. The king was so fond of her that, in spite of the opposition of Sully, he was about to divorce his consort, Marguerite de Valois, that he might marry Mme. de Liancourt, when the latter suddenly died at Paris, April 10, 1599.

ETANG DE BERRE, a salt lake of France, in the south of the department of Bouches-du-Rhone, communicating with the sea by a narrow channel, called Port-de-Bouc. It is 11 miles long by 9 broad at its widest part. This lake contains great quantities of eels and other fish. Salt works are in operation on its banks.

ÉTEX, Antoine, a French artist, born at Paris, March 20, 1808. He early devoted himself to art, receiving instruction from Ingres and Duban, and in 1828 he secured the second *prix de Rome* by his *Hyacinthus Slain by Apollo*. His statue of Cain, exhibited at the salon of 1833, secured him a commission for two groups for the Arc de l'Étoile, and in 1841 his *Tomb of Géricault* won the decoration of the Legion of Honor. Among his statues are *Hero and Leander*, at the museum of Caen; *Blanche of Castile*, at Versailles; *Charlemagne*, at the Luxembourg; *Shipwrecked*, exhibited at the exposition of 1867; *Susanna Surprised at the Bath*. Among his paintings are: *Romeo and Juliet; Dante and Beatrice; The Great Men of the United States* (now in City Hall, New York); *The Flight to Egypt*. He executed designs for monuments and public works, and engraved a series of designs from the Greek tragic poets. He died in 1888.

ETHELREDA, St., a daughter of the king of the East Angles, canonized in the 7th century for her saintly virtues. Her festival in the calendar is October 17. Her name was popularly abbreviated or corrupted into St. Audrey.

ETHIOPS, or **Æthiops**, a term applied by the ancient chemists to certain oxides and sulphides of the metals which possessed a dull, dingy, or black appearance.

ETHMOID BONE, one of the eight bones which collectively form the cavity of the cranium. It is of a somewhat cubical form, and is situated between the two orbits of the eye, at the root of the nose. Its upper surface is perforated by a number of small openings (whence its name), through which the filaments of the olfactory nerve pass downwards from the interior of the skull to the seat of the sense of smell, in the upper part of the nose. It consists of a perpendicular central plate or lamella, which articulates with the vomer and with the central fibro-cartilage, and thus assists in forming the septum or partition between the two nostrils.

ETHYLAMINE, a substance strongly resembling ordinary ammonia and hartshorn in odor and other properties. It is found in coal tar, in the oil obtained during the destructive distillation of bones, in the gases evolved during putrefaction, and may be produced by certain complicated chemical processes. Ethylamine is a mobile liquid of specific gravity 696 (water=1000), and boils at 66° F. It has an alkaline action with coloring matters, forms white fumes with strong acids, and in composition is analogous to gaseous ammonia (NH_3 or $N\,H\,H\,H$), with one of the atoms of hydrogen replaced by ethyl (C_2H_5 or A_3), and is represented by the symbol C_2H_7N or $N\left\{\begin{matrix}H\\H\\C_2H_5.\end{matrix}\right.$

ETIQUETTE: originally, a little piece of paper affixed to a bag or other object to signify its contents. The word came probably to possess the secondary meaning which we now attach to it, of the forms observed in the intercourse of life, more particularly on state occasions, from its having been customary to deliver such tickets, instructing each person who was to take part in the ceremony as to the part which he was expected to play. Cards which are still delivered to mourners at funerals, and those on which the order of the dances is set forth at balls, are of this nature.

ETIVE, a sea-loch in the north of Argyleshire, running inland from the Firth of Lorn, 20 miles east and northeast, with a width of from a quarter of a mile to three miles. It is bordered by granite in its upper part, and by trap in its lower. Near its mouth there is mica-slate on the north side, and Permian strata on the south. The loch abounds in seals, salmon, porpoises, and cod. At the south side of the mouth of Loch Etive, on a projecting conglomerate rock 10 to 30 feet high, are the ruins of Dunstaffnage Castle, the ancient stronghold of the MacDougals, a building in the Edwardian style, with walls 400 feet in circumference, 30 to 50 feet high, and 10 feet thick, and with three round towers.

ETRETAT, a Norman watering-place, 18 miles northeast of Havre, in a country remarkable for picturesque rock-formations. Population, 2,000.

ETRURIA, a village of Staffordshire, England, between Burslem and Hanley. Here, in 1769, Josiah Wedgwood and Thomas Bentley opened their celebrated Etruria potteries. Population, about 4,785.

ETTRICK, a pastoral vale in the south of Selkirkshire, Scotland. In this vale at Tushielaw, dwelt the celebrated freebooter or king of the border, Adam Scot, who was summarily executed by James V. Thomas Boston, a Scottish divine, and James Hogg, the Scottish poet, also lived in Ettrick Vale.

ÉTUDE, a term used in music to designate compositions intended either to train or to test the player's technical skill.

EUCHLORINE, a very explosive green-colored gas, possessing bleaching properties, and prepared by heating gently a mixture of two parts hydrochloric acid, two of water, and one of chlorate of potash. It will explode if merely touched with a hot wire.

EUDÆMONISM, the doctrine that happiness is the chief good.

EUFAULA, a city of Barbour county, Ala., on the Chattahoochee River. It is a winter health resort, has a female college, water-works, bagging factory, fair ground, and is a great cotton-shipping point, over 50,000 bales being sent out annually,

EUGANEAN HILLS, a range of well-wooded hills, with a north and south axis, lying southwest of Padua in Northern Italy. They owe their origin to eruptions of trachyte during the Jurassic period. The highest point, Monte Venda, reaches 1,749 feet.

EUGENE CITY, the county-seat of Lane county, Oregon, 71 miles south of Salem, on the west bank of the Willamette River. It is a business and educational center, and contains the University of Oregon, a flouring-mill, woolen, saw, and planing mills.

EUGENIA, a genus of plants of the natural order *Myrtaceæ*, nearly allied to *Myrtus*, and differing only in having a 4-parted instead of a 5-cleft calyx, four instead of five petals, and one or two-celled berry, with one seed in each cell. The species are trees and shrubs, natives chiefly of tropical and sub-tropical countries.

EUGÉNIE-MARIE DE MONTIJO, empress of the French and wife of Napoleon III, born at Granada, in Spain, May 5, 1826. She is descended on the father's side from an old and noble Spanish family, and by her mother is connected with an ancient Scottish family, the Kirkpatricks of Closeburn. She was educated principally at Madrid, and spent a great portion of her youth in traveling with her mother. In 1851 she appeared in Paris, where her beauty and graceful demeanor won the admiration of the emperor of the French. The wedding was celebrated Jan. 30, 1853, at the church of Notre Dame. One son, the fruit of this union, was born March 16, 1856. On the deposition of the emperor in September, 1870, and the declaration of a republic, Eugénie fled almost alone from France, and took refuge in England, where she was joined by the prince imperial, and in the following March by her husband. The ex-emperor died in 1873, and the prince was killed in the Zulu war, June 1, 1879. Eugénie's residence in exile is at Chiselhurst, Kent.

EUMOLPUS: in mythology, the son of Poseidon and Chione. He was brought up in Ethiopia, went to Thrace, and afterwards marched into Attica at the head of a body of Thracians to assist the Eleusinians in their war against Erechtheus, king of Athens. He is said to have been slain in battle. He is spoken of as the founder of the Eleusinian mysteries.

EUOMPHALUS, a large genus of fossil gasteropodous shells, characterized by its depressed and discoidal shell, with angled or coronated whorls, five-sided mouth, and very large umbilicus. The operculum was shelly, round, and multi-spiral. The genus seems related to *Trochus*. It appears among the earliest tenants of the globe, and keeps its place till the Triassic period. Eighty species have been described.

EUONYMIN, an extract from the bark of the *Euonymus atropurpureus*, the Spindle Tree, or Wahoo, a shrub indigenous to the United States. It is used in America as a tonic and diuretic, and in Britain for its stimulant action on the liver.

EUPATORIUM, a genus of plants of the natural order *Compositæ*, sub-order *Corymbiferæ*, having small flowers (heads of flowers) in corymbs, florets all tubular and hermaphrodite, club-shaped stigmas imbricated bracts, a naked receptacle, and a hairy pappus. The species are numerous and mostly American. Thorough-wort (*E. perfoliatum*), a species having the opposite leaves joined at the base, is used as a medicine.

EUPHEMISM, a figure of rhetoric by which an unpleasant or offensive matter is designated in indirect and milder terms.

EUPHON, or EUPHONON, a musical instrument invented by Chladni in 1790. It is similar in tone to the harmonica, and, like it, the tone is produced from the sounding body by the finger direct, without mechanism, and is regulated in quality and effect by the taste and feelings of the performer.

EUPHONIUM, a bass Saxhorn. The *Euphonon*, a variation of the harmonica, was invented by Chladni in 1790.

EUPHORBIA. See Britannica, Vol. VIII, p. 668.

EUPHORBIA, OIL OF, or OIL OF CAPER SPURGE, an extremely acrid fixed oil, obtained by expression, or by the aid of alcohol or ether from the seeds of the caper spurge. This oil much resembles croton oil, for which it is sometimes used as a substitute.

EUPHORBIACEÆ, a very extensive order of dicotyledons, containing upwards of 3,500 known species—trees, shrubs and herbaceous plants—of the most extraordinarily varied, often even cactus-like, habit. They abound in warm countries, and most in tropical America. The few species found in the colder parts of the world are all herbaceous. The *Euphorbiaceæ* usually abound in an acrid and poisonous milky juice; although there are species whose juice is bland, or becomes so through the application of heat. Many of them are valued for their medicinal properties.

EUPHROSYNE, one of the Graces.

EUPODA, a family of coleopterous insects of the tetramerous section of the order, deriving their name (well-footed) from the great size of the hinder thighs of many of the species. The body is oblong, the antennæ filiform. Some of them are among the most beautiful of tropical insects.

EURASIANS, a name applied to the offspring of European parents on the one side and Asiatics on the other side, and chiefly used in India of the children whose fathers are Europeans and whose mothers are Hindoos, and their descendants. The term Eurasian is also used in geography for facts true of Europe and Asia (Eurasia) taken as one continent.

EUREKA, a city and county-seat of Humboldt county, Cal., on Humboldt bay, seven miles from the ocean. It has a good harbor and is a shipping-point for redwood lumber.

EUREKA, a village in Olio township, Woodford county, Ill., 19 miles east of Peoria. It contains Eureka College, with which is connected a normal school and a Biblical school under the direction of the Disciples of Christ.

EUREKA, a city and county-seat of Greenwood county, Kan.

EUREKA, the county-seat of Eureka county, Nev., midway between Salt Lake and San Francisco. Mining is the chief business, and large quantities of lead and silver ore are produced. This place is third in importance in the State.

EUREKA SPRINGS, a city and county-seat of Carroll county, Ark., situated in the White River Mountains. Its medicinal springs attract thousands of health-seekers.

EURYALE, a genus of plants of the natural order *Nymphæaceæ*, or Water-lilies, closely allied to *Victoria*, although of very different appearance.

EUSTATIUS, ST., one of the Dutch West India Islands. Area, 190 square miles. It is a pyramidal rock of volcanic formation, showing two extinct craters, and is subject to earthquakes. Several hurricanes often occur. Along its entire circuit, of 29 miles, it has but one landing-place. The whole island is very fertile. Population, about 3,270. See Britannica, Vol. XXI, p. 168.

EUSTIS, a village of Lake county, Fla., on Lake Eustis, in the center of the peninsula and of the lake region of the State. The surrounding country is engaged in raising oranges and vegetables.

EUTAW, the county-seat of Green county, Ala., 35 miles southwest of Tuscaloosa. It contains two seminaries.

EUTAW SPRINGS, a small affluent of the Santee River, in South Carolina, near which the last serious battle in the American War of Independence was fought, Sept. 8, 1781.

EUTERPE, a genus of palms, having male and female flowers intermingled on the same spadix, the spadices springing from beneath the leaves; the spathe entire, membranaceous and deciduous. They are very elegant, with lofty, slender, smooth faintly fringed stems and pinnate leaves, forming a graceful feathery plume; the base of the leafstalk sheathing far down the stem, and so forming a thick column of several feet in length at its summit.

EUTHANASIA, an easy death, or a painless method of putting to death.

EVANGELICAL, an adjective derived from the Gr. *euanggelion*, "good news," or "the Gospel," and applied in general to anything which is marked by the spirit of the Gospel of Jesus Christ.

EVANGELIST (a bringer of good tidings): in the New Testament, a person appointed by an apostle to itinerate among the heathen. The word evangelist is also used to denote the four writers of the life and Gospel of Jesus Christ.

EVANS, Frederick William, an American reformer, born in 1808. In 1830 he joined the Shakers at Mt. Lebanon, N. Y.; was appointed assistant elder in the "North Family" in 1838, and twenty years later became elder of the three "families." Besides contributing to seventy different publications, he is the author of several works concerning his sect.

EVANSTON, a post-village of Illinois, on Lake Michigan 12 miles north of Chicago by rail. It has many handsome residences, a ladies' college, the Garrett Biblical Institute, and the Northwestern University (Methodist).

EVANSTON, the county-seat of Uintah county, Wyo., on the Bear River, midway between Omaha and San Francisco. Coal and iron are found in the vicinity. The town has railroad machine shops, employing a large number of men.

EVANSVILLE, a city of Indiana, and county-seat of Vanderburg county (see Britannica, Vol. VIII, p. 727). Evansville has 10 lines of railway, and 8 steamboat lines. The city is built over two veins of soft coal, and within a radius of 30 miles 60 coal shafts are in operation. The public school system is excellent. There are 12 public school buildings, valued at $423,207. High schools are provided for both colored and whites, the races being taught separately. There is a fine public library and art gallery. There were, in 1891, 260 manufacturing establishments. The hard wood lumber trade is enormous, said to be the largest in the country. The production of flour reaches 630,000 barrels annually, and 15,000,000 brick are yearly manufactured within the city limits. Evansville has grown rapidly during the last decade. Population in 1880, 29,280; in 1890, 50,674.

EVANSVILLE, a village of Rock county, Wis. It contains a seminary, a steam cabinet-manufactory, and a machine shop.

EVART, a lumbering town of Osceola county, Mich., containing saw and shingle-mills, a machine shop, and a foundry.

EVARTS, Jeremiah (1781–1831), an American philanthropist. From 1806 to 1810 he practiced law in New Haven, Conn.; was editor of the "Panoplist" from 1810 to 1820, when he was made editor of the "Missionary Herald"; in 1812 became treasurer of the American board of commissions for foreign missions. In 1821 he was chosen corresponding secretary of the board, and retained the position until his death. He published several essays and speeches.

EVARTS, William Maxwell, a United States ex-Senator, born in 1818. He studied in the Harvard Law School, and was admitted to the bar in New York in 1841; was chairman of the New York delegation in the National Republican convention of 1860; was Attorney-General of the United States from July 15, 1868, to March 3, 1869; received the degree of LL.D. from Union College in 1857, from Yale in 1865, and from Harvard in 1870; was counsel for President Johnson on his trial upon his impeachment in 1868; was counsel for the United States before the tribunal of arbitration on the Alabama claims at Geneva, Switzerland, in 1872; was counsel for President Hayes, in behalf of the Republican party, before the Electoral Commission; was Secretary of State of the United States from 1877 to 1881; was elected to the United States Senate as a Republican from New York, in the place of Elbridge G. Lapham, Republican, and took his seat March 4, 1885. His term of service expired March 3, 1891.

EVE, Paul Fitzsimons (1806–77), an American physician. He graduated at the medical department of the University of Pennsylvania in 1828; studied in London and Paris; served as an ambulance surgeon during the revolution of 1830, and as a regimental surgeon in the Polish war. In 1831 he returned to the United States, and in 1832 became professor of surgery in the Medical College of Georgia. In 1849 he was elected surgical professor in the University of Louisville; in 1850 in the University of Nashville; in 1868 in the University of Missouri, and later returned to Nashville as professor of operative and clinical surgery. In 1877 he became professor of the principles of surgery in the Medical College at Nashville. During the civil war he served with the Confederate army in Mississippi and Georgia. He published several works on surgery, besides contributing extensively to various medical journals.

EVERETT, a city of Massachusetts, located in Middlesex county, in the extreme eastern portion of the State. It adjoins Boston, with which it is connected by the Eastern Railroad. It is supplied with water from the Mystic Water-works of Boston. Prior to 1870 it formed a part of Malden. It has an excellent system of public schools. Population in 1880, 4,159; in 1890, 11,068.

EVERETT, a borough of Bedford county, Pa., 9 miles east of Bedford.

EVERETT, Robert W., a farmer, born near Hayneville, Ga., March 3, 1839. He was educated at Mercer University, Ga., graduating in 1859, and becoming a teacher. He served in the Confederate army during the war of the Rebellion. In politics a Democrat, he served two years as commissioner of revenues, and twelve years as a member of the board of education, being its chairman four years. He was elected a member of the State House of Representatives in 1882, and served four years, being chairman of the committee on agriculture in 1884 and 1885. In 1890 he was elected a Representative from the Seventh Congressional District of North Carolina to the 52d Congress.

EVERGREENS. See Britannica, Vol. II, p. 319.

EVERSLEY, a village of northeast Hampshire, England, 13 miles northeast of Basingstoke. Charles Kingsley was rector of the parish from 1842 until his death in January, 1875, and is buried in the churchyard.

EVICTION. See Britannica, Vol. XIV, p. 275; Vol. XX, p. 403.

EWBANK, Thomas (1792–1870), an American scientist. From 1819 to 1836 he was employed in New York, first as a machinist, and then in the manufacture of metallic tubing. He retired in 1836 to devote himself to literature and scientific pursuits. From 1849 to 1852 he was United States Commissioner of Patents. He published, among other works, many books on scientific subjects.

EWELL, Richard Stoddert (1817–72), an American soldier. He served in the Mexican war, and against the Apaches in New Mexico in 1857. At the beginning of the civil war he entered the Confederate army, and was actively engaged throughout the war. He several times won distinction and attained the rank of lieutenant-general. After the war he retired to private life.

EWER, Ferdinand Cartwright (1826–83), an American clergyman. In 1857 he was ordained deacon in the Protestant Episcopal church, and a year later became priest. He labored two years in Grace church, San Francisco, and then returned to the East, where he was appointed assistant minister in St. Ann's church, New York city. From 1862 to 1871 he was rector of Christ church, and then for a time of St. Ignatius. In 1883, while preaching in St. John's church, Montreal, he was stricken with paralysis, and died three days later. He was the author of several works on theology.

EWING, a village of Franklin county, Ill. It is the seat of Ewing College, and contains a large woolen factory.

EWING, Juliana Horatia Orr, writer for children, born at Ecclesfield, Yorkshire, in 1842, died at Bath, May 13, 1885. She early began to compose nursery plays for her brothers and sisters, which they performed, her brother, Alfred Scott Gatty, acting as musical director. Mrs. Ewing was a graceful writer, and her studies of children and child-life were simple and natural. In 1867 she married Major Alexander Ewing.

EWING, Thomas (1789–1871), an American statesman. From 1816 to 1831 he practiced law in Lancaster, Ohio, and from 1831 to 1837 served as United States Senator. In 1841 he became Secretary of the Treasury, and in 1849 Secretary of the Interior. In 1850 he was appointed United States Senator, but resigned the following year and resumed his law practice in Lancaster. In 1829 Mr. Ewing adopted William T. Sherman, then a boy of nine, into his family.

EXCALIBUR, the famous mystic sword of King Arthur, which was given him, as Merlin promised, by the Lady of the Lake, and at his death was flung into the river and caught up by a hand which rose above the waters.

EXCEMENTOSIS, a new word now used in dental literature as a substitute for *exostosis*, in describing a morbid, bony growth on the surface of the teeth. See Dentistry, in these Revisions and Additions.

EXCIPIENT, an inert or slightly active substance, introduced into a medical prescription as a *vehicle*, or medium of administration for the strictly medicinal ingredients.

EXCITANTS, or Stimulants, those pharmaceutical preparations which, acting through the nervous system, tend to increase the action of the heart and other organs. They all possess an acrid and pungent taste, and give a sensation of warmth when placed on a tender part of the skin.

EXCLUSION BILL, a proposed measure for excluding the Duke of York, afterwards James II, from succession to the throne, on account of his avowed Roman Catholicism. A bill to this effect passed the Commons in 1679, but was thrown out by the Upper House (see Britannica, Vol. VIII, p. 350). As the new Parliament summoned in 1681 seemed determined to revert to this measure, it was dissolved, and Charles ruled henceforth without control.

EXCULPATION, Letters of: in the law of Scotland, the warrants granted to the accused party, or panel as he is called, in a criminal prosecution, to enable him to cite and compel the attendance of such witnesses as he may judge necessary for his defense.

EXECUTION: in criminal law, the infliction on criminals of the punishment of death in conformity with legal decree.

EXECUTION: in law, the act of completion or carrying into effect. Thus a writ is executed by obeying the instructions contained in it; a deed when it is signed, sealed, and delivered; a power when it is exercised; a judgment of a court when it is enforced.

EXECUTORY: in English law, a term applied to contracts, etc., which are not executed—that is, not completed with the forms required to make them legally operative. In American law, the term executory is used as in England.

EXERCISE, a very important element of medical regimen, both in the preservation of health and in the cure of disease.

EXETER, one of the county-seats of Rockingham county, N. H., on the Squamscott River, 50 miles north of Boston. The well-known Phillips Academy is here, also Robinson Female Seminary. It has a cotton mill, railroad round-house, and manufactures castings, lumber and carriages.

EXETER HALL, a large proprietary building, on the north side of the Strand, London. It was completed in 1831, and can contain upwards of 5,000 persons. It is let chiefly for religious assemblies, and is in great demand during the "May Meetings" of the several religious societies. It has also been used for musical fêtes. In 1880 it was purchased for £25,000 for the Young Men's Christian Association.

EXHAUSTIONS, Method of, a mode of proving mathematical propositions regarding quantities by continually taking away parts of them. The method was frequently employed by the ancient geometers; its fundamental maxim, as stated by Euclid, being that those quantities are equal whose difference is less than any assignable quantity.

EXMOOR FOREST, a moory, mostly uncultivated waste, consisting of dark ranges of hills and lonely valleys, 14 square miles in area, in the west of Somersetshire and northeast of Devonshire, England. It is bordered by deep-wooded glens. The hills rise in Dunkery Beacon to 1,668 feet, in Chapman Barrow to 1,540, and in Span Head to 1,510. Devonian slates, with some New Red Sandstone in the north, form the substratum. It is covered with heath, juniper, cranberry, and whortleberry, and has some meadow-land. Throughout this tract there is a native breed of ponies, known as Exmoor ponies, reputed stout and hardy. Iron is mined here.

EXOGENOUS PLANTS, or Exogens, a term applied to dicotyledons by Lindley to express an erroneous view of the difference in the mode of stem-thickening from that of monocotyledons, and now wholly disused by botanists.

EXOSTEMMA, a genus of American trees and shrubs of the natural order *Cinchonaceæ*, nearly allied to *Cinchona*. Several species yield febrifugal barks, which, however, do not contain the cinchona alkaloids. The most valued are Caribbee Bark and Saint Lucia Bark.

EXOTIC PLANTS, or Exotics, cultivated plants originally derived from foreign countries. The term is generally applied to those whose native country differs so much in soil or climate from that into which they have been conveyed that their cultivation is attended with difficulty, requiring artificial heat or other means unlike those requisite in the case of indigenous plants.

EXPECTATION WEEK, the name given to the period elapsing between Ascension Day and Whitsunday, because during this time the Apostles continued praying in earnest expectation of the Comforter.

EXPECTORANTS, medicines given to carry off the secretions of the air-tubes.

EXPECTORATION, the mucus or other secretion discharged from the air-passages.

EXPERIMENT, the means by which we extend and confirm our knowledge of Nature. An experiment is properly a proceeding by which the inquirer interferes with the usual course of a phenomenon, and makes the powers of Nature act under conditions that, without his interference, would never, perhaps, have presented themselves all together.

EXPERT, a person of special practical experience or education in regard to a particular subject—a word commonly applied to medical or scientific witnesses in a court of justice, when selected on account of special qualifications, as in the case of an analysis of the contents of the stomach in suspected poisoning. It is also applied to one professionally skilled in handwriting, for detecting forgery of deeds and signatures.

EXPLOSIVES, substances by whose decomposition or combustion gas is generated with such rapidity that they can be used for blasting or in fire-arms (see Britannica, Vol. VIII, pp. 806–813). They may be classed generally as follows:

Gunpowder.
Gun-cotton.
Fulminates.
Nitro compounds.
Picric acid.

The nitro-compounds are nitro-cellulose, nitro-glucose, nitro-starch, and nitro-glycerine and its compounds. The fulminates are fulminating mercury, fulminating silver, chlorate of potassium and sulphide of antimony, sulphur and chlorate of potassium, and red phosphorus and chloride of potassium. The mixture of nitro-glycerine with dry pulverized absorbent substances has given rise to a variety of explosives, of which the name dynamite is perhaps generic. Among these mixtures are:

Dualin.
Giant powder.
Hercules powder.
Neptune powder.
Potentia powder.
Rendrock.
Sebastine.
Thunderbolt powder.
Jupiter powder.
Lignose.
Mica powder.
Titanite.
Titan powder.
Vigorite.
Vulcan powder.

The relative efficiency of the various modern explosives is shown by the following table, which is the result of two years' trial by the United States Board of Army Engineers. Ordinary dynamite is taken as the standard:

Dualin	111.
Hercules powder No. 1	106.
Dynamite, No. 1	100.
Rendrock	94.
Gun-cotton	87.
Dynamite, No. 2	83.
Hercules powder, No. 2	83.
Mica powder	83.
Vulcan powder	82.
Nitro-glycerine	81.
Blasting gunpowder, No. 1	80.

For a description of the various explosives, see their respective headings.

EXPONENT AND EXPONENTIAL. When wanting to express the multiplication of unity for any number of successive times by the same number or quantity, *e. g.*, 1x5x5, or 1xaxaxa, it was found more convenient to write $1x5^3$ $1xa^3$, or simply, 5^2 and a^3, and the numbers, 2 and 3, indicating how often the operation of multiplication is repeated, were called exponents. But the theory of exponents gradually received extensions not originally contemplated, and has now an extensive notation of its own. Thus $a^0=1$, $a^1=a$, $a^{-2}=1\div a^2$, $a^{\frac{1}{2}}=\sqrt{a}$, $a^{\frac{1}{3}}=\sqrt[3]{a}$, $a^{\frac{2}{3}}=\sqrt[3]{a^2}$, or the cube root of the square of a. Also A^x is the Xth power of A, X being any number integral or fractional; and, A continuing the same, X may be so chosen that A^x shall be equal to any given number. In this case, X is called the logarithm of the number represented by A^x. Considered by itself, A^x is an exponential. Generally, any quantity representing a power whose exponent is variable, is an exponential, as A^x, H^x, Y^x, etc. Exponential equations are those which involve exponentials, such as $A^x=b$, $11^x=c$.

EX POST FACTO LAW, any criminal or penal statute rendering an act punishable in a manner in which it was not punishable when it was committed. Any law which would make an act criminal which was not criminal when done, or which would increase the severity of the punishment of a previous act, or which would alter the rules of evidence or procedure so as to put one accused of a crime committed previous to the law in a worse position before the courts, is prohibited by the Constitution of the United States.

EXPRESS, in the United States, specifically a system organized for the speedy transmission of parcels or merchandise of any kind, and their safe delivery in good condition. It originated in the trip made from Boston to New York by William Frederick Harnden, the first "express package carrier," March 4, 1839. A feature of the American express system is the "collect on delivery" business, goods when sent to strange firms at a distance being marked C. O. D., with the amount to be collected on the outside of the package, and the payment being collected by the express company. The express companies in America also, issue money orders which are payable at any of their offices.

EXTENSION: in logic, a word put into contrast with another term, COMPREHENSION, and the two mutually explain each other. A general notion is said to be extensive according to the extent of its application, or the number of objects included under it.

EXTENT: in English law, a writ issuing out of the court of exchequer to compel payment of debts to the crown.

EXTENUATING CIRCUMSTANCES, those circumstances, in connection either with the position of the prisoner or with the act alone which are taken into consideration by the court in mitigation of the punishment. The previous good character of the person convicted may always be proved as a circumstance giving him some claim to lieniency of punishment. Besides character, there are other circumstances which sometimes serve to mitigate the sentence, sometimes to take the act done out of the category of crime altogether. One is youth. Thus, no act done by any person under seven years of age is a crime. Defective mental power in the person convicted will always be considered in determining the severity of his sentence. Disease of mind, such as prevents a man from knowing that the act he does is wrong, will excuse him from consequences of an act otherwise criminal.

EXTORTION: in law, the offense or illegal act committed by a public officer who, under color of his office, takes from any person any money or valuable thing, which is not due from him at the time when it is taken. The act is a misdemeanor, and punishable as such.

EXTRACT OF MEAT is obtained by acting upon chopped meat by cold water, and gradually heating, when about one-eighth of the weight of the meat is extracted, leaving an almost tasteless insoluble fibrine.

EXTRACTIVE MATTER, the term applied to certain organic matters resembling humine, which are found in soils during the decay of vegetable matter, and are precipitated during the concentration of water solutions.

EXTRACTS: in a technical sense, medicinal preparations of vegetable principles, obtained either by putting the plants in a solvent or menstruum, and then evaporating the liquid down to about the consistency of honey, or by expressing the juice of the plants and evaporating; this last is properly *inspissated juice*. Extracts, therefore, contain only those vegetable principles that are either held in solution in the juices of the plants themselves, or are soluble in the liquids employed in extracting them, and at the same time are not so volatile as to be lost during evaporation. As many extractive matters are more or less volatile it makes a great difference whether the operation is conducted at a low or a high temperature. Extracts are called *watery* or *alcoholic* according as the menstruum employed is water or spirits. Ether is sometimes used in extracting.

EXTRAVASATION, the escape of any of the fluids of the living body from their proper vessels through a rupture or injury in their walls. Excrementitious matter thus sometimes escapes into the abdomen through a wound or ulceration of the bowels. But the term is oftenest used in speaking of the escape of blood from injured blood-vessels. Extravasation is distinguished from exudation by this, that in the latter the vessels remain entire, and the effusion takes place by filtration through their walls; only a part of the blood escapes, the blood globules being retained, while in extravasation perfect blood is effused. Many kinds of extravasation are immediately fatal, such as that of urine or gall into the abdomen, or of blood from the vessels of the brain in many cases of apoplexy. The dark color resulting from a bruise is owing to extravasated blood from ruptured capillary vessels.

EXUMAS, a part of the group of the Bahama Islands, comprising Great Exuma, Little Exuma and the Exuma Keys. They contain about 2,000 inhabitants, who are employed partly in agriculture, but chiefly in salt making. In 1851, the Exumas exported 115,356 bushels of salt. Little Exuma is the second most important port of entry in the Bahamas.

EXUVIÆ, a term applied to organic remains, now seldom employed, but frequently used by the older geologists.

EYALET, next to a province, the largest and most important of the divisions of the Turkish Empire, which contains in all 36 eyalets. Each eyalet or general government is administered by a pasha, who is governor. The governors belong to the Dignities of the Sword, and are pashas of two tails; when they are raised to the rank of vizier, as is frequently the case, they become pashas of three tails.

EYAM, a village in North Derbyshire, England, five miles north of Bakewell, with a population of 1,038, chiefly engaged in lead mining. Here, in September, 1665, the plague, then raging in London, broke out in its most virulent form. William Monpesson, the rector of the parish, aided by Thomas Stanley, devoted himself to the care of the dying with the most heroic courage. The plague lingered 13 months and 260 out of a population of 350 parished.

EYE, JOHANN LUDOLF AUGUST VON, a German art historian, born at Fürstanau, in Hanover, May 24, 1825, and educated at the gymnasium in Osnaburg, and at the University of Göttingen. In 1853 he was appointed director of the collection of art and antiquities in the museum at Nuremberg, in 1874 accepted a professorship in Rio Janeiro, Brazil, but the following year returned to take charge of the art museum in Dresden. In 1881 he returned to Brazil. He has published *Deutschland vor drei hundert Jahren in Leben und Kunst* (1857), *Eine Menschenseele, Spiegelbild aus dem 18 Jahrhundert* (1863), *Wesen und Werth des Daseins* (1870), and *Das Reich des Schönen* (1878).

EYEBRIGHT (*Euphrasia*), a genus of plants of the natural order *Scrophulariceæ*, having a tubular calyx, the upper lip of the corolla divided, the lower of three nearly equal lobes, the cells of the anthers spurred at the base, a two-celled capsule and striated seeds. Some of the species are root parasites. They are natives of Europe and Asia. The common eyebright (*E. officinalis*) is a little plant about six inches high, with ovate serrated leaves, and white or reddish flowers streaked with purple, appearing singly in the axils of the leaves. It is abundant in pastures and on mountains, and has been used as a medicine in diseases of the eyes, and catarrhal affections. It is a weak astringent.

EYOT, a little island in a river, especially one overgrown with willows, as in the Thames.

EYRE, a salt lake of South Australia, lying north of Spencer Gulf, at an altitude of 79 feet, and having an area of 3,706 square miles. Except in the rainy season, this lake is generally a mere salt marsh. It was discovered in 1840 by Eyre.

EYRE, EDWARD JOHN, a British diplomatist, born in 1815. He served for sometime as governor of New Zealand, and in 1854 was appointed lieutenant-governor of the island of St. Vincent. In 1859–60 he acted as the administrator of the Leeward Islands. In 1862 he was appointed to administer the government of Jamaica and its dependencies, and in 1864 was appointed captain-general, governor and vice-admiral. He was afterwards recalled on charges of unnecessary severity in suppressing an insurrection; but the accusations were never substantiated. See Britannica, Vol. III, p. 105, and JAMAICA, Vol. XIII, p. 551.

EYRIA PENINSULA, on the south coast of South Australia, triangular in shape, its base being formed by the Gawler Range, while its sides are washed on the southeast by Spencer Gulf, and on the southwest by the Great Australian Bight. It is a rich pastoral country.

F

F, in music, is the fourth note of the natural diatonic scale of C, and stands in proportion to C as 4 to 3, and is a perfect fourth above C as fundamental note. F major, as a key, has one flat at its signature: namely, B flat. F minor has four flats, the same as A flat major, of which it is the relative minor.

FAAM, or Faham, an orchid, native of Madagascar, prized for the fragrance of its leaves, which is owing to the presence of *Coumarin*. In Mauritius an infusion of faam leaves is in great repute as a cure for pulmonary consumption.

FABLIAUX, an appellation given in old French literature to a class of short metrical narratives, intended for recitation; the tales of the Trouvères.

FABRICIUS, or Fabrizio, Girolamo, a celebrated anatomist and surgeon, born near Orvieto in 1537, died at Padua, May 21, 1619. He studied anatomy and surgery at Padua, under Fallopius. On the death of the latter in 1562 Fabricius was appointed to the vacant professorship, a position he held for nearly half a century. Harvey, the discoverer of the circulation of the blood, was one of his pupils. Fabricius's chief contribution to anatomy was the discovery of the valves of the veins in 1574.

FABRONI, Giovanni, V. M. (1752–1822), director of the physical cabinet of the Grand Duke of Tuscany. He constructed many important military bridges, and in 1815 became professor of natural science at Pisa University.

FABVIER, Charles N. Baron (1782–1855), a French officer who became a peer of France in 1845, and a member of the legislative assembly in 1849. He served in Spain, Greece and France.

FAÇADE, the exterior front or face of a building. This term, although frequently restricted to classic architecture, may be applied to the front elevation of a building in any style. It is generally used with reference to buildings of some magnitude and pretensions; thus, we speak of the *front* of a house, and the façade of a palace. The sides of a court or cortile are also called façades.

FACET, a term employed to denote the plane surfaces of crystals, or those artificially cut upon precious stones.

FACIAL NEURALGIA, pain in parts of the head and face rendered sensible by connection with the trigeminus nerve. It is caused by a morbid state of the nerve-center or other pathological condition.

FACIAL PARALYSIS arises from a loss of the motor property of the nerve supplying the facial muscles, and results in a loss of expression on the affected side, and a drawing of the mouth and other features to the healthy one.

FAC-SIMILE, an exact copy, as of handwriting.

FACTOR: in mathematics, one of the quantities which, multiplied together, form the product. The numbers 6 and 4 multiplied together, make 24; hence 6 and 4 are called factors of the product 24. Most numbers are products of two or more factors: $12 = 3 \times 4$, or 2×6, or $2 \times 2 \times 3$.

FACTORY, a term contracted from *manufactory*, applied to a building, or collection of buildings, appropriated to the making of goods on an extensive scale. In the United States the factory system has had a rapid growth. At the close of the Revolutionary war factories were practically unknown in this country, while now the number of manufacturing establishments exceeds 300,000, and the value of the products is greater than that of any other country. For information concerning the number of factories of the various countries, hands employed, wages paid, value of products, etc., see Manufactures, in these Additions and Revisions.

FACTORY LEGISLATION IN AMERICA. The British "Factory and Workshop act" has no counterpart in the United States. A few of the States have adopted laws regulating the age at which children can be employed in factories, and prescribing the number of hours constituting a day's work.

In New Hampshire, Vermont, Massachusetts and New Jersey, no child under ten years of age can be employed in any factory. In Rhode Island the minimum age is twelve, and in Pennsylvania, thirteen. The factory legislation of Connecticut forbids the employment of any child under 14 years of age, unless such child shall have attended school at least two months during the preceding year; and no child under 15 can be employed in any factory more than ten hours per day.

In Maine no child under 12 years of age can be employed in any cotton or wool factory without having attended a public or private school at least four months during the year preceding such employment. Between 12 and 15 years of age such child must have attended school at least three months during the previous year.

In Maryland, no children under 16 years of age may be employed in factories for more than ten hours per day.

Massachusetts has taken more advanced steps in factory laws, and provides inspectors for their enforcement. In this State no child under 14 may be employed, except during school vacations, unless he has for 20 weeks during the preceding year attended school. No minor under 18 years and no woman shall be employed more than 60 hours in a week.

In New Hampshire no child under 12 years of age shall be employed in any factory unless he has attended the school of his district the whole time it was in session. Between 12 and 14 such child must have attended school six months. Between 14 and 16 twelve weeks' school attendance is required. No child under 15 years of age can be employed more than 10 hours per day, except by the written consent of parent or guardian.

In New Jersey no minor may be required to work more than ten hours on any day.

The New York act provides that no children under 14 years of age shall be employed during school hours, unless they attended school 14 weeks of the preceding year.

In Ohio 14 is the age under which no child may be employed during school-hours unless he has attended school 12 weeks during the year preceding.

In Pennsylvania no child between the ages of 13 and 16 shall be employed more than nine months; three consecutive months being allotted to school attendance.

In Rhode Island no child between 12 and 15 years of age may be employed more than nine months in any year; and then not unless he has devoted three months of the preceding year to schooling.

The factory act of Vermont provides that children between 10 and 15 years of age shall not be employed in factory or mill unless they have attended school at least three months during the preceding year, and are not to be employed more than ten hours per day.

FACULÆ, in astronomy, are spots brighter than the rest of the surface, which are sometimes seen on the sun's disc. They are assumed to be elevated portions of the photosphere.

FACULTY, a name applied to certain powers of the mind, chiefly of the intellect. In discussing the intellect, whatever are considered its fundamental functions are its faculties. According to the older metaphysicians, the leading intellectual faculties are perception, memory, reasoning and imagination; these, however, would not now be considered as giving the ultimate analysis of the intellect. Conscience, or the moral sense, has sometimes been called the *moral* faculty.

FAED, John, a Scottish painter, born at Burley Mill, near Gatehouse-of-Fleet, Kirkcudbrightshire, in 1820. His love of art was early manifested, and when hardly in his teens he made tours through the villages of Galloway, painting miniatures. In 1841 he went to Edinburgh and in 1861 to London, where his talents won recognition. In 1880 he returned to Gatehouse-of-Fleet, and his recent pictures have been chiefly landscapes.

FAED, Thomas, R. A., brother of John Faed, born at Burley Mill, June 8, 1826, and in 1842 began his regular art studies in Edinburgh. At the Trustees Academy he took several prizes. In 1849 he was made an associate of the Royal Scottish Academy; in 1861 he was made A. R. A. and R. A. in 1864, and elected an honorary member of the Vienna Royal Academy in 1875.

FAGGING, a usage in the great public schools of England, in virtue of which the senior boys are authorized to exact a variety of services from the junior boys. A lower form boy has certain duties to perform to all the upper form boys, as in stopping the balls for them when practicing cricket—and others which he owes to a special master, such as stoking his fire and carrying his messages of a more or less private kind. In American colleges the freedoms taken, under the name of *hazing*, by sophomore and senior students with freshmen, is somewhat analogous.

FAGOT-VOTES, votes manufactured chiefly for county elections, by the nominal sale of property, under mortgage or otherwise, so as to qualify the holder to vote. The term *fagot* described formerly a person who was hired to fill up another's place at the muster of a regiment, or to conceal a deficiency in its strength.

FAIENCE, or Fayence, a general term for all sorts of glazed earthenware and porcelain. The origin of the name is disputed. Some derive it from Fayence, a small town of Provence, others from Faenza, a city of Italy; while certain writers consider the Isle of Majorca the place where it was originally manufactured, as the Italians still call faience *Majolica* or *Mayolina*.

FAI-FO, a seaport of Anam in Cochin-China in the province of Quang-Nan situated on a river, near its mouth, communicating with Tooron, 15 miles to the north, by means of a canal. It exports sugar and cinnamon, its principal trade being with China. Population, 15,500.

FAILLON, Michel E. (1799–1870). He was a priest of the Sulpician order, who came from Paris to Canada as visitor to Sulpician houses of the country, and wrote biographies and histories of the French in Canada.

FAILLY, de Charles Achille, born in 1810, a French general, who introduced the Chassepot gun. He distinguished himself in the Crimean war, and at the battle of Solferino, but was unfortunate during the Franco-German war, and lost his command the day before the battle of Sedan.

FAIDHERBE, Louis Léon César, French general, statesman, and archæologist, born at Lille, June 3, 1818, died in 1889. He studied at the École Polytechnique and at Metz, afterwards serving as a military engineer in Algeria and the West Indies. Made governor of Senegal in 1854, he rendered the French dominion in Africa great service by his accurate knowledge of the country and its population. At the commencement of the war with Germany he had command of Bona in Algeria, and when the armies were reorganized in 1870 he was appointed general of division and commander-in-chief of the North. He commanded in the battle of Point-Noyelles, relieving Havre from siege, and also in that of Bayaume. Although his little practiced forces were afterwards defeated by the Germans, he proved himself a very able commander. Joining the party of Gambetta, he was elected to the national assembly in 1871. He retired from public life when the government of Thiers came into power. He was sent on a scientific expedition to Egypt, and subsequently published several works on archæological topics. He also published a book on the war, *Campagne de l'Armée du Nord.* Gen. Faidherbe was grand-chancellor of the Legion of Honor.

FAINÉANTS ROIS (the "Do-nothing Kings"), the sarcastic designation of the later Merovingian sovereigns of France, under whom the famous mayors of the palace really governed the country. The first of the series was Thierry III, nominally monarch of Burgundy, Neustria, and Austriasia; the others were Clovis III, Childebert III, Dagobert III, Chilperic II, Thierry IV, and Childeric III. The last of these was dethroned in 730 by Pepin le Bref, mayor of the palace, who caused himself to be formally proclaimed king. Louis V, the last of the Carlovingians, and a descendant of Pepin le Bref also received the epithet of *Fainéant.*

FAIRBAIRN, Andrew M., theologian, principal since 1886 of Mansfield College, Oxford, was born in 1838 in Edinburgh, Scotland, and educated at the Universities of that place, of Glasgow and of Berlin. His first pastorate, in 1860, was at Bathgate, Linlithgow, Scotland. In 1877 he was principal of Airedale (Congregational) College at Bradford, England, and in 1883 was chairman of the Congregational Union of England and Wales. Dr. Fairbairn has written *Studies in the Philosophy of Religion and History*, *Studies in the Life of Christ*, and other works, and is an eloquent preacher. He visited America in 1890.

FAIRBAIRN, Patrick, D.D., born in Scotland in 1805, died in 1874. He was principal and professor of systematic theology and New Testament exegesis in the Free Church Theological College of Glasgow. He visited the United States in 1871.

FAIRBANKS, Erastus (1792–1864), an American manufacturer. In 1824, with his brother Thaddeus, he began the manufacture of cast-iron plows and stove-castings, in St. Johnsburg, Vt., and in 1831 they gave their entire attention to making platform scales. In 1836–38 Erastus was a member of the legislature, and in 1849 was president of the Passumsic Railroad company; in 1851 and again in 1860 was elected governor of Vermont.

FAIRBURY, the county-seat of Jefferson county, Neb., on the Little Blue River. It has fine wate h
